# ASYMPTOTIC BEHAVIOR FOR A CLASS OF MULTIBUMP SOLUTIONS TO DUFFING-LIKE SYSTEMS 

Paolo CALDIROLI, Piero MONTECCHIARI and Margherita NOLASCO<br>SISSA, International School for Advanced Studies, via Beirut 4 34013 Trieste, Italy

#### Abstract

We consider a class of second order Hamiltonian systems $\ddot{q}=q-V^{\prime}(t, q)$ where $V(t, q)$ is asymptotic at infinity to a time periodic and superquadratic function $V_{+}(t, q)$. We prove the existence of a class of multibump solutions whose $\omega$-limit is a suitable homoclinic orbit of the system at infinity $\ddot{q}=q-V_{+}^{\prime}(t, q)$.

## 1. Statement of the results

In this paper we study a class of second order Hamiltonian systems of the type:

$$
\begin{equation*}
\ddot{q}=-U^{\prime}(t, q) \tag{HS}
\end{equation*}
$$

where $U^{\prime}(t, q)$ denotes the gradient with respect to $q$ of a smooth potential $U: \mathbf{R} \times$ $\mathbf{R}^{N} \rightarrow \mathbf{R}$, having a strict local maximum at the origin. Precisely, we assume:
(h1) $U \in C^{1}\left(\mathbf{R} \times \mathbf{R}^{N}, \mathbf{R}\right)$ with $U^{\prime}(t, \cdot)$ locally Lipschitz continuous uniformly with respect to $t \in \mathbf{R}$;
(h2) $U(t, 0)=0$ and $U(t, q)=-\frac{1}{2} q \cdot L(t) q+V(t, q)$ with $V^{\prime}(t, q)=o(|q|)$, as $q \rightarrow 0$, uniformly with respect to $t \in \mathbf{R}$ and $L(t)$ is a symmetric matrix such that $c_{1}|q|^{2} \leq$ $q \cdot L(t) q \leq c_{2}|q|^{2}$ for any $(t, q) \in \mathbf{R} \times \mathbf{R}^{N}$ with $c_{1}, c_{2}$ positive constants.
Moreover, we ask the potential $U$ to be asymptotic to a time periodic potential $U_{+}$ in the limit $t \rightarrow+\infty$. In fact we assume that there exists $U_{+}: \mathbf{R} \times \mathbf{R}^{N} \rightarrow \mathbf{R}$ of the form $U_{+}(t, q)=-\frac{1}{2} q \cdot L_{+}(t) q+V_{+}(t, q)$, satisfying $(h 1),(h 2)$ and
(h3) there is $T>0$ such that $U_{+}(t, q)=U_{+}(t+T, q)$ for any $(t, q) \in \mathbf{R} \times \mathbf{R}^{N}$;
(h4) (i) there is $(\bar{t}, \bar{q}) \in \mathbf{R} \times \mathbf{R}^{N}$ such that $U_{+}(\bar{t}, \bar{q})>0$;
(ii) there are two constants $\beta>2$ and $\alpha<\frac{\beta}{2}-1$ such that:

$$
\beta V_{+}(t, q)-V_{+}^{\prime}(t, q) \cdot q \leq \alpha q \cdot L_{+}(t) q \text { for all }(t, q) \in \mathbf{R} \times \mathbf{R}^{N} ;
$$

(h5) $U^{\prime}(t, q)-U_{+}^{\prime}(t, q) \rightarrow 0$ as $t \rightarrow+\infty$ uniformly on the compact sets of $\mathbf{R}^{N}$.
The problem of existence and multiplicity of homoclinic orbits (i.e., solutions to (HS) satisfying $q(t) \rightarrow 0$ and $\dot{q}(t) \rightarrow 0$ as $t \rightarrow \pm \infty$ ) has been deeply investigated by variational methods in several papers [1-6]. We also mention [7-11] for the first order systems.

In particular we refer to [12] for the case of asymptotically time periodic potential $U$ satisfying ( $h 1$ )-(h5) (see also [13]). In [12] it is proved that if, in addition,
(*) the set of homoclinics of the system at infinity

$$
\begin{equation*}
\ddot{q}=-U_{+}^{\prime}(t, q) \tag{HS}
\end{equation*}
$$

is countable,
then (HS) admits an uncountable set of bounded motions and countably many homoclinics of multibump type. These solutions leave the origin and come back in a neighborhood of it finitely or infinitely many times staying near translations of a particular homoclinic solution $v_{+}$of $(\mathrm{HS})_{+}$. This dynamics was firstly shown in [10] for first order convex Hamiltonian systems periodic in time.

In the present work we prove the following theorem.
Theorem 1.1. If $U$ satisfies ( $h 1$ ), ( $h 2$ ) and there exists $U_{+}$for which $(h 1)-(h 5)$ and $(*)$ hold then there is a homoclinic solution $v_{+}$of $(\mathrm{HS})_{+}$such that for any sequence $\left(r_{n}\right) \subset \mathbf{R}_{+}$there are $N \in \mathbf{R}$ and a sequence $\left(d_{n}\right) \subset \mathbf{N}$ for which if $\left(p_{n}\right) \subset \mathbf{Z}$ satisfies $p_{1} \geq N$ and $p_{n+1}-p_{n} \geq d_{n} \quad(n \in \mathbf{N})$, and if $\sigma=\left(\sigma_{n}\right) \in\{0,1\}^{\mathbf{N}}$, then there is a solution $v_{\sigma}$ of $(H S)$ such that

$$
\left|v_{\sigma}(t)-\sigma_{n} v_{+}\left(t-p_{n} T\right)\right|<r_{n} \quad \text { and } \quad\left|\dot{v}_{\sigma}(t)-\sigma_{n} \dot{v}_{+}\left(t-p_{n} T\right)\right|<r_{n}
$$

for any $t \in\left[\frac{1}{2}\left(p_{n-1}+p_{n}\right) T, \frac{1}{2}\left(p_{n}+p_{n+1}\right) T\right]$ and $n \in \mathbf{N}$, whit the agreement $p_{0}=-\infty$. In addition, any $v_{\sigma}$ satisfies $v_{\sigma}(t) \rightarrow 0$ and $\dot{v}_{\sigma}(t) \rightarrow 0$, as $t \rightarrow-\infty$, and, if $\sigma_{n}=0$ definitively, then $v_{\sigma}$ is a homoclinic orbit.

We remark that for a constant sequence $r_{n}=r(n \in \mathbf{N})$, theorem 1.1 gives the main result contained in [12]. By theorem 1.1, choosing $r_{n} \rightarrow 0$, we obtain the following result, which we think interesting in its own.
Corollary 1.2. Under the same assumptions of theorem 1.1, (HS) admits an uncountable set of multibump solutions whose $\alpha$-limit is $\{0\}$ and whose $\omega$-limit is $\Gamma_{+}$, where $\Gamma_{+}=\left\{\left(v_{+}(t), \dot{v}_{+}(t)\right): t \in \mathbf{R}\right\} \cup\{0\}$.
We recall that the $\alpha$-limit and the $\omega$-limit of a solution $q$ are respectively the sets $\alpha(q)=\left\{(\bar{q}, \bar{p}) \in \mathbf{R}^{2 N}: \exists t_{n} \rightarrow-\infty\right.$ s.t. $\left.\left(q\left(t_{n}\right), \dot{q}\left(t_{n}\right)\right) \rightarrow(\bar{q}, \bar{p})\right\}$ and $\omega(q)=\{(\bar{q}, \bar{p}) \in$ $\mathbf{R}^{2 N}: \exists t_{n} \rightarrow+\infty$ s.t. $\left.\left(q\left(t_{n}\right), \dot{q}\left(t_{n}\right)\right) \rightarrow(\bar{q}, \bar{p})\right\}$.

If the potential $U$ is doubly asymptotic to two, possibly distinct periodic potentials $U_{+}$as $t \rightarrow+\infty$ and $U_{-}$, as $t \rightarrow-\infty$, we can prove the existence of multibump solutions of (HS) of mixed type.
Theorem 1.3. If $U$ satisfies $(h 1),(h 2)$ and there exist $U_{ \pm}$for which ( $h 1$ )-( $h 5$ ) and $(*)$ hold, then there are homoclinic orbits $v_{ \pm}$of $(\mathrm{HS})_{ \pm}$such that (HS) admits an uncountable set of multibump solutions whose $\alpha$-limit is 0 or $\Gamma_{\text {- }}$ and whose $\omega$-limit is 0 or $\Gamma_{+}$.
Remark 1.4. If we specialize theorem 1.3 to the case $U$ periodic in time, we get the existence of a homoclinic $v$ of (HS) and an uncountable set of connecting orbits between 0 and $v$ and between $v$ and itself.

We conclude by noting that, as shown in [12], the hypotheses $(h 1)-(h 5)$ and $(*)$ are verified in the case of the perturbed Duffing-like equation

$$
\ddot{q}=q-a(t)(1+\epsilon \cos (\omega(t) t)) q^{3}
$$

where $a, \omega \in C^{1}(\mathbf{R}), a(t) \rightarrow a_{+}>0, \omega(t) \rightarrow \omega_{+} \neq 0$ as $t \rightarrow+\infty, a$ is bounded and $\epsilon \neq 0$ is sufficiently small.

## 2. Outline of the proof of Theorem 1.1

For simplicity we consider the case $L(t)=L_{+}(t)=I$ and $T=1$. The general case can be studied by similar arguments.

## Variational setting and notation

It is well known that the system (HS) defines a variational problem in a natural way. In fact, the homoclinic solutions to (HS) are the critical points of the action functional $\varphi: X=H^{1}\left(\mathbf{R}, \mathbf{R}^{N}\right) \rightarrow \mathbf{R}$ defined by

$$
\varphi(u)=\frac{1}{2}\|u\|^{2}-\int_{\mathbf{R}} V(t, u) d t
$$

where $\|u\|$ is the standard norm of $H^{1}\left(\mathbf{R}, \mathbf{R}^{N}\right)$ induced by the inner product $\langle u, v\rangle=$ $\int_{\mathbf{R}}(\dot{u} \cdot \dot{v}+u \cdot v) d t$. Analogously we define the functional $\varphi_{+}$associated to $V_{+}$.

It turns out that $\varphi$ and $\varphi_{+}$are of class $C^{1}$ and $\varphi^{\prime}(u) v=\langle u, v\rangle-\int_{\mathbf{R}} V^{\prime}(t, u) \cdot v d t$ for any $u, v \in X$ (the corresponding expression holds for $\varphi_{+}^{\prime}$ ).

For $a, b \in \mathbf{R}$ we denote $\{a \leq \varphi \leq b\}=\{u \in X: a \leq \varphi(u) \leq b\}, K=\{u \in$ $\left.X: u \neq 0, \varphi^{\prime}(u)=0\right\}, K^{b}=K \cap\{\varphi \leq b\}$ and $K(a)=K \cap\{\varphi=a\}$, and similarly for $\left\{a \leq \varphi_{+} \leq b\right\}, K_{+}, K_{+}^{b}$ and $K_{+}(a)$.

We denote $B_{r}(v)$ the open ball in $X$ of radius $r$ centered in $v \in X$ and for any interval $I \subset \mathbf{R}, B_{r}(v ; I)=\left\{u \in X:\|u-v\|_{I}<r\right\}$, where $\|u\|_{I}^{2}=\int_{I}\left(|\dot{u}|^{2}+|u|^{2}\right) d t$. Moreover, for $S \subseteq X$ and $0 \leq r_{1}<r_{2}$ we denote $A_{r_{1}, r_{2}}(S)=\bigcup_{v \in S} B_{r_{2}}(v) \backslash \bar{B}_{r_{1}}(v)$.

Palais Smale sequences
First of all we note that thanks to $(h 1)$ and $(h 2)$ the origin is a strict local minimum for $\varphi\left(\right.$ and $\left.\varphi_{+}\right)$.
Lemma 2.1. For any $\epsilon>0$ there exists $\delta>0$ such that for any given interval $I \subseteq \mathbf{R}$, with $|I| \geq 1$ and for any $u \in X$ with $\|u\|_{I} \leq \delta$ we have

$$
\int_{I} V(t, u) d t \leq \epsilon\|u\|_{I}^{2} \text { and } \int_{I} V^{\prime}(t, u) \cdot v d t \leq \epsilon\|u\|_{I}\|v\|_{I}, \forall v \in X .
$$

In particular we have that

$$
\varphi(u)=\frac{1}{2}\|u\|^{2}+o\left(\|u\|^{2}\right) \text { and } \varphi^{\prime}(u)=\langle u, \cdot\rangle+o(\|u\|) \quad \text { as } \quad u \rightarrow 0 .
$$

Now, we study the bounded Palais Smale (PS) sequences for $\varphi$ and $\varphi_{+}$. We point out that the results stated in the next two lemmas follow assuming only ( $h 1$ ) and ( $h 2$ ), and they are inspired to concentration-compactness arguments [14]. We refer to [12] for the proofs.
Lemma 2.2. If $\left(u_{n}\right) \subset X$ is a PS sequence at the level $b$ (namely $\varphi\left(u_{n}\right) \rightarrow b$ and $\left\|\varphi^{\prime}\left(u_{n}\right)\right\| \rightarrow 0$ ) weakly convergent to some $u \in X$, then $\varphi^{\prime}(u)=0$ and $\left(u_{n}-u\right)$ is a $P S$ sequence at the level $b-\varphi(u)$. Moreover, $u_{n} \rightarrow u$ strongly in $H_{\mathrm{loc}}^{1}\left(\mathbf{R}, \mathbf{R}^{N}\right)$ and the following alternative holds: either
(i) $u_{n} \rightarrow u$ strongly in $X$, or (ii) $\exists\left|t_{n_{k}}\right| \rightarrow \infty$ s.t. $\quad \inf _{k}\left|u_{n_{k}}\left(t_{n_{k}}\right)\right|>0$.

Therefore, if $\left(u_{n}\right) \subset X$ is a PS sequence which converges weakly but not strongly to some $u \in X$, then there exists a positive number $r$ such that for any $T>0$ we have
$\lim \sup \left\|u_{n}\right\|_{|t|>T}>r$. Thanks to lemma 2.1 this value $r$ can be taken independent of the sequence $\left(u_{n}\right)$. In fact,
$\exists \rho>0$ such that if limsup $\left\|u_{n}\right\| \leq 2 \rho$ and $\varphi^{\prime}\left(u_{n}\right) \rightarrow 0$ then $u_{n} \rightarrow 0$.
By (2.3) and lemma 2.2 we obtain the following local compactness property.
Lemma 2.4. Let $u_{n} \rightarrow u$ weakly in $X$ and $\varphi^{\prime}\left(u_{n}\right) \rightarrow 0$. If there exists $T>0$ for which $\lim \sup \left\|u_{n}\right\|_{|t|>T}<\rho$ or if $\operatorname{diam}\left\{u_{n}\right\}<\rho$, then $u_{n} \rightarrow u$ strongly in $X$.

By assuming also the hypotheses (h3) and (h4) we can state further properties concerning the PS sequences for $\varphi_{+}$.

First of all we point out that the hypothesis ( $h 4 . i i$ ) implies that

$$
\left(\frac{1}{2}-\frac{1}{\beta}-\frac{\alpha}{\beta}\right)\|u\|^{2} \leq \frac{1}{\beta}\left\|\varphi_{+}^{\prime}(u)\right\|\|u\|+\varphi_{+}(u) \quad \forall u \in X .
$$

Therefore, any PS sequence $\left(u_{n}\right)$ for $\varphi_{+}$is bounded in $X$ and $\liminf \varphi_{+}\left(u_{n}\right) \geq 0$.
Thanks to ( $h 3$ ) the functionals $\varphi_{+}$and $\left\|\varphi_{+}^{\prime}(\cdot)\right\|$ are invariant under $\mathbf{Z}$-translations. By these facts and lemma 2.2, it is possible to characterize in a sharp way the PS sequences for $\varphi_{+}$, as already done in [4] and [7].
Lemma 2.5. Let $\left(u_{n}\right) \subset X$ be a PS sequence for $\varphi_{+}$at the level $b$. Then there are $v_{0} \in K_{+} \cup\{0\}, v_{1}, \ldots, v_{k} \in K_{+}$, a subsequence of $\left(u_{n}\right)$, denoted again $\left(u_{n}\right)$, and corresponding sequences $\left(t_{n}^{1}\right), \ldots,\left(t_{n}^{k}\right) \subseteq \mathbf{Z}$, with $\left|t_{n}^{j}\right| \rightarrow+\infty \quad(j=1, \ldots, k)$ and $t_{n}^{j+1}-t_{n}^{j} \rightarrow+\infty \quad(j=1, \ldots, k-1)$, as $n \rightarrow \infty$, and such that:

$$
\begin{aligned}
& \left\|u_{n}-\left(v_{0}+v_{1}\left(\cdot-t_{n}^{1}\right)+\ldots+v_{k}\left(\cdot-t_{n}^{k}\right)\right)\right\| \rightarrow 0 \\
& b=\varphi_{+}\left(v_{0}\right)+\cdots+\varphi_{+}\left(v_{k}\right) .
\end{aligned}
$$

By lemma 2.1 and the assumption (h4), we infer (see [15]) that the functional $\varphi_{+}$ verifies the geometrical hypotheses of the mountain pass theorem.

Then, if we define $\Gamma=\left\{\gamma \in C([0,1], X): \gamma(0)=0, \varphi_{+}(\gamma(1))<0\right\}$ and $c=\inf _{\gamma \in \Gamma} \max _{s \in[0,1]} \varphi_{+}(\gamma(s))$, we have that $c>0$ and that there is a PS sequence at the level $c$. This fact and lemma 2.5 imply that $K_{+} \neq \emptyset$.

## Consequences of the assumption (*)

To get further compactness properties of the functional $\varphi_{+}$, it is convenient to introduce, following [10], two suitable sets of real numbers. Let us fix a level $b>c$. Setting $\mathcal{S}_{P S}^{b}=\left\{\left(u_{n}\right) \subset X: \varphi_{+}^{\prime}\left(u_{n}\right) \rightarrow 0, \lim \sup \varphi_{+}\left(u_{n}\right) \leq b\right\}$, we define

$$
\begin{aligned}
D & =\left\{r \in \mathbf{R}: \exists\left(u_{n}\right),\left(\bar{u}_{n}\right) \in \mathcal{S}_{P S}^{b} \text { s.t. }\left\|u_{n}-\bar{u}_{n}\right\| \rightarrow r\right\} . \\
\Phi & =\left\{l \in \mathbf{R}: \exists\left(u_{n}\right) \in \mathcal{S}_{P S}^{b} \text { s.t. } \varphi_{+}\left(u_{n}\right) \rightarrow l\right\} .
\end{aligned}
$$

By lemma $2.5, D$ and $\Phi$ can be characterized by means of the set $K_{+}$. As proved in [15, lemma 3.10] we get
$D=\left\{\left(\sum_{j=1}^{k}\left\|v_{j}-\bar{v}_{j}\right\|^{2}\right)^{\frac{1}{2}}: k \in \mathbf{N}, v_{j}, \bar{v}_{j} \in K_{+} \cup\{0\}, \sum \varphi_{+}\left(v_{j}\right) \leq b, \sum \varphi_{+}\left(\bar{v}_{j}\right) \leq b\right\}$, $\Phi=\left\{\sum_{j=1}^{k} \varphi_{+}\left(v_{j}\right): k \in \mathbf{N}, v_{j} \in K_{+}\right\} \cap[0, b]$.
By the assumption (*), the sets $D$ and $\Phi$ are countable and, since they are closed ([15, lemma 3.7]), we obtain the following lemma.
Lemma 2.6. (i) For any $r \subset\left(0, \frac{\rho}{2}\right) \backslash D$, there exists $\delta=\delta(r)>0$ such that

$$
\inf \left\{\left\|\varphi_{+}^{\prime}(u)\right\|: u \in A_{r-\delta, r+\delta}\left(K_{+}^{b}\right) \cap\left\{\varphi_{+} \leq b\right\}\right\}>0
$$

(ii) For any interval $\left[a_{1}, a_{2}\right] \subset \mathbf{R}_{+} \backslash \Phi$ it holds that

$$
\inf \left\{\left\|\varphi_{+}^{\prime}(u)\right\|: a_{1} \leq \varphi_{+}(u) \leq a_{2}\right\}>0 .
$$

From lemmas 2.4 and 2.6(i), using a deformation argument, it is possible to show that the functional $\varphi_{+}$admits a critical point of local mountain pass type (see [15; section 4] for the proof).
Lemma 2.7. There exist $\bar{c} \in[c, b), \bar{r} \in\left(0, \frac{\rho}{2}\right)$, a sequence $\left(r_{n}\right) \subset(0, \bar{r}) \backslash D$ with $r_{n} \rightarrow 0$ and a sequence $\left(v_{n}\right) \subset K_{+}(\bar{c})$ with $v_{n} \rightarrow v_{+} \in K_{+}(\bar{c})$, such that for any $h>0$ there is a sequence of paths $\left(\gamma_{n, h}\right) \subset C([0,1], X)$ satisfying:
(i) $\gamma_{n, h}(0), \gamma_{n, h}(1) \in \partial B_{r_{n}}\left(v_{n}\right)$;
(ii) $\gamma_{n, h}(0)$ and $\gamma_{n, h}(1)$ are not connectible in $B_{\bar{r}}\left(v_{+}\right) \cap\left\{\varphi_{+}<\bar{c}\right\}$;
(iii) range $\gamma_{n, h} \subseteq \bar{B}_{r_{n}}\left(v_{n}\right) \cap\left\{\varphi_{+} \leq \bar{c}+h\right\}$;
(iv) range $\gamma_{n, h} \cap A_{r_{n}-\frac{1}{2} \delta_{n}, r_{n}}\left(v_{n}\right) \subseteq\left\{\varphi_{+} \leq \bar{c}-h\right\}$;
(v) $\operatorname{supp} \gamma_{n, h}(s) \subset\left[-R_{n, h}, R_{n, h}\right]$ for any $s \in[0,1]$, where $R_{n, h}>0$ is independent of $s$, and $\delta_{n}=\delta\left(r_{n}\right)$ is given by lemma 2.6(i).

We recall that two points $u_{0}, u_{1} \in X$ are not connectible in $a \subset X$ if there is no path joining $u_{0}$ and $u_{1}$ with range contained in $A$.

We point out that, by the $\mathbf{Z}$-invariance of $\varphi_{+}$, any translation by $p \in \mathbf{Z}$ of a path $\gamma_{n, h}$ satisfies properties $(i)-(v)$ with respect to $v_{n}(\cdot-p)$.

## Multibump functions

We introduce some notation. For $k \in \mathbf{N}$ and $d=\left(d_{1}, \ldots, d_{k-1}\right) \in \mathbf{N}^{k-1}$ we set $P(k, d)=\left\{\left(p_{1}, \ldots, p_{k}\right) \in \mathbf{Z}^{k}: p_{i+1}-p_{i} \geq 2 d_{i}^{2}+3 d_{i} \forall i=1, \ldots, k-1\right\}$, and, for $p \in P(k, d)$ we define the intervals:

$$
\begin{array}{lr}
I_{i}=\left(\frac{1}{2}\left(p_{i-1}+p_{i}\right), \frac{1}{2}\left(p_{i}+p_{i+1}\right)\right) & (i=1, \ldots, k) \\
M_{i}=\left(p_{i}+d_{i}\left(d_{i}+1\right), p_{i+1}-d_{i}\left(d_{i}+1\right)\right) & (i=1, \ldots, k-1)
\end{array}
$$

$M_{0}=\left(-\infty, p_{1}-d_{1}\left(d_{1}+1\right)\right), M_{k}=\left(p_{k}+d_{k-1}\left(d_{k-1}+1\right),+\infty\right)$ and $M=\bigcup_{i=0}^{k} M_{i}$, with the agreement that $p_{0}=-\infty$ and $p_{k+1}=+\infty$.

In addition we introduce the functionals $\varphi_{i}: X \rightarrow \mathbf{R}(i=1, \ldots, k)$ defined by $\varphi_{i}(u)=\frac{1}{2}\|u\|_{I_{i}}^{2}-\int_{I_{i}} V_{+}(t, u) d t$. We notice that $\varphi_{+}=\sum_{i=1}^{k} \varphi_{i}$ and any $\varphi_{i}$ is of class $C^{1}$ on $X$ with $\varphi_{i}^{\prime}(u) v=\langle u, v\rangle_{I_{i}}-\int_{I_{i}} V_{+}^{\prime}(t, u) \cdot v d t$ for any $u, v \in X$.

Thanks to lemma 2.7 we obtain the following result. Let $\left(r_{n}\right) \subset(0, \bar{r}) \backslash D, r_{n} \rightarrow 0$, and $\left(v_{n}\right) \subset K_{+}(\bar{c})$ be given by lemma 2.7 and let $\left(\delta_{n}\right) \subset \mathbf{R}_{+}$be assigned by lemma 2.6(i). Let us denote $r_{1, n}=r_{n}-\frac{1}{3} \delta_{n}, r_{2, n}=r_{n}-\frac{1}{4} \delta_{n}$ and $r_{3, n}=r_{n}-\frac{1}{5} \delta_{n}$. Then we have:
Corollary 2.8. Taking a sequence $\left(h_{n}\right) \subset \mathbf{R}_{+}$and setting for $n \in \mathbf{N} \tilde{d}_{n}=$ $\max \left\{R_{n, h_{n}}, R_{n+1, h_{n+1}}\right\}$, then for any $k \in \mathbf{N}$ and $p \in P(k, \tilde{d})$, the surface $G: Q=$ $[0,1]^{k} \rightarrow X$ defined by $G\left(\theta_{1}, \ldots, \theta_{k}\right)=\sum_{i=1}^{k} \gamma_{i, h_{i}}\left(\theta_{i}\right)\left(\cdot-p_{i}\right)$. satisfies the following properties:
(i) $G(\partial Q) \subseteq X \backslash \bigcap_{i=1}^{k} B_{r_{3, i}}\left(v_{i}\left(\cdot-p_{i}\right) ; I_{i}\right)$;
(ii) $\left.G(\theta)\right|_{M_{i}}=0$ for any $\theta \in Q$ and $i \in\{1, \ldots, k\}$;
(iii) for any $\theta \in Q$ such that $G(\theta) \in X \backslash \bigcap_{i=1}^{k} B_{r_{1, i}}\left(v_{i}\left(\cdot-p_{i}\right) ; I_{i}\right)$ there exists $i=i(\theta)$ for which $G(\theta) \in\left\{\varphi_{i} \leq \bar{c}-h_{i}\right\}$;
(iv) range $G \subset \bigcap_{i=1}^{k}\left\{\varphi_{i} \leq \bar{c}+h_{i}\right\}$;
(v) $\varphi_{i}(G(\theta))=\varphi_{+}\left(\gamma_{i, h_{i}}\left(\theta_{i}\right)\left(\cdot-p_{i}\right)\right)$.

A common pseudogradient vector field for $\varphi$ and $\varphi_{i}$
We point out that by $(h 5)$, the operator $\varphi^{\prime}(u)$ is close to $\varphi_{+}^{\prime}(u)$ for those elements $u \in X$ with support at infinity, as stated in the next lemma (see [12; lemma 4.2] for a proof).
Lemma 2.9. For any $\epsilon>0$ and for any $C>0$ there exists $N \in \mathbf{R}$ such that $\left\|\varphi^{\prime}(u)-\varphi_{+}^{\prime}(u)\right\| \leq \epsilon$,
for any $u \in X$ with $\|u\| \leq C$ and supp $u \subseteq[N,+\infty)$.
Next lemma states the existence of a common pseudogradient vector field for $\varphi$ and $\varphi_{i}$.

Let $\left(r_{n}\right) \subset(0, \bar{r}) \backslash D, r_{n} \rightarrow 0$, and $\left(v_{n}\right) \subset K(\bar{c})$ be given by lemma 2.7. Let us fix $r_{1, n}, r_{2, n}, r_{3, n}$ as above. Moreover, let us fix sequences $\left(a_{n}\right),\left(b_{n}\right)$ and $\left(\lambda_{n}\right) \subset \mathbf{R}_{+}$such that $\left[a_{n}-\lambda_{n}, a_{n}+2 \lambda_{n}\right] \subset\left(\bar{c}-h_{n}, \bar{c}\right) \backslash \Phi$ and $\left[b_{n}-\lambda_{n}, b_{n}+2 \lambda_{n}\right] \subset\left(\bar{c}+h_{n}, \bar{c}+\frac{3}{2} h_{n}\right) \backslash \Phi$.
Lemma 2.10. There exist $\mu_{n}=\mu_{n}\left(r_{n}\right)>0, N \in \mathbf{R}$ and $\bar{\epsilon}_{n}=\bar{\epsilon}_{n}\left(r_{n}, a_{n}, b_{n}, \lambda_{n}\right)>0$ such that: for any $\epsilon_{n} \in\left(0, \bar{\epsilon}_{n}\right)$ there exists $\bar{d}_{n} \in \mathbf{N}(n \in \mathbf{N})$ for which for any $k \in \mathbf{N}$ and $p \in P(k, d)$, with $p_{1}>N$ there exists a locally Lipschitz continuous function $\mathcal{W}: X \rightarrow X$ which verifies
$\left(\mathcal{W}_{0}\right) \max _{1 \leq i \leq k}\|\mathcal{W}(u)\|_{I_{i}} \leq 1, \varphi^{\prime}(u) \mathcal{W}(u) \geq 0, \forall u \in X, \mathcal{W}(u)=0 \forall u \in X \backslash B_{3} ;$
$\left(\mathcal{W}_{1}\right) \varphi_{i}^{\prime}(u) \overline{\mathcal{W}}(u) \geq \mu_{i}$ if $r_{1, i} \leq\left\|u-v_{i}\left(\cdot-p_{i}\right)\right\|_{I_{i}} \leq r_{2, i}, u \in B_{2} \cap\left\{\varphi_{i} \leq b_{i}\right\} ;$
$\left(\mathcal{W}_{2}\right) \varphi_{i}^{\prime}(u) \mathcal{W}(u) \geq 0 \forall u \in\left\{b_{i} \leq \varphi_{i} \leq b_{i}+\lambda_{i}\right\} \cup\left\{a_{i} \leq \varphi_{i} \leq a_{i}+\lambda_{i}\right\}$;
$\left(\mathcal{W}_{3}\right)\langle u, \mathcal{W}(u)\rangle_{M_{i}} \geq 0 \forall i \in\{0, \ldots, k\}$ if $u \in X \backslash \mathcal{M}$,
where $\mathcal{M} \equiv \bigcap_{i=0}^{k} B_{\sqrt{\epsilon}}\left(0 ; M_{i}\right)$ and $B_{j} \equiv \bigcap_{i=1}^{k} B_{r_{j, i}}\left(v_{i}\left(\cdot-p_{i}\right) ; I_{i}\right)$ for $j=1,2,3$.
Moreover if $K \cap B_{2}=\emptyset$ then there exists $\mu_{p}>0$ such that
$\left(\mathcal{W}_{4}\right) \varphi^{\prime}(u) \mathcal{W}(u) \geq \mu_{p}, \forall u \in B_{2}$.

## Approximating $k$-bump solutions

Theorem 2.11. If $U$ satisfies $(h 1),(h 2)$ and there exists $U_{+}$for which $(h 1)-(h 5)$ and $(*)$ hold then for any given sequence $\left(\rho_{n}\right) \in \mathbf{R}_{+}$there exist $N \in \mathbf{R}$ and a sequence $\left(d_{n}\right) \subset \mathbf{N}$ such that for every $k \in \mathbf{N}$ and $p \in P(k, d)$, with $p_{1}>N$, we have $K \cap \cap_{i=1}^{k} B_{\rho_{i}}\left(v_{+}\left(\cdot-p_{i}\right) ; I_{i}\right) \neq \emptyset$, where $v_{+}$is given by lemma 2.7.
Proof. Arguing by contradiction there exists a sequence $\left(\rho_{n}\right) \subset \mathbf{R}_{+}$such that for any $N \in \mathbf{R}$ and for any sequence $\left(d_{n}\right) \subset \mathbf{N}$ there exist $k \in \mathbf{N}$ and $p \in P(k, d)$, with $p_{1}>N$, for which $K \cap \bigcap_{i=1}^{k} B_{\rho_{i}}\left(v_{+}\left(\cdot-p_{i}\right) ; I_{i}\right)=\emptyset$. Let $\left(r_{n}\right) \subset(0, \bar{r}) \backslash D, r_{n} \rightarrow 0$ and $\left(v_{n}\right) \subset K(\bar{c})$ be given by lemma 2.7. Without loss of generality, passing to a subsequence if necessary, we can assume $B_{2 r_{n}}\left(v_{n}\right) \subset B_{\rho_{n}}\left(v_{+}\right)$for any $n \in \mathbf{N}$.

Let $\mu_{n}$ and $\bar{\epsilon}_{n}$ be given by lemma 2.10. Let us define $\Delta_{n}=\frac{1}{4} \mu_{n}\left(r_{2, n}-r_{1, n}\right)$. Then, we fix $h_{n}<\frac{1}{8} \Delta_{n}, a_{n}$ and $b_{n}$ as above, with $b_{n}-a_{n}<\frac{1}{4} \Delta_{n}$ and $0<\epsilon_{n}<$ $\min \left\{\bar{\epsilon}_{n}, \frac{1}{4} \delta_{r_{n-1}}^{2}, \frac{1}{4} \delta_{r_{n}}^{2}, \frac{1}{8}\left(\bar{c}-a_{n}\right)\right\}$ such that $\int_{I} \left\lvert\, V_{+}(t, u) d t \leq \frac{1}{8}\|u\|_{I}^{2}\right.$ for $|I| \geq 1$.

Now, we fix $d_{n}>\max \left\{\tilde{d}_{n}, \bar{d}_{n}, 2\right\}$ and such that $\max \left\{\left\|v_{n+1}\right\|_{t<-d_{n}}^{2},\left\|v_{n}\right\|_{t>d_{n}}^{2}\right\}$ $<\epsilon_{n}$, where $\tilde{d}_{n}$ is given by corollary 2.8 and $\bar{d}_{n}$ by lemma 2.10 .

For these values of $d_{n}$ and for $N$ given by lemma 2.10 there exist $k \in \mathbf{N}$ and $p \in$ $P(k, d)$, with $p_{1}>N$, for which $\bigcap_{i=1}^{k} B_{r_{i}}\left(v_{i}\left(\cdot-p_{i}\right) ; I_{i}\right) \subseteq \bigcap_{i=1}^{k} B_{p_{i}}\left(v_{+}\left(\cdot-p_{i}\right) ; I_{i}\right)$. So that, by the contrary assumptions, there exists a vector field $\mathcal{W}$ satisfying properties $\left(\mathcal{W}_{0}\right)-\left(\mathcal{W}_{4}\right)$.

Now, we consider the flow associated to the Cauchy problem

$$
\frac{d \eta}{d s}=-\mathcal{W}(\eta), \quad \eta(0, u)=u
$$

to deform the surface G given by corollary 2.8 for this values of $\left(h_{i}\right)_{i=1, \ldots, k}$ and $\left(p_{i}\right)_{i=1, \ldots, k}$.

Since $\mathcal{W}$ is a bounded locally Lipschitz continuous vector field, the flow $\eta$ is globally defined. Moreover, by $\left(\mathcal{W}_{0}\right)$ the flow does not move the points outside $B_{3}$. This implies, by corollary 2.8(i),

$$
\begin{equation*}
\eta(s, G(\theta))=G(\theta) \quad \forall \theta \in \partial Q, \quad \forall s \in \mathbf{R} . \tag{2.12}
\end{equation*}
$$

Since $\varphi\left(B_{2}\right)$ is a bounded set, by $\left(\mathcal{W}_{4}\right)$ there exists $\tau>0$ such that for any $\theta \in Q$ for which $G(\theta) \in B_{1}$ there is $\left[s_{1}, s_{2}\right] \subset(0, \tau]$ with $\eta\left(s_{1}, G(\theta)\right) \in \partial B_{1}$, $\eta\left(s_{2}, G(\theta)\right) \in \partial B_{2}$ and $\eta(s, G(\theta)) \in B_{2} \backslash \bar{B}_{1}$ for any $s \in\left(s_{1}, s_{2}\right)$. Therefore for any $\theta \in Q$ there is an index $i=i(\theta) \in\{1, \ldots, k\}$ such that, by $\left(\mathcal{W}_{1}\right), \varphi_{i}\left(\eta\left(s_{2}, G(\theta)\right)\right) \leq$ $\varphi_{i}\left(\eta\left(s_{1}, G(\theta)\right)\right)-2 \Delta_{i}$. By corollary 2.8(iv) and since, by $\left(\mathcal{W}_{2}\right)$, the sets $\left\{\varphi_{i} \leq b_{i}\right\}$ and $\left\{\varphi_{i} \leq a_{i}\right\}$ are positively invariant, we obtain $\varphi_{i}\left(\eta\left(s_{2}, G(\theta)\right)\right) \leq b_{i}-2 \Delta_{i}<a_{i}$ and hence $\varphi_{i}(\eta(\tau, G(\theta))) \leq a_{i}$. Moreover, by (iii) of corollary 2.8 , for any $\theta$ for which $G(\theta) \in X \backslash B_{1}$ there exists $i=i(\theta)$ such that $\eta(s, G(\theta)) \in\left\{\varphi_{i} \leq a_{i}\right\}$ for any $s \in \mathbf{R}_{+}$. Hence, setting $\bar{G}(\theta)=\eta(\tau, G(\theta))$, we get

$$
\begin{equation*}
\forall \theta \in Q, \exists i \in\{1, \ldots, k\} \text { such that } \varphi_{i}(\bar{G}(\theta))<a_{i} \text {. } \tag{2.13}
\end{equation*}
$$

By (2.13) we have that
(2.14) there exists $i \in\{1, \ldots, k\}$ and $\xi \in C([0,1], Q)$ such that $\xi(0) \in\left\{\theta_{i}=0\right\}, \xi(1) \in$ $\left\{\theta_{i}=1\right\}$ and $\varphi_{i}(\bar{G}(\theta))<a_{i}$, for any $\theta \in$ range $\xi$.
Indeed, assuming the contrary, the set $D_{i}=\left\{\theta \in Q: \varphi_{i}(\bar{G}(\theta)) \geq a_{i}\right\}$ separates in $Q$ the faces $\left\{\theta_{i}=0\right\}$ and $\left\{\theta_{i}=1\right\}$, for any $i \in\{1, \ldots, k\}$. Then, using a Miranda fixed point theorem, it follows that $\bigcap_{i} D_{i} \neq \emptyset$, in contradiction with the property (2.13) (see [15]).

By $\left(\mathcal{W}_{3}\right)$, the set $\mathcal{M}$ is positively invariant under the flow. Then, by corollary 2.8(ii),

$$
\begin{equation*}
\eta(s, G(Q)) \in \mathcal{M} \quad \forall s \in \mathbf{R}_{+} . \tag{2.15}
\end{equation*}
$$

Now, let us take a cut-off function $\chi \in C^{\infty}(\mathbf{R},[0,1])$ with $\sup _{t \in \mathbf{R}}|\dot{\chi}(t)|<\frac{1}{2}$ (this can be done since $\inf _{i=1 \ldots k} d_{i}>2$ ) such that $\chi(t)=1$ if $t \in I_{i} \backslash M$ and $\chi(t)=0$ if $t \in \mathbf{R} \backslash I_{i}$, where the index $i$ is given by (2.14). Then $\|\chi u\|_{I_{i} \cap M}^{2} \leq$ $2\|u\|_{I_{i} \cap M}^{2}$ and $\|(1-\chi) u\|_{I_{i} \cap M}^{2} \leq 2\|u\|_{I_{i} \cap M}^{2}$ for any $u \in X$. We define a path $g:[0,1] \rightarrow X$ by setting $g(s)=\chi \bar{G}(\xi(s)), s \in[0,1]$. By (2.12) and lemma 2.7(v),
we have that $g(0)=\gamma_{i, h_{i}}(0)\left(\cdot-p_{i}\right)$ and $g(1)=\gamma_{i, h_{i}}(1)\left(\cdot-p_{i}\right)$. We finally show that $g(s) \in B_{\bar{r}}\left(v_{+}\left(\cdot-p_{i}\right)\right) \cap\left\{\varphi_{+}<\bar{c}\right\}$, for any $s \in[0,1]$ contradicting lemma 2.7(ii). In fact one easily get that range $g \subset B_{2 r_{i}}\left(v_{i}\left(\cdot-p_{i}\right)\right)$.

Then, setting $u=\bar{G}(\xi(s))$, we have $\varphi_{+}(g(s))=\varphi_{i}(g(s)) \leq \varphi_{i}(u)+\frac{1}{2}\|\chi u\|_{I_{i} \cap M}^{2}+$ $\int_{I_{i} \cap M}\left(V_{+}(t, u)-V_{+}(t, \chi u)\right) d t \leq a_{i}+4\|\chi u\|_{I_{i} \cap M}^{2}$. Since, by (2.15) $\|u\|_{I_{i} \cap M} \leq \epsilon_{i}+\epsilon_{i-1}$, we get $\varphi_{+}(g(s))<\bar{c}$.

Remarks. (i) The multibump homoclinic solutions of (HS) given by theorem 2.11 are close to translations of $v_{+}$in the $H^{1}$ norm on suitable intervals. Hence they are close in the $C^{0}$ norm and, since they verify (HS), in the $C^{1}$ norm, too.
(ii) Taking the $C_{\text {loc }}^{1}$ closure of the set of the multibump homoclinic solutions of (HS), using the Ascoli-Arzelà theorem, we get solutions with infinitely many bumps, as stated in theorem 1.1.
(iii) Corollary 1.2 follows from theorem 1.1, taking a sequence $r_{n} \rightarrow 0$ and any sequence ( $\sigma_{n}$ ) with infinitely many 1 's. Thus we have multiplicity both for the arbitrariness of $\left(r_{n}\right)$ and for the arbitrariness of $\left(\sigma_{n}\right)$.
(iv) Similar arguments apply to prove theorem 1.3. We refer to [12] for the construction of multibump solutions of mixed type.
