Avocado (*Persea americana* Mill.) is grown in some areas of southern Italy. In spring 2011, a previously unknown rot was observed on fruit marketed in Torino (northern Italy). The decayed area started from the stalk and appeared irregular, soft, and was surrounded by a dark brown margin. The internal decayed area appeared rotten, brown, and surrounded by bleached tissue. Fragments (approximately 3 mm) were taken from the margin of the internal diseased tissues, cultured on potato dextrose agar (PDA) and incubated at temperatures between 21-25°C, under alternating light and darkness. Colonies of the fungus initially appeared whitish, later turning mouse grey to black. Mature mycelium was septate and produced a dark pigment. The fungus, grown on oat-agar (2) and incubated at temperatures between 21-25°C, under alternating light and darkness produced grayish colonies, with a fluffy aerial mycelium which became dark with age and produced black pigments. After 18 day, such colonies produced pycnidia aggregated into stromatic masses, emerging from decayed tissues, up to 3-4 mm in diameter. Conidia produced in the pycnidia were initially unicellular, hyaline, granulose, ovoid to ellipsoidal, measuring 20.8 – 26.9 x 12.5 -16.1 (average 24.4 x 13.5) µm. After 7 days, mature conidia became darker and uniseptate. The morphological characteristics of mycelia, pycnidia and conidia observed with a light microscope permitted to identify the fungus as *Lasiodiplodia theobromae* (3). The Internal Transcribed Spacer (ITS) region of rDNA was amplified using the primers ITS1/ITS4, and sequenced. BLAST analysis (1) of the 488 bp segment showed a 100% similarity with the
sequence of *Lasiodiplodia theobromae* Pat. Griffon & Maubl (GeneBank accession GQ502453). The nucleotide sequence has been assigned the GenBank Accession JN849098. Pathogenicity tests were performed by inoculating three avocado fruits after surface-disinfesting in 1% sodium hypochlorite and wounding. Mycelial disks (8 mm diameter), obtained from PDA cultures of one strain, were placed on wounds. Three control fruits were inoculated with plain PDA. Fruits were incubated at 14-20 °C. The first symptoms developed 5 days after the artificial inoculation. After 7 days, the rot was very evident and *L. theobromae* was consistently reisolated. Non-inoculated fruit remained healthy. The pathogenicity test was performed twice. To our knowledge, this is the first report of the presence of *L. theobromae* on avocado in Italy, as well as in Europe. The occurrence of postharvest fruit rot on avocado caused by *L. theobromae* was described in many producing areas such as the US (4), South Africa and Israel. In Italy, the economic importance of avocado cultivation is at present limited.
