Running title: Tropical ulcer, an environmental indicator?

Key words: Tropical ulcer, osteomyelitis, Italy, climate, skin, semantic confusion

Abstract

The term tropical ulcer, as applied to bone pathology, describes the specific pathologic phenomenon of the presence of a well defined osteomatous shelf formation on the anteromedial aspect of the tibia. Despite the appellation “tropical,” this pathology is not geographically limited to tropical regions, although it has not previously been reported from continental Europe.

Observations of a 4583 BP burial from the Tanaro River area of Northern Italy represent the first such case. Dating of the site to the time of climate change at the end of the first Glacial suggests

1 that hot-warm, humid conditions may have allowed occurrence of this bone pathology, the first  
2  
3 observed in continental Europe. A second explanation is the possible migration of an individual to  
4  
5 Italy from an area that is more conventionally considered tropical.

## 11 12 13 14 15 16 Introduction

17  
18  
19  
20 Semantics and preconceptions often confuse and prematurely limit diagnostic consideration  
21  
22 when bone abnormalities are discovered (Rothschild and Martin, 2006). This is especially true for  
23  
24 the isolated, well-delineated, broad-based, elevated, plaque-like excrescence on the anteromedial  
25  
26 aspect of tibiae, a pathologic phenomenon that has been traditionally termed a tropical ulcer, or an  
27  
28 osteomatous response to a tropical ulcer (Adamson, 1949; Brown and Middlemiss, 1956; Ennis et  
29  
30 al., 1972; Kolawole and Bohrer, 1970; Ngu, 1967; Resnick, 2002). The plaque-like surface is  
31  
32 typically irregular and related to the presence of an overlying skin ulcer. Despite its name, the  
33  
34 pathology referred to as tropical ulcer is not limited geographically to tropical regions (Ngu, 1967).  
35  
36 However, the phenomenon does not appear to have been previously reported from continental  
37  
38 Europe. Observation of the classic pathology in Copper Age Italy stimulated this study and provides  
39  
40 new perspective to climate change.  
41

Gambari et al., 1999, 2011b; Zoppi et al., 2001). The site was in an alluvial plain outside the ancient course of the Tanaro River. Archaeological and pedological evidence suggests that the structure could be a mortuary room devised as a definitive closed space that suffered ceiling collapse (Fig. 2).

The tomb contained severely damaged skeletal and dental remains, minute copper plate fragments, and a bone awl (Venturino Gambari et al., 1999). The human remains were found in the mortuary room on the stone floor (arenaria). The pathologic tibia (AB PAP 14/36) was located in the northeast corner (Fig. 3).

The presence of remains of four adult individuals and six children suggests a kind of ancestors' house (Micheletti Cremasco et al., 2011a,b). Dating eight of these remains, sampled from secondary burials, revealed a temporal range from the end of the Neolithic to the Copper Age, from  $4762 \pm 53$  BP calibration  $2\sigma$ : 3646-3499 BC (skull fragment -OZE027) to  $3679 \pm 41$  BP calibration  $2\sigma$ : 2194-2170 BC (coxa fragment-OZF826) (Venturino Gambari et al., 2011a).

Evaluations of burial manner (secondary and synchronic burial of human remains from different earlier grave-places) allow us to identify the later Copper age as a *post quem* end date. We can date use of the monumental tomb use as a secondary burial, but not before the second half III millennium BC latest Copper age (Radiometric Dating ANSTO, Physics Division – Menai – Australia. Venturino Gambari et al., 2011a).

#### Methods

The antiquity of the affected tibia was assessed by radiocarbon dating (ANSTO Physics Division Menai NSW 2234 AUSTRALIA) and corrected dates determined (Venturino Gambari et al., 2011a; Zoppi et al., 2001). Non-destructive investigation methodologies were otherwise employed for the paleopathological assessment. Osteological remains were evaluated only macroscopically and by radiologic examination.

1  
2  
3  
4 The pathologic tibial diaphysis AB\_PAP 14/36 was associated with insufficient other  
5 skeletal elements to determine age or gender. It (AB PAP 36) was assigned by radiocarbon dating  
6 to the mid 5<sup>th</sup> millennium B.P.: conventional age 4583 +/- 62 B.P. (specimen OZE028 - ANSTO  
7 Physics Division Menai NSW 2234 AUSTRALIA) (Venturino Gambari et al., 2011a; Zoppi et al.,  
8 2001) (Table 1.)  
9  
10  
11  
12  
13

14  
15 Macroscopic examination of the bone surface reveals a well-delineated, broad-based  
16 elevated, 4.5 cm oval plaque-like excrescence/bony pad on the anteromedial aspect of tibiae (Fig.  
17 4). A well-defined depressed area is present centrally (Figures 4,5). A post-mortem fracture  
18 permits recognition of thickening of the subjacent compact bone. Radiologic examination (Figures  
19 6,7) reveals apposition of bone on the tibial surface with increased bone density in and around the  
20 lesion.

### 30 Discussion

31  
32 Tropical ulcer is the term utilized to identify a specific pathologic condition of bone that has  
33 been acquired in North, Central and East Africa, South America, Northern Australia, the South  
34 Pacific and Southeast Asia, but which has never been confidently reported in continental Europe  
35 (MacDonald, 2003; Ngu, 1967). It is described as a broad-based excrescence, resembling an  
36 osteoma (region of increased bone density) on the anteromedial aspect of the tibia (Adamson, 1949;  
37 Brown and Middlemiss, 1956; Ennis et al., 1972; Kolawole and Bohrer, 1970; Ngu, 1967; Resnick,  
38 2002). It is caused by a chronic penetrating ulcer, but is not necessarily limited to tropical regions  
39 (Ngu, 1967). It has been alternatively attributed to Vincent's type fusiform bacilli (e.g.,  
40 *Fusobacterium plautivincenti* and *F. fusiformis*), spirochetes (e.g., *Borrelia vincentii*, *Treponema*  
41 *vincenti*, *Spirochaeta schaudinni*) and *Staphylococcal* infections complicating traumatic injuries of  
42 the skin (Adamson, 1949; Adriaans et al., 1987; Kolawole and Bohrer, 1970; MacDonald, 2003;  
43 Ngu, 1967; Resnick, 2002). Malnutrition and poor hygiene have been suggested as contributing  
44  
45

1 factors (Adamson, 1949; Ngu, 1967). A reviewer suggested an alternative pathophysiologic  
2 consideration, that the bone reaction is adaptive to a behavioural activity that puts considerable  
3 sustained pressure on the anterior tibia. It is an interesting consideration, which has not been  
4 previously associated with tropical ulcers. However, sustained pressure usually produces pressure  
5 erosions (indentations of the bone surface), not elevations (Rothschild and Martin, 2006), making  
6 such a pathophysiological contribution less likely.  
7  
8  
9

10  
11  
12  
13  
14  
15 There has been great confusion in application of the term tropical ulcer and distinguishing it  
16 from non-specific skin ulcer disease, which has spread to the adjacent skeleton producing a more  
17 generalized periosteal reaction (Boel and Ortner, 2011). The latter authors suggested tropical ulcers  
18 were present on skeletal elements from the American Civil War (National Museum of health and  
19 Medicine, Walter Reed Army Medical Center, Washington, D.C.), the Terry Human Anatomy and  
20 Huntington Collections (Anthropology Department, Smithsonian Institution, Washington, DC) from  
21 the early part of the 20<sup>th</sup> century, and one each from 3300 BCE Jordan, 1650 Juhle, Maryland and  
22 from Medieval Nordby, Denmark and Malmö, Sweden. These are reviewed in detail below.  
23  
24  
25

26  
27  
28  
29  
30  
31  
32 One of the Civil war cases, the Jordanian case, the Huntington collection case, the Maryland case,  
33 one Terry Collection case, and the Malmö, Sweden cases were reported as having components  
34 characteristic of what has been called a tropical ulcer, but their diagnosis is not confirmed (Table 2).  
35

58  
59  
60  
One of the illustrated Civil War cases is excluded because it actually manifested diffuse  
circumferential expansion, quite different from the elevated excrescence of tropical ulcers. This  
tubular characterization was indistinguishable from the other cases reported by Boel and Ortner  
(2011) and allows their exclusion as examples of tropical ulcer. A second Civil War case had  
fibular involvement, characteristic of generalized osteomyelitis. The illustration of the Terry  
Collection case was actually that of a generalized periosteal reaction of the lower leg and the ulcer  
was actually excavated, not elevated. The Maryland case did have an elevated defined lesion,  
associated with remodeling of the entire tibia to produce a bowed appearance. The Huntington  
Collection case had sequestered bone (but not within the elevated area), characteristic of a bone

1  
2 abscess. The Jordanian case had fibular involvement, suggestive of generalized osteomyelitis. The  
3  
4 un-illustrated Malmö, Sweden case is difficult to assess, as Boel and Ortner (2011) noted neither  
5  
6 smooth, eroded, undulating nor the abnormal surface bone formation, as are found in tropical ulcers.  
7  
8 Thus, only three of the reported cases (Civil War, Maryland and Malmö, Sweden, the latter  
9  
10 unlikely) could represent a tropical ulcer. However, the term ivory osteoma has been applied to  
11  
12 tropical ulcers (Kolawole and Bohrer, 1970), and all reported cases had reduced, not increased  
13  
14 density (Boel and Ortner, 2011).

15  
16  
17 None of these purported cases were from continental Europe. Roberts and Manchester  
18  
19 (2005: 172) illustrate a tibia from 12<sup>th</sup>-16<sup>th</sup> century Chichester, Sussex, England with what they  
20  
21 called “focal new bone formation.” If that case indeed represented a tropical ulcer, could it be the  
22  
23 tibia of a slave infected in their native Africa and therefore not European in origin? Kendall et al  
24  
25 (2013) reported that five of 30 individuals (17%) from an East Smithfield, England cemetery were  
26  
27 not from the local area.

28  
29  
30 Attribution of the derivation of periosteal reaction has been controversial, and is often based  
31  
32 on speculation as to possible manifestations, rather than documented affected cases (e.g., Boel and  
33  
34 Ortner, 2011). Venous stasis has been repeatedly cited as a cause of periosteal reaction, although  
35  
36 documentation has proven elusive in the published record, and a shelf has not been reported  
37  
38 (Rothschild and Martin, 2006). Generalized periosteal reaction does not produce shelves. None  
39  
40 were seen among 300 cases of hypertrophic osteoarthropathy (Rothschild and Rothschild, 1998),  
41  
42 nor in hundreds of cases of treponemal disease (i.e., syphilis, yaws, bejel) (Hershkovitz et al., 1995;  
43  
44 Rothschild and Heathcote, 1993; Rothschild and Rothschild, 1994, 1995, 1996). Hypervitaminosis  
45  
46 A has been incorrectly suggested as a cause of periosteal reaction (e.g., Boel and Ortner, 2011). It  
47  
48 actually caused accentuated bone formation at entheses (Rothschild, Hershkovitz and Rothschild,  
49  
50 1995; Seawright, English and Gartner, 1970), not the shelves seen in tropical ulcer. Sickle cell  
51  
52 disease is associated with bone infarcts and chronic osteomyelitis, but not with the raised shelf  
53  
54 found in the tropical ulcer (Almeida and Roberts, 2005; Resnick, 2002). The Veld sore is a desert  
55  
56  
57  
58  
59  
60

1 ulcer, which usually does not affect bone (Ngu, 1967). Tumors produce a sunburst pattern not seen  
2 here (Kolawole and Bohrer, 1970; Resnick, 2002). The so-called crural ulcers reported by Nemeč,  
3 Kovar and Kachnic (1965) are more extensive examples of osteomyelitis, expanding from the tibia  
4 to the fibula. Tropical ulcers differ from Buruli ulcers, caused by *Mycobacterium ulcerans*. They  
5 produce massive skin and subcutaneous tissue necrosis, but usually without bone alterations, and  
6 the shelf phenomenon has not been reported (Merritt et al., 2010).  
7  
8  
9  
10  
11  
12  
13

14 The osteoma-like shelf of tropical ulcers appears unique to that phenomenon and is  
15 demonstrated in this tibia from the area of Alba, Italy. The specimen site is dated to shortly after the  
16 end of the first Glacial, when the temperature increased (Guidi and Piperno, 1982) and the Tanaro  
17 River location evidenced a warm humid climate. Palynological examination documents the  
18 Neolithic as a period characterized by hot-warm conditions in the Alba area, wherein the tomb was  
19 located (Arobba and Caramiello, 1998). The humidity level might have been significant, owing to  
20 the Tanaro river neighbourhood and presence of residual hygrophilous plants (Arobba and  
21 Caramiello, 1998). Does the current case represent an example of a tropical ulcer in an immigrant  
22 who migrated to Italy from a tropical area, or was it a complication of a local environmental event?  
23 Whichever explanation is accepted, this appears to be the first documentation of a tropical ulcer in  
24 continental Europe, and perhaps in Europe itself.

Figure legends:

Fig. 1. Location map of Papillon-Alba site in northern Italy.

Fig. 2. Papillon monumental tomb (Alba-Cuneo. Northern Italy): on the left of the image you can see the violation damage (south-west corner) (From: Venturino Gambari et al., 2011a photo C.O.R.A. Soc. Coop.).

Fig. 3. Tomb plan: in the center of the structure, there is the rectangular mortuary room with human remains (grey colour) with archaeological code number. The tibia AB\_PAP 14/36 is in the red circle.

Fig. 4. Alba Papillon -Right tibia (Specimen AB\_PAP 14/36): Antero-medial view.

Fig. 5. Alba Papillon - Right tibia (Specimen AB\_PAP 14/36): Detail of the previous view.

Fig. 6. Alba Papillon - Right tibia (Specimen AB\_PAP 14/36): X-ray.

Fig. 7. Alba Papillon - Right tibia (Specimen AB\_PAP 14/36): X-ray: Detail of the previous view.
