

Studies on bio-efficacy and phyto-toxicity of pendimethalin 38.7 % CS against weeds in groundnut (Spanish bunch) and its residual effects on succeeding wheat and sorghum crops in groundnut-sorghum/wheat sequence cropping system (94)

<u>Lokanath H Malligawad</u> (University of Agricultural Sciences (Uasd), Dharwad, India), **Digambarappa P Biradar** (University of Agricultural Sciences (Uasd), Dharwad, India), **Basavaraj M Khadi** (University of Agricultural Sciences (Uasd), Dharwad, India)

Groundnut is an important oilseed crop of India. Weeds pose a serious problem and weeds alone account for one-third of the total losses due to pests. Pre-emergence herbicides such as Alachlor 50 % EC, Pendimethalin (30 % EC and 38.5 % CS) and Oxyfluorfen (23.5 % EC) are being used for control of weeds in groundnut. Pendimethalin is available in emulsifiable (EC) and capsulated suspension (CS) formulations. It is reported that pre-emergence application of Pendimethalin 38.7 % CS is more effective than Pendimethalin 30 % EC in control of weeds. Therefore, a field trial was carried out during two consecutive years (2012-13 and 2013-14) at MARS, UAS, Dharwad on medium Vertisol to determine the efficacy of CS formulation of Pendimethalin @ 483.75 g, 580.50 g, 677.25 g, 750.00 g and 1354.50 g/ ha over EC formulation of Pendimethalin @ 1000 g/ha in controlling weeds in groundnut during kharif and its residual effects on succeeding sorghum and wheat during rabi. Results indicated that pre-emergence application of both formulations of Pendimethalin, in general, were more effective in controlling annual grassy and annual broad leaved weeds. However, pre-emergence application of Pendimethalin 38.7 % CS @ 483.75 g to 1354.50 g/ha was ineffective against congress weed (Parthenium hysterophorus L.). Pre-emergence application of Pendimethalin 30 % EC @ 1000 g/ha was very effective against congress weed. Pre-emergence application of Pendimethalin 38.7% CS resulted in relatively higher weed biomass and lower weed control efficiency than pre-emergence application of Pendimethalin 30 % EC. Both the formulations of Pendimethalin did not cause toxicity on groundnut or succeeding sorghum and wheat. Pre-emergence application of either Oxyfluorfen 23.5 % EC @ 100 g/ha or Alachlor 50 % EC @ 2500 g/ha were effective against congress weed and did not cause any ill effects on succeeding sorghum and wheat.

Chemical control of the invasive weeds *Ambrosia artemisiifolia* and *Acalypha virginica* in maize fields (627)

<u>Marco Milan</u> (Università di Torino, Grugliasco, Italy), **Francesco Vidotto** (University of Torino, Grugliasco, Italy), **Silvia Fogliatto** (University of Torino, Grugliasco, Italy), **Tiziano Pozzi** (University of Torino, Grugliasco, Italy), **Aldo Ferrero** (University of Torino, Grugliasco, Italy)

Ambrosia artemisiifolia and Acalypha virginica are exotic weeds in Europe that are becoming key weeds in summer annual crops. In this study, different chemical weed control strategies were compared in maize: pre-emergence, pre+post emergence, post-emergence, untreated check. The study was carried out in northern Italy during 2015 at two different sites, Grugliasco and Mesero. A. virginica was present only at the Mesero site. A RCBD with 21 m<sup>2</sup> and 25 m<sup>2</sup> plots, and with four and three replicates was used in Grugliasco and Mesero, respectively. The efficacy of each weed control strategy was assessed by measuring plant density (plants/m<sup>2</sup>) and ground cover (%). Weed assessments were carried out about one week after the treatment application. At the first assessment, in Mesero the infestations of A. virginica and A. artemisiifolia in untreated plots were 560 plant/m<sup>2</sup> and 70 plant/m<sup>2</sup>, respectively. At the same assessment, at Grugliasco, more than 47 plants of A. artemisiifolia were recorded. At both sites, all the compared weed control strategies completely controlled A. artemisiifolia infestations. In Mesero site, A. virginica infestation was completely controlled by pre and pre+post emergence treatments. At the assessment carried out after the postemergence application the average plant density of A. virginica was 73 plant/m<sup>2</sup> in treated plots, and 362 plants/m<sup>2</sup> in the untreated checks, with an average efficacy about 89%. The reduced efficacy of the post-emergence strategies is probably due to the advanced growing stage of *A.virginica* plants at the time of post-emergence application.
