INTRODUCTION

TRP channels play a key role in cancer progression, modulating cell proliferation and survival, cancer invasion of surrounding tissues and angiogenesis. TRP expression could therefore characterize the prostate cancer (PCa) cell phenotype. Another well-established concept is that TRPs deeply modulate endothelial cell (EC) biology and tumor angiogenesis. However, a specific TRP expression signature of PCa angiogenesis is still lacking. Our aim was to profile the expression of TRP channels during PCa angiogenesis and then to identify the specific molecular modulators of this process proving novel therapeutic targets.

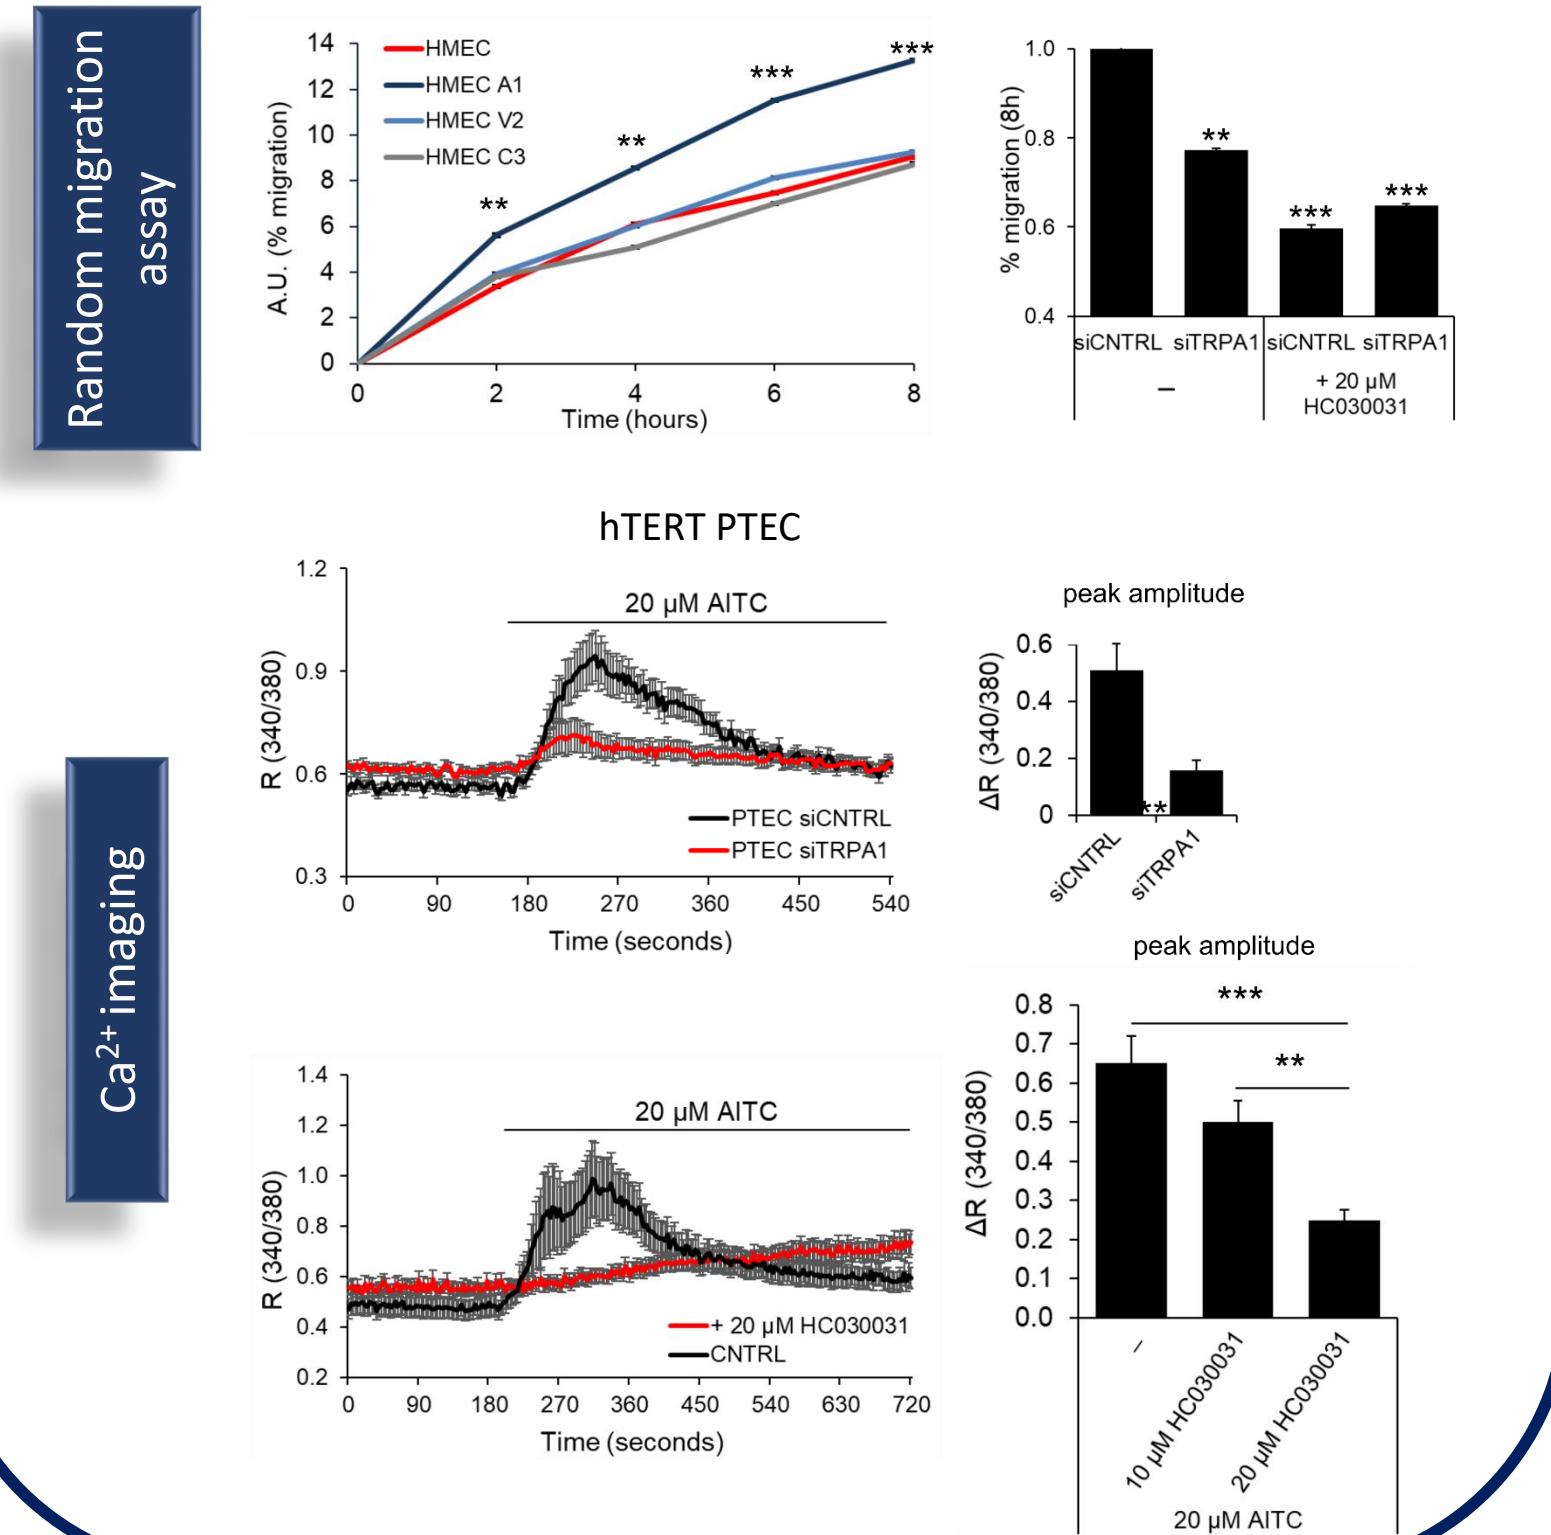

TRP channel expression profile in normal and tumor-derived EC highlights a 'Prostate specific' pattern

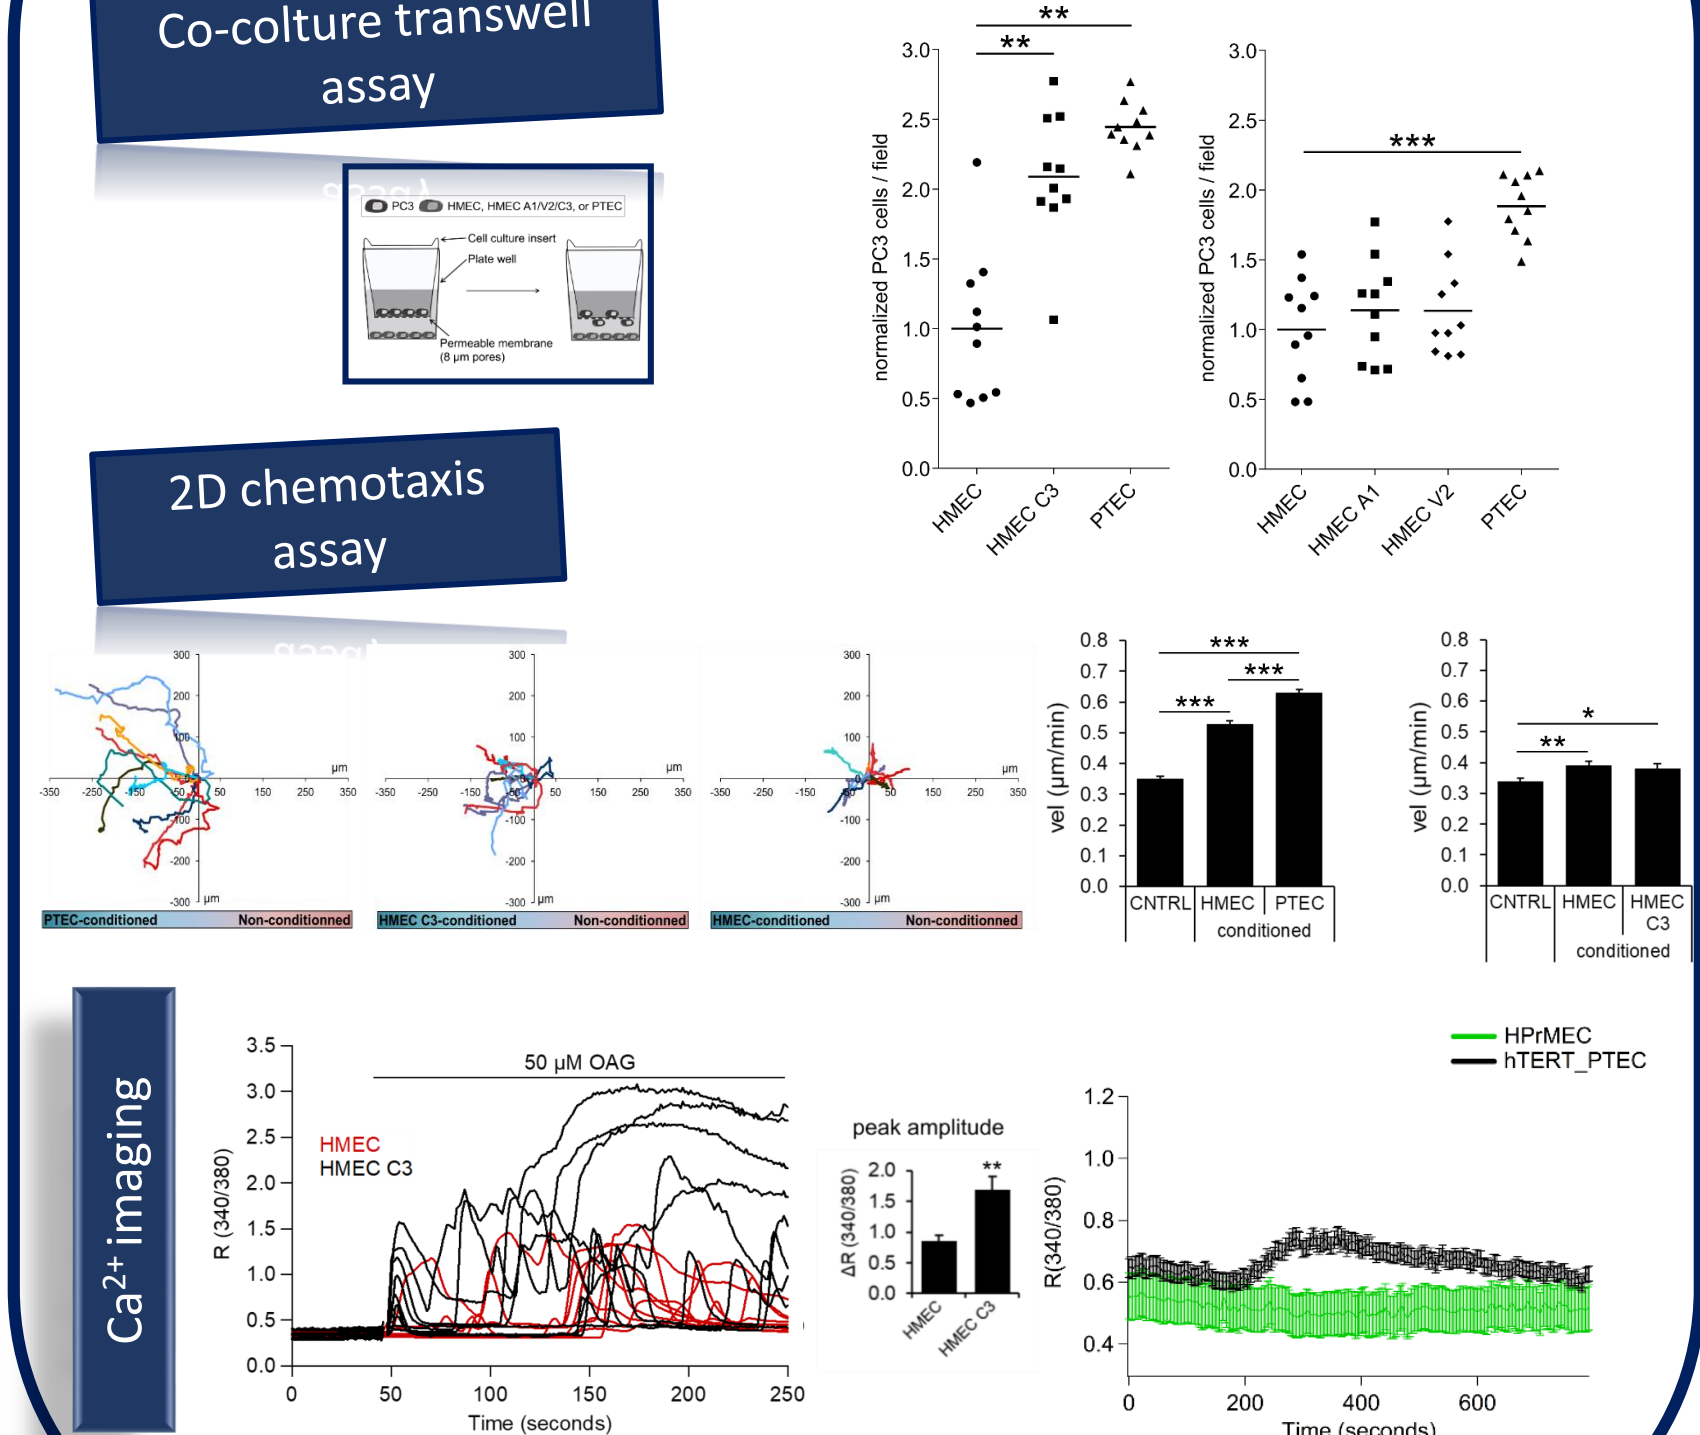

'Prostate-specific' TRPV2 enhances EC proliferation

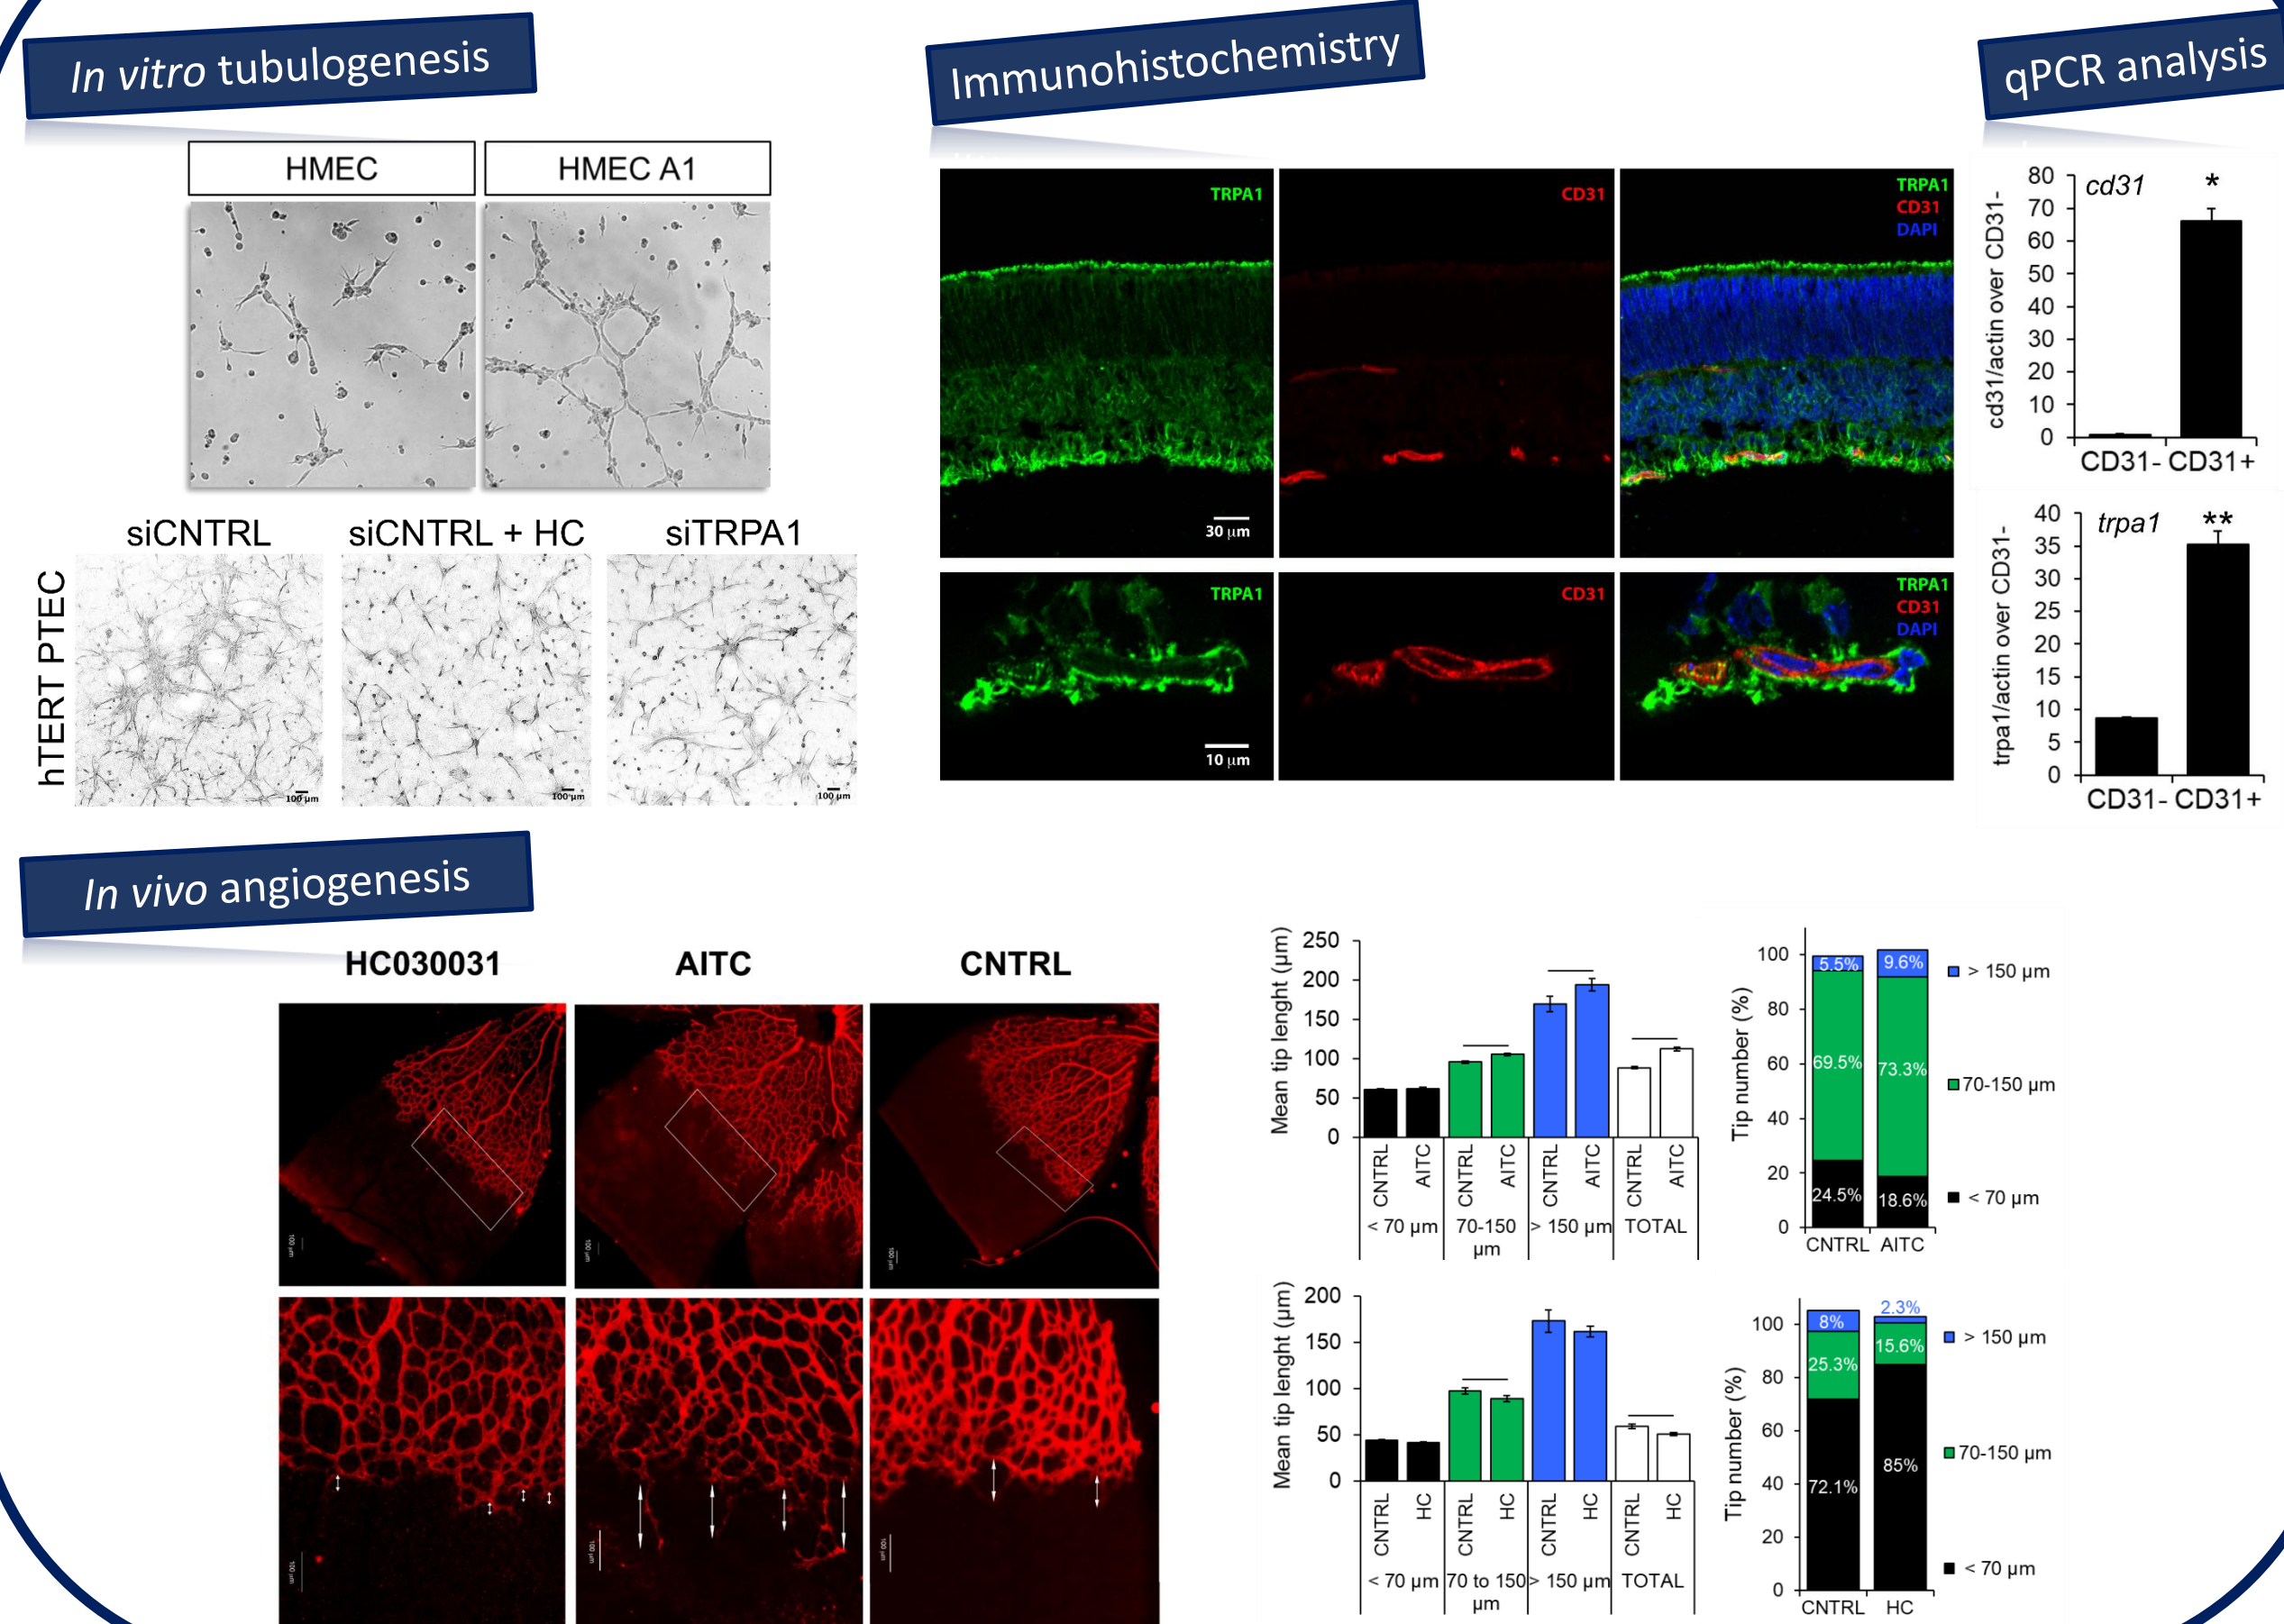

'Prostate-specific' TRPA1 enhances EC migration

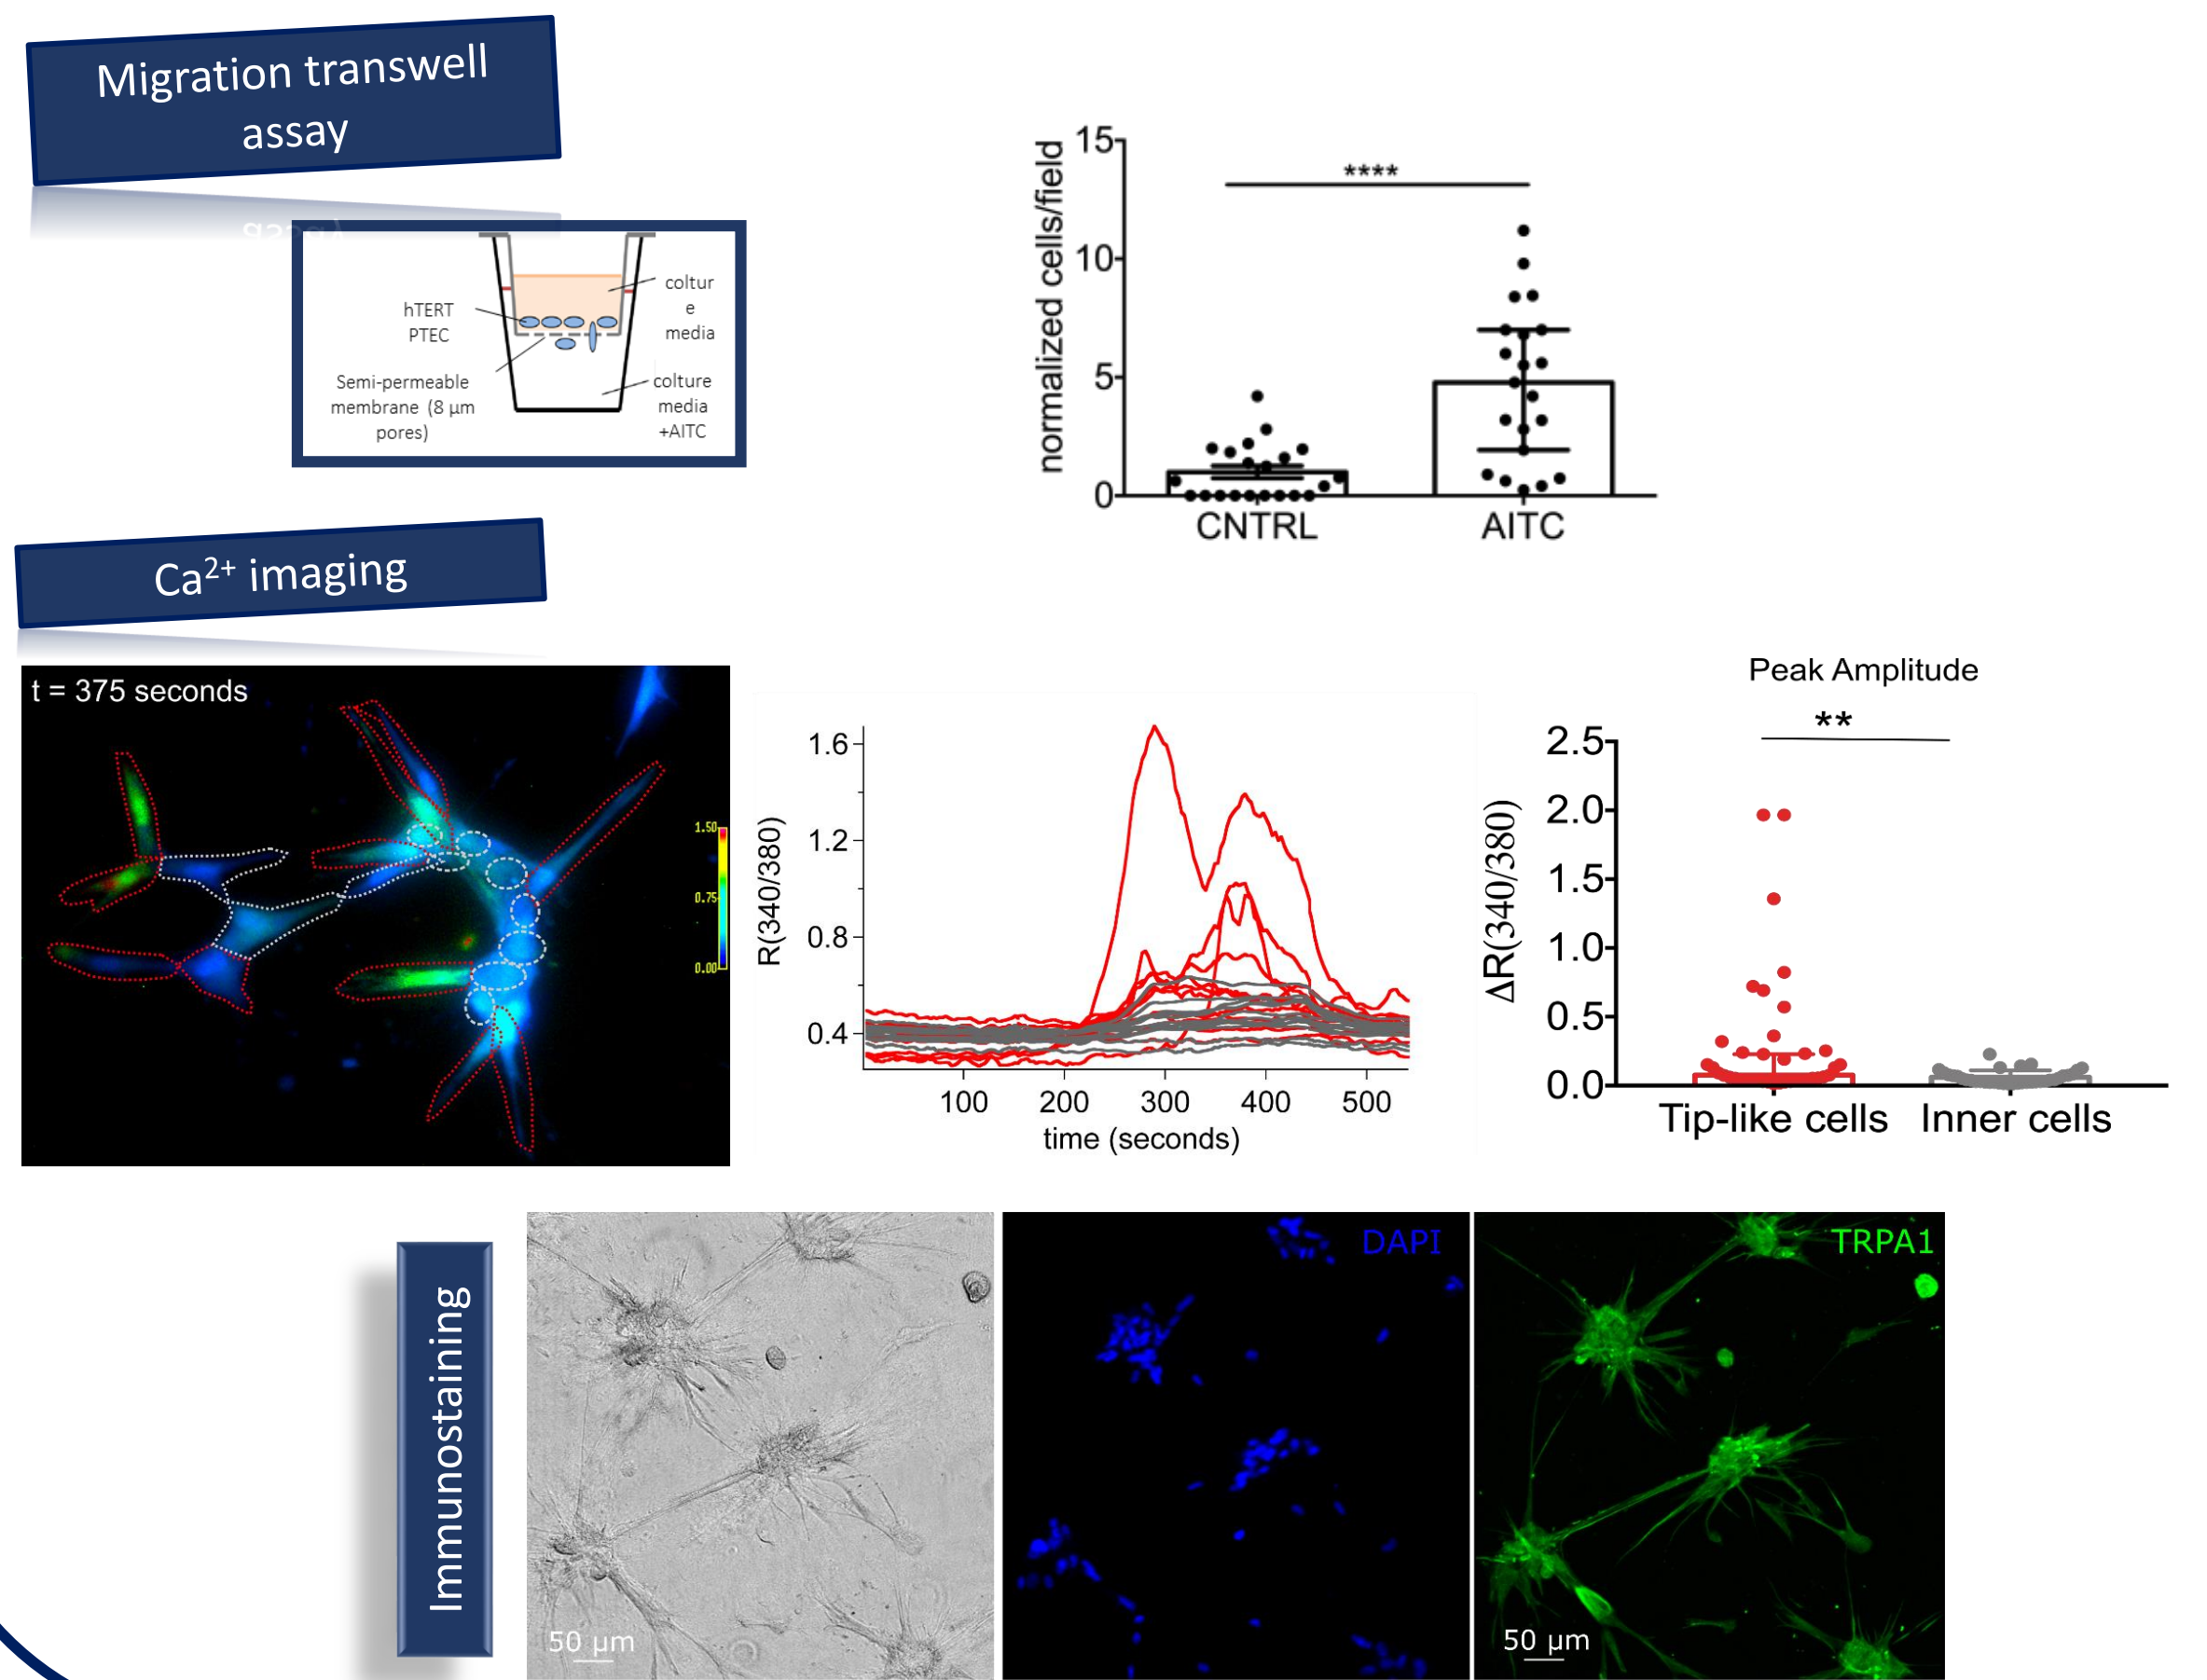

'Prostate-specific' TRPC3 promotes Pca cell attraction

TRPA1 promotes EC tubulogenesis *in vitro* and angiogenesis *in vivo*

TRPA1 is implicated in PTEC chemotaxis and function in tip-like cells

CONCLUSION

It was previously shown that PTEC exhibit the aggressive phenotype typical of TECs (Fiorio Pla et al. 2014). Here we identified three 'prostate specific' TEC overexpressed TRPs: TRPV2, TRPC3 and TRPA1 involved in different aspects of the angiogenic process. Taken together, our expression profiling and functional data could explain the transition of prostate endothelial cells to their aggressive tumor phenotype, proposing novel molecular players to selectively target PCa progression and angiogenesis. Results recently published (Bernardini *et al.*, *Cancers* 2019).
