1. INTRODUCTION

After two years of virtual-only conferences, we are very pleased that Berlin 2022 will be in person again. That our network has a high interest in meeting in person to intensify the networking was clearly reflected in the new record of abstract and workshop submissions. Our dedicated International Scientific Committee had the difficult job of scoring all the submissions and we are—as always—very grateful for their work, as their work ensures the high scientific quality of the conference programme.

This supplement to the European Journal of Public Health contains the abstracts of presentations at the 15th European Public Health (EPH) Conference, held in Berlin from 9-12 November and includes abstracts for presentations for the main part of the conference (plenary sessions, oral presentations, workshops and poster displays).

For the EPH Conference 2022, we received a record 2.371 abstracts including 186 workshops. All abstracts were scored by the members of the International Scientific Committee (ISC) of the EPH Conference. The ISC 2022 consisted of 132 public health experts from 31 countries and was chaired by Prof Verena Vogt. To ensure scientific quality without bias, each abstract was scored by on average 3,81 reviewers, each workshop by 3,95. We are extremely grateful to the ISC members who scored in 2022. These members are listed below.

International Scientific Committee, 2022, active

- Prof Verena Vogt, Germany—Chair
- Dr Oboh Achioyamen, United Kingdom
- Prof Róza Ádány, Hungary
- Dr Nina Adelberger, Germany
- Prof Charles Agyemang, Netherlands
- Prof Kristina Alexanderson, Sweden
- Prof Peter Allebeck, Sweden
- Mrs Tatiana Alves, Portugal
- Prof Arja Aro, Finland
- Prof Kevin Balanda, Ireland
- Dr Gabriela Barbaglia, Spain
- Dr Andrea Barbara, Italy
- Dr Marleen Bekker, Netherlands
- Prof Fabrizio Bert, Italy
- Dr Regien Biesma-Blanco, Netherlands
- Prof Johan Bilsen, Belgium
- Dr Christopher Birt, United Kingdom
- Dr Henrik Bøggild, Denmark
- Dr Richard Bränström, Sweden
- Prof Ute Bültmann, Netherlands
- Prof Genc Burazeri, Albania
- Prof Reinhard Busse, Germany
- Dr Stefan Buttigieg, Malta
- Dr John M Cachia, Malta
- Prof Stefano Capolongo, Italy
- Dr Marion Carey, Australia
- Paloma Carrillo-Santisteve, Belgium
- Dr Evangelia Chrysikou, United Kingdom
- Prof Nesrin Cilingiroglu, Turkey
- Dr Thomas Classen, Germany
- Prof Nadav Davidovitch, Israel
- Prof Judith de Jong, Netherlands
- Prof Corrado De Vito, Italy
- Prof Chiara de Waure, Italy
- Prof George Delclos, United States
- Prof Marie-Luise Dierks, Germany
- Prof Julia Dratva, Switzerland
- Natalie Durbeej, Sweden
- Mr Gilles Dussault, Portugal
- Prof Paksoy Erbaydar, Turkey
- Prof Carlo Favaretti, Italy
- Prof Rainer Fehr, Germany
- Prof Patricia Fitzpatrick, Ireland
- Dr Silvia Florescu, Romania
- Prof Anders Foldspang, Denmark
- Dr Kimberley Foley, United Kingdom
- Mr Marthein Gaasbeek Janzen, Netherlands
- Prof Maria Gańczak, Poland
- Mr Manuel García Goñi, Spain
- Prof Amandine Garde, United Kingdom
- Dr Abby Gold, United States
- Prof Beatriz González-Valcarcel, Spain
- Prof Marcus Grant, United Kingdom
- Prof Peter Groenewegen, Netherlands
- Prof Giuseppe Grosso, Italy
- Dr Stefano Guicciardi, Italy
- Prof Catherine Hayes, Ireland
- Dr Gunnel Hensing, Sweden
- Dr Thomas Hone, United Kingdom
- Prof Kate Hunt, United Kingdom
- Mr Damir Ivankovic, Netherlands
- Dr Danielle Jansen, Netherlands
- Prof Marta Cecilia Jaramillo-Mejia, Colombia
- Prof Marija Jevtic, Serbia
- Prof Ramune Kalediene, Lithuania
- Prof Ilona Koupil, Sweden
- Prof Allan Krasnik, Denmark
- Dr Ellen Kuhlmann, Germany
- Dr Bernadette Kumar, Norway
- Prof Tobias Kurth, Germany
- Prof Giuseppe La Torre, Italy
- Prof Lucie Laflamme, Sweden
- Prof Alastair Leyland, United Kingdom
- Prof Jutta Lindert, Germany
- Dr Tomi Mäki-Opas, Finland
- Prof Julian Mamo, Malta
- Dr Marco Marchetti, Italy
- Prof Piedad Martin-Olmedo, Spain
- Ms Sara Mc Quinn, Ireland
- Dr Odile Mekel, Germany
- Prof Anjum Memon, United Kingdom
- Mrs Monika Mensing, Germany
- Dr Gabriele Messina, Italy
- Mrs Joana Moreno, Portugal
- Dr Anne Mosnier Mantel, France
- Dr Iveta Nagyova, Slovakia
- Prof Saoirse Nic Gabhainn, Ireland
- Dr Emer O'Connell, Ireland
- Prof Orkan Okan, Germany
- Dr Maria Papadakaki, Greece
- Prof Julian Perelman, Portugal
- Prof Ivan Perry, Ireland
- Dr Elena Petelos, Greece
- Dr Paulo Pinheiro, Germany
- Mr Klaus D. Pluemer, Germany
- Prof Ileana Prejbeanu, Romania
- Prof Ossi Rahkonen, Finland
- Dr Muhammad Aziz Rahman, Australia
- Dr Bina Ram, United Kingdom
- Prof Andrea Rebecchi, Italy
- Dr Sofia Ribeiro, Portugal
- Prof Eva Roos, Finland
- Dr Nicole Rosenkötter, Germany
- Prof Luís Saboga-Nunes, Portugal

- Prof João Vasco Santos, Portugal
- Prof Milena Šantrić Milićević, Serbia
- Prof Sonia Saxena, United Kingdom
- Prof Andreia SilvaCosta, Portugal
- Prof Luis Souza, Brazil
- Prof Anthony Staines, Ireland
- Prof Danijela Stimac Grbic, Croatia
- Prof Christiane Stock, Germany
- Prof Saverio Stranges, Canada
- Prof Birute Strukcinskiene, Lithuania
- Dr Amets Suess Schwend, Spain
- Prof Pernille Tanggaard Andersen, Denmark
- Dr Marius-Ionut Ungureanu, Romania
- Dr Arjan van der Star, Sweden
- Dr Aurélie Van Hoye, Ireland
- Ms Caroline Vass, United Kingdom
- Dr M Luisa Vázquez Navarrete, Spain
- Prof Arnoud Verhoeff, Netherlands
- Prof Susana Viegas, Portugal
- Prof Paolo Villari, Italy
- Prof Anne Vuillemin, France
- Dr Georgina Warner, Sweden
- Mr Greg Williams, United Kingdom
- Prof Silviya Yankulovska, Bulgaria
- Dr Dineke Zeegers Paget

The abstracts were scored on a scale of 0–7. The average score of the single abstracts was 4.517 (Virtual 2021–4.381). The highest score was 6.667 and the lowest 1.000. The average score of workshops was 4.546 (Virtual 2021–5.050). The highest score was 6.667 and the lowest 2.000. Only the highest scoring abstracts are accepted for the EPH Conference. The rejection rate for the single abstracts was 30% and for workshops, the rejection rate was 35%. The EPH Conference Executive Board decided on 10 June 2022 on cut-off points for workshops, oral presentations and poster presentations, resulting in an excellent selection of workshops and presentations, as showcased in this abstract supplement.

Workshops	average score of 4.333 or higher were accepted
Oral presentations (8-minute presentation)	average score of 5.750 or higher were accepted
Pitch presentations (5-minute presentation)	average score of 5.333 or higher were accepted
E-Poster walks (3-minute presentation)	average score of 5.100 or higher were accepted
E-Poster displays (throughout the programme)	average score of 4.200 or higher were accepted

Following these decisions, abstracts were grouped in sessions, sessions in tracks and tracks were linked to the contents of the plenary programme. The programme for EPH Conference 2022 is organised in 16 thematic tracks, that mix workshops and oral sessions.

The 16 thematic tracks are:

A. Strengthening health systems: improving population health
B. Preparing for the unexpected: lessons learned from Covid-19
C. European public health/Food and nutrition
D. Chronic diseases
E. Environment, climate and health
F. Digital health and communication
G. Health data, information and assessments
H. Health determinants and health inequalities
I. Health services and welfare systems
J. Health promotion, health literacy, behavioural insights
K. Health workforce, training and practice
L. Infectious diseases, preparedness and vaccines
M. Maternal, child and adolescent public health
N. Mental health/Migration and minority health/LGBTQI+ health
O. Policy, politics and public health
P. Public health monitoring, reporting and foresight

The posters are on display throughout the whole conference.

As always, the International Scientific Committee members greatly enjoyed reading the submissions, many of them stating that it is a great exercise to learn about new developments in their field of expertise. We hope that you will find this volume equally interesting, and even more so the actual presentations, which promise to be of high quality yet again.

Looking forward to welcoming you all in Berlin,

Prof Reinhard Busse, Chair of the 15th European Public Health Conference
Prof Verena Vogt, Chair of the International Scientific Committee
Dr Dineke Zeegers Paget, Strategic advisor EUPHA

Plenary Sessions

PLENARY 1

Abstract citation ID: ckac128.001

Can people afford to pay for health care? Evidence on inequity in financial protection in Europe

Organised by: WHO Europe
Moderator: Natasha Azzopardi Muscat (WHO Europe)

Governments have repeatedly affirmed their commitment to meeting the goals of universal health coverage (UHC) – to ensure that everyone can use the quality health services they need without experiencing financial hardship. In spite of strong political commitment to UHC, research from the WHO Regional Office for Europe shows that:

- gaps in health coverage lead to unmet need for health care and financial hardship among people using health services
- these negative outcomes are heavily concentrated among people in poverty and those with multiple chronic conditions
- countries can reduce unmet need and financial hardship by re-designing coverage policy (the way in which health coverage is designed and implemented)

This session aims to raise awareness about the most prevalent gaps in coverage in European health systems, the policies that cause them and what countries can do to address them. It will draw on findings from an updated version of the WHO study 'Can people afford to pay for health care? New evidence on financial protection in Europe', which covers over 35 countries in Europe, including all EU member states and many middle-income countries
The session will highlight common gaps in coverage that systematically harm people with low incomes:

- the basis for population entitlement to publicly financed health services: exclusion of undocumented migrants; linking entitlement to employment or payment of contributions
- the scope and quality of publicly financed health services: poor coverage of medicines and dental care for adults; unreasonable waiting times leading to use of private services or non-covered medicines and unmet need
- user charges (co-payments): the absence of exemptions for people with low incomes; the absence of annual caps on all user charges; heavy reliance on percentage co-payments

The session will focus on how to make progress by:

- drawing attention to key principles for re-designing coverage policy, especially for people who are 'left behind' (adopting progressive universalism)
- showing how countries in Europe have done this, using examples of good practice

Keynote speaker:
Charles Normand
Trinity College Dublin, Dublin, Ireland

Panellists:
Sarah Thomson
WHO Europe

Kaisa Immonen
European Patients' Forum (EPF)

PLENARY 2

Abstract citation ID: ckac128.002

Plenary 2 Benefits and challenges of the European Health Data Space

Organised by: EUPHA, European Commission
Moderators: Iveta Nagyova (EUPHA), Isabel de la Mata (European Commission)

The creation of a European Health Data Space (EHDS) is one of the key components of a strong European Health Union. The objectives of the EHDS are: i) Empower individuals through better digital access to their personal health data; support free movement by ensuring that health data follow people; ii) Unleash the data economy by fostering a genuine single market for digital health services and products; and iii) Set up strict rules for the use of individual's non-identifiable health data for research, innovation, policy-making and regulatory activities. As such, the EHDS aims to improve and support healthcare delivery within Europe by allowing public health data to be accessible throughout Europe. The EHDS also aims to promote better access and exchange of different types of health data for research and policy purposes. The aim is to have the EHDS up and running in 2025.

The EHDS is expected to bring great benefit, but it also brings challenges related to technology, governance and privacy. The exchange of data at European level means that health data from different sources need to be able to talk to each other. Making the data Findable, Accessible, Interoperable, and Re-usable is key to the success of the EHDS. Moreover, the diversity of Europe's health information systems need to be taken in account. The EHDS will also have to be transparent to ensure privacy of personal information included in the EHDS.

Speakers:
Fulvia Raffaelli
European Commission, Brussels, Belgium

Petronille Bogaert
Sciensano, Brussels, Belgium

Irene Schlünder
TMF, Germany

Emmanuel Bacry
Health Data Hub, France

PLENARY 3

Abstract citation ID: ckac128.003

Plenary 3 Health Systems Performance Assessment for Policy: Uses and Abuses

Organised by: European Observatory on Health Systems and Policies, European Commission
Moderators: Isabel de la Mata (European Commission), Dimitra Panteli (European Observatory on Health Systems and Policies)

The COVID-19 pandemic constitutes a powerful reminder of the importance of health systems strengthening in protecting and improving the health of our populations. For policy makers 'to build back better' systems to face future shocks, they will need to be able to determine which areas work best (in terms of providing access, quality, population health, responsiveness or efficiency) to prioritize and direct resources towards. More than ever, we need now to count with strong health systems monitoring, appraisal and assessment to draw practical policy implications.

This plenary will look at the effective application of Health Systems Performance Assessment (HSPA) to health systems' improvement as we face key challenges in the sustainability of our health systems. Too often the results of HSPA exercises, particularly when benchmarking is involved, are not well interpreted, and understood. When translating HSPA results into policy changes, we need to address a series of questions not only about the quality and validity of the indicators but, importantly, about the causal attribution and accountability implications and about the kinds of policy interventions required to address the performance failures.

Following an introductory keynote providing practical illustrations of those issues and drawing policy lessons, the panelists will focus on three key HSPA questions particularly relevant in the current policy context. First, how to interpret and attribute overall health system performance outcomes to individual health system functions and strategies in need of reform. Second, how best to benchmark and compare performance between European countries to identify and learn from best practices. Finally, how to measure resilience as core component of systems performance and draw lessons to prepare for future shocks.

Introductory keynote speaker:
Reinhard Busse
European Observatory on Health Systems and Policies and Technical University Berlin, Germany

Panellists:
Kenneth Grech
EU Expert Group Health Systems Performance Assessment & Ministry of Health Malta, Malta

Irini Papanicolas
Department of Health Policy, London School of Economics and Political Science, UK

Marina Karanikolos
Research Fellow, European Observatory on Health Systems and Policies; London School of Economics and Political Science, UK

PLENARY 4

Abstract citation ID: ckac128.004

Plenary 4 Reorienting health services: the transformational potential of health promotion

Organised by: EuroHealthNet
Moderators: Martin Dietrich (EuroHealthNet), Caroline Costongs (EuroHealthNet)

Over the past decades, in Europe, the nature of our disease burden has shifted from more communicable and acute to chronic diseases such as cardiovascular diseases, diabetes, cancer and mental ill health. These diseases usually manifest themselves later in life, but they are not necessarily related to biological ageing. They mostly result from an accumulation of unhealthy living patterns since childhood and across the life course. Consumption of processed foods high in fat, salt, and sugar, smoking, excessive alcohol use, too little physical activity and too much stress all contribute to the growing and worsening burden of chronic diseases. These behaviours in turn are shaped by the social, environmental, cultural and economic conditions in which we live, grow, work and age.

Once they have developed, chronic diseases can be difficult, or even impossible to cure. Our health services, with a traditional curative approach, are not equipped for this chronic epidemic. There is an urgent need to shift our health services away from the predominant focus on cure and towards prevention, and for policy makers to invest in ensuring healthy living environments and societies. Health promotion and enabling people and population groups to increase control over their health, particularly those facing disadvantage, has the potential to transform our health services, and is critical to ensuring their resilience and sustainability.

Despite a growing awareness of the need for change, reorienting structures and systems in practice is challenging, as people can be resistant to change. Siloed approaches within the health sector, but also between social, health, and education sectors continue to prevail, and it is not always easy to find the right levers for change and to build bridges across administrations. This is compounded by a lack of infrastructure, organizational and workforce capacity for health promotion, and sustainable financing mechanisms. Much innovative work is however taking place, which we can learn from and scale up.

This plenary session will provide examples of different ways in which health-promoting approaches can reorient health services, strengthen health-promoting and community oriented primary care and prevent chronic diseases. It will highlight what we can learn from behavioural and cultural insights and social prescribing, as well as integrated community initiatives to further support people, across the social gradient, to lead and to maintain healthy lives. It will discuss target setting for further advocacy among policy makers.

Speakers:
Rüdiger Krech
WHO, Geneva, Switzerland

Susan Michie
University College London, UCL Centre for Behaviour Change, London, UK

Jan De Maeseneer
European Commission Expert Panel on Effective Ways of Investing in Health and Ghent University, Belgium

Jet Bussemaker
Council of Public Health & Society, Netherlands, Leiden University Medical Center, Leiden, Netherlands

Cristiano Figueiredo
USF da Baixa, Central Lisbon Health Centre Cluster, National School of Public Health, NOVA University Lisbon, Portugal

PLENARY 5

Abstract citation ID: ckac128.005

Plenary 5 Sustaining high quality care: interprofessional training for our clinical and public health workforce

Organised by: ASPHER, EHMA
Moderators: John Middleton (ASPHER), Tara Chen (ASPHER)

The plenary session will align with the main conference theme ‘Strengthening health systems: improving population health and being prepared for the unexpected’ and providing a balanced perspective on public health and healthcare interprofessional linkages for training of the two workforces integral for a well-functioning, responsive and robust health system.

Natasha Azzopardi-Muscat, WHO Regional Office for Europe who will set the scene for the first Keynote with the WHO Athens Office work on European Programme of Work (EPW) 2020–2025 – ‘United Action for Better Health in Europe’ reflecting on the coherence of policies, structures and resources for quality of health care and implications for policy dialogue, policy formulation and technical assistance at the regional, sub-regional and country levels. She will also speak to the WHO/EURO Regional HRH Report presented in September 2022 and the WHO-ASPHER Roadmap to Professionalization launched in February 2022 offering pragmatic recommendations for action to professionalize the public health workforce as a response to growing public health needs.

EHMA Director George Valiotis will follow with a Keynote speaking to the key EU agenda on skills for health, with the EHMA led BeWell (2022-2025) project: Investing in the upskilling and reskilling of the European health workforce. The multi-partner consortium aims to build a movement of healthcare stakeholders which support and contribute to the development, implementation, and upscaling of a strategy on the upskilling and reskilling of the European health workforce addressing the skills needed to support the digital and green transition within the health ecosystem enabling all health professionals to be better prepared to face future challenges and adapt to ever-evolving societal contexts.

Fatai Ogunlayi, UK Public Health Specialty Registrar will speak to the global level agenda with focus on the WHO Roadmap: ‘‘Building the Public Health and Emergency Workforce’. The roadmap is designed to provide countries with a differentiated and progressive approach to acknowledge varying capacities and contexts with provision of guidance and tools; and support progress to full implementation towards a strengthened public health workforce delivering all essential public health functions for universal health coverage, health security and improved health and wellbeing.

Laurent Chambaud, Dean, EHESP School of Public Health, will provide a country perspective with discussion of work toward official agreements on the One Health approach, which recognizes that the health of people is closely connected to the health of animals and our shared environment, and the interprofessional context and training required to achieve it.

Keynote speaker:
Natasha Azzopardi Muscat
WHO Europe

George Valiotis
European Health Management Association, Brussels, Belgium

Speakers/Panellists:
Fatai Ogunlayi
UK Public Health Specialty Registrar, UK

Laurent Chambaud
Andrija Stampar Medallist 2022, France

Anett Ruszanov
Director of Policy and Programmes, EHMA

Parallel Programme

1.A. Workshop: EU nutrition policies: from rhetoric to practice

Abstract citation ID: ckac129.001

Organised by: EUPHA-LAW, EUPHA-FN, University of Essex (UK), University of Liverpool Law & NCD Unit (UK), European Public Health Alliance
Chair persons: Giuseppe Grosso (EUPHA-FN)
Contact: nikhil.gokani@essex.ac.uk

Unhealthy diets result in over a million deaths each year in Europe, and over half the EU adult population is overweight or obese. Since it took office, the von der Leyen Commission published major policy documents which, amongst others, seek to tackle poor nutrition. The 2020 Farm to Fork Strategy claims that ''European food is already a global standard for food that is safe, plentiful, nutritious and of high quality''. However, it also acknowledges that the European diet is typically high in fat, sugar, salt and calories and red and processed meat, but low in fruit, vegetables, wholegrains, legumes and nuts. The Strategy notes that the transition to a healthy, sustainable food system - and the concomitant health, economic, societal and environmental benefits this will bring - requires that the food environment should make healthy food easier to choose. Similarly, the 2022 Europe's Beating Cancer Plan accepts that about 40% of cancers in the EU are preventable and, prevention being more effective than any cure, places great emphasis on the promotion of healthier consumption. This workshop will consider two policy interventions that the WHO has recognised as key to the promotion of healthier food environments and that have been at the heart of the EU's strategic documents on nutrition and obesity prevention for now well over 15 years: food labelling and food marketing. This workshop will seek to contextualise the Commission's current proposals on food labelling, and its lack of robust proposals on food marketing, with a view to discussing the extent to which its actions are aligned with its rhetoric. It will also discuss how the Commission can move in the right direction to bring real improvements in these fields in practice. EUPHA-LAW has been supporting the development of effective EU policies on food labelling and food marketing through a number of initiatives. In relation to food labelling, EUPHA-LAW responded to three Commission consultations, members of the Steering Committee held a meeting with the Commissioner's team on the new proposals, co-hosted a major conference on regulating FoPNL with almost 300 attendees from over 39 countries, and participated in workshops specifically intended to inform the impact assessment accompanying the forthcoming proposals. In relation to food marketing, EUPHA-LAW is closely involved in the Food Marketing Initiative supported by over 20 pan-EU federations of public health, consumer and children's rights organisations. This Initiative has called on the EU to adopt a directive imposing EU-wide legally binding restrictions on the cross-border marketing of unhealthy food to children. This would allow the EU to go further than it has to date and therefore align the EU regulatory framework with international recommendations and adopt a children's rights-based approach to such marketing.

Key messages:

- The Commission has recognised that front-of-pack nutrition labelling and food marketing are two necessary policy interventions to promote healthier food environments.
- However, the EU's actions in this field highlight a significant gap between rhetoric and practice which needs to be addressed through the adoption of rights-based approaches.

Abstract citation ID: ckac129.002
Food labelling

Nikhil Gokani

N Gokani[1]
[1]School of Law, University of Essex, Colchester, UK
Contact: nikhil.gokani@essex.ac.uk

The Commission has undertaken to regulate the information provided to consumers on food. In particular, it intends to propose mandatory front-of-pack nutrition labelling (FoPNL) for food by the end of 2022. Even though nutrition labelling has been regulated by the EU since 1990, the tactics of industry, with the support of a minority of Member States, have prevented, so far, the adoption of a single, EU-wide, mandatory FoPNL scheme. Questions therefore arise regarding the extent to which the EU may secure agreement for the adoption of an EU-wide scheme which could effectively contribute to a high level of public health protection.

Abstract citation ID: ckac129.003
Food marketing

Amandine Garde

A Garde[1]
[1]School of Law and Social Justice, University of Liverpool, Liverpool, UK
Contact: amandine.garde@liverpool.ac.uk

The Commission has established a joint action with Member States through the Best ReMaP joint action (2020-2023) to facilitate the effective implementation of the Audiovisual Media Services Directive which, in its revised version, calls on Member States to ensure that codes of conduct protect children from exposure to unhealthy food marketing. This provision itself highlights the tension between, on the one hand, the desire to limit the exposure of children to harmful food marketing and, on the other, the likelihood of achieving this objective through the implementation of codes of conduct.

Speakers/Panellists:
Nikolai Pushkarev
Healthy Environments & EPHA Policy, European Public Health Alliance, Brussels, Belgium
Contact: nikolai.pushkarev@epha.org
EPHA will present the perspective of the public health advocacy community, and discuss some of the initiatives civil society are engaged in to help the EU move from rhetoric to practice.

1.B. Workshop: Adaptations in a time of crisis – public health practice in Sweden during the COVID-19 pandemic

Abstract citation ID: ckac129.004

Organised by: The Public Health Agency of Sweden
Chair persons: Anna Månsdotter (Sweden), Karin Guldbrandsson (Sweden)
Contact: karin.guldbrandsson@fohm.se

Background:
The Public Health Agency of Sweden has assessed the consequences of the COVID-19-pandemic in relation to the Swedish public health goals, aiming at good and equitable health. This assessment indicated 1) that preconditions for good and equitable health have changed during the pandemic, 2) that groups with higher risk of ill-health before the pandemic were more severely affected, 3) that the general health of the population remains good although some groups appear to have suffered from increased minor mental health problems, 4) that physical activity has decreased and sedentary behaviour has increased, and 5) that many activities of relevance for public health, such as prevention of alcohol, drugs, and tobacco (ADT) at the local and regional levels were paused or were replaced with other, often digital, alternatives.
Objectives:
The objective of this workshop is to present and discuss the results of four projects studying the consequences of the COVID-19-pandemic for public health practice in Sweden. Special attention is paid to ADT-prevention at the local and regional levels, focusing on how such work has developed digitally during the pandemic. Potential implications will be discussed with the audience. The added value of organizing this workshop: This workshop will contribute to an improved understanding of how public health practice, particularly ADT prevention, has navigated through a time of a crisis (i.e. a pandemic) in order to provide important lessons for the future. The presentations in this workshop will lay the foundation for discussing with the audience what might happen within the arena of health promotion and disease prevention as a result of a pandemic as well as ways to cope with the consequences of such a pandemic at the local and regional levels. The coherence between the presentations and the topic of the workshop: There is an obvious logic between the main topic of the workshop and the four presentations. In different ways, they all discuss consequences of the COVID-19-pandemic on public health practice in Sweden.
The format of the workshop:
The workshop will start with a brief introduction, aiming to give a short background and set the scene. Four presentations will then follow, with time allocated for questions after each presentation. The presentations will contain descriptions of each subproject, including the background, methods, results, and conclusions. Finally, the moderator will lead a discussion with the audience and the presenters.
Key messages:
- The pandemic forced public health practice to adapt its ways of working.
- When challenged, public health practice can operate in new ways, although with some regional differences.

Abstract citation ID: ckac129.005
Public health in Sweden during the COVID-19 pandemic

Anna Månsdotter

A Månsdotter[1,2], *G Fochsen*[1]
[1]Living Conditions and Lifestyles, Public Health Agency of Sweden, Solna, Sweden
[2]Department of Epidemiology and Global Health, Umeå University, Umeå, Sweden
Contact: anna.mansdotter@folkhalsomyndigheten.se

Background and objectives:
The COVID 19 pandemic has highlighted how public health is dependent on many areas of society, and several aspects of public health can be affected. We have evaluated how the COVID-19 pandemic and the measures taken to reduce its spread have impacted public health in Sweden during 2020.
Methods:
We systematically compiled international research on the pandemic's impact on public health, we examined living conditions of groups at a particularly increased risk of ill health, and we collected and analysed Swedish data on lifestyles, health, injury, and illness during the pandemic compared to previous years.
Results:
Most people have, in one way or another, been affected by the pandemic and by societýs preventive measures. However, some groups have suffered more than others. Groups who were already at an increased risk of ill health before the pandemic have been most affected, e.g. in schools, on the labour market, and in society in general. There is a risk of increased health inequality, not only related to morbidity and mortality of COVID-19 during 2020, but also when it comes to the effects on living conditions.
Conclusions:
The consequences of the COVID-19 pandemic pose major challenges for public health, and the measures taken to limit its spread inter-relate with social and economic conditions. In Sweden, health inequalities have remained the same or increased over the years. Our study suggests that the consequences of the pandemic will reinforce health inequalities. It is too early to determine what the pandemic's full impact on public health will be. Nevertheless, health promotion and preventive measures need to be strengthened and prioritized in order to maintain good public health and reduce inequalities.

Public health work in Sweden during the COVID-19 pandemic

Karin Guldbrandsson

K Guldbrandsson[1], *A Månsdotter*[1,2]
[1]Living Conditions and Lifestyles, Public Health Agency of Sweden, Solna, Sweden
[2]Department of Epidemiology and Global Health, Umeå University, Umeå, Sweden
Contact: karin.guldbrandsson@fohm.se

Background and objectives:
This study examines the consequences of the COVID-19 pandemic for public health practice carried out at local and regional levels in Sweden. The work includes, for example, interventions in health care, schools and preschools, social services, and non-profit organisations.
Methods:
By means of written questions and interviews in municipalities, regions, county administrative boards, networks, and organisations, we investigated whether public health-related interventions had decreased, increased, or changed as a result of the COVID-19 pandemic. Data were analysed by content analysis.

Results:

The results show that a large number of interventions from a variety of local and regional actors aimed at broad target groups were cancelled or paused during the time of our survey. Eventually, many, but not all of the cancelled interventions were replaced with other options, most of which are included in the following themes:

- Digital solutions and support over the phone instead of physical meetings.
- Outdoor activities instead of indoor activities.
- Organisational adaptations, for example, from drop-in visits to booked appointments and from open activities to scheduled visits.

The interviews also revealed that public health issues had been highlighted and that existing collaboration structures were a success factor in managing the consequences of the COVID-19 pandemic. The risk of and concern for the spread of infection and compliance with the authorities' recommendations were stated to be the main reasons why public health-related interventions had decreased, increased, or changed.

Conclusions:

Both general public health practice and targeted interventions in health care and municipal activities have been cancelled or rescheduled according to our survey. Because many public health-related interventions have an equalising effect on health, this can be of great importance for groups that are socially, economically, or health-relatedly vulnerable.

Prevention of alcohol, drugs and tobacco during the COVID-19-pandemic – consequences and inequalities in Swedish municipalities

Ulrika Owen

U Owen[1], E Lindström[2]
[1]Living Conditions and Lifestyles, Public Health Agency of Sweden, Östersund, Sweden
[2]Living Conditions and Lifestyles, Public Health Agency of Sweden, Solna, Sweden
Contact: ulrika.owen@folkhalsomyndigheten.se

Background and objectives:

The COVID-19 pandemic and measures to prevent the spread of the virus challenged public health practice at the local and regional level in Sweden. The objective of this study was to follow-up how local preventive ADT prevention (alcohol, drugs, and tobacco) in Sweden was affected during 2020-2021.

Methods:

All Swedish municipalities (N = 290) were included in surveys on how the pandemic affected local ADT prevention. Response rates ranged between 82 and 91 percent. Quantitative data were analysed with reference to socioeconomic and demographic conditions. Qualitative data were analysed thematically.

Results:

A majority of the municipalities reported a decrease in ADT prevention, especially aimed at groups such as parents, children, and young people. There was no correlation between the decrease in municipal ADT prevention and sociodemographic conditions. A majority of the municipalities reported that activities were adapted, often with a digital approach. Adaptation of ADT prevention was less common in smaller municipalities and municipalities where residents had lower levels of education and lower incomes. An increase in activities, as a consequence of measures to prevent the spread of the virus, was more common in larger municipalities and municipalities with a greater proportion of residents with higher educational backgrounds and higher incomes.

Conclusions:

ADT prevention carried out by municipalities in Sweden was initially deeply affected by the COVID-19 pandemic and by measures to prevent the spread of the virus. However, activities were adapted over time, mainly with a digital approach. The ability to adapt differed depending on the sociodemographic conditions of the municipalities. Follow-up studies on ADT prevention and the consequences of the digital approach during 2021 will be presented at the conference.

Abstract citation ID: ckac129.008
Digitalisation in the area of alcohol, drug, and tobacco during the COVID-19-pandemic: supporting the drive towards an equitable health?

Frida Jonsson

F Jonsson[1], R Schimmer[2]
[1]Department of Epidemiology and Global Health, Umeå University, Umeå, Sweden
[2]Department of Psychology, Umeå University, Umeå, Sweden
Contact: frida.jonsson@umu.se

Background and objectives:

The COVID-19 pandemic has posed challenges for traditional public health practice. In the area of alcohol, drugs, and tobacco, local and regional actors have largely moved from physical to digital solutions to handle the barriers imposed by the pandemic. To strengthen the knowledge base in the area, this project aimed to explore how the local transition to, and management of, digital solutions within alcohol, drugs, and tobacco prevention might support the policy drive in Sweden towards equity in health.

Methods:

This was a qualitative study where 13 local coordinators from 7 municipalities participated. Data were collected through 9 individual and 2 group interviews (semi-structured). The analysis was inductive and followed a thematic analysis approach to identify, analyse, and present patterns (themes) in the data.

Results:

Three themes were developed illustrating how the local implementation of digital solutions in the area of alcohol, drugs, doping, and tobacco prevention might support the transition towards equity in health by 'making time and resources available for development and innovation', 'improving the ability to reach and engage with vulnerable groups', and '(re)shape initiatives to act inclusively'.

Conclusions:

As illustrated by experiences of the local coordinators, the municipalities seemed to have managed the challenges of the pandemic in a good way. To a large extent, they appeared to have adapted their work to remain operational by transitioning into digital solutions. Considering that the pandemic has been challenging in various ways, the finding of ensuring operations were running should not be underestimated. However, besides being able to largely maintain a ''status quo'' in a time when traditional modes of working were inadequate or inappropriate, the results illustrated how the municipalities have added numerous (digital) tools to their toolbox for use in the continuing drive towards good and equitable health.

1.C. Workshop: What has the EU ever done for my health system? Using EU tools effectively for health system change

Abstract citation ID: ckac129.009

Organised by: European Observatory on Health Systems and Policies
Chair persons: Dimitra Panteli (Belgium), Nick Fahy (UK)
Contact: mauern@obs.who.int

Health systems face a broad range of evolving challenges: from infectious cross-border threats to climate change, potential backlogs caused by the pandemic and the concurrent burden of non-communicable diseases growing worldwide. They need to be dynamic to respond in ways that help them achieve their goals and adapt to an ever-changing landscape of health system stressors. While improving health and care systems is primarily the responsibility of Member States within the European Union (EU), the EU has a wide range of instruments that can potentially provide support. However, they are scattered across different policy areas and, for most of them, health systems strengthening is not among the principal objectives. This can make it challenging for Member States to identify, combine and make best use of the different support options in an effective way. The objective of this workshop will be to provide an overview of the different types of available EU instruments, while also delineating a range of practical examples of how countries have used them to address health system challenges and implement large-scale change. The European Observatory on Health Systems and Policies will kick off the workshop with a keynote presentation of its policy brief ''EU support for improving health and care systems'', conceived in cooperation with the 2021 Slovenian Presidency of the EU Council as a toolbox for policy makers trying to navigate and maximise the potential of EU support tools. Beyond having to identify the best possible tools for health system transformation, policy makers must pave the way for system change and propel the implementation of innovative solutions at national, regional, and local levels. The new European Partnership on ''Transforming Health and Care Systems'' under Horizon Europe will join the workshop to discuss how to best support policy makers in bringing about organisational change and ensure European populations get access to innovative, sustainable, and high-quality health care. In addition, the workshop will give voice to insights from other relevant stakeholders, including a country-level perspective from Slovenia, an EU Member State which has successfully leveraged EU support to strengthen its health system in the past. This viewpoint will be complemented by an outlook from the European Commission into current priorities and upcoming opportunities under the most relevant EU support instruments for health systems, including EU4Health and Horizon Europe. Finally, the presenters and panellists will engage in an interactive discussion with the audience to help participants consider the possibilities and challenges of using EU tools for health system strengthening and to support them in designing their own initiatives.

Key messages:

- Reaping maximal benefits of EU support requires combining various instruments.
- Health system transformation is a context-specific process, yet it can greatly benefit from cross-country learning.

Abstract citation ID: ckac129.010
What are the tools provided by the EU to support health and care improvement?

Nicole Mauer

N Mauer[1]
[1]European Observatory on Health Systems and Policies, Brussels, Belgium
Contact: mauern@obs.who.int

Improving health and care systems is primarily the responsibility of Member States within the EU. Nevertheless, the EU provides a lot of potential support to Member States that can help to improve health systems. However, the range of EU tools that can help to strengthen health systems has grown up over decades across different policy fields, and most potential EU support is incorporated within instruments that have wider objectives. This can make it challenging to identify and optimise the use of the different instruments, as well as to create synergies across tools as part of an overall process of improving a health system. For example, the EU's wide-ranging support across diverse instruments and policy areas has contributed towards improving the prevention, monitoring, and management of cancer, as well as modernising dedicated health infrastructure and developing common cancer policy guidance in Europe over several decades. This presentation will help with understanding what different tools can be used for, showcasing content from the policy brief and how it can be helpful with addressing the challenges faced by health policy makers. Using concrete case studies, it will illustrate how different instruments might be combined in pursuit of a specific process of health system strengthening and transformation.

The Transforming Health Care Systems Partnership – collaboration for improvement post-pandemic

Sabrina Montante

S Montante[1]
[1]Coordinating Team Transforming Health and Care Systems Partnership, Brussels, Belgium
Contact: sabrina.montante@iss.it

Building on the experience and results of important European initiatives like the TO-REACH Action, the new European Partnership on Transforming Health and Care Systems aims to accelerate the sustainable transformation of European health systems. By means of multidisciplinary research with a focus on improving the uptake of innovative solutions by health system actors, including organisational, service, and overarching policy innovations, the partnership plans to achieve access to high quality, sustainable and innovative health care for European populations. This presentation will explore current and upcoming plans for the Partnership, as well as discuss some of the lessons learnt from past initiatives and how these, combined with the experiences from the pandemic, have contributed to shaping the new Partnership's agenda. Inputs from stakeholders in the audience will be collected to inform the Partnership's ongoing learning process.

Incremental net benefit of wearable devices for home monitoring of chronically ill patients

Gerardo Altamura

G Altamura[1], *MC Nurchis*[1,2], *G Santoli*[1], *MT Riccardi*[1], *M Sapienza*[1], *G Sessa*[1], *G Damiani*[1,2]
[1]Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Department of Woman, Child Health and Public Health, Fondazione Policlinico Universitario A. Gemelli, Rome, Italy
Contact: gerardoaltamura@outlook.it

Background:

Hospital overcrowding is a growing problem worldwide. Studies demonstrated that up to 40% to 67% of hospitalizations of residents in nursing homes may be avoidable, causing health and economic damages. Furthermore, research shows that for non-critical patients there are arguably no differences between home and hospital recovery in terms of health outcomes, with a preference for home settings in most patients. During COVID-19 pandemic, telemedicine and homecare increased its range of possible intervention, allowing efficient and cost-effective processes of care. Transdermal sensors are indeed a cheap and easy to use alternative to conventional instruments, allowing a continuously operative and ready-to-use tool to care providers. This systematic review aims to map the application fields of these technologies, demonstrating their accuracy and assessing their cost-effectiveness in chronically ill home-assisted patients.

Methods:

Articles were retrieved from Scopus, Web of Science, and PubMed. The dominance ranking matrix (DRM) tool was applied to allow a qualitative synthesis of the studies. Incremental net benefits (INBs) were estimated and meta-analysis was implemented to pool INBs across studies. A comparison between wearables and conventional tools accuracy was simultaneously carried out through a literature review.

Results:

The database search identified 1156 publications of which six articles were considered eligible for the meta-analysis. According to DRM, 80% of evaluated studies showed the cost-effectiveness of wearable devices. The pooled INB of wearables over conventional measurement was estimated at US$1280 (95% CI US$952 - US$2849). In 85% of evaluated wearables the accuracy resulted comparable to conventional measurement tools.

Conclusions:

Wearables performances resulted as accurate as conventional methods and their application cost-effective. A continuous measurement of parameters may relate to a better process of care for chronically ill outpatients.

Key messages:

- Wearables are a cheap and accurate alternative to conventional life parameters measurement tools.
- Technology evolution might soon reduce the pressure on hospitals, changing the care process of chronically ill outpatients allowing continuous evaluation of their health status.

Abstract citation ID: ckac129.013

Artificial sweeteners and risk of cardiovascular diseases in the prospective NutriNet-Santé cohort

Charlotte Debras

C Debras[1,2], *E Chazelas*[1,2], *L Sellem*[1,2], *C Julia*[1,3], *E Kesse-Guyot*[1,2], *B Allès*[1], *M Deschasaux-Tanguy*[1,2], *I Huybrechts*[2,4], *B Srour*[1,2], *M Touvier*[1,2]
[1]Nutritional Epidemiology Research Team, Sorbonne Paris Nord University, Bobigny, France

[3]Public Health Department, Avicenne Hospital, Bobigny, France
[4]International Agency for Research on Cancer, WHO, Lyon, France
Contact: c.debras@eren.smbh.univ-paris13.fr

Background:

Artificial sweeteners are widely used today by the food industry as sugar alternatives. Potential adverse effects of these food additives on cardiovascular disease (CVD) have been suggested in experimental studies, but data from studies involving humans remain very limited. Previous cohorts have focused on artificially sweetened beverages. Our objective was to study the associations between artificial sweeteners from all dietary sources, overall and by molecule (aspartame, acesulfame-potassium and sucralose), and risk of CVDs (overall, coronary heart and cerebrovascular).

Methods:

The study included 103,388 participants of the web-based NutriNet-Santé cohort (2009-2021). Artificial sweetener intakes were assessed using repeated 24h dietary records including names and brands of industrial products consumed. Multi-adjusted Cox proportional hazard models were performed. Exposure to artificial sweeteners were coded as 3-category variables: non-consumers, lower consumers (artificial sweetener intake below the sex-specific median) and higher consumers (above the sex-specific median).

Results:

Compared to non-consumers, higher consumers of total artificial sweeteners had increased risk for CVD (n = 1502 incident cases, HR = 1.17 [1.01-1.35], P-trend = 0.04) and more specifically cerebrovascular diseases (n = 777, HR = 1.34 [1.10-1.62], P = 0.004). Higher consumption of aspartame was associated with increased cerebrovascular diseases (HR = 1.29 [1.03-1.60], P = 0.01). Higher consumption of acesulfame-K was associated with a higher risk of CVD (HR = 1.24 [1.04-1.47], P = 0.02) and cerebrovascular diseases (HR = 1.29 [1.02-1.64], P = 0.1). No association was detected for coronary heart diseases (n = 730 incident cases).

Conclusions:

These findings suggest a direct association between higher artificial sweetener consumption and increased CVD risk, in particular cerebrovascular. These results provide key novel information for the ongoing re-evaluation of sweeteners by the European Food Safety Authority.

Key messages:

- In this large-scale prospective cohort (n = 103,388), artificial sweeteners (especially aspartame and acesulfame-K) were associated with increased risks of cardiovascular and cerebrovascular diseases.
- These results provide key insights to feed EFSA's expertise for the ongoing risk assessment of artificial sweeteners.

Contact: miao.jiang@usi.ch

Introduction:
Evidence on the incidence and risk factors of frailty in low- and middle-income countries is very limited. We aimed to compare the incidence of frailty and explore its determinants in rural and urban areas in six Latin American countries and China.

Methods:
The 10/66 is a multi-site cohort study in older adults. We conducted baseline and follow-up surveys in 2003-2006, and 2007-2010. We assessed frailty using a modified Fried frailty phenotype criterion, and adjudicated frailty (yes/no) when two or more of the following indicators were present: exhaustion, low physical activity, slow gait speed, and weight loss. We excluded frail participants at baseline and calculated person-years as the time interval between baseline and follow-up for frailty-free people who were survived and reinterviewed or the midpoint of it for incident frailty cases. We used Poisson and Cox regressions to model the incidence of frailty and its risk factors.

Results:
We included 9,747 participants ($\geq$65 years) for the analysis of frailty risk factors. Of whom, 8,212 were reinterviewed with an average of 4.0 years of follow-up, the incidence of frailty was lowest in Venezuela (21.9 per 1000 person-years) and rural Peru (24.3 per 1000 person-years), highest in rural Mexico (110.5 per 1000 person-years) and urban Peru (84.0 per 1000 person-years). In the overall Cox regression, we found significant prospective associations of incident frailty with living in rural areas (HR: 1.97, 95% CI: 1.69, 2.29), dementia (HR: 1.76, 95% CI: 1.42, 2.18), depression (HR: 1.69, 95% CI: 1.49, 1.93), comorbidity, female gender, older age, disability, hearing, and vision problems. Higher arm circumference was associated with a lower frailty risk (HR: 0.97, 95% CI: 0.96, 0.98).

Conclusions:
The incidence of frailty varied substantially in Latin America and China, and between urban and rural areas. The identified risk factors could be potential intervention targets to decrease the global burden of frailty.

Key messages:
- In Latin America and China, the incidence of frailty varied from 21.9 to 110.5 cases per 1000 person-years.
- We identified 9 risk factors and 1 protective factor for developing frailty, and the most relevant risk factors were living in the rural area, dementia, and depression.

Food additive emulsifiers and cancer risk: results from the French prospective NutriNet-Santé cohort

Mélanie Deschasaux-Tanguy

L Sellem[1,2], B Srour[1,2], E Chazelas[1,2], C Debras[1,2], B Chassaing[2,3], I Huybrechts[4], F Pierre[2,5], X Coumoul[2,6], M Deschasaux-Tanguy[1,2], M Touvier[1,2]
[1]Sorbonne Paris Nord University, INSERM U1153, Bobigny, France
[2]Nutrition and Cancer Research Network, Jouy-en-Josas, France
[3]INSERM U1016, Paris, France
[4]International Agency for Research on Cancer, Lyon, France
[5]Toxalim, Research Centre in Food Toxicology, Toulouse, France
[6]INSERM UMR-S 1124, Université de Paris, Paris, France
Contact: m.deschasaux@eren.smbh.univ-paris13.fr

Background:
Food additive emulsifiers are found in thousands of industrial foods and may exert deleterious effects on gut microbiota and carcinogenesis according to experimental studies. However, their associations with cancer risk has not been investigated yet. This study aimed to investigate these associations in a large population-based prospective cohort.

Methods:
This study included 102,485 French adults from the NutriNet-Santé cohort (42.1y [14.5], 78.8% female, 2009-2021). Food additive emulsifier intakes were estimated using repeated 24h dietary records linked to brand-specific food composition databases on food additives. Associations with incident cancer risk were assessed using Multivariable Cox models.

Results:
3,511 incident cancer cases were diagnosed during follow-up (1,026 breast, 431 prostate, and 279 colorectal cancers). Intakes of sodium citrate (E331, HR = 1.12 [1.02-1.23], p-trend = 0.009), xanthan gum (E415, HR = 1.11 [1.02-1.21], p-trend = 0.02), and mono- and diglycerides of fatty acids (E471, HR = 1.17 [1.06-1.28], p-trend = 0.001 and total: E471, E472a-b-c-e, HR = 1.11, [1.02-1.22], p-trend = 0.02) were associated with increased overall cancer risk. Higher intakes of E331 (p-trend = 0.046), sodium stearoyl-2-lactylate (E481, p-trend = 0.01), total lactylates (E481-482, p-trend = 0.01), total celluloses (E460-468, p-trend = 0.03), carob bean gum (E410, p-trend = 0.01), and E471 (p-trend = 0.006) were associated with increased overall breast cancer risk. Higher intakes of carrageenan (E407, p-trend = 0.04), E415 (p-trend = 0.02), and triphosphates (E451, p-trend = 0.03) were associated with increased post-menopausal breast cancer risk.

Conclusions:
These results are the first to investigate and report direct associations between cancer risk and exposures to seven individual and three groups of food additive emulsifiers. If replicated, they may have an important public health impact, considering the omnipresence of these additives in industrial foods globally.

Key messages:
- This study is the first to precisely assess exposures to food additive emulsifiers in a population-based study.
- Intakes of food additive emulsifiers were associated with increased risk of cancer.

1.E. Workshop: Accelerating the action on SDGs applying a One Health approach

Abstract citation ID: ckac129.016

Organised by: Instituto Universitário Egas Moniz, NOVA National School of Public Health (Portugal)
Chair persons: Ricardo Assunção (Portugal), Susana Viegas (Portugal)
Contact: carla.martins@ensp.unl.pt

In the sequence of a pandemic, with a tremendous impact in our lives, more than never the challenges for humankind are enormous. Despite the future is impossible to predict, there are some certain trends that could compromise the health of humans, living systems and Earth. Environmental degradation and climate change, poverty and inequalities, demography, shocks and crises, constitute some of the core dares that should be seriously considered. Recognizing the importance of tackling the challenges posed to humankind, world's governments signed an agreement to eradicate poverty, improve the living standards and well-being of all people, promote peace and more inclusive societies, and reverse the trend of environmental degradation, in a document called 2030 Agenda for Sustainable Development. This document contains the 17 Sustainable Development Goals (SDGs), promoting the development in a balanced way, leaving no one behind. After this historic initiative, several strategies, debates and efforts have been advanced, tried and implemented to tackle these challenges. However, sophisticated policy responses of preparedness, investment and cooperation are still needed. One Health is considered an approach to designing and implementing programmes, policies, legislation and research in which multiple sectors communicate and work together to achieve better public health outcomes. The current challenges identified, e.g. infectious diseases, climate change, the sustainability of food systems, the destruction of biodiversity, could affect transversally health, are related differently with several SDGs, and demand for a holistic approach that should be efficient enough to tackle these threats. Through presenting some case studies, this workshop aims to promote the discussion regarding the implementation of a One Health approach to accelerate the action targeting SDGs accomplishment, focusing particularly on actions that can have an impact on Health in a broader sense, i.e. human, animal and environment health. Each presentation will emphasize specific examples (air pollution, food systems and climate change, intensive animal production, biodiversity), relating the concept of One Health and the linked SDGs that could be faced through this approach. Altogether, these presentations will highlight the need for a multi- and trans-sectorial intervention, using the concept of One Health to maximize the co-benefits within the three domains, human, animal, and environmental health. The challenges are enormous, but as Nelson Mandela said, "It always seems impossible until it's done".

Key messages:

- The importance of the One Health approach to tackle the goals on sustainable development, health and wellbeing.
- The One Health approach brings more easily co-benefits in different sectors that result in more relevant gains in Health in the three domains (human, animal and environment health).

Abstract citation ID: ckac129.017
One Health approach for the SDGs achievement

Susana Viegas

S Viegas[1,2]
[1]NOVA National School of Public Health, Lisbon, Portugal
[2]Comprehensive Health Research Center, Lisbon, Portugal
Contact: susana.viegas@ensp.unl.pt

One Health is an approach characterized by the integration of human and animal health, plants, and ecosystems and encourages multisectoral and multidisciplinary efforts to achieve optimal levels of health and collaboration among different sectors and scientific areas to address challenging health problems. Through this approach is possible to obtained better results since the actions taken are normally focused to obtained co-benefits in several of the Sustainable Development Goals, including health for all and cost savings. The dissemination of One Health research and experiences is important to raise awareness for this approach. In this workshop, this will be done with the presentation and discussion of several themes where the One Health approach is of most relevance allowing to identify the most relevant barriers and opportunities for integrating One Health more widely.

Abstract citation ID: ckac129.018
Air pollution and health – the importance of air monitoring and burden of disease for attaining SDGs

Carla Martins

C Martins[1,2]
[1]NOVA National School of Public Health, Lisbon, Portugal
[2]Comprehensive Health Research Center, Lisbon, Portugal
Contact: carla.martins@ensp.unl.pt

Pollution is the worldwide largest environmental cause of disease and premature death, being also considered a risk for planetary health, a cause of ecosystems destruction and intimately linked to global climate change. Pollution is considered costly, with attributable diseases resulting in health-care costs that are responsible for 1.7% of annual health spending in high-income countries. Moreover, in utero and early childhood exposures are responsible for health effects in children. The importance of air pollution as a cause of disease is well reflected in the Sustainable Development Goals (SDG), mainly in the SDG 3, SDG 11, and SDG 15, but indirectly in all the SDGs. To tackle this issue, an integrative and holistic approach linking human and environmental health such as One Health is needed, to provide evidence-based data to support the establishment of reduced air pollutants' maximum admissible levels. A case-study developed in Portugal in the scope of PMCardImpact project, regarding the exposure of population to particulate matter with a diameter of 2.5 μm or less (PM2.5) and the associated number of cases of cardiovascular diseases will be presented herewith. Four scenarios of exposure will be considered for presenting the results: current scenario of exposure, new WHO Air Quality guidelines, European Commission Air Quality Directive and lastly, a worst-case scenario. This assessment is the starting point for calculation of the burden of disease of CVD that exposure to PM2.5 represent in Portugal. With a view to promote the science to policy interface, PMCardImpact project will make available to policy makers the needed supporting information to act, including actionable knowledge on air pollution trends and related health effects, to implement reducing air pollution policies.

This work is funded by FCT/MCTES through national funds to PMCardImpact (EXPL/SAU-PUB/0944/2021) and CESAM (UIDP/50017/2020 + UIDB/50017/2020 + LA/P/0094/2020).

Impact of climate change on food systems – the One Health approach

Ricardo Assunção

R Assunção[1,2]
[1]IUEM, Instituto Universitário Egas Moniz, Caparica, Portugal
[2]Centre for Environmental Sciences and Marine, Aveiro, Portugal
Contact: rassuncao@egasmoniz.edu.pt

In recent decades, changes in climate have caused impacts on natural and human systems on all continents and across the oceans. Climate change has become one of the most critical issues for the sustainable development of human societies and the functioning of ecosystems on Earth. In one hand, climate change threatens our ability to ensure global food security, eradicate poverty and achieve sustainable development. Agriculture and animal production are affected by changing rainfall patterns, drought, flooding and the geographical redistribution of pests and diseases, with consequent implications in the food availability, a key requirement for food security. On the other hand, despite less debated, climate change could also affect food safety, impacting the occurrence of food safety hazards at various stages of food chain, from ''farm to fork''. The tendency to increase the use of agrochemicals to balance the effects of more frequent extreme weather events and water scarcity in some regions could become more frequent. In addition to pesticide residues, both chemical and microbiological risks are expected to impair food and feed safety as a consequence of climate change: in particular mycotoxins, marine biotoxins (phycotoxins), trace metals, among others. Humans, animals and the environment are/will be affected by the consequences of climate change, with an expected impact on the food systems. Thus, a One Health perspective, representing a holistic view of the problems, defining and establishing adequate strategies to tackle these challenges, is more than needed. On this presentation, main issues relating the impact of climate change on health of humans, animals and environment and how a One Health perspective, as a holistic approach, represent a key contribution to the definition of proper policies to ensure the public health will be approached and debated.

Pandemics have their origin in diverse microbes carried by animal hosts, but their emergence is entirely driven by human activities. These include deforestation, land- and sea-use change, agricultural expansion and intensification, and wildlife trade and consumption. These activities bring wildlife, livestock, and people into closer contact, allowing animal microbes to spillover into people and causing infections, sometimes outbreaks, and more rarely epidemics and pandemics. Domestic animals and peri-domestic wildlife also have a role in creating bridges for the emergence of human diseases, since this can happen in an evolutionary sense, or the animal could serve as a physical transmitter. The most important reservoirs of pathogens with pandemic potential are mammals (in particular bats, rodents and primates) and some birds, as well as livestock (e.g. pigs, mink, poultry). In fact, intensive animal production is also considered one of the drivers for biodiversity loss and potentially for future pandemics. As an example, intensive poultry farming not only poses a significant risk to workers, but can also act as a potential public health menace evidencing the One health approach to tackle all the menaces in this particular setting.

Contact: susana.viegas@ensp.unl.pt

Biodiversity underpins all life on Earth, and refers to biological variety in all its forms, from the genetic makeup of plants and animals to cultural diversity. Human health depends upon ecosystem products and services (e.g. availability of fresh water, food and fuel sources) which are requisite for human and animal health. Biodiversity loss can have significant direct human health impacts if ecosystem services are degraded and not able to guarantee social needs. The ecosystems also control disease and stabilize the climate. However, biodiversity loss is occurring at unprecedented rates, impacting human health worldwide, according to the report jointly published by the Convention on Biological Diversity (CBD) and the World Health Organization (WHO). In this report, awareness is provided to the need to promote integrated approaches to biodiversity and health by highlighting that biodiversity contributes to human health and wellbeing, and emphasizing also that biodiversity needs protection for development to be sustainable. Indirectly, changes in ecosystem services affect livelihoods, income, local migration and, on occasion, may even cause or exacerbate political conflict. Some features will be presented and discussed to describe in detail the most relevant impact that biodiversity has in human health and wellbeing and how the loss of biodiversity can imply risk for animal and human health.

1.F. Skills building seminar: Podcast 101 - Lessons learnt and how you can create your own unique experience

Abstract citation ID: ckac129.022

Organised by: EUPHA-DH
Chair persons: Stefan Buttigieg (EUPHA-DH), Brian Li Han Wong (UK)
Contact: info@stefanbuttigieg.com

Podcasts are one of the fastest growing communication channels globally with more than 850,000 podcasts available globally through all the different podcast distributors. Furthermore, Health-related podcasts are gathering steam on their own front and herein lies the opportunity for public health and digital health professionals to embrace this channel and develop the necessary skills to start communicating their visions in a world that is plagued by misinformation and disinformation. This skills building workshop intends to cover the experience of three public health professionals in their involvement as co-hosts of three different podcasts that have their own voice with differences in their setup and availability of resources. Furthermore, the authors intend to cover the following aspects:

Getting started with your own podcasts
The typical setup for Podcast Recording
Promoting and growing your podcasts
Ensuring sustainability and consistency in your approach
Tips and Tricks for Podcast Success

Key messages:

- Podcasts are a unique opportunity to create a meaningful connection with a wide audience in a world plagued by misinformation and disinformation.
- Setting up a Podcast has gotten much less complicated and this workshop will provide the basic knowledge to get you started with tools that you already own.

Abstract citation ID: ckac129.023
Getting started with Podcasts

There are a world of opportunities waiting for public health professionals to get started with a regular audio-visual communication channel. The barrier of entry to start creating your very own podcast has been reduced to a bare minimum. This presentation intends to cover the basics to get started with your own podcast and intends to share the lessons from the author's involvement as a co-host of ''The Digital Health Voice'' podcast.

The main challenges after getting started with a podcast will be growth and sustainability. This presentation will focus on promotion tactics for digital health podcasts, including the pros and cons of different hosting platforms and the use of social and academic networks for promotion. The importance of sustainability and consistency for growth will also be discussed, including some practical tips on productivity and team management for content producers.

1.G. Workshop: The German National Cohort (NAKO): Design, current state, and first results

Abstract citation ID: ckac129.025

Organised by: NAKO e.V. (Germany)
Chair persons: Tobias Pischon (Germany), Lilian Krist (Germany)
Contact: barbara.bohn@nako.de

This workshop aims to give an overview of design, methods and first results of the largest cohort study in Germany: the German National Cohort (NAKO).This organized session will consist of one overview presentation and three presentations on selected topics: mental disorders, COVID-19, and Magnetic Resonance Imaging (MRI) in the NAKO. NAKO is a multidisciplinary, population-based cohort study that provides a central resource for population-based epidemiologic research. NAKO aims to investigate the development and aetiology of diseases, identify risk factors and enhance early detection and prevention of diseases with a focus on diabetes, cancer, cardiovascular, pulmonary, neurological, psychiatric, and infectious diseases. Between 2014 and 2019, overall 205,415 persons aged 20-74 years were recruited and examined at 18 study centres across Germany. During their visit to the study centre, they participated in a face-to-face interview, completed self-administered, computer-based questionnaires, underwent a battery of biomedical examinations, and provided various biosamples. In addition, whole-body Magnet Resonance Imaging (MRI) was performed on 30,861 participants using dedicated 3 Tesla MRI scanners at 5 study centres. The whole-body MRI protocol focuses on brain and cardiac structures, musculoskeletal system and body fat distribution. In 4-5 year intervals, all study participants are re-invited for examinations at the study centres. The programme for the first re-examination (including MRI scanning) was similar to the baseline programme. Thereby, longitudinal information on changes in risk factor profiles and in vascular, cardiac, metabolic, neurocognitive, pulmonary and sensory function is collected. Since October 2018, 77,896 participants have been re-examined, including 11,382 with additional MRI examination. A supplemental COVID-19 questionnaire collected data on 161,849 participants of NAKO during the first COVID-19-related lockdown in Spring 2020. This survey started on 30 April 2020 and ended on 30 June 2020. The questionnaire included questions on general state of health, Sars-CoV-2 symptoms and test results, and on changes in behavioural, psychosocial and socioeconomic factors as well as social contacts and occupational situation during the pandemic. Thus, psychological and socioeconomic effects of the pandemic situation can be addressed. Moreover, questions on pandemic-related aspects including the history of infection, severity and long-term health impacts of COVID-19 were added to the regular study programme in the study centres as of July 2021. The longitudinal design of NAKO provides the unique opportunity to compare the participants' situation before and during the pandemic. The presentations describe the main design of the NAKO and exemplary results of main research questions, e. g., on mental health, association of occupational factors with COVID-19, and MRI findings.

Key messages:

- The workshop introduces the design and collected data of the NAKO to foster collaboration between scientists, enabling further harmonization of data collection between large cohort studies.
- The workshop aims to facilitate (future) joint scientific exploitation of this unique epidemiological resource of population-based data.

Depression Assessment in the German National Cohort (NAKO)

Klaus Berger

K Berger[1], M Rietschel[2], F Streit[2]
[1]Institute of Epidemiology and Social Medicine, University of Münster, Münster, Germany
[2]Medical Faculty Mannheim, University of Heidelberg, Heidelberg, Germany
Contact: bergerk@uni-muenster.de

Background:

The mental health status of populations (public mental health) and its effect on societies has gained considerable attention in recent years, especially during the current pandemic. The measurement of depressive symptoms is at core of the assessment of mental health. The detailedness of this assessment defines the range of public mental health problems that can be answered.

Methods:

Between 2014 and 2019 the German National Cohort (NAKO) recruited 205,000 participants aged 20-70 years into the baseline examination in 18 study centers. Depression and depressive symptoms were assessed by different instruments including a lifetime diagnosis of depression and current treatment, the Major Depressive Disorder (MDD) section of the Mini-International-Neuropsychiatric-Interview (M.I.N.I. 5.0) and the depression scale of the Patient Health Questionnaire (PHQ-9). These instruments include different time periods and interpretations. Associations between these depression outcomes and age, gender and education are analysed in linear and logistic regression models.

Results:

A lifetime physician's diagnosis of depression was reported by 14.7% of participants with considerable regional variation and almost 50% of this group received treatment within the last 12 months. Based on PHQ-9 7.9% of the participants were classified as depressive according to the dimensional assessment (score$\geq$10) and 3% of them as having a major depression subtype. In contrast 32.8% screened positive based on the MINI and 15.4% of those receiving the full MINI had a diagnosis MDD. Associations with important socioeconomic determinants for these different depression outcomes will be reported.

Conclusions:

The large NAKO sample size and the detailed assessment of depression symptoms and status enables the analysis of a broad range of public mental health questions. The analysis of depression frequencies and the distribution of depressive symptoms allow the establishment of population references.

Increase in Mental Disorders During the COVID-19 Pandemic - Role of Occupational & Financial Strains

Nico Dragano

N Dragano[1], M Reuter[1], A Peters[2,3], B Schmidt[4], B Bohn[5], K Berger[6]
[1]Institute of Medical Sociology, University of Düsseldorf, Düsseldorf, Germany
[2]Institute for Epidemiology, Helmholtz Center Munich, Munich, Germany
[3]Medical Faculty, Ludwig-Maximilians-Universität München, Munich, Germany
[4]Medical Faculty, University Hospital of Essen, Essen, Germany
[5]NAKO e.V., Heidelberg, Germany
[6]Institute of Epidemiology and Social Medicine, University of Münster, Münster, Germany
Contact: Dragano@med.uni-duesseldorf.de

Background:

Numerous studies reported an increase in mental disorders during the COVID-19 pandemic, but the specific causes for this increase are unclear. We therefore investigate whether pandemic-related occupational and financial changes (e.g., reduced working hours, working from home, financial losses) were associated with increased symptoms of depression and anxiety compared with the situation before the pandemic.

Methods:

We analyzed data from the German National Cohort Study (NAKO). Between May and November 2020, 161,849 participants answered questions on their mental state and social circumstances. Responses were compared with data from the baseline survey before the pandemic (2014-2019). Linear fixed-effects models were used to determine whether individual changes in the symptoms of depression (PHQ-9) or anxiety (GAD-7) were associated with occupational/financial changes (controlling for covariates).

Results:

A pronounced increase in symptoms was observed among those who became unemployed during the pandemic (+ 1.16 points on the depression scale, 95% confidence interval [0.91; 1.41], range 0-27). Increases were also seen for reduced working hours without short-term working allowance, increased working hours, working from home, insecurity regarding employment, and financial strain. The deterioration in mental health was largely statistically explained by the occupational and financial changes investigated in the model.

Conclusions:

Depressive symptoms and anxiety disorders increased in the study population during the first year of the COVID-19 pandemic and occupational and financial difficulties were an essential contributory factor. These strains should be taken into account both in the care of individual patients and in the

planning of targeted prevention measures. Results suggest that welfare state benefits such as short-time allowance in times of crises may reduce mental load in affected populations.

Abstract citation ID: ckac129.029
Whole-body Magnetic Resonance Imaging in the German National Cohort (NAKO): Design & Current Status

Fabian Bamberg

F Bamberg[1]
[1]Department of Radiology, University Hospital Freiburg, Freiburg, Germany
Contact: fabian.bamberg@uniklinik-freiburg.de

Background:
Whole-body magnetic resonance imaging (MRI) permits non-invasive, non-ionizing phenotyping of the human body and ideally complements the epidemiological assessment of the NAKO participants. As such, it allows for the detection of morphologic or functional predisposition, early disease stages prior to overt clinical events as well as evident pathological changes. The assessment of progression and regression of imaging phenotypes over time will provide the basis to identify and understand the relevance of imaging-based risk factor profiles for disease development.

Methods:
Integrated in the general NAKO study program and managed by a central Imaging Core, study participants underwent whole-body imaging at five dedicated MR imaging sites. Imaging was performed on five identical 3 Tesla scanners (Magnetom Skyra, Siemens Healthineers, Erlangen, Germany) applying a one hour protocol, including sequences for the brain, the cardiovascular and musculoskeletal system as well as for the thorax and abdomen. Comprehensive measures to assure high image quality and management of incidental findings were established.

Results:
As part of the baseline examination program, a total of 30,861 participants successfully underwent the MR imaging program. All measures of quality assurance and incidental findings management were successfully employed throughout the study period and obtained image quality and completeness of all MR sequences was excellent (>94.2% completeness). While MR imaging as part of the first re-examination is ongoing, baseline MRI data is currently accessible for scientific analyses.

Conclusions:
The MRI-Study of the NAKO will provide a comprehensive imaging phenotypic biobank covering different organ systems with highest morphological and functional detail. MRI data analysis will gain novel insights into the natural history of disease development, the role of subclinical disease burden, and revolutionize our understanding of imaging biomarkers of risk.

Reducing health inequalities through general practice in the UK: a realist review (EQUALISE)

Anna Gkiouleka

A Gkiouleka[1]*, G Wong*[2]*, I Kuhn*[1]*, S Sowden*[3]*, F Head*[4]*, C Bambra*[3]*, R Harmston*[5]*, S Manji*[5]*, A Moseley*[5]*, J Ford*[1]
[1]Public Health and Primary Care, University of Cambridge, Cambridge, UK
[2]University of Oxford, Oxford, UK
[3]Newcastle University, Newcastle Upon Tyne, UK
[4]NHS Cambridgeshire and Peterborough CCG, Cambridge, UK
[5]Patient and Public Involvement Representative, Cambridge, UK
Contact: ag2192@medschl.cam.ac.uk

Background:
In the UK, chronic conditions such as cancer, heart disease, stroke, and chronic obstructive pulmonary disease are driving health inequalities in life expectancy and were responsible for two-thirds of premature mortality in 2017. Voices that stress the importance of primary care in reducing health inequalities have been strengthening during the last decade. However, defining the most effective strategies to reduce health inequalities through general practice remains a challenge.

Aims:
This study examines the evidence on interventions in primary care that are likely to decrease inequalities in NCDs and especially cancer, diabetes, cardiovascular and chronic obstructive pulmonary disease and will provide healthcare organisations with guiding principles on what should be commissioned.

Methods:
The study is a realist review following Pawson's model. Based on a programme theory, we screened systematic reviews of interventions delivered in primary care and through their references, we identified primary studies reporting on inequalities across PROGRESS-Plus criteria. The data were analysed in light of the initial program theory and organised in a model informed by Collins' Domains of Power framework.

Results:
Out of 251 included reviews we retrieved 6,555 primary studies which resulted in 333 studies for data extraction. We found that there are five guiding principles operating simultaneously across four different domains which can reduce health inequalities in General Practice. The principles include flexibility, continuity, inclusivity, intersectionality, and community and operate simultaneously across the domains of structures and policies; narratives and ideas; rules and practices; and relationships and experience.

Conclusions:
Flexibility, continuity, inclusivity, intersectionality, and community are the five principles which should guide the design and delivery of General Practice for the reduction of health inequalities.

Key messages:
- Flexibility, continuity, inclusivity, intersectionality, and community are the five principles which should guide the design and delivery of General Practice for the reduction of health inequalities.
- Action to reduce health inequalities should be taken simultaneously across the domains of structures and policies; narratives and ideas; rules and practices; and relationships and experience.

Abstract citation ID: ckac129.031

The Berlin index of health and social deprivation: a data based tool to tackle health inequality

Johannes Zeiher

J Zeiher[1], *K Häßler*[1], *JD Finger*[1], *A Haase*[1], *S Hermann*[1]
[1]Department of Health, Senate Department for Health, Berlin, Germany
Contact: johannes.zeiher@senwgpg.berlin.de

Background:

Reducing socially induced health inequalities is a key task of urban and regional public health authorities. The Berlin index of health and social deprivation (BIHSD) 2022 aims to show regional differences in health and social situation in sub-areas of the city, to observe developments over time and to identify socially deprived sub-areas of the city.

Methods:

The BIHSD 2022 is based on 20 indicators, most of which come from official statistics. Principal component analyses were applied to calculate subindices for the dimensions employment (e.g. unemployment rate), social conditions (e.g. risk-of-poverty rate) and health (e.g. premature mortality). Based on these subindices the final health and social index was derived. The (sub)indices are available on different spatial levels. Relative changes compared to the BIHSD 2013 were calculated to identify regional trends in the transitions in the social structure and health of the city over time.

Results:

Besides improvements for most indicators over time in most regions of Berlin, there is still significant evidence for health and social inequality across the city. For example, long-term unemployment rate varies between 0.5% and 40.4% on the lowest spatial level. Following a secular trend, there are substantial improvements in former deprived areas in the inner city while in many peripheral residential areas with an average social structure in the past a downwards trend was observed.

Conclusions:

Deprivation indices are helpful tools for research and health reporting in providing evidence for regional inequality. Additionally, they can be used to tailor health promotion strategies and to promote a targeted allocation of financial resources. For example, results of the BIHSD 2022 are being used in epidemiological analyses (e.g. regional inequalities in the risk of SARS-CoV-2 infection) and for (health) policy planning (e.g. needs- and demand-based planning of healthcare).

Key messages:

- The Berlin index of health and social deprivation 2022 show regional differences in health and social situation in sub-areas of the city and documents developments over time.
- The index is being used in epidemiological analyses, to tailor health promotion strategies, and to promote a targeted allocation of financial resources.

Abstract citation ID: ckac129.032

Health inequalities in very old age: Continuity, accumulation or convergence?

Judith Wenner

J Wenner[1], *J Fey*[1], *S Zank*[1], *M Wagner*[1]
[1]University of Cologne, Köln, Germany
Contact: judith.wenner@uni-koeln.de

Background:

Health inequalities are well documented empirically. However, it is unclear whether health inequalities persist in very old age (continuity), whether they accumulate steadily (accumulation), or whether they even attenuate in old age (convergence) - not least because of social inequalities in life expectancy, which make it less likely for individuals with lower social status to reach old age at all. The aim of this study is to empirically test these three hypotheses.

Methods:

The analyses are based on representative cross-sectional data from 1,863 very old people and panel data from 912 participants in the 1st and 2nd wave (W1, W2) living in North Rhine-Westphalia the largest federal state in Germany (NRW80+ study). Health outcomes of the analyses are subjective health, multimorbidity and need for long-term care. Indicators of socioeconomic status (SES) are education, occupational status, and net equivalent income. Regression models (linear, logistic, ordinal) are used to analyze cross-sectional and longitudinal data. Panel selectivity is also considered by means of a failure model.

Results:

Cross-sectional findings show health inequalities for all SES variables: persons with low education and low income have poorer subjective health and higher need for care. Low status is associated with higher need for care. Preliminary results from longitudinal analyses show a slight increase in health inequality: low income and low status are associated with higher multimorbidity and low education with higher dependency on long-term care at W2.

Conclusions:

Despite the socially conditioned unequal chances of reaching old age, health inequality is still present in very old age and even increases slightly over time. The results argue against the convergence hypothesis and in favor of the continuity or even the accumulation hypothesis. A better understanding of the mechanisms leading to the persistent inequality is needed to development targeted interventions also in old age.

Key messages:

- Health inequalities persist and even increase in very old age (80+).
- It is imperative that the oldest old – an increasingly large population group – be considered when designing strategies to reduce health inequalities.

1.J. Round table: Research Methods for Public Health Oriented Health Services Research – what works where and for what?

Abstract citation ID: ckac129.033

Organised by: EUPHA-HSR, EUPHA-HIA, EUPHA-HTA, EUPHA-EPI, EUPHA-ECO, EUPHA-PHPP, German Public Health Association Section Research, German Network Health Service Research WG IHSR, Charité Institute for General Practice WG HPSRI
Chair persons: Lorena Dini (EUPHA-HSR), Johan Hansen (EUPHA-HSR)
Contact: lorena.dini@charite.de

This workshop will present the different methodological approaches relevant to the field of public health. This includes approaches of health systems and health policy research, epidemiology, health technology assessment, health impact assessment, health systems performance and economic evaluations. Presentations will be hold by presidents and vice-presidents of the EUPHA Sections in the form of a panel, presenting the overview of each methodology and providing case examples. All organizers might invite special contributions from their members and students to share innovations of case examples from their counties. During the first half of the workshop the EUPHA Sections will provide input on traditional and innovative methods the following topics:

1. Health Policy and Systems Research (HPSR) applied to Primary Care.
2. The use of traditional and innovative epidemiological study designs for public health relevant inferences.
3. Overview of methods used for the quantification of health impacts, both following a risk assessment approach or an epidemiological approach.
4. Methodologies and techniques applied in Health Technology Assessment (HTA) and how their contribute to decision-making and evidence-informed policymaking.
5. Health Systems Performance Assessment (HSPA) and Economic evaluations.
6. Research methods from the public health policy and politics perspective.

In the second half of the workshop we will discuss and share examples on innovation in research methods and seek to find an answer to the question: what is being done in the countries? Input from DGPH-FO, DNVF-IHRS, Charité WG HPSRI and from all participants will be welcome. Target audience: young and old professionals interested in updating their methods skills and sharing their own experiences on innovation in methods for a stronger public health research.

Key messages:

- There are no better or worse research methods; they are just a tool, that when applied properly support evidence and action for a stronger public health.
- As knowledge on research methods evolve, sharing knowledge amongst different fields is key to contribute to a stronger health system, better health policy decisions and a better health for all.

Speakers/Panellists:

Is Ireland ready for tobacco endgame? A national survey of knowledge and attitudes to tobacco endgame

Ellen Cosgrave

E Cosgrave[1], *M Blake*[2], *E Murphy*[2], *A Sheridan*[2], *F Doyle*[3], *P Kavanagh*[2]
[1]Department of Public Health HSE South East, Health Service Executive, Kilkenny, Ireland
[2]HSE Tobacco Free Ireland Programme, Health Service Executive, Dublin, Ireland
[3]Department of Health Psychology, Royal College of Surgeons in Ireland, Dublin, Ireland
Contact: cosgraej@tcd.ie

Background:

In 2013 'Tobacco-Free Ireland' (TFI) shifted Irish national policy from tobacco control to "tobacco endgame": policies, plans and interventions seeking to end the tobacco epidemic completely. Recent trends suggest the current 2025 TFI goal will not be achieved. This cross-sectional study is a timely assessment of public knowledge and attitude to re-focus Irish "tobacco endgame" planning.

Methods:

A literature-informed, pre-tested survey instrument was telephone-administered to a representative sample of 1000 members of the Irish public aged $\geq$15 years recruited via random digit dialling in February 2022. Prevalence of "tobacco endgame" views was measured; logistic regression determined factors associated with key responses.

Results:

Response rate was 30% (n = 1,000, post-hoc weighting applied). While TFI goal awareness was low (34%), support was high (75%), albeit most (61%) recognised postponement beyond 2025 was required for achievability. There was majority support for 18/22 endgame measures assessed. Product-focused tactics were popular, while views on targeting users were mixed: e.g. 86% supported a reduction in tobacco-product nicotine content; 40% supported introduction of a tobacco-user license. Phasing-out tobacco sales was highly-supported (83%); however, this was contingent on special supports for those currently addicted. Support for the TFI goal was higher among non-tobacco users (aOR 2.66, 95%CI 1.89-3.76), females (aOR 1.57, 95%CI 1.17-2.11) and those of higher social class (aOR 1.72, 95%CI 1.25-2.35).

Conclusions:

While achievement by 2025 is increasingly unrealistic, findings strongly affirm Irish public opinion is ready for "tobacco endgame". Recognition of the needs of currently addicted tobacco users and focusing on subgroups with lower support levels should be integral to equitable "tobacco endgame" planning and communication. This study should mobilise renewed Irish political commitment to bold actions aimed at ending smoking-related harm.

Key messages:

- There is strong support for tobacco endgame measures among the Irish population, which is a supportive factor for bold political leadership to make these radical ideas a reality.
- Public preference for product and non-user-focused measures aligns with tobacco endgame discourse and should aid policy reframing to tackle structures and dynamics sustaining the tobacco epidemic.

Abstract citation ID: ckac129.035
Creating smoke free environments by local policy

Selinde Rouwenhorst

S Rouwenhorst[1], *A Koornstra*[1]
[1]GGD GHOR Nederland, Utrecht, Netherlands
Contact: srouwenhorst@ggdghor.nl

In The Netherlands, around 20.000 people die each year from the effects of smoking and passive smoking. Every week, hundreds of children become addicted to smoking. To improve the overall public health in the Netherlands, it is important to substantially reduce the prevalence of smokers. Until recent years, municipalities played next to no role in helping to reduce smoking in the Netherlands. The start of a large campaign that aims a smokefree generation by 2040 has changed that. Part of that campaign is to create smoke-free environments. In a two-year program, 90% of the Dutch municipalities started policy and actions to ban smoking from public places, as part of the National Prevention Agreement. The participating municipalities were supported by all 25 Regional Health Services (GGDs) by providing knowledge and manpower on a regional level, together with national, regional and local organisations. The project has a number of successful elements: the GGD received a (very small) budget to actively participate in the region; knowledge was shared between the regions and from national to local level and legal issues were dealt with by the Nat Assoc of Municipalities (VNG). In 2021, 317 out of 352 Dutch municipalities were active in this project. There is a significant increase of smoke-free environments, mostly schoolyards, playgrounds, sports facilities, smoke-free bus stops and municipal institutions. Other results are integrated plans for smoking cessation care and accessible stop smoking service, e.g. in GGD Fryslan the number of registrations for smoking cessation care increased dramatically and 80% actually quit smoking. All parties involved agree that the strength of this project is its positive approach and the broad social support it generates for the Smokefree Generation. It is about persuasion, not compulsion. Working from a national focus towards a smoke-free environment, while taking into account local differences and needs, makes this project a success.

Key messages:

- This project resulted in more local and regional partnerships and an increase of smoke-free environments, bringing the ultimate goal of a Smokefree Generation closer.
- 90% of Dutch municipalities have created smoke-free environments with the guidance of the regional GGD, financed by Ministry of Health: multilevel governance works.

Abstract citation ID: ckac129.036
Evaluation of Factors Associated with Dual Use of E-Cigarettes in University Students

Feyza Nehir Öznur Muz

[2]Public Health, Odunpazari District Health Directorate, Eskisehir, Turkey
Contact: feyzamuz@gmail.com

Background:

The World Health Organization defined smoking as the fastest spreading and longest lasting epidemic globally. It has been reported that two-thirds of all tobacco consumption in the world is in developing countries, and with today's technology, the use of electronic cigarettes (e-cigarettes) has increased rapidly among young people and adults, especially in recent years. The study aimed to evaluate the factors associated with dual use of e-cigarettes (e-cigarette plus one of the tobacco products) in university students.

Methods:

This study was carried out with the participation of 2477 students at Eskişehir Osmangazi University in the 2019-2020 academic year, and it was designed as a nested case-control study from a study in which 49 were determined to be dual smokers. A randomized 1:3 for age and gender with 147 non-smokers (NS) and 147 classic cigarette smokers (CSS) selected by the propensity score matching method was performed, with the final sample consisting of 343 participants. Chi-square and multinomial logistic regression analyzes were used in the study.

Results:

In the multinomial logistic regression, the belief that e-cigarettes do not help quit classical cigarette smoking was 4.0 (95% CI; 1.7 - 9.6) times higher in NS and 4.1 (1.6 - 10.0) times higher in CCS compared to dual smokers, while the belief that e-cigarettes may suppress the desire to smoke was 4.4 (1.7 - 11.2) times higher in NS and 6.8 (2.6 - 17.6) times higher in CCS.

Conclusions:

The study determined that dual smokers were less likely to believe that e-cigarettes are more innocent than other tobacco products. While dual smokers believed that e-cigarettes might not suppress the desire to smoke, CCS believed e-cigarettes could even increase classical cigarette smoking.

Key messages:

- Since the effects of e-cigarette use on human health are controversial, it is still a significant public health problem in developing countries.
- Although it was initially marketed to help quit or reduce the use of classical cigarettes, it should be noted that e-cigarettes are also a type of tobacco product addiction.

Global market trends of flavour capsule and menthol cigarettes in 78 countries, 2010-2020

Christina Kyriakos

CN Kyriakos[1], *D Qi*[1], *K Chang*[1], *AA Laverty*[1], *FT Filippidis*[1]
[1]Department of Primary Care and Public Health, Imperial College London, London, UK
Contact: c.kyriakos20@imperial.ac.uk

Background:

Flavoured tobacco products, including innovative flavour capsule cigarettes (FCCs) and menthol cigarettes, can increase appeal and encourage smoking initiation and use. Global epidemiological data on these products are scarce.

Methods:

This study examined market trends of FCCs and menthol (non-capsule) cigarettes across 78 countries from 2010 to 2020 and assessed ecological-level factors associated with market shares of these products. Market share and retail volume data came from Euromonitor Passport and country-specific socio-demographic data come from the WHO and World Bank. Adjusted linear fixed effects panel regression analyses were used to evaluate the relationship between predictors variables and market outcomes.

Results:

Global total retail volume of FCCs increased over time (0.2% in 2010 to 4.5% in 2020) and market share was associated with year and unemployment rate and inversely associated with % urban population and smoking prevalence ($p < 0.001$). In contrast, menthol retail volume decreased over time (5.0% to 3.8%) and market share was associated with % urban population ($p = 0.001$) and inversely associated with year ($p = 0.004$) and unemployment rate ($p = 0.017$). The greatest market increase of FCCs was observed in the Americas region and among upper-middle income countries. In Europe, there was a decrease of 0.64 percentage points from 2019 to 2020.

Conclusions:

Overall, FCCs experienced substantial global growth in the recent decade, with the exception of Europe whose slight decrease may be attributable to the European Union ban on flavours in cigarettes. Findings indicate that there is a need for increased efforts to address flavours and innovative features used in tobacco products, which are known to appeal to youth.

Key messages:

- This study contributes to global monitoring of tobacco products.
- Findings can be used by advocates and policy makers to support countries in adopting measures to ban flavoured tobacco products.

Abstract citation ID: ckac129.038
Effectiveness of Behavior Change interventions for smoking cessation among expectant and new fathers

Sudeepa Khanal Bhattarai

S Khanal Bhattarai[1], *C Miani*[1], *E Finne*[1], *JM Morawe*[1], *M Boeckmann*[2]
[1]School of Public Health, University of Bielefeld, Bielefeld, Germany
[2]Faculty of Human and Health Sciences, University of Bremen, Bremen, Germany
Contact: sudeepa.khanal@uni-bielefeld.de

Background:

The perinatal period is an optimal time to intervene for achieving smoking cessation in expectant parents and offers multiple health benefits for women and the newborn. While Behavior Change Technique (BCT) interventions are a promising approach to support pregnant smokers to quit smoking, effectiveness of these interventions among expectant and new fathers is not equally well documented. Better understanding of the potential utility of these BCT interventions for this group is important for the development of effective gender-sensitive programmes.

Methods:

This systematic review examines the existing evidence on effectiveness of BCTs on smoking cessation outcomes when offered to expectant and new fathers (child < 1 year) both through individual and/or couple-based interventions. Eight databases were searched for peer-reviewed articles. Studies were subjected to systematic retrieval and quality-assessment by two independent reviewers.

Results:

We identified 9 randomised control trial studies (including 4,681 men) that fulfilled the inclusion criteria. In terms of quit outcome data, 8 studies reported biochemically verified quit rates for men. While 5 BCT interventions targeted expectant/new fathers, 3 were directed to couples and 1 primarily focused on women with a component directed at men. Though most of the interventions were found to be effective, they showed small significant positive effects on cessation outcomes. Findings are suggestive of gender specific interventions being more likely to have positive outcomes. High heterogeneity across the studies made it difficult to determine the most effective BCT approach.

Conclusions:

This review suggests that use of BCT interventions for smoking cessation among expectant and new fathers is effective in achieving positive quit rates; however, these studies are limited. Further research is needed to determine the most effective BCT approach associated with smoking cessation among this group.

Key messages:

- BCT interventions for smoking cessation among expectant and new fathers are a promising approach to increase quit rates.
- Future research needs to develop evidence based BCT interventions for smoking cessation specifically targeting expectant and new fathers to inform policy and practice.

1.L. Workshop: Building capacity for a resilient and healthy post-COVID health workforce

Abstract citation ID: ckac129.039

Organised by: EUPHA-HWR, WHO Europe
Chair persons: Ellen Kuhlmann (EUPHA-HWR), Tomas Zapata (Denmark)
Contact: kuhlmann.ellen@mh-hannover.de

Background:

The COVID-19 pandemic added new challenges to health workforce resilience. High workload, increased risk of COVID infection and continuing stress threaten the health and wellbeing of healthcare workers (HCWs) and increase existing (gendered) inequalities, thus reinforcing health labour market problems. Investment in the health workforce and prioritisation of the health and wellbeing needs of healthcare workers in health policy and pandemic recovery plans is therefore called for by the WHO, the European Union and others. However, health systems and policymakers across countries have not sufficiently understood the importance of HCWs.

Objectives:

This workshop brings health workforce needs onto the health policy agenda. It seeks to build capacity for a resilient and healthy health workforce, setting the focus on protection and preparedness of HCWs and their individual wellbeing, and reduction of gendered inequalities. The following major questions will be addressed: What do we know about COVID-19 and the health and wellbeing of HCWs? What skills are needed to respond to new demands? What policy approaches are available to improve protection, preparedness and mental health support of HCWs? How to integrate gender equality and the situation of migrant/refugee HCWs in these approaches, and finally build capacity for effective health workforce governance and its implementation.

The workshop introduces novel results drawn from European comparative research and country case studies. It connects policy and practice, as well as health system and individual HCW needs. A number of important policy recommendations are emerging from the research. (1) The health and wellbeing of the health workforce must be addressed systematically across all levels of health policy and governance, including the organisation settings. (2) Health systems must take responsibility and leadership in responding to health workforce needs. (3) Important lessons to be learned from HCWs' experiences should guide future health workforce policy and pandemic recovery plans. (4) Participatory governance and inclusion of HCWs must be strengthened, including gender equality and diversity.

The workshop will stimulate critical debate and improve knowledge exchange across countries and between researchers. It will contribute to strengthen resilience of the health workforce and health systems, and to build back better after COVID-19 in a fair and equitable manner.

Key messages:

- Health workforce needs and mental health support must become policy priorities and addressed as part of health system resilience.
- Action has to be taken to strengthen participatory health workforce governance sensitive to new needs.

Abstract citation ID: ckac129.040
Investing in the health workforce, protecting mental health: policy and action taken by WHO

Tomas Zapata

T Zapata[1], *M Langins*[1]
[1]WHO Regional Office for Europe, Copenhagen, Denmark
Contact: zapatat@who.int

Background:

The COVID-19 pandemic and the current war in Ukraine have presented opportunities to increase national leadership on mental health, including support health and care workers. Member States across the region have worked closely with the WHO to strengthen their policy levers to support the mental health and occupational safety policies for the workforce at various levels including government, organization and local service levels. To complement these policies, the WHO will launch the WHO Global Health and Care Compact at the Seventy-fifth World Health Assembly in May 2022.

Methods:

The WHO has convened Member States to discuss the policy levers that can support the mental health of health and care workers. These include online multistakeholder webinar series, national policy dialogs, ministerial discussions during the Regional Committee, preparatory consultations for the World Health Assembly to discuss priority areas and policy. More recently with the crisis in Ukraine, the WHO has been working closely with the UN Interagency Steering Committee (IASC) Reference Group on Mental Health and Psychosocial Support in Emergency Settings rolling out services for refugees, including health workers in these settings.

Results:

A number of important policy recommendations are emerging from this work: (1) strengthening national and political leadership; (2) adopting stepped approaches; (3) facilitating collaboration across professions, sectors and levels of syste for more effective responses; (4) strengthening capacity and expertise; (5) monitoring effectiveness for continuous improvement; (6) ensuring acceptability and accessibility.

Conclusions:

Promoting health and well-being and mental health support to the health and care workforce has become a key priority for health systems to enable sustainable national health workforces. WHO will prioritize country support on this area and the development of regional guidance.

Health workforce governance during the COVID-19 pandemic: learning lessons from Europe

Gemma Williams

G Williams[1], *J Buchan*[2,3], *T Zapata*[4]
[1]European Observatory on Health Systems and Policies, London, UK
[2]University of Edinburgh, Edinburgh, UK
[3]Health Foundation, London, UK
[4]WHO Regional Office for Europe, Copenhagen, Denmark
Contact: g.a.williams@lse.ac.uk

Background:

This study considers some of the effective governance tools that have been utilised to mobilise, redeploy and repurpose the health workforce during the COVID-19 pandemic to create surge capacity, protect workforce health and wellbeing and ensure effective implementation of vaccination programmes.

Methods:

Data were systematically extracted from the Observatory/WHO Europe/European Commission Health System and Response Monitor, covering the period from March 2020 to May 2021 with a focus on four dimensions of health workforce governance: national/regional government policies; legislation; regulation; the role and remit of employers and management.

Results:

A wide-range of governance actions across all levels were required to ensure the health workforce could provide effective pandemic responses. Creating surge capacity, for example, often required adoption of emergency legislation to facilitate exceptional hiring procedures and the changing of (re-)registration requirements, as well as additional training and development of new competencies among other actions. Putting in place physical and mental health support meanwhile required defining infection control policies, monitoring PPE supply and distribution, ensuring access to free mental health support, and implementation of breaks. Some countries also allowed ‘‘new’’ types of workers to vaccinate; online or in person training; adjustments to payment mechanisms; and creating new supervision requirements.

Conclusions:

Pandemic responses have broken up sclerotic governance structures which have hampered past health workforce development and reform, new training programmes have been rapidly developed, leadership roles have been delegated to a wider-range of health professionals than before and monitoring systems that provide more rapid data on staffing levels have been put into place. Learning from and evaluating these changes will be important to help inform future pandemic responses.

[5]Instituto de Higiene e Medicina Tropical, Universidade Nova de Lisboa, Lisbon, Portugal
[6]Department of Public and Ecosystem Health, Cornell University, Ithaca, New York, USA
Contact: kuhlmann.ellen@mh-hannover.de

Background:

The COVID-19 pandemic revealed the importance of the health workforce for health system resilience. This study aims to explore whether and how healthcare system in Europe have responded to new emergent needs and transformed their health workforce policies.

Methods:

A qualitative comparative approach is applied, based on multi-level governance theory and a rapid assessment of three areas of health workforce policy: mental health, gender equality, and public health competencies. We consider two years of the pandemic with a focus on recent waves, October 2021-January 2022. Denmark, Germany, Portugal, Romania and Switzerland are selected for comparison, representing different health systems, health workforce conditions and COVID-19 indicators in the European Union and European Economic Area.

Results:

Across countries the pandemic has highlighted mental health needs, persisting gender inequalities and demand for public health competencies. Our comparison reveals similar weaknesses and governance gaps. (1) Mental health needs of healthcare workers are increasingly recognised (more strongly in Denmark and less in Romania with the other countries clustering in-between); however, health workers' perceptions are not used as guidance and effective programmes are lacking. (2) The situation is worst in relation to gender equality goals that are largely ignored in pandemic policy and recovery plans.

(3) Public health competences are more advanced and integrated in the NHS systems in Denmark and Portugal, but no country has taken action to innovate health workforce education and strengthen public health.

Conclusions:

The comparative assessment highlights that health systems failed to adequately respond to health workforce needs and the COVID-19 challenges. Action has to be taken to implement participatory governance and step up efforts towards more responsive and resilient health workforce policy.

Interventions to improve teamwork and wellbeing in primary care settings: a mixed method review

Maria Panagioti

M Panagioti[1], N Tyler[1], A Hodkinson[1]
[1]Manchester University, Manchester, UK
Contact: maria.panagioti@manchester.ac.uk

Background:

General practices are experiencing increasing pressures due to rising demand, declining staff numbers, and knock-on impacts on patient care. The COVID-19 pandemic has added further challenges and reinforced the importance of teamwork and organisational settings. We undertook a mixed-method systematic review to explore which interventions can improve teamwork within primary care and improve inter-sector partnerships with other health and social care services.

Methods:

Five major bibliographic databases were systematically searched for relevant studies from inception to February 2022. We included controlled intervention study designs and linked qualitative studies. For amenable data, meta-analysis is being undertaken using random effects models taking into account the between study heterogeneity (quantified using the I2 statistic) and potential publication bias (funnel plots and Egger's test). The qualitative studies are analysed using thematic analyses.

Results:

The original search yield of 3012 studies, of which 14 studies with 1,534 participants were include in our analyses. Most of the evaluated interventions focused on improving non-technical skills and provided evidence of improvements in the quality of teamwork in primary care. Meta-analysis and narrative synthesis is undertaken to examine the impact of the teamwork interventions on staff outcomes (team attitudes, knowledge, and functioning; wellbeing), and patient outcomes (e.g. quality of patient care, patient satisfaction/experience).

Conclusions:

The findings provide information of immediate importance for the mental health and wellbeing and teamwork support of professionals entering primary care and for the organisation of primary care services.

Abstract citation ID: ckac129.044
Hospital doctors in Ireland working through COVID-19 pandemic: learning from individual experience

Niamh Humphries

N Humphries[1], J-P Byrne[1], J Creese[2]
[1]RCSI Graduate School of Healthcare Management, Dublin, Ireland
[2]College of Life Sciences, University of Leicester, Leicester, UK
Contact: nhumphries@rcsi.ie

Background:

This study was part of a 5-year, HRB-funded research project about hospital doctor retention and emigration.

Methods:

In 2021, we conducted a Mobile Instant Messaging Ethnography (MIME) with 28 hospital doctors in Ireland. This involved interviewing doctors via Zoom and engaging them in a 12-week work-related conversation via WhatsApp.

Results:

Our findings illustrate that the pandemic intensified already difficult working conditions. Respondents described working in an under-staffed and under-resourced system, in which they were unable to protect their own wellbeing or achieve a work-life balance. Morale was low and few had hope of health system improvement.

Conclusions:

The findings reveal a workforce under strain and raise concerns about health worker wellbeing and health worker attrition, post-pandemic. However, they also highlight the importance (and value) of listening to the voices of frontline health workers and using their insights to inform and enhance retention policies.

Risk factors for SARS-CoV-2 infection: a case-control study in college students after vaccination

Erika Renzi

E Renzi[1], V Baccolini[1], A Covelli[1], G Migliara[1], A Massimi[1], C De Vito[1], C Marzuillo[1], P Villari[1]
[1]Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy
Contact: erika.renzi@uniroma1.it

Background:

Within the SARS-CoV-2 screening campaign offered through RT-PCR test by Sapienza University of Rome, we conducted a case-control study to identify the risk factors for the acquisition of SARS-CoV-2 infection among university students.

Methods:

Positive students identified through the SARS-CoV-2 screening campaign (September 2021 - February 2022) were enrolled as cases and matched to two randomly selected students who tested negative on the same day. The interview questionnaire consisted of 39 questions investigating exposure to modifiable and nonmodifiable risk factors for SARS-CoV-2 in the two weeks before testing. A multivariable conditional logistic regression model was constructed to identify predictors of SARS-CoV-2 infection. Adjusted odds ratio (aOR) and 95% CI were calculated.

Results:

Out of 8.730 tests for SARS-CoV-2, 173 students tested positive (2.0%), of which 122 were included in the case-control study (response rate: 70.5%). Most students were female (73.2%), with a mean age of 23.3 years (SD ± 3.6), vaccinated for SARS-CoV-2 (97.8%) and enrolled in non-health faculty (56.8%). At the multivariable analysis, significant positive associations were found with having had contact with a person who tested positive for SARS-CoV-2 (aOR: 3.04, 95% CI: 1.59-5.82) or having been to a disco/nightclub (aOR: 5.37, 95% CI: 2.00-14.38). Instead, being vaccinated against SARS-CoV-2 (aOR: 0.13, 95% CI: 0.01-0.93), having a valid EU COVID digital certificate (aOR: 0.06, 95% CI: 0.01-0.30) and attending lectures in-person (aOR: 0.35, 95% CI: 0.17-0.70) were negatively predictors. No association was found for sex, age, health faculty students, use of public transportation, attendance at restaurants or gyms.

Conclusions:

The results highlight how anti-COVID-19 vaccinations and the reasons for students to obtain an EU COVID digital certificate may prevent students from getting infected. In addition, university environment seems to be safe for students.

Key messages:

- Promoting SARS-CoV-2 vaccination adherence in the college-age population is crucial to limiting the SARS-CoV-2 spread.
- Attending in-person educational activities in regulated settings (e.g., low occupancy, mask use) may not be a risk factor for COVID-19 infection.

COVID-19 vaccination uptake in Belgium: socioeconomic and sociodemographic disparities

Lisa Cavillot

L Cavillot[1,2], J Van Loenhout[1], L Catteau[1], L Van den Borre[1,3], R De Pauw[1,4], K Blot[1], N Speybroeck[2], B Devleesschauwer[1,5], P Hubin[1]
[1]Epidemiology and Public Health, Sciensano, Brussels, Belgium
[2]Research Institute of Health and Society, University of Louvain, Brussels, Belgium
[3]Interface Demography, Free University of Brussels, Brussels, Belgium
[4]Rehabilitation Sciences, University of Ghent, Ghent, Belgium
[5]Department of Translational Physiology, Infectiology and Public Health, University of Ghent, Merelbeke, Belgium
Contact: lisa.cavillot@sciensano.be

Background:

Recent studies have identified important social inequalities in SARS-CoV-2 infection and related COVID-19 outcomes in the Belgian population. This study aims to investigate socioeconomic and -demographic characteristics associated with the uptake of COVID-19 vaccine in Belgium.

Methods:

We conducted a retrospective analysis of the uptake of the first dose of COVID-19 vaccine among 5,341,584 adults ($\geq$ 18 years) tested for COVID-19 in Belgium until August 31, 2021. We integrated four national data sources: the Belgian vaccine registry (vaccination status), COVID-19 Healthdata (laboratory test results), STATBEL (socioeconomic/-demographic data) and the Common Base Registry for HealthCare Actors (people licensed to practice a healthcare profession in Belgium). Unvaccinated and vaccinated people (with at least one dose) were compared using multivariate logistic regression analysis.

Results:

During the study period, 53,887 people (10%) did not receive the first COVID-19 vaccine dose in Belgium. Migrant background was associated with vaccine uptake (e.g., non-Europeans were almost three times [2.96-3.00] more likely to be unvaccinated compared to Belgian nationals). Single parents (OR 1.27 [1.26-1.28]) and people living alone (OR 1.18 [1.17-1.19]) were more likely to be unvaccinated compared to couples with children. Having a low or moderate education level (OR 1.36 [1.35-1.38] for low; OR 1.30 [1.29-1.32] for moderate) and income (OR 2.36 [2.34-2.38] for low; OR 1.54 [1.52-1.55] for moderate), being unemployed, (OR 1.50 [1.49-1.51), and having low health literacy (OR 1.41 [1.39-1.43]) led to a greater likelihood of being unvaccinated.

Conclusions:

Migrants, people living alone, single parents or socioeconomically disadvantaged groups have lower uptake of COVID-19 vaccine in Belgium. The identification of these socioeconomic and -demographic disparities is critical to develop strategies guaranteeing a more equitable COVID-19 vaccination coverage in Belgium.

Key messages:

- The study highlight important determinants in the uptake of the first dose of COVID-19 vaccine in Belgium.
- These results highlight the importance to focus efforts on socioeconomically disadvantaged groups currently underrepresented in COVID-19 vaccination uptake in Belgium.

Abstract citation ID: ckac129.047
SARS-CoV-2 Seroprevalence in Germany: results from the second wave of the RKI-SOEP study

Elisabetta Mercuri

E Mercuri[1], C Poethko-Müller[1], A Schaffrath Rosario[1], L Schmid[1], M Schlaud[1], A Gößwald[1], RKI-SOEP-2-study group[2,3,4]
[1]Department of Epidemiology and Health Monitoring, Robert Koch Institute, Berlin, Germany
[2]Socio-Economic Panel, German Institute for Economic Research, Berlin, Germany
[3]Federal Office for Migration and Refugees, Nurnberg, Germany
[4]Institute for Employment Research, Nurnberg, Germany
Contact: MercuriE@rki.de

Introduction:

The first wave of the ''Corona Monitoring bundesweit'' (RKI-SOEP) study showed that shortly before the start of the German vaccination program only about 2% of adults (> 18 years) had already experienced SARS-CoV-2 infection and more than half of these cases had been detected and notified. The objectives of the second wave of this study are to further investigate the spread of SARS-CoV-2 in Germanýs population aged over 14 years. It aims to determine the seroprevalence of infection- and vaccine-induced IgG antibodies against SARS-CoV-2. Finally, it examines health, demographic and socioeconomic risk and protective factors for infection and vaccine acceptance.

Methods:

From November 2021 to February 2022, the second wave of this cross-sectional study collected biospecimens (capillary blood samples) and interview data, including information on infection and vaccination, from a nationwide population sample drawn from the German Socio-Economic Panel (SOEP). The dried self-collected blood samples were then analyzed for the detection of SARS-CoV-2 IgG antibodies by Euroimmun ELISA assay.

Results:

Based on preliminary, unweighted data of around 11,000 participants aged >14 years (52% response rate), we expect the final seroprevalence of SARS-CoV-2 antibodies to be in the range of 80 to 90%. Thus, around 10 to 20% of the German population may still be susceptible to a severe disease progression because they are neither infected nor vaccinated. Final results, weighted for non-response and adjusted for test sensitivity and specificity, will be presented.

Conclusions:

The RKI-SOEP-2 study will be pivotal in both, contributing to an improved understanding of SARS-CoV-2 propagation in different regional and sub-group settings and in identifying vulnerable target groups that need to be protected against future infections.

Key messages:

- Dried blood self-sampling in a nationwide sample is a robust tool to estimate seroprevalence at a population level.
- As of February 2022, presumably 80 to 90% of the German population has previously been infected and/or vaccinated against SARS-CoV-2.

Waning of SARS-CoV-2 IgG antibodies after vaccination: first results from the CoMoLo follow-up 2021

Cânâ Kußmaul

C Kußmaul[1], A Schaffrath Rosario[1], J Allen[1], M Lange[1], C Koschollek[1], S Haller[2], M Schlaud[1], RKI CoMoLo Study Team[1]
[1]Department of Epidemiology and Health Monitoring, Robert Koch Institute, Berlin, Germany
[2]Department of Infectious Disease Epidemiology, Robert Koch Institute, Berlin, Germany
Contact: c.kussmaul@rki.de

Background:
In 2020, the study “Corona-Monitoring Lokal” (CoMoLo) assessed seroprevalences of SARS-CoV-2 IgG antibodies in four study locations that were particularly affected by outbreaks in the early stages of the pandemic in Germany. One of the objectives of the 2021 follow-up was to examine the development of immunological parameters over time, including the extent of IgG antibody waning after vaccination.

Methods:
Venous blood specimens were collected from a sample of initial study participants over a 2-week period between May and October 2021, with an oversampling of seropositive or previously infected individuals. Levels of IgG antibodies to the SARS-CoV-2 spike protein were measured from serum using Anti-SARS-CoV-2-QuantiVac-ELISA (IgG) tests by Euroimmun. Information on SARS-CoV-2 vaccinations or known infections was collected via online questionnaires or telephone interviews.

Results:
A total of 3328 participants (74% response) gave blood specimens for this follow-up study, with questionnaire information available for 2843 (85%) of these. Preliminary analyses suggest that in participants who had received two doses of a vaccine more than 3 weeks before giving blood (n = 1583), IgG levels decreased exponentially by about 9.8% (95%CI 9.1% - 10.4%) with each additional week since the last dose, when controlling for age, sex, and type of vaccine. There was evidence of this waning effect differing by vaccine type. Antibody levels also appear to decline with increasing age, according to preliminary results. Final results of the linear model used to assess the dynamics and predictive factors of antibody levels will be reported.

Conclusions:
This follow-up study will add evidence to an improved understanding of antibody waning after SARS-CoV-2 vaccination. Preliminary results are in line with international studies and may be helpful for discussions on potential benefits of further vaccinations in Germany.

Key messages:
- Antibodies induced by COVID-19 vaccination wane over time. The magnitude of this effect differs by vaccine type. Antibodies also decreased with increasing age.
- Our results may be helpful for discussions on potential benefits of further COVID-19 vaccinations in Germany.

Abstract citation ID: ckac129.049
Predictors of seropositivity against SARS-COV-2: a population-based seroepidemiological study

Lusine Musheghyan

L Musheghyan[1], S Sahakyan[1], Z Sargsyan[1], D Muradyan[1], L Aslanyan[1], N Gharibyan[1], A Harutyunyan[1], V Khachadourian[1], V Petrosyan[1]
[1]Turpanjian College of Health Sciences, American University of Armenia, Yerevan, Armenia
Contact: lmusheghyan@aua.am

Background:
Data on parameters of actual exposure to SARS-CoV-2 is limited, and specific population groups might be at a higher risk of infection. In line with the growing need for large-scale investigations to determine the presence of antibodies against SARS-CoV-2 among different population groups, we conducted a nationwide assessment in Armenia.

Methods:
We performed a cross-sectional seroepidemiological study among the adult population in Armenia, in May-September 2021. A multi-stage cluster random sampling was performed to recruit the participants across the capital city and regions. The study had two main components: blood sampling, which took place in primary care facilities and a phone survey on socio-demographic characteristics, comorbidities, and previous history of COVID-19.

Results:
The number of participants included in both blood sampling and phone survey was 3483. The nationwide prevalence of SARS-CoV 2 antibodies weighted by age and gender was 66.4% with significantly higher prevalence in urban compared to rural areas (67.3% vs 59.3%, $p < 0.001$). Only 22.7% (n = 772) of the total sample reported a previous history of PCR confirmed COVID-19, among whom antibodies were detected in 94.2% (n = 727). In the final adjusted model, the seropositivity was associated with being female (OR = 1.60, 95% CI: 1.32; 1.92), employed (OR = 1.41, 95% CI: 1.17; 1.69), and having previous PCR confirmed COVID-19 (OR = 10.6, 95% CI: 7.39; 15.21).

Conclusions:
Over 66% of the population were seropositive for antibodies against SARS-CoV 2; and over 1/5 of the sample reported a previous PCR diagnosis. Factors associated with increased odds of seropositivity included gender, employment status, and place of residence. Targeted interventions are recommended to minimize the risk of infection among those groups, including vaccination and infection prevention and control measures.

Key messages:
- The prevalence of SARS-CoV 2 antibodies is about three times higher than the rate of infection based on PCR confirmed prevalence of COVID-19.
- Women, people living in urban areas, and those employed are at a higher risk for exposure to SARS-CoV 2.

Do preventive child examinations in general practice reduce the risk of overweight and obesity?

Signe Heuckendorff

S Heuckendorff[1], C Eggertsen[2], JL Thomsen[3,4], K Fonager[1,4]
[1]Department of Social Medicine, Aalborg University Hospital, Aalborg, Denmark

[3]Center for General Medicine, Aalborg University, Aalborg, Denmark
[4]Department of Clinical Medicine, Aalborg University, Aalborg, Denmark
Contact: s.heuckendorff@rn.dk

Background:
The prevalence of children with overweight and obesity is increasing. General practitioners in Denmark follow children throughout early childhood via the preventive child health examinations. These examinations are offered to all children

from birth to the age of five. Thus, the general practitioners have a unique opportunity for early tracing and identification of overweight and obesity, but the impact of the examinations are not examined. Therefore, the aim of this study was to examine the association between attending preventive child health examinations and the risk of overweight and obesity at the age of six both for the total pediatric population and within groups of vulnerable children such as children of parents with low educational level or low household income.

Methods:

A population-based birth cohort study was conducted including all Danish children born from 2000-2012 using the Danish nationwide registers. Data included information on child participation in preventive health examinations at general practice, height and weight at the age of six, and parental information on socioeconomic factors.

Results:

The analyses included 801,444 children. Attending preventive child health examinations were not associated with a lower risk of overweight at the age of six. A lower risk of obesity was seen in children attending the examinations, both in the general population (RR 0.71, 95% CI 0.66-0.76) and within vulnerable groups (low level of maternal education: RR 0.80, 95% CI 0.72-0.89), low household income (RR 0.79, 95% CI 0.72-0.87). The risk of obesity was greater in the vulnerable groups than in the not-vulnerable groups.

Conclusions:

Attending preventive child health examinations were associated with a lower risk of obesity at the age of six, but not overweight. This was seen for both the general pediatric population and within vulnerable groups. The lowest risk of obesity was seen in the not-vulnerable groups.

Key messages:

- The results indicated that attending preventive child health examinations in general practice reduced the risk of obesity at the age of six, but not the risk of overweight.
- The lowest risk of obesity was seen in the not-vulnerable groups attending the preventive child health examinations in general practice.

How did the covid-19 pandemic affect lower respiratory tract infections in young children in England?

Kimberley Foley

KA Foley[1]*, EJ Maile*[1]*, A Bottle*[1]*, FK Neale*[1]*, RM Viner*[2]*, SE Kenny*[3,4]*, A Majeed*[1]*, DS Hargreaves*[5]*, S Saxena*[1]
[1]Department of Primary Care and Public Health, Imperial College London, London, UK
[2]Population, Policy & Practice Department, UCL Great Ormand Street Institute of Child Health, London, UK
[3]Department of Women's and Children's Health, Alder Hey Children's NHS Foundation Trust, Liverpool, UK
[4]NHS England and NHS Improvement, NHS, London, UK
[5]Mohn Centre for Children's Health, Imperial College London, London, UK
Contact: k.foley@imperial.ac.uk

Background:

Social distancing policies to reduce transmission of covid-19 also reduced children's exposures to endemic respiratory viruses. We aimed to examine the impact of the covid-19 pandemic on lower respiratory tract infections in under 5s presenting to primary care in England.

Methods:

Longitudinal trends analysis using electronic health records from a nationally representative primary care database. Our target population was children aged <5 years registered with a primary care practice from January 2015 to March 2021.

Our main outcome was total weekly contacts with primary care for a lower respiratory tract infection (LRTI). We defined three pandemic phases from March 2020 - March 2021: i) first national lockdown (late March to early June 2020), ii) childcare settings reopened and second national lockdown with schools open (mid-June to mid-December 2020) and iii) third national lockdown with schools closed (late December 2020 to end of March 2021). We compared outcomes during each of the three phases with corresponding calendar weeks during pre-pandemic years 2015 to 2019.

Results:

Our study population included 843 020 children <5 years who had 1 076 181 contacts with primary care for LRTIs. During the first phase (first lockdown) there were falls of 79.3% (95% CI: 73.6 to 84.5) from an average of 28 547 primary care contacts for LRTI in 2015 - 2019 to 5915 in 2020; there was a 78.9% (95% CI: 73.7 to 83.9) fall in phase two (childcare settings reopened and second lockdown) from 107 873 to 22 792 contacts; and a 77.7% (95% CI: 73.5 to 81.4) fall in phase three (third lockdown) from 57 200 to 12 764 contacts.

Conclusions:

Children under 5 in England had fewer contacts with primary care for LRTIs during the covid-19 pandemic. This change likely reflects lower prevalence of respiratory illness due to fewer social contacts. This may impact on future health service use as these children have had less exposure, and therefore may have less immunity, to respiratory diseases.

Key messages:

- Children under 5 had fewer contacts with primary care for lower respiratory tract infections during the covid-19 pandemic in England likely due to the restrictions in place to reduce social contacts.
- The falls in lower respiratory tract infections during the covid-19 pandemic in under 5s may mean they have less immunity to respiratory viruses which may impact upon their future health service use.

Abstract citation ID: ckac129.052
Long-term immunity after HBV vaccine: shall we consider a change? A 20-year-follow-up study

Marco Fonzo

M Fonzo[1]*, I Amoruso*[1]*, T Baldovin*[1]*, A Trevisan*[1]*, C Bertoncello*[1]
[1]Hygiene and Public Health Unit, DCTVSP, University, Padua, Italy
Contact: marco.fonzo@unipd.it

Introduction:

Although vaccines against HBV have been available since the 1980s, the long-term immunity is still debated. When assessing immune persistence, a number of clearly defined variables must be taken into account. Often the expression 'infant vaccination' means the administration within the first year of life at any age, but a difference of a few months may imply a different antibody persistence over the years. This study assessed the anti-HBs titre 20 years after the primary vaccination course and estimated the effect of age at 1st dose and time interval between doses on long-term protection.

Methods:

Data on age, sex and date of administration were collected. Inclusion criteria: born to negative mother, 3-dose schedule, no previous HBV infection, age at enrolment 18-24 years; age at 1st dose 2-12 months. Titres ≥10IU/l were considered protective. A logistic regression was performed, adjusting for sex, follow-up time and date of 1st dose and analysis.

Results:

We included 5,485 participants (64% female). The mean anti-HBsAg increased from 46, 52, 85 to 193IU/l when the 1st dose was administered in the I, II, III or IV trimester of life, respectively. Similarly, the proportion of individuals with titre <10IU/l decreased from 51 to 18% between the two extreme quarters. The risk of a titre <10IU/l decreased with age at the

1st dose (AOR: 0.84; 95%CI: 0.78-0.91 per one-month increase) and time between the 2nd and 3rd doses (AOR: 0.89; 95%CI:0.85-0.94).

Conclusions:

The mere presence of a titre <10IU/l does not equate lack of protection. However, antibody levels are very different depending on the actual age of vaccination. One-month delay within the first year is associated with a -18% chance of a titre <10IU/l 20 years later. Although this information needs to be combined with local epidemiology and surveillance to obtain an informed risk-benefit balance, the implications from a public health and economic perspective may be diverse and worth considering.

Key messages:

- Still within the first year of life, a delay in the administration of the 1st dose of HBV vaccine and a longer time between the 2nd and 3rd dose imply a higher antibody persistence even 20 years later.
- Considering the local circulation of HBV and surveillance, this result could be taken into account to obtain an informed risk-benefit balance.

Country-level social mobility and inequalities in adolescent health behaviours in 32 countries

Heiko Schmengler

H Schmengler[1], M Peeters[1], GWJM Stevens[1], AE Kunst[2], K Delaruelle[3,4], M Dierckens[3], L Charrier[5], D Weinberg[1], AJ Oldehinkel[6], WAM Vollebergh[1]

[6]Department of Psychiatry, University Medical Center of Groningen, Groningen, Netherlands
Contact: heiko.schmengler@live.de

Background:

Higher family affluence is associated with healthier behaviours in adolescents, but the strength of this association varies across countries. Differences in social mobility at the country-level, i.e. the extent to which adolescents develop a different socioeconomic status (SES) than their parents, may partially explain why the association between family affluence and adolescent health behaviours is stronger in some countries than in others.

Methods:

Using data from adolescents aged 11-15 years from 32 different countries, participating in the 2017/2018 wave of the Health Behaviour in School-aged Children (HBSC) study (N = 185,086), we employed multilevel regression models with cross-level interactions to examine whether country-level social mobility moderates the association between family affluence and adolescent health behaviours (i.e. moderate-to-vigorous physical activity, vigorous physical activity, healthy foods consumed, unhealthy foods consumed, having breakfast regularly, weekly smoking).

Results:

Higher family affluence was more strongly associated with higher levels of physical activity in countries characterized by high levels of social mobility (cross-level interaction linear regression coefficient 0.34; 95% CI 0.08 to 0.60; p = 0.009 for moderate-to-vigorous physical activity, and 0.31; 0.11 to 0.50; p = 0.002 for vigorous physical activity). No cross-level interactions were found for any of the other health behaviours.

Conclusions:

Our findings suggest that differences in social mobility at the country-level may contribute to cross-national variations in socioeconomic inequalities in adolescent physical activity. Further research can shed light on the mechanisms linking country-level social mobility to inequalities in adolescent physical activity to identify targets for policy and interventions.

Key messages:

- This is one of the first studies to investigate country-level social mobility in relation to health equity. Inequalities in adolescent physical activity were steeper in socially mobile countries.
- Stronger efforts to engage adolescents from low-affluent families in physical activity may be necessary in countries characterized by high levels of social mobility.

The longitudinal impact of social media use on adolescent mental health in the UK

Ruth Plackett

R Plackett[1], J Sheringham[2], J Dykxhoorn[1]
[1]Primary Care & Population Healt, University College London, London, UK
[2]Department of Applied Health Research, University College London, London, UK
Contact: ruth.plackett.15@ucl.ac.uk

Background:

Cross-sectional studies have suggested a relationship between social media use and depression and anxiety in young people. We examined the longitudinal relationship between social media use and young people's mental health and the role of self-esteem and social connectedness as potential mediators.

Methods:

The sample comprised 3,228 young people from the UK Longitudinal Household Study (waves 1-10). Mental health at age 14 or 15 was measured by the SDQ Total Difficulties score. The number of hours spent on social media was measured at age 12 or 13. Self-esteem at age 13 or 14 was measured via eight questions and social connectedness was measured by two questions. Multilevel linear regression models explored whether social media use at age 12 or 13 predicted mental health at age 14 or 15. Path analysis with structural equation modelling investigated the mediation pathways.

Results:

In unadjusted analysis, for those who spent 7 or more hours on social media vs none, their mental health problems trended upwards by 3.87 (95% CI, 0.71-7.03) but this relationship was attenuated after including covariates. In unadjusted path analysis, more social media use was associated with lower self-esteem ($b = -0.10$, $p < 0.05$), which in turn was associated with more mental health problems ($b = -6.80$, $p < 0.001$). The indirect effect ($b = 0.70$, $p < 0.05$) showed that 68% of the effect of social media use on mental health two years later was mediated by self-esteem. This relationship was attenuated after adjusting for covariates and in imputed data, and social connectedness was not associated.

Conclusions:

This study shows the importance of longitudinal evidence, as we found there was little evidence to suggest a causal relationship between social media use and mental health issues two years later. Interventions that address social media use alone may not improve young people's mental health but those that consider factors like self-esteem may be more effective.

Key messages:

- Longitudinal data suggests there is limited evidence that high social media use causes poorer mental health in adolescents despite indications from cross-sectional analyses.
- Policy makers should consider that targeting social media use alone is unlikely to prevent poor adolescent mental health and factors like self-esteem may be more important prevention targets.

Abstract citation ID: ckac129.055

Conceptual views of mental health among adolescents in Sweden

Veronica Hermann

N Durbeej[1], *AC Karlsson*[1], *A Sarkadi*[1]

[1]Department of Public Health and Caring Sciences, Uppsala University, Uppsala, Sweden

Contact: veronica.hermann@pubcare.uu.se

Background:

Lay and professional people may use terms for mental health and mental health problems differently, causing difficulties in adequately addressing associated needs. Despite the public health issue of increased mental health problems among adolescents, there is limited research on perceptions of mental health concepts among young people. This study aimed to explore conceptual views of mental health and mental health problems among adolescents.

Methods:

During October and November 2020, a total of 32 adolescents (15-18 years old) living on Sweden's largest island Gotland were interviewed in focus groups or individual interviews. The interviews were semi-structured and audio recorded. Data were analysed thematically according to Systematic Text Condensation.

Results:

Three themes emerged from the analysis: Mental health is about how we feel; One's mental health depends on one's situation, thoughts and ways of coping; and Mental health problems should be taken seriously and can get severe. The adolescents described mental health as an overarching concept encompassing both positive mental health and mental health problems. Mental health problems were perceived as something other than normal challenges in life, however ranging from minor problems to severe illness. Good mental health was understood as a condition with absence of mental health problems and presence of symptoms of positive mental health.

Conclusions:

The adolescents' had a complex and holistic understanding of mental health concepts, consistent with definitions used by the World Health Organization and Swedish authorities. They suggested both positive mental health and mental health problems to be considered when assessing and discussing their mental health. Further, the results highlight the need of support for young people on how to cope with difficulties in life and support for those suffering from minor mental health problems.

Key messages:

- The adolescents' understanding of mental health and mental health problems were highly consistent with current accepted definitions of the concepts.
- According to the participants, both positive mental health and mental health problems should be considered simultaneously to understand and address adolescents' mental health.

Abstract citation ID: ckac129.056

Help-seeking behaviors among survivors of intimate partner violence during pregnancy in 54 LMICs

Mariella Stiller

M Stiller[1], *ML Wilson*[1,2], *T Bärnighausen*[1], *AA Adedimeji*[3], *ER Lewis*[3,4], *A Abio*[1,2]

[1]Heidelberg Institute of Global Health, Heidelberg University Hospital, Heidelberg, Germany

[2]Injury Epidemiology & Prevention Research Group, Turku Brain Injury Center, Turku, Finland

[3]Department of Epidemiology & Population Health, Albert Einstein College of Medicine, New York, USA

[4]Department of Surgery, Jacobi Medical Center, New York, USA

Contact: M.Stiller@stud.uni-heidelberg.de

Background:

Intimate partner violence (IPV) experienced by pregnant women is pervasive worldwide. As survivors rarely seek help, there exists a paucity of research on their help-seeking behaviors. The present study provides a multi-national perspective into the nature of help-seeking behaviors among survivors of IPV during pregnancy.

Methods:

Population-based data from 54 LMICs were abstracted from the Demographic and Health Surveys Program between 2005 and 2020 (N = 359,027). Bivariate and multivariable logistic regression were used to analyze the extent to which - and from whom - survivors of IPV during pregnancy sought help and assess associated factors.

Results:

Half of respondents (51.87%) sought help following IPV while pregnant (ranging from 39.02% in Asia and Oceania to 63.18% in sub-Saharan Africa). Support was primarily obtained from informal contacts (44.02%), such as family, neighbors, and friends, and rarely from formal institutions (10.45%), such as law enforcement, social and medical services. Help-seeking behaviors were positively associated with higher education, employment, earnings exceeding that of their spouse, exposure to mass media, intimate partner's alcohol consumption, fear of their intimate partner, parental violence, richer wealth status, partner's controlling behaviors, and facing barriers to access health care. Conversely, being married, and justifying wife beating were negatively associated with help-seeking.

Conclusions:

The research findings highlight the need for interventions, ranging in scope from the individual to familial and societal levels, to increase and improve help-seeking opportunities for IPV survivors. Efforts should be made on strengthening women's decision-making capacity, reducing poverty, ensuring educational attainment, improving employment opportunities, disseminating information about help sources, IPV screening within health care, and promoting the diffusion of gender equality by engaging communities as a whole.

Key messages:

- IPV during pregnancy is still pervasive in LMICs, and only half of survivors seek help. Women's individual, partner's/family's, and community's factors are associated with IPV survivors' help-seeking.

- The research findings highlight the need for interventions, ranging in scope from the individual to familial and societal levels, to increase and improve help-seeking opportunities for IPV survivors.

Abstract citation ID: ckac129.057

Young men's gambling and violence perpetration in Mwanza, Tanzania

Rebecca Brambilla

H Stöckl[1,4], R Brambilla[1], G Mshana[2,3], D Malibwa[3], S Sichalwe[3], S Kapiga[3,4]
[1]Ludwig-Maximilians-Universität München, München, Germany
[2]National Institute for Medical Research, Mwanza, Tanzania
[3]Mwanza Intervention Trials Unit, Mwanza, Tanzania
[4]LSHTM, London, UK
Contact: rebecca.brambilla@ibe.med.uni-muenchen.de

Background:
The prevalence of intimate partner violence (IPV) in Tanzania is one of the highest in the sub-Saharan African region. Studies have shown that traditionally ''manly'' behaviours, such as risk-taking, are at the root of IPV perpetration. Only few studies investigated the co-occurrence of gambling and IPV, and none from LMICs.

Methods:
Cross-sectional survey data of 1002 men aged 18-24 from Mwanza, Tanzania were analysed. Physical, sexual, emotional and economic IPV perpetration were measured using acts-based questions. Gambling was assessed through a question on whether the man bet or spent money on gambling or gambling machines. Consequences of gambling behaviours were assessed through four further questions. We conducted multivariate logistic regressions to control for potential confounders.

Results:
21% of the men in the sample confirmed they had bet or spent money on gambling in the previous 12 months; the prevalence raises to 24% for men who had been in a relationship in the previous 12 months (N = 755). Of these, 23% had ever perpetrated physical IPV, 29% sexual IPV, 56% emotional IPV and 37% economic IPV in their lifetimes. Of those who gambled, 24% had ever perpetrated physical IPV, 46% ever committed sexual IPV, 66% emotional IPV and 45% economic IPV. Gambling was statistically significantly associated sexual IPV (aOR: 2.39; 95% CI: 1.66-3.45) and emotional IPV (aOR: 1.48; 95% CI: 1.03-2.14) even after controlling for age, alcohol use, depressive symptoms and suicidal ideation. Gambling was not associated with physical and economic IPV after adjusting for those confounders.

Implications:
The analysis shows that young men's practice of gambling is an additional risk factor for IPV perpetration that needs to be addressed. More research is needed to understand how current prevention efforts can be expanded to include problem gambling treatment to curb the incidence of IPV and give couples conflict resolutions skills for issues that might arise from gambling.

Key messages:
- Problem gambling has so far remained vastly under-researched in violence research.
- Gambling as well as drinking were associated with increased odds of physical and sexual IPV perpetration.

1.P. Skills building seminar: Taking the elevator pitch to the next level: how to convince a policymaker in less than 2 minutes

Abstract citation ID: ckac129.058

Organised by: EUPHA
Chair persons: Maaike Droogers (EUPHA), Monica Brînzac (EUPHAnxt)
Contact: m.droogers@euphaoffice.org

Since a number of years the European Public Health Association (EUPHA), the European Public Health Conferences and other organisations have been working hard to translate the evidence in a such a format that policymakers take notice. For example, the WHO Regional Office for Europe works on 'telling the public health narrative' and provides factsheets and infographics, in order to effectively communicate public health messages to policymakers. At the European Public Health Conference so-called pitch presentations were introduced (at Glasgow 2014), where researchers are asked to present their work in 5 minutes with maximum 5 slides (no animations), as a way to learn to present key messages from research in just a few minutes. EUPHA has organised several skills building workshops on translation of evidence in the past years, including the 2019 session 'making the elevator pitch work', then in 2020 'making the elevator pitch more effective', and last year 'making the elevator pitch perfect'. Building forward on those three successful and well-attended workshops, the current workshop will follow up on this series and dive deeper into communicating the evidence through the elevator pitch. Lessons learned at the previous elevator pitch workshops:
– Have a clear ask (keep it simple).
– Appeal to the policymaker's own interests and priorities.
– Spell out how action will be beneficial for the policymaker.
– Be aware of upcoming elections.
– Built a relationship with the assistants of politicians.
– Considering the 'policy window'.
– Make the comparison with the policy plan.
– Propose an action the politician should undertake.
– Identifying the relevant stakeholders and groups affected by the problem.
The importance of effectively communicating the evidence to policymakers is highlighted by infodemics, e.g. called out by the WHO and UN in the context of the COVID-19 pandemic with the spreading of mis- and disinformation about the pandemic. Considering the physical distancing measures that were in place the past years, which made teleworking (working from home) more common, the workshop will also cover virtual tactics. Communicating the science in an increasingly virtual world has made it a whole different kind of sports. In this skills-building workshop, we will select a number of abstracts that have been accepted by the International Scientific Committee as posters and we will invite the presenting authors to this dare: Present your work and key messages in less than 2 minutes. In order to see whether the policymaker/politician is convinced, we are organising a small panel of policymakers and politicians and ask them to give their feedback. Are they interested? Do they remember the key message? And if all goes well, do you get an invitation to come back and present more of your work?

Key messages:

- Being able to present your key messages anywhere, anytime is needed (including virtual tactics).
- Telling the public health narrative and telling a story are important skills for public health professionals to have.

Speakers/Panellists:
Marleen Bekker
EUPHA (PHPP)

1.Q. Workshop: Summarising research evidence related to COVID-19 impact

Abstract citation ID: ckac129.059

Organised by: PHIRI
Chair persons: Maria João Forjaz (Spain), Paulo Nogueira (Portugal)
Contact: jforjaz@isciii.es

After the first SARS-CoV-2 infections surge in late 2019, and its spreading worldwide, COVID-19 rapidly became a pandemic by March 2020. Facing a new public health crisis, the scientific community deployed research efforts to study this new disease, generating a large amount of scientific evidence in a very fast way. This research was developed in several directions, for instance, describing how COVID-19 impacts the population's health and well-being. Specifically, the research aimed at describing and evaluating the risk factors either for being infected or evolving toward adverse outcomes, such as hospitalisation or death. Moreover, the effectiveness of implemented public health measures was assessed since countries' governments rapidly implemented them to mitigate the pandemic.Therefore, several literature reviews have been performed within the European Project 'Population Health Information Research Infrastructure (PHIRI)' to summarise and share the published COVID-19 evidence through a health information portal, where researchers and other stakeholders can exchange best practices and expertise. This workshop aims at sharing the collaborative work and experience of a large group of European researchers within the PHIRI consortium, consisting in preliminary results and lessons learnt with the scientific community. The workshop format consists of five presentations by PHIRI members, each one presenting their literature review work, followed by a discussion among the presenters and with the audience. The first workshop presentation will describe the methodological aspects of research conducted to assess the COVID-19 impact on the population's health and well-being, including research methods and statistical methods. The subject for the second talk will show a representative sample of health indicators used to evaluate the direct impact of COVID-19 in the scientific literature. The third presentation will elaborate on a short and long-term impact of COVID-19 crisis on population with frailty, multimorbidity or with different socioeconomic status; evidence derived from systematic literature reviews of population-based studies. The fourth presentation will describe the effectiveness and impact of tracking COVID-19 patients using digital contact tracing tools. The last presentation describes the methodological aspects of a systematic literature review conducted to gain an overview of the foresight studies that have been done throughout the World about COVID-19.

Key messages:

- During the pandemic, a literature reviews provide an important tool to summarise the large amount of scientific evidence that was generated.
- This workshop aims at sharing the collaborative work and experience of a large group of European researchers participating at PHIRI, the results and lessons learned with the scientific community.

Abstract citation ID: ckac129.060
Looking for methodologies and data pathways used in research to assess the COVID-19 impact: a scientific literature review

Rodrigo Santos

R Feteira-Santos[1,2], Dr Nogueira[1,2]
[1]Área Disciplinar Autónoma de Bioestatística, Instituto de Medicina Preventiva e Saúde Pública, Lisbon, Portugal
[2]Instituto de Saúde Ambiental, Universidade de Lisboa, Lisbon, Portugal
Contact: rodrigosantos@medicina.ulisboa.pt

COVID-19 spread worldwide after the surge of a novel coronavirus infecting humans in late 2019, rapidly becoming a pandemic in early 2020. Then, the scientific community started studying SARS-CoV-2 infection to address the uncertainties around the impact of this new disease on the population health and sustain public health measures to mitigate it. As a result, the research on COVID-19 proliferated fast, and the number of related records also multiplied in research databases. By November 2020, one year after starting the outbreak, PubMed counted more than 80 thousand records, which had already tripled by April 2022. Facing that large body of research, the PHIRI WP5 team deployed a literature review to identify research methods and the research paths from the generation and collection of data used to assess the COVID-19 impact on the population's health and well-being. Consequently, this work aims to describe the evidence gathered according to the location where the research was conducted, its design and statistical methods used to analyse the COVID-19 impact. Therefore, the sample of COVID-19-related records indexed in the PubMed database until November 2020, which concomitantly matched the "data" search term, was considered. As a large sample was retrieved (19837 records), automated text analysis and text mining methods were considered to summarise the information. Then, titles and abstracts were screened for inclusion, and more than half of the initial sample was excluded. The main reasons to exclude were not using original data, not being related to the assessment of the impact of COVID-19 on the population's health or well-being, or not having complete information on the title and abstract. This work is intended to highlight gaps in the evidence on the COVID-19 impact on the population's health and well-being, leading to further research that could enhance the countries' preparedness for future pandemics.

Contact: cgarriga@isciii.es

Background:

The Joint Action Population Health Information Research Infrastructure (PHIRI) seeks to create infrastructures to generate quality data on the COVID-19 pandemic between European countries. The aim of this study is to present a synthesis of health indicators used to evaluate the direct impact of COVID-19

Methods:

Scoping review using a common search strategy in Pubmed, Embase and WHO Covid-19 databases. Health indicators of direct impact of COVID-19 were obtained from observational studies in the general population, hospitals and long-term care facilities from papers published worldwide in English between 01/01/2020 and 06/31/2021. Titles and abstracts were screened first by 15 reviewers using the Rayyan tool. Any discrepancies were solved by agreement between reviewers. Then, articles containing indicators of direct impact were selected in a full-text reading phase. Of them, a random sample of 35 was drawn and their indicators were described.

Results:

After eliminating 262 duplicates 3891 records were reviewed. Screening discarded 3171 abstracts. Of 720 articles sought for retrieval, 445 met inclusion criteria for indicators extraction. In a sample of 35 papers (8.1%), 116 direct impact indicators of COVID-19 were identified. 28 morbidity indicators were found, classified as indicators of prevalence (n = 15), incidence (6), transmissibility (4) and underreported infection (4); 32 of mortality (mortality rate, 9; case fatality rate, 17; time to death, 2); and 54 for severity (complications, 27; mechanical ventilation, 12; hospitalization, 8; requiring ICU admission, 1; time from hospitalization to ICU admission, 1). Two composite indicators of severity and mortality were also identified.

Conclusions:

According to the scientific literature, a wide variety of health indicators has been used to measure the direct impact of COVID-19. The systematization of indicators used in the current COVID-19 pandemic could help for future health crises management.

Etiologic and prognostic roles of frailty, multimorbidity and socioeconomic characteristics in the development of SARS-CoV-2 infection and related severe health outcomes: systematic reviews of population-based studies

Tatjana Makovski

T Makovski[1], J Ghattas[2], B Devleesschauwer[3,4], L Carcaillon-Bentata[1], PHIRI WP5.2working group[3]
[1]Department of Non-communicable Diseases and Trauma, Santé Publique France, Paris, France
[2]Institute of Health and Society, Université Catholique de Louvain, Louvain, Belgium
[3]Department of Epidemiology and Public Health, Sciensano, Brussels, Belgium
[4]Department of Translational Physiology, Infectiology and Public Health, Ghent University, Merelbeke, Belgium
Contact: tatjanamakovski@hotmail.com

The study had 2 objectives, to: 1) evaluate the etiologic roles of frailty, multimorbidity and socioeconomic status on SARS-CoV-2 infection probability, hospitalization, intensive care unit (ICU) admission, mechanical ventilation and COVID-19 related mortality; 2) investigate the prognostic roles of mentioned risk factors on the likelihood of hospitalization, ICU admission, mechanical ventilation, COVID-19 mortality, functioning, quality of life, disability, mental health and work absence. Three systematic reviews were performed, for each risk factor. The reviews shared first screening steps relying on a common population-based approach. Initial search took place on 7 April 2021 in PubMed, Embase, PsycINFO and WHO Covid-19 database. An update was performed for frailty only, on 1 February 2022, due to the scarce literature retained initially. Prospero registration number: CRD42021249444. Initial search retrieved 10 139 records; 411 studies were read in full text. An update for frailty retrieved 565 records. Finally, the total number of included studies was: for multimorbidity, objective 1 N = 2, objective 2 N = 13; frailty, objective 1 N = 2, objective 2 N = 3; socioeconomic characteristics, objective 1 N = 57, objective 2 N = 30. The risk of severe short-term outcomes such as mortality, ICU admission or hospitalization increased with increasing disease burden and socioeconomic deprivation. Literature on long-term impacts was not identified. The evidence indicates a dose-effect association across all risk factors and outcomes. There is a lack of work conducted on population-based representative samples accounting for frailty and multimorbidity. Measures of multimorbidity and frailty were heterogeneous between studies. Most of the studies observing socioeconomic determinants were performed in the USA and the UK; hence the need for more research in different contexts. Further evidence is required in order to estimate the impact of crisis among general population.

[2]Centre Disease Prevention and Control of Latvia, Riga, Latvia
[3]Population Health, Policies and Services, NOVA University of Lisbon, Lisbon, Portugal
Contact: brigid.unim@iss.it

Background:

Contact tracing is a public health intervention implemented in synergy with other measures, such as testing, physical distancing, and vaccination, to curb the COVID-19 pandemic. Digital solutions have been developed worldwide to enhance the contact tracing process. The aim of the study was to evaluate the effectiveness and impact of tracking COVID-19 patients using digital tools.

Methods:

A systematic literature review was performed on eight online databases to identify observational studies on digital contact tracing, published 2020-2021, in English. Studies identified through the ‘Population Health Information Research Infrastructure’ project were also included. An ad hoc form has been deployed for data extraction of relevant information. Quality assessment of the included studies will be performed using validated tools.

Results:

Over 8000 records were identified, of which 27 met the inclusion criteria: 16 modelling and 11 population-based studies. A study was based on GPS technology, four were Bluetooth-based, and others used digital technologies and manual tracing. The uptake rate of the tools ranged 19-100% across the studies. Most studies compared digital contact tracing with other strategies (e.g., no intervention, lockdown). Digital contact tracing was associated with improved identification of contact persons (9 studies), reduction of the effective reproduction number or covid-19 infections (8 studies), and increased effectiveness in combination with other containment measures (9 studies). Security and privacy issues were considered in 8 studies.

Conclusions:

Digital contact tracing contributes in reducing further transmission, especially with sufficient population uptake of the applications and in combination with other public health measures. However, its deployment has been limited by security and privacy issues. Further studies are required to investigate the combined impact of digital and conventional contact tracing and enhance privacy and security.

Foresight and Preparedness Studies on COVID-19 in the World: A Systematic Literature Review

Mariana Peyroteo dos Santos

M Peyroteo[1], J Vukovic[2], L Lapão[1]
[1]Comprehensive Health Research Center, NOVA University of Lisbon, Lisbon, Portugal
[2]Croatian Institute of Public Health, Zagreb, Croatia
Contact: mariana.peyroteo@nms.unl.pt

A foresight study refers to a broad range of methodologies to describe possible futures. Also, foresight can be described as 'a university human capacity that allows people to think ahead and consider, model, create and respond to future eventualities' (Foresight International, 2006). Foresight studies in public health are research tools to support the understanding of possible future developments, which is essential for policy makers to anticipate and possibly influence trends. Therefore, we aimed at providing an overview of COVID-19's foresight activities across Europe and beyond. A systematic literature review was conducted following Preferred Reporting Items for Systematic Reviews and Meta-Analysis Methodology. The databases searched were Scopus and Web of Science Core Collection and the literature screening was conducted through March 2022. The exclusion and inclusion criteria were previously defined by the team and all the results had to be journal papers, published between 2019-2021 (except for "Foresight" query that was between 2015-2021) and written in English or Portuguese. The documents collected were only about Population Health and Non-Pharmaceutical Approaches. Among the topics under study (foresight, scenarios, modelling and preparation) it was possible to collect 9 550 articles. After removing duplicates and filtering out those that did not meet the inclusion criteria, 2 434 articles were selected for analysis. The literature review revealed that a large number of studies on the pandemic of COVID-19 have already been conducted using predictive methodologies, but that the focus of attention is on analysing how countries are prepared for the pandemic and what direction it will stat using mathematical modelling methods (e.g. in the short term). This study highlights the importance of predictive studies and that their use needs to be well-founded and cohesive if the conclusions drawn are to have impact and value in the future.

2.A. Round table: From Ebola to COVID-19: lessons learned from health systems strengthening efforts and system shocks

Abstract citation ID: ckac129.065

Organised by: Robert Koch Institute
Chair persons: Johanna Hanefeld (Germany), Hanna-Tina Fischer (Germany)
Contact: geurtsb@rki.de

Five years after the devastating Ebola outbreak in West Africa, the health systems in Guinea and Sierra Leone are facing a new shock with the advent of the COVID-19 pandemic. After the Ebola outbreak, countries of the European Union including Germany played a major role in responding to Ebola in these countries and in strengthening their health systems. Guinea, Liberia and Sierra Leone received 115 million Euros combined, in terms of development assistance for health dedicated to health system strengthening and sector wide approaches. For these countries that are now facing the COVID-19 pandemic, the situation is ideal to assess how well health systems have absorbed the current pandemic, and reflect on the effectiveness of health system strengthening interventions received. The objectives of the workshop are two-fold: 1, to illustrate the extent to which health systems in Guinea and Sierra Leone were able to absorb the demands of the COVID-19 pandemic whilst continuing the ongoing delivery of essential health services; 2, to provide German and European policy makers with evidence relating to the effectiveness of investments that have been made over the last half-decade in strengthening health systems following the 2014 Ebola outbreak. To achieve this, three 10-minute presentations will be made followed by a 30-minute moderated discussion between the speakers and with the audience. In the first presentation, Dr Charbel El-Bcheraoui will provide insight into the scope and scale of health system strengthening interventions that were implemented in Guinea and Sierra Leone after the Ebola outbreak, and will describe a research project that was carried out to assess the impact of the COVID-19 pandemic on health systems in these two countries. In the second and third presentations, Prof Alexandre Delamou and Dr Abdul Mbawah evidence will be shared from Guinea and Sierra Leone respectively on the impact of COVID-19 on the health systems. Malaria will be used as a case study as is a leading cause of morbidity and mortality in both countries and it is a multifaceted disease that requires interventions through the whole spectrum of the health system, ranging from public health prevention activities like vector control, to delivery of treatment through health care services. Together, the three presentations will provide insights into the effectiveness of interventions implemented in the two West African countries to strengthen the capacity of the health systems to respond to new health emergencies. The subsequent 30-minute discussion will be chaired by Prof Johanna Hanefeld, Head of the Center for International Health Protection, Robert Koch Institute, Germany. It will focus on highlighting key issues that have been identified in the three presentations and on discussing specific recommendations that can be derived to improve health systems strengthening.

Key messages:

- Understanding how health systems responded to the COVID-19 pandemic illustrates what is needed now to make them more resilient to future shocks.
- Learning from what was done to strengthen health systems in past outbreaks will improve the effectiveness of future health system strengthening interventions.

2.B. Round table: Rethinking innovation systems to meet the challenges of AMR: Lessons from the Covid-19 pandemic

Abstract citation ID: ckac129.066

Organised by: RAND Europe and the European Observatory on Health Systems and Policy
Chair persons: Sonja Marjanovic (UK), Sarah Parkinson (UK)
Contact: smarjano@randeurope.org

Innovations have always been essential to solving our most pressing public health issues - from diagnostics to vaccines, to various therapeutics including antimicrobials. The ability of innovations to improve public health depends on the wider healthcare innovation systems that frame their development, uptake and diffusion. These innovation systems are made up of diverse actors including researchers and innovators in the public sector and industry, regulators, international bodies, not-for-profits, investors, healthcare professionals and patients and the public. However, the needs and interests of these diverse actors do not always align, nor do innovations systems always align with societal needs, particularly where there are market failures. Antimicrobial resistance (AMR) is an example of a public health issue that is challenging to solve within existing innovation systems, as incentive structures for developing and (not inappropriately) using antimicrobials are not sufficient to address the threat of growing resistance. In this workshop, we will facilitate a discussion of how innovation systems can be rethought to better align with societal needs, with a specific focus on how learning from the Covid-19 pandemic may be applied to innovation in response to the ‘‘silent pandemic’’ of AMR. This type of discussion matters greatly for tackling one of the most pressing public health challenges of our time and for harnessing the potential for timely learning and action. This panel discussion is co-hosted by RAND Europe and the European Observatory on Health Systems and Policy. Researchers from RAND Europe will first introduce the session and present key insights from their recent research on AMR-relevant innovation and lessons from the Covid-19 pandemic. This will provide the foundation for a panel discussion in which panelists will share their expertise and views on what lessons from the Covid-19 response mean for AMR and how these lessons can be feasibly applied to AMR-relevant innovation. Some areas for reflection include economic push and pull incentives, regulation, surveillance, data-sharing and data linkage, public-private collaboration, awareness raising and political will. Throughout the session, we will encourage participation from the audience and will ask participants to identify relevant questions in small groups at the beginning of the session. In bringing together diverse voices (on the panel and in the audience) that approach the innovation system from different angles, we hope to build an understanding of how the innovation system and mechanisms by which it operates can work better for everyone and tackle the urgent societal challenge of AMR, as well as explore whether any of the insights gained may apply more widely to other pressing public health challenges where there are market failures.

Key messages:

- Participants will gain a better understanding of how aspects of the Covid-19 response may be transferrable or adaptable to AMR-relevant innovation and how this can be achieved in a timely manner.
- Participants will identify needs for further research, policy and action to support innovation systems that are more responsive to AMR needs and potentially also to other public health challenges.

Speakers/ Panellists:

2.C. Oral presentations: Comparitive public health analysis

Abstract citation ID: ckac129.067

Measuring health expectancy in the European Union

[7]Section of Hygiene, Institute of Public Health, Università Cattolica del Sacro Cuore, Rome, Italy
Contact: jvasco.santos@gmail.com

Background:

Healthy life expectancy (HLE) is a population health measure that combines mortality and morbidity, which can be calculated using different methods. In this study, we aimed to assess the correlation, reliability and (dis)agreement between two estimates monitored in the European Union (EU), that is, the European Commission’s HLE based on self-perceived health (SPH-HLE) and the Institute for Health Metrics and Evaluation’s HLE based on disability weight (DW-

HLE), by sex, and comparing these results with LE and proportion of life spent in good health (%GH).

Methods:

We performed a retrospective study in the EU28 countries, between 2010 and 2017. The HLE methods differ in definition, measurement and valuation of health states. While SPH-HLE relies directly on one question, DW-HLE relies on epidemiological data adjusted for DW. Spearman's r, intraclass correlation coefficient, information-based measure of disagreement and Bland-Altman plots were used to assess reliability, correlation and disagreement in HLE resulting from both methods and in LE or %GH measured by both institutions.

Results:

Correlation and reliability between SPH-HLE and DW-HLE were good (better for males), with low disagreement, and were even better for LE between both institutions. The HLE Bland-Altman plots suggest a variability range of approximately 6 years for both sexes, higher for females. There was also an increasing HLE difference between methods with higher average HLE for both sexes.

Conclusions:

We showed wide variations between both methods with a clear and different high impact on female and male HLE, showing a tendency for countries with higher health expectancies to yield larger gaps between SPH-HLE and DW-HLE.

Acknowledgements: This presentation was supported by National Funds through FCT - Fundação para a Ciência e a Tecnologia,I.P., within CINTESIS, R&D Unit (reference UIDP/4255/2020)

Key messages:

- Different methods for evaluating health expectancy lead to significantly different results.
- There is a systematic tendency with countries with higher health expectancies to yield larger gaps between SPH-HLE and DW-HLE.

Abstract citation ID: ckac129.068
Barriers and facilitators to healthcare access for homeless people in four European countries

Tobias Schiffler

T Schiffler[1], C Carmichael[2], L Lehner[1,3], A Gil-Salmeron[4], M Kouvari[5], P Karnaki[5], I Grabovac[1]
[1]Center for Public Health, Department of Social and Preventive Medicine, Medical University of Vienna, Vienna, Austria

[3]Ambermed, Diakonie Refugee Services, Vienna, Austria
[4]International Foundation for Integrated Care, Oxford, UK
[5]PROLEPSIS Institute, Athens, Greece
Contact: tobias.schiffler@meduniwien.ac.at

Background:

People experiencing homelessness (PEH) have higher prevalence of adverse health outcomes and premature mortality compared to the general population, and often experience significant barriers in accessing healthcare services. This study aimed to better understand the health needs of PEH, as well as to identify the barriers and facilitators to their timely and equitable access to health services from the perspective of PEH and relevant health professionals and social care workers.

Methods:

During autumn 2021, a cross-national qualitative study was conducted within the framework of the Horizon 2020 funded CANCERLESS project. Semi-structured interviews were conducted across four European settings (Austria, Greece, Spain and the UK). Interviews were audio-recorded, transcribed verbatim and analyzed according to the inductive thematic approach set out by Saldaña (2021).

Results:

In total, 69 interviews were completed with a sample comprising 15 professionals working in homelessness support services, 19 health professionals, and 35 PEH. Three overarching themes relating to the research question were identified: (a) Health needs of people experiencing homelessness; (b) Barriers to access healthcare services and (c) Facilitators to access healthcare services. Overall, the general health of PEH was depicted as extremely poor and mainstream health services were portrayed as ill-equipped to respond to the needs of this population, with many organizational and system-level barriers noted. Tailored approaches to care, and in particular involving trusted professionals in the delivery of care, were identified as a key strategy for overcoming existing barriers.

Conclusions:

While a number of context-specific findings were identified, results indicated there to be a high degree of overlap and consistency in the health needs of PEH, and in the barriers and facilitators that exist when accessing healthcare across four different healthcare systems.

Key messages:

- Homelessness is a determinant of health that is linked to poor health outcomes. Tailored approaches that draw upon trusting relationships have the potential to overcome this problem.
- The array of identified barriers indicates that general healthcare services are not currently structured in a way that facilitates timely and equitable access and appropriate care for PEH.

Abstract citation ID: ckac129.069
Barriers to access cancer prevention services for the homeless population in four European countries

Tobias Schiffler

T Schiffler[1], C Carmichael[2], A Gil-Salmeron[3], M Kouvari[4], P Karnaki[4], I Grabovac[1]
[1]Center for Public Health, Department of Social and Preventive Medicine, Medical University of Vienna, Vienna, Austria
[2]Centre for Health, Performance and Wellbeing, Anglia Ruskin University, Cambridge, UK
[3]International Foundation for Integrated Care, Oxford, UK
[4]PROLEPSIS Institute, Athens, Greece
Contact: tobias.schiffler@meduniwien.ac.at

Background:

People experiencing homelessness (PEH) are known to have increased burden of cancer and higher cancer-related mortality when compared to the general population. These outcomes are linked to a variety of etiological factors, as well as the existence of significant barriers in accessing cancer prevention services. The aim of this study was to better understand current practices and knowledge relating to cancer prevention among PEH, health professionals and social care workers.

Methods:

During autumn 2021, a cross-national qualitative study was conducted within the framework of the Horizon 2020 funded CANCERLESS project. Data were collected in Austria, Greece, Spain and the UK through semi-structured interviews. Interviews were transcribed verbatim and thematically analyzed in accordance with the approach set out by Saldaña (2021).

Results:

In total, 69 interviews were conducted with a sample comprising 15 professionals working in homelessness support services, 19 health professionals, and 35 PEH. Two overarching themes relating to the research question were identified, namely (a) experiences and understanding of cancer prevention and treatment, and (b) considerations for program intervention. While cancer was a major source of concern, tailored cancer prevention programs for the homeless population were described as effectively non-existent, and very few homeless participants recalled being invited to a screening appointment. Health professionals also indicated that because of barriers to health care, opportunities for the early diagnosis of cancer among PEH were often being missed.

Conclusions:

The results indicate that PEH have limited knowledge around the importance of cancer prevention programs, and that more focused input on the part of health and social care services is required in this area. Culturally sensitive and person-centered approaches should be adopted to facilitate access to cancer prevention for PEH.

Key messages:

- Specialized cancer prevention and health care pathways that take account of the living conditions and support needs of PEH should be established to improve health and cancer-related outcomes.
- Cancer prevention programs should focus on improving health literacy by using accessible and tailored approaches, both for PEH and those that work directly with the homeless population.

Trans* people's access to gender-affirming health care: A European comparison

Yudit Namer

J Breckenkamp[1,2], J Thirugnanamohan[1,2], A Stern[1,2], O Razum[1,2], Y Namer[1,2]
[1]School of Public Health, Bielefeld University, Bielefeld, Germany
[2]Research Institute Social Cohesion, Bielefeld, Germany
Contact: yudit.namer@uni-bielefeld.de

Background:

Trans* people's life satisfaction is correlated with established legal frameworks for gender recognition and access to trans*-specific health care (Transgender Europe [TGEU], 2021). TGEU's guidelines to human rights-based principles of trans*-specific health care highlight bodily integrity/autonomy, free self-determination of gender, quality, specialized and decentralized care, and the right to determine reproductive paths as important pillars of gender affirming health care. We conducted a policy comparison across Europe regarding access to gender-affirming health care to assess how adherence to human rights-based principles could be strengthened.

Methods:

We compared access to health care across four main domains: legal framework (e.g., legally recognised genders), insurance coverage (e.g., out of pocket costs), access barriers (e.g., legal requirements to access gender-affirming surgery), and health care offers (e.g., hormone replacement therapy). Criteria were developed in guided brainstorming sessions. Three researchers rated 28 countries across 28 items based on available policy documents.

Results:

The majority of European countries prescribes a medicalised gender-affirming process rather than a self-decided process. Psychiatric diagnosis is also required in most countries to access gender-affirming health care. Gender-affirming health care is partly financed by statutory health insurance in most of the countries. Not all countries authorise full gender-affirming health care. Especially where statutory health insurance-covered gender-affirming health care relied centralised on single outpatient clinics or hospitals, waiting times between 6-24 months are found.

Conclusions:

Many European countries fail to fully comply with TGEU's guidelines to human rights-based principles of trans* health care. Given the negative impact of access barriers on life satisfaction, European countries should target these shortfalls in ensuring gender-affirming health care.

Key messages:

- Non- or only partly covered trans* health care contributes to health inequality.
- Regarding trans* people, European countries need to strengthen human-rights based access to gender-affirming health care.

Abstract citation ID: ckac129.071
A longitudinal study of how disability has affected survival in Swedish populations across 150 years

Johan Junkka

J Junkka[1], F Namatovu[2,1], E Häggström Lundevaller[1], K Karhina[3,1], L Vikström[3,1]
[1]Centre for Demographic and Ageing Research, Umeå University, Umeå, Sweden
[2]Department of Epidemiology and Global Health, Umeå University, Umeå, Sweden
[3]Department of Philosophical, Historical and Religious Studies, Umeå University, Umeå, Sweden
Contact: johan.junkka@umu.se

Background:

Studies from across the world report that disability jeopardizes people's health and increases the risk of premature death. The trend has been demonstrated in present-day populations but there has been little research about whether disability affected survival in historical populations. Our objective was to identify long-term developments in the relationship between disability and survival.

Methods:

We focused on all causes of mortality in ages 25-42 among groups with any type of disability in Swedish populations in the 1800s, 1900s and 2000s. We used Cox proportional regression and longitudinal micro-level data, measuring both relative differences (HRs) and absolute differences (excess LYL) in premature mortality, across time by disability status and sex.

Results:

Although the overall mortality declined profoundly in Sweden during the centuries studied, the strong association between disability and premature mortality persisted, generating a significant disability-survival gap that has held since the 1800s. The absolute difference in this gap narrowed only slightly during the 1900s, from excess LYL due to disability for men of 1.67 (CI 0.17-3.44) in the 1800s, to 0.69 (CI 0.54-0.85) in the 2000s, while for women the change was even smaller, from 1.24 (CI -0.46-3.12) to 0.59 (CI 0.43-0.69). However, the relative difference widened, particularly for women, from HR of 2.46 (CI 0.91-6.70) in the 1800s to HR 12.00 (CI 9.88-14.60) in the 2000s. For men we found a change in HR from 2.30 (CI 1.31-4.06) to 8.48 (CI 7.26-9.92).

Conclusions:

Our study is unique in providing comprehensive results about how disability has limited survival for more than 150 years. In Sweden, fundamental societal changes and extensive welfare provisions promoting equality in health and social wellbeing of all citizens have not been enough to improve the survival of younger generations with disabilities.

Key messages:

- The strong association between disability and premature mortality persisted from the 1800s to the 2000s.
- In Sweden, fundamental societal changes and extensive welfare provisions promoting equality in health have not improved survival of young adults with disabilities.

2.D. Workshop: The challenges of developing population health intervention research in cancer health promotion

Abstract citation ID: ckac129.072

Organised by: French National Cancer Institute
Chair persons: Jérôme Foucaud (France)
Contact: afguillemin@institutcancer.fr

As the leading cause of death in Europe and the second leading cause of death in North America, it is known that about 40% of cancers are preventable. Until recently, it was considered that if we know the risk factor, then we can act on it: experience has shown that this knowledge is necessary but insufficient to know how to act. Population health intervention research (PHIR), a 'solution' science, addresses this challenge. It is concerned with the design, implementation, evaluation, adaptation, transferability and durability of interventions aimed at improving the health of populations, in order to produce valid knowledge with a high potential for social and health impacts. This scientific approach apprehends interventions as 'events in systems' and challenges the methodological hegemony imposed for many years by the biomedical sciences.

Today, the development of PHIR in health promotion in the domain of cancer faces three major challenges:
– Policy;
– Methodology;
– Transferability.

Three complementary presentations are proposed, each of which will respond directly to these challenges and each of which will be based on concrete examples of implementation in the domain of cancer. The aim of this workshop is to offer a time for exchange and discussion on the challenges to be met in developing PHIR in health promotion, in the domain of cancer and at all stages of the disease, as an innovative model of research within an innovative paradigm shift. It will enable participants to clarify their conceptions of PHIR for the advancement of health promotion in oncology and to evolve these concepts in relation to these three key issues. An interactive format is proposed, including time for discussion based on participants' perceptions and time for presentations.

Key messages:

- PHIR: an effective scientific approach and a relevant tool for thinking about and developing health promotion policies in the field of cancer.
- a new research paradigm for cancer control based on intervention with populations to act on health determinants.

Abstract citation ID: ckac129.073
Intervention research in health promotion: policy issues, the example of the ten-year cancer strategy in France

Jérôme Foucaud

J Foucaud[1]
[1]Research Department, French National Cancer Institute, Boulogne-Billancourt, France
Contact: jfoucaud@institutcancer.fr

Prevention research covers a wide domain of studies, including identification of unknown risk factors for certain cancers, for example prostate cancer; or health promotion with approaches by population, by living environment or by territory. This research focuses in particular on identified carcinogenic factors (e.g. tobacco, alcohol, certain pesticides) but also on the causes of the prevalence of these factors in certain populations. PHIR makes it possible to meet these challenges. In 2010, the French National Cancer Institute was a pioneer in the development of PHIR in France and decided in 2021 to make it one of the spearheads of its ten-year strategy. This presentation will aim to give an account of this policy of developing RISP as a relevant tool for thinking about health promotion policies and actions, by targeting the issue of inequalities as one of the priority research objects as well as certain audiences (young people, vulnerable populations). The presentation will discuss four challenges for the implementation of this research policy: the development of the French scientific community in order to be able to respond to priority issues; the structuring and animation of this community; the evaluation of research projects and the mobilisation of a still timid global community; the articulation of academic and concrete/experiential knowledge. Through a concrete example of a national research development policy, the aim of this presentation is to help participants understand the challenges of RISP (its obstacles and levers, not limited to financial issues), the organisation of research, and the links between the actors involved (researchers and field workers, beneficiaries, health professionals). The first part will focus on identifying the participants' representations of the obstacles to the development of RISP. The second part will be an interactive presentation of 12 minutes, the last 2-3 minutes will be devoted to final questions.

Abstract citation ID: ckac129.074
Intervention research in health promotion: methodological issues

Anne-Fleur Guillemin

A-F Guillemin[1]
[1]Research Department, French National Cancer Institute, Boulogne-Billancourt, France
Contact: afguillemin@institutcancer.fr

Intervention research in population health focuses on actions carried out by researchers in partnership with those involved in the intervention: health professionals, patients, carers, public policy makers and population communities. The diversity of actors shapes PHIR projects, testifies to the richness of this research and gives it a privileged place to analyse and intervene as accurately as possible in different contexts and populations. It also implies the need for a better understanding of how to intervene by considering the determinants of health in these interventions. PHIR in health promotion in the domain of cancer thus proposes a paradigm shift from describing the problem and its causes to intervention. RISP bases its theoretical anchors on the one hand on the contributions and models of public health, health promotion and human and social sciences and on the other hand, on its own contributions to theorise and build its own theoretical and methodological corpus. This presentation will aim to clarify this paradigm shift and five methodological challenges of PHIR: the imperialism of epidemiology as a research model; the evaluation models of PHIR and their polymorphism; the complexity of the objects of study; the partnership dynamics between researchers and field actors without which research cannot be carried out. Finally, the challenges of publication and valorisation of this type of research. Through concrete examples, participants will be invited to understand the challenges of the RISP methodology, and to analyse different concrete perspectives to address them. The first part will focus on identifying the participants' representations of the methodological difficulties of PHIR. The second part will be an interactive presentation of 12 minutes, the last 2-3 minutes will be devoted to final questions.

Intervention research in health promotion: transferability issues, from project to structuring

Florence Cousson-Gélie

F Cousson-Gélie[1]
[1]Psychology Department, University of Montpellier, Montpellier, France
Contact: florence.cousson-gelie@icm.unicancer.fr2

The work carried out in intervention research has revealed the complexity of health interventions, particularly in health promotion. Even if these interventions are in themselves complex systems interacting with their context or 'intervention systems', PHIR is making considerable progress in understanding the mechanisms thus revealed, a key element for their transferability, which is an essential issue in public health.Transferability assesses the extent to which the outcome of a successful intervention, evaluated in one context, can be achieved in another context. It is through the concrete example of the interventional research that has made it possible to evaluate the transferability of the project 'P2P, peer action for the prevention of smoking among high school students in vocational training'', that the issues presented in the two previous presentations will be analyzed. Using the example of this transferability study, which aimed to assess whether the P2P programme developed and conducted in the south of France is transferable to other regions and under what conditions, participants will be invited to analyse the conditions of this implementation. Thus, the question of the reproducibility of the effectiveness results with a similar population but in a different geographical context, implying differences in the functioning of the intervening structures and the high schools involved, but also in the characteristics of the high school students targeted, will be examined. After the presentation of the project and its transferability in different spaces, an interactive debate will be organised on the challenges of transferability.

2.E. Workshop: The city of proximity: Accessible, Inclusive, Sustainable, Healthy and Salutogenic

Abstract citation ID: ckac129.076

Organised by: EUPHA-URB, EUPHA-ENV
Chair persons: Stefano Capolongo (EUPHA-URB), Marija Jevtic (EUPHA-ENV)
Contact: andrea.rebecchi@polimi.it

According to the ''Urban Health Rome Declaration'' at European meeting ''G7 Health'' that defines the strategic aspects and actions to improve Urban, Environmental and Public Mental Health into the cities, and referring to the Agenda 2030 in which the 11th SDG argue about ''Sustainable Cities and Communities. Make cities and human settlements inclusive, safe, resilient and sustainable'', one of the most expressive syntheses of the challenging relationship between urban planning and Public Health is stated by WHO (2016): ''Health is the precondition of urban sustainable development and the first priority for urban planners''. Referring to the Healthy Cities & Urban Health definitions, we can consider Public Health not merely an aspect of individual health protection and promotion, but a collective condition, strongly influenced by the environmental context and by the strategies implemented by local Governments. The ''Health in All Policies'' strategy, clearly underlines how health depend by the quality of outdoor and indoor living environments. In this scenario, healthy living and the requirements for healthy places, infrastructure for the public good and Public Health, cycling, walking, disintegrating the role of polluting traffic from the urban environments, social vulnerability and equality are just a few aspects in complex puzzle when designing the urban spaces for healthy, active, walkable cities. The lockdown due to the pandemic has prevented travels, forcing many people to work at home and reducing the possibility of accessing services in the territory. This condition has further highlighted the importance of urban living areas capable of satisfying basic needs within a reasonably easy range of accessibility. The concept of the ''15 minutes city'' is a useful vision to represent the city of proximity, where it is possible to meet the needs for sustainable, fair, quality, and healthy living. This dimension of proximity can be central to formulating strategies to improve the quality of urban life. A place of proximity, therefore not only defined based on the physical characteristics and people's uses, but also based on the data collected from a public health perspective in which it is also possible to try to test different types of information and build the conditions to suggest suitable policies and projects. Aim of the Workshop - organized by the two EUPHA Section URB+ENV - it would like to be to build the capacity and knowledge between participants about the main topics and urban features capable to have relevant Urban Public and Environmental Health outcomes. Additional scope is to collected case studies and research experiences considered virtuous at the international level, analyzed in detail to highlight the main urban and architectural features of those healthy experiences and the related health outcomes, such as sedentary lifestyle reduction, increase of the attractiveness of places, reduction of air and noise pollution.

Key messages:

- Cities for people, promoting Urban Public Health, Environmental Health and active mobility, require optimization of public spaces for citizens and their activities.
- Case studies and research experiences to highlight the main urban and architectural features of those healthy experiences and the related health outcomes, such as sedentary lifestyle reduction.

COVID-19 pandemic yet again showed that health crises and epidemics are introducing urban planning as a public health response. Globally, we saw a renewed interest in urban environment and healthy living and the changes in urban environments which can make for a healthier living. Even before the pandemic, various urban concepts and models that take as basis a health-oriented, holistic approach are being implemented in many cities. To name a few: car-free centres or neighbourhoods, the so-called 'Superblocks', neighbourhoods with low-speed traffic, walkable and cyclable cities aiming at all amenities being easy reach so-called '15 Minutes city'. COVID-19 crisis only accelerated many of these initiatives and brought them to global level need and attention. Such interventions are being introduced to demotivate the use of polluting cars, to ease up and to promote healthy and active transportation such as walking and cycling. As a consequence, those interventions not only are hoped to lead to an increase in physical activity, but also better air quality, reduction of noise. Cities have accelerated urban transformations of the space for active transportation such as the introduction of more cycling lanes in their networks, transforming 'car' streets to mix use streets, etc. Particularly during the pandemic, the streets that were previously dominated by car use, parking lots, parking spaces, and car lanes have shifted their focus to the pedestrians, healthy and active mobility. Though, not so optimistic continuation of the speed of the changes in urban planning are seen at the end of the pandemic. It is still clear that spaces for people, spaces promoting mental health such as green spaces, green islands, green pedestrian streets and healthy mobility, are missing. Lockdown measures of reducing the car traffic and increasing the walkable spaces for citizens were primarily imposed to save public health but had one important co-benefit - improved air quality in many areas.

As centres of population and human activities, nowadays urban environments are simultaneously the main cause of and solution to a growing number of health-related challenges. In this setting, COVID-19 pandemic has helped reiterate this and serves as a wake-up call and an opportunity to rethink the way we approach cities. Aim of this paper is to research what today seems the most promising urban model for long-term individual and global resilience: the "city of proximity", namely about inclusive walkable and cycling environments where people can access all basic destinations within reasonable times and distances from home. Therefore, urban proximity dimension, methodological approach and urban features and functions become the main subject of a quanti-qualitative matrix of comparison of five international case studies centred on the topic, by which it is possible to set out general criteria for such model, along with a methodology to measure all cities in its respect. As a result, residential density, functional mix, pedestrian surface, cycle routes, public transport stops, green areas, schools, cultural facilities, sport facilities, retail services and urban gardens make up the fix components of a comprehensive set of 11+n urban features, whose occurrence is investigated through GIS-based analysis within designated distance ranges, creating a comprehensive assessment framework that is adjustable to all urban contexts worldwide. In the end, the application of such framework to the city of Milan finally helps to validate its effectiveness in providing a picture of city-wide accessibility to proximity services, and in highlighting the value of integrated analysis in view of shaping public policies and informed planning choices which put health and sustainability at the centre.

The ecological dimension is expressed, among other things, in the matter of movement and the process of appropriation of local spaces. The creation of public space is oriented towards centralising and bringing exchanges closer together. It is a recognition of the ways of life of the individual who has become aware of the other essentials for human well-being. How does the proximity of multimodality and culture strengthen the urbanity? And how does it influence urban intensity, livability, health & the salutogenic approach of public space? The study investigates the quality of public mobility spaces through design, multimodality and sustainable planning by surveying the case of Bourse-Grand-Place station in Brussels. This transformation project is the subject of an empirical method using the material of recent research on urban design and professional practice. Falling within the scope of the "Cities for People" vision of the future, the design of this project integrates socio-cultural activities around the idea of "Station for People". A concept based on universal accessibility ensures that all individuals can access it. Thereafter, an evolving social economy programme promoted cycling through equipment, maintenance, recycling, training, innovation and the encouragement of cycling culture. The breakthrough of the innovative multimodal design process based on multidisciplinarity could become a helpful urban strategy, oriented toward making proximate neighbourhoods both residentially and practically attractive. The present article carries out an enquiry of how design and urban activities take part in strategies to improve the quality of the public spaces. It reveals some hints that could help urban practitioners when making decisions regarding the quality of an urban place and 'living together' oriented developments. With a contribution to climate change issues, this article demonstrates how urban design can contribute to the quality of life of users and citizens.

Environmental health perception by Brussels inhabitants: comparison between a top-down raising awareness and citizen science

Pascaline Incourt

P Incourt[1], *L Herbrich*[1], *C Bouland*[1]
[1]School of Public Health, Université Libre de Bruxelles, Brussels, Belgium
Contact: Pascaline.Incourt@ulb.be

The effects of the environment on health are well documented and prove to be a real public health problem. It is therefore essential to raise public awareness of these issues to induce preventive and protective behaviours. We focused on two methods: passive information transmission (top-down approach) and citizen science (bottom-up approach). The study aims to compare both approaches while raising awareness among Brussels citizens. We created two groups: a traditional awareness group, receiving infographics by email,

and a citizen science group, carrying out immersive activities with researchers. All enrolled participants filled out a questionnaire before and after. The ''top-down'' group (n = 137) received 3 infographics. The citizen science participants deep-dived into the environmental health body of knowledge, carried out individual measurements of air quality and noise pollution along a city walk and analysed, together, the results in groups to design actions. The citizen science sessions were finalised by a focus group. All sessions enjoyed and developed knowledge and awareness of environmental health. Accompanying citizens in developing knowledge was beneficial and required for environmental health empowerment. It showed the added value of citizen science in raising curiosity, creativity, and capacity building. The participants showed different socioeconomic statuses and demonstrated an appetite for understanding the exposures measured during the walks. Our results integrate several SDGs among those SDG4 and SDG3, since by raising awareness of participants, we enabled them to improve their capacities in becoming actors in their health. The risk of developing health problems related to the environment is higher in lower socio-economic groups, due to a greater vulnerability and the inequitable environment distribution between neighbourhoods. Pro-environmental behaviour fosters reduced exposure for now and future generations.

2.F. Skills building seminar: Health Data Pipelines: moving away from Excel to scalable, insightful and future-proof infostructure

Abstract citation ID: ckac129.081

Organised by: EUPHA-DH
Chair persons: Stefan Buttigieg (EUPHA-DH), Juan Rachadell (Portugal)
Contact: info@stefanbuttigieg.com

Public Health Data Pipelines are critical in the implementation of scalable Digital Public Health projects as part of the reporting, evaluation and monitoring aspects of any public health intervention. The WHO Europe Programme of Work covering the period 2020 to 2025 puts an emphasis on ''developing big-data capacity in surveillance, modelling and policy monitoring''. This workshop will provide an initial insight into the world of Health Data Pipelines and will give you the necessary ingredients to get closer to establishing processes and systems that provide you the right information at the right time and context.

Key messages:

- Data Linking is critical in the transition between legacy systems and data sets based on decades old technology to reliable and robust information infrastructure (infostructure).
- Kicking off the necessary internal discussions to consolidate data and processes into health data pipelines do not require advanced technical knowledge.

Abstract citation ID: ckac129.082
From Personal to Public Health - building Health Data Pipelines

Stefan Buttigieg

S Buttigieg[1,2]
[1]EUPHA-DH
[2]Digital Health Malta, Msida, Malta
Contact: info@stefanbuttigieg.com

The creation of future proof infostructures requires a number of efforts on different levels within a health organisation. One important thing that we need to be genuinely realise and grow aware of is that there is an inherent need to move away from Excel Spreadsheets, Access Databases and legacy data tools (including paper) towards interoperable information systems that are focused on high-quality data coordination mechanisms, robust processes and documentation and most of all design of data flows that enable sustainable data collection and analysis. This hands-on session will inform users on the following elements:

- Doing a thorough situation analysis of your current data situation
- Design your health data pipeline - paper and imagination required
- Resources to help you design the ideal infostructure
- Setting your next steps forward
- Being aware of your organisational culture to ensure maximum success

Abstract citation ID: ckac129.083
Data protection and fairness by design

Juan Rachadell

J Rachadell[1,2,3]

[2]Institute for Evidence Based Health, Lisbon, Portugal
[3]EUPHA-DH
Contact: juan.rachadell@campus.ul.pt

Building a health data pipeline is an opportunity not only to review the efficiency of data flows and organisational processes but also to guarantee that the resulting data system incorporates data protection and fairness principles by design. This session will cover some key aspects of data protection and the principles of data fairness and ethics:
Transparency, simplicity and fairness
The importance of a diverse team with diverse expertise
Keeping the business objectives in mind and purpose limitation
Compliance with data protection directives (GDPR)

2.G. Workshop: The development of HTA collaboration in Europe: where we are and where we are going

Abstract citation ID: ckac129.084

Organised by: EUPHA-HTA; EUPHAnxt
Chair persons: Chiara de Waure (EUPHA-HTA), Elena Petelos (EUPHA-HTA)
Contact: chiara.dewaure@unipg.it

Health decision-making should be always well-informed. This draws the attention on the need to make the best use of available evidence in respect to different clinical and non-clinical issues to make a value-based allocation of resources. Health Technology Assessment (HTA) is a method for supporting evidence-informed health policymaking as it is defined as a multidisciplinary process that uses explicit methods to determine the value of a health technology at different points in its lifecycle. The role of HTA is of utmost importance at European Union level considering that citizens have the right to access healthcare in any EU country with reimbursement by their home country. Therefore, Member States (MS) cooperation in the evaluation of health technologies is envisaged to ensure safe, high-quality, and efficient healthcare. Several efforts have been put in place at EU level to make this collaboration possible. The cross-border healthcare directive 2011/24/EU have led to the establishment of a voluntary network of MS to facilitate their cooperation and the exchange of scientific information. This network has been supported by another network, namely the European Health Technology Assessment Network (EUnetHTA) that was launched in 2006 with the aim to increase the contribution of HTA to decision-making in EU MS, strengthen the link between HTA and health policymaking, and reduce the overlap and duplication of HTA efforts by promoting a more effective use of resources. EUnetHTA has created a long-lasting Joint Action that has developed principles, methodological guidelines, as well as functional online tools for the sharing production of HTA. In the meantime, starting from 2018, a proposal for an EU regulation on HTA has been discussed within the European Commission first and the European Council and Parliament later. The discussion led to the approval of the Regulation (EU) 2021/2282 on health technology assessment (HTAR) that entered into force on 11 January 2022 and will apply from 12 January 2025 onwards. The HTAR calls for mandatory participation in and use of joint clinical assessments at MS level opening a new era for HTA at EU level. In order to make public health professionals ready for the challenge, this skill-building seminar will provide the audience with basic knowledge in respect to the objective, the application, the methods, and the history of HTA at European level. After two formal presentations on these issues, a case study will lead the following interactive discussion with the audience.

Key messages:

- Health decisions should be informed by the determination of the value of health technologies through shared methods, such as Health Technology Assessment.
- Collaboration on Health Technology Assessment at European level has had a long-lasting story and is now looking out into a new challenging era that will be the EU regulation being implemented.

Abstract citation ID: ckac129.085

Why and how can HTA support evidence-informed health policymaking?

Iñaki Gutiérrez-Ibarluzea

I Gutiérrez-Ibarluzea[1], N Ibargoyen-Roteta[1], G Benguria-Arrate[1], L Galnares-Cordero[1]
[1]Basque Office for Health Technology Assessment, La Fundación Vasca de Innovación e Investigación Sanitarias, Barakaldo, Spain
Contact: ebaluatek@gmail.com

Issue:

Health care systems actors are in need to take decisions every day. The basis for a good decision is to consider all the factors, the value of the action, the values that support a ‘‘go’’ or ‘‘not go’’ decision and the intended and unintended consequences that those decisions could entail. Furthermore, understanding decisions implies knowing which the context and the circumstances that surround decisions are.

Description of the issue:

HTA should cover all those aforementioned aspects and make it along the life cycle of health technologies. Thus, it should be the pivotal element that health systems should look at when making decisions. Nevertheless, this is not the case in all the countries/regions or health systems. Empirical research (facts) and normative inquiry (values) are not consistently considered and holistic approaches to the determination of value are lacking.

Results:

Policymakers, health care systems and HTA bodies are differentially approaching to value determination, and, in most cases, this is not explicitly shared with the stakeholders concerned. The consideration of the implication of life cycle concept is not well addressed and decisions are mainly focused on introduction and implementation, meanwhile decisions on deletion or modification of use are lacking, although relevant for health systems sustainability. Mostly systems failed by individual determination of technologies’ value without considering that they are used on systems in combination to other technologies, by different professionals, applied to different patients and within different contexts.

Lessons:

There is a need for a holistic approach of value determination. Likewise, the life cycle concept offers a unique opportunity to promote proactive actions in improving added value generation for technologies under development. Similarly, the assessment of value once solutions are introduced is substantially a way to improve systems’ outcomes and their efficiency.

Abstract citation ID: ckac129.086

The development of HTA collaboration at European level and the challenge of the EU regulation

Alric Ruether

A Ruether[1], E Petelos[2,3]
[1]IQWiG, Köln, Germany
[2]Health Services Research, CAPHRI, Maastricht, Netherlands
[3]Clinic of Social and Family Medicine, University of Crete, Iraklion, Greece
Contact: alric.ruether@iqwig.de

Issue:

The establishment of HTA has been an important topic in Europe for many years. The engagement of HTA agencies, scientists, politicians and many other stakeholders throughout more than 20 years lead to the EU-HTA regulation, which came into force beginning of 2022. Now it is time to prepare for a sustainable European Network for HTA.

Description:

The implementation of HTA in Europe is of high importance of the EU-commission for more than 20 years. Started with the first projects in 1994 (EUR-ASSESS) it needed quite a bunch of different projects and, in the end, three joint actions for finally providing legal ground for HTA with the EU-HTA regulation. This journey seemed a long one. However, referring to the need of addressing the requirements of Health Care of 27 Member States combined with the demand of reliable high methodological quality and applicability, investing all the time and effort for a sustainable European Network of HTA was definitely worthwhile. Joint Scientific Consultation (JSC) and Joint Clinical Assessments (JCA) will play a central role for national HTA and decision making in health care. But for understanding role, content, national uptake and further development of means, products and results of a European Network for HTA it is quite important to get a perception of the development of HTA collaboration in Europe. Based on this the challenge of the EU-HTA regulation and its implementation will be tackled easier.

Effects:

Through provision of the main pillars of the previous EU-HTA collaboration the appreciation and understanding of the differences and complexities behind the HTA processes in the EU-healthcare systems will made aware. Based on this understanding the challenges of the implementation of the EU-HTA regulation will be discussed.

2.H. Workshop: Commercial determinants and global capture of public health- cases spanning the world

Abstract citation ID: ckac129.087

Organised by: Governance, Ethics and Conflict of Interest in Public Health Network, UK Faculty of Public Health
Chair persons: Jihad Makhoul (Lebanon)
Contact: jm04@aub.edu.lb

Growing research around the globe shows that for-profit corporations incur increasingly adverse impacts on health and well-being of people, the planet and the global economy. Their health damaging products and practices fuel non-communicable disease epidemics, damage the earth's natural environment and interfere in health policy making. Such corporate interference in social and public health policy, research and practice is well documented for the pharmaceutical, tobacco, food and beverage, alcohol and arms industries. A commercial determinant lens allows a better understanding of heath inequalities by drawing attention to corporate actors and their tactics as drivers of ill-health rather than people's behaviors. This framework also makes it possible to present interventions to counter these influences. This workshop panel of 5 scholars and activists from around the world who are members of the Governance, Ethics and Conflict of Interest in Public Health Network serves to confirm the detrimental reach of industry practices and the global responses to this interference in public health. It aims to add to the emerging body of knowledge on commercial determinants of health using innovative research approaches and findings. The format is a series of 5 short sequential presentations, followed by an interactive discussion with the audience, moderated by the panel organizer. The presentations will showcase the research methods used including multi-stakeholder interviews, policy analyses, systems mapping and analyses of policy debates. The presentations will also document examples and cases of corporate capture of food industry in Europe, a global mapping of corporate systems, industry interference in health-protecting laws in Columbia, exploitation of humanitarian emergencies in Lebanon, and suggestions of ways forward to protect adults and children from industry vested interests with a Public Health Playbook.

Key messages:

- Corporate interference in public health is a growing concern globally for its health harming influence on health systems and future generations.
- Continued concerted research revealing overt and covert health harming industry practices is needed to counter their impact on PH in a world fraught with global challenges and uncertainty.

Abstract citation ID: ckac129.088

Building a qualitative systems map: applying systems thinking to the commercial determinants of health and industry influence on health policy

Adam Bertscher

A Bertscher[1], J Nobles[2], M Zatonski[1], A Van Den Akker[1], S Dance[1], K Bondy[4], A Gilmore[1], M Bloomfield[3]
[1]Department of Health, University of Bath, Bath, UK
[2]Bristol Medical School, University of Bristol, Bristol, UK
[3]Department of Social and Policy Sciences, University of Bath, Bath, UK
[4]School of Management, University of Bath, Bath, UK
Contact: ab3298@bath.ac.uk

Background:

Unhealthy commodities are major drivers of the global burden of noncommunicable diseases. Commercial actors attempt to influence policy to undermine regulation and existing literature draws attention to the underlying macro-level factors that enable this influence. Public health literature also suggests that industry adapts to regulation and such influence may thus be considered a complex adaptive system. Therefore, this study aimed to build a qualitative systems map to help communicate the complexity of industry influence and develop a tool to facilitate the identification of interventions in follow up research.

Methods:

In-person group model grouping workshops were adapted for the online environment. A preliminary qualitative systems map was developed by synthesising two recent studies to facilitate workshop discussions and expedite the mapping process. Twenty-three small group system mapping workshops were conducted with a total of 52 stakeholders, representing researchers, civil society, and public officials from various geographical regions.

Results:

The qualitative systems map identifies five pathways through which industry influences policy: a) direct access to public sector decisionmakers; b) creation of confusion and doubt about policy decisions; c) prioritisation of commercial growth; d) industry leveraging the legal and dispute settlement processes; and e) industry leveraging policymaking rules and processes. The pathways contribute to perpetuating macro-level factors that enable industry to deploy practices to influence policy.

Conclusions:

A system thinking approach can be applied to industry influence on health policy to depict a complex adaptive system. Interventions need to take into consideration the system's complexity and adaptivity. Further research is needed to test, and improve the systems map and identify interventions to achieve systems change.

Abstract citation ID: ckac129.089
''We will take money from anywhere to support our work'': industry funding of humanitarian assistance in crises

Jihad Makhoul

J Makhoul[1], *C El-Ashkar*[1], *R Nakkash*[1]
[1]Health Promotion and Community Health, American University of Beirut, Beirut, Lebanon
Contact: jm04@aub.edu.lb

Background:

Corporate funding has been described to be beneficial for humanitarian assistance in times of shrinking financial resources globally. Despite the growing global research on commercial determinants and their impact on population health, evaluations of corporate partnerships with humanitarian organizations and victims of multiple crises are rare. Conflicts of interest and corporate interference in public health policy and practice are well-documented. Health-harming industries are currently funding large scale projects for refugees in the eastern Mediterranean region which has witnessed humanitarian crises from armed conflicts. For example, food and beverage corporations and tobacco industries have funded projects to integrate migrants in their host countries, and offered educational scholarships to refugee children in Europe and beyond.

Methods:

This research presents the experiences of humanitarian agencies in Lebanon on their funding from corporations, and the perceived influences on the populations served over a two-year period coinciding with a long-lasting refugee crisis, the COVID-19 pandemic, an epic economic collapse and the devastation of a large part of Beirut from a cataclysmic explosion in its port. The study used qualitative in-depth interviews with representatives of non-governmental organizations working in Lebanon with Lebanese and refugees.

Results:

Funding from corporations starts with a two-way communication process between the organizations and the corporations, which recently started to be initiated by the corporations themselves after the Beirut blast. Funding from the tobacco, food and beverage industries is reported to come with conditions described to enhance their visibility, yet described as necessary, helps disadvantaged communities and sustains the organizations' operations. Other results relating to the availability of guidelines for detecting and managing COI from corporate funding are discussed.

Corporate Capture of the laws application in Colombia: a new form of capture for public policy actions

Hernando Salcedo Fidalgo

H Salcedo Fidalgo[1]
[1]Main, FIAN Colombia, Cartagena de Indias, Colombia
Contact: investigacion1@fiancolombia.org

The law popularly known by the title 'Junk Food', was approved in Colombia in 2021 after years of advocacy from the Civil Society. Many authors as M. Mialon (2019, 2020, 2021) have documented the level of actions to intervene in the legislative space of the Parliament in Colombia created by the food industries to change the terms of the content of this law. Nowadays and after the approval of the text interpreted as a victory for Civil Society, Colombia is confronted with the re-regulation of the law, leading to a new form of capture: the capture of the spaces of decision-making actors in public health policy in the country. We present an analysis of the case from a follow-up study designed by our organization FIAN Colombia (human rights organization that advocates for the right to adequate food and nutrition). The data used in this process of monitoring and action research comes from the observational data of the advocacy scenario made during the debates of the law in the Colombian parliament, based on the proceedings of the work meetings with congressmen, academia and civil society. This research-action process makes it clear that the collective action of advocacy from civil society manages to mobilize conditions to denounce the corporate capture of decision-making spaces and the execution of public health policies, and generates pressures based on research free of conflict of interest to reduce this capture. Similarly, there is a capacity to demand accountability that was generated from this process in Colombia, and that turns out to be a pilot experience for other regions.

Abstract citation ID: ckac129.091
Corporate capture of public health by food industries in Europe

Miguel Ángel Royo Bordonada

M Royo Bordonada[1]
[1]National School of Public Health, Institute of Health Carlos III, Madrid, Spain
Contact: mroyo@isciii.es

Corporate capture is the deliberately planned process whereby political decisions respond to a particular interest of a private nature, in detriment to the public interest. The result is an unjust regulation or the absence of regulation where this is necessary for the protection of the common good. Corporate capture of public health has to do with commercial determinants of health, such as alcohol, tobacco, sugar-sweetened beverages and ultra-processed foods. Capture-related actions are targeted at civil society, experts, public-health officials, civil servants and politicians. These actions range from material (corruption, revolving doors and donations to political parties) to intellectual (distortion of science and professional training), social (control of information and communication) and/or cultural (group identity, status and relationship of the regulator with the representatives of private corporations). The most common capture strategies are aimed at biasing scientific results, creating consumers from an early age, promoting a good image of corporations, questioning the legitimacy and appropriateness of governmental intervention aimed at regulating their activity, controlling professional education; and exerting pressure on governments and international bodies. To illustrate this phenomenon, we present findings from several examples of corporate capture of food policies in Europe. Preliminary results from publicly available information suggest that most of the mentioned tactics were used in Europe in order to block nutritional profiles, health warnings on food and effective food advertising regulations. We suggest implications for how European legislation can better protect European citizens, especially children, from vested interests aimed at promoting the consumption of unhealthy food and beverages.

Background:

Many commercial actors use a range of coordinated and sophisticated strategies to protect business interests at the expense of public health, for example: attacking and undermining legitimate science, intimidating and vilifying critics, and framing and reframing discussion and debate. These strategies can be thought of as a ‘Corporate Playbook’ that spans numerous health and planet-harming industries. To counter this Corporate Playbook and advance health and wellbeing, public health actors need to develop, refine, and modernize their own Public Health Playbook.

Methods:

This paper seeks to consolidate thinking around how public health can counter and proactively minimize powerful commercial influences. It draws on previous attempts to develop approaches to counter commercial influence for public health, sustainability, human rights and democracy, and develops eight thematically grouped strategies.

Results:

We propose an initial eight strategies: 1) Expand the public health workforce and coalitions; 2) Increase public sector resources; 3) Link with and learn from social movements to foster collective solidarity; 4) Protect public health advocates from industry threats; 5) Develop and implement rigorous conflict of interest safeguards; 6) Monitor and expose corporate activities; 7) Debunk corporate arguments; and 8) Leverage diverse commercial interests.

Conclusions:

This set of strategies seeks to amplify inherent assets of the public health community and create opportunities to explicitly counter the Corporate Playbook. These strategies are not exhaustive, and our aim is to provoke further discussion and exploration on this topic. Moving forward, there is a need for further work to develop a rigorously researched and tested Public Health Playbook.

Life events as predictors of unsustainable working life trajectories from a life course perspective

Mo Wang

Contact: mo.wang@ki.se

Background:

The association between family-related life events (e.g., getting married or having children) and unsustainable working life in terms of unemployment, sickness absence and disability pension (SA/DP) are rarely studied from a life-course perspective although having public health importance. We investigated trajectories of unsustainable working life, and the associations between change in family-related life events and unsustainable working life trajectories by controlling for familial factors.

Methods:

This is a prospective cohort study of 37,867 Swedish twins aged between 20-40 years on 31st December 1994. Data on trajectories of annual unemployment, SA/DP, and a combined measure of unsustainable working life months was collected from the Swedish national registers. The trajectories over a 23-year period were analysed by group-based trajectory modelling. Associations of change in family-related life events with trajectory groups in the whole sample were estimated by multinomial logistic regression and in discordant twin pairs (n = 4,647 pairs) with conditional models.

Results:

Most participants had no or low levels of unemployment, SA/DP or combined unsustainable working life during 1994-2016. Individuals who were stably married or changed from being single living without children to married living with children had a decreased risk of unsustainable working life compared to individuals with stable family-related life events. The risk of unsustainable working life months over time was higher among individuals who changed from married to single status regardless of having children (range of HRs:1.31-4.44).

Conclusions:

Family-related life events such as maintaining the relationship or getting married and having children decreases the risk of unsustainable working life while divorce is a risk factor for unsustainable working life. From a public health perspective, actions to support family formation or life would consequently promote a sustainable working life.

Key messages:

- Unsustainable working life was less likely among married and among those who changed from single living without children to married with children compared to those with stable family life events.
- Individuals who changed from being married to divorced status had an increased risk of unsustainable working life over time and therefore being potentially an important group for public health.

Abstract citation ID: ckac129.094
Contribution of compositional changes in the workforce to sickness absence trends in Finland

Elli Hartikainen

T Leinonen[1], E Hartikainen[1], L Salonen[1], E Viikari-Juntura[1], S Solovieva[1]
[1]Finnish Institution of Occupational Health, Helsinki, Finland
Contact: elli.hartikainen@ttl.fi

Background:

Information on factors driving work disability trends helps to evaluate the potential of interventions to improve the health and work ability of the workforce. We assessed whether the long-term decrease in sickness absences in Finland is explained by observed and unobserved compositional changes in the workforce.

Methods:

Utilising register-based panel data on Finnish private and public sector employees aged 30-62, we examined the annual onset of compensated full sickness absence (granted after 10 working days) in the period 2005-2016. We applied random effects models adjusting for changes in observed sociodemographic factors of the study population. We also applied fixed effects models, with corrections of the estimates for cohort ageing, to additionally account for unobserved time-invariant characteristics of the study population over the years.

Results:

Of the observed factors, increases in educational level partly explained the decreasing trend in sickness absences, and more so among women than men and among private than public sector employees. Changes in occupational class and industrial sector played little role in the public sector and only slightly further explained the sickness absence trend in the private sector. The decreasing trend in sickness absences appeared to be largely explained by unobserved time-invariant individual characteristics.

Conclusions:

The decrease in sickness absences appeared to be more strongly influenced by compositional changes in factors that are established before fully entering the labour market - such as educational level as well as unmeasured individual characteristics that remain unchanged after childhood and early adulthood - than in the work environment or other factors contributing at working age. Attempts to improve the health and work ability of the workforce should not only rely on interventions directed at the working age population, but also on those carried out early during the life course.

Key messages:

- Compositional changes in the workforce should be taken into account when assessing sickness absence trends.
- Interventions aiming to improve the health and work ability of the workforce should be implemented already early in the life course and not only in working age.

Abstract citation ID: ckac129.095
Employer support for employees returning to work from sick leave – evidence for Europe

Thomas Leoni

T Leoni[1]
[1]University of Applied Sciences Wiener Neustadt, Wiener Neustadt, Austria
Contact: thomas.leoni@fhwn.ac.at

Background:

Employers play an important role in facilitating the return-to-work (RTW) of employees after a prolonged sick leave. The involvement of employers in RTW efforts is however largely unexplored in an international comparative context. This paper provides evidence on the diffusion of procedures to support RTW after sick leave in European workplaces and discusses different policy approaches to involve employers in RTW.

Methods:

Employer activities are examined using microdata from the three waves of the European Survey on New and Emerging Risks (ESENER), collected in 2009, 2014 and 2019 (N = 47,425). ESENER is a representative company survey, conducted on behalf of the European Agency for Safety and Health at Work (EU-OSHA). The outcome of interest is information on the existence of a procedure to support employees' RTW after a long sickness absence. The analysis is carried out using logistic models, comparing countries and welfare state regimes.

Results:

Overall, 71.8% percent of workplaces with more than 50 employees have procedures to support RTW. Employer support is most common in Nordic and Anglo-Saxon countries (OR = 3.2, 95% CI 2.58-4.05 and OR = 8.9, 95% CI 5.41-14.68 respectively, compared to Continental countries and accounting for firm size and sector of activity). In Southern and Eastern Europe, the diffusion of RTW support is lowest (OR = 0.3, 95% CI 0.26-0.37 and OR = 0.2, 95% CI 0.17-0.24). With the exception of Nordic and Anglo-Saxon countries, smaller establishments are significantly less likely to have procedures in place than larger ones. The observed patterns are stable over time.

Conclusions:

Employer support for RTW varies greatly across countries and welfare state regimes, indicating that institutional settings and policies matter for employer involvement in RTW, particularly in smaller workplaces. Countries with high levels of RTW support display different combinations of legal obligations and/or incentives for employers to support RTW.

Key messages:

- There are large differences in employer support for RTW after sick leave across Europe.
- High support levels are associated with policies combining obligations and/or incentives for employers.

[9]Working Life Science, Business School, Karlstad University, Karlstad, Sweden
Contact: Virginia.gunn@utoronto.ca

Background:

Precarious employment (PE), characterized by reduced worker rights, and employment and income insecurity, has complex public health implications including negative impacts on workers' mental and physical health, occupational health and safety, wellbeing, and inequities in access to health and social protections. There is, however, a knowledge gap regarding effectiveness of interventions. We describe findings from a review of evaluated interventions with potential to address PE.

Methods:

Our systematic review followed the 2020 PRISMA framework and covered PubMed, Scopus, Web of Science, and sources of grey literature. We included qualitative, quantitative, or mixed-methods studies evaluating initiatives to reduce workers' PE published from 2000 to 2021 and focused on adult workers.

Results:

The 23 eligible studies from across the world evaluated diverse strategies addressing PE including tax and trade reforms, industrial disputes legislation, business registration, and use of incentives to stimulate permanent contracts. Also included were union strategies to reach precarious workers, the provision of social benefits, and youth apprenticeships.

Generally, while most initiatives had the potential to tackle certain PE aspects, they usually acted only on one or two PE dimensions. Additionally, the evaluation components were missing key details, thus, limiting the generalizability of findings, as did the heterogeneity of study designs, initiative purposes, economic and political context, and diverse populations targeted.

Conclusions:

The increase in PE prevalence and its complex health implications requires sustainable upstream public health solutions. Multidisciplinary collaborations among public health and occupational health practitioners along with researchers, evaluation specialists, economists, and politicians could facilitate the implementation and evaluation of policies and standards regulating and monitoring PE and its health impacts.

Key messages:

- Precarious employment has complex public health implications.
- Sustainable solutions to address precarious employment must be upstream and multidisciplinary.

Excess costs of multiple sclerosis: A register-based study in Sweden

Chantelle Murley

C Murley[1]*, P Tinghög*[2,1]*, FS Sebsibe Teni*[1]*, A Machado*[1]*, K Alexanderson*[1]*, J Hillert*[1]*, K Karampampa*[1]*, E Friberg*[1]
[1]Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden
[2]Department of Health Sciences, Swedish Red Cross University, Stockholm, Sweden
Contact: chantelle.murley@ki.se

Background and Objective:

Population-based estimates of the socioeconomic burden of multiple sclerosis (MS) are limited, especially regarding primary healthcare. This study aimed to estimate the excess costs of people with MS that could be attributed to MS, including primary healthcare.

Methods:

An observational study was conducted of the 2806 working-aged people with MS in Stockholm, Sweden and 28,060 propensity score matched references without MS. Register-based resource use was quantified for 2018. Annual healthcare costs (primary, specialised outpatient, and inpatient healthcare visits along with prescribed drugs) and productivity losses (operationalised by sickness absence and disability pension days) were quantified using bottom-up costing. Costs were compared between the people with MS and references with independent t-tests with bootstrapped 95% confidence intervals (CIs) to isolate the excess costs of MS.

Results:

The mean annual excess costs of MS for healthcare were €7381 (95% CI: 6991-7816) per person with MS with disease modifying therapies as the largest component (€4262, 95% CI: 4026-4497). There was a mean annual excess cost for primary healthcare of €695 (95% CI: 585-832) per person with MS, comprising 9.4% of the excess healthcare costs of MS. The mean annual excess costs of MS for productivity losses were €13,173 (95% CI: 12,325-14,019) per person with MS, predominately from disability pension (79.3%).

Conclusions:

The socioeconomic burden of MS in Sweden from healthcare consumption and productivity losses was quantified, updating knowledge on the cost structure of the substantial excess costs of MS.

Key messages:

- Primary healthcare contributes around a tenth of the excess healthcare costs of MS in Sweden, primarily owing to contacts with healthcare professionals other than physicians.
- Overall, the excess costs of MS in Sweden from lost production are larger in magnitude than the excess costs for healthcare consumption.

2.K. Round table: Navigational health literacy. Perspectives from Austria, Germany and Switzerland

Abstract citation ID: ckac129.098

Organised by: Bielefeld University, School of Public Health, EUPHA Working Group on Health Literacy
Chair persons: Jürgen Pelikan (Austria)
Contact: lennert.griese@uni-bielefeld.de

Background:

Theoretical and empirical studies indicate that a lack of transparency and highly complexity makes it difficult for patients to navigate healthcare systems. This requires the competence to access, understand, appraise, and apply information about the healthcare system, its organizations and proceedings, i.e., navigational health literacy. Since little is known about navigational health literacy, partly due to a lack of measurement tools, a new instrument measuring navigational health literacy was developed as part of the Health Literacy Population Survey Project 2019-2021 (HLS19). It was applied in national health literacy surveys of the three German-speaking countries Austria, Germany and Switzerland among others. The empirical findings obtained in the three German-speaking countries and further perspectives on the topic will be presented and discussed in the workshop.

Objectives of the workshop:

The workshop on navigational health literacy has three key objectives: 1) It gives an overview on the newly developed instrument for measuring navigational health literacy in HLS19, its development and validation; 2) it aims to discuss the distribution of navigational health literacy among the Austrian, German, and Swiss population and to highlight barriers and challenges for patients regarding navigation health literacy; and finally 3) it proposes steps to promote and strengthen navigational health literacy.

Added value of the workshop:

The workshop is designed to enhance the understanding of navigational health literacy and to propose future scenarios and steps for action to develop and implement better health literacy outcomes. By the end of the workshop, participants

– will have discussed the methodological approach for measuring navigational health literacy;

– will have heard of current data and developments regarding navigation health literacy in Austria, Germany and Switzerland;

– will have exchanged ideas and sustainable strategies to strengthen healthcare systems by developing navigational health literacy.

The four panelists will give short presentations on: HLS19, navigational health literacy research, the newly developed instrument measuring navigational health literacy in HLS19, key findings of their respective national health literacy surveys, and recommendations and current navigational health literacy initiatives in their countries. In a panel discussion, the panelists and workshop participants will discuss the presented findings and recommendations as well as the need for action regarding implementation strategies, hands-on initiatives, and sustainable solution approaches.

Key messages:

- Navigating healthcare systems and related information proves difficult for major parts of the general population.
- There is a need of health literate healthcare systems and organizations reducing the demands placed on patients by providing guidance and support.

Speakers/Panellists:

Doris Schaeffer
Bielefeld University, Bielefeld, Germany

Lennert Griese
Bielefeld University, Bielefeld, Germany

Saskia De Gani
Careum Center for Health Literacy, Zürich, Switzerland

Robert Griebler
Austrian National Public Health Institute, Vienna, Austria

2.L. Workshop: Public Health Institution and Academia's role in building capacity for Health Impact Assessment

Abstract citation ID: ckac129.099

Organised by: EUPHA-HIA, EUPHA-HWR, ASPHER
Chair persons: Piedad Martin-Olmedo (EUPHA-HIA), Ellen Kuhlmann (EUPHA-HWR)
Contact: piedad.martin.easp@juntadeandalucia.es

Health impact assessment (HIA) is a process, which systematically judges the potential, and sometimes unintended effects of any new proposal (policy, project, program or strategy) on the population health, and the distribution of those effects within the population. It was conceived in 1999 as the supporting tool for the implementation of Health in All Policies (HiAP), but its practical use remains quite partial worldwide, with exceptional regions and countries (e.g. Wales (UK), Australia). Several surveys conducted nationally, but also across Europe by the World Health Organization-Regional Office for Europe identified several barriers that hinder a broader and more extensive practical application of HIA. One of these limitations lies in the lack of understanding and knowledge of professionals from non-health sectors about the benefits that addressing health considerations in the planning process of their projects, strategies or programs may have. In this sense, the HIA is frequently seen as an additional bureaucratic burden. Other common constraints reported refer to inadequate resources (guidelines, tools, evidence) and lack of qualified staff experienced in conducting HIA. Respondents from those surveys also deplored a history of unsatisfactory experiences involving intersectoral collaboration with health professionals, decision makers and other public sector stakeholders. Health agencies, such as national and regional Public Health Institutes (PHIs) can play a critical role in overcoming these limitations. They can act by providing independent advice and support based on the best available evidence to governments and proposal developers (projects, programs, strategies). However, they need to have knowledge, resources and capacity to do so. On the other hand, these basic concepts and procedures related to HiAP or HIA are rarely addressed in depth in the university curricular training of health sectors or other sectors such as environmental science or urbanism. Present workshop intends to analyse different experiences in Europe regarding the role of PHIs and also the academia in overcoming those reported exiting barriers, and reach a more sustainable and healthy societies. The fundamentals of what could be a training program on HIA principles across Europe will be also discussed.

Key messages:

- PHIs can demonstrate leadership for HIA and HiAP by providing support to decision makers in better understand the wider health impacts and how they will manifest themselves across the population.
- HIA practice requires of the design of proper training programs and of certain validation process, which avoids conflicts regarding consultants' impartiality and independence in conducting a HIA.

Abstract citation ID: ckac129.100
Driving HIA implementation in Ireland: The role of academia and public health institutions

Monica O'Mullane

M O'Mullane[1]
[1]Institute for Social Science in the 21st Century, University College Cork, Cork, Ireland
Contact: m.omullane@ucc.ie

Over the past decades public health research has presented compelling evidence that health is socially determined. To address structural inequalities and inequities in health, public policies require intersectoral development and implementation. Health Impact Assessment (HIA) is an established tool for analysing potentially detrimental health outcomes of policies, programmes and projects. In Ireland, we are presented with a unique opportunity to examine HIA implementation by capitalising on the synergy of recent policy commitments driving HIA implementation. Specifically, the national public health framework Healthy Ireland 2013-2025, and the newly developed all-island Institute of Public Health HIA guidance (2021), have coalesced in steering the strategic direction of HIA. This presentation outlines the current synergistic policy context on the island of Ireland, including the publication of new HIA guidance, which opens opportunities and new possibilities for implementing HIA. Reflections will be made on the potential and reality of current HIA training programmes in Ireland. Learning from the lessons of a dearth of HIA implementation at varying time periods since 2000, this presentation discusses the mechanisms in place, such as the successful World Health organization-led healthy cities projects in Ireland, such as Cork Healthy Cities, and those key drivers that are required to capture policy synergy for meaningful HIA implementation.

Abstract citation ID: ckac129.101
Health impact Assessment practice in Wales: factors conditioning its success

Liz Green

L Green[1,2]
[1]HIA, Public Health Wales, Wrexham, UK
[2]Healthy Urban Environments, University of West of England, Bristol, UK
Contact: Liz.Green@wales.nhs.uk

Historically, Public Health Institutes (PHIs) were formed to address emergency public health and environmental health related challenges for example, infectious disease outbreaks and sanitary conditions which will affect health. The COVID-19 pandemic has demonstrated the importance and value of PHIs and the specific knowledge and expertise sat within them in the 21st century in relation to critical health issues. However, PHIs have also the potential expertise to look at the wider determinants of health and how they might affect population health and inequalities. In doing so, they play a critical role to advocate for Health in All Policies (HiAP) and Health Impact Assessment (HIA) by engaging with decision makers from health and non-health sectors and providing evidence and health intelligence. Public Health Wales (PHW) has conducted very complex studies as the HIA of the impact of Brexit on the population of Wales, which was praised as very useful by the Welsh Government and local decision makers at a time when, otherwise, little robust evidence-based information was available. Other positive HIA experiences are the recently published HIA about impacts of climate change or COVID-19 pandemic. Those achievements were possible thanks to the establishment of a specific unit dedicated to HIA within PHW, and to the political support and resources. This has built awareness raising and trust in HIA as a tool to support decision making from all sectors in Wales, enabled also by much training and stakeholder participation.

Within the European framework on health, adopted in 2012 by the Member States in the World Health Organization European Region, Health Impact Assessment (HIA) plays a crucial role in achieving the Sustainable Development Goals by supporting decision-makers to address health impacts and inequalities and ensure health gains. In Portugal, the integration of HIA in the Public Health Services (PHS) is still lacking despite of several attempts to implement HIA. In the pandemic and post-pandemic context, Public Health Authorities are busy with a lot of mandatory tasks, and the absence of a national policy framework for HIA that puts into practice the legal obligations arising from the Environment Impact Assessment Directive 2014/52/EU inhibits its sustainable implementation. The National Institute of Health Doutor Ricardo Jorge (INSA) has been involved in capacity building initiatives designed to further support the institutionalization of HIA in Portugal. This presentation outlines the lessons learned from this experience and will identify key facilitators and barriers elements for HIA implementation in specific contexts. The role of PHS in HIA development and execution will be discussed taking into consideration policy dialogue conclusions, and data collected from a survey aim to address the use and perception of this methodology in Public Health Units at the local level. The more recent Portuguese Fundamental Law on Health (Law nº95/2019) provides an important policy support ensuring Health in All Policies (HiAP) and it also opens a new pathway to enable HIA implementation at the national, regional, and local levels. In this respect, the PHS could play a crucial role taking leadership for HIA in Portugal. Novel and old approaches are still withstanding challenges.

The Health Impact Assessment (HIA) is a useful tool that allows policymakers and project developers to predict and control the consequences of their proposals on the health and equity of the affected population. The existence of a legislative framework for the institutionalization of HIA has been proposed as a critical factor in providing permanent rules and in legitimizing HIA within the decision-making process. In Andalusia (Southern Spain), the HIA is legally binding after the approval of the Public Health Act 16/2011 and Decree 169/2014, which establishes the HIA procedure in the Andalusian context. This new legal framework made necessary to promote capacity-building programs in HIA, but also to develop an online platform that would allow sharing experiences and knowledge among all those public health professionals involved in the review and approval of HIA reports submitted by the developers of proposals. These tasks were addressed by a leading group of the HIA network made up of officials from the Regional Ministry of Health and experts from the Andalusian School of Public Health (EASP). The platform, set up in 2018, integrates around 90 professionals from different administrative bodies according to the proposal's scope (local, regional), covering the great geographical dispersion of Andalusia, and allowing to evaluate more than 2400 proposals in 4 years. The platform also facilitates the traceability of files (both for improving internal management and in responding to external queries), and acts as a source of relevant evidence, supporting the work of professionals involved in HIA. The platform allows extracting data and generating figures, showing information on the number of files created and resolved by different periods, provinces, type of proposals, etc. This tool has been very useful for the continuous training of professionals involved in HIA in Andalusia, following a coaching approach.

2.M. Workshop: Empowering examples of high vaccination in minorities: learning from three underserved communities

Abstract citation ID: ckac129.104

Organised by: RIVER-EU Project
Chair persons: Michael Edelstein (Israel), Danielle Jansen (EUPHA-CAPH)

Contact: jumanah.essa-hadad@biu.ac.il

Childhood vaccine uptake in most minority or ethnic communities in Europe is typically substantially and unacceptably lower compared to the general population. Ethnic, religious, or cultural minorities are more likely to encounter health system barriers to accessing health care services which are a major contributor to comparatively low vaccine uptake among these disadvantaged communities. Despite these challenges, some minority communities manage to achieve high uptake for childhood immunization sometimes higher than the general population in their respective countries. We have called these populations ''empowering examples''. As part of RIVER-EU (Reducing Inequalities in Vaccine uptake in the European region - Engaging Underserved communities) an EU funded project aiming to improve access to vaccine services for children and youth, reducing inequality and improving vaccine uptake of HPV and MMR vaccination in underserved communities in Europe, we collected evidence on health system barriers and enablers to vaccination among underserved communities, including three empowering examples of underserved minority communities that achieve high vaccine uptake: the Somali community in Finland, the Arab community in Israel, and the Bangladeshi community in the United Kingdom. Understanding enablers to vaccination in these populations will help generate knowledge that will be translated to other populations in order to facilitate similar enablers, thus improving vaccine uptake. The main objective of this workshop is to share and discuss the preliminary findings related to health system enablers from these three ''empowering examples.'' The workshop will be structured in 3 presentations of 12 minutes each. Each empowering example will present preliminary findings from interviews and focus group sessions conducted with each minority community. Presentations will be followed by a moderated questions and answers session that will help the audience understand what factors have contributed high vaccine uptake in these populations and how they can be applied to others. Participants will be invited to share experiences from their own countries.

Key messages:

- Accessibility, trust in the health care system, and perceived vaccine safety, were found to be powerful health system enablers to HPV and MMR vaccination among three underserved populations studied.
- Normalizing vaccination as ''just something you do'' seems to be a common approach among the highly vaccinated minorities.

Abstract citation ID: ckac129.105
The Empowering Example of High Vaccine Uptake among the Arab Minority in Israel

Jumanah Essa-Hadad

J Essa-Hadad[1]
[1]Faculty of Medicine, Bar-Ilan University, Safed, Israel
Contact: jumanah.essa-hadad@biu.ac.il

Introduction:
Over 1.9 million Arabs live in Israel and constitute 21% of the total population. Despite being a disadvantaged minority population with wide gaps in health indicators, Arabs have higher Human Papillomavirus (HPV) and Measles, Mumps, and Rubella (MMR) vaccination rates compared with the general Jewish population.

Methods:
In-depth interviews with 20 health care providers and 30-40 Arab mothers and teens will be conducted to collect information about health system enablers to HPV and MMR vaccination. All interviews are conducted in Arabic by an Arab researcher, audio-recorded, transcribed, and analysed using thematic analysis of the transcripts. Themes will be mapped on the theoretical Social-Ecological Model.

Results and discussion:
Preliminary results indicate several health system enablers, such as accessible vaccination services through the school system and mother child clinics, vaccination provided at no cost, and high levels of trust towards healthcare professionals, who are Arab and understand the social and cultural norms of the community. Despite high vaccine uptakes, parents and teens had limited knowledge regarding vaccination, particularly HPV.

Conclusions:
This research provides important insights into health system enablers regarding HPV and MMR vaccination among the Arab minority in Israel. Such evidence can serve as a basis for interventions and guidance to improve vaccine uptake among other underserved minority communities in Europe.

Abstract citation ID: ckac129.106
Enablers and barriers associated with high MMR uptake among the Finnish Somali population

Idil Hussein

I Hussein[1]
[1]Finnish Institute of Health and Welfare, Helsinki, Finland
Contact: idil.hussein@thl.fi

Introduction:
In Finland, the Somali-speaking community is the fourth largest migrant group after Russian, Estonian, and Arabic-speaking communities. Finland is home to 21,000 Somali-speaking individuals, with around 70 % of them living in the capital region. Even though vaccine uptake in most ethnic minority communities is usually lower, MMR coverage in Finnish Somali children is partly higher than that of ethnic Finns.

Methods:
We interviewed 30 Somali-origin mothers living in the capital region of Finland in terms of childhood vaccination acceptance, and in specific, issues affecting their children's MMR vaccine uptake. All interviews were conducted by a Somali researcher either in Somali or Finnish language. The interviews were recorded, transcribed, translated, and analysed using thematic analysis of the transcripts. To understand the enablers presented by the health care system in Finland, 10-15 public health nurses working in maternal and child health clinics in the capital region will be interviewed.

Results and discussion:
Preliminary results show that trust in the health care system is the main enabler of high MMR vaccine coverage in the Somali population - even when mother's knowledge of the vaccine was

very limited. In terms of information sources, mothers indicated that they ask, and trust maternal and child health clinics in all vaccine-related information- often more than any other source, including the internet.

Conclusions:

This study enhances our understanding of system level enablers in the Finnish Somali community regarding MMR vaccination. The results of this study are applicable to improve vaccine uptake in other underserved minority communities throughout Europe.

Reported Barriers and Enablers to Undertaking Childhood Vaccinations by Bangladeshi Parents in East London

Ifra Ali

I Ali[1]
[1]LSHTM, London, UK
Contact: Ifra.Ali@lshtm.ac.uk

Introduction:

The Bangladeshi community living in the East London borough of Tower Hamlets is one of the UK's most socioeconomically deprived communities. Despite being a highly disadvantaged ethnic group with suboptimal health, the data suggests the uptake of several childhood vaccinations including the MMR vaccine is notably higher amongst this group, relative to other ethnic groups in Tower Hamlets.

Methods:

This study employs a qualitative research design. One-to-one, semi-structured interviews will be conducted with Bangladeshi parents, alongside relevant healthcare and public health professionals involved in vaccination delivery in Tower Hamlets to understand the barriers and enablers to childhood vaccinations. Interviews will be conducted in English by the researcher or in Bengali/Sylheti using an interpreter. Interviews will be audio-recorded, transcribed, translated and analysed using a thematic analysis. The socioecological model will be utilised as a theoretical framework to guide the data collection and analysis.

Results and discussion:

The preliminary results indicate parental trust in the safety of vaccinations, perceived health importance of childhood vaccinations, ease in accessibility and positive attitudes towards vaccinations within the community are notable enablers. Regarding barriers, parents have expressed reluctance on religious grounds towards childhood vaccinations which contain animal derivatives. The data also suggests differences exist between immigrant and non-immigrant parents in the decision-making process to undertake the vaccinations, with non-immigrant parents demonstrating a higher level of agency in their decision-making.

Conclusions:

The study provides valuable insight into the barriers and enablers for childhood vaccinations amongst the Bangladeshi community in Tower Hamlets. This data may inform tailored initiatives to improve childhood vaccination uptake amongst other underserved communities with suboptimal uptake.

2.N. Workshop: Improving perinatal health and reducing inequality: the value of European population comparisons

Abstract citation ID: ckac129.108

Organised by: Euro-Peristat Network
Chair persons: Guenther Heller (Germany), Mika Gissler (Finland)
Contact: jennifer.zeitlin@inserm.fr

In Europe, maternal and child mortality and morbidity during pregnancy and childbirth have declined markedly since the turn of the 20th century, but recent data suggest this trend may be slowing or reversing. Improvements in perinatal health were due primarily to increases in overall standards of living and clinical advances in obstetrics and neonatology which successfully increased maternal and newborn survival when pregnancy complications arose. However, fewer gains have been made in prevention and, in many countries, preterm birth and low birthweight rates have increased. To further improve perinatal health, a population-level approach focusing on prevention and appropriate use of clinical interventions is required. Prevention strategies include reducing risk factors (e.g., smoking and obesity) and ensuring universal access to high-quality health care due to the key roles played by early antenatal care, regular antenatal appointments and referral pathways in the timely identification and management of pregnancy complications. A population approach is particularly essential because both the burden of disease and the dangers of poor care organization fall disproportionately on socially disadvantaged women and babies, contributing to lifelong health inequalities. A final challenge is to avoid over-medicalising pregnancy and childbirth for the large majority of women with uncomplicated pregnancies. Medical technology has contributed greatly to the decline in maternal and infant mortality and morbidity, but clinical intervention can carry risks and must be used appropriately to optimise health outcomes. Despite commonalties such as universal access to health care and access to scientific knowledge, perinatal health outcomes and approaches to maternity care differ greatly between European countries. In this context, comparisons between different European models can be powerful tools for identifying population risk factors, assessing care practices, setting targets for population policies and for understanding their strengths and weaknesses to provide insight into the efficacy of health and medical policies. Currently, European comparisons are limited by the availability, timeliness and quality of population data on maternal and newborn health. This workshop reports on a new protocol implemented by the Euro-Peristat network to provide comparable perinatal indicators from countries across Europe. Based on select core indicators collected using a common protocol, we provide a proof of concept study for a future health information system and report up-to-date data on perinatal outcomes. The four presentations in this workshop present this protocol, describe most recent trends and disparities between countries, explore social inequalities in perinatal outcomes across Europe and raise questions about approaches which can achieve low mortality and morbidity while keeping intervention rates low.

Key messages:

- A federated analytical approach is an efficient and feasible way to collect timely, high-quality and comparable population data on perinatal health in Europe.
- Marked disparities in perinatal health remain between and within European countries. Our results demonstrate a need

for targeted policies in many countries and offer data to inform these initiatives.

Background:

International comparisons of population indicators of maternal and newborn health are valuable for guiding health policy and practice. The Covid-19 pandemic revealed the difficulties of compiling comparable, timely data in Europe. As part of the PHIRI (Population Health Information Research Infrastructure) project, we developed a protocol to facilitate the exchange and analysis of population birth data in Europe.

Methods:

The Euro-Peristat network, which includes experts from 31 European countries, developed a common data model and R scripts to facilitate rapid exchange of anonymised aggregate tables (https://zenodo.org/record/5148032#.YmlUttpBxPY). These tables were used to compile comparable perinatal health indicators from routine population-based sources for the years 2015 to 2020. We assessed the feasibility of this approach and the availability, quality and comparability of the data.

Results:

Building on previous Euro-Peristat recommendations and a structured consensus process, the network defined a common data model including 22 variables for the testing phase. 17 additional variables were considered important and feasible for a second phase. 25 countries created patient-level data files. Most countries had 20 or more of the data items, whereas 1 had 18, 3 had 16 and 2 had 15 variables. Limiting factors included not having all data in a single database, most often the case for neonatal and infant mortality or vital statistics versus healthcare data, and the diversity or absence of data on socioeconomic status. Setting up the model was time consuming, but once established, running the R scripts was easy and quick (<15 min). The protocol requires the active participation of each country to ensure it is correctly applied.

Conclusions:

We illustrated the feasibility of using a common data model with open source scripts to facilitate rapid production of data and analysis on key perinatal health indicators in European countries

Background:

The Euro-Peristat network documented disparities in perinatal outcomes between countries in Europe in its reports published every 5 years, but trend analyses were limited because data were not collected annually.

Methods:

Using the Euro-Peristat PHIRI protocol, we estimated rates and assessed trends between 2015 and 2019 for preterm birth, stillbirth, neonatal mortality and caesarean delivery. Country-specific relative risks (RR) for year, modelled as a continuous variable, were estimated and random effects meta-analysis used to generate pooled RRs. Heterogeneity was measured with the I2 statistic (percentage of variability in estimates due to heterogeneity rather than sampling error).

Results:

Stillbirth rates ≥24 weeks of gestational age (GA) varied in 2019 from <2.5 per 1000 births in Denmark, Estonia, Finland and Slovenia to over 4 per 1000 in Belgium, Cyprus, UK Wales and Lithuania. Preterm birth rates ranged from <6% in Lithuania, Finland, Latvia, Estonia and Denmark to 8% or more in Portugal, Belgium, UK Scotland and Cyprus. Fewer than 20% of births were by caesarean in Norway, the Netherlands, Finland, Estonia in comparison to one-third in Cyprus, Ireland, Italy, UK Scotland. Trends over time differed between countries and were not related to the level of the indicator: the pooled RR by year for preterm birth was 0.99 [0.99; 1.00] with five countries having significant decreases and three countries having increases. Caesarean section rates were stable overall (RR: 1.00 [0.99; 1.01]RR:1.00, 95% CI: 0.99-1.01), but with high heterogeneity (I2 = 99%); in six countries rates increased significantly, whereas in nine rates decreased between 2015 and 2019.

Conclusions:

European countries have varying rates and trends of the principal perinatal health indicators. Investigation of policies in high-performing countries could provide guidance for improvement elsewhere.

Background:

Socioeconomic status (SES) is strongly associated with perinatal health outcomes, perpetuating intergenerational health inequalities. Our aim was to assess the utility of population data in Europe to monitor social inequalities in key perinatal health indicators.

Methods:

Using the PHIRI federated analysis protocol to aggregate routine birth data from across Europe, we collected data on selected perinatal health indicators by SES from 2015 to 2020. Mothers' education level (primary/lower secondary; upper secondary; postsecondary) was the preferred SES indicator; if unavailable, parents' occupation or area-based deprivation scores were provided. The International Standard Classification of Occupations was used to group parents' occupations into 4 categories, while area-based deprivation scores were measured in quintiles. For each country, we calculated risk ratios (RR) for preterm birth, stillbirth, neonatal death and caesarean delivery (CD) comparing the most with the least disadvantaged group

Results:

17 countries provided data on maternal education, 5 on area-based deprivation, 1 on parents' occupation and 2 could not provide data. For preterm birth, stillbirth and neonatal death, lower SES was associated with worse outcomes with most RR between lowest and highest groups in the range of 1.5 to 3.0. In contrast, in some countries, such as Croatia, Latvia, Lithuania and Spain, CD rates were higher for socially advantaged groups whereas the gradient was reversed in others (Denmark, Luxembourg, the Netherlands and Italy).

Conclusions:

European countries can provide perinatal health indicators by SES, revealing marked socioeconomic inequalities in perinatal health. The differing SES gradient between countries for CD raise questions about care organization and clinical practice. Further exploration of the harmonization of differing SES measure across countries is required, while countries that do not monitor SES data should aim to improve existing systems.

Background:

There is consensus that caesarean delivery (CD) is a lifesaving procedure for both mother and child in emergency situations and that CD without medical indication should be avoided. However, the rate that optimally balances the risks and benefits of CD is unresolved. In 1985, the World Health Organization concluded that the CD rate should be no more than 10-15%; subsequent reviews relating CD rates to infant mortality show no benefits at the country-level for rates higher than 15-19%. However, stillbirth has not been investigated because comparable international stillbirth data are not readily available.

Methods:

We conducted an ecological study in 25 European countries from 2015 to 2019 utilizing data from routine birth data sources aggregated using the Euro-Peristat PHIRI federated data analysis protocol. We assessed country-level associations between CD rates and perinatal outcomes (singleton preterm birth, stillbirth at ≤ 24 weeks' gestational age, neonatal death) for all years using Pearson correlations, adjusted for clustering of years within country. Correlations were also estimated between linear trends over time in the indicators.

Results:

The median [range] of CD rates was 23.1% [16.2 to 56.9] in 21 participating countries, while these were 6.9% [5.3 to 11.9] for preterm birth, 3.3 per 1000 total births [1.8 to 7.6] for stillbirth and 1.9 per 1000 live births [0.7 to 6.1] for neonatal mortality. The CD rate was not associated with the stillbirth rate (cluster-adjusted rho: -.01, $P = .94$) or with the neonatal mortality rate (rho:.27, $P = .27$). However, there was a strong positive correlation with the preterm birth rate (rho:.81, $P < .001$). Results were similar in time trend analyses.

Conclusions:

Higher CD rates were not associated with lower stillbirth or neonatal mortality rates, but were strongly correlated with higher preterm birth rates. This study suggests no benefits and indicates potential harms for higher CD rates in Europe.

2.O. Workshop: Initial health assessments and catch-up vaccination for forcibly displaced migrants to Europe

Abstract citation ID: ckac129.113

Organised by: St George's, Lancet Migration European Hub, ESGITM
Chair persons: Sally Hargreaves (UK), Ana Requena Mendez (Spain)
Contact: s.hargreaves@sgul.ac.uk

Objectives:

Recent crises in Ukraine, Afghanistan, Syria and other countries have, again, resulted in large populations of asylum seekers and other migrant groups arriving in Europe. However, European countries still grapple with questions about what level of health care should be offered to forcibly displaced people (emergency care, preventative care, multi-disease screening and catch-up vaccination?), and when and where in the migration trajectory provision should be made (should it be at borders, reception centres, once settled via the national health system, via specialist or routine services, or left to non-governmental organisations?), and what their subsequent level of right to access the mainstream health-care system should be. Countries do not have a uniform approach to the provision of health care for these populations, with some countries more inclusive than others, and wide discrepancies between evidence and implementation in policy and practice. In this workshop we will discuss current approaches, implementation, research and policy gaps, and models of good practice from the clinic to the community to ensure both the immediate and long-term health needs of these diverse mobile populations are met.

Workshop plan:

The workshop will start with 10-minute presentations by each of the 4 speakers (to include a short Q&A after each talk). This will then move into a 20-minute audience discussion centred seeking specific feedback on examples of successful interventions, good practice, and lessons learned across EU/EEA countries in delivering multi-disease and catch-up vaccination and holistic and inclusive healthcare approaches.

Key messages:

- Governments should develop clear short-term and long-term policy and evidence-led research strategies to ensure the equitable provision of health services.
- Strategies must include multi-disease and catch-up vaccination approaches, alongside meaningful access to mainstream health systems.

Health care provision to migrants: what did we learn from the Ukraine, Afghan, and Syrian crises?

Apostolos Veizis

A Veizis[1]
[1]Intersos, Lancet Migration European Hub, Athens, Greece
Contact: a.veizis@intersos.gr

Dr Veizis was involved in the immediate health care provision to Ukrainian people fleeing to neighbouring countries including Poland and Moldova, as well as health care provision to Syrian people residing in Greece, working for the non-governmental organisation INTERSOS and previously MSF. He will discuss his experiences to date in terms of immediate and long-term provision to these groups and the role of both NGOs and mainstream health services in meeting the needs of forcibly displaced migrants to Europe.

2.P. Round table: Covid-19 pandemic: the rise or downfall of public health

Abstract citation ID: ckac129.118

Organised by: EUPHA
Chair persons: Iveta Nagyova (EUPHA), Marieke Verschuuren (EUPHA)
Contact: d.zeegers@euphaoffice.org

This year, we are celebrating 30 years of the European Public Health Association. But celebrating this after over two years of COVID-19 and the Russian reinvasion of Ukraine, invites us all to reflect on the use, misuse and non-use of public health. Over the years, our approach to public health has evolved. At the start of the 20th century, public health emphasized the inequalities created by the environments in which people lived, including housing, sanitation, and nutrition. By the end of the century, this extended to the political and commercial determinants of health and the concept of planetary health, which would later be encapsulated by the 2016 Vienna Declaration on Public Health. Given this comprehensive approach, supported by a much greater body of knowledge produced by many disciplines, public health should have been in the driver's seat when the world was hit with COVID-19. But it was not. Its expertise was often absent from COVID-19 response teams. Policies were often driven by panic in the face of visions of overwhelmed hospitals. Restrictions on mixing were essential until more was known about this new virus but there were failures to appreciate the impact that these measures would have on those already disadvantaged, many in precarious employment in public-facing jobs and overcrowded accommodation. As a consequence, existing health inequalities deepened. It seemed that much that had been learned over the preceding decades had been forgotten. In this roundtable, we seek to explain why, and what needs to change in order to refocus the centrality of public health on supporting and creating fair societies as a prerequisite for health for all.

So, is COVID-19 the downfall or the new rise of public health? In this Round Table, we will discuss the questions as follows.

1. Where was public health during COVID-19?
2. Why were social factors ignored during COVID-19?
3. Why has public health not used/is not using the momentum created by COVID-19?
4. And the main question: How can we create a fair society?

Key messages:

- Public health needs to strengthen its core activities.
- Advocacy is a key role for public health.

2.Q. Workshop: Prepared for the unexpected: using foresight to address uncertainty

Abstract citation ID: ckac129.119

Organised by: RIVM (Netherlands)
Chair persons: Henk Hilderink (EUPHA-FS), Ana Vieira (Netherlands)
Contact: henk.hilderink@rivm.nl

All future trends carry uncertainty in them. For example, the COVID-19 pandemic showed great uncertainty about current and future health impacts and how the virus may directly impact our health. Foresight (as a systematic, participatory, future-intelligence-gathering and medium-to-long term vision-building process aimed at enabling present-day decisions and mobilising joint actions) explicitly addresses uncertainty. Doing a foresight study one has to deal with different sources of uncertainty. Next to commonly known statistical uncertainty, foresight studies have to deal with cognitive uncertainty, i.e. uncertainty related to the limited knowledge that we have regarding the complexity of the underlying system or limited knowledge of what future economic growth will be. A better understanding of the location, level, and nature of the cognitive uncertainties helps assess the robustness of future scenarios. In addition to cognitive uncertainty, normative uncertainty are distinguished. This refers to uncertainty related to differences in what we consider a desirable future. Especially in the field of public health people differ on what they consider to be ''good health''. In this workshop, we will focus on the different aspects of uncertainty and how they are considered in existing foresight studies. The workshop will start with an interactive Mentimeter session to better understand how the audience is familiar with foresight and uncertainty. Then, a brief presentation is given as introduction to foresight and a systematic way of accounting for uncertainty, explaining the basic concepts to level understanding of the audience. This is followed by a presentation of a Foresight study (FRESHER) that addresses cognitive uncertainties consistently and systematically. The second foresight study (Dutch PHFS, RVIM) is a good example of how normative uncertainties are considered. Finally, the last presentation (CEG-IST) gives the policy perspective about how policy makers can incorporate uncertainty, as modelled through foresight, into policy evaluation. The workshop will be concluded by a discussion with the three presenters on the lessons learned regarding foresight and uncertainty.

Key messages:

- Foresight studies addressing uncertainty are essential to be better prepared for the future.
- Acknowledging different types of uncertainty is needed to support foresight-informed policy making.

Abstract citation ID: ckac129.120
The inseparable relation between foresight and uncertainty

Henk Hilderink

H Hilderink[1], D Moye Holz[1]
[1]RIVM, Bilthoven, Netherlands
Contact: henk.hilderink@rivm.nl

This presentation starts with an interactive mentimeter poll to involve the audience. They will be asked several questions about what they find important in dealing with uncertainty in public health foresight studies.

Background:

The future is per definition uncertain. Our knowledge about the future is obviously limited, especially when we look further into the future. Next to limited knowledge, people also have different ideas about what they consider a desirable future. All these aspects of uncertainty play a role when doing a foresight study. One of the challenges when doing a foresight study is to address these uncertainties in a systematic manner.

Methods:

The cognitive uncertainty addresses the lack of knowledge, which can easily be extended to the information that can be inaccurate or unreliable. These cognitive uncertainties can vary widely, and can be classified according to location, level and nature of the uncertainty. Especially in foresight studies with a strong quantitative character, the cognitive uncertainties can be crucial and can form the basis of developing scenarios. Next to the cognitive uncertainties, normative uncertainties can be distinguished which address desirable futures. These represent the obvious differences in norms and values that people have when valuing health. There are several examples of public health foresight studies that include a proper consideration of uncertainties involved.

Conclusions:

Applications of foresight studies in the field of public health are still limited. However, the recent years we see a broadening of initiatives of doing a foresight study, including addressing uncertainty in an more systematic way. Especially in public health, the normative uncertainty might play a rather relevant role.

FRESHER: Challenges and opportunities for building Health/Healthy futures

Giovanna Giuffrè

G Giuffrè[1], S Giesecke[2]
[1]ISINNOVA, Rome, Italy
[2]Austrian Institute of Technology GmbH, Vienna, Austria
Contact: ggiuffre@isinnova.org

Background:
FRESHER (2016-2018) Foresight and modelling for European health policy and regulation - is a H2020 project that aimed at representing alternative health Scenarios to test future policies for tacking Non-Communicable Diseases (NCDs). The key added-value consists in the combination of qualitative foresight and quantitative forecast approaches: a micro-simulation model, specifically developed by the project, computed the health outcomes of the four FRESHER Scenarios.

Methods:
The Scenarios building activities involved overall more than four-hundred experts and stakeholders, with different backgrounds within and beyond health fields, throughout all the steps of the process, in two surveys and nine workshops. The horizon scanning phase led to identify a wide range of societal trends that impact health and NCDs. Considering a long-term horizon at 2050, eight trends were then selected and ranked according to their importance and uncertainty.

Results:
In the Scenario Building phase, the combination of different evolutions of the selected trends resulted in four alternative futures: a Business as Usual Scenario, ‘‘The rich get healthier’’, two response Scenarios, ‘‘We will Health you’’ and ‘‘Healthy together’’, and a worst case Scenario ‘‘Desolation Health’’. The scenarios imagine different futures and depict how health would subsequently change in such worlds.

Conclusions:
Given the increasing need to put health at the centre of all policies, it is necessary to make more evident the relationship between societal trends and their impact on health, specifically for NCDs. The translation of trends, and their evolutions, into changes of risk factors is a viable option to assess the impact of public health policy. FRESHER aimed to trigger a dialogue across different scientific and policy communities outside the health sector in order to define innovative strategies and identify disruptive innovations.

Abstract citation ID: ckac129.122
Normative uncertainties in public health foresight

Frank Den Hertog

F Den Hertog[1], H Ruiter[1], H Hilderink[1]
[1]RIVM, Bilthoven, Netherlands
Contact: frank.den.hertog@rivm.nl

Background:
People value health differently, based on the norms and values. This is important when looking into the future trends in health and health care., and the perception of challenges they may arise from these trends.

Methods:
Together with stakeholders from a broad range of health-related professions, we identified several challenges for public health and healthy environments. Professionals working on these subjects came up with different goals and different ways to achieve them. These normative goals in health policies provide uncertainties in foresight, because they can be either synergetic or conflicting.

Results:
In the Dutch Public Health foresight study of 2014 four societal challenges for public health and healthcare were identified and formulated, as follows: (1) to keep people healthy as long as possible and cure illness promptly; (2) to support vulnerable people and enable social participation’ (3) to promote individual autonomy and freedom of choice; and (4) to keep healthcare affordable. In 2022 we will update and deepen these perspectives on public health and at the same time we will broaden the usability of working with this method by focussing on environmental health.

Conclusions:
To explicitly distinguish different perspectives on health leads to a better understanding and dealing with normative uncertainties by taking into account the trade-offs between competing interests and values. The challenge then is to identify policy options that have positive effect from different perspective, the win-wins.

Abstract citation ID: ckac129.123
How can policymakers incorporate uncertainty (as modelled through foresight) into policy evaluation?

Ana Vieira

CA Bana e Costa[1], MD Oliveira[1], TC Rodrigues[1], A Vieira[1]
[1]CEG-IST, Instituto Superior Técnico, Technical University of Lisbon, Lisbon, Portugal
Contact: ana.lopesvieira@tecnico.ulisboa.pt

Background:
Using a robust policy evaluation framework is critical to inform policymakers about the relevance of a policy in a structured way, clarifying its implications and providing arguments and criteria to compare competing options and decide which policy should be prioritised. In the current context of complex societal, environmental and public health challenges, decision-makers demand tools that allow a comparative assessment of the effectiveness of multisectoral policies and their comparison under different scenarios.

Methods:
This presentation will detail a socio-technical ‘‘desirability-doability’’ framework (2xD). In 2xD, an additive value model is constructed to measure the desirability of public policies, and their doability is appraised under two contrasted scenarios. For these purposes, the MACBETH approach is used in developing the three group modelling phases of 2xD: (I) Structuring facilitated workshops, (II) Evaluation decision conference, and (III) Desirability-doability decision conference. Tailor-made interactive protocols or questioning procedures are used to elicit group judgements, based on which objective-specific value scores are assigned to the policies, and the objectives are weighted (in II). Finally, we elicit doability scores for the policies under each scenario (in III).

Results:
We present how the 2xD framework was applied in Lisbon’s urban health policymaking setting and discuss case insights regarding the role of scenario analysis in the appraisal and selection of policies.

Conclusions:
The 2xD framework advances knowledge on how to assist policymakers in evaluating and selecting policies and contributes to the literature on overall policy formulation and evaluation. Specifically, the framework enabled a group of policymakers to balance (multicriteria) desirability versus doability of policies under the light of two contrasting scenarios, therefore incorporating uncertainty in their decision-making process.

3.A. Round table: Evidence-informed decision-making in patient care, public health, and health policy: the road ahead

Abstract citation ID: ckac129.124

Organised by: European Observatory on Health Systems and Policies
Chair persons: Dimitra Panteli (Belgium), Samuel Sieber (Belgium)
Contact: pantelid@obs.who.int

This year marks the fiftieth anniversary of Archie Cochrane's seminal report "Effectiveness and Efficiency: random reflections on health services", which spurred a paradigm shift in basing health policy and practice on robust empirical evidence. Indeed, evidence-informed decision- and policy-making has since permeated different levels of healthcare, public health, and health systems. More recently, the notion of "evidence-based" medicine has seen a shift towards "evidence-informed" health policy and practice, explicitly acknowledging that research evidence is but one of several factors influencing decision-making. In patient care, clinical expertise and a patient's own values and beliefs influence treatment and care; while in health policy-making, political and social factors, financial concerns, timing, and stakeholder relationships are decisive to successful implementation. Nonetheless, evidence-informed decision-making in health revolves around several core tenets, including a clear and well-communicated definition of objectives, using best-available, empirical evidence sourced from multiple sources, excellence and interdisciplinarity in the methods of analysis, and active collaboration across sectors and stakeholders to drive change. Across healthcare, public health, health systems and global health, actors continue to adapt these core principles into increasingly sophisticated strategies of evidence-informed decision-making. In the shadow of the global COVID-19 pandemic, exchanging best practices across these areas of application within the complex evidence ecosystem is a key driver for building more sustainable capacities in evidence-informed decision-making and partnerships to accelerate progress towards strengthening health systems and achieving global health equity. This panel aims to bring together major actors in knowledge translation and evidence-to-policy processes, highlighting latest resources and their relevance to public health, and stimulating collaboration and future action. With brief inputs from knowledge brokers, such as the European Observatory on Health Systems and Policies and the World Health Organization's (WHO) Evidence-informed Policy Network (EVIPNet), the panel will reflect on the current state of evidence-informed policy- and decision-making, showcase latest tools and resources, and discuss them from the specific perspectives of public health, coverage (with a focus on Health Technology Assessment), and patient and citizen involvement (with a focus on shared decision-making). Contributions from the audience will be sought in an open discussion round following initial inputs from panelists, with the objective of further shaping collaboration with involved stakeholders towards improving population health.

Key messages:

- Building on current best practices in evidence-informed decision-making is crucial to achieving better outcomes in healthcare, public health and health systems.
- Leveraging synergies and collaborating between different areas of application of evidence-informed decision-making can help ensure maximum impact and strengthen the evidence ecosystem.

Speakers/Panellists:

Suszy Lessof
European Observatory On Health Systems and Policies, Brussels, Belgium

3.B. Workshop: Quality of COVID-19 science: meta-research and the ethical implications for public health

Abstract citation ID: ckac129.125

Organised by: EUPHA-EPI, EUPHA Research Pillar, EUPHA-ETH, EUPHA-PHG, EUPHA-HTA, UK Faculty of Public Health
Chair persons: Stefania Boccia (EUPHA-EPI), Alastair Leyland (EUPHA)
Contact: angelo.pezzullo@unicatt.it

Since the beginning of the COVID-19 pandemic, scientific researchers have had to balance the need to disseminate information rapidly while still maintaining high-quality standards of research design and reporting. Early meta-research efforts comparing the methodological quality of COVID-19 research with pre-pandemic medical research found a higher prevalence of observational studies with a shorter time from submission to acceptance, lower methodological quality scores, higher risk of bias, and lower number of participants. This workshop is intended to showcase some public health relevant meta-research that has assessed COVID-19 study quality during later phases of the COVID-19 pandemic, analysed transparency and integrity indicators, and revisited earlier studies in the light of stronger evidence. After three more technical presentations that will examine the role of meta-research in addressing some of the COVID-19 pandemic research challenges, an ethical overview of the concept of "the science" as an idea used in public decision-making and policy will be given.

Key messages:

- Meta-research role of scrutinizing evidence as it is produced is even more important when scientific information is diffused at an expedited rate.
- Ethical questions might be as relevant as epidemiological ones when science is not able to be all that leads decision-making.

Abstract citation ID: ckac129.126
Quality of COVID-19 research: An overview of large-scale assessments and a case study on excess mortality estimates

Lazaros Belbasis

L Belbasis[1]
[1]METRIC-B, QUEST Center, BIH, Charité – Universitätsmedizin Berlin, Berlin, Germany
Contact: lazaros.belbasis@gmail.com

COVID-19 is an ongoing public health emergency, which affected individual and population health, whereas it disrupted social and economic activities for more than 2 years. High-quality research evidence, which is published without delays in the peer-review and publication pipeline, is the most powerful tool for evidence-based decision-making by physicians, public health and health policy specialists, and politicians. However, from the early stages of the pandemic till now, there is a debate on the quality of COVID-19 research, whereas it has been observed that the decrease in the time from submission to publication was accompanied by a decrease in research quality. This presentation discusses the findings and main conclusions from two research projects. The first part focuses on a systematic review of published large-scale qualitative evaluations of COVID-19 research. By taking advantage of these large-scale assessments, we will provide a bird's eye view on the quality of COVID-19 research done so far. The second part focuses on a case study describing the methodological quality of studies calculating excess mortality estimates during COVID-19 pandemic. Excess mortality estimates depend on important choices about the pre-pandemic reference period, the pandemic period of interest, and the modelling of the comparison between these two periods. Such an assessment has not been done yet although there is an abundance of published approaches to estimate excess mortality during the COVID-19 pandemic. Overall, these two projects highlight the importance of meta-research in the time of pandemic by scrutinizing and assessing scientific evidence while deriving recommendations for improvement of future research. This presentation concludes with a summary of the implications of low-quality COVID-19 research in decision-making and some general considerations to improve research quality and integrity in the case of future pandemics.

Abstract citation ID: ckac129.127
Lessons learned from automated screening of COVID-19 preprints

Preprints occupied the spotlight early in the pandemic, as scientists, the media and the public sought information on the evolving pandemic. While some in the scientific community embraced this shift, others were concerned about the quality of these papers, which had not yet undergone peer review. Furthermore, the flood of COVID-19 preprints quickly overwhelmed the scientific community's ability to monitor and assess new preprints. Automated screening tools that detect beneficial practices, or common problems, in preprints are one potential solution to this problem. These tools could potentially provide individualized feedback, allowing authors to improve their manuscripts prior to publication in a peer-reviewed journal. We have combined many tools into a single pipeline, called ScreenIT. ScreenIT assess factors such as open data and open code, blinding, randomization, power calculations, limitations sections, and data visualization problems. Since June 2020, we have used ScreenIT to screen and post daily reports on more than 23,000 new COVID-19 preprints deposited on bioRxiv and medRxiv. Results show that practices such as sharing data and code are relatively uncommon. Sample size calculations, blinding and randomization are rarely reported and most papers do not report the sex of participants, animals or samples. This work demonstrates the feasibility of using automated tools to rapidly screen many preprints in real time, and provide authors and readers with rapid feedback. However, this approach has important limitations. Automated screening tools can make mistakes. Tools can't always determine whether an item is relevant to a particular manuscript. Further studies are needed to determine whether feedback from automated tools is effective in encouraging authors to improve reporting.

Contact: angelo.pezzullo@unicatt.it

Since the beginning of the devastating COVID-19 pandemic, there has been a great debate about various public health relevant parameters such as the number of people infected with SARS-CoV-2, the number of deaths from COVID-19, and the resulting infection fatality rate (IFR), calculated as a ratio of the number of deaths from COVID-19 and the number of people infected with SARS-CoV-2. Among people dying from COVID-19, the largest burden is carried by the elderly, and locations with an older population will have a higher average IFR. Drawing from a project on the estimation of age-stratified IFR at an international level, in this methodological presentation, I will review the considered sources of bias for COVID-19 IFR calculation and interpretation. Both numerator and denominator can be overestimated or underestimated leading to biased estimates, while different locations can present sources of true variability. The estimation of the number of people infected with SARS-CoV-2 (the denominator of the IFR) presents several challenges. Relying on testing is inadequate due to a substantial undiagnosed proportion, and seroprevalence studies have been used to estimate the number of people infected with COVID-19, but selection bias can arise when the examined population might have a lower or higher risk than the target population. This can be the case when factors such as ethnicity, working status, and comorbidity are not considered in the recruitment. Information bias can result from suboptimal test performance and seroreversion. The number of deaths can be underestimated in situations where testing is not widely available and overestimated by the attribution of COVID-19 deaths to patients that have died with COVID-19 but not from it. Sources of true variability between locations are the population age distribution, protection of the vulnerable populations, as well as the presence of a prepared and efficient healthcare system.

Public Health Ethics and 'the Science' in Public Decision-Making

John Coggon

J Coggon[1,2]
[1]Centre for Health, Law, and Society, University of Bristol Law School, Bristol, UK
[2]UK Faculty of Public Health, London, UK
Contact: john.coggon@bristol.ac.uk

In this presentation, I aim to complement the ideas presented by the other speakers by raising questions about ethics and (different senses of) integrity. In particular, against the pressures of providing evidence bases for governmental decision-making during the COVID-19 pandemic, I ask critically whether, or to what extent, we find harmony between the integrity of science, scientists, and democratic decision-makers. The potential for tensions is explained through consideration of public communication, pluralism in scientific knowledge bases, basic uncertainty, and fundamental principles such as transparency in political decisions. The reality of the tensions is found by considering some limits of 'the science' as it has been used in political turns of phrases such as 'we are following the science'. The tensions are particularly evident where there are gaps given expedited methodologies, when we explore how 'the science' actually represents a plural concept, and where we acknowledge that science even broadly conceived is not able to be all that leads decision-making. And they are compounded by factors that might motivate silence or simplification in public communication, such as the apparent appeal of making 'the science' seem clearer or more uniformly agreed than may be the case, or by using 'the science' to avoid or obfuscate discussion of value judgments. The complexities of these ethical points provide their own important context for evaluating evidence-based policy within and beyond the pandemic.

3.C. Workshop: The WHO European Health Report 2021: overcoming gaps in data and health information systems

Abstract citation ID: ckac129.130

Organised by: WHO Europe
Chair persons: Natasha Azzopardi Muscat (WHO Europe)
Contact: dnovilloo@gmail.com

The publication of the European Health Report every three years gives readers a vital snapshot of health in the WHO European Region and progress towards health and well-being for all. The European Health Report 2021 (EHR2021) shows trends in and progress towards the health-related Sustainable Development Goals (SDGs) and the goals of the European Programme of Work 2020-2025 (EPW). It reveals gaps in progress, persistent health inequalities and other areas of concern and uncertainty, where action must be taken. The Report also lays bare, and not for the first time, considerable data gaps for key indicators, as well as operational problems in Member States' (MS) health information systems (HISs). As strong HIS are a prerequisite for evidence-informed policy-making, overcoming these issues is critical. In this workshop, we will first present the main findings of the EHR2021, showing which challenges the European Region is facing related to the three core priorities of the EPW: moving towards universal health coverage (UHC), protecting people better against health emergencies and ensuring healthy lives and well-being. Although from the EHR2021 it shows that data for many SDG indicators can be reported, there are also many areas that we cannot monitor well due a lack of data. Such data gaps are not stand-alone problems but relate to wider issues with the functioning of HISs. In the second presentation we will present an overview of the most important data gaps for key indicators and common issues in national HISs in the European Region, providing insight into where concretely action needs to be taken to ensure a stronger evidence-base for policy-making. Supporting MS in strengthening their HIS has traditionally been an important focus in WHO Regional Office for Europe's (WHO-Euro's) work and continues to be so under the EPW. One important tool that WHO-Euro uses for this purpose is a HIS assessment. Such an assessment provides insight into the strengths and weaknesses of the HIS and is the starting point for an evidence-informed process of HIS strengthening. In the third presentation, we will present WHO-Euro's HIS assessment approach. Lacking or incomplete digitalisation is a common issue in HISs in the Region, and the COVID-19 pandemic has emphasized the need for implementing digital solutions to improve the efficiency of HISs. Therefore, supporting Member States in the further digitalisation of their HIS is an important focus of WHO-Euros HIS strengthening work for the coming years. In the final presentation, we will present WHO-Euro's existing tools and planned activities related to this. Participants of this workshop will get a comprehensive overview of current challenges related to achieving the health-related SDGs in Europe, with a specific focus on challenges related to health information. They will learn about WHO-Euro's approaches and plans for how to tackle these challenges.

Key messages:

- Although the European Health Report 2021 shows data for many health-related SDGs, there are important areas that we cannot monitor well due to a lack of data and issues in health information systems.
- Overcoming these issues is crucial for a strong evidence-base for health policy, and therefore WHO Regional Office for Europe has a series of tools and activities to support Member States in this.

Main findings of the European Health Report 2021

Ausra Zelviene

A Zelviene[1]
[1]Data and Digital Health Unit, WHO Regional Office for Europe, Copenhagen, Denmark
Contact: zelvienea@who.int

The EHR2021 examines the WHO European Region's progress towards the health-related SDGs, the impact of the COVID-19 pandemic on population health, and approaches to build back better from 2022 onwards. It provides insight into the main challenges related to the 3 core priorities of the EPW, which are moving towards UHC, protecting people better against health emergencies, and ensuring healthy lives and well-being for all at all ages. In this presentation, we will have look at these 3 core priorities in more detail. Although the European Region is making good progress for some of the SDG targets, challenges and delays exist across the core priorities. For example, the incidence of catastrophic health spending ranges from 1% to 19% across countries, and the European Region is one of two global regions where the overall number of new HIV infections is increasing. One year into the pandemic, 29% of health services were still at least partially disrupted in the Region. The impact of the pandemic aggravates the effort Member States will have to make to reach the health-related SDGs by 2030. Furthermore, there are large and persistent differences between Member States. The COVID-19 pandemic has exacerbated existing health inequalities by impacting vulnerable groups most severely. To build back after the COVID-19 crisis, the EPW will be the leading policy framework for the coming years to take on the challenges identified. The report shows that the evidence base for supporting the policy efforts that Member States will have to make for reaching the SDGs and working on the EPW core priorities is suboptimal. While the COVID-19 pandemic has emphasized the importance of health information and sparked innovative ways of data collection and processing, there are still data gaps for key indicators and operational challenges in HISs. Overcoming these issues in health information is critical for improving the health of the people in the WHO European Region.

Current gaps in data and health information system in the European Region

Stefania Davia

S Davia[1]
[1]Data and Digital Health Unit, WHO Regional Office for Europe, Copenhagen, Denmark
Contact: davias@who.int

When the SDGs were adopted in 2015, it was already clear that major issues regarding data availability would need to be tackled to enable comprehensive and policy-relevant monitoring and reporting. The SDG Report 2019 found that most MS were still not regularly collecting data for more than half of the global indicators. The measurement framework (MF) of the EPW builds on the SDGs. Also here, important data gaps for the included health-related SDG indicators exist. These gaps relate, e.g., to coverage of treatment for substance use disorders and the proportion of women with satisfied family planning needs. In addition, the MF exposed data gaps for several other areas that are highly relevant for the WHO European Region, such as health inequalities, intersectoral action for health, ageing populations and mental health. To help overcome these gaps, the EPW MF includes a development list. This list contains 20 indicator areas for which either no well-defined measures have yet been included in Region-wide international data collections or where data are available only for a limited number of MS. It will serve as a priority list for developmental work on indicators in the European Region in the coming years. Data gaps as described above are not stand-alone problems but are linked to wider issues with the functioning of HISs. In the European Region, the main HIS challenges relate to limited resources and capacity; insufficient coordination and collaboration, leading to fragmentation and problems with interoperability; lack of central governance; and limited use of health information for decision-making. In this presentation, we will give an overview of the main gaps in data and HISs in the European Region and explain the roadmap for the implementation of the EPW MF, which will be an important tool to achieve sustainable improvement of data availability and quality for key indicators. Tools to improve HIS performance overall will be addressed in the next presentation.

Health information system (HIS) assessments as the starting point for HIS strengthening

Marieke Verschuuren

David Ortiz[1]
[1]Data and Digital Health Unit, WHO Regional Office for Europe, Copenhagen, Denmark
Contact: info@mariekeverschuuren.nl

One of main the HIS strengthening tools applied by WHO-Euro is the ‘Support tool to assess health information systems and develop and strengthen health information strategies’, which was first published in 2015 and updated in 2021. The support tool comprises two main parts: it provides guidance firstly for performing an overall assessment of the full HIS, and secondly, for the subsequent development of an HIS strategy. The common mode of application of this tool is an external HIS assessment by a WHO team and a subsequent country-led process of HIS strategy development. So far, experience in the field has been gained mainly with the assessment part of the tool, which has been applied in 15 MS. The assessment process starts with a preparatory desk review, followed by a country visit during which semi-structured interviews are held with key HIS stakeholders. The guidance for the interviews consists of a core module and several add-on modules. The aim of the core module is to provide an overview of the functioning of the entire national HIS, while the add-on modules shed more light on specific parts or functions of the HIS, such as noncommunicable diseases monitoring, human resources for health or health data governance. The core module forms the basis of the HIS assessments, and one or several add-on modules can be added to it, according to the needs of the assessed country. The country visit is finalised with a multi-stakeholder debriefing. After the visit, a report is written with a summary of the situation in the country including an HIS maturity score, an analysis of strengths, weaknesses, opportunities, and threats (SWOT), and recommendations for improvement for the short, medium, and long term. In this presentation, we will explain the methodology of the assessment tool, and reflect on its added value as well as challenges encountered when applying it in practice.

The importance of digitalisation and data science for HIS strengthening

David Novillo

D Novillo[1]
[1]Data and Digital Health Unit, WHO Regional Office for Europe, Copenhagen, Denmark
Contact: dnovilloo@gmail.com

The COVID-19 (coronavirus disease 2019) pandemic has underscored the critical need for all countries to strengthen their health data and information systems and ensure the routes the data travel, from submission to use, are unobstructed. Timely, credible, reliable, and actionable data are key to ensuring that political decisions are data driven and facilitate understanding, monitoring, and forecasting. To ensure that critical decisions related to the wider health and socioeconomic effects of this pandemic are data driven, each country needs to develop or enhance a national data governance plan that includes a clear coordination mechanism, well-defined and documented data processes (manual or electronic), the exchange of data, and a data culture to empower users. In addition, countries should now more than ever invest and enhance their data and health information systems to ensure that all decisions are data driven and that they are prepared for what is next. Furthermore, strong enabling environments and advanced and digitized health information systems are vital to controlling epidemics. Sustainable finance and government support are required for the continued implementation and enhancement of HIS. It is important to promote digital solutions beyond the COVID-19 pandemic. Now is the time to discuss potential solutions to obtain timely, accurate, and reliable health information and steer policy-making while protecting privacy rights and meeting the highest ethical standards.

3.D. Workshop: An urgent need to fully understand Long Covid-19 and its sequela

Abstract citation ID: ckac129.135

Organised by: EUPHA-CHR
Chair persons: Sarah Cuschieri (Malta), Julian Mamo (EUPHA-CHR)
Contact: sarah.cuschieri@um.edu.mt

Introduction:

Covid-19 has been a pandemic for the past two years. From early on, it became obvious that some of the individuals surviving the infection continued to experience symptoms beyond the acute phase of the infection or else developed symptoms after the acute infection. Multiple terminologies describing this phenomenon started to appear with 'Long Covid' being a popular nomenclature. It soon became evident that Long Covid can affect almost all the body's systems with a plethora of associated symptoms, while new symptoms keep on emerging across time. These persistent symptoms are noted to act differently among different individuals, irrelevant whether they were previously healthy or previously suffering from any chronic disease/s. Indeed, while some experienced persistent symptoms for a couple of weeks, some had persistent symptoms for months. The variations in the severity of symptoms are another feature that became evident among Long Covid sufferers. The year 2021 saw the approval of different Covid-19 vaccines and the initiation of vaccination rollouts across Europe. As the vaccine population coverage progressed, it was anticipated that the lower viral infectivity rate will also decrease the occurrence of Long Covid-19 among the vaccinated as compared to the unvaccinated. Yet breakthrough Covid-19 infections still occurred along with the development of Long Covid-19 among vaccinated, especially as new variants emerged and immunity waned. Long Covid-19 is still a relatively new condition with unspecified pathophysiology and unknown long-term disability trajectory. Therefore, it is imperative that this condition is put into the spotlight to comprehend this pandora's box while trying to prevent its occurrence and the associated sequela.

Aim:

Considering the fluidly of this condition with speculations that Long Covid might be the new chronic disease of this decade, this workshop is set to provide a multidisciplinary platform for emerging evidence on Long Covid originating from across Europe. In fact, the presentations in this workshop will tackle various aspects pertaining to Long Covid. The first presentation will provide evidence on the different risk factors and symptoms of Long Covid. The second presentation will discuss the association of multimorbidity and socio-economic factors as risk factors of Long-Covid. The third presentation will bring forward the perspectives of those suffering from the condition and the need for an integration of health care targeting both Long Covid and chronic diseases. While the fourth presentation will discuss the burden of Long-Covid symptoms and its impact on the quality of life. Finally, the bidirectional relationship between Long Covid-19 and NCDs along with the required public health action will be discussed. This will be followed by a discussion between the presenters and the audience.

Key messages:

- Long Covid-19 is a common occurrence among healthy and chronic diseases population alike with a plethora of contributing risk factors.
- An integrated healthcare plan is required to decrease the impact of Long Covid-19 on the population while simultaneously managing other underlying conditions and diseases.

Classification and risk factors of Post COVID-19 condition: a longitudinal study in the Belgian population

Pierre Smith

P Smith[1]
[1]Department of Epidemiology and Public Health, Sciensano, Brussels, Belgium
Contact: Pierre.Smith@sciensano.be

Background:

Since the onset of the COVID-19 pandemic, most research has focused on the pathophysiology and management of the acute symptoms of COVID-19, yet some people tend to experience symptoms beyond the acute phase of infection, that is, Post COVID-19 condition (PCC). However, evidence on the prevalence of PCC, its symptoms, and mechanisms are still scarce. This study aimed to assess the distribution, patterns of symptoms, and associated factors of PCC in adult with confirmed COVID-19 infection in Belgium.

Methods:

This is a longitudinal cohort study of Belgian adult population with recent COVID-19 infection confirmed via a molecular test and systematically recruited via national tracing call centers. A total of 5181 people were followed-up using online questionnaires at the time of their infection and 3 months later (from April 2021 to February 2022). Their physical, social and mental health was evaluated as well as their acute COVID-19 symptoms and persistent PCC symptoms. These different variables were self-reported.

Results:

Half of the participants reported PCC (49.6%). The most frequent persistent symptoms 3 months after infection were fatigue (28%), headache (18%), and memory problems (12%). Women (OR = 1.67,CI95% = 1.40-1.99), people with a lower level of education (OR = 1.23,CI95% = 1.02-1.48), obese people (OR = 1.23,CI95% = 1.02-1.48), people with chronic disease (OR = 1.97,CI95% = 1.40-2.77), and people with a higher number of acute COVID-19 symptoms (OR = 2.56, CI95% = 1.83-3.58) or hospitalised (OR = 2.19,CI95% = 1.25-3.82) were more likely to report PCC. Finally, a latent class analysis on the 29 PCC symptoms highlighted 3 different classes of symptoms.

Conclusions:

With the growing number of people infected with COVID-19, PCC is becoming an important public health issue. To allow people with PCC to recover, it is essential to have a multidisciplinary approach and to provide early post-acute physical and psychological rehabilitation interventions according to symptom patterns.

How multimorbidity and socio-economic factors affect Long Covid: Evidence from European Countries

Piotr Wilk

P Wilk[1,2,3], M Ruiz-Castell[3], V Moran[3,4], M Noel Pi Alperin[4], T Bohn[3], G Fagherazzi[3], M Suhrcke[4]
[1]Department of Epidemiology and Biostatistics, Western University, London Ontario, Canada
[2]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland
[3]Department of Precision Health, Luxembourg Institute of Health, Luxembourg, Luxembourg
[4]Living Conditions, Luxembourg Institute of Socio-Economic Research, Luxembourg, Luxembourg
Contact: pwilk3@uwo.ca

Introduction:
An increasing number of individuals continue reporting symptoms following the acute stage of Covid-19 infection. Few studies have investigated the factors related to Long Covid. Our aim was to assess how multimorbidity, socio-economic factors (immigration, education, employment, and income), and country of residence affect the presence and number of persistent symptoms attributable to Covid-19 illness in Europe.
Methods:
We used data from the SHARE Corona surveys collected in 2020 and 2021. The sample included 4,004 respondents aged 50 years and older who were affected by the Corona virus. The outcome was the number of persistent symptoms attributable to Covid-19 illness, including: fatigue; cough, congestion, shortness of breath; loss of taste or smell; headache; body aches, joint pain; chest or abdominal pain; diarrhoea, nausea; and confusion. We conducted a multilevel analysis for a hurdle model with negative binomial distribution.
Results:
Overall, 73% of respondents were estimated to have at least one persistent symptom associated with Covid-19 illness and, on average, they had 2.73 symptoms. However, there were some statistically significant across country differences in the presence and number of symptoms. Respondents who were employed were more likely to report at least one symptom (OR = 1.40) and those with higher levels of education were less likely to report any symptoms (OR = 0.67). Respondents with multimorbidity had an increased risk of experiencing an additional symptom (RR = 1.12) while respondents who were employed had a decreased risk of experiencing an additional symptom (RR = 0.85).
Discussion and conclusions:
Presence and number of persistent symptoms associated with Covid-19 illness was highly prevalent and varied significantly across European countries. Evidence from the present work underscores the need to target high-risk groups and those with multimorbidity to reduce long-term health consequences of Covid-19.

Perspectives of long COVID patients on their (unmet) needs: a national quantitative and qualitative study

Marie Dauvrin

M Dauvrin[1], L Kohn[1], J Detollenaere[1], C Primus-de Jong[1], C Maertens de Noordhout[1], D Castanares-Zapatero[1], I Cleemput[1], K Van den Heede[1]
[1]Belgian Health Care Knowledge Centre, Expert Health Service Research, Brussels, Belgium
Contact: marie.dauvrin@kce.fgov.be

Introduction:
After COVID-19, many people continue to experience various symptoms for several weeks, even after a mild acute phase, and encounter difficulties when confronted with the healthcare system. Patient associations asked the Belgian Health Care Knowledge Centre to investigate the needs of these patients to improve their management.
Purpose of research:
An online quantitative survey was conducted in 2021 among Belgian patients with history of COVID-19; having/had persisting symptoms for at least 4 weeks. Alongside questions on symptoms, treatment and impact on employment, Health-Related Quality of Life (HRQoL) before and after COVID-19 was measured through the EQ-5D-5L. A regression analysis identified the factors associated with the impact of long COVID on HRQoL. The qualitative approach consisted in 33 interviews and forum discussions among 101 patients.
Results:
1320 patients completed the online survey, most were symptomatic for more than 3 months. The average EQ-5D-5L index score was 0.85(95%CI:0.83-0.86) before and 0.65(95%CI:0.63-0.66) after infection. Duration, number and type of symptoms of long COVID significantly impacted HRQoL. More than half of the patients were unable to work. Qualitative part identified lack of empathy of health professionals, of systematic diagnostic approach, of interdisciplinary coordination. Patients felt misunderstood and developed their own diagnostic or treatment strategies. They questioned the value of medicine and resorted to non-reimbursed alternative therapies.
Conclusions:
Long COVID has a significant impact on HRQoL and employment. Because of long COVID, patients were confronted, sometimes for the first time, with the imperfections of the health system. Better informing the health professionals on Long COVID patterns and management options, including reimbursement possibilities, and a comprehensive interdisciplinary assessment would give them the tools to respond to the needs of these patients.

Long COVID: health symptoms, impact on health-related quality of life and mapping to disability weights

Juanita Haagsma

J Haagsma[1]
[1]Public Health, Erasmus MC, Rotterdam, Netherlands
Contact: j.haagsma@erasmusmc.nl

Introduction:
Previous studies indicated that a significant share of COVID-19 patients experiences long lasting health complaints; a condition also referred to as ‘‘long COVID’’. In order to assess the long term burden of disease of COVID-19, including long COVID, information is needed on health symptoms, health-related quality of life and duration of symptoms of long COVID patients. Therefore, the aim of this study was to assess health symptoms and health-related quality of life of long COVID in the general population of the Netherlands.
Methods:
A total of 33,903 COVID-19 patients from the region South-Holland South (the Netherlands) whom tested positive between June 2020 and May 2021 at the municipal health services were invited to complete a web-based questionnaire on the presence, nature and consequences of long COVID and health-related quality of life, measured with the EQ-5D-5L.
Results:
In total, 3,768 participants who completed the questionnaire experienced long COVID. Most commonly reporting symptoms were reduced physical condition (65.5%), fatigue (59.6%), problems concentrating (49.6%), loss of smell

(41.2%) and shortness of breath (37.8%). 648 participants indicated that they experienced long COVID symptoms for 5 months or longer. Preliminary analysis showed that increasing number of symptoms was associated with a decrease in health-related quality of life.

Discussion and conclusions:

Long COVID covers a range of health symptoms of varying severity and duration. This complicates the calculation of the non-fatal burden of disease of COVID-19, particularly because mapping of long COVID to existing disability weights is hampered.

Long COVID and NCDs: the Elephant in the Room

Iveta Nagyova

I Nagyova[1,2]
[1]Faculty of Medicine, Department of Social and Behavioural Medicine, PJ Safarik University, Kosice, Slovakia
[2]EUPHA
Contact: iveta.nagyova@upjs.sk

Issue/problem:

COVID-19 has now emerged as a public health concern that not only disrupted healthcare services of people living with non-communicable diseases (NCDs) but likely also increase the burden of NCDs.

Description of the problem:

Before the pandemic, SDG target 3.4, which calls for a reduction in premature mortality from NCDs by one third by 2030, was expected to be achieved by 17.5% of countries, and a further of 23% could achieve the target with a slight acceleration in decline. Currently, most countries are off track due to disruption of healthcare services for people with NCDs, overstretched health systems, and fewer resources than before the pandemic. In addition, only around one in four people who had COVID-19 reported feeling fully recovered within a year of being discharged from hospital. The adverse health effects from long COVID range from ‘invisible symptoms’ such as fatigue and difficulty concentrating, to neurological and neuropsychiatric symptoms, respiratory and cardiovascular problems, and metabolic disease.

Results:

The COVID-19 pandemic has shown that siloed programmes are increasingly unfit, and the bidirectional relationships between communicable diseases and NCDs underscore the need to dismantle disease-specific silos, emphasising reforms and investments that improve a wide range of health outcomes. Cost-effective, feasible, and relevant interventions that target both physical and mental health impairments are urgently required.

Lessons:

By 2030, ministries of health would need to contribute about 20% of their budgets to high-priority NCD interventions. Protecting current investments and scaling up cost-effective public health interventions is especially crucial in the context of long haul COVID and NCDs. Policy makers and planners will need concrete guidance for making progress on SDG target 3.4, often with overburdened health systems and scarcer resources.

3.E. Workshop: Is (Planetary) health a priority in international deals?

Abstract citation ID: ckac129.141

Organised by: EUPHA-ENV
Chair persons: Marija Jevtic (EUPHA-ENV), Vlatka Matkovic (Belgium)
Contact: marija.jevtic@uns.ac.rs

This workshop is dedicated to different types of deals/arrangements relating environmental health to planetary health, healthy energy, arrangements linking science to actions, and statement given by experts to recognise health in ambitious initiatives toward zero pollution. By presentations about planetary health education, it will underline the role of training as a cornerstone for international sustainable public health deals. The Lancet Public Health underlines: “No public health without planetary health”, the future health of the planet and human health are inextricably linked. Planetary health should be part of all global, national but also regional and local deals to improve sustainability worldwide. Further research and applications of the public health (PH) Education Framework are needed in order to increase evidence and awareness in PH and strengthen PH collaboration in Europe and beyond. Workshop will also discuss the European response and transformation towards healthy energy, as a part of many agreements/deals, especially European Green Deal. Science and the accelerating scale of environmental degradation tells us we have to be more ambitious and strive to zero pollution. Health-based approach can be the overarching principle to deliver on these ambitions. For a healthy planet for healthy people we need to have more determined action plans that will deliver on zero pollution and have a sound health-based approach. To achieve better public health, false solutions to the current energy, unsustainable and polluting energy crisis, is to go ambitiously for zero-pollution solutions. Looking for a strong argument for Clean air deals, the researchers will present their preliminary results of costs of air pollution impact on health in the Western Balkans (WB). It is well documented that poor air quality is responsible for increased risk of mortality and morbidity. The WB region was selected for this study because it is one of the air pollution hotspots in Europe where the levels of PM2.5, PM10, NO2 and O3 are frequently above the EU Air Quality Directive guidelines. Air pollution impact on health has a relatively higher economic burden in the WB compared to EU27 due to both the higher pollution levels and the lower per capita GDP. The external costs of air pollution is a strong argument to consider health as a priority in every policy area at national level as well as international agreements. Furthermore workshop will also present an initiative regarding health experts’ voice for Healthier Choice - a call for Zero Air Pollution in the WB. Health experts in the WB have joined forces to highlight the importance of air quality actions and achieving zero air pollution as a prevention intervention for public health. Health experts highlight that in Green Agenda for the WB the most needed are clear goals of achieving zero pollution and a timeline in the near future.

Key messages:

- Planetary health should be part of all global, national but also regional and local deals to improve sustainability worldwide.
- The external costs of air pollution is a strong argument to consider health as a priority in every policy area at national level as well as international agreements.

As stated in The Lancet Public Health editorial, "No public health without planetary health", the future health of the planet and human health are inextricably linked. For this reason, global citizens, practitioners, and professionals, especially those involved in Public Health, must be equipped to address and understand the field of Planetary Health (PH), which looks at the complex connections associated with disruptions to natural systems and resulting impacts on human health. Strategies aimed at incorporating PH education into high schools and academic curricula are required to build capacity for future national and local PH leadership. One of the most relevant tools used to achieve these goals is the PH Education Framework, designed by the Planetary Health Alliance (PHA). This framework considers five foundational domains as essential for PH knowledge, values, and practice, and has been currently applied by different institutions involved in PH. The Italian Institute for PH (IIPH) applied this framework to a school-based project for education in urban health, which will be better described in the workshop presentation. The PH Education Framework domains were used for the development of four interactive sessions oriented to raise students' interest on the topic and stimulate active participation during and after the intervention, also with simple pro-environmental behaviours. The experience was shown to be fruitful for Public Health residents as well, who were deeply involved in and led the interactive sessions held in the high school. By means of a qualitative assessment, residents demonstrated to have increased their self-confidence, knowledge and leadership skills in PH. Further research and applications of the PH Education Framework are needed in order to increase evidence and awareness in PH and strengthen PH collaboration in Europe and beyond.

The European response and transformation towards healthy energy

Vlatka Matkovic

V Matkovic[1], S Anne[1]
[1]Health & Environment Alliance HEAL, Brussels, Belgium
Contact: vlatka@env-health.org

The EU Green Deal is the framework to achieve carbon neutrality by 2050, and decarbonisation and sustainability in the main economic sectors. This includes a revised greenhouse gas reductions goal of at least 55% for 2030, as well as commitments on zero pollution, healthier agricultural production, sustainable mobility and energy. Moreover, as part of the EU Green Deal, the European Commission has established a Just Transition Mechanism (JTM), to ensure that the transition towards a climate-neutral economy happens in a fair way, leaving no one behind. The aim is to mobilise at least €100 billion over the period 2021-2027 for carbon-intensive industries. But health costs of pollution are absent in Just Transition considerations. The Green Deal includes all the right "buzz words" and commitments for a healthy planet for healthy people. However, policy-makers also need to walk the talk when it comes to adopting the right laws and measures. The science and the acceleration of the climate change, environmental and health crises show us that we need to step up. HEAL believes a zero pollution- and health-based approach can be the overarching principle to deliver on these ambitions. The war in Ukraine as the latest crisis has brought up once again the need for the swift, without any delay, phase-out of all fossil fuels. In Europe, the recently proposed RePower EU plan aims to set a pathway for increased renewables, energy savings and diversification well before 2030. However, with a holistic view of the problem under a health lens, it is clear that in this transition from fossil fuels inequalities and social considerations need to be placed central. Of particular importance is to not give space for false solutions such as replacing Russian imports with fuels from other authoritarian regimes or economies which will only continue to perpetuate Europe's energy dependence, or to build up infrastructure that will continue the pollution (gas and biomass included).

Air pollution is the main environmental driver associated with health. It is well documented that poor air quality is responsible for increased risk of mortality and morbidity. The social cost of mortality in 2015 was estimated in 3 trillion (OECD, 2016). The Western Balkans (WB) comprise Albania, Bosnia and Herzegovina, Kosovo*, North Macedonia, Montenegro and Serbia covering area of 218 750 km2 and a population of 19.9 million with total GDP of €94.2 billion (Banja et al., 2020). The WB was selected for this study because it is one of the air pollution hotspots in Europe where the levels of PM2.5, PM10, NO2 and O3 are frequently above the EU Air Quality Directive guidelines. This situation has been associated with a higher proportion of premature deaths attributable to air pollution exposure (4-19% of total deaths) in this region compared to EU member states (EEA, 2021). The health impacts including mortality and morbidity were estimated for particulate matter PM2.5, ozone (O3) and nitrogen dioxide (NO2) at country and city level on the basis of exposure in 2019 derived from monitoring stations and model estimations. Mortality impacts were parameterised using the number of premature deaths. Morbidity costs included: chronic bronchitis, hospital admissions due to respiratory diseases, hospital admissions due to cardiovascular diseases, bronchitis in children, asthma in children, reduced activity days and work lost days. The costs of mortality attributable to air pollution were estimated on the basis of non-market welfare based methods (WTP approach) while morbidity costs were estimated mainly with market based methods combining both direct and indirect costs. The 2019 health costs, both per capita and as share of the GDP, associated with air pollution in the WB were considerably higher than those in EU27.

Health Experts' voice for Healthier Choice – a call for Zero Air Pollution in the Western Balkans

Marija Jevtic

M Jevtic[1,2], V Matkovic[3]

[1]Faculty of Medicine University of Novi Sad, Novi Sad, Serbia
[2]Institute of Public Health of Vojvodina, Novi Sad, Serbia
[3]Health & Environment Alliance HEAL, Brussels, Belgium
Contact: marija.jevtic@uns.ac.rs

In 2019, the European Environment Agency has shown that the fine particulate matter PM2.5 caused more than 25 000 premature deaths in six Western Balkans countries alone, namely Albania 4 000, Bosnia and Herzegovina 5 900, Kosovo* 2 800, Montenegro 900, North Macedonia 3 400 and Serbia 11 400. In the same year, more than 2 200 lives were lost due to nitrogen dioxide (NO2) and ozone (O3) pollution. Air pollution and climate change are major health problems in the region. Health experts in the Western Balkans region have joined forces to highlight the importance of air quality actions and achieving zero air pollution as a prevention intervention for public health. We brought together a call for the Western Balkans policy-makers to invite them to commit to full alignment of all national air quality standards with the World Health Organization guidelines, to establish regional inter-sectoral cooperation to accelerate the moving to zero pollution, to including health authorities, public health institutes, and medical societies, patient representative and all health care experts and providers; to end direct or indirect public subsidies of polluting processes, especially fossil fuel activities such as coal power plants; to finalise the process of the ratification of the Convention on Long-range Transboundary Air Pollution and its protocols; to support modelling to establish economy-wide emission reduction commitments for the five main pollutants; to develop and implement Air Quality Strategies; to increase the uptake of Best Available Technologies (BAT) in accordance with the Industrial Emissions Directive; to establish an adequate air quality monitoring system, and to including through accreditation of air quality monitoring networks. Public health experts from the WB, united in the regional call, highlight the urgent need for improvements in air quality in the region together with a zero air pollution objective and a timeline to reach it.

How much global climate adaptation finance is targeting the health sector?

Tilly Alcayna

T Alcayna[1], D O'Donnell[1]
[1]Red Cross Climate Centre, The Hague, Netherlands
Contact: alcayna@climatecentre.org

Climate change seriously threatens health and wellbeing with projected health burdens estimated to cost USD 2-4 billion a year by 2030. Adaptation in the health sector is critical to keep pace with the ongoing consequences of the climate crisis and the impacts projected to occur in the next decade and beyond. Yet estimates by the WHO indicate that climate finance targeting the health sector to date is extremely low: less than 0.5% of multilateral climate adaptation funding has targeted the health sector. In this study, we trace and quantify the amount of adaptation financing targeting the health sector from both multilateral and bilateral sources using publicly available information on the OECD-DAC database and Climate Funds Update. We find that between 2009-2019 only 0.39% of multilateral and bilateral climate adaptation funding targeted health-related efforts specifically. Despite the relatively higher number of health-related projects in Sub-Saharan Africa compared to other regions, a smaller amount of funding is allocated per project compared to other regions. Regional variations in funding are concerning as the countries with the most vulnerability to the climate crisis coincide with regions getting the least amount of funding per project. There is a significant gap in globally financed adaptation efforts in the health sector. Swift and committed remediation is needed to minimise the spiralling risk of high negative health outcomes.

Key messages:

- Between 2009-2019 only 0.39% of multilateral and bilateral climate adaptation funding targeted health-related efforts specifically.
- The countries with the most vulnerability to the climate crisis coincide with regions getting the least amount of funding per health project.

3.F. Round table: Better DiPH – To plan, implement, evaluate, and the future of digital public health interventions

Abstract citation ID: ckac129.147

Organised by: Leibniz ScienceCampus Digital Public Health Bremen LSC (Germany), EUPHA-DH
Chair persons: Laura Maass (Germany), Chen-Chia Pan (Germany)
Contact: laura.maass@uni-bremen.de

The potential of digital technology for improving the health of individuals, communities, and populations is unprecedented. Technological advancements empower individuals to engage in self-monitoring and self-management of their chronic conditions or health and well-being. There is an unparalleled opportunity to reform prevention, health promotion, and healthcare services with lower cost and better reach and accessibility. However, health technologies are often developed without supportive evidence or a user-centred design. This leads to a lack of long-term user engagement in digital public health interventions. Our workshop aims to facilitate a mutual understanding of the specific properties of digital public health tools by creating a space for discussing the various perspectives of such technologies. We want to start a conversation of essential steps for conceptualising, implementing, and evaluating needs-based and society-centred digital public health interventions to improve the acceptability and sustainability of such interventions in users. The workshop will address digital public health tools on different steps and describe the progression as an iterative approach to highlight where these aspects are linked. The first speaker will provide a theory-guided overview of digitalisation in health to create a shared understanding of the terminology for the workshop. This includes the differentiation between digital health and digital public health. The talk will highlight the importance of digital tools for surveillance, monitoring, healthcare, health promotion, and their significant meaning for society. Following this input, the other panellists will guide us through different aspects of digital public health tools: The second speaker will discuss the importance of society-centred designs based on users' needs rather than on technological advancements for interventions. Our third speaker will present a meta-framework of extended criteria for developing and evaluating digital technologies for public health. The fourth panellist will share Malta's COVID-19 contact tracing app as a case study. He will discuss the challenges and facilitators in implementing and evaluating digital public health interventions. The last presentation will cover the need for governmental support in the future to ensure the success of digital public health interventions and holistic systems. The workshop will take place as a round table discussion. Each panellist will give a short (7 minute) input talk on the specific properties of digital public health tools. After the panellists present their opinion, we will open the floor for a discussion. Here, the audience is invited to share their knowledge and experiences to build a mutual understanding of the crucial steps in digital public health interventions. After the workshop, we will create a white paper on digital public health based on the panellists' input and the discussion results.

Key messages:

- A mutual understanding of digital public health may facilitate public sector cooperation and aim towards needs-based and society-centred technology development to improve the population's health.
- Digital public health offers unique challenges, and there is an opportunity to outline these specific nuances to ensure maximum success in implementing such projects.

[2]Leibniz ScienceCampus Digital Public Health, Bremen, Germany
[3]Institute of Public Health and Nursing Research, University of Bremen, Bremen, Germany
[4]EUPHA-DH
Contact: zeeb@leibniz-bips.de

What is the appropriate differentiation of digital public health versus digital health - or is there none? This is an essential question when pondering digitalisation and public health, especially with a view to the potential development of the field. Digital health seems to be a general term related to information and communication technology in health care. Putting a public health lens on this general descriptive term can be done by simply expanding it towards public health as a population science and practice field, rather than the narrow medical and health care arena. However, a more specific approach towards outlining similarities and differences will also focus on digital technologies and their challenges in the core areas of prevention and health promotion. Considering the leading public health functions, their relationship with digitalisation and their specific requirements towards digitalisation can be a valuable path to describe and discuss what digital public health is all about. We will also highlight where interfaces and interrelations with digital health need to be considered for research and practice. This contribution will aim to provide such a perspective.

Moving from human-centred to society-centred design of health technologies

Jasmin Niess

J Niess[1,2]
[1]Human-Computer-Interaction, University of St. Gallen, St. Gallen, Switzerland
[2]Leibniz ScienceCampus Digital Public Health, Bremen, Germany
Contact: jasmin.niess@unisg.ch

The digitised society promises technological solutions to support mental and physical health and well-being. Amongst others, the consumer market, health insurance providers, and companies offer technologies to, among other things, track one's mood, improve diet and fitness habits, foster healthy sleep patterns or track our brain waves to enhance relaxation. However, while the potential benefits of such technologies are apparent and technologies might increase individual and public health, long-term engagement with health technologies is comparably low. This hints at ineffective solutions and insufficient knowledge of user needs. Understanding the specific context of use and user needs is vital to increasing technology adoption, personal benefits, and profitability of health technologies. Taking the user perspective into account when designing technologies is essential to support health and well-being. To foster long-term engagement with health technologies, we argue for considering the broader social context of digital health tools and reflecting on ways how we can empower society to design better and more inclusive health technologies. Hence, when developing digital public health tools, it is essential to go beyond conceptualising people as users and instead shift the focus to humans as part of society and embed such consideration in the design process.

To paraphrase a classic, evaluating digital technologies in health is a bit like eating spinach - no one is against it in principle because it is good for you. However, no one would do it unless being asked to. In recent years, the sheer number of digital health technologies that potentially fulfil public health purposes has increased tremendously. The basis for evaluating such tools for public health purposes however has not met this pace, and in particular frameworks for the systematic development and evaluation of digital technologies in public health are rare. Existing frameworks for digital technologies focus on clinical aspects of digital health applications (e.g., NICE Evidence standards framework for digital health technologies), thus lacking both a population and prevention focus. Generic frameworks such as the Health Technology Assessment (HTA) methodology do not contain items specific to digital technologies and public health purposes. Here, we describe the process of developing a framework specific for the development and evaluation of digital public health technologies based on the core HTA model. We conduct a scoping review of frameworks for the development and the evaluation of technologies in public health and digital health, following PRISMA-SCR guidelines. The identified frameworks are then mapped onto the core HTA model to develop additional items specific for the development and the evaluation of digital technologies in public health. These additional items can be used to integrate the development and evaluation of digital technologies for public health purposes within the wider HTA context, making this process both transferable and scalable.

[3]Digital Health Malta, Valletta, Malta
[4]University of Malta, Valletta, Malta
Contact: info@stefanbuttigieg.com

The demand for the digitalisation of public health has been ongoing for more than a decade. The COVID-19 pandemic was the tipping point that accelerated the ideation, implementation, and scale-up of such public health projects. Despite the well-needed push, the same challenges that face every similar implementation will nonetheless be the same if not accentuated. The scope of the presentation is to highlight the difficulties and facilitators that such implementations and evaluations bring forward. We will also see what we can learn as public health professionals to ensure that present and future information systems are well-planned. We have to ensure that they do not succumb to the pressure of well-intended stakeholders who are yearning for such solutions to help their business workflows. This presentation will be enhanced with the lessons learned from implementing, monitoring, and following up on Malta's national contact tracing app and Customer Relationship Management systems based on Microsoft Dynamics 365 technologies that tackled the Test, Track and Trace workflows that were integral to the COVID response in Malta.

Making the case for the governance of (digital public) health futures

Brian Li Han Wong

B Wong[1,2]
[1]GHFutures2030 Commission Secretariat, Geneva, Switzerland
[2]EUPHA-DH
Contact: Brian.Wong@graduateinstitute.ch

Digital and data tools are fundamentally changing approaches to health and the design of health systems, but governance models have neither followed nor kept up with the pace of innovation. In response to this challenge, The Lancet & Financial Times Commission on Governing health futures 2030: Growing up in a digital world explores the convergence of digital health, artificial intelligence, and other frontier technologies with universal health coverage to support attaining the SDG 3. Children and young people are crucial groups requiring particular attention to ensure that no one is left behind in achieving universal health coverage and SDG 3 amidst the digital transformation in health. Today, there are 1.8 billion people between the ages of 10 and 24 - the largest youth population in history - 90 percent of whom live in developing countries. This cohort represents an unprecedented powerhouse of human potential and digital engagement that could transform health to reach sustainable development goals. This presentation introduces several key findings from the Commission's report which pertain to the governance of (digital public) health futures amidst digital transformations in health. It will highlight how human-centred approaches to health are vital to navigating the digital transformations and maximising their benefits for population health and well-being. Further, it will provide an action plan for meaningful youth engagement in the design, development, implementation, and evaluation of digital public health policies, programmes, and services.

Association of hospital/ICU characteristics with HAIs: findings from the SPIN-UTI project

Martina Barchitta

M Barchitta[1,2]*, A Maugeri*[1,2]*, G Favara*[1]*, R Magnano San Lio*[1]*, C La Mastra*[1]*, MC La Rosa*[1]*, E Campisi*[1]*, I Mura*[3,2]*, A Agodi*[1,2]*, SPIN-UTI network*[2]
[1]Department GF Ingrassia, University of Catania, Catania, Italy
[2]GISIO, SItI, Rome, Italy
[3]University of Sassari, Sassari, Italy
Contact: martina.barchitta@unict.it

Background:
Preventing the spread of healthcare-associated infections (HAIs) in Intensive Care Units (ICUs) constitutes a priority for Public Health. In a country with decentralized healthcare system, the comparison between and within regions might represent a useful approach to identify what hospital and ICU indicators are associated with HAIs.

Methods:
Using data from the SPIN-UTI (''Sorveglianza attiva Prospettica delle Infezioni Nosocomiali nelle Unità di Terapia Intensiva'') network, the present analyses aimed to identify the main hospital and ICU indicators associated with HAI incidence at national level, and to stratify the analyses between Italian regions.

Results:
No associations between hospital/ICU characteristics and HAIs were evident at national level. However, ICUs in Southern Italy showed the highest incidence density of HAIs if compared with those in Central and Northern Italy ($p < 0.001$). Stratified analyses found a positive association of incidence density of HAIs and total days in ICU in Northern Italy ($\beta = 0.3$; SE = 0.1; $p = 0.002$); a positive associations with ICU size ($\beta = 1.8$; SE = 0.7; $p = 0.020$), total days in hospital ($\beta = 0.06$; SE = 0.02; $p = 0.037$) and total days in ICU ($\beta = 0.5$; SE = 0.1; $p = 0.006$) in Center Italy; a positive association with hospital size in Southern Italy ($\beta = 20.3$; SE = 9.4; $p = 0.033$).

Conclusions:
Although our study confirms that HAIs still represent an important issue in Italian ICUs, there is some variation between regions from Northern, Central and Southern Italy. In general, we found that HAI incidence increased with increasing number of beds in hospital and in ICU, as well as with the the increasing number of patient-days. However, further research is necessary to better understand if additional hospital and ICU characteristics could motivate the observed regional differences.

Key messages:
- There is a large regional variation in the incidence of HAIs in Italian ICUs and hospitals.
- This difference that could be motivated by specific hospital and ICU characteristics.

Association between socio-economic deprivation and AHRQ composite indicator during pandemic

Fabrizio Cedrone

F Cedrone[1,2]*, P Di Giovanni*[3]*, G Di Martino*[4]*, F Romano*[5]*, T Staniscia*[1]
[1]Department of Medicine and Ageing Sciences, ''G. d'Annunzio'' University of Chieti-Pescara, Chieti, Italy
[2]Health Management of ''SS. Spirito'' Hospital, Local Health Authority of Pescara, Pescara, Italy

[3]Department of Pharmacy, ''G. d'Annunzio'' University of Chieti-Pescara, Chieti, Italy
[4]Unit of Hygiene Epidemiology & Public Health, Local Health Authority of Pescara, Pescara, Italy
[5]Department of Infectious Diseases and Public Health, ''La Sapienza'' University of Rome, Rome, Italy
Contact: cedronefab@gmail.com

Background:

The Agency for Healthcare Research and Quality (AHRQ) identifies preventable hospitalizations as proxy of potentially low-quality of care. Previous studies showed as socio-economic status was associated to poor diseases outcomes and to the performance of health services. Recently a particular attention was focused on the effect of the pandemic on this context. The aim of this research is to analyze the association between poor quality of primary care and socio-economic status before and during the pandemic.

Methods:

A retrospective observational study was conducted in Abruzzo Region, Italy. Hospital discharge records (HDR) of two different periods were selected: from April to December for 2019 and 2020. The aggregate Prevention Quality Indicator 90 (PQI-90) has been coded according to the indications of the AHRQ. The Italian socioeconomic deprivation index (DI), divided in quintiles (from 1st less deprived to the 5th most deprived) was attributed to all patient, based on the municipality of residence. A multivariate logistic regression model was performed to evaluate the association between PQI-90 and DI.

Results:

Totally were analyzed 253,063 HDR, of which 14,845 attributable to the PQI-90. By correcting for gender, age and number of comorbidities, the DI was not associated with the PQI-90 during 2019. During 2020 the PQI-90 was associated to 4th DI quintile (aOR 1.19;95%CI 1.09-1.30) and 5th DI quintile (aOR 1.13; 95%CI 1.03-1.23), compared to the 1st quintile.

Conclusions:

The impact of the pandemic on primary care has been substantial. Compared to the pre-pandemic era, during the pandemic, an association between potentially poor quality of care and the most disadvantaged socio-economic areas has been shown in Abruzzo. This evidence must be an interesting starting point for health planning in order to fight against inequalities in health services access.

Key messages:

- The reduction in the primary care quality during pandemic caused potentially preventable hospitalizations and it was associated to socioeconomic deprivation.
- The analysis of hospital admission linked to context indicators such as the deprivation index, can be a useful tool for the policy maker in order to reduce healthcare inequalities.

Factors influencing general practitioners' decisions in migrant patients with mental health disorder

Camille Duveau

[5]Department of Public Health and Primary Care, Ghent University, Ghent, Belgium
Contact: camille.duveau@uclouvain.be

Background:

Patients with a migration background (MB) have more mental health disorders than those without migration background. Yet, those patients are still underrepresented in mental healthcare services and have more unmet medical needs. Although providers' bias has been well studied, up to date, little is still known about the factors explaining those biases. We assessed the effect of general practitioners' (GPs') individual and organizational factors on their decision-making regarding diagnosis, treatment and referral recommendations for patient with MB with symptoms of major depression.

Methods:

An experimental study staged a video-vignette of a depressed patient with or without MB. GPs had to make decision about diagnosis, treatment and referral. We then assessed the influence of several factors on their decisions such as age, ethnicity, workload and patient confidence. ANOVA and MANOVA were used for analyses.

Results:

Overall, we found more unfavourable decisions in GPs diagnosis and treatment recommendations regarding the patient with a MB ($F = 3.56$, $p < 0.001$). In addition, they considered the symptoms of the patient with a MB as less severe ($F = 7.68$, $p < 0.01$) and would prescribe less often a medical treatment to these patients ($F = 4.09$, $p < 0.05$). Nevertheless, few factors explained these differences, except the age, the workload and the patient trustworthiness.

Conclusions:

This paper highlighted GPs biases based on apparent migration background of a patient with major depression that perpetuates ethnic inequalities in mental health care. Further research into the origins of discrimination in primary mental health care are needed to explain how and when those discriminations arise.

Key messages:

- This paper shed light on pervasive unintentional discrimination still persist in mental health care among migrants in Europe.
- These findings may help us to further understand the role of general practitioner behaviour in primary mental health care discrimination.

Abstract citation ID: ckac129.156
Socio-economic inequalities in mental health: a new framework and analysis across 113 countries

Christoph Henking

C Henking[1]
[1]Department of Social Policy and Intervention, University of Oxford, Oxford, UK
Contact: c.henking@gmx.net

Background:

Socio-economic inequalities in common mental health disorders (CMDs) cut across each step in the cascade of care: (1) Less affluent individuals have a higher prevalence of CMDs, (2) are less likely to utilise treatment and (3) might benefit less from treatment when they do receive it. Here, we propose a new framework for distinguishing between these three types of inequalities in CMDs and test if such 'triple inequalities' exist globally and how they vary across countries.

Methods:

We use the Wellcome Global Monitor 2020 ($N = 119{,}088$ in 113 countries) to test if socio-economic factors, psychological factors (stigma and trust) and country-level factors (GDP, GINI and health expenditure) predict CMD lifetime prevalence, utilisation and perceived helpfulness of talking therapy and medication. Multi-level logistic regression models were used.

Results:

As predicted, people with higher household income are less likely to experience anxiety or depression ($OR = 0.90$ for each income quintile, $p < 0.01$), more likely to talk to a mental health professional ($OR = 1.05$; $OR = 1.34$ for higher education, $p < 0.01$) and more likely rate this treatment as very helpful (OR = 1.06, p = 0.02) across countries. In contrast, income is not linked with utilisation (OR = 0.99, p = 0.18) and helpfulness of 'taking medication' for CMDs (OR = 1.02, p = 0.26). In LMICs, the highly educated take less medication (OR = 0.74, $p < 0.01$). Local stigma reduces utilisation (OR = 0.95) and helpfulness of talking therapy (OR = 0.77), while trust in health practitioners increases both (OR = 1.07 util. and OR = 1.31 helpf., $p < 0.01$ in all cases).

Conclusions:

Three types of socio-economic inequalities for CMDs (in prevalence, talking therapy utilisation and helpfulness) deepen disadvantages for the less affluent across 113 countries. For pharmacological treatment, inequalities in utilisation and helpfulness are weaker and have a different social gradient in LMICs. Here, less educated people are more likely to take medication.

Key messages:

- Three types of socio-economic inequalities in common mental health disorders (in prevalence, talking therapy utilisation and helpfulness) exacerbate disadvantages for less affluent individuals.
- These Inequalities in CMD treatment utilisation and helpfulness are stronger for talking therapies than for medication, and depend on country contexts, stigma and trust in health practitioners.

Adapting and testing a tool to map digital health resources use by older adults in Israel and Taiwan

Diane Levin-Zamir

D Levin-Zamir[2,1,6], O Baron-Epel[2], P Chang[4], E Neter[3], E Eliahu[2], T Duong[5]

[4]Show Chwan Memorial Hospital, Lugan, Taiwan
[5]School of Nutrition, Taipei Medical University, Taipei, Taiwan
[6]Department of Health Education and Promotion, Clalit, Tel Aviv, Israel
Contact: diamos@inter.net.il

Background:

Despite the potential of digital health tools for improving health outcomes, older adults are known to use digital health tools differently than younger adults. Focusing on needs of older populations is critical, as their numbers and proportions are projected to increase dramatically in the coming decades, both in Israel and in Taiwan. A bi-national collaboration was developed to map existing digital health resources available to older adults, as part of a larger study on digital health services use among older adults.

Methods:

A mapping tool was adapted from the WHO classification of digital health interventions, based on the experience in the Taiwanese and Israeli health systems. The areas included public health, prevention, self- monitoring and self-care information and services in primary and tertiary care. The mapping documented digital resources offered by governmental/ Ministry of Health, public primary care (HMOs), hospitals, and non-governmental organizations. Sources of information were institutional websites, evaluated by two specially trained reviewers for each organization who assigned a dichotomous value (yes/no) for each category. Interrater reliability was computed using a Kappa coefficient.

Results:

The instrument included 17 categories and 44 sub-categories of digital resources, ranging from public health information for emergency situations to specific health service characteristics. To date, the Kappa coefficients range from 0.59-0.68 for NGO, MOH and hospital resources, considered substantial; for 3 HMOs, the values ranged from 0.41-0.49, considered moderate.

Conclusions:

The mapping tool adapted to the countries' digital resources allowed for bi-national research to compare/contrast the countries' experience. The next stage of the study will validate the results through expert interviews, followed by an end user survey with older adults to assess both reported use of services and enabling digital health literacy skills.

Key messages:

- To meet the needs of aging populations, attention needs to be given to their engagement with digital health services and resources.
- Mapping digital health resources is essential for estimating how health needs are met nationally.

Abstract citation ID: ckac129.158
Sexual health inequalities among women aged 16-24

Danielle Solomon

Introduction:

Gonorrhoea is the second most commonly diagnosed sexually transmitted infection in England, and diagnoses among young women increased 31% between 2018 and 2019. Understanding the patterns of testing and diagnosis among young women is likely to aid prevention among the most vulnerable segments of this population.

Methods:

Data on gonorrhoea diagnoses at sexual health services among women aged 16-24 in England were obtained using the GUMCAD STI Surveillance System. We investigated the relationship between two exposure variables (deprivation and ethnicity), and two outcome variables (number of gonorrhoea tests and number of gonorrhoea diagnoses). Poisson regression was used to calculate rate ratios for the relationship between the exposure and outcome variables. The testing analysis was offset for the size of the population, and the diagnosis analysis was offset for the number of tests within the population.

Results:

Between 2012 and 2019, gonorrhoea testing and diagnosis rates were highest among women living in the most deprived areas. The rate of testing in the least deprived 10% of neighbourhoods was significantly lower than that seen in the most deprived 10% of neighbourhoods (rate ratio (RR) 0.79; 95% confidence interval 0.79 - 0.80), and the rate of diagnosis in the least deprived 10% of neighbourhoods was around a third of that seen in the most deprived 10% of neighbourhoods (0.35; 0.33 - 0.36). When compared to White British women, the rate of gonorrhoea diagnosis was lower among Bangladeshi (RR 0.89; 0.75 - 1.05), Indian (0.76; 0.68 - 0.84), Pakistani (0.87; 0.77 - 1.00) and Chinese women (0.60; 0.51 - 0.71) and was highest among Black Caribbean (2.26; 2.18 - 2.33) and Black African (1.40; 1.34 - 1.45) women.

Conclusions:

This analysis found inequalities in the distribution of gonorrhoea among young women in England that may indicate structural barriers to STI prevention that are affecting Black women and those living within the most deprived populations.

Key messages:

- Gonorrhoea testing rates among young women in England are highest among women from deprived areas and Black women.
- Gonorrhoea diagnosis rates among young women in England are highest among women from deprived areas and Black women.

Abstract citation ID: ckac129.159
Diabetes Prevention Programme and socioeconomic inequalities in Type 2 Diabetes in England

Georgia Chatzi

G Chatzi[1], W Whittaker[2], T Chandola[1,3], T Mason[2], C Soiland-Reyes[4], M Sutton[5], P Bower[5]

[5]Centre for Primary Care and Health Services, University of Manchester, Manchester, UK
Contact: georgia.chatzi@manchester.ac.uk

The National Diabetes Prevention Programme (DPP) in England is a behavioural intervention for preventing Type 2 Diabetes Mellitus (T2DM) among people with non-diabetic hyperglycaemia (NDH, HbA1c 42-47 mmol/mol or 6.0-6.4%). How this programme affects inequalities by age, gender, disability, ethnicity, or deprivation is not known. We used multinomial logistic regression models to compare population characteristics at three stages along the prevention programme pathway: prevalence of NDH [using survey data from UK Household Longitudinal Study (N = 794) and Health Survey for England (N = 1,383)]; identification in primary care and offer of the programme [using administrative data from the National Diabetes Audit (N = 1,267,350)]; and programme participation [using programme provider records (N = 98,024)]). Younger adults (aged under 40) [4% of the NDH population (95% CIs 2%-6%)] and older adults (aged 80 and above) [12% (95%CIs 10%-14%] were both under-represented amongst DPP participants [2% of DPP participants (95%CIs 1.8%-2.2%) and 8% (95%CIs 7.7%-8.3%) respectively]. People with disabilities were underrepresented in the DPP [15% (95%CIs 14.9%-15.1%) vs 60% (95%CIs 58%-62%)] compared to the general population. People living in more deprived areas were under-represented [14% (95% CIs 13.7%-14.3%) vs 20% (95%CIs 16%-24%) in the general population]. Ethnic minorities were overrepresented [36% (95%CIs 35.8%-36.2%) vs 13% (95%CIs 9%-17%) in the general population] among DPP referrals, though the proportion dropped at programme completion stage [19% (95%CI 18.5%-19.5%)]. The DPP has the potential to reduce ethnic inequalities but may widen socioeconomic, age, and disability-related inequalities in T2DM. Whilst ethnic minority groups are overrepresented at identification and offer stage, efforts are required to support the completion of the programme. Programme providers should target underrepresented groups to ensure equitable access and narrow inequalities in T2DM.

Key messages:

- The DPP intervention may result in a widening of socio-economic and disability related inequalities amongst people with NDH as the programme had fewer adults in deprived areas and with a disability.
- The programme has the potential to reduce ethnic inequalities, but efforts are required to support the completion of the programme by minority ethnic groups.

A community-based participatory approach to engaging Congolese migrants in intervention co-design

Alison Crawshaw

AF Crawshaw[1], C Hickey[2], LM Lutumba[3], LM Kitoko[3], SL Nkembi[3], F Knights[1], Y Ciftci[4], T Vandrevala[5], AS Forster[6], S Hargreaves[1]

[6]Our Future Health, Manchester, UK
Contact: acrawsha@sgul.ac.uk

Issue:

The World Health Organization has called for tailored, community-based interventions to address disparities in vaccination uptake affecting migrant and minoritised populations, however few exist. This study directly responds to global calls for community-centred and participatory approaches to engaging migrants in routine and COVID-19 vaccination.

Problem description:

Black and African migrants are known to be at risk of under-immunisation and have lower COVID-19 vaccine uptake rates in high-income countries. This UK study will use community-based participatory approaches to engage Congolese migrants in co-developing a tailored intervention to increase vaccine uptake. A community-academic coalition will lead the study. Community members will be trained as peer researchers and financially compensated. The final output will be an intervention strategy tailored to and embedded within the Congolese migrant community.

Preliminary results:

The coalition held 20 hours of planning meetings and peer researcher training in 2021 and co-developed a phased study involving 1) community days with poster walls and qualitative in-depth interviews with Congolese migrants, 2) interviews and workshops with local stakeholders, and 3) co-design workshops with Congolese migrants. Following outreach and pre-engagement, approximately 80 migrants attended the community days, with more than 50 interviews and 100% left positive feedback (including: felt valued, welcomed, Congolese language recognised).

Lessons:

Community-academic partnerships are resource-intensive but can be an effective means to build and maintain trust required to deliver a community-based research study. Academic partners should support community partners in understanding the research process to help manage expectations and provide financial compensation for their time and effort. This study offers an innovative engagement model and study design that can be adapted to other underserved populations.

Key messages:

- Global policy-setting organisations have called urgently for participatory research that engages migrants in the co-production of tailored initiatives to address vaccination inequalities.
- This study uses a novel, theory-driven, participatory approach to engage with and identify barriers to vaccination in Congolese migrants and co-design a tailored strategy to increase uptake.

How can school-based interventions reduce health inequalities? Results from two reviews

Irene Moor

I Moor[1], A Schneider[1], L Niederschuh[1], K Winter[1], M Richter[2]
[1]Martin-Luther-University Halle-Wittenberg, Institute of Medical Sociology, Medical Faculty, Halle, Germany
[2]Technical University of Munich, Department of Sport and Health Sciences, Munich, Germany
Contact: irene.moor@medizin.uni-halle.de

Background:
Even in young people the chances to grow up healthy are unequal, depending on their socioeconomic position (SEP). In order to reduce these health inequalities, the school is an important field of action for health promotion. However, the evidence is limited regarding interventions focusing on health inequalities. Thus, the aim of the current research is to investigate 1) which school-based interventions contribute to the reduction of socio-economic inequalities in health and health behaviour of children and adolescents and 2) how and under what conditions they are successful.

Methods:
A systematic and a realist review were conducted. Some steps of the methodological approach were used synergistically for both reviews: development of the search strategy, selection of the databases (MEDLINE, SSCI, SCIE, DoPHER and TRoPHI) and some inclusion and exclusion criteria. The search covered the years 2000-2020. The screening and subsequent steps were applied specific to each review design.

Preliminary results:
The search resulted in 10,524 hits of which 37 publications were included for the systematic review. Most of the interventions focused on nutrition (14), followed by mental health (8) and substance use (5). The results indicate that structural preventive interventions are more likely to reduce health inequalities compared to behavioral preventive interventions. For the Realist Review 7 studies were included. Intrapersonal, interpersonal, and institutional factors were extracted that are relevant for school-based interventions focusing on adolescents with low SEP.

Conclusions:
The systematic review showed that school-based interventions are able to reduce health inequalities, but also to increase them. Structural preventive measures seem to be helpful in increasing health equity. The Realist review identified mechanisms of interventions which help to address students with lower SEP.

Key messages:
- The evidence regarding interventions with focus on health inequalities is limited. We present two reviews analysing what interventions are needed and how and why they work.
- Structural preventive measures seem to be helpful in increasing health equity. Factors on the intrapersonal, interpersonal, and institutional level are important to address students with low SEP.

Abstract citation ID: ckac129.162
School tobacco policies and social inequalities in adolescent smoking

Nora Mélard

N Mélard[1], V Lorant[1]
[1]Institute of Health and Society, UCLouvain, Brussels, Belgium
Contact: nora.melard@uclouvain.be

Background:
Adolescents of lower socio-economic status initiate smoking earlier and smoke more frequently than those of higher socio-economic status. Tobacco control policies, such as school tobacco policies, aim to reduce adolescent smoking, but their implementation has been found to vary greatly from one school to another. Such differences in the implementation might therefore contribute to social inequalities in smoking. This study examines whether school tobacco policies are implemented where they are most needed, and how this implementation according to needs has changed over time.

Methods:
Student (n = 18,805) and staff surveys (n = 438) were conducted in 2013 and 2016 in 38 schools from six European cities in six countries. School tobacco policies were measured as a 10-point score taking into account their multidimensionality, and the perceptions of both students and staff. We used concentration curves and indices to measure the inequality in the implementation of these policies depending on the smoking prevalence and on adolescents' socio-economic status.

Results:
A concentration curve below the perfect equity line indicated a concentration of school tobacco policies where smoking prevalence was lower. Moreover, this inequality was larger in 2016 compared to 2013 (concentration indices of .038 in 2013 and .041 in 2016). On the contrary, a concentration curve overlaying the perfect equity line indicated no inequality in the implementation of these policies depending on adolescents' socio-economic status (concentration indices of .016 in 2013 and -.013 in 2016).

Conclusions:
School tobacco policies have been developed to reduce adolescent smoking. They, however, seem to be less implemented in schools where they are most needed. This confirms that smoking prevention is still driven by the inverse prevention law. Next to evaluating the impact of such policies on smoking outcomes, research should also focus on their contribution to social inequalities in adolescent smoking.

Key messages:
- School tobacco policies, developed to reduce adolescent smoking, might contribute to social inequalities in smoking.
- School tobacco policies are less implemented where they are most needed.

Abstract citation ID: ckac129.163
The role of gender equity in healthy life expectancy in 27 European countries

Teresa Leão

T Leão[1]
[1]EPI Unit, Instituto de Saúde Pública da Universidade do Porto, Porto, Portugal
Contact: teresacostaleao@gmail.com

Background:
The number of years - and healthy years - a person is expected to live differs according to gender: women tend to live longer than men, but with a shorter healthy life expectancy (HLE). Power imbalance, such as income, prestige, or autonomy gaps, may lead to an unequal health distribution across gender in the older ages. The association between gender equality and longer life expectancies has been described, but little is known about its association with HLE. We aimed to study the association between gender equality, and its components, and HLE in Europe, in the last decade.

Methods:
We combined HLE estimates from Eurostat with the Gender Equality Index (and its components) for 27 European countries, from 2013 to 2019. The associations between gender equality and HLE, and its gender gap, were assessed using regression analyses adjusted for Gross Domestic Product, number of medical doctors per 1000 inhabitants (as proxies of economic wellbeing and access to healthcare), and year.

Results:
Higher gender equality was associated with longer HLE in men ($\beta = 0.22$ $p < 0.01$), but not in women. Yet, higher equality in education was associated with longer HLE in both genders (βmen = 0.49, βwomen = 0.40, $p < 0.001$), as was access to financial resources (βmen = 0.27, βwomen = 0.20, $p < 0.005$),

and social power (βmen = 0.09, βwomen = 0.07, $p < 0.05$). Differently, equality in participation in full-time work was associated with shorter HLE in both genders (βmen = -0.33, βwomen = -0.30, $p < 0.001$) and a higher HLE gender gap (β = 0.05, $p < 0.05$). The HLE gender gap was smaller in contexts with higher equality in access to financial resources (β = -0.06, $p < 0.001$) and education (β = -0.04, $p < 0.01$).

Conclusions:

These results point to a country-level relation between gender equality and HLE. Beyond the social issue, gender inequalities in education, income and social power seem to play a role in the health of women and men through their aging course.

Key messages:

- Higher gender equality in education, income and social power are associated with longer healthy life expectancies in 27 European countries.
- Gender equality benefits not only women's healthy life expectancies but also men's, and is reflected in smaller gender gaps.

Social context matters: the role of social support and social norms in healthcare solidarity

Marloes Meijer

MA Meijer[1], AEM Brabers[1], JD De Jong[1,2]
[1]Healthcare System and Governance, NIVEL, Utrecht, Netherlands
[2]Faculty of Health, Medicine and Life Sciences, Maastricht University, Maastricht, Netherlands
Contact: m.meijer@nivel.nl

Background:

In many European countries, including the Netherlands, the healthcare system is based upon solidarity. It is important that public support for solidarity-based systems is sufficient, to ensure that people remain willing to contribute to them. Although support is generally high, as indicated by high levels of willingness to pay for the healthcare costs of others, there are differences between groups. Previous research has focused on individual and institutional characteristics when explaining these differences. However, people's social context may also play a role. Little research has been conducted into this. To fill this gap, we examined the role of perceived social support and social norms in order to explain differences in the willingness to pay for other people's healthcare costs.

Methods:

A questionnaire was sent to a representative sample of 1,500 members of the Dutch Healthcare Consumer Panel in November 2021 (56% response rate, N = 837). The relationship between the social context of people and their willingness to pay was studied via logistic regression analysis.

Results:

Higher levels of perceived social support are associated with higher levels of willingness to pay for other people's healthcare costs ($p = 0.038$). We also found that willingness to pay is higher when someone's social context is more supportive of the solidarity-based healthcare system ($p = 0.001$). Contrary to our expectations, the effect of social norms does not differ between people who perceive low and high levels of socials support.

Conclusions:

The degree to which people feel connected to others and the degree to which someone's social context supports the solidarity-based healthcare system affect the willingness to contribute to the healthcare system. Our results suggest that the social context of people has to be taken into account in both policy and research that addresses healthcare solidarity, next to individual and institutional characteristics.

Key messages:

- Social support and social norms play a role in the willingness to pay for healthcare costs of others.
- People's social context must be taken into account in policy and research on healthcare solidarity.

Abstract citation ID: ckac129.165
How do countries plan, purchase and use imaging technologies to prevent over-purchase and overuse?

Ruth Waitzberg

R Waitzberg[2,1]
[1]Health Systems and Management, Technische Universitat Berlin, Berlin, Germany
[2]Smokler Center for Health Policy Research, Myers-JDC-Brookdale Institute, Jerusalem, Israel
Contact: ruthw@jdc.org

Background:

The adoption of new and expensive technologies is one of the main causes of the growing expenditure on health. Regulators are concerned that health care providers purchase (and use) imaging technologies in quantities that exceed the need, increasing expenditure with little value. We review how countries regulate the purchase and use of imaging technologies.

Methods:

Qualitative. We collected data using a questionnaire completed by researchers from 17 high-income countries purposefully selected based on variation of policies. We built and compared case studies.

Results:

Eleven of the 17 countries analyzed have clear criteria for planning and purchasing imaging technologies. Countries plan different areas, such as supply of specialist care, hospitals by level and type of services, quantity or type of equipment, as well as expenditure on health services and resource allocation. Most countries combine three mechanisms that manage the purchase or use of imaging technologies: (1) seven countries regulate by requiring certificates of need, licenses, or purchase approvals; others regulate by directly limiting the amounts, types and quality of technologies. (2) All countries use financial tools such as activity-based payment, limited and conditional budgets, and caps on income or volume of services. (3) Nine countries centralize purchase by a government agency. The literature provides inconclusive evidence regarding the impact of these mechanisms on expenditure on health and access to imaging services.

Conclusions:

Planning the imaging technologies market with clear criteria is essential to avoid abuse. Most countries combine the three mechanisms (regulation, financial tools, centralized purchase). Financial tools are more common and effective. Countries with single payers implement more regulation than countries with multiple, competing, payers. In the later, regulated competition seems to replace regulation. There is a trend of adopting centralized procurement.

Key messages:

- Planning the imaging technology market is a precondition to avoid abuse.
- Regulation, financial tools, and centralized purchase can be combined to manage the use of imaging technologies.

Abstract citation ID: ckac129.166
Exploring the link between cancer policies and cancer survival: a comparison of seven countries

Ellen Nolte

E Nolte[1], *M Morris*[1], *S Landon*[1], *M McKee*[1], *M Seguin*[1], *J Butler*[2,3], *M Lawler*[4]
[1]Department of Health Services Research and Policy, LSHTM, London, UK
[2]The Royal Marsden Hospital, London, UK
[3]Cancer Research UK, London, UK
[4]Patrick G Johnston Centre for Cancer Research, Queen's University Belfast, Belfast, UK
Contact: ellen.nolte@lshtm.ac.uk

Background:

Disparity in cancer survival across countries has been linked to variation in cancer policy delivery but there is lack of empirical evidence for this association. We traced the evolution of cancer policies in 20 jurisdictions in Australia, Canada, Denmark, Ireland, Norway, New Zealand and the UK since 1995 and present the findings of an exploratory analysis linking cancer policy consistency to cancer survival.

Methods:

We systematically searched and analysed national/regional cancer plans and strategies, mapping timelines of cancer policy evolution. For 10 jurisdictions, evidence was synthesised into five categories: oversight function; cancer plan; implementation plan; budget for plan implementation; and evaluation. We assigned scores evaluating whether a category was present or absent, and weighted scores for consistency. Summed scores were correlated with trends in survival from seven cancers between 1995-2014.

Results:

All ten jurisdictions had implemented a high-level structure overseeing, steering or delivering cancer control policies (1995 - 2014); all had also published at least one major cancer plan. There was great variation in oversight mechanisms, ranging from institutionalising cancer control (New South Wales, Ontario) to cancer steering groups or taskforces (Denmark, Northern Ireland, Wales). Frequency and consistency of cancer plans also varied, from a succession of plans that build on each other (Denmark, New South Wales, Ontario) to the publication of isolated plans (New Zealand, Northern Ireland). We found a positive, albeit weak, correlation of cancer policy consistency and improvements in survival over time for six of the seven cancers.

Conclusions:

Jurisdictions that have implemented consistent cancer control policies over time tended to be more successful in improving survival for a wide range of cancers. Our findings can help guide policymakers seeking approaches and frameworks to improve cancer services and, ultimately, cancer outcomes.

Key messages:

- Sustained and consistent strategic cancer planning and investment are crucial for ensuring better patient outcomes, and this requires strong and sustained commitment at all levels.
- The findings can help guide policymakers seeking approaches and frameworks to improve cancer services and, ultimately, cancer outcomes.

Abstract citation ID: ckac129.167
Hospital admissions in Austria during the COVID-19 Pandemic – a rapid analysis for 2020 and 2021

Herwig Ostermann

H Ostermann[1,2], *K Eglau*[1]
[1]Austrian National Public Health Institute, Gesundheit Österreich GmbH, Vienna, Austria
[2]Department of Public Health and HTA, University for Health Sciences, Medical Informatics and Technology, Hall/Tyrol, Austria
Contact: herwig.ostermann@goeg.at

Background:

The COVID-19 pandemic posed a substantial shock to health service provision, in particular regarding hospital services. The reasons and also rationales for reduced health service provision were manifold ranging from limited supply due to resource restrictions, limited demand in order to avoid infections or due to reduced incidence of various diseases, and postponement of elective services. Nevertheless, the provision of services for acute care at an adequate level is paramount to avoid patient harm.

Methods:

Hospital admissions were analysed via administrative DRG data reported by Austrian hospitals. We compared health service provision on a monthly basis between 01/2018 and 12/2021. Services were classified according to ICD-10 and encompassed admissions due to acute heart failure, stroke, accidents, knee and hip surgery and breast cancer surgery.

Results:

Our findings show that hospital admissions for acute heart failure decreased by up to 25% between 03/2020 and 05/2020. In contrast, no significant difference to the initial pre-pandemic levels could be observed in the later stages of the pandemic. Stroke admissions remained at the initial levels throughout the whole period of analysis, while a substantial decrease (up to 50%) in admissions because of accidents was observed whenever severe NPIs were in place. Knee and hip surgery levels dropped in line with increasing ICU occupancy rates caused by COVID-19 patients. Decreases in breast cancer surgery could only be observed (up to 20%) during the four months of the pandemic (03-06/2020).

Conclusions:

Our analysis provides an aggregated insight into service provision management in Austrian hospitals throughout the pandemic. While acute care was continuously provided for most areas of diseases and elective surgeries were widely postponed in line with pressure on ICU capacities, the decline in breast cancer surgery demands attention and further clarification of whether this decline was supply- or demand-driven.

Key messages:

- During the pandemic inpatient acute care services were continuously provided for most diseases in Austrian hospitals while elective surgeries were postponed in line with pressure on ICU capacities.
- The pandemic posed a substantial challenge to service provision management in hospitals and unwarranted levels of service provision so far indicate areas of action for future (pandemic) preparedness.

Barriers for using amoxycillin dispersible tablet in pediatric pneumonia treatment in Bangladesh

Golam Mothabbir Miah

M Shah[1], *S Ahmed*[2], *S Rana*[2], *G Mothabbir*[2], *J Islam*[3], *S Islam*[3]

[2]Health and Nutrition, Save the Children International, Dhaka, Bangladesh
[3]NNHP & IMCI, Ministry of Health, Dhaka, Bangladesh
Contact: golam.mothabbir@savethechildren.org

World Health Organization recommends guideline for integrated management of childhood illnesses (IMCI) where Amoxicillin Dispersible Tablet (DT) appears as the first drug of choice for treating childhood pneumonia. The Government of Bangladesh adopted the IMCI strategy in 1998, and scaled it up nationwide by 2014. But, even today, the use of Amoxicillin DT, either in public or private sector, for managing childhood pneumonia is a rare event in Bangladesh. We conducted this exploratory study to understand the existing barriers, both in public and private sector, those have influences on reduced availability of Amoxicillin DT and non-compliance of health service providers to follow IMCI guideline by using Amoxicillin DT for treating a child with pneumonia, in Bangladesh. We conducted desk review of relevant strategy and policy documents, key informant interviews with 19 key individuals from Ministry of Health and national / international NGOs. Collected information were analyzed and interpreted using thematic analysis method. Identified barriers through this study pointed to inadequate policy level focus on IMCI implementation, non-inclusion of Amoxicillin DT in the national essential drug list, single source of Amoxicillin DT producing pharmaceutical in the country coupled with bureaucracy and procurement procedural complexity, lack of training of health service providers and abundant availability of antibiotic over the counter. Study respondents recommended for policy level strengthening of IMCI program, increasing coverage of training for health care provider, including practicing pediatricians both at public and private sectors, facilitating production and procurement procedures and prohibiting antibiotic sell over the counter.

Key messages:

- Facilitation of production and procurement procedure coupled with enforcement of law prohibiting antibiotics availability over the counter are urgent needs.
- Policy level support emphasizing full compliance of service providers for quality of implementation of IMCI program in Bangladesh (and similar other settings) is also important.

[6]Public Health and the Environment, National Institute, Bilthoven, Netherlands
Contact: y.zhu@umcg.nl

Background:

Fish intake is included in several national food-based dietary guidelines as a component of healthy diet because of its rich source of beneficial omega-3 fatty acids eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). However, heterogeneity among types of fish intake is rarely studied. We investigated the associations of socio-economic status (SES) with total and types of fish intake and validated whether types of fish intake was associated with plasma EPA and DHA.

Methods:

From the Lifelines cohort study, 94 246 participants aged 44 ± 13 years old were included to test the association of two SES indicators, i.e., education level and income level, with dietary intakes of total, fatty, lean, fried, and other types of fish. Plasma EPA and DHA were measured in a minor subset of 575 participants (mean age: 50 ± 13 years old). Total and types of fish intake was assessed using Food Frequency Questionnaire. Linear regressions were applied, adjusted for relevant covariates.

Results:

After adjusting for covariates, middle and low education were negatively associated with total, fatty, lean, and other fish intake ($p < 0.001$ for all), and positively associated with fried fish intake (β (SE): 0.04 (0.04), $p < 0.001$ for middle education; 0.07 (0.04), $p < 0.001$ for high education), with high education as the reference group. Similar results were observed for income level. In the subset population, total and fatty fish were positively associated with plasma EPA and DHA ($p < 0.02$ for all). Lean and other fish intake were positively associated with only DHA ($p < 0.008$ for all), but not EPA, while fried fish was not associated with either EPA or DHA in plasma ($p > 0.1$ for all).

Conclusions:

Lower SES was associated with higher intake of fried fish, which did not seem to be associated with the fish-based EPA and DHA in plasma. Both nutrition education and food price policy could be implemented to increase the awareness and shape people's choice on types of fish.

Key messages:

- People with low socio-economic status are consuming the type of fish that is not associated with fish-based omega-3 fatty acids, so nutrition education focusing on avoidance of fried fish is needed.
- Food subsidy programs promoting intake and increasing affordability of healthier fish are needed to improve the nutritional awareness and status of our population.

Abstract citation ID: ckac129.170
Whole grain intake, overall diet quality and key components of sustainable diets in Finnish adults

Rilla Tammi

R Tammi[1], S Männistö[1], H Reinivuo[1], H Tapanainen[1], J Rautanen[1], M Maukonen[1], E Päivärinta[2], A-M Pajari[2], NE Kaartinen[1]
[1]Department of Public Health and Welfare, Finnish Institute for Health and Welfare, Helsinki, Finland
[2]Department of Food and Nutrition, University of Helsinki, Helsinki, Finland
Contact: rilla.tammi@thl.fi

Background and objectives:

Whole grains have been deemed a core component in diets promoting human health and environmental sustainability. Yet, research is scarce on whole grain intake in relation to overall diet quality and diet sustainability. We aimed to examine the association of whole grain intake with overall diet quality and key components of sustainable diets (fruits, vegetables, legumes, red and processed meat, plant-based and animal-based proteins) in Finnish adults.

Methods:

Our data comprised 3127 adults (58% women, energy underreporters excluded) aged $18-74$ years participating in the population-based FinHealth 2017 Study. Dietary intake was assessed by a validated 134-item food frequency questionnaire. Food, nutrient, energy and whole grain intakes were calculated utilizing the Finnish Food Composition Database. Overall diet quality was examined by the modified Baltic Sea Diet Score (excluding cereals). Associations were assessed by linear regression analysis adjusted for relevant confounders.

Results:

Whole grain intake was positively associated with overall diet quality and fruit consumption ($p < 0.001$) in women and men.

A positive association also occurred with plant-based protein intake ($p < 0.001$, women and men). Yet, whole grain intake was inversely associated with legume consumption in women ($p = 0.001$), while no association was found in men ($p > 0.05$). The association between whole grain intake and the intake of animal-based proteins and red and processed meat was inverse ($p < 0.001$) in both sexes. No association was found between whole grain and vegetable intakes ($p > 0.05$).

Conclusions:

Our results suggest that whole grain intake is associated with healthier diets and more sustainable protein intake in Finnish adults. However, challenges in furthering healthy and sustainable diets in the population may occur regarding legume consumption. Legumes are especially important in plant-based diets as they complement cereals as a source of essential amino acids.

Key messages:

- Higher whole grain intake may indicate higher overall diet quality and more sustainable protein intake in Finnish adults.
- Legume consumption requires further attention among Finnish adults with high whole grain intake despite their generally higher overall diet quality and more sustainable protein intake.

[5]Faculty of Medicine, School of Public Health, Imperial College London, London, UK

Contact: m.deschasaux@eren.smbh.univ-paris13.fr

Background:

Nutrition is a well-established risk factor for cardiovascular diseases (CVD) that can be leveraged by public health prevention strategies. In addition to dietary guidelines, front-of-pack nutrition labels (FoPNL) can help consumers make healthier food choices. Nutri-Score, a scientifically validated 5-color FopNL based on the nutrient profile FSAm-NPS has been adopted by several European countries but remains optional under current EU labeling regulation, which is to be revised end of 2022. Scientific evidence is therefore needed on the relevance of the Nutri-Score at the European level. Our objective was to study the association between the consumption of food as graded by the FSAm-NPS and CVD risk in a large European population.

Methods:

This prospective analysis was conducted on a case-cohort comprising 13,308 participants without CVD risk factors at baseline, among which 5,326 first incident cases of CVD from the EPIC-CVD study (8 European countries). Food intakes were assessed using country-specific dietary questionnaires. The FSAm-NPS was calculated for each food based on its 100g content in energy, sugar, saturated fatty acid, sodium, fibre, protein, and fruits/vegetables/legumes/nuts. Multi-adjusted Cox models were computed.

Results:

Overall, associations were observed between the consumption of foods with a higher FSAm-NPS score (lower nutritional value) and a higher risk of myocardial infarction (MI; HR1-SD = 1.12 [1.05,1.21]; HRQ5/Q1 = 1.23 [1.00,1.52]). Associations with stroke were not significant. Overall, associations were more particularly observed in men.

Conclusions:

In this large European population, a higher risk of MI was observed in individuals consuming on average a diet with higher FSAm-NPS foods (reflecting consumption of foods with a lower nutritional value/less favourable Nutri-Score). This adds to the evidence on the relevance of Nutri-Score as a public health tool to help consumers choose healthier food products.

Key messages:

- The consumption of foods with a lower nutritional quality as graded by the Nutri-Score was associated with a higher risk of myocardial infarction in the large European EPIC-CVD case-cohort study.
- This adds to the evidence supporting the relevance of the Nutri-Score as a complementary tool to dietary guidelines to help consumers make healthier food choices.

[2]Cardiocentro, Clinica Mediterranea, Naples, Italy

[3]Department of Medicine and Surgery, University of Insubria, Varese, Italy

Contact: marialaura.bonaccio@neuromed.it

Background:

Vegetarians diets are characterized by the absence of some animal foods (e.g. red and processed meats), and a high consumption of plant-based foods. However, plant-based foods can include foods with varying nutritional value and health effects. We examined the association of three different pro-vegetarian (PVG) food patterns defined as general (gPVG), healthful (hPVG) and unhealthful (uPVG), with the risk of all-cause and cardiovascular disease (CVD) mortality in Italians.

Methods:

Longitudinal analysis on 22,912 men and women (mean age 55±12 y) from the Moli-sani Study (2005-2010) followed up for 11.2 y (median). Food intake was assessed by a 188-item FFQ. A provegetarian food pattern (FP) was constructed by assigning positive scores to plant foods and reverse scores to animal foods. A healthful and an unhealthful pro-vegetarian FP, which distinguished between healthy (e.g. fruits, vegetables, legumes) and less-healthy plant foods (e.g. fruit juices, potatoes, sugary beverages), were also built up.

Results:

In multivariable-adjusted analyses controlled for known risk factors, higher adherence to a gPVG was associated with lower all-cause (HR = 0.83; 95%CI 0.73-0.94) but not CVD mortality (HR = 0.90; 0.72-1.12). Increasing adherence to a hPVG was associated with reduced all-cause mortality risk (HR = 0.82; 0.72-0.95) as well as lower risk of CVD mortality (HR = 0.75; 0.59-0.95). Finally, the uPVG was directly associated with both all-cause (HR = 1.17; 1.03-1.33) and CVD mortality risks (HR = 1.23; 0.99-1.53).

Conclusions:

A general pro-vegetarian food pattern was associated with longer survival in Italians. Preferring healthful vegetarian foods provided protection against CVD mortality too. Consistently, a large dietary share of unhealthful vegetarian foods, mostly highly processed, was associated with increased risk mortality. Thus the quality of the plant food consumed is paramount to achieve diet-related benefits on mortality.

Key messages:

- A pro-vegetarian food pattern was associated with longer survival but preferring healthful vegetarian foods provided protection against CVD mortality too.

- The quality of the plant food consumed is paramount to achieve diet-related benefits on mortality.

Abstract citation ID: ckac129.173
Ultra-processed food consumption and survival in older Italians from the Moli-sani Study

Marialaura Bonaccio

M Bonaccio[1], A Di Castelnuovo[2], S Costanzo[1], E Ruggiero[1], S Esposito[1], M Persichillo[1], C Cerletti[1], MB Donati[1], G de Gaetano[1], L Iacoviello[1,3]

[1]Department of Epidemiology and Prevention, IRCCS NEUROMED, Pozzilli, Italy
[2]Cardiocentro, Clinica Mediterranea, Naples, Italy
[3]Department of Medicine and Surgery, University of Insubria, Varese, Italy
Contact: marialaura.bonaccio@neuromed.it

Background:

Ultra-processed food (UPF) is a major public health concern being reportedly associated with increased risk of non-communicable diseases and lower survival. However, most of the epidemiological evidence has been almost exclusively provided by research conducted in populations of youths or middle-aged adults. We tested the hypothesis that a large dietary share of UPF could be a risk factor also for vulnerable groups, as older adults (≥65 years).

Methods:

Longitudinal analysis on 5,215 men and women (mean age 72±5 y) from the Moli-sani Study (2005-2010, Italy) followed up for 10.9 y (median). Food intake was assessed by a 188-item FFQ. UPF was defined using the NOVA classification according to degree of processing, and categorized as quartiles of the ratio (%) between UPF (g/d) and total food consumed (g/d; weight ratio). The overall nutritional quality of the diet was measured by the Food Standard Agency nutrient profiling system dietary index (FSAm-NPS DI).

Results:

UPF contributed to 8% (min-max 0.0-58.4%) of the total food eaten daily and represented 14.4% (0.0-70.0%) of daily energy intake. In multivariable-adjusted analyses controlled for known risk factors, higher intake of UPF (Q4, ≥10.2% of total food), as opposed to the lowest (Q1, UPF<4.3%), was associated with increased all-cause mortality (Hazard ratio [HR] = 1.19; 95%CI 1.03-1.39); these results remained unchanged after adjustment for the FSAm-NPS DI (HR = 1.21; 95%CI, 1.04-1.41). A linear dose-response relationship of 1% increment in UPF intake with all-cause mortality was also observed (p = 0.017; p for non-linearity = 0.85).

Conclusions:

A large dietary share of UPF was associated with lower survival in older Italians consuming relatively low amounts of these foods. Expanding on previous studies on different age groups, these findings provide further justification to advise people to limit consumption of UPF even at older age.

Key messages:

- A large dietary share of ultra-processed food was associated with lower survival in older Italians consuming relatively low amounts of these foods.
- These findings provide further justification to advise people to limit consumption of ultra-processed food even at older age.

Abstract citation ID: ckac129.174
An exploration of reformulation efforts by the food industry in Ireland

Mary Rose Sweeney

D McMenemy[1], MR Sweeney[1]

[1]School of Nursing, Psychotherapy, and Community Health, Dublin City University, Donabate, Ireland
Contact: maryrose.sweeney@dcu.ie

Background:

Previous research conducted in 2020 by our team examined the progress made by food manufacturers in reformulation between 2014 and 2017 (i.e., improving the nutrition profile of food staples by reducing salt, sugar, saturated fat and overall energy contribution). Our previous study showed improvements in salt and sugars levels across many food staples, but we found rising energy levels, total fat, and saturated fat in many food categories.

Methods:

This study aimed to explore the ongoing progress in reformulation between 2017 to 2021. We photographed the labels of food staples in supermarkets with the leading market share in the Republic of Ireland (Tesco's, Dunnes, SuperValu, Lidl, Centra, Aldi, and M&S). We extracted the data, collated it in an excel spreadsheet, and analysed it to examine the nutrients of interest to the study (i.e., salt, sugar, fat, saturated fat, energy, carbohydrates, protein, fibre, and micronutrients). We compared the levels captured at this time point with those previously recorded in 2017.

Results:

Eight hundred and seventy-two products were directly compared, including 80 spreads, 34 cereal snacks, 87 fruit juices, 193 cereals, 210 breads, 88 milks, and 169 yoghourts. This study shows that previously reported improvements in salt and sugar levels now appear to be going in the wrong direction.

Conclusions:

Fat and saturated fat levels that were once on the increase now appear to be reducing, possibly implying that as salt and sugar go up, fat levels go down and vice versa. This may relate to product taste and palatability.

Key messages:

- This study shows that previously reported improvements in salt and sugar levels now appear to be going in the wrong direction.
- Fat and saturated fat levels that were once on the increase now appear to be reducing, as salt and sugar go up, fat levels go down.

Mental health of healthcare workers during the first year of the COVID-19 pandemic in the Netherlands

Maaike van der Noordt

M van der Noordt[1], KI Proper[2,3], B Loef[2], CRL Boot[3], FM Kroese[1], M de Bruin[1], SH van Oostrom[2]

[1]Center for Health and Society, RIVM, Bilthoven, Netherlands
[2]Center for Nutrition, RIVM, Bilthoven, Netherlands
[3]Department of Public and Occupational Health, Amsterdam UMC, VU University Amsterdam, Amsterdam, Netherlands
Contact: maaike.van.der.noordt@rivm.nl

Purpose:

In March 2020, the WHO declared COVID-19 a pandemic. Previous virus outbreaks, such as the SARS outbreak in 2003, appeared to have a great impact on the mental health of healthcare workers. The aim of this paper is to study to what extent mental health of healthcare workers differed from non-healthcare workers during the first year of the COVID-19 pandemic.

Methods:

We used data from a large-scale longitudinal online survey conducted by the Corona Behavioral Unit in the Netherlands. Eleven measurement rounds were analyzed, from April 2020 to March 2021 (N = 16,657; number of observations = 64,316). Mental health, as measured by the 5-item Mental Health Inventory, was compared between healthcare workers and non-healthcare workers over time, by performing linear GEE-analyses.

Results:

Mental health scores were higher among healthcare workers compared to non-healthcare workers during the first year of the pandemic (1.29 on a 0-100 scale; 95%-CI = 0.75-1.84). During peak periods of the pandemic, with over 100 hospital admissions or over 25 ICU admissions per day and subsequently more restrictive measures, mental health scores were observed to be lower in both healthcare workers and non-healthcare workers.

Conclusions:

During the first year of the COVID-19 pandemic, we observed no relevant difference in mental health between healthcare workers and non-healthcare workers in the Netherlands. To be better prepared for another pandemic, future research should investigate which factors hinder and which factors support healthcare workers to maintain a good mental health.

Key messages:

- During the first year of the COVID-19 pandemic, we observed no relevant difference in mental health between healthcare workers and non-healthcare workers in the Netherlands.
- During peak periods of the pandemic, mental health was observed to be poorer in both healthcare workers and non-healthcare workers.

Abstract citation ID: ckac129.176

Health workers' perception vs medically approved COVID-19 infection risk: the risk communication gap

Ellen Kuhlmann

E Kuhlmann[1], GMN Behrens[1], A Cossmann[1], S Homann[1], C Happle[1], A Dopfer-Jablonka[1]
[1]Clinic for Rheumatology and Immunology, Medizinische Hochschule Hannover, Hannover, Germany
Contact: kuhlmann.ellen@mh-hannover.de

Background:

This study analyses how healthcare workers (HCWs) perceived risks, protection and preventive measures during the COVID-19 pandemic in relation to medically approved risks and organisational measures. We aim to explore 'blind spots' of pandemic protection and identify mental health needs.

Methods:

A German multi-method hospital study at Hannover Medical School serves as an 'optimal-case' scenario of a high-income country, well-resourced hospital sector and an organisation with low HCW infection rate serves to explore governance gaps in HCW protection. Document analysis, expert information and survey data (n = 1163) were collected as part of a clinical study into SARS-CoV-2 serology testing during the second wave of the pandemic (November 2020-February 2021). Selected survey items included perceptions of risks, protection and preventive measures. Descriptive statistical analysis and regression were undertaken for gender, profession and COVID-19 patient care.

Results:

Our study reveals a low risk of 1% medically approved infections among participants, but a much higher mean personal risk estimate of 15%. The majority (68.4%) expressed 'some' to 'very strong' fear of acquiring infection at the workplace. Individual protective behaviour and compliance with protective workplace measures were estimated as very high. Yet only about half of the respondents felt strongly protected by the employer; 12% even perceived 'no' or 'little' protection. Gender and contact with COVID-19 patients had no significant effect on the estimations of infection risks and protective workplace behaviour, but nursing was correlated with higher levels of personal risk estimations and fear of infection.

Conclusions:

A strong mismatch between low medically approved risk and personal risk perceptions of HCWs brings stressors and threats into view, that may be preventable through improved information, risk communication and inclusion of mental health support in pandemic preparedness.

Key messages:

- Healthcare workers' perceptions of COVID-19 infection risks are much higher than medically approved infection risk.
- Pandemic preparedness and protection plans must pay greater attention to information, risk communication and mental health needs.

Abstract citation ID: ckac129.177

Nurses' coping with patients' relatives: Attachment style, burnout, and intentions to leave nursing

Amit Gur

A Gur[1], N Gur-Yaish[2], E Sher-Censor[3], A Zisberg[4]
[1]Department of Health Systems Management, The Max Stern Yezreel Valley College, Yezreel Valley, Israel
[2]Faculty of Graduate Studies, Oranim Academic College of Education, Tivon, Israel
[3]School of Psychological Sciences, University of Haifa, Haifa, Israel
[4]The Cheryl Spencer Department of Nursing, University of Haifa, Haifa, Israel
Contact: amitgu@yvc.ac.il

Background:

Conflictual interactions with patients' relatives are prevalent in the work of hospital nurses. These situations may increase burnout and result in intentions to leave the nursing profession and high rates of turnover. It is important to understand the coping mechanisms and behaviours that nurses employ in such conflicts, to help them develop more adequate strategies that could prevent these outcomes. This study aimed at revealing how nurses' attachment styles colour their behavioural coping mechanisms when dealing with such interactions with patients' relatives, and how they are related to burnout and intentions to leave the profession.

Methods:

An online survey was completed by 140 hospital nurses that included three scenarios of typical conflicts with patients' relatives. Each scenario was followed by questions that assess stress and inadequacy when handling such situations, and behaviours: problem-solving responses, emotional support seeking, avoidance, and escalating responses. The survey also included self-reports of attachment styles, burnout, and intentions to leave nursing. Data were analysed using SEM (Amos 23).

Results:

The model shows an acceptable fit ($\chi 2(24) = 39.33$, $p = .025$; CFI = .963; RMSEA = .068). Higher anxious attachment was associated with higher stress and feelings of inadequacy in handling the situation, which in turn were associated with more emotional support seeking, avoidance, and escalating responses. Escalating responses were indirectly associated with intentions to leave the nursing profession via higher burnout. Higher avoidant attachment was associated with fewer problem-solving responses.

Conclusions:

Evaluating nurses' attachment style, cognitions, and behaviours in conflicts with patients' relatives is imperative for understanding burnout and intentions to leave nursing. Nursing training should include simulations of conflictual interactions with patients' relatives to help modify maladaptive coping.

Key messages:

- Evaluating nurses' attachment style, cognitions, and behaviours in conflicts with patients' relatives is imperative for understanding burnout and intentions to leave nursing.
- Training for nursing staff should consider nurses' awareness of their attachment style to modify maladaptive cognitions and behaviours in conflicts with patients' relatives.

Abstract citation ID: ckac129.178
Improving communication with hard of hearing and D/deaf patients: a capacity-building intervention

Véronique S Grazioli

P Bodenmann[1], P Singy[2], M Graells[1], E Schmutz[1], T Sebai[1], V Favre[1], J Richème-Roos[1], O Cantero[1], K Morisod[1], VS Grazioli[1]
[1]Department of Vulnerabilities and Social Medicine, Center for Primary Care and Public Health, University of Lausanne, Lausanne, Switzerland
[2]Psychiatric Liason Service, Lausanne University Hospital, Lausanne, Switzerland
Contact: veronique.grazioli@unisante.ch

Background:

D/deaf and hard of hearing (D&HoH) populations are disproportionally affected by physical and mental health problems while facing barriers to accessing health services. These barriers stem from communication challenges with healthcare providers, who are often unprepared to meet their specific needs. This study aimed to develop and evaluate an intervention to improve healthcare providers' skills to communicate with these patients.

Methods:

This study featured a participative action research design. Consistently, the intervention was developed through iterative phases together with the target populations and key stakeholders. The finale version was tested in healthcare workers in Canton of Vaud in Switzerland. Participants completed a questionnaire before (T0) and 6 months after (T1) the intervention, assessing perceived knowledge of deafness and hard of hearing and tools to improve communication, self-efficacy on how to communicate with D&HoH patients and institutional benefits (application frequency of communication rules and tools).

Results:

The final intervention aimed to increase participants' 1) awareness of D&HoH experience and communication needs, 2) knowledge of the tools and basic rules to improve communication. Two D&HoH trainers led one half-day intervention among 28 healthcare providers (e.g., nurses, pharmacists; mean age = 43.6). Paired-sample t-tests revealed significant increases in knowledge between T0 and T1, t (23) = -7.81, $p < .001$ and in self-efficacy, t (24) = -10.23, $p < .001$, whereas there was no significant difference between institutional benefits at T0 and T1.

Conclusions:

Although findings suggest the intervention is a promising means to increase perceived knowledge and self-efficacy on how communicating with D&HoH patients, complementary approaches, such as a resource person within the institutions providing day-to-day support to the teams besides the intervention, may be necessary to induce institutional changes.

Key messages:

- Future research should implement the intervention more broadly within inpatient and outpatient settings in Switzerland to increase knowledge on how communicating with D&HoH patients.
- Intervention implementation should be complemented by an additional structural approach to induce sustainable changes in practice and evaluated over 12 months to ensure sustainability.

Background:

Determining and maintaining optimal staffing level in hospitals is crucial, as understaffing may have serious consequences and even increase mortality risk among patients. There is no consensus, however, on the optimal way to determine staffing requirements in hospitals as patients' care needs vary between wards and days. Nurse work experience may also affect quality of care and ultimately patients' survival but research on this topic is scarce.

Methods:

Administrative register data on patients (N = 254,308) and employees of 40 hospital units was used in one hospital district in Finland from years 2013-2019. Both nurse understaffing and nurse work experience were measured with two different indicators in each unit-day. Mixed-effects survival models were used to analyse the associations of these exposures with mortality at patient-level, when adjusted for patients' characteristics, such as age, sex and comorbidities.

Results:

Preliminary results showed that every one percent increase in the cumulative proportion of understaffed days - measured as low nursing hours relative to planned - was associated with 1.002-fold mortality risk among patients (95% CI, 1.000-1.004, p-value = 0.044). Short work experience was not associated with increased risk of death.

Conclusions:

This study supports previous findings on the associations between nurse understaffing and increased mortality risk among patients in Finland although no association with mortality was found for the other three staffing characteristics. However, the average daily shares of actualized nursing hours relative to planned hours were quite high in hospital units. An indicator based on actualized relative to planned working hours in routine administrative data could be useful in evaluating understaffing in hospitals.

Key messages:

- Adequate level of nursing professional in hospitals is related to patient survival.
- It is also crucial of develop efficient ways to evaluate understaffing in hospitals.

Abstract citation ID: ckac129.180
Opportunities to increase the attractiveness of the German Public Health Service as an employer

Laura Arnold

L Arnold[1,2], F Hommes[1], L Kellermann[1], F Fischer[1], L Jung[1], A Mohsenpour[1], JM Stratil[1]
[1]German Network of Young Professionals in Public Health, Berlin, Germany
[2]Applied Research and Transfer, Academy of Public Health Services, Duesseldorf, Germany
Contact: arnold@akademie-oegw.de

For decades, the public health service in Germany (PHS) experienced shortages of young professionals and challenges in recruiting qualified personnel. To sustainably counteract this challenge, it is necessary to understand the reasons of the perceived low attractiveness of PHS as a potential employer among students and young professionals. Two cross-sectional online surveys were conducted to assess the attitudes of medical, public health, and health science students towards the PHS as a potential employer. Wave 1, conducted from 2019-12 to 2020-04, focused on factors associated with high and with low interest in working for the PHS. Wave 2 was conducted from 2020-06 to 2020-09 to capture changes that may have resulted from the newfound attention of the PHS during the SARS-CoV-2 pandemic. Participants in both waves were asked about opportunities to increase the attractiveness of the PHS, which were analyzed using qualitative content analysis. In total 3040 students participated. Low interest in the PHS was associated with limited knowledge about public health, primary interest in clinical medicine, and a negative image of the public service. The qualitative analysis indicated as major obstacles: low visibility of and low awareness about the PHS, a perception of hierarchical and bureaucratic workplaces, and perceptions of repetitive occupations, among others. The participants suggested: improving awareness about the PHS in the population, including PHS in curriculum, and reducing entry barriers for non-medical students. The results of the largest survey of students on the attractiveness of the ÖGD in Germany provide valuable insights for ongoing reform processes. In addition to approaches to increase external visibility, existing processes and procedures within the ÖGD should be considered.

Key messages:

- To counteract the shortage of skilled workers, the PHS must become more attractive to young professionals. This requires both, greater external visibility and modernization of internal structures.
- Successful inclusion of the perspective of young professionals in the current modernization processes introduces opportunities to increase the attractiveness of the PHS in the long-term.

Abstract citation ID: ckac129.181
Workplace health promotion programs for employees in long-term care facilities - a systematic review

Michael Herz

M Herz[1], *D Gebhard*[1]
[1]TUM Department of Sport and Health Sciences, Technical University of Munich, Munich, Germany
Contact: mi.herz@tum.de

Background:

Employees in long-term care facilities (LTC) are exposed to physically and mentally demanding workloads. Due to the specific working conditions and processes in LTC, recent literature recommends that care setting-specific health promotion is required. The objective was to systematically review the current evidence of workplace health promotion programs among employees in LTC.

Methods:

A systematic review was conducted in accordance with the PRISMA 2020 Statement. The literature search was applied in the online databases PubMed, Web of Science, Cochrane Central Register of Controlled Trials, and APA PsycArticles (Jan 2000 - Feb 2022). Studies were included if (1) participants worked in any occupational setting in LTC, (2) personal health and outcomes related to occupational health were measured as primary outcome, and (3) studies were randomized controlled trials. Methodological quality was assessed using the Cochrane risk of bias assessment tool (RoB 2).

Results:

The literature search yielded 23.007 articles, resulting in 24 included studies and 21 unique interventions with a total of 6.625 participants at baseline. Most participants were female (85.2% to 100%). Interventions were grouped into person-directed (n = 4), person/work interface-directed (n = 10), work-directed (n = 0), and combined approaches (n = 7). Of these studies, two studies (2/4) using a person-directed approach, four studies (4/10) using a person/work interface-directed approach, and four studies (4/7) using a combined approach demonstrated significant improvements in personal health-related outcomes and occupational health-related outcomes. Methodological quality can be rated as some concerns.

Conclusions:

Interventions that incorporate a combination of intervention approaches appear promising for improving health and work-related outcomes among employees in LTC. There is a lack of evidence for only work-directed approaches to health promotion in LTC. High-level quality studies are still needed.

Key messages:

- Combined intervention approaches to workplace health promotion in long-term care facility settings appear to be beneficial.
- High-level quality studies on workplace health promotion in long-term care facilities are still needed.

Abstract citation ID: ckac129.182
Hospital hand hygiene after COVID-19: has the pandemic heightened healthcare workers' awareness?

Giacomo Pietro Vigezzi

M Zeduri[1], *AC Sgueglia*[1], *GP Vigezzi*[1], *P Ferrara*[1], *M Lanave*[2], *R Galvi*[2], *S Abela*[2], *V Novelli*[2], *A Muzzi*[2], *A Odone*[1]
[1]Department of Public Health, Università degli Studi di Pavia, Pavia, Italy
[2]Medical Direction, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy
Contact: gvigezzi@hotmail.com

Background:

Hand hygiene (HH) is the leading measure for preventing the transmission of healthcare-associated infections (HAI), and a cornerstone to prevent COVID-19 spread. Aim of the research was the assessment of HCWs' adherence to the application of WHO optimal practices, with the goal to promote a culture of safety and quality infection prevention and control (IPC) activities.

Methods:

Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, implemented a HH monitoring plan in which HCWs' adherence to HH procedures is evaluated using WHO guidelines, technical manual and observation form. Direct field observations took place in March and April 2022 by trained personnel. Process index was HH adherence, stratified by profession, opportunity and unit, which has been visited at least twice.

Results:

Overall, 302 HCWs were observed from 18 hospital units (105 physicians, 108 nurses, 84 healthcare assistants and 5 students). Out of 1382 opportunities, global adherence was 52% with 190 handwashing and 598 hand rubbing. The indication with the highest adherence was ''after body fluid exposure risk'' (76%), whereas the lowest were ''after touching the patient's setting'' (40%) and ''before touching a patient'' (43%). Adherence was higher in specialistic surgeries and haematology units, while the worst performances were reported in general medicine ward (29%). Physicians' and nurses' adherence was respectively 45% and 61%. Audits occasionally revealed nonconformities in glove use (i.e., unnecessary use, not changed between patients, hand rubbing on gloves).

Conclusions:

These preliminary findings could be directly linked to habits acquired during the pandemic, when HW tended to consider COVID-19 patients as a unique block to shield themselves from infections, rather than safeguarding individual patient units. HH awareness could have changed in the wake of COVID-19 pandemic and our study described how HCWs' adherence to optimal practices needs specific initiatives to promote correct HH.

Key messages:

- The COVID-19 pandemic reinforced the importance of handwashing and IPC, showing the key role of the HCWs' adherence to hand hygiene (HH) procedures.
- HH audits play a leading part in clinical governance and IPC, aiming at enhancing the quality of care and patient safety, particularly to strengthen health system resilience in post-COVID era.

3.M. Workshop: Health system barriers to vaccination in underserved communities: a tale of four countries

Abstract citation ID: ckac129.183

Organised by: EUPHA-IDC, EUPHA-MIG

Chair persons: Bernadette Kumar (EUPHA-MIG), Maria Gańczak (EUPHA-IDC)

Contact: ganczak2@wp.pl

The literature highlights low vaccination coverage among most minority or ethnic pediatric communities in EU, including migrants. In addition to being less likely to get a vaccine, such communities may be vulnerable to developing certain infectious diseases. It is particularly important in the context of the current humanitarian crisis connected with Russia's aggression towards Ukraine. Identification of potential barriers to vaccination and system gaps is crucial to further ensure that underserved pediatric communities benefit from the same level of protection as the general population in terms of disease prevention and control, including those diseases which can be prevented by routine vaccinations. The proposed workshop moderated by well-known experts of the subject (Bernardette Kumar and Maria Ganczak) will be based on the results from qualitative data collected as a part of the 5-year RIVER-EU (Reducing Inequalities in Vaccine uptake in the European region - Engaging Underserved communities) project which tackles health system barriers among selected underserved communities living in four countries: Ukrainian migrants in Poland, females with a Turkish and Moroccan migration background in the Netherlands, marginalized Roma communities in Slovakia and migrants/refugees in Greece. This interactive workshop will provide short (5 minutes per country) comparisons of the health system barriers to vaccination against MMR (measles, mumps, rubella) and Human Papillomavirus (HPV) in children living in different underserved communities, and contrast barriers to vaccination experienced by the community members with barriers perceived by the health care professionals. International comparisons of in-depth information collected during qualitative studies (interviews and focus groups) will help to provide an increased understanding of the health system determinants of low vaccine uptake in their specific multi-factorial contexts that will vary in terms of geography, size, wealth, health sector structures, culture and vaccination law. Such qualitative research is particularly valuable regarding its potential for producing comprehensive and refinement analyses adjusted for understanding the voices of underserved communities. The session will go beyond describing those. Based on the presentations the participants will be divided into 4 groups to discuss (15 minutes) the Key Barriers; Key Facilitators to vaccination; Main lessons Learnt; Ways forward for the future to increase vaccine uptake among underserved pediatric communities to reduce the burden of vaccine preventable diseases. These 4 groups of workshop participants will be led by experts from the MEMH and IDC sections. Then, concluding remarks will be presented by each group (5 minutes per group). The final resume delivered by session chairs will end the workshop.

Key messages:

- The health system barriers to child vaccination among underserved communities vary among European countries, and the optimal way to adequately address them is likely to be context specific.
- The RIVER-EU project gives an opportunity to discuss lessons already learnt around the different components of the vaccination process and to pinpoint ways forward for the future to reduce the VPD.

Health System Barriers for HPV-vaccine uptake in females with a Turkish or Moroccan Migration background in the Netherlands

Janine De Zeeuw

J De Zeeuw[1], *J De Zeeuw*[2], *JPM Vervoort*[2], *DEMC Jansen*[1]

[1]Department of General Practice and Elderly Care Medicine, University Medical Center Groningen, Groningen, Netherlands

[2]Department of Health Sciences, University Medical Center Groningen, Groningen, Netherlands

Contact: j.de.zeeuw@umcg.nl

Background:

HPV vaccine uptake in female adolescents with a Turkish or Moroccan migration background in the Netherlands is lower as compared to the national average. This study aimed to study health system barriers for HPV vaccine uptake in these groups.

Methods:

Semi-structured interviews with Turkish/Moroccan (2nd and 3rd degree migrants) female adolescents (12-18 years old), their parents and grandparents were conducted. In addition a focus group discussion with healthcare providers with particular experience with HPV immunization and the target groups was organized. Data was collected between November 2021-April 2022.

Results:

22 interviews were conducted among twenty-three individual participants. Sixteen participants with a Turkish migration background were recruited and seven participants were having a Moroccan migration background. In thirteen cases young women in the families did not receive an HPV vaccination. Health system barriers identified were: language barriers in the information provided, focus on HPV being a sexually transmitted disease in information campaigns, lack of knowledge and awareness on HPV among participants and healthcare providers and inability to reach the target groups with tailored immunization programs. Similar health system barriers were mentioned by the healthcare providers, but also included a lack of trust in the government and healthcare institutions, insufficient coordination and collaboration between different healthcare providers. National

immunization programs with mass campaign vaccination is mentioned as a barrier to reach families with a Turkish/Moroccan migration background.

Conclusions:

Various health system barriers were addressed to be related to HPV vaccine uptake in females with a Turkish/Moroccan migration background in the Netherlands. Despite similarities concerning health system barriers among community members and healthcare providers, different health system barriers were also mentioned.

Abstract citation ID: ckac129.185
Health system barriers to vaccination among Ukrainian economic migrants in Poland

Maria Gańczak

M Gańczak[1], *P Kalinowski*[2], *M Kowalska*[2]
[1]Department of Infectious Diseases, University of Zielona Gora, Zielona Gora, Poland
[2]Department of Hygiene and Epidemiology, Medical University Lublin, Lublin, Poland
Contact: ganczak2@wp.pl

Background:

Before Russia's aggression, Ukrainians were the largest migrant group in Poland. However, data on health system barriers to vaccination in this vulnerable group were not collected. The study aimed to explore barriers to child MMR/HPV vaccination and related access to Polish healthcare services.

Methods:

Between December 2021-January 2022, a qualitative study of Ukrainian migrants (UM) living in Poland, recruited through a snowball sampling method, was conducted as a part of RIVER-EU project. 8 focus groups were held with 49 UM aged 16-44 years, followed by interviews with 12 health care providers (HCP).

Results:

UM and HCP experienced communication barriers despite language similarities. HCP reported that since a UM is not willing to register at a GP practice he cannot be reached by the Polish vaccination system. UM experienced challenges in navigating the system and accessing credible information in Ukrainian, no official local health authority vaccination material existed either. UM complained that there are no translated versions of vaccination materials accessible at the PHC facilities and they are not adequately informed about the possible side effects of vaccines; HCP reported the lack of time provided by the system for health promotion. UM were not familiar and rather hesitant regarding self-paid vaccines, such as HPV vaccine. In Poland and Ukraine this topic is not targeted at school curriculum neither by information campaigns. UM reported that HPV vaccine is not of interest for them due to the high cost, however they might consider it for their daughters, if the cost was fully refunded.

Conclusions:

The study identified main health system barriers to child vaccination regarding economic UM in Poland, seen from the perspective of migrants and HCP and pinpointed issues for improvement. This can serve as a starting point to confront vaccination related challenges in the context of Ukrainian refugee crisis Poland is currently dealing with.

Abstract citation ID: ckac129.186
Health system barriers to HPV vaccination in marginalized Roma communities in Slovakia

Daniela Filakovska Bobakova

D Filakovska Bobakova[1], *Z Dankulincova Veselska*[1], *M Halanova*[2], *P Jarcuska*[3]
[1]Department of Health Psychology and Research Methodology, PJ Safarik University, Kosice, Slovakia
[2]Department of Epidemiology, PJ Safarik University, Kosice, Slovakia
[3]Department of Infectology and Travel Medicine, PJ Safarik University, Kosice, Slovakia
Contact: daniela.filakovska@upjs.sk

Background:

People from marginalized Roma communities often experience poverty, limited access to education, employment, housing, and health care (HC). The aim of the study was to explore the perceptions of people from marginalized Roma communities and health professionals regarding health system (HS) barriers to HPV vaccination.

Methods:

A qualitative study was conducted in the Kosice region as a part of the RIVER-EU project. Semi-structured interviews with marginalized Roma parents (N = 18), children (N = 15), and health professionals (N = 18) were audio-recorded and thematic analysis of the transcripts was performed in MAXQDA.

Findings:

Four main themes were identified regarding HS barriers: 1. Lack of information (lack of culturally and linguistically appropriate information, lack of information provision from HC providers, unreliable and conflicting information on the internet), 2. Restricted access to HC providers (lack of capacities, work overload, long wait in the waiting room, distance, traffic connection), 3. Financial and organizational barriers (limited coverage of vaccination expenses from health insurance, picking up prescribed vaccines in a pharmacy by parents, parental consent), 4. Attitudes and behaviours of HC providers (neglect of care, double standard, inappropriate behaviour and communication, prejudices, racism).

Conclusions:

The reasoning and perception of several barriers to HPV vaccination differ among groups of respondents. Nevertheless, HPV is not viewed as a priority by both - marginalized Roma and health professionals. HS fails to reach marginalized Roma with appropriate information about HPV and HPV vaccination. Moreover, the lack of capacities and motivation of HC providers to address these topics lead to a lack of awareness. Organization and health insurance coverage of vaccination pose additional barriers to HPV vaccination.

Abstract citation ID: ckac129.187
Health system barriers to HPV and MMR vaccination in recent migrants/refugees in Greece

Pania Karnaki

P Karnaki[1], *A Dalma*[1], *N Papaevgeniou*[1], *K Katsas*[1], *A Linos*[1]
[1]Prolepsis, Institute of Preventive Medicine Environmental and Occupational Health, Marousi, Greece
Contact: p.karnaki@prolepsis.gr

Background:

Migrants have lower vaccination rates compared to the general population and report multiple barriers in accessing related services. We explored practices and perceptions regarding MMR & HPV vaccinations in migrant children & adolescents from third countries to inform the development of tailored interventions to increase vaccination coverage. Third country nationals for the RIVER-EU project are migrants arriving to the EU from countries beyond Europe (the Middle East, Asia & Africa) escaping civil conflict, war, and poverty.

Methods:

A qualitative study was conducted in the wider Athens area as part of the RIVER-EU project. Four Focus Groups and 23 semi-structured interviews were conducted with health care professionals, children and parents with a migrant background. Data were analysed using thematic content analysis. Findings: Identified barriers relate to the lack of standard operational procedures at system level that would define a schedule of vaccinations for migrants. Migrant vaccinations are subject to availability of vaccines (MMR as opposed to HPV) and potential threat of outbreaks (MMR vs HPV). There is no consistent, unified recording system of vaccinations while at system level there is a lack of trained cultural mediators. Targeted health promotion campaigns are rare while the few related activities that do exist are not systematically evaluated.

Conclusions:

MMR vaccination is more frequent compared to HPV which is not prioritised by the target group or health professionals. Nevertheless, the target group is open to learning more about HPV while the important role of mothers concerning vaccinations emerged as crucial. Health professionals focus more on MMR due to the availability of the vaccine and the threat of outbreaks. The vaccination system has flaws and inconsistencies with a lack of vaccination related data. There is urgent need for culturally appropriate vaccination and appropriately evaluated vaccination campaigns.

3.N. Workshop: IMAgiNE EURO: Quality of maternity care in the WHO European Region during the COVID-19 pandemic

Abstract citation ID: ckac129.188

Organised by: IMAgiNE EURO Study Group
Chair persons: Céline Miani (Germany), Marzia Lazzerini (Italy)
Contact: celine.miani@uni-bielefeld.de

From 2020 the COVID-19 pandemic has deeply affected maternal and neonatal care. The implementation of governmental policy responses to limit the spread of the disease and the development of new hospital protocols have forced healthcare workers and women alike to adapt. The perception of the quality of hospital care by both groups has been at the core of the IMAgiNE EURO project, led by the WHO Collaborating Center for Maternal and Child Health (Trieste, IT). With a network of 18 countries and more than 40 institutions, this collaborative project has gathered so far data from more than 50 000 births and 5000 health workers, through two validated online surveys. It allows monitoring the quality of maternal and newborn care in four domains: the three domains of the WHO Standards for improving quality of maternal and newborn care in health facilities (namely provision of care, experience of care, and availability of human and essential physical resources) and the additional domain of key organisational changes related to the COVID-19 pandemic. Following multi-country analyses, and analyses at the regional and national level, the project findings show major gaps in the perceived quality of maternal and neonatal care in hospitals during the pandemic, as well as large variations in practices across different countries of the WHO European Region. In this workshop, Dr. Emanuelle Valente (WHO Collaborating Center for Maternal and Child Health, Trieste, IT) first introduces the methodological development of the project and the two validated data collection instruments. Dr. Marzia Lazzerini (WHO Collaborating Center for Maternal and Child Health, Trieste, IT) then presents the main results of the women's questionnaire for all countries. The focus will be on the Quality of Maternal and Newborn Care Index (QMNC Index) and how the different countries perform with regard to the four above-mentioned dimensions. Then, we carry on with two presentations focusing on specific topics relevant to maternity and newborn care. Dr. Ilana Chertock (College of Health Sciences and Professions, Ohio University, Athens, Ohio, USA) and Dr. Rada Artzi-Medvedik (Ben-Gurion University, Beersheva, Israel) will present findings on the factors influencing exclusive breastfeeding in healthcare facilities during the pandemic. Dr. Céline Miani (Institute of Public Health, Bielefeld University, Bielefeld, Germany) will discuss the topic of medicalisation, looking at the potential associations between individual and country-level factors and medicalisation of birth. We will conclude the workshop with a panel discussion on the implications of our research for policies and practice, and examples of the first steps already taken to bridge the gap between monitoring and implementation.

Key messages:

- This workshop will present two new, validated tools to monitor the quality of maternal and newborn care in WHO European Region, from the perspective of the women and of the healthcare providers.
- It will also provide an overview of key findings so far, highlighting inequalities and gaps in the quality of maternal and neonatal care at hospital level in the WHO European Region.

Background:

Multi-country studies assessing the quality of maternal and newborn care (QMNC) during the COVID19 pandemic, as defined by WHO Standards, are lacking.

Methods:

Women who gave birth in 12 countries of the WHO European Region from March 1, 2020 - March 15, 2021 answered an online questionnaire, including 40 WHO Standard-based Quality Measures.

Results:

21,027 mothers were included in the analysis. Among those who experienced labour (N = 18,063), 41.8% (26.1%- 63.5%) experienced difficulties in accessing antenatal care, 62% (12.6%-99.0%) were not allowed a companion of choice, 31.1% (16.5%-56.9%) received inadequate breastfeeding support, 34.4% (5.2%-64.8%) reported that health workers were not always using protective personal equipment, and 31.8% (17.8%-53.1%) rated the health workers' number as ''insufficient''. Episiotomy was performed in 20.1% (6.1%-66.0%) of spontaneous vaginal births and fundal pressure applied in 41.2% (11.5% -100%) of instrumental vaginal births. In addition, 23.9% women felt they were not treated with dignity (12.8%-59.8%), 12.5% (7.0%-23.4%) suffered abuse, and 2.4% (0.1%-26.2%) made informal payments. Most findings were significantly worse among women with prelabour caesarean birth (N = 2,964). Multivariate analyses confirmed significant differences among countries, with Croatia, Romania, Serbia showing significantly lower QMNC Indexes and Luxemburg showing a significantly higher QMNC Index than the total sample. Younger women and those with operative births also reported significantly lower QMNC Indexes.

Conclusions:

Mothers reports revealed large inequities in QMNC across countries of the WHO European Region. Quality improvement initiatives to reduce these inequities and promote evidence-based, patient-centred respectful care for all mothers and newborns during the COVID-19 pandemic and beyond are urgently needed.

Funding: The study was financially supported by the Institute for Maternal and Child Health IRCCS Burlo Garofolo, Trieste, Italy.

Background:

Maternal experience of labour and delivery is multidimensional and is influenced by a variety of factors.

Aim:

to report maternal childbirth experience as described by the women themselves during the COVID-19 pandemic in Sweden using a WHO Standards-based tool adapted for an online survey (Quality of maternal and newborn care-QMNC).

Methods:

Women $\geq$ 18 years of age who gave birth from March 1, 2020 to June 30, 2021 were asked to give voluntary consent to participate in an online survey. The survey included 40 questions on four key domains: provision of care, experience of care, availability of human and physical resources and organisational changes due to COVID-19.

Results:

5003 women were included in the analysis. Among those who underwent labour (n = 4528), 46.7% perceived a reduction in QMNC due to the COVID-19 pandemic, 50.7% were not allowed a companion of choice, 62.5% reported that health workers were not always using protective personal equipment and 36.5% rated the number of health workers as ‘‘insufficient’’. Fundal pressure was applied in 22.2% of instrumental vaginal births and 36.8% received inadequate breastfeeding support. In addition, 18.4% of women did not feel treated with dignity and 6.9% reported some form of abuse. In general, findings were significantly worse among women who did not undergo labour (n = 475).

Conclusions:

Swedish mothers’ satisfaction of care provided during childbirth was strongly influenced by many variables. Actions to promote high-quality, evidence-based, patient-centered respectful care for all mothers and newborns are urgently needed.

Introduction:

According to the World Health Organization, the medicalisation of birth tends ‘‘to undermine the woman’s own capability to give birth and negatively impacts her childbirth experience’’. The COVID-19 pandemic has disrupted maternity care, with potential increase in the medicalisation of birth and in occurrences of disrespectful maternity care. We aim to investigate potential associations between individual and country-level factors and medicalisation of birth in 15 European countries during the COVID-19 pandemic.

Methods:

We collected data through an online, anonymous survey for women who gave birth in 2020-2021. We ran multivariable, multi-level logistic regression models estimating associations between indicators of medicalisation (caesarean section (CS), instrumental vaginal birth (IVB), episiotomy, fundal pressure) and proxy variables related to care culture and contextual factors at the individual and country-level.

Results:

Among 27173 women, 24.4% had a CS, and 8.8% an IVB. Among women with IVB, 41.9% reported receiving fundal pressure. Among women with spontaneous vaginal births, 22.3% had an episiotomy. Less respectful care, as perceived by the women, was associated with higher levels of medicalisation. For example, women who reported having CS, IVB and episiotomy reported not feeling treated with dignity more frequently than women who didn’t have those interventions (respectively: OR: 1.37; OR: 1.61; OR: 1.51; all: $p < 0.001$). Country-level variables contributed to explaining some of the variance between countries.

Conclusions:

We recommend a greater emphasis in health policies on the promotion of respectful and patient-centered care approaches to birth to enhance women’s experiences of care, and the development of a European-level indicator to monitor the medicalisation of reproductive care.

3.O. Workshop: Structural stigma shapes LGBTQ+ mental health and well-being across countries

Abstract citation ID: ckac129.192

Organised by: University of Exeter (UK)
Chair persons: David Doyle (UK)
Contact: d.doyle@exeter.ac.uk

Lesbian, gay, bisexual, transgender and queer (LGBTQ+) people around the world have been shown to suffer from disparities in mental health and well-being relative to cisgender heterosexual people. Past research aiming to explain these gaps has referenced the added stress experienced by LGBTQ+ people in the form of, for example, interpersonal discrimination, rejection, and harassment (i.e., minority stress). While these phenomena exist at the interpersonal level, emerging evidence suggests that discriminatory structural-level factors, such as policies, norms and rules (i.e., structural stigma), may be just as influential in shaping LGBTQ+ mental health and well-being. Given the passage of a slate of bills limiting sexual and gender minority rights and banning open speech around these issues across many different countries, this is an extremely timely issue for sexual and gender minority health. This workshop will give examples of cutting-edge research on the ways in which structural stigma affects mental health and well-being for LGBTQ+ people. Dr. Dinah Gutermuth (University of Exeter, UK) will discuss findings from a global study (conducted in partnership with the BBC) including older and younger LGB individuals from 113 different countries, showing that structural stigma impairs social capital and creates disparities in loneliness between younger and older LGB individuals. Berk Can Ünsal (Eötvös Loránd University, Hungary) will present data from Europe highlighting structural stigma as a risk factor, and community participation as a protective factor, for depression in sexual and gender minority people. Dr. John Pachankis (Yale University, USA) will present results on how migration from countries of varying levels of structural stigma shapes depression and suicidality in sexual minority men. Finally, Dr. Richard Bränström (Karolinska Instituet, Sweden), will discuss how average life satisfaction improved from 2012-2019 for sexual minority people across Europe, with greater increases in countries with higher levels of structural stigma. Together, these presentations will demonstrate the far-reaching effects of structural stigma on LGBTQ+ mental health and well-being around the world.

Key messages:

- Lesbian, gay, bisexual, transgender and queer (LGBTQ+) people around the world have been shown to suffer from disparities in mental health and well-being relative to cisgender heterosexual people.
- Structural stigma is an important factor determining risk for poor mental health among LGBTQ+ individuals across countries.

Background:

The mental health gap between sexual minorities and heterosexuals remains a pressing issue for policy makers and scholars. In past years, numerous studies from the US found support for the vast impact structural stigma on a state level can have on the lives of LGB individuals. However, most research has been conducted within a US context and research capturing structural stigma on a country level remains scarce. In the current study we aim to close this gap by examining whether country-level structural stigma can explain loneliness and social capital among sexual minorities across the world and testing whether these relationships are different for LGB individuals from different age groups.

Methods:

The current study analysed a sample of over 7000 LGB people from across 113 European and non-European countries to examine the influence of country-level structural stigma on individual level loneliness and social capital.

Results:

Multilevel models showed that the greater structural stigma present in a country, the lower social capital was experienced by LGB respondents (b = -0.05, 95% CI: -0.07, -0.02, $p < 0.001$). This relationship was unaffected by respondent age. Further, multilevel models showed the following for loneliness as an outcome: The greater structural stigma present in a country, the more loneliness was experienced by LGB individuals (b = .01, 95% CI: .01, .21, p = .048). Furthermore, this relationship was moderated by respondent age (b = -.03, 95% CI: -.06, -.01, p = .01), in the sense that younger LGB people showed significantly higher levels of loneliness than older LGB people in countries with greater, but not lesser, levels of structural stigma. These effects remained robust to adjustment for demographics as well as adding country-level covariates.

Conclusions:

The findings of this study demonstrate the impact structural stigma on a country level can have on LGB individuals' loneliness and social capital, differing for older and younger individuals.

Stronger together: Community participation, structural stigma, and depressive symptoms of sexual and gender minority individuals living across 28 European countries

Berk Can Ünsal

B Ünsal[1], Z Demetrovics[1], M Reinhardt[1]
[1]Institute of Psychology, ELTE Eötvös Loránd University, Budapest, Hungary
Contact: berk.unsal@ppk.elte.hu

Background:

Although previous studies demonstrated that structural stigma (i.e., discriminatory state laws, public policies, and attitudes) predicts adverse mental health outcomes among sexual and gender minority (SGM) populations, less is known how protective factors interact with structural stigma. Thus, we aimed to examine the associations between structural stigma, community participation, and depressive symptoms in a large sample of SGM adults.

Methods:

Discriminatory laws, policies, and attitudes affecting SGM people were assessed to measure each country's structural stigma levels (i.e., sexual and gender). Data from the 2019 EU-LGBTI-II-Survey assessing community participation levels and depressive symptoms of sexual minority men (n = 62.825), women (n = 38.912), and gender minority adults (n = 15.801) in 28 European countries were analyzed by using multilevel models.

Results:

The results demonstrated that structural stigma was positively, and community participation was negatively associated with depressive symptoms of sexual minority men (β = .147, p < .001; β = -.020, p < .05), women (β = .149, p < .01; β = −.040, p < .01), and gender minority adults (β = .085, p < .05; β = -.088, p < .001), respectively. Unlike sexual minority women and gender minority adults, for sexual minority men, a statistically significant interaction was found (β = .018, p < .05) such that participating to the community predicted lower depressive symptoms only in lower-stigma countries.

Conclusions:

The results highlight the need for changes in discriminatory laws, social policies, and negative attitudes that impact depressive symptoms of SGM individuals. Although community participation protects individuals from depression, these findings suggest that sexual minority men in higher-stigma countries benefit less from community participation. Thus, interventions aiming to increase SGM individuals' community participation should consider structural factors and gender differences.

Abstract citation ID: ckac129.195

Structural stigma and sexual minority men's depression and suicidality: A multi-level examination of mechanisms and mobility across 48 countries

Contact: john.pachankis@yale.edu

Background:

Sexual minority men are at greater risk of depression and suicidality than heterosexuals. Stigma, the most frequently hypothesized risk factor for this disparity, operates across socioecological levels-structural (e.g., laws), interpersonal (e.g., discrimination), and individual (e.g., self-stigma). However, there is limited data on whether changes in structural stigma, such as when a stigmatized person moves to a lower stigma context, affect mental health, and on the mechanisms underlying this association

Methods:

The current study uses data from the 2017/18 European Men-who-have-sex-with-men Internet Survey (n = 123,428), which assessed mental health and psychosocial mediators. We linked these data to an objective indicator of structural stigma related to sexual orientation in respondents' countries of origin (N = 178) and receiving (N = 48) countries

Results:

Among respondents who moved from higher-to-lower structural stigma countries (n = 11,831), longer exposure to the lower structural stigma environments of their receiving countries was associated with a significantly: 1) lower risk of depression and suicidality; 2) lower odds of concealment, internalized homonegativity, and social isolation; and 3) smaller indirect effect of structural stigma on mental health through these mediators.

Conclusions:

This study provides evidence that structural stigma is associated with the mental health of sexual minority men, both through proximal experiences and as a function of length of exposure to structurally diverse contexts, at least for those who move higher-to-lower structural stigma contexts. Findings suggest the importance of routinely assessing life-course structural influences on mental health and deploying interventions to address those influences.

Abstract citation ID: ckac129.196

Structural stigma and 7-year improvement in life satisfaction: A repeated cross-sectional study of sexual minority individuals across 28 countries

Richard Bränström

R Bränström[1], *J Pachankis*[2]
[1]Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden
[2]Department of Social and Behavioral Sciences, Yale School of Public Health, New Haven, USA
Contact: richard.branstrom@ki.se

Background:

Structural stigma toward sexual minority individuals varies widely across countries and is associated with psychosocial health outcomes. Yet, the association of changes in country-level structural stigma over time, as has recently characterized many European countries, with such outcomes is largely unknown. The current study examined the association between change in structural stigma from 2012 to 2019 across European Union countries and change in life satisfaction among sexual minority individuals during the same period. Secondary analyses examined whether changes in structural stigma differentially benefitted some subgroups of sexual minority individuals more than others.

Methods:

The current study analyzed data from sexual minority respondents (2012: n = 82,668; 2019: n = 96,576) living in 28 European countries.

Results:

Adjusted multilevel models showed that life satisfaction had improved among sexual minority individuals in all countries between 2012 and 2019 (β = 0.32, 95% CI: 0.29, 0.35), but the improvement was stronger among those living in higher stigma countries compared to those living in lower stigma countries. Changes also varied by relationship status; the strongest improvement in life satisfaction as a function of improvement in structural stigma was found among sexual minority individuals in a relationship.

Conclusions:

Although life satisfaction has increased during the past decade among sexual minority individuals living in Europe, significant variation in this change exists across countries as a function of country-level structural stigma and individual sociodemographic characteristics. The findings support the relevance of structural stigma for sexual minority individuals' life satisfaction and call for further research to understand the differential impact of structural stigma across sexual minority subgroups.

3.P. Round table: The Commercial Determinants of Health: Industry tactics shaping science, policy and our environment

Abstract citation ID: ckac129.197

Organised by: LSHTM (UK)
Chair persons: Mark Petticrew (UK)
Contact: claire.mulrenan@lshtm.ac.uk

Prevailing narratives on health and illness emphasise individual choice and product 'misuse' for the disease and environmental burdens associated with harmful industries, deflecting from the wider environment in which these choices are made. Public Health frameworks such as the Dahlgren and Whitehead model enable us to consider the broader socio-economic, cultural and environmental conditions that influence these choices (or lack thereof). Until recently, the influence of multinational corporations on these broader conditions has often been ignored, despite the global impact these corporations have in shaping science, policy and our environment. Increasingly Public Health academics and advocates are calling for an enhanced focus on these 'commercial determinants of health' (CDoH) to understand the ways through which corporate interests affect health, sustainability, and health inequities. The concept of CDoH considers (among other things) the harmful or damaging nature of certain products and the tactics employed by industries to protect their commercial interests. The harmful tactics employed by the tobacco industry are well documented, but there is growing evidence that similar tactics are employed by other harmful industries more generally, from alcohol, gambling and food, to agrichemical and fossil fuel industries. In addition to driving consumption (with resulting population and planetary ill health), these tactics have a cross-industry, complementary, cumulative effect; spreading misinformation, shaping 'personal responsibility' and 'nanny state' narratives, weakening regulation and undermining science and policy-making. The impact of these harms accumulates across the life-course, with differential exposure to both harmful products and tactics driving health inequities. We argue there is a need to make visible, or 'resurface' these tactics; at present, Public Health often fails to challenge corporate strategies and, more concerningly, can be complicit in reinforcing industry framings of issues. This session will outline how a life-course, complex systems approach can support this endeavour, exploring a range of industry strategies through a series of case studies and discussing actions needed to safeguard public understanding and policy from commercial interests. This workshop will include 3 short presentations to illuminate some of the more insidious and less overt tactics, with opportunities for questions and panel discussion.

The CDoH is an emerging field in Public Health and this session will give audience members an introduction to industry strategies and influences within a life-course framework, focusing on less overt channels of influence and some of the lesser-known industries.

Key messages:

- The commercial determinants of health present a significant threat to public and planetary health but are conspicuously absent in the majority of public health conceptual frameworks.
- Framing these hidden harms and exposures within the life-course model can support awareness of CDoH and facilitate public health professionals to counter corporate influences.

3.Q. Workshop: Using foresight to anticipate future public health challenges

Abstract citation ID: ckac129.198

Organised by: RIVM (Netherlands), Sciensano (Belgium), PHIRI, EUPHA-PHMR, EUPHA-FS
Chair persons: Henk Hilderink (EUPHA-FS), Petronille Bogaert (EUPHA-PHMR)
Contact: henk.hilderink@rivm.nl

The COVID-19 pandemic brought great uncertainty about current and future health impacts. Uncertainty about how the virus would directly impact our health. And uncertainty about indirect impacts of COVID-19 on long-term health and wellbeing, including consequences due to delayed prevention, diagnosis, and medical treatment. At this point in time, we know a lot more about the immediate mortality and morbidity aspects. How we fare on the wider impacts on the longer term is more difficult to say. A structured tool for gaining in sight in this, is foresight. We use this tool within the Population Health Information Research Infrastructure (PHIRI). PHIRI supports research across Europe through the identification, access, assessment and reuse of population health and non-health data to underpin public health policy decisions. PHIRI is a practical use case and lays the foundation for ultimately developing a Distributed Infrastructure on Population Health (DIPoH). The joint workshop aims to show ways to better understand the complexity of the wider impacts of the SARS-COV-2 virus on population health across Europe; show how a research infrastructure might help researchers in Europe build capacity and helping each other to achieve higher goals. The workshop will begin with a presentation providing a brief overview of the PHIRI foresight work. This will be followed by two researchers who participated in the PHIRI foresight training program and undertook their own Public Health Foresight study. In the last presentation of the session foresight will be reflected on from a policy perspective. How can researchers and health policy makers better interact to have better foresight-informed policy making. Interaction with the audience will be guaranteed using Mentimeter questions. With this interactive element, insights art obtained what people find the most important trends to act upon, what they consider most important future challenges and how researchers and policymakers can better interact.

Key messages:

- Foresight studies are essential to be better prepared for and to anticipate to future challenges.
- With foresight-informed policy making direct and indirect health impacts of COVID-19 are addressed.

Abstract citation ID: ckac129.199
Using foresight methodologies to tackle SARS-COV-2 related health impacts

Mariken Tijhuis

M Tijhuis[1]*, D Moye Holz*[1]*, M Rodriguez*[1]*, M Peyroteo*[2]*, H Hilderink*[1]
[1]RIVM, Bilthoven, Netherlands
[2]NOVA, Lisbon, Portugal
Contact: mariken.tijhuis@rivm.nl

Background:

A better understanding of possible future developments is essential for policy makers to anticipate and influence these trends. Public health foresight studies (PHFS) are tools to support this. The current health crisis makes clear that PHFS are necessary more than ever to target possible future impacts resulting from SARS-COV-2 induced changes in e.g. regular health care services, lifestyle and socio-economic developments. To support European countries in doing their own foresight studies, PHIRI aims to strengthen foresight capacity.

Methods:

PHIRI follows a 4-step approach: 1. Making an inventory of current PHFS capacities and capacity needs across European countries using desk research and an online survey; 2. Providing PHFS capacity building via a training course and workshops; 3. Supporting the development of public health scenarios for the short term (0-5 years) and longer-term (5-20 years); 4. Supporting the identification of promising policy strategies, using policy dialogues.

Results:

The online survey was completed by participants of 21 countries and shed light on existing national PHFS and needs for capacity building. It also provided a basis for the development of a professional network on PHFS within the project. A PHFS capacity building course was developed, including videos posted on the PHIRI website and a template structuring the different foresight elements. Around 15 researchers undertook their own PHFS, covering a wide range of public health topics, using the material provided during the course. In addition, a compact guide was developed and provided, explaining the different foresight elements. Based on these studies, common challenges and promising policies are identified.

Conclusions:

Foresight in public health is gaining more and more interest, especially now in these times of crisis. PHIRI provides more insight in the wider public health impacts of the SARS-CoV-2 pandemic and in translating this into policy options.

Abstract citation ID: ckac129.200
The future of health digitalization: The case of Primary Health Care in Portugal

Mariana Peyroteo dos Santos

M Peyroteo dos Santos[1]*, L Lapao*[1]
[1]NOVA, Lisbon, Portugal
Contact: mariana.peyroteo@nms.unl.pt

Background:

The sustainability of Healthcare Services will depend on the proper implementation of the digital transformation of Primary Health Care (PHC) Services. COVID-19 Pandemic have shown precisely this, where there was pressure from health Professionals and managers for the integration of teleconsultations within the health work processes. This study aims at developing scenarios for the digitalization of PHC in the Portuguese Health System.

Methods:

This study follows the methodology of scenario development, similar to the future of community pharmacy services scenario study. A conceptual model of PHC services was developed, based on the literature and a set of interviews. The target group was the primary healthcare professionals: family doctors, nurses, and operational assistants. The time horizon was 2032 and, by selecting actors from different regions of Portugal, it was possible to achieve broad representativeness.

Results:

Three focus groups were conducted. The first enabled to identify the two driving forces that may influence the digitalization of PHCs in the next 10 years: 1) service innovation and 2) Governance and Regulations. These two driving forces enabled to design three plausible scenarios: a) Innovate or Fade-away; b) Isolated PHC and c) Digital PHC. These scenarios were developed, and their impacts were reflected upon. It was found that the role of human Resources is critical.

Conclusions:

The process of reflection and discussion for the identification of the different driving forces made the different actors discuss the different points of view and find a meeting point to reach a conclusion. Furthermore, this study allowed the different stakeholders to understand the measures and actions to be taken for PHC digitization to be implemented in the most effective way, allowing the sustainability of the National Health Service in Portugal, which until this point were only ideas discussed at the institutional and individual level.

Abstract citation ID: ckac129.201
Potential gains by effective early detection of diseases: proposal to approach informing public health policy in the Czech Republic

Ondrej Majek

O Majek[1]*, O Ngo*[1]*, K Hejduk*[1,2]
[1]Institute of Health Information and Statistic, Prague, Czechia
[2]Institute of Biostatistics and Analyses, Prague, Czechia
Contact: ondrej.majek@uzis.cz

Background:

Significant amount of disease burden could be averted by early detection and treatment of diseases. In the Czech Republic, National Screening Centre (NSC) of the Institute of Health Information and Statistics is responsible for informing public health policy in the field of early disease detection. The objective of the proposed early detection public health foresight study (PHFS) is to gather evidence, use available computational tools, utilise knowledge and opinions of stakeholders, and summarize it in a systematic manner to inform public health policies. The presentation outlines the approach undertaken within the proposed early detection PHFS.

Methods:

The key source of data for monitoring of population health status and healthcare system in the Czech Republic is the National Health Information System (NHIS). The study will also utilise external sources of data, namely demographic projections and data on global burden of disease, as well as qualitative data from stakeholders. The study will also utilise analytical tools and outputs developed by NSC (situational analyses, decision modelling, etc.). The conceptual model of the study will cover important underlying aspects like public policies, driving forces, population health and healthcare system, and health impact variables.

Results:

The proposal for early detection PHFS has been developed within the PHFS capacity building course, utilising the experience and insights of tutors and fellow participants. The development of study methodology was accompanied by gathering of evidence and consultations with relevant stakeholders.

Conclusions:

PHFS is a very useful approach to assess possible future developments of public health system, achieve participation of stakeholders, and to inform public health strategies. Following finalisation of the early detection PHFS protocol, governing board of the NSC will decide on the degree of implementation of the study.

Abstract citation ID: ckac129.202
Foresight methodologies to unravel the indirect health economic impact of the COVID-19 pandemic on cancer care and management in Belgium studied in the HELICON project

Yasmine Khan

Y Khan[1,2]
[1]Department of Public Health and Primary Care, Ghent, Belgium
[2]Department of Epidemiology and Public Health, Sciensano, Belgium
Contact: yasmine.khan@ugent.be

Background:

The COVID-19 pandemic had indirect effects on segments of the population affected with non-COVID-19 diseases e.g. through delayed care and management of cancer patients. Early diagnosis and appropriate treatment are key to improving patient outcomes and reducing societal and health care costs. Tio support policymakers to anticipate these trends a public health foresight study (PHFS) was done.

Methods:

The PHFS follows a structured approach provided through a compact guide and is supervised by PHIRI team members. Its evolution is measured through a template gathering data on the study's contextual information, objective, main target groups, conceptual model, indicators, driving forces, time horizon, spatial unit, identifying uncertainties, scenario logics, scenario type, stakeholders, data, tools and instruments, projection methods, communication strategy/products, and the uptake of results and evaluation.

Results:

Several foresight elements were identified. Contextual information on the resources and governance structure were elucidated. The objective was made clear by identifying the topic, general issue, and sub-issues of the initial study. A conceptual model was developed to analyse the interaction of the topic with other aspects that could influence it. The main driving forces, which are factors that influence the studied topic, were then determined through the DESTEP method. Stakeholders were identified and classified through the power-interest matrix.

Conclusions:

Establishing a foresight study on the indirect impact of the COVID-19 pandemic on the care and management of cancer patients allows exploring potential and unsuspected issues that may affect society, health care systems, and patients. Those groups should not be considered individually but as an ecosystem continuously interacting, where a decision may affect everyone. This type of information may be of high relevance to policy- and decision-makers in their public health interventions.

Abstract citation ID: ckac129.203
Foresight for policy – addressing the challenges for policy impact

Laurent Bontoux

L Bontoux[1]
[1]JRC, ISPRA, Italy
Contact: laurent.bontoux@ec.europa.eu

Background:

The role of policymaking is to create the future that we want. In its communication on Better Regulation, the European Commission recognises the need for strategic foresight to play a key role in helping to 'future-proof' EU policymaking. The aim is to ensure that decisions are grounded in a longer-term perspective. In times of rapid change, EU policymaking needs to have impact assessments, fitness checks and major regulatory evaluations informed by foresight. Strategic foresight is also a powerful way to engage with stakeholders and not only capture their perspectives, but also generate collective intelligence in the areas of policy interest.

Lessons from EU policy making:

This fits within a broader effort at the Commission to be at the forefront of excellence in policymaking in Europe and worldwide. This is why the EU Policymaking Hub was launched 2020. It offers a platform for policymakers to learn, collaborate and share knowledge in EU policymaking, introducing new capacity building offers. It aims at strengthening the Commission's policymaking capacity through anticipating, developing, implementing, monitoring, and evaluating policies in an evidence-informed, transparent, and collaborative way with stakeholders, citizens and experts. Providing the policymaking community with a framework for long-term competence development will strengthen the profession, make it fit for the future, contribute to colleagues' motivation and help the Commission to achieve its goals.

Conclusions:

Being futures literate covers a range of skills from anticipation to the ability to run in-depth foresight processes. It spans a range of abilities from having an anticipatory mindset to scanning for change, understanding change and being able to influence change. Since its inception, this competence framework is at the base of an effort to train European civil servants in foresight and to increase foresight literacy for application in policymaking.

4.A. Workshop: Lessons from the response to COVID-19 to inform strengthening of Essential Public Health Functions

Abstract citation ID: ckac129.204

Organised by: Health Information and Quality Authority, WHO, Department of Health in Ireland
Chair persons: Michelle O'Neill (Ireland), Ronan Glynn (Ireland)
Contact: kcardwell@hiqa.ie

Internationally, the COVID-19 pandemic has increased disease burden and mortality, impacted mental health and wellbeing and delayed diagnosis and treatment of non-COVID care. It has been argued that, had sufficient funding of Public Health, including pandemic preparedness, been in place historically, many shortcomings of the pandemic response could have been mitigated. Thus, strengthening Public Health systems is on the agenda of governments internationally. Areas of specific interest are, emergency preparedness, international cooperation and solidarity, promoting vaccination uptake, health equity and community engagement, health literacy and misinformation (particularly online), planning for future workforce requirements and harnessing digitalization in health to address communicable and non-communicable disease threats. The Essential Public Health Functions (EPHFs) provide a comprehensive, cost effective and operational approach to strengthening Public Health and are recognized by the WHO as key to building health system resilience. In a recent report, the WHO has proposed an approach to operationalizing the EPHFs, identifying key enablers that can be applied within specific country contexts. This workshop will describe the national and international research undertaken by the Irish Health Information and Quality Authority (HIQA) and the WHO at the request of the Department of Health to inform reform of the delivery model of Public Health in Ireland. HIQA and WHO will present the evidence base in terms of the value of EPHFs for health system strengthening, the findings of research to describe changes in Public Health structures and lessons learned in Ireland and across 12 countries during the COVID-19 pandemic, a description of the current state of delivery of the EPHFs within Ireland, and the results of a consultation survey distributed by the Department of Health in Ireland, investigating the experiences of organisations involved in the delivery of Public Health in light of the pandemic. The presenters will allow ample time for audience engagement and discussion with the expert panel to enable shared learning and to discuss the applicability of these findings to the reform and strengthening of the delivery of the EPHFs.

The workshop objectives are to:

- Describe the current evidence base in terms of the value of EPHFs for health system strengthening and the key enablers to support their application at country level.
- Describe the recent changes and lessons learned regarding the delivery of the EPHFs during the COVID-19 pandemic in 12 countries.
- Describe the delivery of the EPHFs in the Irish system in light of experience with COVID-19 and with awareness of current and future health system stressors.
- Describe Public Health organisations' experiences of delivering the EPHFs in Ireland in light of the pandemic.
- Provide insights into how the delivery of the EPHFs could be reformed and strengthened for the future.

Key messages:

- Lessons from the Public Health response to COVID-19, internationally and in Ireland will be discussed.
- The workshop will provide a space to share ideas on reform and strengthening EPHF delivery.

Abstract citation ID: ckac129.205

Applying Essential Public Health Functions in building health systems' resilience globally

Yu Zhang

Y Zhang[1], S Mustafa[1], G McDarby[1], R Seifieldin[1], S Saikat[1], G Schmets[1]
[1]Health Services Resilience Team, WHO, Geneva, Switzerland
Contact: zhangyu@who.int

Background:

The COVID-19 pandemic has exposed Public Health system weaknesses due to chronic underinvestment in Public Health. In this context, Essential Public Health Functions (EPHFs) have been revitalized as an integrated, cost effective and sustainable approach to operationalising Public Health. The World Health Organization's recent position paper on building health systems resilience towards universal health coverage and health security recommended investing in EPHFs as a key mean for countries' health systems recovery and transformation during COVID-19 and beyond. There is a need for conceptual and operational clarity of EPHFs to support countries to build back better, fairer and more resilient health systems.

Methods:

A rapid review of peer-reviewed and grey literature regarding the EPHFs was conducted to identify different actors' understandings of EPHFs and key lessons of applying the EPHFs at the global, regional and national levels, in order to identify the added value and key enablers to operationalising EPHFs. A crosswalk analysis of different authoritative lists of EPHFs was conducted to develop a common list of EPHFs as a reference for countries in response to Public Health challenges.

Results:

A consolidated list of 12 EPHFs derived from the crosswalk analysis of different authoritative lists is presented, underpinning the consideration of health systems components and pressing health challenges. Six key enablers are identified from evidence and experience. These enablers are fundamental for countries to build holistic and strong Public Health capacities.

Conclusions:

The EPHFs provide a clear and integrated framing to operationalise Public Health in countries that can be adapted to country contexts to build resilience. Health authorities and other Public Health stakeholders must seize the opportunity brought by COVID-19 recovery to continue advocating for and strengthening Public Health as a priority in health systems' reconstruction and reform.

Abstract citation ID: ckac129.206

High level review of configuration and reform of Public Health systems in selected countries

Karen Cardwell

[4]Department of Pharmacology and Therapeutics, Trinity College Dublin, Dublin, Ireland
Contact: kcardwell@hiqa.ie

Background:

The impact of the COVID-19 pandemic has prompted governments internationally to consider reform and strengthening of their Public Health systems. To support this work in Ireland, we undertook a review Public Health systems internationally (research question [RQ] 1), and identified lessons learned from the COVID-19 pandemic (RQ2).

Methods:

Data relating to Public Health systems (RQ1), and lessons learned (RQ2) for a select group of 12 countries were identified from organisations' websites, an electronic database and grey literature search and representatives from key national-level organisations. Data for RQ1 were extracted, mapped to the 12 Essential Public Health functions (EPHFs) at national, regional and local levels, and verified by participating representatives. For RQ2, thematic analysis of semi-structured interviews with participating representatives was undertaken and.

Results:

Typically, across all included countries, there is national strategic oversight of all EPHFs and, for certain functions, there is regional and local level implementation. Lessons learned from the COVID-19 pandemic broadly related to the themes of legislation and decision making; data collection, surveillance, evidence synthesis and collaboration; public

health interventions; public participation, public messaging and communication; continuation of healthcare services; and workforce capacity and resilience.

Conclusions:

When structuring Public Health systems, there is a need to identify which functions, and or which elements of a function, should be delivered at a national, regional or local level to ensure a sustainable and comprehensive Public Health system. Appropriate IT infrastructure, strong communication and an established evidence synthesis function are key to timely and informed decision making. Ideally, these functions should be established during periods of relative stability to permit a faster response during a pandemic or emergency situation.

Background:

COVID-19 has caused unprecedented disruptions to health, social and economic systems in countries worldwide including Ireland. Weaknesses in Public Health capacities have undermined health system resilience compounding the effects of the pandemic. The Essential Public Health Functions (EPHFs) provide a comprehensive, cost-effective approach to operationalising public health and a means to build health systems resilience. As Ireland looks to recovery, the Department of Health engaged the World Health Organization (WHO) to undertake a mapping of the current state of delivery of EPHFs to identify opportunities for improvement and support wider health system strengthening towards resilience.

Methods:

A strategic review of the delivery of EPHFs in Ireland was conducted with respect to policy, infrastructure, service provision and coordination and integration. Findings were reported in the context of international lessons identified through experience with COVID-19 and major health system challenges within the Irish context.

Results:

There are significant capacities present within the Irish context to support the delivery of the EPHFs though they are limited in strategic cohesion, coordination and implementation. These include a high level of Public Health expertise, an agile and resourceful workforce, a strongly engaged community and significant evidence generation and synthesis capacities. Gaps recognised included ICT infrastructure and capacity, workforce resourcing and support, pandemic planning and public health governance, visibility, legislation, strategy and resourcing. COVID-19 has led to the development and strengthening of mechanisms to leverage a whole-of-government and -society approach to health that should be sustained to tackle ongoing and future stressors.

Conclusions:

The use of the EPHFs within the Irish setting provides a comprehensive approach to strengthening capacities for public health and enhanced population health and wellbeing.

Contact: mnorris@hiqa.ie

Background:

The COVID-19 pandemic has placed healthcare systems worldwide under unprecedented pressure, with the Irish Public Health system no different. To strengthen delivery of Essential Public Health Functions (EPHFs) and increase future pandemic preparedness, Public Health leaders are now focused on identifying learnings from the pandemic. Within Ireland, given their experience, organisations situated within the Public Health system may be in a unique position to provide valuable information around the delivery of EPHFs, both prior to and in light of the COVID-19 pandemic, and how this can be improved in the future.

Methods:

An online survey was distributed by the Department of Health, from 2 March 2022 to 25 March 2022, amongst organisations situated within the Public Health domain in Ireland. The survey consisted of six open-ended questions around the delivery of EPHFs prior to and in light of the pandemic, success stories that could provide scalable solutions to EPHF delivery and current health system barriers, key areas in the public health system that require strengthening, and barriers to achieving these actions. Thematic analysis to identify key themes was conducted on survey responses.

Results:

Twenty-eight organisational responses were received. Themes around the workforce were apparent throughout, with staff training, staff diversity and staff morale, identified as areas for strengthening EPHF delivery. Themes around ICT, data collection and research were frequently identified with a lack of adequate ICT identified as a key lesson from the pandemic, while the Public Health ICT strategy was identified as key to strengthening future EPHF delivery.

Conclusions:

In general, themes around the workforce; leadership, management and governance and ICT, data collection and research were reoccurring across organisational responses and therefore may be key areas for consideration when strengthening delivery of the EPHFs in Ireland.

4.B. Workshop: Addressing backlogs and managing waiting lists during and beyond the COVID-19 pandemic

Abstract citation ID: ckac129.209

Organised by: European Observatory on Health Systems and Policies
Chair persons: Ewout Van Ginneken (Germany), Sarah Reed (UK)
Contact: ewout.vanginneken@tu-berlin.de

As COVID-19 cases started to rise in early 2020 and hospitalisation rates increased, health systems began to postpone non-emergency (elective) procedures to keep capacity available for COVID-19 patients, and to avoid elective patients being infected. This has subsequently led to longer waiting lists and waiting times in virtually all countries. Issues around staff recruitment and retention, which have been exacerbated by the COVID-19 pandemic, have further aggravated the problem. For patients with common elective surgeries, such as hip and knee replacements, the backlog in care means that improvements in health and quality of life are postponed. For urgent care, such as missed chemotherapy sessions for cancer care, the delays can have more severe consequences. For other patients, the postponement of specialist appointments may lead to missed referrals for serious ailments. Increasingly also primary care has become affected leading to late diagnosis of chronic diseases, as well as inadequate follow up and control of these patients. Each delay in diagnosis and treatment may worsen health problems, prolong recovery and decrease the patients' chances of survival. Countries are now left playing catch-up on these backlogs. There is however great uncertainty regarding the size of the backlogs, how much current and future capacity will be required to address them, and how much provider and workforce capacity will be needed for COVID-19 patients which will detract capacity for non-COVID patients. If health systems do not manage to reduce the backlog, they risk worsening health outcomes and wasting important health gains made in the last years. This workshop will discuss what we know about (1) the level of service disruptions and resulting backlog, (2) the drivers of backlog, and (3) which policies countries are using to address this. The workshop will conclude with an audience discussion about how to measure the true size of the backlog, the policy options for overcoming backlog and key priorities for further research.

Key messages:

- The COVID-19 pandemic has led to substantial disruptions in care delivery leading to care backlogs in virtually all countries.
- Countries have various policy options to tackle backlogs and bring down waiting times in the wake of the pandemic.

[2]Health Workforce and Service Delivery, WHO Regional Office for Europe, Copenhagen, Denmark
Contact: tillef@who.int

Since the onset of the COVID-19 pandemic, there have been concerns that shifting health system capacities towards acute COVID-19 cases can affect the provision of non-COVID-19 essential health services, causing severe disruptions and lack of care. Examples of this have been seen during other epidemic outbreaks, such as the 2014-2016 Ebola outbreak in West Africa. To capture the degree of service disruption across the European and Central Asian region, we analysed data from the World Health Organization's Pulse Survey on the Continuity of Essential Health Services, conducted in three rounds in 2020 and 2021. The key findings include:

– Health service provision has been heavily disrupted in virtually all countries. 91% of countries reported service disruptions in late 2021, indicating that health services continue to be disrupted at large scale.

– Service discontinuation has been substantial across all levels of care and in most service areas, often resulting in delays and cancellations of elective and emergency procedures, routine visits, prescription renewals, and referrals to specialty care. This has led to growing backlogs and record waiting times for services.

– Countries have been affected to varying degrees and report different levels of service disruption, size of the backlog, recovery of services aiming for pre-pandemic levels, and interventions to manage waiting lists.

The findings indicate that even as health systems are better learning to care for acute COVID-19 patients, the pandemic's impact on essential health services is massive and likely to affect the care for people's health and well-being post the acute phase of the public health emergency. Measuring the size of backlogs and implementing innovative care solutions are urgent and paramount.

What are the drivers of waiting times, waiting lists and backlog during and following the COVID-19 pandemic?

Luigi Siciliani

L Siciliani[1]
[1]Department of Economics and Related Studies, University of York, York, UK
Contact: luigi.siciliani@york.ac.uk

The COVID-19 pandemic put a halt to the number of patients being treated thus generating larger excess demand and a greater mismatch between demand for health care services and the supply of services provided. This presentation will provide a conceptual framework for understanding the dynamic interrelation between waiting times, waiting lists and the backlog over time. Data from different countries will be used to illustrate and rationalise how waiting times, lists and volumes evolved over time. It will then discuss factors driving the demand and supply of care during Covid, and emphasise the critical role of supply in absorbing the backlog and reducing the waiting list under different scenarios, as well as factors on the demand side both in the short run and the long run. Supply determinants include the availability of health workers as key factor to "bounce back", their productivity and provider capacity (hospital beds, operating theatres), the cost of providing treatment in a safe environment, financial capacity to fund additional supply both by public and private providers, interventions to minimise staff exhaustion and burnout, payment systems which are aligned with higher volumes, and technologies and digital solutions. Demand determinants include ageing and rising chronic conditions, and multi-morbidity patients (including long-COVID patients), increasing expectations, new technologies, prioritisation protocols, but also fear of infection which can leading to a temporary or permanent reduction in demand but an increase in unmet need. The framework will be used to discuss policy options both on the demand and the supply side to deal with the backlog, but also to improve the resilience and efficiency of health systems.

Abstract citation ID: ckac129.212
Health system recovery from Covid-19: What policies are health systems using to tackle backlogs and bring down waiting times in the wake of the pandemic?

Sarah Reed

S Reed[1], L Schlepper[1], N Edwards[1]
[1]Nuffield Trust, London, UK
Contact: sarah.reed@nuffieldtrust.org.uk

The pandemic has left even the most well-equipped health systems vulnerable and required difficult trade-offs to balance both Covid-19 and non-Covid-19 health services. Across the globe, planned and routine health services have been scaled down during peaks of the crisis to meet the needs of acute and Covid-19-related care, resulting in growing care backlogs and increase in the number of patients waiting for treatment. To identify potential policy solutions, we have consulted the Covid-19 Health System Response Monitor, interviewed experts and analysed recovery strategies in 16 OECD and EU countries. Many country responses display striking similarities despite very real differences in the organisation of health and care services. These include:

1) increasing the supply of workforce by widening the scope of authority for different roles, investing heavily in recruitment and training for key roles, and improving the terms and conditions of work;
2) boosting productivity by introducing financial incentives and targets, reconfiguring facilities to better separate planned and emergency work'', optimising referrals and waiting list management, and outsourcing more care to the private sector; and
3) investing in out-of-hospital alternatives to care, including expanding primary and community care models and developing digital, home care and rehabilitative capacity

Policymakers will need to balance the immediate pressures of clearing backlogs with long-term measures that place services on a more sustainable footing. International experience shows how these can be at odds, especially if actions taken in the short term exhaust an already depleted workforce, or resolve Covid-19-specific problems but leave services less prepared for tomorrow's challenges.

4.C. Workshop: Promoting health without borders: cross-border public health policy in the Euregio Meuse-Rhine

Abstract citation ID: ckac129.213

Organised by: EUPHA-PHPP, Gesundheitsamt Düren (Germany), Foundation euPrevent (Netherlands)
Chair persons: Sofia Ribeiro (EUPHA-PHPP)
Contact: sofiafigribeiro@gmail.com

For more than 20 years, different public health institutions in the German-Belgian-Dutch border triangle have been involved in cross-border public health activities. The partners in the Euregio Meuse-Rhine (EMR), as this area is called, have jointly implemented studies on COVID-19 and on adolescent risk behaviour. They have established joint health reporting for various purposes and implemented prevention measures together. The special problems in the border regions during the Corona pandemic have once again impressively shown how important cross-border cooperation is - also for cross-border public health policy. In the health sector, orientation towards municipal, state and federal borders does not lead to the desired results. The results of the Euregional COVID 19 study of 2021 show that in this way a 'borderless' life - and partly also cross-border health care - cannot be adequately served. In fact, in the everyday life of a border community, there is hardly any difference between a district border and a national border. In the EMR, this is exemplary for the entire European Union, with its many national or local responsibilities. For infectious diseases, lifestyle risks, environmental toxins or climate risks, borders have no meaning. For health, however, they do. Cross-border policy and politics is the appropriate response to real European conditions. The workshop will show the possibilities and results of cross-border policy on the basis of 3 examples from the long-standing cooperation of public health actors from the Euregio Meuse-Rhine. Finally, we will present these factors and put them up for discussion. From these and other activities, the factors that enable or hinder policy along borders can be deduced. We will present these factors, classify their significance and present the possibility of generalisation for cross-border work for discussion.

Key messages:
- Cross-border policy and coordination are the appropriate responses to the current realities in the European Union.
- National differences in culture, administration and policy can be obstacles to cooperation; but are usually inspiration for new approaches and input for best practice.

Euregional Youth Survey Structure and results of the cross border youth surveys

Dirk Philippsen

D Philippsen[1]
[1]Department of Public Health Reporting, Gesundheitsamt Kreis Düren, Düren, Germany
Contact: d.philippsen@kreis-dueren.de

The Euregional Youth Study takes place at intervals of currently 4 years since 2001. The Dutch, German and Belgian municipalities of the Euregio Meuse-Rhine (EMR) can participate. Pupils in the 8th and 10th grades are asked about various topics in an online questionnaire. These include: physical and emotional well-being, physical activity, nutrition, media behaviour, drug use and school behaviour. In 2019, 88 schools with more than 13,500 participants took part. With its cross-border approach, the study provides the opportunity to compare the living conditions, behaviour and health situation of pupils in the three countries. Ideally, this would result in common policy and prevention approaches and best practice options. For example, there are differences between the regions of the EMR regarding drug use or overweight, while risky media use is rather universal. It is striking that the Dutch participants almost consistently show the best values. It is also important to stress the importance of insight in policy along the border. Changes in policy actions have a huge effect on border regions. Examples are:

The change in drinking age in the Netherlands: from 16 to 18 resulted in organizing their parties in the neighbouring countries.

The change in cannabis policy in the Netherlands in the 2000s, is clearly reflected in the purchasing behaviour of German young people.

Independent of the cross-border aspects, the Euregional Youth Survey provides a standard data set (also with trends over time) for the adolescents of the participating districts, which the local health offices could not realise on their own and which is not self-evident for German municipalities.On the other hand, it is certainly considered as problematic that there is no binding and uniform participation of the EMR partners in the study. This leads to a partial loss of comparability and significance of the Euregional Youth Study.

The Euregional policy impact of COVID 19 on the border region between the Netherlands, North-Rhine Westphalia and Belgium

Christian JPA Hoebe

C Hoebe[1,2]
[1]GGD, Zuid-Limburg, Heerlen, Netherlands
[2]Department of Social Medicine, University of Maastricht, Maastricht, Netherlands
Contact: Christian.Hoebe@ggdzl.nl

During the Coronavirus pandemic, internal European borders were temporarily re-established with the argument to mitigate the outbreak. Also in the border region between the Netherlands, North-Rhine Westphalia and Belgium (EMR). Existing evidence on the effectiveness of border control for infectious disease control (IDC) has been dominated by studies that focused on scenarios within countries with limited attention to border regions. To address this gap, we analysed the experiences of public health professionals working in European border regions. We conducted three studies: 1. seroprevalence and questionnaire study among 10.001 Dutch persons with and without cross border mobility, 2. analyses of incidence data in municipalities in 4 cross border regions to analyse cross border differences, and 3. we conducted 27 semi-structured interviews with public health professionals in the EMR. Participants were asked about their perspectives on border controls and the spread of Covid-19.

Four key-results: First, border regions are characterised by dynamic social life and cross-border movements. Incidence was mainly determined by country policy, Second, the impact of border control and closing on local infectious disease epidemics is likely marginal. Third, due to the dynamic social life, border control measures cannot be fully implemented in border regions, and thus their effectiveness is even more questionable. Fourth, border control measures may harm the social fabric of border regions more than they do in in-countries territories. Our study results highlighted the ineffective role of border control measures for regional infectious disease control. Sustainable cross-border collaboration is crucial to ensure effective pandemic management in border regions. The results of our study impacted on policy makers, to be much more reluctant with closing borders.

Euregional Health Atlas: how to use it for cross-border public health policy Building a common health monitoring platform for the Meuse-Rhine Euroregion

Christina Stabourlos

C Stabourlos[1]
[1]Service Lifestyle and Chronic Diseases Team, Sciensano, Brussels, Belgium
Contact: Christina.stabourlos@sciensano.be

Studies show that European border regions -that account for over 30% of all European citizens- are faced with more deficits. Living in a border region still means fewer possibilities in the fields of employment, mobility, care and well-being. In order to tackle this, an absolute prerequisite is to dispose of relevant and comparable data across borders. The Euregional Health Atlas is an initiative that aims to collect and to visualize validated and comparable data for the municipalities of the Euregio Meuse-Rhine (EMR: Zuid Limburg (Nl), Zweckverband Aachen (De), the provinces Limburg, Liège, Ostbelgien (Be)). Themes addressed are: demographics (population, socioeconomic status, vulnerable groups), health care (care contacts, difficulties in daily living, chronic diseases, mortality), lifestyle (use of alcohol, smoking, weight, nutrition) and quality of life (perceived health, happiness).

Data used to feed the Euregional Health Atlas are derived from registers, health surveys and from former and current Interreg projects like the Youth Euregional Scan (YES). During the COVID-19 pandemic, data on the daily number of cases and 7-day incidence, the number of tests performed, the hospitalisation rate and the number of reported deaths related to Covid-19 were processed and presented on our dashboard and this not only for the Euregio Meuse-Rhine, but also for other Euregios. The Euregional Health Atlas is a work in progress: existing data are continuously being updated to improve their suitability for comparison purposes and new data are added to broaden the perspective. It contributes to knowledge-sharing, mutual understanding and cross-border policy development. The Atlas is a free, easily accessible platform, available for everybody; health care professionals, policy makers and citizens, see www.euregionalhealthatlas.eu!

Abstract citation ID: ckac129.217
Concept of cross border policy in public health: what is it and how does it

Brigitte Van der Zanden

B Van der Zanden[1]
[1]Foundation euPrevent, Heerlen, Netherlands
Contact: anderzanden@euprevent.eu

Cross-border cooperation depends on many factors. Not least because of the perception of a border and its influence. Literature shows that the perception of a border is different for different stakeholders. A citizen has a different perception of a border than a policy worker of the government. This influences the effects of cross-border policies. The first three presentations already show this indirectly. Apart from the perception of a border, it is important to look at how cross-border policy in the field of public health is actually made in Europe. On the basis of European policy documents, it has been analysed how policy and policy issues concerning cross-border public health care in Europe are established and what can be deduced from this for policy in cross-border regions such as the EMR. Elements in this are the 'existence', 'genesis', 'influencers' (+/- stakeholders) of cross-border policy and the potential relation with public health. Questions that will be addressed during the presentation are: What does cross-border policy look like? Is this also available in the field of public health? When yes how has this come about (genesis)? How is this concept of cross-border policy influencing the current way of looking at cross-border public health? Are there currently main 'influencers' that have impact on creating cross-border public health policy?

4.D. Workshop: The interaction of environmental impact and chronic diseases: from theory to practice

Abstract citation ID: ckac129.218

Organised by: EUPHA-CHR, EUPHA-ENV
Chair persons: Sarah Cuschieri (Malta), Marija Jevtic (EUPHA-ENV)
Contact: sarah.cuschieri@um.edu.mt

Both chronic diseases and environmental change are growing global public health challenges even amidst the ongoing Covid-19 pandemic. Every country is faced with these challenges, although small states and islands have an additional burden imposed on their sustainability, however this is rarely investigated. The intertwined relationship that exists between both epidemics is acknowledged, yet seldom explored or tackled together on a public health research level with bleak effect on policies outcome. People's lifestyles are a contributing factor to the progressive deterrent relationship between chronic diseases and environmental change. Indeed, many public health interventions promoting a healthier life will also produce the double benefit of tackling climate and the environment. For example, promoting more active transportation such as through the increase in bike lanes accessibility and incentives to promote active commuting will both reduce the dependency of carbon-based motor vehicle transportation, with a positive impact on the environment and climate, and on health. In fact, increase in physical activity is a well-known preventive and management action for most chronic diseases. Similarly, lower levels of pollution are also associated to decreases in many chronic diseases. Many other examples exist including the relationship between the food production, food security and carbon emissions. It is therefore imminent that urgent public health action is taken targeting the dominating urbanization and obesogenic environment that concomitantly have a role in the progressive development of chronic diseases and negative environmental impact. The aim of this workshop is to follow a multidisciplinary approach by bringing together different stakeholders to discuss the relationship between chronic diseases and the environment with a focus on small island states. While addressing the need to ensure that both public health and economic sustainability along with decelerating environmental change are on the imminent agenda. The workshop will be composed of four presenters discussing the various impacts on the environment from food production and security, sustainable dietetic models, the impact of city design on healthy living and finally the link between change in climate change and chronic diseases from a small state perspective. This will be followed by an engaging discussion between the presenters and the audience.

Key messages:

- An intertwined relationship exists between environmental change (ranging from food security to city planning) and chronic diseases.
- A One Health approach and public health interventions are required to halt the dual epidemic.

Abstract citation ID: ckac129.219
Food Production as a challenge for One Health Approach and Public Health

Marija Jevtic

M Jevtic[1,2,3], *C Bouland*[3]

A sustainable food production is essential for human sustainability. According to available data, the world's diets and food habits must evolve and change intensely. Nowadays, more than 800 million people suffer from deficient food. On the other hand, more consumers have an unhealthy diet contributing to premature death, obesity, food related non-communicable diseases. Diets must provide an appropriate calorie intake, different of plant-based food, low amounts of animal-based food, unsaturated fats, vitamins and minerals (rather than saturated, refined grains, highly processed foods, and added sugars). It is needed adjustment to various agro-systems, cultural traditions, and individual dietary preferences. However, production must also be sustainably adjusted to meet the global population's growing food demands, as well as using the doughnut economy principle. A sustainable food production requires a One Health approach, and also evolving towards a decarbonized agricultural production by eliminating the use of fossil fuels and land use change losses of CO2 in agriculture. Policies to encourage people to choose healthy diets are needed. Those should include the improvement of the availability and accessibility to healthy food through improved logistics and storage, increased food security, policies that promote buying from sustainable sources, as well as reducing food waste. The mindset change regarding to the agro-system, food production and food usage in a healthy way at individual level, community level, national level and global level are essential for sustainable human population. Healthy eating should be the highest priority of food consumers, as well as its mindset shift from 'live to eat' to 'eat to live'. Consumers should feel safe and healthy, but also think about future generations, respecting agriculture and food production. Sustainable, equitable, healthier, and more inclusive food systems have the power to catalyze the achievement of all 17 SDGs by 2030.

Abstract citation ID: ckac129.220
Sustainable dietetic models: strategies for communication and promotion

Francesca Scazzina

F Scazzina[1], *B Biasini*[1], *A Rosi*[1], *C Franchini*[1]
[1]Department of Food and Drugs, University of Parma, Parma, Italy
Contact: francesca.scazzina@unipr.it

Global Burden of Disease identifies the makeup of diets as a significant risk factor for mortality and morbidity, with 11 million deaths and 255 million disability-adjusted life years attributable to dietary risk factors. 690 million people lack sufficient food and economic projections suggest that COVID-19 pandemic may add an additional 83 to 132 million people to the ranks of the undernourished, as the outbreak has exacerbated the global food flaws and insufficiencies, impacting the most vulnerable populations. Diets and related food systems also contribute to significant environmental degradation and climate change. Demand for animal-source foods is also increasing, particularly in emerging economies, which entails risks for the environment. 1.3 billion tons of food are wasted globally yearly, utilizing 38% of total energy consumption in the global food system. The real cost of acquiring enough nutrient-rich food to meet national dietary guidelines for a healthy diet exceeds available income for ∼38% of the world's population. A balanced diet that meets food-based dietary guidelines calls for even larger quantities of more costly food groups than would be needed just for nutrient adequacy, owing to their many functional attributes beyond just the essential nutrients that they contain. Faced with this scenario, there is urgent need for an appropriate strategy to increase people's awareness of the relationship between specific food choices and health and to facilitate the educational environment on this issue. Actual examples of current strategies for communication and promotion of healthy and sustainable diets will be discussed. With awareness and knowledge, clear and precise information, a supportive social environment, available and accessible healthy and sustainable food items, and the implementation of related policies, individuals have a great potential to achieve healthiness and environmental sustainability by choosing healthier and more sustainable foods.

Abstract citation ID: ckac129.221
Rethink cities to promote an active lifestyle and tackle climate change: best practices from the OECD

Michele Cecchini

M Cecchini[1]*, A Piatrova*[1]*, A Aldea*[1]*, A Lerouge*[1]*, J Cheatley*[1]
[1]OECD, Paris, France
Contact: Michele.CECCHINI@oecd.org

Background:
City design can have major health and environmental implications. The overall layout of cities influences air quality, as urban sprawl can encourage the use of motorised vehicles and decrease active travelling. Furthermore, lack of trees has a negative impact on particulate matter levels and contributes to the urban heat island effect. There is a growing interest for creating an urban environment conducive of healthier lifestyles.

Methods:
The analysis uses the five OECD criteria to assess best practices in public health - Effectiveness, Efficiency, Equity, Evidence-base, and Extent of coverage - to carry out a systematic assessment of selected candidate best practices to improve the public health potential of cities. The impact of scaling up these interventions within and across countries is evaluated by using the OECD SPHeP-NCD microsimulation model.

Results:
Interventions such as Superblocks in Barcelona, which reshapes the city layout to make them more people centric and less vehicles reliant, or Cycle Superhighways from Denmark, which develops cycling networks, have a the potential to avoid a significant number of chronic diseases by promoting an active lifestyle and decreasing transport-related pollution. Such interventions can also decrease healthcare expenditure and, if well designed, health disparities.

Discussion:
While many urban design interventions are a good investment for countries and, in general, there is good support, a number of implementation hurdles exist. First, extent of coverage is still relatively limited across European countries. Second, changes take time to be implemented and some of the health impact materializes in the longer-term. Third, the implementation of such interventions is generally competence of other authorities, other than the health authorities. Building strong multi-stakeholder approaches and making a strong case for such investments can promote change.

Abstract citation ID: ckac129.222
Strengthening resilience to address climate change and chronic diseases: evidence from small states

Stefano Moncada

S Moncada[1]*, M Spiteri*[1]
[1]Islands and Small States Institute, University of Malta, Msida, Malta
Contact: stefano.moncada@um.edu.mt

Background:
Climate & environmental change are disproportionally impacting small states, given higher costs per capita associated with coping with the immediate risks of environmental & climatic events. Climate change has been identified as a serious public health threat. This is especially true for heatwaves in the Mediterranean Basin, with poor air quality worsening the health impacts during periods of extreme heat, often affecting already high levels of chronic diseases. Promoting climate change adaptation measures is crucial to address the negative socio-economic impacts brought by heatwaves, & its interactions with poor air quality. While awareness about the link between poor air quality & heat-waves is gaining momentum, there is still a gap in policy responses, especially in small states. This research assesses the level of preparedness of the European Union, with a focus on adaptation to heat-waves since the extreme European heat-wave of 2003. A case study on Malta is also presented, aiming at discovering what measures the island is adopting to tackle the problems arising from the interaction between poor air quality & heatwaves.

Methods:
A systematic literature review is conducted, investigating the links between heat-waves & air pollution post 2003, followed by a qualitative content analysis to assess the preparedness of climate change adaptation measures in this regard.

Results and conclusions:
The findings of this research show that the link between heat waves & poor air quality has not been sufficiently acknowledged by academia, with evident gaps in applied small states research. Also, a closer look at key adaptation policies & measures in Malta finds that heat waves & poor air quality are hardly been linked, leaving much scope to introduce policy & economic instruments to tackle both public health risks to address growing chronic diseases, & not to compromise current & future socioeconomic wellbeing.

4.E. Workshop: The role of National Public Health Institutes and IANPHI as Key Climate Actors

Abstract citation ID: ckac129.223

Organised by: Robert Koch Institute, IANPHI (France)
Chair persons: Angela Fehr (Germany), Sébastien Denys (France)
Contact: taylora@rki.de

Climate change is arguably the greatest threat to population health worldwide. Urgent action is needed to mitigate and adapt to the impacts. National public health institutes (NPHIs) are key actors in preventing illness and improving the health and wellbeing of their populations. They therefore have a crucial role to play in addressing climate change and making it central to their agendas. They can contribute to a better understanding of how climate change affects health, translate this knowledge into policy advice, and identify health co-benefits and possible harms of mitigation and adaptation measures to support the implementation of healthy measures within and beyond the health sector. NPHIs are also responsible for reducing their own footprint through "greening" and can role model and support other organisations in this regard. The International Association of National Public Health Institutes (IANPHI) recognises the threat that climate change poses and, to this end, published the "IANPHI Roadmap for Action on Health and Climate Change" in November 2021. This roadmap highlights the essential role of NPHIs' as "key climate actors". NPHIs are at different stages of progress on climate change and health, and there is therefore need and opportunity to learn from best practices and to liaise and work together to address shared challenges. It is also essential that NPHIs have an ongoing collaboration with other actors, such as academics, civil society, NGOs and other non-state actors, within and beyond the health sector, in order to learn from other perspectives and sources of knowledge and to ensure coherence and joint action on climate change and health across the system. This workshop therefore aims to promote discussion and exchange and to raise the visibility of NPHIs as key climate actors in order to strengthen their individual and shared contribution. The workshop will also ensure that the IANPHI Roadmap remains front of mind a year after publication. It will also give the opportunity to NPHIs to share their progress since then, as well as promote coherence and exchange in their continued efforts. The workshop will start with a presentation of the IANPHI Roadmap, followed by three examples from NPHIs on their progress on climate change strategy development and implementation. It will then be followed by an interactive session and discussion on NPHIs' priorities in this area, on how NPHIs and other actors can best exchange and work together, and on how IANPHI as a global network of NPHIs can promote and support NPHI and stakeholder cooperation. The presentations are coherent together in offering the Roadmap's vision as well as a set of diverse examples that illustrate the role of NPHIs on climate change and health in practice.

Key messages:

- Emphasis of the important role that NPHIs have in addressing climate change and health, as well as the value of their partnerships and intersectoral working, which can be supported by IANPHI.
- Promotion of discussion and new ideas between the presenters and the audience on how to ensure health is at the forefront when tackling climate change.

Abstract citation ID: ckac129.224
Engaging and supporting national public health institutes as key climate actors

Amandine Ballart

A Ballart[1,2], *S Denys*[1,3]
[1]International Association of National Public Health Institutes, Paris, France
[2]Santé Publique France, Paris, France
[3]Global Health Institute, Emory University, Atlanta, USA
Contact: amandine.ballart@emory.edu

The International Association of National Public Health Institutes (IANPHI) collectively builds public health capacity by connecting, developing and strengthening national public health institutes worldwide. IANPHI recognizes climate action as a critical global public health intervention and acknowledges that public health interventions on environmental and socio-economic determinants of health are essential drivers of climate adaptation and mitigation. Recovery from the COVID-19 pandemic also provides a unique opportunity to reset business as usual and strengthen actions on climate change, biodiversity and health, while reducing social and health inequities in the long term. However, effective contributions of National Public Health Institutes (NPHIs) to adaptation plans and mitigation strategies for climate change have remained limited, with a primary focus on health surveillance to date. In this context, IANPHI developed a roadmap to support and reinforce the role of NPHIs in climate change mitigation and adaptation policies. Five priority actions were identified:
1. Advocate for strengthening NPHIs capacities to contribute effectively to climate and biodiversity research, policies, and action
2. Enhance capacity, competence and training through peer-to-peer support and knowledge sharing between NPHIs
3. Increase collaboration with international and regional organizations active in the fields of public health and climate change
4. Support the greening of public health services
5. Monitor progress in the NPHIs' involvement in climate change policies through key indicators
In addition to discussing the roadmap, the presentation will focus on actions that IANPHI's Climate Change and Health committee initiated to reinforce the role of NPHIs in climate change mitigation and adaptation policies. This presentation will also provide information on how IANPHI can engage and support national public health institutes as key actors in the fight against climate change.

Abstract citation ID: ckac129.225
How RIVM is responding to the challenge of protecting human health from the effects of climate change – now and in the future

Lisbeth Hall

L Hall[1], *J Zwartkruis*[1], *G Velders*[1]
[1]Environment and Safety Division, RIVM, Bilthoven, Netherlands
Contact: lisbeth.hall@rivm.nl

In 2020 the Dutch National Institute for Public Health and the Environment (RIVM) published its vision on climate change and health. This vision reflects the position of RIVM in society and highlights the transdisciplinary and collaborative nature of our work on this topic. We define this societal challenge as: protecting and promoting the health of people throughout society with regard to climate change and climate measures. The purpose of our work on this challenge is to support all levels of Dutch government with policy development and implementation and to forge links with both national and international organisations to further knowledge and expertise. The focus of our work, in collaboration with the aforementioned actors, is as follows:
1. Knowledge translation of the health impacts of climate change for the public and government.
2. Developing instruments to promote health in relation to climate change and mitigation and adaptation measures.
3. Implementation research on solutions to mitigate and adapt to climate change.
4. Strengthening national and international cooperation to enhance synergies in our work.
In the workshop we will present examples of our work:

- Quantifying the health impacts of climate change, now and in the future under different global warming scenarios.
- Developing a set of indicators to monitor the health impacts of climate change and mitigation and adaptation plans and actions.
- Collating and disseminating easily digestible information for public health services on evidence-based, effective adaptation measures.
- Developing tools and instruments to ensure health benefits and limit unintended consequences of adaptation measures, such as green and blue spaces.
- Prioritising research on climate change and health through a research agenda.

Workshop participants will be encouraged to provide feedback to inform RIVM's future work and that of other national public health institutes, and to ensure we are fully supporting our stakeholders.

Abstract citation ID: ckac129.226
The NIPH's response to the climate and environmental crisis

Ågot Aakra

A Aakra[1]
[1]Division for Climate and Environmental Health, Norwegian Institute of Public Health, Oslo, Norway
Contact: Agot.Aakra@fhi.no

The vision of the Norwegian Institute of Public Health (NIPH) is better health for all. Climate changes and health are among our main strategic priorities. The NIPH aims to become a key actor in questions relating to climate, environment, food and health. An action plan on climate changes and environmental health is under development and will be presented. Climate and environmental changes affect the mental and physical health in several ways. The NIPH will in the coming years develop new knowledge on health consequences of climate changes: causes, risks, health effects and measures, based on our methodological expertise, research activities and infrastructures, such as health registers, health examinations, laboratories and biobanks. A key issue, and a main priority of the NIPH, is sustainable and climate-adapted food systems. There is a strong need to strengthen knowledge on healthy, safe and globally sustainable food. We will present and discuss our action plan for addressing climate and environmental health: Priorities, experiences, and challenges in implementation regarding e.g. competence and capacity building.

The following examples will be given:

– Research that addresses the food problem, and how to ensure a sustainable diet.

– The development of the MoBa Human Environmental Biobank to understand how climate and environmental changes affect exposure and public health, and how to follow the changes over time and help prevent disease.

– Examples of activities relating to clean air, clean and safe drinking water, and safe products from a One Health perspective: Achievements, projects, networks.

– Challenges in communicating health risks associated with the climate, environmental and pollution crisis to the public.

We encourage feedback and suggestions on NIPH's efforts to address the climate crisis, to ensure good knowledge sharing and that we are fully supporting our stakeholders.

Abstract citation ID: ckac129.227
The German national public health institute's journey to becoming a Key Climate Actor: The Robert Koch Institute's strategy development process

Angelina Taylor

A Taylor[1]
[1]Department Epidemiology and Health Monitoring, Robert Koch Institute, Berlin, Germany
Contact: taylora@rki.de

The Robert Koch Institute (RKI) is Germany's national public health institute. It has been working for a number of years on One Health topics such as zoonotic diseases and antimicrobial resistance, as well as wider areas relevant to climate change such as environmental health. Climate change has, however, only been a specific area of focus since 2019. This was signalled through the creation of a coordination role called One Health Climate Change (OHCC). In addition, a number of projects on climate change have been initiated independently of one another during this time across the RKI. Since summer 2021, RKI has been more active in its strategic development and set up a climate change and health working group of over 50 members of staff representing all departments. This offers a hub structure for pulling the relevant work and activities together under one umbrella, thereby promoting exchange, cooperation and cohesion across RKI. The RKI is currently at an early and dynamic phase in its journey as a key Climate Actor. It is developing a strategy on the topic, guided by the "IANPHI Roadmap for Action on Health and Climate Change" in order to further strengthen its contribution in this area. This presentation will share how RKI has developed its strategy and its action plan for implementation, as well as some of the successes and challenges in their development.

The presentation aims to:

- promote shared learning between national public health institutes on climate change and health strategy development;
- provide an opportunity for shaping future planning at RKI through audience input;
- stimulate thinking on how national public health institutes can remain in exchange with key stakeholder groups and open to learning and adaptation of their strategies in order to be effective Key Climate Actors over the long term.

4.F. Skills building seminar: How can we achieve effective interdisciplinarity in digital public health practice?

Abstract citation ID: ckac129.228

Organised by: Leibniz ScienceCampus Digital Public Health (Germany)
Chair persons: Laura Maass (Germany), Chen-Chia Pan (Germany)
Contact: laura.maass@uni-bremen.de

Digital technology, which is driven by technical opportunities rather than by demands, can fail to realise the critical objectives of evidence-based public health and pose novel ethical, legal, sociocultural, and equity-related challenges. While individual health already needs various disciplines to be adequately addressed, even more fields gain importance when it comes to population health. Public health requires collaboration across all domains: Those that tackle an individual's health but also those that set the framework for health practices (e.g., law, medicine, psychology, ethics, or sociology), measure health outcomes on a population-level (e.g., epidemiology), or that develop interventions to improve the populations' health (e.g., health promotion, health management, implementation science). During the last years, health has become more and more digitalised. Adding the digital level to public health also brings more and increasingly important players on the stage (e.g., human-computer-interaction, computer science, or engineering), who are needed to develop and improve evidence-based digital technologies and innovations on a population level. Having various disciplines collaborating with each other can offer new opportunities but also create new challenges if there is no mutual understanding of digital public health. This skill-building workshop aims to foster awareness of interdisciplinary approaches in public health research and practice. Two short introductory presentations (10 minutes each) will form the frame for the workshop. The first talk will introduce participants to the idea of interdisciplinarity in research and practice and highlight the prerequisites for effective and sustainable interdisciplinary collaborations. The second talk will build on this understanding and present a holistic (digital) public health model that displays how different disciplines contribute to the field and how an interdisciplinary approach can be used to overcome individual challenges. Based on the talks, participants will be invited to work on a case study regarding mobile mental health apps as a digital public health intervention. We will apply the world coffee method, in which each table will display one individual discipline (epidemiology, health economics, psychology, law, ethics, and computer science). An expert in the field will support each table to assist the participants if needed. Every participant will be able to discuss their ideas at three tables (10 min. each). The goal will be to work out how one could best integrate the individual disciplines when developing, implementing, and evaluating mental health apps in the digital public health environment. We discuss what each discipline can contribute to the topic and for which aspects it needs support from other scientific fields. The final results will be collected and summarised as a chapter in a digital public health handbook published by the Leibniz ScienceCampus Digital Public Health.

Key messages:

- Considering different disciplines when developing and implementing digital public health interventions improves the interventions' outcomes and long-term acceptability in user groups.
- Interdisciplinarity in digital public health requires a mindset from researchers that is characterised by empathy/curiosity towards other disciplines and a common understanding of the intervention.

Abstract citation ID: ckac129.229
What is interdisciplinarity, and how can we apply it to research and practice?

Merle Freye

M Freye[1,2]
[1]IGMR, University of Bremen, Bremen, Germany
[2]Leibniz ScienceCampus Digital Public Health, Bremen, Germany
Contact: mfreye@uni-bremen.de

The concept of interdisciplinarity is an integral part of contemporary academia. Successful academic careers or innovative study programs: Interdisciplinarity is often claimed, expected, or required. Public health scientists also claim to facilitate health-related interdisciplinary research under the umbrella of public health and to apply findings from interdisciplinary research in practice. These aspects already point to one of many problems in using the term interdisciplinarity: When using the term, it is not always evident whether it is a merely descriptive term or whether normative expectations are also associated with it. We consider that successful interdisciplinary research is enabled by a shared understanding of what is meant by interdisciplinarity in concrete research projects. This urgency is re-emphasised by the participation of new disciplines in digital public health. Through this presentation, we would like to give participants a brief theoretical overview of the concept of interdisciplinarity and related concepts such as transdisciplinarity and multidisciplinarity. In this way, all workshop participants will have a shared understanding that will serve as a basis for further work in groups during the workshop. After the terminological distinctions, we will turn to the practical challenges of interdisciplinary research, which arise beyond the clarification of terms. We will outline these challenges in fundamental terms and then provide some best practice examples on how interdisciplinarity in scientific competence can be promoted among individual scientists and in research groups. In the best case, the workshop participants will draw inspiration for the subsequent group work from the best practice examples to generate new motivation for interdisciplinary work in this way. A concise summary will conclude this compact-informative presentation. Merle Freye will host the tables on law and ethics during the world coffee.

Which disciplines form digital public health, and how do they relate to each other?

Chen-Chia Pan

C Pan[1,2]
[1]Leibniz Institute for Prevention Research and, Epidemiology - BIPS, Bremen, Germany
[2]Leibniz ScienceCampus Digital Public Health, Bremen, Germany
Contact: pan@leibniz-bips.de

A standard public health definition, coined by Acheson in 1998 and adapted by the World Health Organization, describes public health as 'the art and science of preventing disease, prolonging life and promoting health through the organised efforts of society'. Several other definitions emphasise different foci such as living conditions, the efficient use and equitable distribution of resources, or sustainability. Yet, they all share the dual nature as a science and practice of public health, its focus on the health of entire populations, and its interdisciplinary nature. In particular, joint efforts of individual disciplines are needed to combine subject matter knowledge and approaches to protect and promote population health. Traditional core public health disciplines comprise the social sciences, humanities, natural sciences, and environmental sciences. Their key tasks are summarised in the ten essential public health services, which can be further extended to digital public health. This extension leads to increasing use and integration of technological innovation and advancement into public health functions which require intensive collaborations with disciplines from the engineering field. In this presentation, we aim to describe the transition from public health to digital public health, emphasising the disciplines needed to tackle population health challenges in a digitalised world. In a first step, we will illustrate core disciplines and their subdisciplines that are traditionally known in the public health field. In a second step, we will introduce further core and subdisciplines prominent in digital public health. Finally, we will briefly present examples of key strengths and challenges of some of the disciplines. After this presentation, workshop participants should have a first understanding of the role and importance of interdisciplinarity in digital public health. Stefanie Do will host the table on epidemiology during the world coffee.

4.G. Workshop: Economic evaluations of public health interventions: from case studies to next methodological steps

Abstract citation ID: ckac129.234

Organised by: EUPHA-ECO, EUPHA-HTA
Chair persons: João Vasco Santos (EUPHA-ECO), Vanessa Gorasso (EUPHA-ECO)
Contact: jvasco.santos@gmail.com

For establishing evidence-based or evidence-informed decision making in health systems, it is essential to determine which public health interventions and health policies are worth investing in, considering that public budgets are always limited. For that purpose, we can use well-established economic evaluation methods based on marginal analysis as cost-benefit and cost-effectiveness analyses. While the use of economic evaluations is a common practice in health technology assessment of drug and medical device in many high-income countries, the systematic assessment of public health interventions is marginal and non-compulsory. In fact, if conducted at all, many economic evaluations of public health interventions are performed internally without dissemination outside organisations. In general, there is already some guidance on how to perform and report economic evaluations that can also be used for public health interventions, as the recent update version of Consolidated Health Economic Evaluation Reporting Standards (CHEERS) check list. However, some methodological and implementation difficulties still persist, including insufficient or low-quality data on costs and outcomes (e.g. absence of experimental studies), complexities related to the need of measuring outcomes in the very long term an on aspects beyond the healthcare sector, or high relevance of contextual factors that are difficult to measure. This workshop will take on some examples of economic evaluations of public health interventions and explore how analyses, methods and implementation can be improved in order to allow a more evidence-based or evidence-informed decision making process.

Key messages:

- Economic evaluations of public health interventions could be performed more frequently when it comes to the decision making. Planning and implementation difficulties are highlighted in this workshop.
- Methods used in current economic evaluations of public health interventions can still be improved with a correct estimation of costs and outcomes, based on good quality data.

Abstract citation ID: ckac129.235
Economic evaluation of legislation-based public health interventions – the case of tobacco control

Julian Perelman

J Perelman[1,2]*, T Leão*[3,4]*, M Serrano-Alarcon*[5]

[4]Faculdade de Medicina, Universidade do Porto, Porto, Portugal
[5]DONDENA, Bocconi University, Milan, Italy
Contact: jperelman@ensp.unl.pt

Economic evaluation of public health interventions have mostly been performed for interventions whose cost and effectiveness can be well identified, such as protective interventions (vaccination or screening), clinical interventions (prevention drugs) or counselling and education programs. Yet, following the Thomas Frieden's health impact pyramid, these public health interventions are less effective than those ‘‘changing the context to make individuals' default decision healthy''. The economic evaluation of population-based interventions that modify the context is rather challenging. First, such interventions include various components, e.g., taxes and subsidies, media campaigns or bans. Second, since they correspond to political decisions applied at a wide scale, their effectiveness can hardly be measured using experimental designs. Third, the cost of such interventions is difficult to assess, since they are not represented by a specific product or service, but rather by political decisions and their implementation, whose costing is not straightforward. Using the case of tobacco control policies, we show how alternative methods can be used to assess their economic value. We show that quasi-experimental methods with country comparisons allow identify the effectiveness of specific policies, and that qualitative approaches are needed to quantify their costs. Results indicate that tobacco-control policies have low costs and are highly effective, so that their cost-effectiveness is quite favorable in light of commonly referred thresholds, and in comparison with widely financed clinical interventions. Population-based interventions that focus contextual factors must also be carefully evaluated from an economic viewpoint. Although economic evaluations are challenging, alternative approaches help obtain results that are valuable for decision making.

Abstract citation ID: ckac129.236
A perspective on the assessment of the broad value of vaccinations

Chiara de Waure

C de Waure[1], GE Calabrò[2], W Ricciardi[2]
[1]Department of Medicine and Surgery, University of Perugia, Perugia, Italy
[2]Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy
Contact: chiara.dewaure@unipg.it

Vaccinations are considered a cost-effective public health intervention to control vaccine-preventable diseases and are commonly evaluated in respect to several domains, including efficacy, safety and cost-effectiveness, before being implemented nationwide. There are plenty of evidence of economic evaluations performed on single vaccines or vaccinations. They commonly relies on static or dynamic models and considers both direct and indirect costs, i.e., those linked to productivity loss, of vaccine-preventable diseases. Nevertheless, vaccinations are expected to provide also societal benefits that call to the development and implementation of methods to value them, also from an economic point of view. The scientific debate on the assessment of the broad value of vaccinations has pinpointed several relevant aspects that need to be paid attention in future evaluations. They include the antibiotic sparing effect of vaccination, their impact on antimicrobial resistance - which is a challenge of our days -, their effect on social cohesion, their role in avoiding the loss of school days and in ameliorating educational attainment. The economic evaluation of vaccinations need to be further developed in order to allow a quantitative exploitation of their broad value according to the aspects described above. As the experience is still scant, we need to work on several fronts, including capacity building, data production and sharing and new methods development.

Abstract citation ID: ckac129.237
Challenges in economic evaluation of public health interventions: the example of surveillance of high risk pancreatic tumour patients

Paolo Angelo Cortesi

P Cortesi[1]
[1]Research Centre on Public Health, University of Milano-Bicocca, Monza, Italy
Contact: paolo.cortesi@unimib.it

Evaluation of public health interventions raises a number of potential challenges in applying and performing economic analyses. The impact of interventions may extend beyond the health sector, and even within the health sector, the value may be difficult to estimate and extended beyond the health improvement of individuals. Screening and surveillance cancer programmes give the possibility to detect patients in a curable and treatable stage. Increasing number of expert recommendations and guidelines of cancer screening and surveillance have been recorded in the last decades. This scenario has increased the uncertainty on the most valuable and affordable approach to adopt. A case study can be provided by the premalignant pancreatic primarily cystic tumours surveillance. American, European and International guidelines for surveillance of asymptomatic cysts are available with significant differences in patients stratification, surveillance intensity (frequency of visits-exams), and duration. Further, real-world data suggest a significant variability in the surveillance approach even within Europe. However, no comparative data on different programmes efficacy are available, neither reliable medium-long term data on cancer risk. The lack of evidence must be considered with methodological issue associated to the inclusion of method to estimate inequalities created by the different programs and the indirect effect of healthcare resources consumption (e.g. CT and MRI) to access and allocation of these resources to other subjects (cancer and no cancer patients). Economic evaluations of surveillance or screening cancer program raise significant challenges, as data availability and methodological approach to apply. This scenario highlight the need of specific recommendation on data quality and type required to assess the programmes value and on methodological approach required (e.g. type of decision analytical models) to provide useful information for public health decision makers.

Methodological advancements in costing methods for (public) health economic evaluations: results from the European PECUNIA project

Judit Simon

J Simon[1,2]
[1]Department of Health Economics, Center for Public Health, Medical University, Vienna, Austria
[2]Department of Psychiatry, University of Oxford, Oxford, UK
Contact: judit.simon@meduniwien.ac.at

(Public) health economic evaluations face significant problems regarding the standardization and comparability of their methods. In addition, at least a quarter of the total direct cost impact of healthcare interventions affects other economic sectors. International methods and tools are lacking for the rigorous and comparable assessment of the costs and outcomes of (public) health care from a societal perspective. The H2020 PECUNIA project (grant No 779292) brought together ten partners from six countries (AT/DE/ES/HU/NL/UK) between 2018 and 2021 aiming to improve the comparability and feasibility of multi-sectoral, multi-national health economic evaluations in Europe. A multi-step, mixed methods approach was used following a new harmonized costing concept to develop new methods and tools for the standardised identification, definition, measurement and valuation of costs in multiple sectors (health care, social care, (criminal) justice, education, employment and productivity, and patient, family and informal care), and for the broader, harmonised, supra-national assessment of outcomes using selected mental disorders as illustrative examples. This presentation will summarise the relevant advances in costing methods, give an overview of the developed tools that are now publicly available (www.pecunia-project.eu/tools), and discuss the lessons learned regarding how far it is possible to harmonize costing evidence with standardised tools in Europe, and what the necessary future research directions may be.

4.J. Workshop: Health system performance assessment in Europe – recent developments, evidence, and challenges

Abstract citation ID: ckac129.243

Organised by: Berlin University of Technology
Chair persons: Reinhard Busse (Germany), Carine Van de Voorde (Belgium)
Contact: miriam.bluemel@tu-berlin.de

Assessing the performance of health systems is essential to initiate policy processes that further strengthen health systems to improve population health. Starting with WHO's World Health Report of 2000, Health System Performance Assessments (HSPA) gained increasing attention in research and policy. By now, several comparative HSPA initiatives of international organisations (e.g., OECD's Health at a Glance) and country specific HSPA (e.g., Sweden, Netherlands, Austria, Belgium) were implemented in Europe. Further countries are currently in the process of developing or piloting an HSPA (e.g., Germany). The objective of the workshop is to foster and strengthen the interchange of different HSPA initiatives in Europe and beyond. While each health system has its specifics, initiatives likely face similar challenges in the implementation and ongoing development, which holds a lot of potential for learning from each other. The workshop is supposed to be a platform for the exchange of and about HSPA initiatives and related topics by bringing together stakeholders of different countries and professions. Participants are supposed to gain new insights into recent activities in Europe and will be able to discuss challenges and lessons learned. The presentations give insights into recent activities of selected HSPA initiatives in Europe. One presentation originates from the Belgian HSPA which is well established. This presentation will focus on the transversal dimension of equity, on which a separate report was recently published. The second presentation is about the German HSPA which is still in development and currently tested in a pilot study. Both presentations represent HSPA initiatives at different stages, which provides a good basis for the following panel and discussion with all workshop participants. The two presentations of about 20 minutes each will be combined with a panel discussion. Afterwards, there will be room for exchange and discussions between all participants and presenters.

Key messages:

- Recent developments of HSPA initiatives in Europe will be presented along two examples from Belgium and Germany and lessons learned and challenges will be discussed.
- The workshop provides a platform for the exchange of and about HSPA initiatives and related topics by bringing together stakeholders of different countries and professions.

Abstract citation ID: ckac129.244
Health System Performance Assessment: how equitable is the Belgian health system?

Carine Van de Voorde

M Van de Voorde[1], N Bouckaert[1]
[1]Belgian Healthcare Knowledge Center, KCE, Brussels, Belgium
Contact: Carine.Vandevoorde@kce.fgov.be

Access to and delivery of effective, high quality and affordable healthcare are fundamental objectives that have shaped health policy and the universal health insurance system in Belgium. A health system should be evaluated against these objectives. Monitoring equity within a health system - an equitable distribution of healthcare use and of payments for healthcare - is a core component of a health system performance assessment. We use the horizontal equity principle to evaluate equity in healthcare use in Belgium. Unfair inequality in healthcare use is measured by the fairness gap, comparing actual use and expected use corrected for needs. The empirical analysis was conducted using a linked dataset which contains data from the European Union Statistics on Income and Living Conditions (EU-SILC) and administrative data. Two sets of results are reported for a selected set of indicators of use: the deviation between the average fairness gap in the population and the average fairness gap in a subgroup of interest and an assessment of systematic socioeconomic inequity in the fairness gap using the absolute concentration index. We show that important socioeconomic inequities in healthcare use exist. Inequities differ by type of care, e.g., the use of hospital care and medications is more equitable than the use of GP, outpatient specialist and dental care. When accounting for healthcare needs, we find that use among high-income groups and individuals with a high educational attainment is higher compared to financially vulnerable groups (individuals at risk of poverty or with severe material deprivation, unemployed, singles). Also, individuals who are entitled to an increased reimbursement of healthcare costs, show a lower use of outpatient specialist care than expected based on their care needs. On the other hand, increased reimbursement is effective in improving accessibility to GP care, while for other financially vulnerable individuals we find a lower use of GP care.

Piloting the first health system performance assessment for Germany: key results and learnings

Miriam Blümel

M Blümel[1], M Achstetter[1], P Hengel[1], M Schwarzbach[1], R Busse[1]
[1]Berlin University of Technology, Department of Healthcare Management, Berlin, Germany
Contact: miriam.bluemel@tu-berlin.de

Background:
Health System Performance Assessment (HSPA) is a tool to monitor and evaluate the performance of health systems and to inform evidence-based policymaking. For the first time, a country specific HSPA is currently being piloted for Germany.

Methods:
The HSPA is based on a newly developed conceptual framework including nine dimensions (e.g., access, quality, efficiency, population health). Indicators were selected based on a systematic search of (inter)national studies and HSPA initiatives. Where possible, indicators were analysed in their development over time (2000-2020), in comparison to eight European countries (e.g., Austria, Denmark, France), and along up to seven equity dimensions (e.g., sex, age, income, education, region).

Results:
Overall, 90 indicators were included in the HSPA. Trend and equity analyses were possible for almost all and country comparisons for most indicators. A few indicators could not be analysed at all due to missing data. The overall HSPA provides an in-detail picture of Germany's health system. Access, for example, can be rated as good in Germany compared to the other countries, as insurance coverage and physician density are high, and unmet needs and waiting times for elective surgery are low. Results for quality are not as good, e.g., cancer survival rates, but most indicators show a positive trend. While population health outcomes are average in country comparison (e.g., fetal and infant mortality), resource input is comparatively high. Consequently, overall efficiency can still be improved (e.g., amenable mortality per total health expenditure).

Conclusions:
This first HSPA for Germany allows new insights to the performance of the German health system which are important for policy and research. While the pilot benefitted a lot from previous HSPA initiatives, data availability remains one of the biggest challenges.

4.K. Workshop: Promoting and enhancing health literacy through school interventions

Abstract citation ID: ckac129.246

Organised by: EUPHA Working Group Health Literacy, EUPHA-HP, EUPHA-CAPH, Technical University Munich
Chair persons: Orkan Okan (EUPHA-HP), Julia Dratva (EUPHA-CAPH)
Contact: orkan.okan@tum.de

The promotion and enhancement of health literacy in school-aged children is an important public health and education goal. To ensure healthy behaviours and attitudes in adulthood, children and adolescents have to learn about health and well-being early in life. Toward this goal, schools are considered the most important setting to address health literacy. Interventions delivered in schools can reach all children regardless of their social, cultural or development background. In the education sector, health literacy interventions can address not only the skills, attitudes and knowledge of students, but that of teachers, principals, health and education staff, as well as the whole school setting. Health literacy is linked to education, while it mainly addresses how people manage health information. In this context, health literacy enables children and adolescent to find, understand and critically appraise health information and use it to guide informed health decisions and promote health behaviour. While this understanding targets personal competencies of individuals, health literacy is also directed towards the environment. For example, the concept of organizational health literacy aims at increasing health literacy capacities of the environment and within settings, such as schools. This makes health literacy an important concept at the intersection of behaviour change (agency: personal health literacy) and social change (structure: organizational health literacy). While the behavioural approach is most promising to equip students with the necessary skills to act as their own agents of health information management and improve their health agency capacities, the social approach further includes consideration of social determinants of health to provide child- and adolescent-friendly environments and conditions. Therefore, effective health literacy interventions should aim at combining behavioural and social approaches, especially in such vulnerable groups as children and adolescents. The purpose of this workshop is to present and discuss four interventions on health literacy drawing on behavioural and social sciences. (i) The first presentation will introduce the Health Literacy Toolbox for Schools (Tool-HLCA). (ii) The second presentation will introduce a school curriculum for classroom based Mental Health Literacy (HLCA-IMPRES). (iii) The third presentation will provide the organizational health literacy school intervention: Health Literate Schools (HeLit-Schools). (iv) The fourth will present applied data on mental health literacy in teachers and an instrument to measure action competencies of teachers with respect to promoting their students' mental health (MHAC). Each project will be given ten minutes to present their interventions and main findings, including time to discuss with the audiences and get feedback. The participants in turn will learn about recent empirical findings they can use in health literacy practice and policy.

Key messages:
- Children and adolescent will benefit from early interventions to develop healthy behaviours and lifestyles in their life-course.
- Health literacy is an important school topic and should be addressed within behavioural and social approaches.

Abstract citation ID: ckac129.247
Tool-HLCA: An intervention to promote the health literacy of school-aged children

Tessa Schulenkorf

T Schulenkorf[1]*, U Bauer*[2]*, O Okan*[1]
[1]Department of Sport and Health Science, Technical University Munich, Munich, Germany
[2]Faculty of Educational Science, Bielefeld University, Bielefeld, Germany
Contact: t.schulenkorf@uni-bielefeld.de

Background:
In the age of 'infodemic,' children and young people encounter health-related information in digital environments at an early age. They should therefore learn how to deal with these in a health-competent way while still at school. Above all, it is relevant that they learn how to distinguish good health information from false. This can be achieved by promoting health literacy. The intervention "Toolbox" combines areas of media education in schools and health literacy to be implemented in schools and curricula in the long term.
Methods:
The intervention was designed to address existing health topics in the classroom while strengthening digital health literacy in grades 7 to 10. The Toolbox was piloted in three school classes in Germany and the feedback provided by teachers and students was implemented in a new version of the intervention.
Results:
The basic understanding of health literacy in the Toolbox is finding, understanding, evaluating and using digital health information. These steps are followed through using quality criteria for good health information. Students learn that they need to find out the type of information, analyze the author, investigate the media provider, and also the sources given. If they are unsure, they can conduct an adapted questionnaire regarding identify misinformation and disinformation. In addition, the students and teachers receive working materials for group work.
Conclusions:
Recognizing disinformation is a relevant skill already for children and adolescents. The intervention should make it easier for students to recognize good health information. For teachers it should be made easier to address health literacy in school without additional effort.

Abstract citation ID: ckac129.248
Results from a systematic review of interventions promoting mental health literacy in youth

Alexandra Fretian

A Fretian[1]*, S Kirchhoff*[1]*, O Okan*[1]*, U Bauer*[2]
[1]Department of Sport and Health Science, Technical University Munich, Munich, Germany
[2]Faculty of Educational Science, Bielefeld University, Bielefeld, Germany
Contact: fretian@uni-bielefeld.de

Background:
Mental illnesses are amongst the leading causes of ill-health and disability, with most onset of many mental health problems (ca. 75%) emerging before the age of 25 years. Thus, adolescence is an important time period for preventive measures, such as strengthening mental health literacy (MHL). This review aims to give an overview of those interventions which promote MHL on the long run.
Methods:
Five databases were searched for English or German articles published between January 1997 and May 2020, leading to a total of 4,375 original articles. Interventions were included only if they had measured MHL and/or stigma on three different time points, had a control group, and delivered an intervention program. Studies reporting means and standard deviations for the outcomes of interest were further included into a meta-analysis using a random effects model. The analysis was carried out with STATA 16.
Results:
25 studies were included into the review, and 13 of them were suitable for the meta-analysis. The great majority of studies (76%) were conducted within schools and the addressed topics were general mental health, depression, and schizophrenia. Interventions mostly used psychoeducation or a combination of educational elements and contact as delivery method. The combined use of educational and contact components led to worse results for mental health literacy, but not stigmatizing attitudes or social distance. Generally, interventions led to positive outcomes. The changes were sustained for mental health literacy d = 0.48, as well as for stigmatizing attitudes d = 0.30, and social distance d = 0.16, after an average follow-up of about 5 months.
Conclusions:
MHL-interventions targeting adolescents are mostly conducted within schools and generally have a brief follow-up period. They show a stable improvement in mental health literacy and are to a smaller degree able to destigmatize mental illness or improve social distance.

Abstract citation ID: ckac129.249
Health Literate Schools: Organizational Health Literacy in the School Setting

Sandra Kirchhoff

S Kirchhoff[1]*, O Okan*[1]
[1]Department of Sport and Health Science, Technical University Munich, Munich, Germany
Contact: sandra.kirchhoff@uni-bielefeld.de

Background:
Fostering health literacy is considered an important objective within school-based strategies of health promotion. To effectively strengthen health literacy in the school setting the approach of organizational health literacy can be transferred to and implemented in schools. This approach combines behaviour-focused measures (providing individual learning opportunities) and environment-orientated measures (changing school's framework conditions). The HeLit-Schools project aims at developing a school-based concept of organizational health literacy and tools to support schools in becoming health-literate schools.
Methods:
Existing concepts of organizational health literacy of other setting are analysed and adapted to the school setting. The concept development includes the expertise of actors from the school field, health literacy research and health sector. They contribute by commenting, reviewing and validating the conceptualization at different stages in the development process. A quantitative assessment of schools' organizational health literacy is planned to further validate the concept. Furthermore, a screening of existing materials and programs for schools to use to foster health literacy is being conducted.
Results:
The developed HeLit-Schools concept describes eight standards of a health-literate school. Every standard focuses on a specific area within the school's organization that can be addressed and changed in order to strengthen everyone's health literacy at school more effectively. To additionally support schools in fostering health literacy in school as well as in the classroom, a structured collection of existing (teaching) materials and programs was assembled.
Conclusions:
Enhancing schools' organizational health literacy and thus promoting school development by optimizing schools' structures, processes and conditions in a health-literate matter can lead to an effective and sustainable strengthening of health literacy of every individual at school.

Abstract citation ID: ckac129.250
Teachers' mental health literacy and action competencies

Julia Dratva

J Dratva[1], M Kerry[1], K Albermann[2], D Robin[1]
[1]Institute for Public Health, ZHAW Zürich University of Applied Sciences, Winterthur, Switzerland
[2]Social Pediatric Center SPZ, Winterthur Cantonal Hospital, Winterthur, Switzerland
Contact: Julia.dratva@zhaw.ch

Background:
Teachers are very important in mental health promotion and early recognition of mental health burden (disorder, illness). Teachers' surrogate mental health literacy (MHL) may be key to improving mental health in youth but has been little investigated. We assessed surrogate MHL in Swiss teachers and tested a measure of mental health action competencies (MHAC).

Methods:
In 2020, all teaching and support staff at compulsory school level were invited to an online survey covering individual and professional characteristics, MHL (finding, understanding, critical appraisal of information) and action competencies (adapted scale Ahnert et al. 2016, range 17 - 68) personal experience with students' MHB. Data was explored descriptively and with multivariate regression. Item response theory analyses were conducted to examine internal psychometric MHAC scale properties, and group-mean differences tested between school levels.

Results:
Participation rate was 38% (N = 459). Nearly all participants had taught at least 1 mentally burdened student in the past year (average 4.7). 77% felt experienced to very experienced regarding these students. Only 32% felt they had sufficient tools and teaching resources. Participants felt it was difficult to very difficult to find (47%), understand (53%) and appraise (90%) information on students' mental health. Kindergarden teachers and teachers without class responsibility showed significantly lower MHL. Internal psychometric properties of the MHAC measure support the use of a 1-factor scale and indicates discriminant validity with respect to age; experience and school level, median score was high (P50 48, P25 44, P75 53), but single items, e.g. on suicide signs, were rated low.

Conclusions:
While overall subjective MHAC are high, teachers are insecure regarding MHL and report a lack of tools and resources. Targeted training could strengthen surrogate mental health literacy with a focus on critical appraisal and certain action competencies.

4.L. Round table: Mobilising coping and support strategies: learning from healthcare workers' experiences of COVID-19

Abstract citation ID: ckac129.251

Organised by: Robert Koch-Institute, EUPHA-HWR
Chair persons: Heide Weishaar (Germany), Ellen Kuhlmann (EUPHA-HWR)
Contact: evansm@rki.de

Background:
During the COVID-19 pandemic, health care workers (HCWs) have experienced considerable stress and shown great resilience. Multiple organisations advocate for better support for the health workforce, both during pandemics and in routine health care. Effective interventions aimed at supporting HCWs should be based on evidence stemming from HCWs' coping strategies and support needs. This workshop highlights coping mechanisms and support strategies for HCWs during public health emergencies. It is chaired by the Robert Koch Institute (RKI), Germany's national public health institute, who played a major role in the pandemic response over the last two years, and the EUPHA Health Workforce Research Section. While the workshop's primary geographical focus is Germany, the roundtable participants will explore, from an international perspective, what lessons can be learned from HCWs' experiences during the COVID-19 pandemic and discuss the relevance to researchers, health professionals, health managers, politicians, and other decision makers.

Objectives:
The aims are to: (i) introduce an analytical framework for coping mechanisms and support strategies for HCWs during public health emergencies, (ii) present reported coping mechanisms among, and support strategies provided to, HCWs during the COVID-19 pandemic, and (iii) discuss the coping mechanisms and support strategies that have been reported to be most effective in improving the situation of HCWs in the future.

The panel workshop starts with two 10-minute presentations followed by a moderated panel and subsequent discussion with the audience. The presentations introduce the workshop topic using a scoping literature review conducted at RKI on HCWs' experiences during the COVID-19 pandemic, and a summary of key findings of a mixed-method study on coping strategies and support needs of HCWs during COVID-19 in Germany, highlighting support needed and received and crucial sources of support. The panel highlights the most effective reported coping mechanism, addresses gaps in support strategies, and collects suggestions for how to make use of the suggested solutions. These as well as lessons to be learned for policy and practice will be discussed with panel members and attendees, connecting the perspectives of health policymakers, management. and professionals. The aim of the workshop is to contribute to the wellbeing of HCWs, who represent one of the most important pillars of a health system.

Key messages:
- Healthcare workers' coping mechanisms and support strategies during the COVID-19 pandemic are an important source of health workforce resilience.
- Lessons learned from the COVID-19 pandemic on supporting health care workers must be jointly implemented across sectors.

Speakers/Panellists:
Megan Evans
Robert Koch Institute, Berlin, Germany

George Valiotis
European Health Management Association, Brussels, Belgium

Bernhard Gibis
Kassenärztliche Bundesvereinigung, Germany

Véronique S Grazioli
Center for Primary Care and Public Health, University of Lausanne, Lausanne, Switzerland

4.M. Oral presentations: COVID-19 impact

Abstract citation ID: ckac129.252
Long COVID among Children: Persistence of Symptoms 12 Weeks and More in a Cohort Study from Turkey

Öykü Turunç

Ö Turunç[1], AN Emecen[1], AF Süner[1], S Keskin[1], E Başoğlu[1], N Şiyve[1], N Belet[2], H Karaoğlu Asrak[2], M Duman[2], B Ünal[1]

[2]Department of Pediatrics, Dokuz Eylul University Faculty of Medicine, Izmir, Turkey
Contact: oykuturunc0@gmail.com

Background:
COVID-19 usually cause a mild infection among children with a low fatality rate. On the other hand, increasing evidence suggests that children may have prolonged symptoms related to COVID-19. This study aims to describe the persistence of COVID-19 symptoms up to 12 or more weeks among children and to investigate associated factors including perceived socioeconomic status and parents' education level.

Methods:
The study group consisted of 759 cases aged <18 years detected as SARS-CoV-2 RT-PCR positive in DEU Hospital between March 2020, and May 2021. Interviews were conducted at 1st 3rd and 6th month of diagnosis. The ongoing self-reported symptoms 12 or more weeks after infection was the dependent variable. Multivariate logistic regression models were used to evaluate associated factors with long COVID, and robust clustering using links algorithm was used to assess long COVID symptoms clusters.

Results:
Among 759 COVID-19 cases, 22 children were hospitalized, and 4 died. 9.6% of the children had at least one symptom related to COVID-19 after 12 weeks of the diagnosis, Symptom duration was minimum 84 days, maximum 344 days (mean±SD: 160±68 days). The most frequent symptoms were fatigue, muscle-joint pain, headache, and loss of smell and/or taste. In multivariate analysis, female gender (OR:2,3 95%CI:1.1-3.6) and symptomatic onset (OR:2,7 95%CI:1.7-20.9) were related to increased risk of long COVID. Age, long-term health conditions, socioeconomic status and mother's education level did not predict the risk of long COVID. No cluster of symptoms was found.

Conclusions:
About 10% of children suffer from symptoms related to COVID-19 for up to six months. Female gender and symptomatic onset of disease increased the risk of prolonged symptoms. Socioeconomic status and mother's education level was not associated with the risk of long COVID, but the evidence of the effect of social determinants of health on the outcomes of COVID-19 among children is still needed.

Key messages:
- One out of ten children may suffer from long COVID represents symptoms such as fatigue, headache, and muscle and joint pain. Girls and children with symptomatic onset have a higher risk of long COVID.
- The effects of social determinants on the susceptibility and outcomes of COVID-19, including death, were well studied among the adult population. There is a need for sound evidence for children.

Abstract citation ID: ckac129.253
Impact of COVID-19 on emergency department use among home care recipients

Alberto Peano

A Peano[1], E Minutiello[1], G Politano[3], M Dalmasso[2], MM Gianino[1]
[1]Department of Sciences of Public Health and Pediatrics, University of Turin, Turin, Italy
[2]Unit of Epidemiology, Local Health Unit TO3, Grugliasco, Italy
[3]Department of Control and Computer Engineering, The Polytechnic University of Turin, Turin, Italy
Contact: alberto.peano@unito.it

Background:
The impact of COVID-19 pandemic on Emergency Department (ED) was remarkable throughout Europe. We focused upon ED utilization among integrated home care (IHC) recipients comparing ED between pandemic period with pre-pandemic (February -December 2020 and 2019, respectively) in Piedmont, Italy.

Methods:
A retrospective observational study was conducted. All recipients of IHC during the two periods studied were enrolled and all ED visits that occurred among IHC recipients were accounted for. Several variables related to IHC admission, reason of ED visits and demographic characteristics were collected. The average of ED visits in pre-pandemic and pandemic periods were calculated. Analyses were stratified by all variables.

Results:
Patients enrolled were 11968 in 2019 and 8938 in 2020. In 2019, 3573 patients had at least one ED visit and 1668 patients in 2020. Number of ED visits was 5503 in 2019 and 2197 in 2020. The average of ED visits in 2020 has reduced in comparison with 2019 (0.464 C.I. [0.44-0.489] and 0.24 C.I. [0.227-0.252], $p < 0.001$ in 2019 and 2020 respectively). This reduction is regardless of sex, age, duration of IHC, presence of a non-family caregiver or reason for ED visits, except for abdominal pain, cardiac rhythm alteration and gynaecological symptoms. The averages of ED visits were significantly lower for IHC recipients with neoplasm (0.549 C.I. [0.513-0.585] and 0.328 C.I. [0.298-0.358], $p < 0.001$, and with low level of emergency (1.77 C.I. [1.662-1.877] and 1.397 C.I. [1.348-1.447], $p < 0.036$), but an increase in mortality rate was not registered.

Conclusions:
Our results showed a reduction of ED visits among integrated home care recipients in pandemic period in comparison with pre-pandemic period. If the reduction can be the consequence of an unprepared health service that needs of necessary changes in its organization, these results suggest a great potential of the home care system to reduce the use of the hospital especially for low-risk conditions.

Key messages:
- The COVID-19 pandemic overwhelmed health services of all European Countries. A reduced utilization of ED has been shown by literature, especially during the early phase of the COVID-19 pandemic.
- We showed a reduction in IHC recipients and a great decrease in ED visits among IHC patients in 2020 versus 2019, mainly in oncological patients, while an increase in mortality rate was not reported.

Abstract citation ID: ckac129.254
Access of Syrian Refugee Women to Sexual and Reproductive Health Services in Turkey during COVID-19

Eray Ontas

E Ontas[1], S Bahar Ozvaris[2], B Guciz Dogan[2], T Kutluk[3]
[1]Zonguldak Provincial Health Directorate, Republic of Türkiye Ministry of Health, Zonguldak, Turkey
[2]Department of Public Health, Hacettepe University Faculty of Medicine, Ankara, Turkey
[3]Department of Pediatrics, Hacettepe University Faculty of Medicine, Ankara, Turkey
Contact: erayontas@gmail.com

Women and girls are more disadvantaged in times of crisis, and their chances of surviving and fleeing are limited. As the Syrian crisis enters its eleventh year, Turkey alone hosts the largest population (over 3.7 million). It aimed to evaluate essential reproductive health services in the shadow of the pandemic that deepens the crisis. The research was conducted in April 2021 with 637 married Syrian refugee women aged 15-49 living in Ankara (mean age: 29.6). The median age at first marriage was 17, and consanguinity with her spouse was 29.8%. 8.6% were illiterate. 36.3% did not/could not benefit from public hospitals free of charge, and 89.8% did not have health insurance. 96.7% had a previous pregnancy (median:4). Since the pandemic's beginning, 35.6% have been pregnant (n = 219), and 14% are still pregnant (n = 86). Of 133 women whose pregnancies ended during this period, 78.2% gave birth (n = 104) and 21.8% miscarried. 12.8% of pregnancy was terminated at home (n = 17, 14 of which could not receive support from anyone). 41.1% of those who became pregnant during the pandemic were not followed up in pregnancy; 45.1% of those whose pregnancies ended were not followed up in the puerperium. 29.5% of all the participants stated that they had not used any birth control method. The most common reason for not using family planning is fear of harm to health and their spouse's disapproval. Only 3.3% of those currently using birth control methods stated difficulty accessing birth control methods. The most used information resources about pregnancy, childbirth and contraception methods were hospitals and Migrant Health Centres.

This study is funded through the UK Research and Innovation GCRF Research for Health In Conflict (R4HC-MENA), developing capability, partnerships and research in the Middle and Near East (MENA) [ES/P010962/1].

Key messages:

- In refugee crises, women's health should be structured as a separate heading in the health system and unmet sexual health needs should be met, especially in culture-oriented primary care services.
- Women should be empowered with a health system where women can determine their own needs and make decisions about their bodies.

Abstract citation ID: ckac129.255
Disruptions of cytological screening procedures due to the COVID-19 pandemic in Slovakia

Juliana Melichová

J Melichova[1], E Marusakova[1], L Bilikova[1], P Sivčo[1], D Plancikova[1], D Hazerova[1], T Pham[1], S Paulik[1], S Putekova[1], M Majdan[1]
[1]Department of Public Health, Trnava University in Trnava, Trnava, Slovakia
Contact: juliana.melichova@truni.sk

Background:
During the COVID-19 pandemic, most settings experienced healthcare service disruptions. The majority of cytological screening procedures were postponed to focus on assisting patients infected with COVID-19. In this study, we aimed to analyse the impact of the impact of the COVID-19 pandemic on the uptake of cervical cancer screening in Slovakia.

Methods:
Data on cytological screening procedures were obtained from two of the three health insurance companies in Slovakia for the years 2019 and 2020, covering the population of women aged 15 and older. All data were calculated stratified for age groups. Rates of cytological screenings were calculated as the number of procedures per women registered in the insurance company in the same age group and rate ratios were calculated as ratios of the rates for the years 2020 and 2019 for the same age group. Incidence rates were calculated as the number of newly diagnosed cervical cancer cases per women registered in the insurance company in the respective year.

Results:
Rate ratios of cytological screening procedures revealed that in both examined health insurance companies, the rate of cytological exams was lower in 2020 compared to 2019 (0.95 and 0.89). This was observed across all age groups. The results showed a clear and statistically significant age gradient, indicating that the level of disruption increased with age. The age group 60-69 years had the highest incidence rate of cervical cancer in 2019, at 54.3 per 100 000. In 2020, the highest rate was 48.3 in the age group 50-59 years. The lowest rates were in children and young adults (<20 years).

Conclusions:
This study confirms the significant impact of the pandemic on cervical cancer screening uptake in Slovakia, which may have delayed the diagnosis of cervical cancer into later stages of the disease with a worse prognosis. This may lead to increased mortality and years lived with disability due to this disease in Slovakia.

Key messages:

- Disruptions in cervical cancer screenings were observed in Slovakia during the COVID-19 pandemic which may result in an increase in cervical cancer incidence and mortality.
- Strategies should be implemented to maintain cancer screening programs during health emergencies to avoid excessive mortality and morbidity.

4.N. Workshop: Maternal Oral Health Models and Initiatives in Global and Public Health Perspectives

Abstract citation ID: ckac129.256

Organised by: World Federation of Public Health Association Oral Health Workgroup
Chair persons: Hyewon Lee (Switzerland)
Contact: hyewon@idasociety.org

Achieving and maintaining good oral health is essential for both the oral and overall health of expecting mothers and the oral health of their young children. Dental caries can negatively affect daily activities, including eating, speaking, and social interaction. When expecting mothers have active dental caries, the risk for dental caries in these children becomes higher. Another common oral disease, periodontitis, was associated with systemic conditions, including cardiovascular disease, respiratory disease, diabetes, and potentially adverse birth outcomes. Some studies also showed the systemic impact of periodontal disease and the related pathogens that can lead to systemic inflammation and adverse birth outcomes, even though periodontal treatment has not been shown to improve birth outcomes. A mother's oral health status, her oral health knowledge, and beliefs also have been shown to significantly affect diet and home oral hygiene practice for young children. All the evidence suggests that pregnancy should be considered a critical period in which oral health education and dental care should be provided to improve the oral health of mothers and their young children. Despite the importance of a mother's oral health and their oral health knowledge in preventing dental caries in young children, maternal oral health is much neglected in primary and prenatal health discussions. This is even more significant in developing countries with inadequate oral health care infrastructure and workforce. In addition, with increased sugar consumption worldwide, oral disease prevention and oral health promotion are the keys to achieving oral health parity among the maternal and child population. This workshop aims to position maternal oral health as essential primary and perinatal health care and discuss the care models and initiatives in various contexts and geographical locations. At the care delivery and community-based interventions, Dr. Sophia will discuss her oral health education and tobacco cessation initiative for pregnant women in India. Dr. Irene will demonstrate her integrated oral health training model for midwives and dental providers in Indonesia. She will describe how her collaboration with the local government achieves collaborative training and care delivery to improve mothers and their spouses' oral health and oral health knowledge in rural Indonesia. Dr. Jane will showcase her material oral health model for refugee and immigrant mothers in Switzerland. Lastly, Dr. Khabiso from South Africa will present how maternal oral health can be integrated at the national policy level through the collective efforts of public health organizations. Dr. Lee, the chair of this workshop, will provide a literature review on maternal oral health studies and how maternal oral health can be an essential part of primary and perinatal care and the WHO oral health initiative set for 2030.

Key messages:

- Maternal oral health is essential in primary and perinatal health care discussion and a critical optic for global and public health agendas.
- There are various maternal oral health programs and initiatives around the globe at care delivery level, community level, and policy level.

Abstract citation ID: ckac129.257
Introducing Maternal Oral Health As Global Health And Public Health Agenda

Hyewon Lee

H Lee[1]
[1]Oral Health Workgroup, WFPHA, Geneva, Switzerland
Contact: hyewon@idasociety.org

Background:

Achieving and maintaining good oral health during pregnancy is essential for both the oral and overall health of expecting mothers and their young children. Dental caries can negatively affect daily activities including eating, speaking, and social interaction, and when expecting mothers have active dental caries, the risk for dental caries in these children becomes higher. Another common oral disease, periodontitis, was found to be associated with systemic conditions, including cardiovascular disease, respiratory disease, diabetes, and potentially adverse birth outcomes.

Importance:

Some studies also showed the systemic impact of periodontal disease and the related pathogens that can lead to systemic inflammation and adverse birth outcomes. A mother's oral health status, her oral health knowledge, and beliefs also have been shown to significantly affect diet and home oral hygiene practice among her children.

Problem:

Despite the importance of mother's oral health and oral health knowledge to prevent dental caries in young children, maternal oral health is much neglected in primary and prenatal health discussion. This is even more significant in developing countries where oral health care infrastructure and workforce are inadequate. With increase in sugar consumption growing worldwide with this lack of oral health care infrastructure, oral diseases prevention and oral health promotion are the key to achieve oral health parity among the maternal and child population.

Solution:

In this presentation, the author will discuss literature on maternal oral health and how to position oral health as an essential part of perinatal care along with WHO oral health initiative set for 2030. This is an introduction presentation for this workshop to set a stage and make a case why maternal oral health is a critical topic to discuss in global health and public health perspectives.

Tobacco Use Prevention and Cessation Programme For Pregnant Women Accessing Antenatal Care In Urban Public Health Facilities In Southern India

Sophia Thomas

S Thomas[1], *H Lee*[2]
[1]Public Health Foundation of India, The Ramalingaswami Centre on Equity, Bengaluru, India
[2]Oral Health Workgroup, WFPHA, Geneva, Switzerland
Contact: drsophiathomas@gmail.com

Backgrounds and problem:

By 2030, tobacco use is estimated to kill more than 8 million people worldwide annually, with LMICs accounting for over 80% of those deaths. In India, about 4.6% of women continue to use tobacco mainly (> 80%) in smokeless (SLT) form during pregnancy. This may lead to: higher risk of anemia (∼ 70%), hypertension, and postpartum hemorrhage; poor fetal development; and 2-3 times higher rate of low-birth and stillbirth babies.

Importance:

Anti-tobacco initiatives often focus on smoking over SLT, which is commonly consumed by women. Drivers of SLT use among women include: cultural appropriateness, medicinal benefits, and poor social determinants of health. These factors must be taken into account while formulating effective anti-tobacco interventions for pregnant women, ensuring safe motherhood and neonatal health.

Solution:

We propose integrating oral health interventions in mitigating tobacco use within the existing antenatal care (ANC) model. Women enrolled in public health facilities in an urban poor neighborhood in South India receive oral health education (OHE) integrated into ANC. The intervention promotes oral hygiene habits, dietary advices, improving dental healthcare utilization, and sensitization on the ill-effects of tobacco-use. Training for ANC providers focuses on delivering antenatal tobacco screening, cessation, and referral services. This includes expanding the medical history to record tobacco use, conduct oral examination and referrals to dentists and/or tobacco cessation centres. Final outcomes of OHE will be measured using pre and post KAP surveys informed by WHO Oral Health Surveys; and training programme using in-depth interviews among providers. Desired policy change is the inclusion of tobacco prevention and cessation programme in the Indian ANC guidelines.

Oral Health Literacy In Young Migrant/Refugee Mothers From Developing Countries

Jane-Frances Esimekara

J Esimekara[1], *H Lee*[2]
[1]Unité de Chirurgie Orale, Département de Chirurgie Hôpitaux Universitai, Geneva, Switzerland
[2]Oral Health Workgroup, WFPHA, Geneva, Switzerland
Contact: jane-francis.esimekara@etu.unige.ch

Background and problems:
In the last decade, migration has increased due to climatic, economic, and social factors. Oral health is an integral part of overall health, but primary health packets for migrants/refugees often neglect oral health education and care in the care delivery system. The present article aims to present a realistic approach to integrating oral health into existing structures for young migrant/refugee mothers on a community level in Switzerland.

Importance:
As a young child's oral health is closely related to mother's oral health status and oral health knowledge level, it would be critical that migrant/refugee mothers have access to timely oral health education and care through the primary health care system.

Solution:
We propose an integrated oral health care model for migrant/refugee mothers that maximizes the existing primary health care system. Using existing maternal oral health resources, a training module is developed for the primary care care workforce that serve migrant/refugee mothers. This training module includes oral health needs and status assessment and delivering preventive oral health services in primary care settings. The module includes drawings and images to describe the dangers of poor oral hygiene during pregnancy related to the health of mothers and babies and how to keep the mouth healthy with low-cariogenic diet practice and home oral hygiene care. Primary health care workforce in selected migrant health centers, like nurses, medical aides, and community health care workers, is trained by this module and evaluated by a set of self-assessed questionnaires before and after the training for knowledge improvement, attainment, and clinical practice changes. Migrant mothers participate in questionnaires on oral health hygiene practice and access to dental care during pregnancy and for their young children. The questionnaires are validated by the affiliated university-hospital clinical research center.

Innovative Ante-Natal Care: Healthy Teeth Healthy Baby, An Interprofessional Collaboration Initiative In Indonesia

Hyewon Lee

I Adyatmaka[1], *H Lee*[2]
[1]Department of Dentistry, Christian Maranatha University, Bandung, India
[2]Oral Health Workgroup, WFPHA, Geneva, Switzerland
Contact: hyewon@idasociety.org

Background and problem:
SDG 3.1 sets out that by 2030, the global maternal mortality ratio (MMR) should be reduced to 70 per 100,000 lives and no country should have MMR above 140 per 100,000 lives. Indonesia still has an MMR of 177 by 2017 data by the World bank. Urgent action is needed to improve the health and survival of women and babies. The main causes of MMR in Indonesia are Hemorrhage, followed by pre-eclampsia, and others, related with diabetes, stroke, etc.

Importance:
Previous studies have shown the association between oral dysbiosis and pre-eclampsia, preterm birth and low birth weight. Oral microbiome of the mother being a key player in pregnancy outcomes. Periodontal disease is considered a possible risk factor for the health of the mother and the newborn.

Solution:
Program goal of this program, "Innovative AnteNatal Care, Healthy Teeth, Healthy Baby", is to create the ecology right from the start, by incorporating oral health diagnosis and prevention into routine antenatal care. This approach achieves a healthy oral condition that can improve systemic health during pregnancy. The program also achieves a healthy and resilient family through oral health empowerment and delivering healthy babies (superior generation 2045-President Joko Widodo). Processes included avocation to provincial health districts, initial survey of the perception and oral health status of pregnant mothers, module preparation, and socialization to health districts and related officers. The program has trained midwives and dental providers and secured governmental budgets for sustainable activities, including socialization and assistance to pregnant mothers and their husbands, field penetration by health professionals, and evaluation of the programs.

Maternal Oral Health and Global Oral Health: Policy Perspective

Khabiso Ramphoma

K Ramphoma[1], *H Lee*[2]
[1]Department of Community Oral Health, University of the Western Cape, Cape Town, South Africa
[2]Oral Health Workgroup, WFPHA, Geneva, Switzerland
Contact: kramphoma@uwc.ac.za

Background and problems:
The findings of the last South African National Children Oral Health Survey conducted between 1999 and 2002 indicated a national prevalence of dental caries at 60% among 6-year-olds, with over 80% of untreated caries. Various studies have shown that one of the successful strategies in preventing dental caries is intervention during pregnancy by providing prenatal oral health education.

Importance and opportunities:
To successfully mitigate the challenge of ECC, South Africa needs a holistic approach strategy that will integrate oral health services into existing general health programmes, especially into antenatal care (ANC). South Africa National Oral Health Policy and Strategy states that "Integrate oral health strategy elements and strategies into programmes and policies of all sectors that impact community health like maternal and women's health." All government health care facilities offer free essential ANC services, identifying risk factors relating to poor maternal and birth outcomes. This existing infrastructure can be utilized to deliver oral health education and care for expecting mothers as essential ANC services.

Solution:
The Public Oral Health Forum, a non-profit organization in South Africa, seeks to develop maternal and oral health policies that can be aligned with its research and policy development strategy. It proposes maternal oral health policy and strategies, which could be applicable in the South African context: Education of pregnant women, prenatal providers, and dental and medical students about perinatal and infant oral health, integration of oral health in primary health care services, interprofessional workforce development and research to improve oral health and access to dental care among pregnant women and new mothers. This presentation will demonstrate how such maternal oral health policy and strategy are developed, aligning with existing policy and infrastructure in South Africa.

Re-admission after early discharge from involuntary hospitalization of psychiatric patients

Zohar Mor

Z Mor[1,2], *C Shachar*[3], *U Shai*[1], *R Sheffer*[1]
[1]Public Health, Ministry of Health, Tel Aviv, Israel
[2]School of Health Sciences, Ashkelon Academic College, Ashkelon, Israel
[3]Medical School, Tel Aviv University, Tel Aviv, Israel
Contact: zmor100@gmail.com

Background:

State psychiatrics in Public Health Departments in Israel can involuntary hospitalize patients (IHP) in psychotic status. IHP who are unsatisfied with the involuntary hospitalization can appeal to a Psychiatric Committee (PC) in the institution to ask to shorten their hospitalization. The PC can decide to discharge the patient to ambulatory treatment. This cohort study aimed to assess re-admission of IHP among patients who shortened their involuntary hospitalization in Tel-Aviv.

Methods:

IHP whose involuntary hospitalization was shortened by PC (research arm) were compared to IHP patients who completed the entire hospitalization length, as was initially recommended by the psychiatrist (control arm). Re-admission was defined as hospitalization within one year after release by the PC/end of hospitalization.

Results:

From 3,160 IHR between 2010 and 2015, 1,338 were re-hospitalized during a year after release, 317 (41.7%) from the research arm and 1,012 (42.6%) from the control arm, $p < 0.7$. Discharge of IHP by PC during first month of the involuntary hospitalization resulted in a higher re-admission rates than IHR from the control group (58.4% vs. 46.4%, respectively, $p < 0.001$). Yet, discharge of IHR by the PC after one month of hospitalization (or end of the hospitalization) resulted in lower re-admission rates (14.8% vs. 53.6%, respectively, $p < 0.001$). Risks factors for re-admission included male gender, Israeli born, single and diagnosis of schizophrenia.

Conclusions:

Re-admission rates were higher in IHR who were released by the PC during the first month of hospitalization. The first month is important for mental and therapeutic stabilization of IHP. After 30 days, release of IHP can be re-assessed according to the patients' situation. Early discharge of males who were diagnosed with schizophrenia should be carefully assessed.

Key messages:

- Early discharge of psychiatric patients from involuntary hospitalization should be assesses only after the first 30 days of hospital admission, especially among young males with schizophrenia.
- Early discharge of psychiatric patients from involuntary hospitalization should be assesses only after the first 30 days of hospital admission, especially among young males with schizophrenia.

Abstract citation ID: ckac129.263
The 2009-2014 economic crisis and deaths by suicide in Portugal: time series analysis

Vera Pinheiro

V Pinheiro[1,2], *C Caetano*[3], *S Pereira da Silva*[3], *B Nunes*[3]
[1]CINTESIS, Centre for Health Technology and Services Research, Porto, Portugal
[2]Public Health Unit, ACES Arco Ribeirinho, ARS LVT, Lisbon, Portugal
[3]National Health Institute Dr. Ricardo Jorge, Lisbon, Portugal
Contact: verafcpinheiro@gmail.com

Introduction:

Population health, including mental health, is influenced by its socioeconomic context. After the 2008 global economic crisis, studies found contradicting results: some showed an increased risk for self-harm and suicidal behavior, while others found the opposite association. To the best of our knowledge, there is no research in Portugal on the subject. Thus, our aim was to estimate the impact of the Portuguese economic crisis of 2009-2014 on the death rate by suicide and self-inflicted injury in Portugal.

Methods:

A retrospective ecological study with an interrupted time series analysis of deaths by suicide and self-inflicted injury (data from the National Statistics Institute) in mainland Portugal, in 2003-2014, was performed. Resident population data was also retrieved from the National Statistics Institute. Binomial negative generalized linear models were used to compare rates and trends before (2003-2008) and during (2009-2014) the economic crisis. All rates were stratified and adjusted for seasonality.

Results:

The economic crisis was associated with 13% a step increase in the death rate due to suicide and self-inflicted injury, with unemployment playing a significant mediating role, being negatively associated to the outcome. Differences between groups exist, with males, working-age groups and the North and Centre regions being the most impacted, globally.

Conclusions:

Economic downturns pose risks for suicidal behavior. Unemployment may play a role in this association. Employment protection schemes can prevent this impact, so urgent action is needed to prevent economic crisis leading to additional suicides, especially in the context of the COVID-19 pandemic and the economic crisis it caused.

Key messages:

- The Portuguese economic crisis of 2009-2014 was associated with an increased death rate due to suicide, especially in males, working-age groups and the North and Centre regions.
- Unemployment may play a role in this association, and active labour market programmes can prevent the negative impacts of economic crisis leading to additional suicides.

Abstract citation ID: ckac129.264
Educational inequalities in major depressive disorder over the adult life course: a microsimulation

Alexander Lepe

A Lepe[1], *LA Hoveling*[2], *M Boissonneault*[3], *JAA de Beer*[3], *SA Reijneveld*[1], *MLA de Kroon*[1,4], *AC Liefbroer*[2,3,5]
[1]Health Sciences, UMC Groningen, Groningen, Netherlands
[2]Epidemiology, UMC Groningen, Groningen, Netherlands
[3]NIDI, The Hague, Netherlands
[4]Public Health and Primary Care, KU Leuven, Leuven, Belgium
[5]Sociology, Vrije Universiteit Amsterdam, Amsterdam, Netherlands
Contact: a.lepe@umcg.nl

Background:

Educational inequalities in major depressive disorder (MDD) pose a major challenge. Tackling this issue requires evidence on the long-term impact of intervening on modifiable factors, e.g. behavioural and psychosocial factors. Therefore, we aim to simulate the development of educational inequalities in MDD across the life course, and to assess the impact of intervening on the modifiable factors that contribute to these inequalities.

Methods:

We used data from the prospective Dutch Lifelines Cohort Study to estimate the required input for a continuous-time microsimulation. The microsimulation allowed us to estimate the development of educational inequalities in MDD with a synthetic cohort of 500,000 individuals followed from ages 18 to 65, and to assess the potential benefit of intervening on quality of social contacts, health literacy, and smoking.

Results:

On average, an additional 19.1% of individuals with low education will ever experience MDD between ages 18 and 65 compared to those with high education (32.0% vs 12.9%, respectively). Additionally, individuals with low education generally will develop MDD 0.9 years earlier (35.6 years vs 36.5 years, respectively) and spend 1.2 years more with MDD (6.2 years vs 5 years, respectively), than individuals with high education. Improving the quality of social contacts in individuals with low education would have the largest impact; it would reduce the inequalities in the prevalence, onset, and duration of MDD by an average of 18.4%, 18.3%, and 28.6%, respectively.

Conclusions:

Intervening on modifiable factors, especially quality of social contacts, in individuals with low education could help reduce the large estimated educational inequalities in MDD over the life course.

Key messages:

- There are large educational inequalities in major depressive disorder (MDD) over the life course, especially with regard to the life course prevalence of MDD.
- Improving quality of social contacts, and to a lesser extent health literacy and smoking behaviours, amongst individuals with low education may help reduce the inequalities in MDD.

Abstract citation ID: ckac129.265
Risk factors for mental health disorders during the COVID-19 pandemic in Spain: A cohort study

Pere Castellvi

A Miranda-Mendizabal[1], J Piqueras[1], P Castellví[1], S Álvarez[1], S Díaz[1], L Gómez[1], S Recoder[2], N Sánchez[1], E García Durán[1], CG Forero[1]
[1]School of Medicine, Universitat Internacional de Catalunya, Sant Cugat del Vallès, Spain
[2]Department of Basic Sciences, Universitat Internacional de Catalunya, Sant Cugat del Vallès, Spain
Contact: pcastellvi@uic.es

Background:

Data comparing the populations' mental health from before, during and after the pandemic is needed. We aim to assess the risk factors for the first-onset and persistence of major depressive disorder (MDD) and suicidal thoughts and behaviours (STB) during the first year of the pandemic among the Spanish general population.

Methods:

Cohort study through two online surveys from before the pandemic (N = 2,005, October/November 2019) and 12-months later (N = 1,357) on an adult Spanish, nationally representative, population-based sample. Multiple logistic regression models were used to assess the association between socio-demographic, COVID-19 related variables and health-care received during the pandemic with the onset and persistence of MDD and STB.

Results:

Women have more than 3-fold risk for the onset (OR 3.18; CI95% 1.40 -7.22) and persistence (OR 8.62; CI95% 1.74-42.48) of MDD. Studying and working at the same time (OR 10.13; CI95% 2.17-47.35) and having close relatives/friends with COVID-19 infection (OR 14.84; CI95% 1.91-115.18) or death (OR 5.26; CI95% 1.56-17.73) due to COVID-19 are risk factors for MDD onset. Sick-leave (OR 17.19; CI95% 2.65-112.56) and unemployment (OR 7.01; CI95% 1.85-26.43) increased the risk for MDD persistence. Death of friends/colleagues due to COVID-19 (OR 8.40; CI95% 1.47-48.07) increased the risk for STB onset, and being on sick-leave (OR 7.91; CI95% 1.80-34.66) for STB persistence.

Conclusions:

During the COVID-19 pandemic, women were consistently more at risk of having worse mental health than men. Direct and indirect consequences caused or aggravated by the pandemic are common risk factors for the increased risk for the onset and persistence of both MDD and STB. Identification of high-risk subgroups and risk factors for MDD and STB among the Spanish general population will allow the developing and implementing of evidence-driven strategies for reducing the long-term impact of the pandemic in populations' mental health.

Key messages:

- The pandemic consequences, whether due to having had COVID-19, having close people affected or who have died from the infection and the social consequences increase the risk for worse mental health.
- Evidence-driven strategies for reducing the long-term impact of the pandemic in populations' mental health should be a public health priority.

Abstract citation ID: ckac129.266
Are loneliness interventions effective in reducing loneliness? A meta-analytic review of 128 studies

Mathias Lasgaard

M Lasgaard[1], C Løvschall[1], P Qualter[2], LM Laustsen[1,3], MH Lim[4], HT Maindal[5], AS Hargaard[1], J Christensen[1,6]
[1]Public Health and Health Services Research, Defactum, Central Denmark Region, Aarhus, Denmark

[3]Department of Clinical Epidemiology, Aarhus University, Aarhus University Hospital, Aarhus, Denmark
[4]Iverson Health Innovation Research Institute, Swinburne University of Technology, Melbourne, Australia
[5]Department of Public Health, Aarhus University, Aarhus, Denmark
[6]Department of Psychology, University of Southern Denmark, Odense, Denmark
Contact: mathias.lasgaard@stab.rm.dk

Loneliness is widely acknowledged as a growing public health concern, accelerated by the onset of the COVID-19 pandemic. However, our knowledge about the effectiveness of interventions to reduce loneliness across the lifespan, including knowledge of different intervention strategies, is limited. This preregistered systematic review and meta-analysis aimed to evaluate the effect of interventions to reduce loneliness. The systematic review identified 136 studies. The meta-analysis included 128 studies comprising 54 randomised controlled trials (RCTs) (n = 6,379), 23 multi-cohort studies (n = 2,882) and 48 single-cohort studies (n = 3,009). A small to moderate statistically significant effect was detected (RCTs; SMD = -0.47, multi-cohort studies; SMD = -0.24, single cohort-studies; SMD = -0.42). Using the GRADE system, confidence in the estimates was assessed as low or very low, implying that the estimates may potentially be higher or lower. No statistically significant differences were found between age groups. Psychological treatment, social support interventions, and social and emotional skills training appeared to be the most effective intervention strategies in reducing loneliness but there is currently no strong reason to prefer one intervention strategy over another. Further analyses demonstrated that the long-term effects (i.e., one to six months after the intervention) were comparable to the short-term effects (i.e., up to four weeks after the intervention). Findings from the current meta-analyses provide overall evidence of the effectiveness of loneliness interventions. Given methodological limitations, including the heterogeneity of the reviewed studies, it remains unclear who the interventions would help the most. Overall, there is a need for rigorous and high-quality development and evaluations of interventions for loneliness.

Key messages:

- The findings of this meta-analytic review suggest that interventions designed to reduce loneliness are effective.
- Psychological treatment, social support interventions, and social and emotional skills training are the most promising interventions, albeit the magnitude of the effects is moderate.

4.P. Workshop: Health promotion policy implementation evaluation: tools, challenges and futures directions

Abstract citation ID: ckac129.267

Organised by: University of Limerick (Ireland)
Chair persons: Aurélie Van Hoye (Ireland), Catherine Woods (Ireland)
Contact: aurelie.vanhoye@ul.ie

Background:

Public policies can enhance opportunities for the whole populations to be more health promoting. They are important tools as they tackle the upstream component of health promotion behaviours to influence the environment and opportunities for the general population. Research has focused on policy development and content, but less on its implementation process and s evaluation. These latter steps are necessary for policy accountability, would serve policy-making process and strengthen policy impact for real change.

Objectives:

The objectives of the workshop are to present different methods and toolkits allowing the evaluation of policy implementation at national level.

Workshop format:

The workshop will include 4 presentations, with two systematic reviews and two tool presentation, to offer opportunities to the audience to understand both theoretical and methodological perspective and applied process in regard to health promotion policy evaluation and implementation evaluation. First, a systematic literature review considering the fitting framework for implementation of policies promoting health nutrition and physically active lifestyle will describe the components and scope of 18 policy implementation frameworks. Second, a systematic literature review on methods of physical activity policy monitoring will help us to learn from the analysis of 112 studies on research-driven, government-driven or co-production approaches, their strengths and weaknesses. The third presentation will introduce the Physical Activity Environment Policy Index, a tool to monitor and benchmark policies to improve the healthiness of physical activity policy environment, as well as provide guidance on how to use it. The fourth presentation will present the health promoting sports clubs national audit tool, aimed at reviewing policy supporting sports clubs to promote health, and present preliminary results from its use in Ireland. During the presentation we will pose questions to the audience, encouraging them to apply the theory/tools to their own context, and to spark conversation and interaction as part of the workshop. After the presentations, questions from the audience will be discussed with each presenter, and a discussion will be open in terms of future challenges for health promotion policies implementation evaluation.

Key messages:

- Guidance is needed to evaluate health promotion policies implementation to improve practice, as well as development of framework and methods to build toolkits.
- Policy implementation evaluation is key for improving policy making process.

Abstract citation ID: ckac129.268

Finding the fitting framework for the implementation of policies promoting healthy nutrition and physically active lifestyle: Results from a systematic review

Sarah Forberger

S Forberger[1], K Lobczowska[2], A Banik[2], P Romaniuk[3], T Kubiak[4], B Meshkovska[5], A Neumann-Podczaska[6], M Kaczmarek[3], M Scheidmeir[4], & al[1]

[6]Department of Palliative Medicine, Poznan University of Medical Sciences, Poznan, Poland
Contact: forberger@leibniz-bips.de

Background:

Policies are an important upstream component of health promotion to influence the general population. Various frameworks exist to help implement policies. However, there is currently no overarching synthesis that describes the differences between policy implementation frameworks. In this study, we examined frameworks for implementing policies to promote healthy eating, physical activity and reduce physical inactivity and aimed to explore the scope of the frameworks, the content of the constructs they contain (e.g. processes, determinants, evaluation), the level at which these constructs operate and the inclusion of equity factors.

Methods:

A systematic review (PROSPERO registration number: CRD42019133251) was conducted using 9 databases and 8 stakeholder websites. The content of 38 policy implementation frameworks was coded and analysed.

Results:

All three constructs were covered by 18 frameworks: description of the process, determinants and evaluation of implementation. The majority of frameworks (25/38) considered constructs from three levels: the individual, organisational/community and system levels, with system level constructs being included less frequently than individual level or organisational/community level constructs. Most frameworks (32/38) contained sections that were exclusively descriptive. In addition, 19 frameworks contained prescriptive and 23 explanatory sections. The complex systems approach was included in 8 of the frameworks. More than half of the frameworks (21/38) did not consider equity constructs.

Conclusions:

Most frameworks have a complex scope, include multi-level constructs, combine sections that are purely descriptive with sections that consider prescriptive and/or explanatory associations, and include few or no equity constructs. The findings of this study can facilitate the process of selecting the framework that best fits the needs and goals of policy makers, researchers and policy implementation actors seeking guidance.

Abstract citation ID: ckac129.269
Methods of policy monitoring in physical activity promotion: a systematic review across different levels of government

Sven Messing

S Messing[1], A Tcymbal[1], K Abu-Omar[1], D Richardson[1], P Gelius[1]
[1]Department of Sport Science and Sport, Friedrich-Alexander-Universität Erlangen-Nürn, Erlangen, Germany
Contact: sven.messing@fau.de

Background:

Even though the importance of policy monitoring in public health has increased in the last decades, there is still a lack of understanding what different approaches of policy monitoring exist and which methodology they employ. In order to address this research gap, this review attempts to provide a comprehensive overview about the methods of policy monitoring in the field of physical activity promotion.

Methods:

A systematic search was conducted in five scientific databases, using the terms ''physical activity'', ''policy'' and ''monitoring'' and their variations. In total, 12.963 studies were identified and, after the elimination of duplicates, screened independently by two reviewers. During full text analysis, information on the methods applied for policy monitoring was extracted and studies were categorized based on their key characteristics (monitoring tool, policy level, and setting).

Results:

The search yielded in a total of 112 studies that were structured into seven categories: Report Cards on Physical Activity for Children and Youth, HEPA Monitoring Framework, HEPA Policy Audit Tool, national policies, subnational policies, school setting, and childcare setting. Across all categories, policy monitoring focused mainly on national level policies in a single country. Differences were identified with regards to the level of government involvement which allowed to differentiate between research-driven approaches (little or no government involvement), government-driven approaches (led by governments), and co-production approaches (strong collaboration between researchers and governments).

Conclusions:

Research-driven, government-driven and co-production approaches have different strengths and weaknesses with regards to the monitoring of policies. Awareness needs to be raised regarding the implications of these approaches, and more research is needed to analyse the impact of policy monitoring on policy-making in public health.

Contact: catherine.woods@ul.ie

Background:

Insufficient physical activity (PA) is a global issue for health. A multifaceted response, including government action, is essential to improve population levels of PA. The purpose of this study was to develop the 'Physical Activity Environment Policy Index' (PA-EPI) monitoring framework to assess government policies and actions for creating a healthy PA environment.

Methods:

An iterative process was undertaken. This involved a review of policy documents from authoritative organisations, a policy audit of four European countries, and systematic reviews of scientific literature. This was followed by an online consultation with academic experts (N = 101; 20 countries, 72% response rate), and policymakers (N = 40, 4 EU countries). During this process, consensus workshops where quantitative and qualitative data alongside theoretical and pragmatic considerations were used to inform PA-EPI development.

Results:

The PA-EPI is conceptualised as a two-component 'policy' and 'infrastructure support' framework. The two components comprise eight policy and seven infrastructure support domains. The policy domains are education, transport, urban design, healthcare, public education (including mass media), sport-for-all, workplaces and community. The infrastructure support domains are leadership, governance, monitoring and intelligence, funding and resources, platforms for interaction, workforce development, and health-in-all-policies. Forty-five 'good practice statements' (GPS) or indicators of ideal good practice within each domain concludes the PA-EPI. A potential eight-step process for conducting the PA-EPI is described.

Conclusions:

Once pre-tested and piloted in several countries of various sizes and income levels, the PA-EPI GPS will evolve into benchmarks established by governments at the forefront of creating and implementing policies to address inactivity.

Background:

Sports clubs have requested support from national governing authorities to invest in health promotion (HP), by developing policies, guidelines and dedicated funding. This manuscript outlines the development of a national audit tool to review policies development and implementation to support HP in sports clubs.

Methods:

A 5-step process was undertaken by an international project team: (1) a rapid literature review to identify items assessing policies in physical activity, HP and sports, (2) a thematic analysis to categorize items, (3) a Delphi method to analyze item relevance, country specificity, reformulation, validation and organization, (4) face validity through an online survey and in-depth interviews with expert representatives on physical activity and sports and (5) audit tool finalization though project team consensus.

Results:

Eight sources were reviewed with 269 items identified. Items were coded into 25 categories with three broad themes: policies, actors and settings-based approach. The Delphi study extracted and refined 50 items and categorized them into 10 sections. After revisions from 22 surveys and 8 interviews, consensus was reached by the international project team on 41 items categorized into 11 sections: Role of ministry or department; Policies; Communication; Implementation & Dissemination; Evaluation & Measurement methods; Sub-national level policies; Funding & Coordination; Participative approach; Actors & Stakeholders; National sporting events; Case studies and Implicated stakeholders.

Conclusions:

To progress HP in the sports club context it is necessary to understand existing national level policies. This national audit tool will aid in monitoring and assessing national policies for health promoting sports clubs.

4.Q. Workshop: Showcasing PHIRI use case results measuring the impact of COVID-19 on population health

Abstract citation ID: ckac129.272

Organised by: PHIRI, EUPHA-PHMR
Chair persons: Enrique Bernal-Delgado (Spain), Thomas Ziese (Germany)
Contact: thissenm@rki.de

The COVID-19 pandemic has clearly demonstrated the urgent need for a cross-border and structured European mechanism to exchange, organise and access reliable health information between countries, especially in the area of population health. Population health information, defined by data on health status, health determinants and healthcare systems performance, allows for oriented research to increase the knowledge base in Europe and underpin political decision-making. Its exchange requires timely and topical provision of high-quality health information. There are many indirect effects of the COVID-19 pandemic that affect health through various pathways including secondary consequences on health and wellbeing due to delayed prevention, diagnosis and medical treatment. Within the Population Health Information Research Infrastructure (PHIRI) we look at four use cases measuring the impact of COVID-19 on population health and demonstrating how a broad variety of routine data can be pooled and/or used for secondary analysis in a distributed way across Europe aiming to facilitate research by making scalable, reproducible methods available. These use cases represent pilot activities for the benefits and added value of an infrastructure supporting federated analysis by bringing together data from different European countries and feeding the results into the federated research infrastructure. In over 20 data hubs, data is mobilised and ready to be analysed in a distributed manner. The use case outputs will be processed in an interoperable way by formalising data models, data management processes and analytical pipelines, all of which are part of the client-server PHIRI federated infrastructure implemented as here 10.5281/zenodo.6483177. The workshop aims to ensure a better understanding of COVID-19 impacts in specific subgroups and risk settings by conducting research through real-life use cases of immediate relevance. The FAIRified use cases analysis results focusing on comparisons between countries are presented and provide actionable outcomes to guide policy makers in preparedness and response scenarios. Knowledge and expertise developed across Europe is shared in this workshop. The four presentations will focus on selected aspects of COVID-19 impacts on population health. The first presentation will be on direct and indirect determinants of COVID-19 infection and outcomes in vulnerable population groups with reference to inequalities. This will be followed by a contribution of COVID-19 related delayed care in breast cancer patients. The third presentation looks at the impacts of COVID-19 on perinatal health inequalities followed by the fourth on insights in COVID-19 related changes in population mental health. Exchange with the audience will facilitate knowledge and opinion exchange through an interactive Mentimeter poll during the session.

Key messages:

- The results will support the exchange of knowledge and expertise by facilitating insights in the impacts of COVID-19 in specific subgroups and risk settings compared across European countries.
- Actionable outcomes to guide political decision-making in preparedness and response scenarios will be provided.

Abstract citation ID: ckac129.273

Impact of COVID-19 on hospitalisation for diverse conditions in European countries

Andrea Schmidt

RA Lyons[1], AE Schmidt[2], S Aldridge[1], S Mathis-Edenhofer[3], F Estupiñán-Romero[4], M Thissen[5], M Gissler[6,7], L Palmieri[8], O Majek[9,10]

Background:

The COVID-19 pandemic has had an unprecedented impact on Europe. Health systems came under strain, with non-urgent treatments postponed and resources reserved for treatment of COVID-19 patients. Delayed care seeking has been reported, for fear of infection with SARS-CoV2. Yet, the scale of this impact remains under researched. This study aims to compare indirect effects of the pandemic in a European cross-country study aiming to highlight the potential of Population Health Information Research Infrastructures (www.phiri.eu).

Methods:

Focusing on (i) major vascular events (MVE) and (ii) elective surgery for joint replacements (ESJR) as well as (iii) serious trauma this study analyses individual level hospital data in a standardised harmonised data model. We compared pre-pandemic incidence rates (2018-2019) with rates for 2020 and 2021. Analyses are systematically contrasted with SARS CoV2 incidence rates, and policy measures taken based on the OxCGRT index.

Results:

A drop in hospital discharge rates was observed during the pandemic in all countries but differing by condition and month. Socio-economic differences also varied by condition. Our evidence suggests that periods of more severe policy measures also correlated with more dramatic drops in regular hospital activities.

Conclusions:

Our findings provide new insights on the dramatic level of deprioritisation of essential services faced by non-COVID-19 patients in Europe. From a public health perspective, hospital escalation plans should be developed early on to avoid negative mid and long-term health and financial consequences of indirect effects. The study demonstrates the tremendous potential in exploiting health information systems in a systematic way across countries and the value of the PHIRI system. Further research should investigate policy trade-offs involved in severe lockdown measures during a pandemic and variations in health service resilience for future pandemic preparedness.

Contact: festupinnan.iacs@aragon.es

Background:

Healthcare systems across Europe reorganized services to provide attention to COVID-19 patients. In the event of the surge of cases, countries were forced to cancel or postpone non-urgent care. The objective of this work is to investigate whether there were time-to-treatment delays in breast cancer due to April-May 2020 restrictions, and whether the delays were permanent and different across countries.

Methods:

Design: Quasi-experimental pre-post study with a historical control. Population: Virtually the universe of breast cancer patients receiving elective surgery, radiotherapy, hormonal therapy or chemotherapy since January 2017 (until December 2021) in the participant regions - Belgium, Marché (IT), Riga (LV), Portugal, Wales, and Aragon (ES). The main endpoint is the change in the median time-to-treatment before and after an empirical joint-point. The study variables are detailed here https://doi.org/10.5281/zenodo.5148022. Analysis: Distributed generalized additive models using https://cran.r-project.org/package = mgcv.

Results:

Preliminary results show that the impact in March-April 2020 time-to-treatment evolved differently across countries. For instance, while the median time from diagnosis to surgery, as the first treatment, increased from approximately 39 days (2018-2019) to more than 45 days (2020-2021) in Wales, in the Marche region (IT) the median time decreased from 52 days in 2017-2019 to 47 days in 2020. Complete analyses for the rest of the participant countries are currently undergoing.

Conclusions:

We have observed differences in time to treatment in women with breast cancer across countries; however, the magnitude and direction of the effect has been uneven across countries.

Background:

The COVID-19 pandemic and lockdowns may adversely affect pregnancy outcomes due to disrupted healthcare provision and increased stress, anxiety and economic hardship. We assessed changes in perinatal outcomes in 2020 using population birth data in Europe.

Methods:

25 Countries in the Euro-Peristat Network implemented a federated analysis using routine national data. Countries generated anonymised aggregate data files using R scripts from individual-level data formatted to a common data model with 22 variables. We compared preterm birth, stillbirth, neonatal death and caesarean delivery rates in 2020 to 2015-2019 for 2 periods: full-year (FY) and pandemic (March-September [MS]). Data from October onward were not included in the MS period because potentially declining pandemic-related fertility may affect perinatal indicators. Country-specific relative risks (RR) for the periods, adjusted for linear trends, overall and by socio-economic (SES) group, were calculated and pooled using random effects meta-analysis.

Results:

Preterm birth rates decreased slightly (pooled RR: 0.97FY [95% confidence interval (CI) 0.95-0.99]; 0.98MS [0.96-1.00]) in 2020. Heterogeneity was high (I2FY = 85%; I2MS = 70%), with 5 countries experiencing significant declines. Neonatal mortality rates were unchanged (0.97FY [0.92-1.01]) while stillbirth rates were higher (1.05FY [1.01; 1.09]; 1.10MS [1.02; 1.19]). Caesarean rates were slightly raised (1.02FY [1.00-1.03]; 1.02MS [0.99-1.04], 5 countries had significant increases). Increases for stillbirth were more pronounced in the lowest (1.08FY [0.99-1.16]) versus highest SES group (1.05 FY [0.93-1.17]).

Conclusions:

In 2020, there was an unexpected decline in preterm birth in some countries, while increases in stillbirths and caesarean occurred in others. High country-level heterogeneity suggests that some government policies to mitigate the pandemic might have been more protective of pregnant women and newborns than others.

[6]Karolinska Institutet, Stockholm, Sweden

Contact: crodb@isciii.es

Background:
The COVID-19 pandemic, and its consequences in terms of control measures and restrictions to normal life, has affected the population mental health. One of the four case studies from the Population Health Information Research Infrastructure (PHIRI) for COVID-19 is focused on mental health with the objective to measure changes in incidence of mental health problems associated with the COVID-19 pandemic in several European countries.
Methods:
Using electronic health records (EHR), data on new episodes of depression or anxiety, prescription of antidepressants and anxiolytics, and visits to primary care, specialized care or emergency units with an episode of depression/anxiety, were collected by participant data hubs at national/regional level for the period 2017-2021. A common data model to collect the data was defined for all participating data hubs and analysis of status prior and during the COVID-19 pandemic was performed using R.
Results:
Data hubs from Austria, Finland, Spain (Aragon), and United Kingdom (Wales) were able to provide aggregated results from raw individual-level data. Preliminary analysis of trends suggests a decrease in new cases of depression and anxiety in the pandemic period (2020-2021) in comparison with previous years. Different trends were observed between data hubs regarding prescription of drugs and the number of primary/specialized care visits due to depression or anxiety. Issues in the access to data in some of the participating data hubs were observed, related to ethical and legal matters, and the lack of centralized registers and of private consultations statistics.
Conclusions:
The results of this use case show that EHR for the secondary use can be retrieved in a common way across Europe to analyse and compare the impact of COVID-19 in population mental health in European countries. However, the process is more complicated and time consuming than expected.

[6]Department of Readaptation and Geriatrics, University of Geneva, Geneva, Switzerland
Contact: cristian.carmeli@unifr.ch

Background:
Low birth weight (LBW) and preterm birth are associated with an increased risk of neonatal death and chronic conditions across the life course. Reducing LBW is a global public health priority and requires strategies to improve healthcare during pregnancy. We aimed to assess the effect of a health policy providing full coverage of illness-related costs from 13 weeks of gestation through 8 weeks postpartum on birth outcomes and neonatal mortality in Switzerland.
Methods:
We applied a regression discontinuity design to administrative data gathered as part of a Swiss research program (NCCR on the Move). We included all children (N = 166,709) born between March 1, 2013 and February 28, 2015. The outcomes were birth weight (BW), gestational age (GA), LBW (<2,500 g) and very low birth weight (VLBW; <1,500 g), preterm (<37 weeks of gestation), and extremely preterm (<28 weeks), and neonatal ($\leq$ 28 days) death. Children were exposed to the policy if they were born from March 1, 2014 onwards. We estimated the intention-to-treat effect of the policy using parametric regression models.
Results:
Children had a mean BW of 3,291 g and mean GA of 275 days. The prevalence of LBW was 6.4%, VLBW 1%, preterm 7.2%, and extremely preterm 0.4%, respectively. Some 0.3% newborn died within one month. The policy increased BW (mean difference = 13 g [95% confidence interval (CI): 1, 25]) and decreased the risk of LBW (odds ratio [OR] = 0.89; 95% CI: 0.82, 0.98) and VLBW (OR = 0.81; 95% CI: 0.64, 1.01). Additionally, the policy slightly decreased the risk of preterm birth (OR = 0.94; 95% CI: 0.87, 1.03), while it did not affect GA. Effect estimates for extremely preterm and neonatal mortality were imprecise and inconclusive.
Conclusions:
This quasi-experimental and population based-study of 166,709 live births between 2013 and 2015 in Switzerland provides evidence of a reduction in the risk of LBW, VLBW and preterm birth thanks to a health policy that fully covered healthcare services during maternity.
Key messages:
- Free access to healthcare during pregnancy may mitigate adverse newborn health outcomes.
- A Swiss health policy that fully covered healthcare services during pregnancy reduced the risk of low birth weight and preterm births.

Abstract citation ID: ckac129.278
Determinants of excess mortality during the COVID-19 pandemic in 18 countries of the CMOR consortium

Christiana Demetriou

C Kneebone-Hopkins[1], A Artemiou[1], CA Demetriou[2]
[1]School of Mathematics, University of Cardiff, Cardiff, UK
[2]Department of Primary Care and Population Health, University of Nicosia Medical School, Nicosia, Cyprus
Contact: demetriou.chri@unic.ac.cy

Many countries suffered excess all-cause mortality during the COVID-19 pandemic. This study aims to identify factors associated with excess mortality rates (EMR) in partaking countries during 2020. Weekly all-cause death counts for 2015-2020 were extracted from national databases for Australia, Austria, Brazil, Cyprus, Denmark, Estonia, France, Georgia, Israel, Italy, Mauritius, Norway, Peru, Slovenia, Sweden, USA, Ukraine and UK. EMR per 100,000 population were gauged using a 5-year mean baseline. Separate OLS multiple linear regressions explored pre-pandemic country profiles including healthcare system, geographic, socio-economic and population factors. Feature selection methods detected the main factors contributing to 2020 EMR. The health system model showed that an extra nurse per 1,000 and a 1% increase in Healthcare Access and Quality Index reduces EMR by 41.7% ($p = 0.019$) and 0.48% ($p = 0.034$). The model was statistically significant ($R^2 = 0.415, p = 0.018$). Although the geographical model suggested that a 1% increase in neighbouring countries increased EMR by 0.42% ($p = 0.078$), population density and the model itself were statistically insignificant ($p > 0.05$). The socio-economic and population model indicated a 1% increase in service employed (% of employed) and investment (% GDP) was linked with a 43.4% ($p = 0.01$) and 43.7% ($p = 0.01$) fall in EMR. The model was significant ($R^2 = 0.488$, $p = 0.007$). Death registration quality and population share over 70 years, improved model performance ($R^2 = 0.632$), but neither approached nominal significance. EMR during the COVID-19 pandemic benefited from higher ratios of nurses to population and able and prompt healthcare. The geographic traits were trivial in explaining EMR variation. Higher ratios of service employed, and investment (% of GDP) were linked to lower EMR. These results help to inform policies now and in future pandemics to strengthen resilience against EMR.

Key messages:

- This study identified which pre-pandemic factors affected EMR in partaking countries, adding to a growing body of work on the COVID-19 pandemic.
- Higher ratios of nurses to population, able and prompt healthcare, higher % employed, and investment (% of GDP) were linked to lower EMR.

Abstract citation ID: ckac129.279
Co-creation of activities to promote health and well-being of older people – a scoping review

Anne Seneca Terkelsen

AS Terkelsen[1], *CT Wester*[2], *G Gulis*[1], *J Jespersen*[1], *PT Andersen*[1]
[1]Public Health, University of Southern Denmark, Esbjerg, Denmark
[2]Public Health, University of Southern Denmark, Odense, Denmark
Contact: asterkelsen@health.sdu.dk

Background:

The global population is ageing and the need to promote health and well-being of this generation is essential. Co-creative practices can be solutions to welfare challenges in the health care sector and local policies. However, literature addressing co-creation of activities to promote health and well-being is sparse. The review aimed to identify health promotive activities co-created between the public and older people, the influence of co-creative activities on health and well-being of older people, and facilitators and barriers for doing co-creation.

Methods:

We searched for peer-reviewed and grey literature in eight scientific and five non-scientific databases. Two reviewers independently screened publications for eligibility according to inclusion and exclusion criteria and extracted data. An inductive thematic content analysis was applied for the analysis.

Results:

We included nineteen publications. Four themes related to co-creative activities emerged: ''Social activities'', ''Activities to create age-friendly environments'', ''Discussions of healthy ageing'', and ''Physical activities''. The co-creative activities influenced the overall well-being, and promoted active and healthy ageing, physical functioning, and quality of life. Identified facilitators for co-creation were the role of the facilitator, a supportive environment, recognition of competencies, while the main barriers were time and resources, and recruitment of participants.

Conclusions:

Few studies have investigated co-creation of activities to promote health and well-being of older people. The included studies dealt with activities in any form and not merely social and physical activities co-created. Future co-creation of activities with older people should consider the role of facilitators, the environment in which the co-creation takes place and value time, resources, and competencies of participants.

Key messages:

- Studies on co-creation of activities to promote health and well-being of older people is sparse and must be explored further.
- Future research may focus on co-creation of social and physical activities to promote health and well-being of older people and consider known facilitators for co-creation.

5.B. Oral presentations: Impact of COVID-19

Abstract citation ID: ckac129.280
Monitoring the reproduction number of COVID-19 in France: estimates compared from 3 datasets

Christophe Bonaldi

C Bonaldi[1], *A Fouillet*[1], *C Sommen*[1], *D Lévy-Bruhl*[2], *J Paireau*[3,2]
[1]DATA Science Division, French Public Health Agency, Saint Maurice, France
[2]Infectious Diseases Division, French Public Health Agency, Saint Maurice, France
[3]Mathematical Modelling of Infectious Diseases, Institut Pasteur, Paris, France
Contact: Christophe.BONALDI@santepubliquefrance.fr

Background:

The effective reproduction number (Rt) represents the average number of secondary cases generated by an infected person. During an outbreak, near-real-time monitoring of Rt constitutes a key indicator for detecting changes in disease transmission and assessing the effectiveness of interventions. The estimation of Rt usually requires identifying infected cases in the population which is in practice challenging from available data. The purpose of this study was to compare Rt estimates for COVID-19 surveillance in France based on three data sources of different sensitivity and specificity for identifying infected cases.

Methods:

By applying a statistical method developed by Cori et al., we estimated Rt using (1) confirmed cases identified from positive virological tests among the tested population (2) suspected cases recorded by a national network of emergency departments (3) hospital admissions for COVID-19 recorded by a national administrative system to manage hospital's organization.

Results:

From June 2020 to March 2022, the estimates of Rt in France showed similar temporal trends regardless of the dataset. Estimates based on the daily number of confirmed cases provided an earlier signal that the two other sources, with a lag of 3 and 6 days compared to estimates based on emergency department visits and hospital admissions, respectively.

Conclusions:

The COVID-19 experience has proven that monitoring temporal changes in Rt was a key indicator to help public health authorities controlling the outbreak in real time. Having data on infected people in the population to estimate the Rt is not straightforward in practice. As this study has shown, the opportunity of using more readily available data, provided that it is highly correlated with the spread of infection, gives a practical solution for monitoring the COVID-19 epidemic and any epidemic in general.

Key messages:

- The effective reproduction number (Rt) is a key parameter to monitor transmission during epidemics but its estimation from available data is often a critical issue.
- Based on COVID-19 experience, data sufficiently correlated with the spread of infection may be appropriate to estimate Rt and monitor its temporal trend.

Abstract citation ID: ckac129.281
Spread of SARS-CoV-2 at school through the pandemic waves: a population-based cohort study in Italy

Marco Fonzo

M Fonzo[1], I Pistellato[2], A Calzavara[1], P Sorrentino[1], V Selle[2], LG Sbrogiò[2], C Bertoncello[1]
[1]Hygiene and Public Health Unit, DCTVSP, University, Padua, Italy
[2]Department of Prevention, Local Health Authority, Venice, Italy
Contact: marco.fonzo@unipd.it

Background:

To limit SARS-CoV-2 transmission, proactive closure of schools is often believed by policy-makers and public an effective strategy. While evidence on the role of students in the spread is ongoing, effects of closure on children's well-being are well known. The number of secondary cases per class has been considered one of main driving criteria to mandate for distance learning. We aimed to calculate the rate of secondary infections per classroom and to identify factors associated with the development of school clusters.

Methods:

We conducted a population-based cohort study between October 2020 and November 2021 in the province of Venice, Italy, a catchment area of 600,000 inhabitants. Primary, middle and high-schools were included.

Results:

We identified 1,623 primary cases of SARS-CoV-2 infection in students. Of these, 72.5% did not lead to any secondary case in the school setting, 15.6% to 1, and 11.9% to 2+ contagions. The so-called second wave (Oct-Dec 2020) was associated with a lower occurrence of 2+ contagions (AOR = 0.37; 95%CI: 0.24-0.56) than the fourth (Sep-Nov 2021). Both primary (AOR = 1.74; 95%CI: 1.16-2.63) and middle schools (AOR = 1.76 95%CI: 1,14-2,72) showed higher odds than high schools for cluster generation of 2+ cases. The involvement of 2+ secondary cases was lesser associated with the index case being a student rather than school staff (AOR = 0.42; 95%CI: 0.29-0.60). The number of 2+ cases clusters per week followed a time trend in line with the general population incidence.

Conclusions:

The school environment does not facilitate viral spread, but rather reflects transmission in the community. Appropriate measures (use of airway protection devices, interpersonal distancing, frequent hand and respiratory hygiene) and timely case tracking make school a safe place. Given the documented negative effects of school closures on children's learning and well-being, maintaining school attendance is as essential as it is desirable.

Key messages:

- A SARS-CoV-2 positive student at school does not generate secondary infections in 3 out of 4 cases. The risk of cluster generation is lower when the index case is a student rather than school staff.
- The school environment does not facilitate viral spread, but rather reflects transmission in the community. School attendance is essential considering the effects on children's learning and wellbeing.

Abstract citation ID: ckac129.282
Long COVID in France: prevalence, management and long-term impact

Tatjana Makovski

TT Makovski[1], V Decio[1], L Carcaillon-Bentata[1], C Alleaume[2], N Beltzer[1], O Robineau[3,4], A Gallay[1], S Tebeka[1], J Coste[1]
[1]Department of Non-communicable Diseases, Santé Publique France, Saint-Maurice, France
[2]Department of Alert and Crisis, Santé Publique France, Saint-Maurice, France
[3]Sorbonne Université, Inserm, Paris, France
[4]University Lille, Centre Hospitalier de Tourcoing, Tourcoing, France
Contact: tatjanamakovski@hotmail.com

Certain percentage of population experiences persistent symptoms months after an acute Covid-19 episode (Long-COVID), with a significant impact on daily-life. Few studies exist on its prevalence and its impact among the general population. The main objective of this survey was to estimate the prevalence of Long COVID among the general adult population in France. Secondary objectives were to evaluate Long COVID management and to assess impact of this clinical condition on quality of life and mental health. Cross-sectional study was performed in March-April 2022 using an online self-administered questionnaire. The sample was selected by the quota method from a panel of volunteers. Its representativeness was ensured by appropriate weighting. Three groups were described: Long-COVID, COVID without persistent symptoms, never COVID. Post COVID-19 condition as defined by the WHO was applied for prevalence estimation. The prevalence was calculated by age and sex. Health care consumption and impact of Long COVID on quality of life and mental health will be studied comparing the three groups, using weighted adjusted polytomic regressions. Here, we present preliminary findings on Long COVID prevalence. There were 27,537 respondents, 52% females, mean age (SD) 49 (±16.5). Confirmed or probable COVID-19 was reported by 33.9% of participants; of whom 85.1% had confirmed laboratory test. Majority (65.1%) had COVID-19 <3 months ago. Long COVID concerned 1,086 (4%) participants. Prevalence was higher for females 4.6% vs. 3.3% for males, and among younger population for both sex groups. Overall, prevalence of Long COVID by age group was: 18-34 (6%), 35-49 (4.7%), 50-64 (3.4%), ≥65 (1.8%). This is a first estimation of Long COVID prevalence among the French population. Representativeness of the sample should be interpreted with caution due to a sample based on volunteers' response. Ongoing analyses will provide clearer understanding of the impact of Long COVID.

Key messages:

- This is a first estimation of Long COVID prevalence among the French population.
- There is a significant portion of the French population impacted by persisting or reoccurring symptoms defined by Long COVID; its impact and care management will be further evaluated.

Abstract citation ID: ckac129.283
Establishing intersectoral 'Schools Teams' to mitigate SARS-CoV-2 school transmission, 2020/2021

Peter Naughton

C Kelly[1], *P Naughton*[2], *E Kennedy*[2], *M Ward*[2]
[1]Health Protection Surveillance Centre, Dublin, Ireland
[2]Department of Public Health HSE East, CHO Area 6, Dublin, Ireland
Contact: Peter.naughton3@hse.ie

The SARS-CoV-2 pandemic disrupted the lives of up to 100,000 school-going children in Ireland. Consequently, intersectoral 'Schools Teams' were established for the 2020/2021 school year to reduce SARS-CoV-2 transmission in school settings. This novel public health intervention provides learning to inform future cross-sectoral collaborative work in Public Health in responding to infectious disease threats. For the 2020/2021 school year in Ireland, intersectoral Schools Teams were formed within each of eight regional Departments of Public Health to manage mitigation of SARS-CoV-2 transmission in school settings. These teams comprised of staff from Departments of Public Health and redeployed staff from the Department of Education. A nationally agreed schools process was followed by Schools Teams to manage SARS-CoV-2 cases and outbreaks in schools. Relevant cases were referred to the regional Schools Team for a public health risk assessment (PHRA). Close contacts were determined using appropriate definitions of close contact within a school setting through the PHRA. This model with centralised procedures and linked health/education teams was novel and adaptable to additional settings. Results from the East region of Ireland showed testing of close contacts of COVID-19 was conducted in 71.8% (676/942) of schools, with 43881 tests completed. Most Schools Team members reported efficient communication within the team (88.7%), a positive team culture (96.3%) and feeling comfortable in their roles following training (82.7%). The majority of members felt the team was able to effectively support schools to reduce COVID-19 transmission (92.5%). Lessons learnt include the synergistic working of educational and health professionals towards a common goal, maximising the skills of all, ensuring a better outcome for school children. Involving educational teams in active contact tracing of COVID-19 cases in schools maximised engagement of the educational sector in the COVID-19 response.

Key messages:

- Establishing intersectoral 'Schools Teams' pooled skills, resources and expertise, enabling development of synergistic solutions to a complex problem.
- This exemplifies a large national cross-sectoral collaborative working process involving education and public health sectors, providing a model for future responses to infectious disease threats.

Abstract citation ID: ckac129.284
Risk of SARS-CoV-2 reinfection 18 months after first infection: population-level observational study

Maria Elena Flacco

ME Flacco[1], *C Acuti Martellucci*[1], *G Soldato*[2], *G Di Martino*[2], *R Carota*[2], *A Caponetti*[2], *L Manzoli*[3]
[1]Environmental and Preventive Sciences, University of Ferrara, Ferrara, Italy

[3]Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy
Contact: mariaelena.flacco@unife.it

Background:

Current data suggest that SARS-CoV-2 reinfections are rare. Uncertainties remain, however, on the duration of the natural immunity, its protection against Omicron variant, and on the impact of vaccination to reduce reinfection rates.

Methods:

In this retrospective cohort analysis of the entire population of an Italian Region, we followed 1,293,941 subjects from the beginning of the pandemic to the current scenario of Omicron predominance (up to mid-February 2022). We assessed the proportion of reinfections overall, and by demographic and clinical characteristics, time after primary infection, and predominant circulating variant. Cox proportional hazard analysis was used to compute the relative hazards of reinfection.

Results:

After an average of 277 days, we recorded 729 reinfections among 119,266 previously infected subjects (overall rate: 6.1‰), eight COVID-19-related hospitalizations (7/100,000), and two deaths. Importantly, the incidence of reinfection did not vary substantially over time: after 18-22 months from the primary infection, the reinfection rate was still 6.7‰, suggesting that protection conferred by natural immunity may last beyond 12 months. The risk of reinfection was significantly higher among females, unvaccinated subjects, and during the Omicron wave.

Conclusions:

This study confirms and expands previous findings reporting a low risk of SARS-CoV-2 reinfection, and a very low risk of severe or lethal COVID-19 for those who recovered from primary infection, suggesting that the protection conferred by the natural immunity lasts beyond 12 months. Although the marked increase of the reinfection rates during the Omicron wave is concerning, the risk of a secondary severe disease or death remained close to zero. Vaccines were able to significantly reduce the likelihood of reinfection in both pre-Omicron and Omicron waves, although the risk-benefit profile of multiple vaccine doses for this population should be carefully evaluated.

Key messages:

- After primary infection, the risk of SARS-CoV-2 reinfection and of severe/lethal COVID-19 was low, suggesting that natural immunity lasts beyond 12 months.
- Despite increasing reinfection rates with Omicron, the risk of a secondary severe/lethal disease was close to zero, and vaccines reduced the likelihood of reinfection before and during Omicron waves.

5.C. Skills building seminar: Learn how to contribute to raising awareness about public health in Europe with the EUPHW

Abstract citation ID: ckac129.285

Organised by: EUPHA
Chair persons: Annemieke Schuffelen (EUPHA), Dineke Zeegers Paget (EUPHA)
Contact: annemieke.schuffelen@live.nl

The European Public Health Association (EUPHA) aims to bring together the public health workforce for professional exchange and collaboration through Europe. EUPHA is always looking for new tools and that is how the European Public Health Week (EUPHW) started: it promotes collaboration among the public health community in Europe and raises awareness about public health. The EUPHW has been an annual initiative since 2019, inspired by similar initiatives in Austria and the USA. The EUPW cannot be a success without the public health professionals who organise their own public health event. EUPHA needs those enthusiasts! And therefore, this workshop aims to encourage individuals to organise an event during the next European Public Health Week. For event hosts, the EUPHW is the perfect opportunity to share your expertise and contribute locally, regionally and nationally to topics of great relevance all across Europe. We are very well aware that organising an event may be daunting which is why EUPHA is organising this workshop. Over the years we built a network and created materials for promotion, which will make it easier to organise an event. In this workshop, we would like to give you the tools for organising an event during the EUPHW. The EUPHW has a rich portfolio: the past four editions of the EUPHW recorded approximately 550 online and in-person activities, hosted by more than 40 different countries in multiple languages. In this workshop, we will let members of EUPHW's steering committee share their favourite activities from the past few EUPHW editions. What made those events successful? We will talk about engagement with the future generation of public health professionals (EUPHAnxt) and building continuity and sustainable partnerships. Hosts will share their experiences of the EUPHW. What is their perspective on organising a public health week event at both national and European levels? How does the day-to-day coordination work? This sharing of knowledge will be followed by interaction. Together, we will imagine the European Public Health Week of 2023: what topics are important for public health professionals? On what subject do you want to make the case and amplify existing messages? What collaborations do you see? What kind of event would you like to organise? The topics that will be covered include choice of themes and key messages, logistics, target audiences, governance, communication, partnerships, stakeholder engagement, as well as involvement types and evaluation.
The EUPHW is supported by the WHO Regional Office for Europe.

Key messages:

- The European Public Health Week offers a unique opportunity to showcase public health, raise awareness about important health themes and promote collaboration among the public health community.
- This workshop aims to inspire individuals to get involved in the European Public Health Week, and contribute locally to topics of great relevance across the European Region.

5.D. Workshop: Challenges and opportunities for health systems in the era of multi-morbidity

Abstract citation ID: ckac129.289

Organised by: Western University (Canada)
Chair persons: Saverio Stranges (EUPHA-CHR), Arnaud Chiolero (Switzerland)
Contact: saverio.stranges@uwo.ca

Multimorbidity, defined as the co-existence of two or more chronic conditions in the same individual, is affecting increasing segments of the population across both high-income and low-resource settings. The workshop will provide a comprehensive and global perspective on the clinical and public health burden of multimorbidity from a health system perspective, including presentations and speakers from Europe, Africa and North America. Current research and policy initiatives are still primarily focused on the clinical management of multimorbidity after it occurs as well as on the prevention of adverse events in those individuals who are already living with multimorbidity. There is still a significant need to develop and establish effective and equitable primary prevention strategies in order to avoid the occurrence of multimorbidity across populations. Also, health systems around the world will need to implement context-specific initiatives and changes to tackle the growing burden of multimorbidity in ageing populations, which will be constrained by available resources, societal and political priorities and values. Any potential health system transformations will need to reconcile the concomitant burden imposed by multimorbidity and other major public health priorities, including the current pandemic, the health impact of climate change and widening health disparities across marginalized populations.

Key messages:

- There is a significant need to develop effective and equitable primary prevention strategies in order to avoid the occurrence of multimorbidity.
- Health systems around the world will need to implement context-specific initiatives and changes, which will be constrained by available resources, societal and political priorities and values.

Abstract citation ID: ckac129.290
Examining existing strategies to prevent multimorbidity – a scoping review

Kathryn Nicholson

[4]Department of Precision Health, Luxembourg Institute of Health, Strassen, Luxembourg
Contact: kathryn.nicholson@schulich.uwo.ca

Multimorbidity has been acknowledged as the "defining challenge" for health systems around the world, but current research and policy are primarily focused on the management of multimorbidity after it occurs or the prevention of adverse events in those individuals who are already living with multimorbidity. There is still a significant need to develop and establish effective and equitable primary prevention strategies in order to avoid the occurrence of multimorbidity across populations. This scoping review aims to identify existing strategies, programs and policies that are focused on the prevention of multimorbidity across various settings and countries around the world. To identify relevant publications, two databases will be searched: PubMed and Embase. The search strategies will be adjusted for each database and will include variations of the keywords multimorbidity, prevention and strategy. This review will specifically include publications that are original research, focused on multimorbidity and published in English. However, there will be no restrictions on the location of the research or the age of the target sample or population. For the full text screening phase, more specific criteria will apply and information will be extracted from the final set of retained studies. This information will be summarized and will include key factors such as study design, study setting, type of prevention programs, scope of programs (e.g. national, regional, local, etc.) and target population (e.g. age groups, socioeconomic groups, etc.). This scoping review will describe existing prevention programs and highlight areas of gaps and opportunities in the prevention of multimorbidity.

Multimorbidity is highly prevalent among older adults and associated with a shorter life expectancy. Many guidelines recommend tailoring preventive care of multimorbid people according to life expectancy. Indeed, there is a time lag between a preventive care intervention and the expected potential benefit, and patients with a relatively short life expectancy might not have the time to benefit from the preventive care intervention. Further, both patients and health care providers tend to overestimate benefits and underestimate risks of interventions. It is therefore necessary to have a valid index for mortality prediction in multimorbid patients, but there is no life expectancy estimator designed and recommended for this population. The paper describes the development and internal validation of a new life expectancy estimator. In this presentation, we focus on the importance of life expectancy estimation in multimorbid older adults: Why does it matter in this population? What is the time lag to benefit of a preventive intervention, e.g., cancer screening? What is the state in this field, in research and clinical practice? How could tailoring preventive care to life expectancy improve patient outcomes?

Abstract citation ID: ckac129.292
Association between functional limitation and quality of life among older adults with multimorbidity in Luxembourg

Piotr Wilk

P Wilk[1,2,3], *M Ruiz-Castell*[2], *T Bohn*[2], *G Fagherazzi*[2], *K Nicholson*[3], *V Moran*[2,4], *TT Makovski*[5], *MN Pi Alperin*[4], *S Stranges*[2,3], *H Samouda*[2]

[5]Department of Epidemiology, Maastricht University, Maastricht, Netherlands
Contact: pwilk3@uwo.ca

Introduction:

Multimorbidity, defined as the co-existence of two or more chronic conditions, is affecting an increasing number of Europeans, leading to poorer quality of life (QoL). This study assessed how functional limitation affects the QoL trajectories in a cohort of older individuals having multimorbidity, and whether there are any gender differences in these effects.

Methods:

We used a longitudinal cohort of 906 multimorbid respondents 50 years of age or older from Luxembourg who participated in four waves of the Survey of Health, Ageing, and Retirement in Europe (2013-2020). We used the Control, Autonomy, Self-Realization, and Pleasure scale (CASP-12) to assess QoL and the Global Activity Limitation Indicator (GALI) to measure functional limitation. Multigroup latent growth curve (LGC) modeling techniques were employed to assess how the measures of functional limitation over time are related to QoL trajectories and whether or not these effects are different by sex.

Results:

In 2013, over 60% of older residents of Luxembourg were affected by multimorbidity. The results from the LGC models suggest that both men and women with multimorbidity experienced a statistically significant decline in QoL between 2013 and 2020 at a constant rate; there were no significant differences in the rate of this change between men and women. The level of QoL at baseline and over time was significantly lower for individuals reporting functional limitation. However, functional limitation had no significant impact on the rate of decline in QoL for both men and women.

Discussion and conclusions:

As an increasing number of individuals in Europe are becoming vulnerable to more years lived with multiple chronic conditions, there is a growing need to identify factors that may lead to improvements in QoL among people affected by multimorbidity. Gaining more knowledge on the role of functional limitation may be particularly important for planning comprehensive care for patients with multimorbidity.

Abstract citation ID: ckac129.293
Prevalence of cardio-metabolic multi-morbidity and associated risk factors in a population-based sample of South Africans

Ngianga-Bakwin Kandala

N-B Kandala[1,2], R Sewpaul[1], AD Mbewu[1], AF Fagbamigbe[1], SP Reddy[1]
[1]Division of Epidemiology and Biostatistics, University of the Witwatersrand, Johannesburg, South Africa
[2]Division of Health Sciences, Warwick University, Coventry, UK
Contact: N-B.Kandala@warwick.ac.uk

Objectives:

Cardio-metabolic multi-morbidity (CM), the co-existence of two or more cardio-metabolic disorders in the same person, is rapidly increasing. We examined the prevalence and risk factors associated with CM in a population-based sample of South African adults.

Study design:

Data were analyzed on individuals aged $\geq$15 years from the South African National Health and Nutrition Examination Survey (SANHANES), a cross sectional population-based survey conducted in 2011-2012.

Methods:

CM was defined as having $\geq$2 of hypertension, diabetes, stroke and angina. Multivariable logistic regression was used to investigate the sociodemographic and modifiable risk factors associated with CM.

Results:

Of the 3832 individuals analyzed, the mean age was 40.8 years (S.D. 18.3), 64.5% were female and 18% were $\geq$60 years. The prevalence of CM was 10.5%. The most prevalent CM cluster was hypertension and diabetes (7.3%), followed by hypertension and angina (2.6%) and hypertension and stroke (1.9%). Of the individuals with diabetes, nearly three quarters had multi-morbidity from co-occurring hypertension, angina and/or stroke and of those with hypertension, 30% had co-occurring diabetes, angina and/or stroke. Age (30-44 years Adjusted Odds Ratio (AOR) = 2.68, 95% CI: 1.15-6.26), 45-59 years AOR = 16.32 (7.38-36.06), 60-74 years AOR = 40.14 (17.86-90.19), and $\geq$75 years AOR = 49.54 (19.25-127.50) compared with 15-29 years); Indian ethnicity (AOR = 2.58 (1.1-6.04) compared with black African ethnicity), overweight (AOR = 2.73 (1.84-4.07)) and obesity (AOR = 4.20 (2.75-6.40)) compared with normal or underweight) were associated with increased odds of CM.

Conclusions:

A tenth of South Africans have two or more cardio-metabolic conditions. The findings call for immediate prioritization of prevention, screening and management of cardio-metabolic conditions and their risk factors to avert large scale health care costs and adverse health outcomes associated with multimorbidity.

Abstract citation ID: ckac129.294
Multimorbidity in Large Canadian Urban Centres

Piotr Wilk

P Wilk[1,2,3], S Stranges[1,3], R Bellocco[4], T Bohn[3], H Samouda[3], K Nicholson[1], TT Makovski[5], A Maltby[1]
[1]Department of Epidemiology and Biostatistics, Western University, London, Canada
[2]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland
[3]Department of Precision Health, Luxembourg Institute of Health, Strassen, Luxembourg
[4]Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Solna, Sweden
[5]Department of Epidemiology, Maastricht University, Maastricht, Netherlands
Contact: pwilk3@uwo.ca

Introduction:

Although health outcomes are related to the characteristics of the geographic areas in which people live, there is limited knowledge on how the prevalence of multimorbidity varies within and across major Canadian urban centres. Our goal was to assess the level of between-neighbourhood variation in the prevalence of multimorbidity in Canada's large urban centres, controlling for compositional effects associated with demographic and socioeconomic factors.

Methods:

Cross-sectional data from the 2015-2018 cycles of the Canadian Community Health Survey (CCHS) were used. Respondents (20 years and older) residing in one of the 35 census metropolitan areas (CMAs) were included (N = 100,803). Census tracts (CTs), relatively small and stable geographic areas nested within CMAs, were used as a measure of neighbourhood. To assess the between-neighbourhood differences in multimorbidity prevalence, we fitted sequential random intercept logistic regression models.

Results:

During the 2015-2018 period, 8.1% of residents of large urban centres in Canada had multimorbidity. The results from the unadjusted model indicate that 13.4% of the total variance in multimorbidity could be attributed to the between-neighbourhood differences. After adjustment for overall characteristics of the CMAs in which these neighbourhoods are located, as well as for individual-level demographic and socioeconomic factors related to compositional effects, 11.0% of the individual variance in multimorbidity could still be attributed to the between-neighbourhood differences.

Discussion and Conclusions:

There is significant and substantial geographic variation in multimorbidity prevalence across neighbourhoods in Canada's large urban centres. Residing in some neighbourhoods could be associated with increased odds of having multimorbidity, even after accounting for overall characteristics of the CMAs in which these neighbourhoods are located, as well as individual-level factors.

Abstract citation ID: ckac129.295

A Holistic Approach to Urban and Children's Mental Health

Peter Van Den Hazel

P Van Den Hazel[1], *G Ristovska*[2], *A Sandionigi*[4], *M Weber*[3], *S Benz*[5]
[1]INCHES, Ellecom, Netherlands
[2]Institute of Public Health of Republic of North Macedonia, Skopje, Republic of North Macedonia
[3]City of Utrecht, Utrecht, Netherlands
[4]Quantia Consulting srl, Milan, Italy
[5]Centre for Applied Psychology, Environmental and Social Research ZEUS, Hagen, Germany
Contact: info@inchesnetwork.net

Background:

EU data show that there is a continuous increase in mental health problems in children. The multiple exposures in the physical and social domain influence the internal exposome and the final health outcomes. The Equal-Life project research focuses on the exposome (physical, social and internal) and mental health of children and adolescents.

Methods:

Literature reviews on children's mental health and a total of physical and social exposures from 9 different European cohorts are used to set a framework of data interpretation. In addition, information gathered from 3 surveys/65 interviews with stakeholders from different fields was used to look for a transdisciplinary framework for analysis of the cohort data. The approach develops (in a co-design approach) tools that help stakeholders to collect and organize the information necessary to make decisions. The exposome is as if it were a multilayer system and requires approaches that are able to manage the interconnections between the various variables involved in the field of children's mental health.

Results:

The main points extracted are an early life exposure to urban planning related factors (noise/air pollution, traffic), social factors (family relations, stress), biomarkers related to environmental and social exposures. Concerning the life course approach, vulnerable settings were identified such as schools, neighbourhoods, accessibility to green restorative spaces. These ingredients are the basis of interaction between scientists and community stakeholders and from the policy domains to find and interpret the scientific results for the implementation of protective and promotive policies in cities.

Conclusions:

Transdisciplinary approach is necessary for management and developing strategies for solving mental health problems in urban spaces when considering all kind of exposures. The development of tools through co-design sessions with different stakeholders gives important contributions for this goal.

Key messages:

- Development of interventions and policies for better mental health of children and adolescents should be based on available evidence for meaning of external and social exposome.
- The main outcome of Equal-Life is to develop tools where stakeholders have access and opportunity to use it for solving mental health issues at national or local level.

Abstract citation ID: ckac129.296

Leveraging Citizen Science to Improve Urban Public Health

Rachel Elands

J Hotting[1,2], *T Clemens*[1], *R Guinto*[4,5], *M Commers*[1], *H Brand*[1], *K Czabanowska*[1], *RJJ Elands*[1,3]
[1]International Health, Maastricht University, Maastricht, Netherlands

[4]Planetary and Global Health Program, St. Luke's Medical Center College of Medicine, Quezon City, Philippines
[5]Sunway Centre for Planetary Health, Sunway University, Selangor, Malaysia
Contact: r.elands@maastrichtuniversity.nl

Background:

Mobile health approaches in community based participatory projects keep the promise to encourage sustainable behavior in citizens by engaging communities in data collection and connecting their individual level behavior to larger level community health. This review evaluates the effectiveness of the implementation of citizen science for health promotion of non-communicable diseases in urban community-based participatory research projects.

Methods:

A scoping review was conducted using PRISMA-ScR. Pubmed and Web of Science were searched for citizen science studies. We included research 1.) conducted in an urban setting, 2.) related to environmental sustainability, 3.) focused on non-communicable diseases, and 4.) applied citizen science methodology.

Results:

32 community-based participatory research projects were identified using the following data collection technologies: mobile applications (n = 7), photovoice (n = 6), Stanford Healthy Neighborhood Discovery Tool (n = 6), monitoring (n = 6), mixed-methods (n = 4) and sensors (n = 3). The Stanford Healthy Neighborhood Discovery Tool was most effective at delivering real time data collection, exploring new communication and dissemination opportunities for remote and marginalized communities, and at offering a flexible and cost-effective approach to identify health promotion interventions. Studies that implemented photovoice tools and mobile applications had challenges with regard to recruitment and retention of participants as well as privacy concerns.

Conclusions:

Mobile health technologies in community-based participatory research projects may be a promising way to uncover unknown local risk factors, raise awareness and identifying targeted policy solutions to promote healthy and sustainable environments in urban spheres. The effectiveness of mobile health applications for health promotion of non-communicable diseases may vary between community-based participatory studies by data collection method.

Key messages:

- Mobile health technologies in communities may be a promising way to promote healthy and sustainable environments by raising awareness and offering targeted policy solutions in urban spheres.
- The effectiveness of mobile health applications for health promotion of non-communicable diseases may vary between community-based participatory studies by data collection method.

Abstract citation ID: ckac129.297
Association between worries about climate change and mental health in Norwegian adolescents

Marja Leonhardt

M Dahhlen Granrud[2], T Bonsaksen[2], L Lien[1,2]
[1]Sykehuset Innlandet HF, Norwegian National Advisory Unit on Concurrent Substance Abuse and Mental Health Disorders, Brumunddal, Norway
[2]Department of Health and Social Science, Inland Norway University of Applied Science, Elverum, Norway
Contact: marja.leonhardt@sykehuset-innlandet.no

Background:

Climate change has a great impact on the future of children and young people. Since the global climate strike movement, many adolescents expressed worries about climate change. But do these worries lead to declined mental health and future optimism? Thus, we aim to explore associations between prevalence of worries about climate change, leisure activities and mental health problems in a representative sample of Norwegian adolescents.

Methods:

In 2021, the youth survey Ungdata collected data from 139,841 Norwegian adolescents, which corresponds to a response rate of 75%. Descriptive analysis was used to calculate the prevalence of worries about climate change cannabis use and bi- and multivariate logistic regression analysis to examine the association between worries about climate change and mental health, leisure activities and alcohol and cannabis use, controlled for sociodemographics.

Results:

Around 37% of Norwegian adolescents are worried about climate change. Worries increased with age and are more prevalent among girls. There is a relationship between mental health problems and worries about climate change (OR = 1.80 (CI:1.75-1.86)) still after adjusting for sociodemographic variables, leisure activities and alcohol and cannabis use (OR = 1.71 (1.10-1.42)).

Conclusions:

The results indicate a real connection between mental health problems and worries about climate change, but the causal relationship needs further study. This knowledge makes it important for all profession, working with adolescents, paying special attention to possible negative effects of worries about climate change on the mental health of young people.

Key messages:

- Worries about climate change has an impact on mental health of young people.
- Adolescent's worries about climate change should be taken seriously.

Abstract citation ID: ckac129.298
Air pollution is associated with the risk of neurodegenerative disorders: a prominent role of PM10

Alessandro Gialluisi

A Gialluisi[1,2], S Costanzo[1], G Veronesi[1], G Zazzaro[3], A Cembalo[3], MM Ferrario[1], F Gianfagna[1,4], S Massari[5], L Iacoviello[1,2]
[1]Department of Medicine and Surgery, University of Insubria, Varese, Italy
[2]Department of Epidemiology and Prevention, IRCCS NEUROMED, Pozzilli, Italy
[3]CIRA-Italian Aerospace Research Centre, Capua, Italy
[4]Mediterranea Cardiocentro, Naples, Italy
[5]Italian Workers' Compensation Authority, INAIL, Rome, Italy
Contact: alessandro.gialluisi@uninsubria.it

Background:

Studies revealed an implication of air pollution in neurodegenerative disorders, although this link remains unclear. Here, we investigated this testing multiple pollutants simultaneously.

Methods:

In the Moli-sani cohort (N = 24,325; ≥35 years; 51.9% women, baseline 2005-2010), we estimated yearly levels of exposure to nitrogen oxides (NOX, NO, NO2), ozone (O3), particulate matter (PM10) and BTX hydrocarbons (benzene, toluene and xylene) in 2006-2018, applying residence geo-localization of participants and Kriging interpolation algorithm to land measurements of air pollutants. We performed a principal component analysis and tested association of the resulting principal components (PCs) with the incident risk of Parkinson (PD) and Alzheimer disease (AD), through multivariable Cox PH regressions adjusted for age, sex and education level completed.

Results:

Over 24,308 subjects with pollution data available (51.9% women, 55.8(12.0) years), we extracted three PCs explaining ≥5% of pollution exposure variance: PC1 (38.2%, tagging PM10 exposure), PC2 (19.5%, O3/CO/SO2), PC3 (8.5%, NOx/BTX hydrocarbons). Over a mean follow-up of 10.9(2.1) years, we observed statistically significant associations of PC1 with an increased risk of PD (HR[CI] = 1.04[1.02-1.05]; 405 incident cases) and AD (1.06[1.04-1.08]; 218 cases). These associations were confirmed when we analyzed PM10 levels averaged over follow-up time, in models further adjusted for professional exposures like working class, compartment and toxic compounds and lifestyles like smoking and drinking habits, physical activity and adherence to Mediterranean diet (PD: 1.27 [1.19-1.37]; AD: 1.22[1.16-1.28] per 1 μg/m3 increase of PM10).

Conclusions:

This evidence supports an influence of air pollution - especially PM10 - on increased neurodegenerative risk in the Italian population, independent on concurring risk factors. This suggests reducing PM10 pollution as a potential strategy to reduce neurodegenerative risk.

Key messages:

- PM10 levels are associated with increased Parkinson and Alzheimer disease risk.
- This suggests to act on air pollution to reduce neurodegenerative risk in the general population.

Abstract citation ID: ckac129.299
Health, Architecture and Wellbeing: building bridges between health and the design of living spaces

Teresa Leão

T Leão[1,2], A Neiva[3]
[1]Instituto de Saúde Pública da Universidade do Porto, Porto, Portugal
[2]Faculdade de Medicina da Universidade do Porto, Porto, Portugal
[3]Faculdade de Arquitectura da Universidade do Porto, Porto, Portugal
Contact: teresacostaleao@gmail.com

Background:

Health is determined by where we live. Nevertheless, medical and architecture students often ignore the relation between health, housing and urban planning. In order to bridge these areas, we designed an interdisciplinary course for students of University of Porto Medical and Architecture schools, winning a 2021 Pedagogic Innovation courses call.

Objectives:

"Health, Architecture and Wellbeing" aimed to explore the effect of living spaces in health, combining the health and architecture perspectives in the analysis of case studies, and discussing strategies to improve health and wellbeing of the population. By exposing students to tools for designing healthy, sustainable, efficient and accessible spaces, and to public participation strategies, we aimed to foster awareness and share knowledge among complementary scientific fields.

Results:

Students were exposed to theoretical and practical sessions with experts from the medical, architecture, landscape architecture, and geography areas, as well as to field visits in social neighbourhoods, collective housing, and green spaces. Besides introducing students to concepts, as health needs and determinants, and to healthy and accessible design methods, students interacted with inhabitants, gathering experiences on how they lived in those spaces, understanding its impact on their wellbeing, while exploring the enablers and barriers of participation strategies. Students were encouraged to complement technical architecture competences with public health evidence, and social participation leading to the development of design proposals improving the existing living environments.

Conclusions:

''Health, Architecture and Wellbeing'' interdisciplinary course connected public health expertise with architecture, promoting knowledge dissemination and awareness among health and architecture students. This experience may be reproduced in other countries, as health continues to be determined by living and public spaces.

Key messages:

- Bridging public health with other disciplines is fundamental to understand the origin of health issues, namely living conditions, and maximise the opportunities of acting near their root causes.
- This course allowed architecture and medical students to gain awareness about the impact of housing and urban design on people's health, and to learn how to propose and design healthier environments.

Factors associated with the perception that eHealth facilitates access to healthcare

Emma Kainiemi

E Kainiemi[1]*, L Virtanen*[1]*, P Saukkonen*[1]*, T Vehko*[1]*, AM Aalto*[1]*, AM Kaihlanen*[1]
[1]Finnish Institute for Health and Welfare, Helsinki, Finland
Contact: emma.kainiemi@thl.fi

Background:

The provision of eHealth has increased in the COVID-19 era with the aim of improving access to care without the risk of infection. Perceiving eHealth beneficial may affect the use. This study examined which patient-related factors are associated with the perception that eHealth facilitates access to care.

Methods:

A nationwide survey was sent to 61,600 Finnish residents during the COVID-19 pandemic (September 2020-February 2021). Binary logistic regression analysis was used to examine whether the service needs (self-rated health, met service needs, challenges accessing traditional care) and eHealth experience (e-visits, need for guidance, data security concerns) were associated with perceiving that eHealth facilitates access to care. The model was adjusted for age, gender and education.

Results:

The study included 21,409 respondents who had used healthcare services in the past 12 months (55.0% female, mean age 52.88, SE .18). The majority (63.8%) agreed with the benefit that eHealth facilitates access to care. Patients in good health (OR 1.24, 95% CI 1.13-1.37), whose service needs were met (OR 1.34, 95% CI 1.19-1.52) and who had no challenges in accessing traditional care (OR 1.18, 95% CI 1.02-1.36) had greater odds of perceiving the benefit compared to their counterparts. Patients with experience of e-visits (OR 2.60, 95% CI 2.28-2.96) and without need for guidance (OR 1.71, 95% CI 1.52-1.91) had greater odds of perceiving the benefit compared to their counterparts.

Conclusions:

Patients in good health, with met service needs and with easy access to traditional care appear to perceive eHealth more beneficial than their counterparts, which might exacerbate the already existing inequalities in healthcare access and health outcomes. Promotion of eHealth skills might increase equitable opportunities to benefit from eHealth for those patients whose service needs could be met without traditional face-to-face encounter.

Key messages:

- Patients in good health, with met service needs and without difficulties accessing traditional healthcare appear to find eHealth more beneficial than their underprivileged counterparts.
- Promotion of eHealth skills might increase equitable opportunities to benefit from eHealth for those patients whose service needs could be met without traditional face-to-face encounter.

Abstract citation ID: ckac129.301
Low confidence in systematic reviews of digital interventions for physical activity promotion

Katja Matthias

K Matthias[1]*, L Mergenthal*[2]*, KK De Santis*[2]
[1]Faculty of Electrical Engineering and Computer Science, University of Applied Sciences Stralsund, Stralsund, Germany
[2]Department of Prevention and Evaluation, Leibniz Institute - BIPS, Bremen, Germany
Contact: Katja.Matthias@hochschule-stralsund.de

Background:

The field of digital public health aims to promote and improve the health of people and communities through the application of digital interventions (DIs). Systematic reviews (SRs) show that many DIs target physical activity (PA) promotion. 'A Measurement Tool to Assess Systematic Reviews' (AMSTAR2) is a valid and moderately reliable appraisal tool with 16 items that can be used to derive an overall confidence rating (OCR: high, moderate, low or critically low) in the results of a SR. This cross-sectional study aimed to appraise SRs of DIs for PA promotion.

Methods:

This study using 30 SRs was embedded within a scoping review with a published protocol (doi:10.2196/35332). Following electronic searches in 03/2021 in MEDLINE, PsycINFO, and CINAHL two authors independently selected and appraised the SRs. AMSTAR2 appraisal outcomes were expressed as (1) OCRs according to the AMSTAR2 scoring guidelines and (2) as percentage scores (fulfilled items/16 items). Appraisal outcomes were assessed using descriptive statistics.

Results:

The 30 SRs were published in 2007-2021 and included 5-60 primary studies. Most SRs (27/30) received 'critically low' OCR, while 'low' (2/30), 'moderate' (1/30) or 'high' (0/30) OCRs were seldom. The 21 SRs published after AMSTAR2 implementation in 2018 onwards received higher percentage scores (mean±SD of 53±15%) compared to 9 SRs published before 2018 (44±13%). In addition, the 11 SR with a protocol received higher percentage scores (59±13%) compared to 19 SRs without a protocol (45±15%) and had fewer critical weaknesses (median: 2 vs. 4).

Conclusions:

High quality SRs are needed for making public health decisions. AMSTAR2 assigns mostly low and critically low OCR to SRs of DIs for PA promotion. These SRs should not be relied on as a source of accurate evidence. Our results show that SR reporting guidelines need to be better followed.

Key messages:

- According to AMSTAR2 the overall methodological quality of systematic reviews of digital interventions for physical activity promotion needs improvement.
- Better adherence to established reporting guidelines for systematic reviews in public health context is needed.

Abstract citation ID: ckac129.302
Ethnicity, deprivation, and the use of patient portals in England's general practices 2018-2020

Abrar Alturkistani

A Alturkistani[1]*, G Greenfield*[1]*, T Beaney*[2,1]*, J Norton*[2]*, CE Costelloe*[3,2,1]
[1]Department of Primary Care and Public Health, Imperial College, London, UK
[2]National Institute for Health Research, Applied Research Collaboration Northwest London, London, UK
[3]Division of Clinical Studies, Institute of Cancer Research, London, UK
Contact: Abrar.alturkistani16@imperial.ac.uk

Background:

Patient portals are made available and widely promoted in healthcare systems in the USA and Europe. These technologies can help patients access healthcare, receive timely treatment, and manage their health through services such as appointment booking and repeat prescription ordering. However, it is not clear if all patients who need the services are using them. This study explored patient portal use (online appointment booking and repeat prescription ordering features) and patient characteristics among NHS England GP practice patients.

Methods:

The study used cross-sectional participant-level data from the GP Patient Survey (GPPS) of 2018, 2019, and 2020. Performing multilevel regression analysis, we explored the association between patient portal feature use and ethnicity and deprivation and controlled for eight other patient characteristics and one GP practice level characteristic, and modelled GP practice as a random effect in the model.

Results:

In the fully adjusted model controlled for all patient characteristics and GP characteristics, participants of the Black and Other ethnic groups were less likely to have used online appointment booking (OR: 0.84, 95% CI:0.81, 0.86, and OR: 0.96, 95% CI: 0.92, 0.99, respectively) and online repeat prescription ordering (OR: 0.76, 95% CI: 0.74-0.78 and OR: 0.78, 95% CI: 0.75-0.81, respectively) compared to the White ethnic group. Association with patient portal use increased proportionally with reduced deprivation ranking.

Conclusions:

In NHS England GP practices, certain ethnic minority groups and high deprivation ranking is associated with a reduced likelihood of using patient portals. If patient portals are the only route to access services, it is likely to lead to inequalities in use by some patient groups introducing unfair access to the services. Patients could continue to be provided with alternatives to patient portals to prevent potential inequities in access to services.

Key messages:

- Patient portals are widely used in the healthcare system and can benefit all patients given that disparities are prevented by understanding patient groups who cannot access portals.
- Understanding patient groups less likely to use patient portals could help adapt healthcare system services and meet the needs of all patient groups.

Abstract citation ID: ckac129.303
Effectiveness and safety of pulse oximetry in remote patient monitoring of patients with COVID-19

Ahmed Alboksmaty

A Alboksmaty[1,2]*, T Beaney*[2]*, S Elkin*[2]*, J Clarke*[2]*, A Darzi*[2]*, P Aylin*[1,2]*, AL Neves*[2]
[1]Department of Primary Care and Public Health, Imperial College London, London, UK
[2]PSTRC, Imperial College London, London, UK
Contact: ama1716@ic.ac.uk

Context:

A surge of COVID cases globally is often portrayed as ''very likely'', which overwhelms health systems and challenges their capacities. A mitigation strategy is seen by remotely monitoring COVID patients in out-of-hospital settings to determine the risk of deterioration.

Description of the problem:

We need an indicator to enable remote monitoring of COVID patients at home that can be measured by a handy tool; pulse oximetry which measures peripheral blood oxygen saturation (SpO2). Evidence shows that SpO2 is a reliable indicator of deterioration among COVID patients. The UK initiated a national programme (COVID Oximetry @ Home (CO@H)) to assess the theory. The concept can be potentially applied in other countries in various settings. As part of CO@H, we conducted a systematic review of the evidence on the safety and effectiveness of pulse oximetry in remote monitoring of COVID patients.

Results:

Our review confirms the safety and potential effectiveness of pulse oximetry in remote home monitoring among COVID patients. We identified 13 research projects involving 2,908 participants that assessed the proposed strategy. Evidence shows the need to monitor at-rest and post-exertional SpO2. At-rest SpO2 of $\leq$ 92% or a decrease of 5% or more in post-exertional SpO2 should indicate care escalation. The recommended method for measuring at-rest SpO2 is after 5-10 min of rest, and assessing post-exertional SpO2 is after conducting a 1-min sit-to-stand test. We could not find explicit evidence on the impact on health service use compared with other models of care.

Lessons:

Remote monitoring of COVID patients could alleviate the pressure on health systems and save hospital resources. Monitoring SpO2 by pulse oximetry can be widely applied, including in resource-limited settings, as the tool is affordable, reliable, and easy to use.

Key messages:

- Adopting relevant health technologies in remote patient monitoring is critical to combat the pandemic.
- Pulse oximetry is an affordable, easy to use and widely available tool to monitor patients with COVID-19 at home.

Metabolic syndrome as predictor of work exit type: A longitudinal study among 55,817 Dutch workers

Katharina Runge

K Runge[1,2], *SKR van Zon*[1], *K Henkens*[1,2,3], *U Bültmann*[1]
[1]Health Sciences, UMCG, University of Groningen, Groningen, Netherlands
[2]Work and Retirement Theme Group, NIDI-KNAW, University of Groningen, The Hague, Netherlands
[3]Faculty of Social and Behavioral Sciences, University of Amsterdam, Amsterdam, Netherlands
Contact: k.runge@umcg.nl

Background:

Chronic diseases like cardiovascular disease or type two diabetes mellitus are related to work exit types such as unemployment and work disability. It is unknown whether metabolic syndrome as a risk factor preceding these chronic diseases is related to work exit type. Metabolic syndrome is present when people have at least three out of the following five risk factors: hypertension, abdominal obesity, raised triglycerides, raised blood glucose, and reduced HDL-cholesterol. We examined the association of metabolic syndrome with work exit type while controlling for socio-demographic and occupational factors.

Methods:

The sample included 55,817 Dutch workers aged 40-65 years from the Lifelines Cohort Study and Biobank. We used data from five measurement waves with a mean follow-up time of 4.1 years. Metabolic syndrome was measured at baseline and based on physical examinations, blood markers, and medication use. Follow-up work exit types were self-reported and included unemployment, work disability, early and regular retirement. Competing risk regression analysis was used.

Preliminary

Results:

Metabolic syndrome increased the risk of work disability (adjusted SHR: 1.69, 95% CI: 1.42, 2.02) and unemployment (adjusted SHR: 1.11, 95% CI: 1.01, 1.22), and was not associated with early and regular retirement.

Conclusions:

Metabolic syndrome increases the risk of work disability and unemployment. More awareness about and prevention of metabolic syndrome is needed among general practitioners and occupational physicians. Early detection of metabolic syndrome as a risk factor preceding chronic diseases might prevent premature work exit in middle- and late-career.

Key messages:

- Metabolic syndrome increases the risk of work disability and unemployment among middle-aged and older workers.
- More metabolic syndrome awareness and prevention might help to extend healthy working years.

Abstract citation ID: ckac129.305
The characteristics of women not-attending screening and their barriers to attendance in Czechia

Anna Altová

A Altová[1], *M Lustigová*[1], *I Kulhánová*[1]
[1]Faculty of Science, Charles University, Praha, Czechia
Contact: anna.altova@natur.cuni.cz

Background:

Cervical screening is one of the most important tools to reduce the incidence and mortality of cervical cancer, but uptake is still insufficient in many European countries with implemented population screening programs. In this study, we analyze the sociodemographic characteristics of women who do not attend cervical screening and describe the barriers that these women may have to attend cervical screening using Czechia as an example.

Methods:

In the representative sample of 902 Czech women, we first employed binary logistic regression to identify groups of women that have higher chances of being non-attendees. Second, we described the reasons non-attendees declared as barriers to attendance. Third, we analyzed whether there were differences in women's characteristics according to the declared barriers.

Results:

In the study sample, 36.7% of the women were considered non-attendees. Women with lower education (primary compared to university education, OR = 2.2, 95%CI 1.2-3.9) single women (compared to married/partnered, OR = 3.6, 95%CI 2.0-5.1), or older women, had a higher chance of not attending the screening. The most frequently declared reasons for not attending were 'not experiencing any symptoms' (36.3%), 'fear of cancer diagnosis' (23.0%), and 'fear of the examination procedure' (20.2%). In most of these barriers, women declaring these reasons did not differ from the other non-attendees.

Conclusions:

Identifying sociodemographic determinants of cervical screening non-attendance and the barriers women have to attend are crucial for improving cervical cancer prevention. Based on this knowledge, public health policies should minimize screening hesitancy by targeting psychological factors and improving screening literacy among women. Although this research is a case study for Czechia, we believe that the results may be applicable in other countries.

Key messages:

- Cervical screening promotion should be targeted on women at higher risk of non-attendance.Those are women with lover education, single women or older women.
- Understanding the specific barriers to cervical screenin attendance could help develop strategies to improve the communication of prevention.

Abstract citation ID: ckac129.306
Vaccination coverage trends in European Union from 1980 to 2020: A joinpoint Regression Analysis

Francesco Andrea Causio

FA Causio[1], *L Villani*[1], *M Mariani*[1], *R Pastorino*[1], *C De Waure*[2], *W Ricciardi*[1], *S Boccia*[1,3]
[1]Section of Hygiene, UCSC Rome, Rome, Italy
[2]Department of Medicine and Surgery, University of Perugia, Perugia, Italy
[3]Department of Woman, Child and Public Health, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy
Contact: francescoandrea.causio01@icatt.it

Vaccinations are successful, cost-effective public health interventions; nevertheless, vaccine hesitancy represents a concern and several EU countries have implemented mandatory vaccinations to counteract it. The assessment of vaccination coverage data is helpful to clarify the reason behind this choice better and assess its impact. Data were extracted from the WUENIC database as of July 2021. All the 27 EU countries were included, considering the period from 1980 to 2020 (depending on data availability). Coverage indicators on seven vaccinations scheduled during the first year of life to prevent nine vaccine-preventable diseases were considered. Joinpoint regression was run using Joinpoint Trend Analysis Software

4.9.0.0. For each coverage indicator, the last two trends in time identified by the joinpoint regression were considered to identify countries with a positive vaccination coverage trend (having either the last trend significantly positive or the second last significantly negative but followed by a trend reversal) or a negative coverage trend (having either the last trend significantly negative or the second last significantly positive but followed by a trend reversal). To assess each country, we collated together information on each coverage indicator. A total of 180 jointpoint regressions were run. At least one joinpoint was observed in 144 cases: 39 (27.1%) showed a significant positive trend, and 49 (34%) had a significantly negative one. In 36 cases, there was a single trend lacking a joinpoint, either positive (21, 58.3%), negative (8, 22.2%), or not showing a change (7, 19.4%). Overall, 14 countries had mostly negative vaccination coverage trends, whereas 13 had mostly positive vaccination coverage trends. Systematised data collection and analysis of vaccination coverage trends are needed to support public health systems. EU countries differ broadly, but the overall situation shows that coverage trends are a key issue to be addressed.

Key messages:

- Vaccination coverage in the EU shows a general negative trend. The assessment and comparison of coverage trends across EU countries could make policymakers able to respond to critical issues timely.
- Mandatory vaccinations have been issued in different countries to prevent vaccination coverages from decreasing. Some countries have not issued any mandate but show high vaccination coverages.

[6]GRASSIR Research Group, Barcelona, Spain
[7]SomiArte Taller, Barcelona, Spain
[8]Universitat de Girona, Girona, Spain
Contact: lmedina@idiapjgol.info

Background:

Menstrual inequity has an impact on (menstrual) health outcomes and emotional wellbeing. It is also a significant barrier to achieve social and gender equity. The aim of this study was to assess menstrual inequity and its associations with sociodemographic factors, among women and people who menstruate (PWM) aged 18-55 in Spain.

Methods:

A cross-sectional online survey-based study was conducted in Spain in March-July 2021. Data were analysed through descriptive statistical analyses and multivariate logistic regression models.

Results:

22,823 women and PWM participated (Mean age = 33.2, SD = 8.7). Over half had accessed healthcare services for menstruation (61.9%) and had partial/no menstrual education pre-menarche (58.4%). Lifetime menstrual poverty was 22.2-39.9%. Main risk factors for menstrual poverty were identifying as non-binary (aOR: 1.67, 95% CI, 1.32-2.11), being born in non-European or Latin American countries (aOR: 2.74, 95% CI, 1.77-4.24), and not having a permit to reside in Spain (aOR: 4.27, 95% CI, 1.94-9.38). In turn, menstrual poverty protective factors were having completed university education (aOR: 0.61, 95% CI, 0.44-0.84) and not experiencing financial hardship in the last 12 months (aOR: 0.06, 95% CI, 0.06-0.07). Besides, 75.2% of participants indicated having overused menstrual products because of not having access to adequate menstrual management facilities. Menstrual-related discrimination was reported by 44.0% of women and PWM. Menstrual discrimination risk was higher among non-binary menstruators (aOR: 1.88, 95% CI, 1.52-2.33). Menstrual-related work (20.3%) and educational (62.7%) absenteeism was reported.

Conclusions:

Our study suggests that menstrual inequity in Spain is widespread, especially among those more socioeconomically deprived, vulnerable migrant populations and non-binary and trans menstruators. Findings from this study are being useful to inform future research and menstrual (health) policies.

Key messages:

- Menstrual inequity especially impacts socioeconomically deprived, gender nonconforming menstruators and vulnerable migrant populations in Spain.
- Menstrual inequity research is crucial to address social inequities of health and develop menstrual policies.

Abstract citation ID: ckac129.308
Associations between area- and individual-level community belonging and self-rated health

Sarah M Mah

S Mah[1], *M Brown*[2], *R Colley*[2], *R Rosella*[1], *C Sanmartin*[2], *G Schellenberg*[2]
[1]Dalla Lana School of Public Health, University of Toronto, Toronto, Canada
[2]Statistics Canada, Ottawa, Canada
Contact: s.mah@utoronto.ca

Background:

Previous studies point to the importance of individuals' sense of community belonging to multiple measures of health and well-being. However, the extent to which collective sense of belonging within neighbourhoods might influence individual health has not been characterized. The objectives of this study are to describe variations in self-rated health by a novel area-level measure of community belonging and determine the impact of including these measures in models of individual-level community belonging and self-rated health.

Methods:

We conducted a cross-sectional study of respondents of the 2020 Canadian Community Health Survey (CCHS) living in census tracts. These data were merged with novel small area estimates of community belonging derived by Statistics Canada from the CCHS 2016-2019. Multinomial logistic regression models were used to analyse associations of individual- and area-level community belonging, and self-rated health. We adjusted for sex, age, recent immigrant status, visible minority status, province, marital status, presence of children in the household, smoking status, presence of chronic conditions, income, and employment status. All results were generated using survey weights and bootstraps representing a subpopulation of 21 million people.

Results:

A greater proportion of CCHS respondents living in neighbourhoods with the strongest collective sense of community belonging reported being in good, very good, or excellent health. Models indicate that living in a neighbourhood with low collective sense of community belonging is associated with higher odds of reporting being in poor or fair health (OR = 1.44, 95% CI 1.15-1.81) even after adjusting for other factors, including individual-level sense of community belonging, which also remained independently associated with self-rated health.

Conclusions:

Both area- and individual-level sense of community belonging are independently associated with self-rated health.

Key messages:

- The collective sense of belonging within neighbourhoods may influence health outcomes.
- Measures of area-level and individual-level community belonging may capture different aspects of social connections with respect to health.

5.H. Round table: Health care systems, health service provision, and equity in health

Abstract citation ID: ckac129.309

Organised by: EUPHA-HSR, EUPHA-EPI
Chair persons: Johan Hansen (EUPHA-HSR), Stefania Boccia (EUPHA-EPI)
Contact: p.groenewegen@nivel.nl

The starting point for this round table is the observation that the research areas of health systems, health services and population health are usually seen as separate academic specialisations. This hampers the potential for getting insights into the role of health care systems and service provision in the development of population health and health inequalities, and of policies to reduce inequalities. As a result of the different mix of disciplines, with different approaches, different research and publication cultures, and different funding sources health systems research, health services research and population health research have tended to grow apart and to ignore the results from the other areas. In this round table session we will discuss the ways health care systems and health service provision influence inequalities in health. This implies looking at different levels of analysis. Health care systems and inequalities in population health refer to the macro level, and both are influenced by the same political and societal context. Health inequalities are also (and more strongly) influenced by structures and processes at macro level outside the health care system and service provision. Health service professionals form the intermediate level; their actual service delivery takes place at the micro level where health care professionals and users meet. Health care professionals and users of services bring their own attitudes, beliefs and resources that influence their interaction and consequent outcomes. Both meso and micro level are influenced by structures and institutions, in society in general as well as in the design of the health care system. The results of the interactions between health care professionals and users are (e.g.) decisions whether or not to use certain types of care, with consequences for the health and functional abilities of users. These decisions and their consequences are patterned by socio-economic characteristics of care users. These aggregate into patterns of inequality at the macro level. Over time, the influence of health care on population health has increased. The responsibility of health care for upstream causes of health inequalities can be strengthened through deliberate policies. With the (long-term) change of morbidity from infectious disease to chronic disease, prevention is often moving to programmes to support people in changing their lifestyle. This in itself exposes the relationships between health care and health inequalities, as those interventions that require a contribution from individuals tend to increase inequalities since those lacking resources will find it harder to participate. In this round table we present a proposal to integrate the three fields of research. We invite specialists from each of these fields and the audience of the round table to react to our proposal. The aim of this round table is to promote cross-disciplinary collaboration. The two organizing EUPHA sections cover the three areas of research in focus.

Key messages:

- The same political and societal context influences the health system, service provision and many of the social determinants of population health.
- The potential to address health inequalities through health care may have increased, and requires specific attention to integration of social care and different parts of health care.

Pain and mental health - separate and joint associations with sickness absence among young employees

Pi Fagerlund

P Fagerlund[1]*, R Shiri*[2]*, J Suur-Uski*[1]*, S Kaartinen*[1,3]*, O Rahkonen*[1]*, T Lallukka*[1]
[1]Department of Public Health, University of Helsinki, Helsinki, Finland
[2]Finnish Institute of Occupational Health, Helsinki, Finland
[3]Department of Physical and Rehabilitation Medicine, Helsinki University Hospital, Hyvinkää, Finland
Contact: pi.fagerlund@helsinki.fi

Background:

Both pain and mental illness associate with work disability. However, few studies have examined the association of concurrent pain and mental distress with sickness absence (SA). We examined separate and joint associations of chronic pain, multisite pain, and mental distress with total and long-term all-cause SA among young and midlife municipal employees.

Methods:

As part of the Young Helsinki Health study, baseline data were collected in 2017 from 19-39-year-old employees of the City of Helsinki, Finland. Chronic ($\geq$3 months) pain, multisite ($\geq$2 body sites) pain and mental distress (RAND-36 emotional wellbeing subscale below median) were reported by 3911 respondents. Register data on total (>1 day) and long-term ((>11 workdays) SA for the following year were obtained from the employer and the Social Insurance Institute of Finland with respondents' informed consent. Negative binomial regression analyses were performed with sociodemographic, socioeconomic, and health-related factors as confounders. The interaction of gender was examined.

Results:

Chronic pain, multisite pain, and mental distress were associated with total SA. Chronic multisite pain was associated with long-term SA (rate ratio [RR] 2.51, 95% CI 1.17-5.42), and chronic pain (RR 5.04, 95% CI 2.14-11.87) and multisite pain (RR 4.88, 95% CI 2.30-10.33) with long-term SA among those with mental distress. For women, there was a synergistic interaction of multisite pain to the association with total SA (synergy index 1.80, 95% CI 1.27-2.54).

Conclusions:

Chronic and multisite pain associate with SA among young and midlife employees. The associations are generally stronger among women and particularly among those with concurrent mental distress. Interventional studies are needed to confirm if early symptom recognition and support could reduce sickness absence.

Key messages:

- Chronic pain and pain at multiple body sites associate with sickness absence among young and midlife employees, particularly among women and those with concurrent mental distress.
- Interventional studies are needed to confirm if sickness absence could be reduced by early recognizing pain and mental distress among employees and providing preventive and therapeutic services.

Abstract citation ID: ckac129.311
Clustering of unhealthy behaviours and subsequent sickness absence among Finnish municipal employees

Jatta Salmela

J Salmela[1], J Lahti[1], N Kanerva[2], O Rahkonen[1], A Kouvonen[3,4], T Lallukka[1]
[1]Department of Public Health, University of Helsinki, Helsinki, Finland
[2]Department of Food and Nutrition, University of Helsinki, Helsinki, Finland
[3]Faculty of Social Sciences, University of Helsinki, Helsinki, Finland
[4]Centre for Public Health, Queen's University Belfast, Belfast, UK
Contact: jatta.salmela@helsinki.fi

Background:

Unhealthy behaviours are associated with increased sickness absence (SA), but few studies have explored these associations using person-oriented approach. We aimed to identify latent classes of unhealthy behaviours among female and male employees and examined their associations with subsequent SA.

Methods:

Health behaviours (leisure-time physical activity, sedentary behaviour, fruit and vegetable [F&V] consumption, sleep, binge drinking, and use of tobacco products) were derived from the Helsinki Health Study questionnaire survey, collected in 2017 among 19-39-year-old employees of the City of Helsinki, Finland. The questionnaire data were linked to employer's SA register. Latent class analysis was used to identify underlying profiles of unhealthy behaviours and negative binomial regression was used to examine their associations with subsequent SA ($\leq$7 days, >7 days, and all lengths) among 3228 women and 771 men. The mean follow-up time was 2.1 years.

Results:

Among women, we identified 3 latent classes: 1) healthy behaviours (81% of women), 2) binge drinking and tobacco use (12%), and 3) inadequate F&V consumption and insufficient sleep (7%). Classes 2 and 3 showed increased rates for subsequent SA compared to class 1, regardless of the length of SA spells (age-adjusted rate ratios [RR] 1.37-1.42 and 1.35-1.64, respectively). Among men, we identified 3 latent classes: 1) healthy behaviours (51% of men), 2) binge drinking and tobacco use (19%), and 3) inadequate F&V consumption, binge drinking and tobacco use (30%). While classes 1 and 2 were not different in terms of subsequent SA, class 3 had increased rates of subsequent, particularly short-term SA (RR 1.24, 95% CI 1.03-1.48).

Conclusions:

Preventive actions should consider simultaneously several unhealthy behaviours while aiming to reduce employees' SA. These actions might benefit from regarding potential gender differences in the clustering of unhealthy behaviours and their associations with SA.

Key messages:

- Preventive actions to reduce sickness absence should consider clustering of unhealthy behaviours among employees.
- Potential gender differences need to be regarded in these actions.

Contact: amaya.ayala@upf.edu

People who have suffered from cancer find it difficult to return to work after a sickness absence (SA). Previous evidence indicates that people who survive a cancer have a higher risk than general population of leaving the labor market prematurely or being unemployed due to sequelae of both treatment and disease. Our objective is to identify barriers and facilitators associated with the return and permanence in the workplace of salaried workers after a SA due to cancer in Catalonia. The research used a descriptive qualitative approach with socio-constructivist perspective. A theoretical sampling was carried out until saturation. Three discussion groups (7 people/group) were conducted with people who had suffered a SA due to cancer in Catalonia. The sessions were held virtually and were recorded, transcribed verbatim, and analyzed using thematic analysis and mixed coding with Atlas.ti. Most of the people had returned to work after SA or were looking for a job that was suitable for their health status. Among the barriers to reincorporation to their job detected: (1) coping with the same workload they had before the SA, (2) sequelae associated with cancer treatment that affected their ability to work (stress, low ability to concentrate, chronic fatigue, mobility limitations), (3) having jobs with a high physical load, (4) expectations of colleagues and bosses. Among the facilitating factors: (1) sessions with psycho-oncologists, (2) availability of holidays to adapt their return after SA, (3) teleworking, and (4) job adaptation. Regarding proposals to improve this process, the most outstanding were the implementation of policies that allow a gradual return to work adjusted to the people who want to adhere to it and generalize the possibility of doing psycho-oncological therapy. End of SA after cancer is a key moment for people who go through it, they suffer many difficulties during the process that could be prevented with measures such as a gradual return to work.

Key messages:

- Workers who suffer a SA due to cancer face difficulties on their return to work.
- Initiatives of adaptation and gradual reincorporation to the workplace could improve return to work process after a SA due to cancer.

Abstract citation ID: ckac129.313
Evaluation of an e-learning on involving significant others in occupational health care

Nicole Snippen

NC Snippen[1], HJ de Vries[1], M Hagedoorn[1], S Brouwer[1]
[1]Department of Health Sciences, University Medical Center Groningen, Groningen, Netherlands
Contact: n.c.snippen@umcg.nl

Background:

Significant others (SOs) like partners, family members or friends can play an important role in how workers cope with chronic disease, thereby influencing work and health outcomes. Despite the potential benefits of involving SOs in the return-to-work (RTW) process of workers with chronic diseases, guidance and training on how to manage this is scarce. Educating work and health professionals on this topic could lead to better RTW support for workers and prevention of long-term sickness absence.

Objectives:

This study aimed to determine the effectiveness of an e-learning for improving occupational health physicians' (OHPs) knowledge, attitudes, and self-efficacy regarding involving SOs in the RTW process. In addition, we explored OHPs' responses to and satisfaction with the e-learning. We conducted a randomized controlled trial with 87 OHPs, involving an intervention group and a waitlisted control group. Between-group differences in knowledge, attitude, self-efficacy outcomes, and retention of effects were assessed using ANOVA and paired t-tests. Reactions to the e-learning were analyzed with descriptive statistics and thematic analysis.

Results:

We found moderate to large effects on OHPs' knowledge ($p < .001$, $\eta p2 = .202$), attitudes ($\eta p2 = .098$), and self-efficacy ($p < .001$, $\eta p2 = .237$), with retention of all changes at 10-week follow-up. OHPs graded the e-learning with a mean score of 7.9 out of 10 (SD = 1.11) and indicated that the e-learning increased their awareness of the role of SOs in RTW and encouraged them to address this more often.

Conclusions:

The developed e-learning is the first evidence-based training to improve the knowledge, attitudes, and self-efficacy of OHPs with regard to involving SOs in the RTW process of workers with chronic diseases. The e-learning and accompanying materials can encourage work and health professionals to more often address the role of significant others in the work re-integration process.

Key messages:

- The developed e-learning is effective in increasing occupational health physicians' knowledge, attitudes and self-efficacy with regard to involving significant others in the return-to-work process.
- The e-learning and accompanying materials can encourage professionals to more often address the role of significant others in the work re-integration process to prevent long-term sickness absence.

Abstract citation ID: ckac129.314
Associations between perceptions and sick leave duration in dyads of workers and significant others

Nicole Snippen

NC Snippen[1], HJ de Vries[1], CAM Roelen[1,2], M Hagedoorn[1], S Brouwer[1]
[1]Department of Health Sciences, University Medical Center Groningen, Groningen, Netherlands
[2]Arbo Unie, Nieuwegein, Netherlands
Contact: n.c.snippen@umcg.nl

Background:

Dyadic processes of workers and significant others like partners, family members and friends can play an important role in adaptation to chronic disease, thereby influencing health and work outcomes. This study aimed to increase our understanding of dyadic processes in sick leave duration of workers with chronic diseases. We examined illness perceptions, return to work expectations (RTWE) and perceptions about significant other responses (i.e., engagement, buffering and overprotection) of workers and their significant others in relation to sick leave duration.

Methods:

This study used survey and registry data of 90 dyads of sick-listed workers with a chronic disease and their significant others. Simple and multiple regressions in which perceptions of workers and significant others were included simultaneously were used to examine associations with sick leave duration.

Results:

Workers' and significant others' perceptions were moderately to strongly correlated (r ranged from .46 to .80). Sick leave duration was associated with illness perceptions of both workers ($b = 8.58$, $p = .001$) and significant others ($b = 6.46$, $p = .008$), with more negative illness perceptions associated with a longer sickness absence. In the multiple regression, illness perceptions explained 12.3% of the variation in sick leave duration. Sick leave duration was also associated with RTWE of workers ($b = -76.87$, $p < .001$) and their significant others ($b = -92.47$, $p < .001$), with more positive RTWE associated with a shorter sickness absence. The RTWE of dyad members accounted for 24.5% of the variance of sick leave duration.

Conclusions:

Illness perceptions and RTWE of workers and their significant others are strongly interdependent and associated with sick leave duration of workers with chronic diseases. A dyadic approach targeted at improving illness perceptions and RTWE of both workers and significant others might be more effective than an individualistic approach in preventing long-term sickness absence.

Key messages:

- Return to work expectations and illness perceptions of workers and their significant others are associated with the duration of sickness absence of workers with chronic diseases.
- A dyadic approach targeted at both workers and their significant others might be more effective than an individualistic approach in the prevention of long-term sickness absence.

Abstract citation ID: ckac129.315
Covid-19 impacts on unemployment on the migration-gender intersections in Spain, a multilevel study

Núria Pedrós Barnils

N Pedrós Barnils[1]
[1]Prevention and Health Promotion, Bremen University, Bremen, Germany
Contact: nupedros@uni-bremen.de

Background:

The covid-19 pandemic has led to several socioeconomic consequences, which ultimately affect individuals' health status. This study aims to assess and explore the short-term impacts of the pandemic on the labour market in Spain, through the intersectional and multilevel analysis of unemployment rates.

Methods:

Cross-sectional study using data from the Spanish Labour Force Survey from the three quarters before and after the outbreak of covid-19 (N = 922,074). Multilevel logistic regressions were used to calculate the odds of being unemployed for the intersectional positions on gender and migration background, nested within 7 educational levels.

Results:

Before (pre) and after (post) the covid-19 outbreak, women had higher odds ($OR_{nw\text{-}pre} = 1.974$; p-value<0.001; $OR_{mw\text{-}pre} = 2.202$; p-value<0.001) of being unemployed than men

(ORmm-pre = 0.887; p-value<0.001). However, the pandemic affected women's employment unequally. Migrant women experienced an increase in the risk of being unemployed 6 times larger than native women (48.67% (ORmw-post = 2.688; p-value<0.001) v 8.78% (ORnw-post = 2.062; p-value<0.001)). Moreover, in the post-covid 19 scenario, individual characteristics of migrant women (ORmw-post = 2.688; p-value<0.001) played a larger role in the risk of being unemployed than their educational level (MOR = 2.537).

Conclusions:

Migrant women are disproportionately bearing the short-term economic consequences of the pandemic by means of higher unemployment rates, underpinning experiences of racism and gender discrimination. Increasingly attention needs to be placed on discriminated groups in society. Targeted protective policies that foster labour market integration and increase social protection are needed to mitigate and decrease existing economic, social, and health inequalities.

Key messages:

- Migrant women have disproportionately carried the economic impact of the covid-19 pandemic in Spain. Targeted protective policies are needed to mitigate existing socioeconomic and health inequalities.
- Migrant women's gender and migration background play a greater role than their education in the risk of being unemployed, underpinning experiences of racism and gender discrimination.

Abstract citation ID: ckac129.316

What do employees on long-term sick leave experience, as barriers for returning to work?

Kine Strømstad

K Strømstad[1], *LS Skarpaas*[2,1], *SE Wiik*[2], *SI Haslerud*[1], *RW Aas*[1,2]
[1]Department of Public Health, University of Stavanger, Stavanger, Norway
[2]Departmentof Occupational Therapy, Prosthetics and Orthotics, OsloMet – Oslo Metropolitan University, Oslo, Norway
Contact: kine.stromstad@uis.no

Background:

The financial burden long-term sick leave places on society are immense and amounted to an annual cost of 180 billion NOK in Norway. Epidemiological and sociodemographic risk factors related to sickness absence and return to work (RTW) are well studied, less is known regarding self-perceived biopsychosocial barriers for RTW. The aim of this study was to investigate the diversity of barriers for RTW as experienced by long term sick listed employees.

Methods:

The study is a large-scale qualitative interview study (n = 85), using semi-structured telephone interviews. Participants were eligible to participate if they had received sick leave benefits >6 months and <1,5 years at the time of recruitment, for at least 50% of their employed work hours. The data was analysed with a directed qualitative content analysis combined with a summative approach. A deductive approach, guided by the theoretical framework provided in Model of Human Occupation (MoHO) were used in the analysis process. In MoHO, the main categories are person specific components and environmental components.

Results:

The study generated 952 coded meaning units describing barriers for RTW. Of these, we were able to deductively code 917 within the framework of MoHO. In the person specific concept, performance capacity barriers were dominant (n = 530). Volitional barriers (n = 164) were related to personal causation, hereunder self-efficacy (n = 24), and one's sense of capacity (n = 91). Barriers related to habituation (n = 64) was expressed as habits, both necessary habits and undesirable habits. Barriers related to the environmental component amounted to 388. The majority was linked to occupational environment (n = 217), including availability of adequate work tasks and barriers related to the healthcare system.

Conclusions:

The experienced RTW-barriers extended beyond health-related barriers, for most of the participants the barriers were related to both person specific components and environmental components.

Key messages:

- By gaining a greater understanding of the experienced RTW-barriers we could possibly provide more tailored RTW-services and help sick listed to a safe and sustainable return to work.
- The experienced RTW barriers for long term sick listed were primarily related to person specific and environmental components, and thus extended beyond health-related barriers.

5.K. Workshop: National and European studies on health literacy in children and adolescents

Abstract citation ID: ckac129.317

Organised by: EUPHA Working Group on Health Literacy, EUPHA-HP, EUPHA-CAPH, Technical University Munich, Robert Koch Institute
Chair persons: Orkan Okan (EUPHA-HP), Kimberley Foley (UK)
Contact: orkan.okan@tum.de

Health literacy describes how people use health information to make informed decisions in context of healthcare, disease prevention and health promotion. Enhancing health literacy of populations is critical and in particular important at an early age, which is understood to be more sustainable because health literacy contributes to improved personal health and development. Low health literacy in child and adolescent populations has been linked to worse health outcomes and health disparities in Europe, making health literacy of children and adolescents an important public health topic. Developing and delivering target group specific interventions and services requires precise data generation on the state of health literacy in early age. In the past decade, several conceptual approaches have been undertaken but methodological sound, validated and reliable measurement tools are still scarce. Available systematic reviews show that most tools originated from North America and/or English speaking countries. However, in the past years European researchers have been involved with research on health literacy in childhood and adolescence, the result of which culminated into heavy progress regarding the development of health literacy measurement instruments, including generic health literacy, digital health and mental health literacy. These new developments lead to the availability of validated tools for school-aged children, including primary and secondary school children. The purpose of this workshop is to bring together five contemporary health literacy studies conducted in child and adolescent populations across Europe, including national and European-wide studies. Both methodological findings regarding the measurement tool and empirical data will be introduced. The first presentation emerges from the HLCA HL-Kids project, which has been conducted in Germany and focusses on primary schoolchildren, using the HLS-Child-Q15 tool. The second presentation originates from the Netherlands where the HLS-Child-Q15 tool was adapted to Dutch children. The third presentation aims at health literacy of adolescents in secondary school-age in Germany, by using the MOHLAA-Q tool. The fourth presentation originates from the WHO-led HBSC study, which has been conducted by using the HLSAC questionnaire. The final presentation will focus on the first digital health literacy measurement tool for secondary schoolchildren, which has been developed within a German study in schools. Each project will be given ten minutes to present their findings, including questions, which will be followed by Q&A and an open discussion with the audiences. This workshop offers a forum for researchers, practitioners and policy-makers interested in health literacy measurement in children and adolescents. By dialogue and two-way communication, vivid interaction will be ensured, allow building synergies, and facilitate networking and capacity building.

Key messages:

- Health literacy contributes to improved personal health and development of children and adolescents.
- The measurement of health literacy is key to public health intervention success and needs theory driven, validated and reliable instruments.

Abstract citation ID: ckac129.318
HL-Kids-NRW – Study of fourth-graders' health literacy

Torsten Michael Bollweg

T Bollweg[1], *O Okan*[1]
[1]Department of Sport and Health Science, Technical University Munich, Munich, Germany
Contact: torsten.bollweg@tum.de

Background:

Although children are identified as a key target group for interventions targeting the development of health literacy, little data is available on children's health literacy and how it is related to health outcomes at a young age. This study addresses this research gap by providing data on fourth-graders' health literacy and associated health outcomes.

Methods:

A cross-sectional study was conducted among fourth-grade students in the state of North-Rhine Westphalia, Germany. The study was designed as a representative survey starting in 12/2020, which could, however, not be realized due to pandemic-related constraints. Data collected between 07/20 and 11/20 is included in the analyses presented here. Among others, we assessed self-reported health literacy with the HLS-Child-Q15 questionnaire, while also assessing various self-reported health outcomes.

Results:

n = 364 students are included in the analysis, 49,5% of which are female. The mean age is 9.5 years (SD = .7). The HLS-Child-Q15 demonstrated high internal consistency (Cronbach's $\alpha = .812$). Self-reported health literacy is high, with a HLS-Child-Q15 mean score of 3.13, indicating that it is rather easy for participants to deal with health-related information. Health literacy is significantly associated with a number of outcomes related to health status (KINDL-R subscales physical wellbeing and mental wellbeing, Spearman's $\rho = .280$ and $\rho = .271$, respectively; $p < .001$) and health behaviour (freq. of brushing teeth: $\rho = .173$; $p < .01$; freq. of eating fruit and vegetable: $\rho = .217$ and $\rho = .299$; $p < .001$; freq. of physical activity: $\rho = .279$; $p < .001$).

Conclusions:

While the overall level of health literacy in our sample is high, higher health literacy is associated with better health behaviours, as well as improved mental and physical wellbeing. Further analyses are necessary to explore the causal pathways between the investigated variables, and representative survey are needed to verify these findings.

Abstract citation ID: ckac129.319
Measuring health literacy and its associations with health behaviors of adolescents in Germany

Anne-Kathrin Mareike Loer

A Loer[1], *OM Domanska*[1], *S Jordan*[1]
[1]Department of Epidemiology and Health Monitoring, Robert Koch Institute, Berlin, Germany
Contact: LoerA@rki.de

Background:

The questionnaire ''Measurement of Health Literacy Among Adolescents Questionnaire'' (MOHLAA-Q) was developed and validated in a multi-stage process to measure generic health literacy among 14- to 17-year-olds. The MOHLAA-Q combines subjective and objective measurements, consisting of four scales. The instrument was applied to explore associations between generic health literacy and different health behaviors among adolescents in Germany. The data should contribute to the age-appropriate development of health promotion interventions.

Methods:

We carried out a nationwide cross-sectional online survey with 1,235 adolescents aged 14-17 years in Germany in 2019. Data on generic health literacy were collected using the four scales of the MOHLAA-Q and data on health behaviors were collected using single established single-item questions on sports, diet, alcohol consumption, and smoking. Bivariate and multiple analyses were performed for investigating associations between generic health literacy and health behaviors, adjusted for age, gender, education and self-efficacy.

Results:

Not consuming fruit and vegetables daily was associated with lower health literacy levels in all examined scales. Doing no sports as well as smoking showed positive associations with low levels in ''health-related communication and interaction skills'' and ''attitudes toward one's own health and health information''. No associations were found between risky alcohol consumption and health literacy.

Conclusions:

The results indicate that strengthening health literacy should be part of health promotion activities for increasing physical activity and healthy diet among adolescents. The MOHLAA-Q allows us to identify which specific dimensions of health literacy might be addressed in order to promote different health behaviors.

Abstract citation ID: ckac129.320
Exploring children's health literacy in the Netherlands – results in a sample of 8-11 year olds

Jany Rademakers

J Rademakers[1,2], *M Hahnraths*[2], *T Bollweg*[3], *O Okan*[3], *M Willeboordse*[4], *M Heijmans*[1]

[2]CAPHRI, Maastricht University, Maastricht, Netherlands
[3]Department of Sport and Health Science, Technical University Munich, Munich, Germany
[4]Mulier Institute, Utrecht, Netherlands
Contact: j.rademakers@nivel.nl

Background:

There are few valid, age-appropriate tools to assess children's HL. The German-language European Health Literacy Survey Questionnaire Adapted for Children (HLS-Child-Q15-DE) is a self-report questionnaire adapted from the adult European Health Literacy Survey Questionnaire. In 2021, this instrument was translated and validated in the Netherlands. In this presentation, we will describe the distribution of Health literacy in a sample of Dutch children, and relate their Health literacy level to certain aspects of their health behaviour such as food intake and physical activity.

Methods:

The HLS-Child-Q15-DE was translated following WHO guidelines and administered digitally to 209 Dutch schoolchildren (eight-to-eleven-year-olds). Its psychometric properties were assessed and the sample's HL distribution was explored by demographic characteristics. Associations with food intake and physical activity were computed.

Results:

Of the sample, 17.2% had a low health literacy score (first quintile), 61.1% medium (second to fourth quintile) and 21.7% high (fifth quintile). Higher HL scores were observed for ten-to-eleven-year-olds (compared with eight-to-nine-year-olds; p = 0.021) and fourth-grade students (compared with third-grade; p = 0.019). A positive association between children's HL and their vegetable consumption and PA behaviour was observed.

Conclusions:

Children's health literacy can have an impact on some aspects of their lifestyle. This supports the idea that health literacy evolves throughout life and stresses the importance of both parents and schools in this process.

Abstract citation ID: ckac129.321
Health literacy among adolescents: summary of some key findings from ten European countries

Leena Paakkari

L Paakkari[1], *H Lahti*[1], *M Kulmala*[1], *O Paakkari*[1], *N Lyyra*[1]
[1]Faculty of Sport and Health Sciences, University of Jyväskylä, Jyväskylä, Finland
Contact: leena.paakkari@jyu.fi

Introduction:

In research on disparities, the concept of health literacy (HL) as a set of competencies to promote and sustain health may help in understanding the disparities better and in addressing avoidable and unfair health disparities. The presentation will present some key findings on adolescents' HL levels in ten European countries, and how HL mediates and moderates between various background factors and health outcomes.

Methods:

Data consisted of cross-sectional data from Health Behaviour in School-aged Children (HBSC) study from year 2017/18 of ten European countries (Austria, Belgium (Fl), Czechia, England, Estonia, Finland, Germany, Macedonia, Poland, and Slovakia). Data (n = 14,590 - 22,291) of 13- and 15-year-old pupils were used. Indicators include background variables (e.g. age, gender), Health literacy, Health indicators (e.g. self-rated health (SRH) and problematic social media use (PSMU)). Analysis include (1) Mediator analysis (with Mplus): pearson correlation coefficients, path models (Mplus 7.3 and Maximum Likelihood estimator) and (2) random effects models and moderator analyses (with R-sofware).

Findings:

HL is an independent factor explaining disparities in health (e.g. SRH), and a mediator as well as a moderator between health outcomes and background factors. Based on the national analyses HL had significant main effects in every country, but group level differences emerged only in some countries. For instance, in Finland and Belgium, among girls HL lowered the likelihood to problematic social media use, but not among boys.

Discussion:

HL is of use in understanding and tackling health disparities among adolescents. Results confirm the need to adopt the principles of proportionate universalism when promoting HL among adolescents to avoid widening the disparities within population groups. Also, country-specific health literacy interventions are needed to secure equity in opportunities of different population groups to benefit from the HL interventions.

[4]HAGE, Frankfurt, Germany
[5]Department of Applied Health Sciences, University of Applied Sciences, Bochum, Germany
Contact: kevin.dadaczynski@pg.hs-fulda.de

Background:

Due to the high availability and use of digital media, health-related information is increasingly shifting into the digital space. While there are increasing empirical findings on general health literacy (HL), there is a lack of evidence on digital HL in adolescence and its association with health behavior.

Methods:

A cross-sectional study of 490 secondary school students (grades eight and nine) from the federal state of Hesse was conducted from October 2019 to February 2020. Digital HL was assessed using five subscales of the Digital Health Literacy Instrument (DHLI), while consumption of fruits, vegetables, soft drinks, and weekly physical activity were used as indicators of health behavior. In addition to gender and grade level, subjective social status (SSS) was used as a social characteristic. Univariate, bivariate, and multivariate analyses were performed, with binary-logistic regression adjusted for gender and SSS.

Results:

Across all items, the percentage of adolescents reporting difficulties in acquiring and dealing with digital health information ranges from 15.3 % to 37.5 %. Stratified by social characteristics, gender and socioeconomic differences were found with girls and respondents reporting a lower SSS more often showing a limited digital HL. Adolescents with moderate and low digital HL report higher levels of low physical activity, non-daily fruit and daily soft drink consumption. Depending on the health behavior, different relationship patterns can be observed for the dimensions of digital HL.

Conclusions:

The findings suggest a need for interventions to promote digital HL among adolescents, particularly for those of low SSS. In this context, the differential relationship patterns with health behaviors provide an avenue for the development of specific interventions.

Health workforce needs of small medical specialties: findings from rheumatology in Germany

Ellen Kuhlmann

E Kuhlmann[1], *K Hoeper*[1,2], *T Witte*[1], *D Ernst*[1], *A Dopfer-Jablonka*[1]
[1]Clinic for Rheumatology and Immunology, Medizinische Hochschule Hannover, Hannover, Germany
[2]Regionales Kooperatives Rheumazentrum Nieders, Hannover, Germany
Contact: kuhlmann.ellen@mh-hannover.de

Background:
Small medical specialties may be more vulnerable to workforce shortage and the COVID-19 pandemic and this may directly impact in the provision of care for chronically-ill patients. This study aims to explore health workforce development and new needs, using rheumatology in Germany as a case study.

Methods:
An explorative multi-methods approach was applied, combining health labour market assessment of rheumatology physicians (public statistics 2000-2019) and a questionnaire-based online survey conducted in early 2021 (n = 101 respondents; rheumatology physicians and residents). Main selected topics: work hours, workload, mental health issues, discrimination and sexual harassment experiences, impact of COVID-19. Descriptive statistical analysis was performed and qualitative content analysis for free-text information.

Results:
Health labour market analysis showed that the numbers of rheumatologists increased markedly between 2000 and 2019 in the groups aged +50 years, but only 9% in younger groups under 50 years; since 2010 the group 40-50 years showed decreases. In 2019, the absolute number of rheumatologists working in healthcare after retirement-age exceeded those aged 40 and under. Survey data revealed a strong mismatch between actual and desired work hours for women and men. 81% rated their workload as high or very high; every sixth rheumatologist has suffered from stress or burnout syndromes at least once in the past. Experiences of gender discrimination and sexual harassment/violence were frequently reported, mostly by women. COVID-19 was an amplifier of stress with major stressors being digitalisation and increased demand for communication and patient education.

Conclusions:
Decreasing health workforce capacities in German rheumatology combine with negative perceptions of work and workplace conditions, threatening both retention and service delivery.

Key messages:
- Small medical specialties, like rheumatology, face severe shortage that threaten healthcare for chronically-ill patients and need greater attention.
- COVID-19 has reinforced rheumatologists' workload and stressors, thus worsing mental health and retention.

Abstract citation ID: ckac129.324
Training health professionals in infodemic management to mitigate the harm caused by infodemics

Tina Purnat

TD Purnat[1], *C Bertrand-Ferrandis*[1], *B Yau*[1], *A Ishizumi*[1], *B White*[1], *S Briand*[1], *T Ngueyn*[1]
[1]High Impact Events Preparedness, WHO, Geneva, Switzerland
Contact: tina.purnat@gmail.com

Background:
Due to their multifaceted impacts on health and society, understanding and controlling infodemics to support uptake of vaccines, public health and social measures, treatments, and health behaviours is rapidly becoming a priority for many health authorities. WHO has developed a comprehensive training programme to support health professionals in the new field of expertise of managing infodemics.

Objectives:
The WHO infodemic management multiformat and transdisciplinary training program builds the skills and knowledge needed to prepare for and respond to infodemics. The trainings are built on WHO competency framework for building an infodemic response workforce. The methodology used relies on human-centred and emotional design evidence and practice and uses evaluation for continuous learning design improvement.

Results:
Since November 2020, three WHO global trainings organized online with US Centers for Disease Control and Prevention, UNICEF and other partners, including four-week-long simulation exercises, creating a network of 772 infodemic managers in 133 countries. A ''train-the-trainers'' companion package was prepared and by April 2022 delivered in Iran and Malaysia. Deep dive training modules on specialist infodemic management practice topics have been prepared for use at country level. In addition, a comprehensive set of self-paced free online courses enhances infodemic literacy and resilience to misinformation. Between December 2021 and April 2022, the OpenWHO Infodemic Management 101 course reached over 17 000 enrolments. The training programme will be updated based on evaluations, the feedback from field responders and the updated to the WHO competency framework for infodemic management workforce.

Conclusions:
The WHO multiformat blended training program allows an efficient and rapid dissemination of infodemic management skills and knowledge.

Key messages:
- A global network of trained infodemic managers is ready to support national preparedness and response planning.
- Skills and knowledge in infodemic management are accessible to all thanks to free online courses.

[6]Accessible Quality Healthcare Project, Prishtina, Kosovo
Contact: ariana.bytyci@swisstph.ch

Background:
Smoking, physical inactivity, low fruit and vegetable consumption, and obesity are common in Kosovo. The Accessible Quality Healthcare project is implementing a primary healthcare intervention that entails nurse-guided motivational counselling to facilitate lifestyle behaviour change. This study assesses the uptake of counselling and the impact on health behaviours and participants' stages of health behaviour change as well as describes experiences and perceived benefits of motivational counselling.

Methods:
Study participants (n = 907) were recruited from 12 municipalities participating in the Kosovo Non-Communicable Disease Cohort study. For the quantitative study, data on lifestyle behaviours, use of counselling, and stages for behavioural change were used. For the qualitative study, in-depth interviews were conducted with 26 cohort participants who had undergone motivational counselling.
Results:
Motivational counselling was received by only 22% of the eligible participants in the intervention municipalities. Unhealthy behaviours remain high even in persons who underwent counselling (of whom 13% are smokers; 86% are physically inactive; 93% with inadequate fruit and vegetable consumption; 61% are obese). According to the qualitative study results, the participants that received counselling were very satisfied with the services but requested additional services such as group physical activity sessions and specialized services for smoking cessation.
Conclusions:
More tailored and additional primary healthcare approaches in accordance with patients' views need to be considered for the motivational counselling intervention to reach patients and efficiently facilitate lifestyle behaviour change.
Key messages:
- The following tailored approaches are suggested: a) strengthened referral mechanism b) specialized services for smoking cessation; c) delivery of group physical activity sessions.
- More tailored and additional primary health care approaches in accordance with patients' views need to be considered for the motivational counselling intervention.

5.M. Workshop: The need to account for vaccine-specificities in the implementation of the EU Regulation on HTA

Abstract citation ID: ckac129.326

Organised by: EUPHA-HTA, Vaccines Europe, HTAi
Chair persons: Chiara de Waure (EUPHA-HTA), Elena Petelos (EUPHA-HTA)
Contact: chiara.dewaure@unipg.it

In January 2022, the EU Regulation on Health Technology Assessment (HTAR) entered into force. The HTAR provides for the centralized conduct of EU-wide joint clinical assessment (JCA) for oncology treatments (2025 onwards), and for other medicinal products incl. vaccines (2030 onwards). HTA is a multidisciplinary process aiming to disentangle the value of a health technology in comparison to other. It has been used, to different extent across EU countries, to inform vaccine price and reimbursement decisions. Nevertheless, existing assessment frameworks utilized by HTA bodies, incl. National Immunization Technical Advisory Groups (NITAGs), as well as the relative effectiveness assessment (REA) framework developed by the European Network for Health Technology Assessment (EUnetHTA), do not fully account for the specificities of vaccines. In fact, to account for the broad value of vaccines several aspects ought to be considered, including societal benefits. Attention has been paid to these topics for years by the public health community, and in particular EUPHA-HTA, and also Vaccines Europe, a specialized vaccines group within the European Federation of Pharmaceutical Industries and Associations (EFPIA), has recently released a position statement on the need to tackle vaccine specificities in future JCA. Furthermore, as the COVID-19 pandemic has highlighted, such aspects are critical for joint procurement efforts to combat the current and future pandemics. The objective of this workshop is to address the current and future role of HTA in vaccine regulation across EU countries, inform on key specificities of vaccines in respect to JCA and HTA as a whole and discuss opportunities to develop vaccine-specific methodological guidelines within the HTAR. Following an introduction, the following topics will be addressed:
- Competent bodies and HTA impact on vaccine decision-making process, incl. a discussion of implementation challenges and potential impacts of the HTAR.
- JCA specificities in respect to vaccines and the importance of addressing the whole value of vaccines and vaccinations.
- The proposal of Vaccines Europe for guiding principles to account for vaccines specificities in JCA built on the outcomes of an 'across-the-industry' project incl. also non-industry experts.

The presentations will be followed by a panel discussion to further explore the themes, consider next steps and address questions from the audience.
Key messages:
- The new EU HTAR is paving the way for JCAs of several medicinal products, incl. vaccines necessitating expert guidance in terms of determining their whole value.
- Vaccines specificities should be duly considered in JCAs to inform national and EU-wide decision-making for vaccination programmes, reimbursement, and pricing.

Abstract citation ID: ckac129.327
HTA and National Immunisation Program: an overview of competent bodies and of the impact of HTA on the decision-making process

Walter Ricciardi

W Ricciardi[1]
[1]Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy
Contact: walter.ricciardi@unicatt.it

Issue/problem:
The WHO has recommended for many years to adopt transparent and standardized methods to decide upon the introduction of vaccines at national level. For this purpose, the Global Vaccine Action Plan has envisaged the establishment of National Immunization Technical Advisory Groups (NITAGs) to issue independent advice relied on the assessment of vaccines efficacy and safety and health technology assessment (HTA).
Description of the problem:
So far, 172 countries worldwide have a NITAG. Despite the growth in the number of NITAGs worldwide and their strengthening following process indicators identified by the WHO, the way how NITAGs issue recommendations and how they are considered in the development of vaccine policy still represent a matter to the attention of the scientific and policy community.

Results:

The evidence shows that assessment frameworks vary across countries. Furthermore, the legal basis and the authority, namely binding or advisory, recognised to them could influence the way how NITAGs work and impact on vaccine policy. Eventually, the final decision is also led by other aspects, including financial and contextual factors that are less standardizable but should be always taken into consideration in health policy. In fact, the final decision on the inclusion of a vaccination into the national immunization program is made by the Ministry of Health also based on the evaluation of HTA bodies working in the country.

Lessons:

Considering the central role of NITAGs in vaccine policy, some efforts should be done in order to make NITAGs more authoritative and collaborative. This could help, from one side, to make the relationship between final decision and NITAGs recommendations clearer and, on other one, to make it possible to have shared and timely evaluations. In this respect, Joint Clinical Assessment envisaged by the new EU regulation on HTA could prepare the way for a more transparent and timely vaccine policy at European level.

Accounting for vaccines specificities in the Joint Clinical Assessment (JCA): a proposal for guiding principles

Sibilia Quilici

E Beck[1], *P D'Agostino*[2], *R Chapman*[3], *N Largeron*[4], *L Louette*[5], *U Sabale*[6], *K Schaible*[3], *S Quilici*[5]

[5]Vaccines Europe, EFPIA, Brussels, Belgium
[6]CORE, MSD, Stockholm, Sweden
Contact: sibilia.quilici@vaccineseurope.eu

Issue/problem:

Vaccines are an important public health intervention protecting the population against infectious diseases. The value of vaccines is broad ranging from individual to societal as achieving community immunity protects the unvaccinated, minimizes the risk of outbreaks, reduces the emergence of antimicrobial resistance, and leads to broader societal benefits.

Description of the problem:

Vaccines' market access processes are characterized by the development of recommendations by NITAGs followed by the assessment of health technology assessment (HTA) bodies in less than half of 27 EU member states. Despite that HTA for therapeutic drugs is well established, there is very limited experience in applying HTA methodologies to vaccines, especially for clinical assessments, as HTA methods and frameworks are traditionally geared toward therapeutics. However, following the adoption of the EU regulation on HTA, Joint Clinical Assessments (JCAs) of vaccines are expected.

Results:

To support a discussion on how to account for vaccine specificities in the JCA, Vaccines Europe has performed a project which aimed at developing a proposal for high-level guiding principles on processes and methodologies for clinical HTA for vaccines. The proposal is informed by findings of literature reviews on currently applied processes, methods, and clinical assessment frameworks of vaccines as well as the outcomes of an advisory board with scientific experts.

Lessons:

A proposal for high-level guiding principles for clinical HTA for vaccines is being developed based on both evidence and the advice from scientific experts which focuses on processes (e.g., horizon scanning, early advice, consideration of vaccine-specific expertise) and methods (e.g., unmet need, safety, efficacy/effectiveness, real-world evidence and technical characteristics of the technology). Lastly, the implementation of vaccines specificities in JCA represents a call for action.

Abstract citation ID: ckac129.329
Needs for a thorough Joint Clinical Assessment of vaccines within the HTAR: perspectives of NITAGs

Ole Wichmann

O Wichmann[1]
[1]Immunization Unit, Robert Koch Institute, Berlin, Germany
Contact: wichmanno@rki.de

Issue/problem:

NITAGs are independent expert advisory committees that provide evidence-based recommendations to the Ministry of Health to guide the introduction of new vaccines and formulate national immunization plans.

Description of the problem:

The evaluation of vaccines has become more and more complex. This is not only because the number of vaccines on the market and the diseases they target has increased, but also because a much wider range of population subgroups can be targeted, and for some diseases several vaccines are available and need to be compared. In addition, vaccines not only have an impact on individual well-being, but can also induce population-level effects and broader socioeconomic value.

Results:

NITAGs consider to a large extent similar key factors in their evaluation processes. These can be divided into context-free and context-specific aspects. Context-free aspects include effectiveness and safety. Local disease epidemiology, potential vaccine impact at population-level, cost-effectiveness and societal or cultural values and preferences are context-specific aspects. Collaboration is possible when jointly assessing the evidence related to context-free aspects, since this is usually easily transferrable across countries. In 2019, a network of NITAGs in the European Union and Economic Area countries was established under the coordination of the European Centre for Disease Prevention and Control. Within this network, working groups have been established and either performed themselves or supported external contractors in conducting systematic reviews on vaccines effectiveness and safety.

Lessons:

The increasing workload of NITAGs and the prospect of joint clinical assessments draw the attention to a number of practical issues to be solved, e.g., consensus on methodological guidelines for systematic reviews, processes to ensure that the products meet NITAGs expectations (content, quality, timing), and approaches how to consider unpublished data.

5.N. Workshop: Children first: do health systems pay enough attention to their youngest constituents?

Abstract citation ID: ckac129.330

Organised by: European Observatory on Health Systems and Policies
Chair persons: Ewout Van Ginneken (Germany), Dimitra Panteli (Belgium)

Contact: pantelid@obs.who.int

This workshop aims to bring together a range of insights on how health systems have dealt with child health and health care, highlighting both successes and challenges. For children, access to health care is vital. It impacts their physical and emotional health and wellbeing and largely determines whether they can reach their full potential as adults, which is also important to their families and society at large. Consequently, it comes as no surprise that he 1989 UN Convention on the Rights of the Child, which was ratified by all European countries, guarantees a fundamental right to healthcare for all children. However, various national governments do not fully comply with the Convention, and evidence exists that children may not always enjoy the necessary access to meet their needs. In 2021, Doctors of the World (DoW) concluded that there are urgent questions about the welfare and health of vulnerable children across Europe, based on the increase in children seeking healthcare from DoW clinics instead of the national health system. This concerning trend is not captured well enough in available statistics. What is more, the COVID-19 pandemic and the Ukrainian refugee crisis raise additional concerns as to how health systems will deal with the observed increases in related paediatric sequelae and mental health needs. The aims of this workshop are therefore to stimulate discussion around better understanding children's access to health care and how it relates to health system performance, and provide impetus for new initiatives that can improve health care for children. The workshop will take a hybrid format, kicking off with three short presentations followed by a round table discussion and engagement with the audience. The presentations will cover the regulatory framework for children's access to health care in European countries; identified bottlenecks of health system performance specific to child services from a range of countries around the world; and the impact of COVID-19 on hospital care for children based on the example of one European country.

Key messages:

- Ensuring children's access to health care is now more important than ever; a lot more can and should be done at all levels.
- More and better data about children's health and health care access is necessary to enable effective policies; collecting it should become a health system priority.

Children's health status varies within and between European countries. To what extent this is associated with access barriers to timely and effective care children may face is not yet fully understood. Article 24 of the UN Convention on the Rights of the Child (UNCRC) guarantees a fundamental right to healthcare for all children, regardless of their legal status in terms of citizenship, residence, or insurance. Using information contained in the Health Systems in Transition reports produced by the European Observatory on Health Systems and Policies, additional relevant literature, and responses to a structured questionnaire filled out by key informants from all 27 EU MS and the United Kingdom, we evaluated whether European countries comply with the specific obligations that can be drawn from the UNCRC. While all countries considered have ratified the UNCRC, only four countries have included a specific disposition in their legislation that establishes an unconditional, universal right to health services for all children living in their territory. In other countries, the fragmented way of defining children's access rights can create gaps in legislation which can leave certain groups of children without coverage. Children with irregular residence are the most vulnerable group when it comes to eligibility problems, but other groups of children may also fall between the cracks or be only entitled to restrict-ed or conditional access to health care. These insights show that international treaties, such as the UNCRC, can help monitor health coverage and ensure that basic human rights to health services are guaranteed in times of crisis, such as the Covid-19 pandemic and the Ukraine Displacement, but may be insufficient without concrete transposition into national legislative frameworks.

Health System Performance Assessment (HSPA) is an established tool that can help identify issues with the way health systems work to achieve their intended goals, improve transparency and account-ability, and provide stimulus for reform. However, HSPA frameworks tend to be adult-centric and therefore not generally sensitive to child health challenges. Using a new HSPA framework for Universal Health Coverage, we show how child health tracer conditions can be used to pinpoint system under-performance and flag major bottlenecks impeding service delivery overall. Based on the HSPA framework, health system bottlenecks can be traced backwards to explore possible origins (areas to be targeted for improvement) or forwards to understand potential implications for the achievement of health system goals. The following qualitative and quantitative data are used to highlight major bottlenecks to child health service delivery: eight health system-focused child health assessments which show that one of the main bottlenecks is weak primary care coverage of sexual, reproductive, maternal, newborn, child, and adolescent health services, leading to parents bypassing PHC in favour of hospitals; results from WHO missions (e.g. in Romania and Tajikistan) showing that paediatric patients were often admitted to hospitals for treatment, even for conditions that could be safely managed in the outpatient setting; quantitative data on responsiveness, user experience, client satisfaction and people-centredness from publicly available datasets and national datasets obtained in collaboration with WHO Country Offices for national level data, to contextualize the aforementioned findings.

Contact: mauern@obs.who.int

The COVID-19 pandemic created substantial disruptions in the delivery of health services around the world. Reductions in hospital admissions have been reported for several conditions in the adult population; less evidence currently exists for children. To what extent such changes reflect a risk for patients due to unmet care needs, or a ‘‘correction’’ of previous overprovision of care has not been thoroughly examined yet. Based on complete national hospital discharge data, we compare the top 30 diagnoses for which children were hospitalised in 2019, 2020 and 2021 in Germany. We also analyse the development of monthly admissions between January 2019 and December 2021 for three tracers of variable urgency and severity. Total admissions were approximately 20% lower in 2020 and 2021 compared to 2019. The composition of the most frequent diagnoses did not change dramatically across years, although changes in rank were observed. The number of admissions for acute lymphoblastic leukaemia (tracer 1) showed a slight increasing trend and a periodicity prima vista unrelated to pandemic factors. Appendicitis admissions (tracer 2) decreased by about 9% in 2020 and a further 8% in 2021, while tonsillectomies/adenoidectomies (tracer 3) decreased by more than 40% in 2020 and a further 30% in 2021; for these tracers, monthly changes are in line with pandemic waves. Observed variations in child hospitalisations reflect the effects of pandemic mitigation measures and/or changes in demand. In Germany, inpatient care for critical conditions appears to have been largely upheld, potentially at the expense of elective treatments. Complementary data on ambulatory care and health outcomes would enable a better understanding of change in healthcare patterns and effects on children’s health.

5.O. Workshop: Psychosocial impact and healthcare utilization after terrorist attacks

Abstract citation ID: ckac129.334

Organised by: EUPHA-PMH
Chair persons: Johan Bilsen (EUPHA-PMH), Jutta Lindert (EUPHA-PMH)
Contact: johan.bilsen@vub.be

Terrorist attacks can be regarded as a major public health issue, confronting not only political leaders with adequate answers to these threats, but also the public healthcare, and especially the public mental healthcare. The impact of terrorist attacks is mostly severe, widespread, affecting those directly exposed and their close ones, but also first responders, healthcare workers, local communities and even the society at large. While the directly involved are often confronted with severe physical and acute, often transient, traumatic stress symptoms, longitudinal studies increasingly show that a much larger group is affected by persistent mental health problems, such as posttraumatic stress disorders, depression, or a general undermining of their mental and physical wellbeing, sometimes seriously impairing their personal and social functioning. These problems may differ by severity of exposure and individual risk factors, but are also related to access to timely, appropriate and effective healthcare and psychosocial support. The mostly unpredictability of these threatening events, the urgency of response, and the often-chaotic circumstances are challenging factors to identify the most vulnerable people that need psychosocial care, and to organize optimal care. It also impedes the assessment of the efficiency of implemented psychosocial care. However, systematic planning and evaluating psychosocial care based on scientific evidence on the best practices is important to efficiently respond to and recover from mass casualty incidents such as terrorist attacks. Until now, scientific knowledge about the current state of utilization of healthcare by the affected population, and about the best practices taking into account specificity of certain vulnerable subgroups is still very scarce. In this workshop four speakers from different countries will present their research findings about the psychosocial impact of terrorist attacks, the way how this is addressed by society and the actual healthcare utilization of the affected people. Recommendations regarding a more adequate response are proposed. Roel Van Overmeire will talk about the long-term psychosocial care response by the Belgium government, from both the level of the policy, as well as from the perspective of victims. Lise Stene will present a register-based study of survivors’utilization of primary care and mental health services before and after the Utoya attack in Norway. Yvon Motreff will inform us about the psychological impact on first responders and their engagement in mental health care after the 2015 terrorist attacks in France. Finally, Ulrich Wesemann will further focus on mental healthcare provided to emergency responders after the Berlin terrorist attack in 2016 in Germany, and will specifically examine the outcome of crisis intervention in relation to gender and occupational characteristics.

Key messages:

- Public mental health impact of terrorist attacks is substantial and needs an adequate and differentiated psychosocial care response.
- Research on healthcare utilization after terrorist attacks is needed to strengthen public health preparedness.

Contact: Roel.Van.Overmeire@vub.be

Introduction:

While many studies have shown how terrorist attacks can have a mental health impact, there currently is little insight into how governments try to aid victims of terrorist attacks. In this study we viewed the long-term governmental psychosocial care response after the attacks of 22/03/2016 in Belgium, from both the level of the policy, as well as from the perspective of victims.

Methods:

This study employed a qualitative design. First, we studied guidelines, reports, policy documents and other relevant grey literature concerning the governmental psychosocial care response to the terrorist attacks. Second, we interviewed 27 victims of the terrorist attacks on their experiences with terrorist attacks for the micro level. We analyzed these interviews using a reflexive thematic analysis.

Results:

On the policy level, a problem occurred in the transfer from responsibilities from the federal level to the community's level. Furthermore, there was no proper psychotraumatology network of therapists, which did not allow for the proper therapy to be easily sought by victims. This was noticed also by the victims, who had issues finding a therapist that fitted their needs and could help with their trauma-related disorders. Furthermore, on both policy level and victim level, a reoccurring problem is the lack of recognition and knowledge of the mental health issues occurring after disasters such as terrorist attacks.

Conclusions:

The Belgian long-term psychosocial care response to the terrorist attacks of 22/03/2016 was not well organized and left some victims without proper aid. To improve the psychosocial response after terrorist attacks in the long-term, a combination of both more knowledge and recognition is needed.

Changes in healthcare utilization after mass trauma: A register-based study of young survivors' utilization of primary care and mental health services before and after the Utøya attack in Norway

Lise Eilin Stene

L Stene[1], S Thoresen[1], T Wentzel-Larsen[1], G Dyb[1]
[1]NKVTS, Norwegian Centre for Violence and Traumatic Stress Studies, Oslo, Norway
Contact: l.e.stene@nkvts.no

Introduction:

Using register-based data, this study had a unique possibility to investigate how young survivors' use of primary care and mental health services (MHS) changed after a terrorist attack.

Methods:

We analyzed data on consultations with primary care physicians (PCP) and MHS among 255 survivors (48% female) of the 2011 Utøya youth camp attack in Norway three years before and after the attack, and their reason for encounter with the PCP according to the International Classification for Primary Care (ICPC-2).

Results:

The majority of survivors consulted PCP both before and after the attack, with a marked increase in psychological reasons for encounter after the attack. Few consulted MHS before the attack, while most survivors did after the attack. In total, 93% of female survivors and 88% of male survivors consulted PCP in the three years before the attack, compared to respectively 98% and 96% in the three years after the attack. Moreover, 17% of female survivors and 11% of male survivors consulted MHS in the 3 years before the attack, compared to respectively 80% and 65% in the 3 years after the attack. From the year before to the year after the attack, the mean yearly consultation rates (CR) increased two-fold for PCP and nearly 8-fold for MHS in female survivors, and more than two-fold for PCP and nearly 12-fold for MHS in male survivors. Both before and after the attack, the consultations rates for PCP and MHS were higher for female than male survivors. The levels of posttraumatic stress, depression and anxiety symptoms and somatic symptoms were also higher in female survivors both early and at long-term after the attack.

Conclusions:

Our study demonstrated that both PCP and MHS played important roles in providing healthcare for psychological problems in young survivors of terrorism in Norway. Potential implications for public health preparedness to mass trauma will be discussed in the presentation.

Abstract citation ID: ckac129.337
Mental health impact and mental health care among first responders following the Paris terror attacks in November 2015

Stéphanie Vandentorren

Y Motreff[1], P Pirard[1], C Vuillermoz[2], G Rabet[1], M Petitclerc[3], L Stene[4], T Baubet[2], S Vandentorren[1,2]

[3]Departement of Psychology, Université Paris, Paris, France
[4]NKVTS, Norwegian Centre for Violence and Traumatic Stress Studies, Oslo, Norway
Contact: stephanie.vandentorren@santepubliquefrance.fr

Introduction:

During the evening of 13 November 2015, a terror attack occurred in France in the Paris area. Overall, 130 people were killed, 643 were injured and several thousands were psychologically impacted. Thousands of first responders (FRs), including health professionals, firefighters, affiliated volunteers and police officers were mobilized that night and during the subsequent weeks. The aims of our study were to measure the psychological impact on FRs, and its associated factors 12 months after the 13 November 2015 terrorist attacks, as well as their engagement in mental health care and its associated factors.

Methods:

FRs who had intervened during the night and/or the aftermath of the terror attacks had the possibility of answering a web-based study 8-12 months after the attacks. They satisfied criterion A of the DSM 5 definition of Post Traumatic Stress Disorder (PTSD). PTSD and partial PTSD were measured using the PTSD checklist for DSM-5 (PCL-5) and depression with the hospital anxiety and depression (HAD) scale.

Results:

Overall, 663 FRs were included in the analysis. Prevalence of PTSD in our sample went from 3.4% among firefighters to 9.5% among police officers. Low educational level, social isolation, intervention on unsecured crime scenes and lack of training were associated with PTSD. Among FRs with PTSD, partial PTSD or depression, 38% sought mental health care. Mental health care engagement was associated with a history of mental health care, post-immediate support and the presence of PTSD, partial PTSD or depression.

Conclusions:

Our results highlight that improving access to mental health care for FRs after terror attacks is needed. Efforts should be made before and after potentially traumatic events to ensure mental health education for FRs. Special attention should be given to FRs living in social isolation, those with low educational levels and those who intervene in unsecured crime scenes.

Gender and occupational differences in post-terrorist mental health outcomes among emergency responders with and without crisis intervention

Ulrich Wesemann

U Wesemann[1], M Mahnke[1,2], S Polk[3], A Bühler[1], G Willmund[1]
[1]Department of Psychiatry, Psychotherapy, Bundeswehr Hospital, Berlin, Germany
[2]Fire Department Berlin, Berlin, Germany
[3]Max Planck Institute for Human Development, Berlin, Germany
Contact: uw@ptzbw.org

Introduction:

After the Berlin terrorist attack at Breitscheidplatz, the gender-specific evaluation of emergency responders (ER) revealed higher perceived levels of paranoid ideation among females. The occupation-specific evaluation revealed higher hostility among police officers and a lower quality of life among firefighters. The aim of this study was to examine the outcome of crisis intervention (CI) provided for ER deployed to this terrorist attack.

Methods:

In total, N = 55 ER were included (n = 37 with and n = 18 w/o CI). Stress, quality of life, post-traumatic stress disorder, and current psychological stress were assessed 4 months after the attack.

Results:

ER with and w/o CI were compared. Participants with CI showed lower quality of life in psychological health ($t(53) = 2.01$, $p = .050$) and higher depressive symptomatology ($t(44) = 2.51$, $p = .016$). Females with CI showed lower quality of life in social relationships ($t(12) = 2.46$, $p = .030$), whereas males showed more posttraumatic stress symptoms ($t(39) = .32$, $p = .026$). Emergency responders from NGOs with CI had higher phobic anxiety ($t(9.2) = 2.72$, $p = .023$). Emergency medical technicians with CI showed more somatic ($t(7.5) = 2.52$, $p = .037$) and depressive ($t(8) = 2.30$, $p = .050$) symptoms.

Conclusions:

This study provides evidence for differences in the mental health burden for ER with and w/o CI, in general and for subgroups of gender and occupation. There is no conclusive explanation for why ER with CI score worse on certain measures. It is possible that CI had a harmful influence due to the reinforcement of negative emotions in some parts of measures like the Critical Incident Stress Debriefing (CISD). While it is known that ERs are vulnerable to develop mental problems, and appropriate and timely help is recommended, it is important to critical evaluate the methods used and to take also into account the identified gender and occupational differences. Further research is needed to better understand the interaction of risk factors.

Background:

Interpretive Front-of-Pack Labels (FoPLs) are supported by WHO as a key policy tool to promote healthy diets. At present, various FoPLs formats co-exist in the European Union (EU). However, as part of the Farm to Fork strategy, the European Commission stated it would adopt a single mandatory FoPL in 2022. The aim of this study was to analyze Spanish consumers reactions to Nutri-Score and NutrInform, two FoPLs that are currently the subject of debate in EU, testing preference through subjective understanding and perception but also performance through objective understanding of the FoPLs.

Methods:

The experimental study was conducted in 2021 on a representative sample of 1026 Spanish adults (50% women, mean age±SD = 46±14 years), through an online randomized questionnaire where participants were exposed to Nutri-Score or NutrInform. Performance of and preference for these two FoPLs were assessed in three food categories (Breakfast Products, Breakfast Cereals and Added Fats). Performance was tested using multivariate logistic regression while preference using principal component analysis and t-tests.

Results:

In terms of objective understanding, Nutri-Score was significantly associated with an increase in consumers' ability to identify healthier food products across all food categories compared to NutrInform (OR = 19.1 [14.2-25.7], $p < 0.0001$). On the preference dimension, Nutri-Score was perceived as significantly easier to use and was more liked than NutrInform (standardized PCA dimension resp. 0.32±1.58 vs. -0.29±1.66, $p < 0.0001$ and 0.080±1.18 vs. -0.072±1.17, $p = 0.039$) and participants found Nutri-Score more helpful to discriminate the nutritional quality of Breakfast Products and Breakfast Cereals (resp. 1.32±1.00 vs. 1.14±1.02, $p < 0.01$ and 1.33±1.00 vs. 1.00±1.03, $p < 0.0001$).

Conclusions:

Results of this study provide new evidence to support Nutri-Score in comparison with the NutrInform battery, on both performance and preference aspects.

Key messages:

- Nutri-Score better helps participants identify healthier food products than NutrInform.
- European Commission should consider results of this study in its decision on a harmonized Front-of-Pack Label.

Abstract citation ID: ckac129.340
Impact of Sugar-Sweetened Beverage Taxation Scenarios in Germany: A Comparative Modelling Study

Karl Emmert-Fees

KMF Emmert-Fees[1,2], A Felea[1], C Kypridemos[3], P Scarborough[4], M Laxy[1,2]
[1]Institute of Health Economics and Health Care, Helmholtz Zentrum München, Neuherberg, Germany
[2]Department of Sport and Health Sciences, Technical University of Munich, Munich, Germany
[3]Department of Public Health, Policy and Systems, University of Liverpool, Liverpool, UK
[4]Nuffield Department of Population Health, University of Oxford, Oxford, UK
Contact: karl.emmert-fees@helmholtz-muenchen.de

Objectives:

Taxing sugar-sweetened beverages (SSBs) is recommended to reduce the burden of obesity, cardiovascular disease (CVD) and type 2 diabetes (T2DM). The objective of this study was to quantify the potential long-term health and economic impact of different SSBs taxation scenarios in Germany using simulation models with different granularity.

Methods:

We used a multi-state life table Markov cohort (MSLT) and a microsimulation (IMPACT) model to simulate the impact of different SSB taxation assumptions and scenarios on CVD and T2DM in the German population aged 20 years and older over 20 years. Data sources included official population counts, anthropometric and dietary intake data from national surveys and published meta-analyses. Change in beverage consumption by sex and age under different taxation scenarios was estimated using de-novo national price elasticities and changes in body weight were based on an energy equilibrium model. We projected incremental disability-adjusted life years (DALYs) and healthcare costs, comparing results between both models.

Results:

Preliminary results from the MSLT model show that a 20% SSB excise tax in Germany could lead to moderate body weight reductions across all age-sex groups. Over 20 years, the tax would reduce healthcare costs by €753 million [95% CI: 527; 1,021] and save 24,380 DALYs [18,460; 33,900] from T2DM alone. Health and economic gains largely depend on the relevance of substitution effects, tax amount and taxed beverage categories. Results including CVD and comparisons with the IMPACT model are work-in-progress.

Conclusions:

We show that SSBs taxation in Germany has the potential to reduce healthcare costs and improve population health. The impact of any SSB tax depends on its implementation scenario, which behavioural assumptions hold, and the obesity-related disease outcomes considered for its evaluation. Further research should compare various obesity prevention approaches to support health policy priority setting.

Key messages:

- Taxation of sugar-sweetened beverages can reduce healthcare costs and improve population health in Germany.
- The estimated health and economic impact of sugar-sweetened beverage taxation critically depends on tax design and behavioural modelling assumptions.

Abstract citation ID: ckac129.341
How much of the unemployment effect on mental health is due to income? Mediation analysis in UK data

Rachel Thomson

RM Thomson[1], D Kopasker[1], A Leyland[1], A Pearce[1], SV Katikireddi[1]
[1]MRC/CSO Social and Public Health Sciences Unit, Glasgow, UK
Contact: rachel.thomson@glasgow.ac.uk

Background:

Employment and income are important determinants of mental health (MH), but the extent to which unemployment effects are mediated by reduced income is unclear. We estimated the total effect (TE) of unemployment on MH and the controlled direct effect (CDE) not acting via income.

Methods:

We studied adults 25-64y from nine waves of the representative UK Household Longitudinal Study (n = 45,497/ obs = 202,297). Unemployment was defined as not being in paid employment; common mental disorder (CMD) was defined as a General Health Questionnaire-12 score $\geq$4. We conducted causal mediation analysis using inverse probability of treatment weights to estimate odds ratios (OR) and absolute differences for the effects of unemployment on CMD as measured in the same sweep, before (TE) and after (CDE) blocking the income pathway. The percentage mediated by income was 100*(TE-CDE)/TE, with standard errors calculated via bootstrapping. Multiple imputation addressed missingness.

Results:

The TE of unemployment on short-term CMD risk was OR: 1.66 (95% CI 1.57-1.76), with 7.09% (6.21-7.97) absolute difference in prevalence; equivalent CDEs were OR 1.55 (1.46-1.66) and 6.08% (5.13-7.03). Income mediated 14.22% (8.04-20.40) of the TE. Percentage mediation was higher for job losses (15.10% [6.81-23.39]) than job gains (8.77% [0.36-17.19]). Mediation by income was lowest for those aged 25-40y (7.99% [-2.57, 18.51]) and those in poverty (2.63% [-2.22, 7.49]).

Conclusions:

In the UK, a high proportion of the short-term effect of unemployment on MH is not explained by income, particularly for those who are younger or already living in poverty. Population attributable fractions suggested 16.5% of CMD burden was due to unemployment, with 13.9% directly attributable to job loss rather than resultant income changes. Further research is needed across different European countries to determine how different welfare regimes might moderate these effects, and to investigate longer-term effects.

Key messages:

- Unemployment has a clear detrimental effect on MH in the short-term.
- Only a small proportion of this effect appears to be mediated by income.

Abstract citation ID: ckac129.342
Do regional characteristics predict developmental delay? Analyses of German school entry examination

Stephanie Hoffmann

S Hoffmann[1], M Tschorn[2,3], N Michalski[4], J Hoebel[4], BR Förstner[3], MA Rapp[2,3], J Spallek[1,2]
[1]Department of Public Health, Brandenburg University of Technology CB-SFB, Senftenberg, Germany
[2]Faculty of Health Sciences Brandenburg, Research Area Services Research and e-Health, Potsdam, Germany
[3]Department of Sports and Health Sciences, Faculty of Human Science, University Potsdam, Potsdam, Germany
[4]Division of Social Determinants of Health, Robert Koch Institute, Berlin, Germany
Contact: stephanie.hoffmann@b-tu.de

Background:

Children's health and development are strongly linked to their living situation, including their family's socioeconomic position (SEP) and living region. However, research on the impact of the living region on children's development beyond family SEP is scarce. This study evaluated whether rurality and regional socioeconomic deprivation (DEP) are associated with children's development independently of family SEP.

Methods:

The study used population-based data of 5-6.5 years old children (n = 22,801) from mandatory school entry examinations (SEE) in the German federal state of Brandenburg, which were examined in 2018/2019. The SEE data have been linked with data on i. rurality that was defined by an inverted population density and ii. regional DEP that were provided by the German Index of Socioeconomic Deprivation. By binary multilevel models, the predictive values of rurality and regional DEP for global developmental delay (GDD) were evaluated, while adjusting for family SEP.

Results:

Children with high family SEP showed reduced odds for GDD compared to medium family SEP (female: OR = 4.26, CI95 = 3.14-5.79, male: OR = 3.46, CI95 = 2.83-4.22) and low family SEP (female: OR = 16.58, CI95 = 11.90-23.09, male: OR = 12.79, CI95 = 10.13-16.16). Regional DEP additionally predicted GDD, with higher odds for children from more deprived regions (female: OR = 1.35, CI95 = 1.13-1.62, male:

OR = 1.20, CI95 = 1.05-1.39). Rurality did not predict GDD beyond family SEP and regional DEP.

Conclusions:

In addition to family SEP, the regional DEP has an effect on children's developmental delay. Hence, Public Health should take into account regional socioeconomic conditions as determinant of health over the life course in addition to family SEP.

Key messages:

- Regional socioeconomic deprivation contributes to inequalities in children's development and health.
- Besides family SEP, regional socioeconomic circumstances are of particular interest to promote health over the life course.

5.Q. Oral presentations: Measuring the health of our population

Abstract citation ID: ckac129.343

Calculation of Purchasing Power Parities for Pharmaceutical Products via EURIPID database

Claudia Habl

C Habl[1], M Zuba[2]
[1]International Affairs & Consulting, Gesundheit Österreich GmbH - Austrian National Public Health Institute, Vienna, Austria
[2]Health Economics and Health System, Gesundheit Österreich GmbH - Austrian National Public Health Institute, Vienna, Austria
Contact: claudia.habl@goeg.at

Background:

Purchasing power parities (PPPs) are indicators of price level differences for all goods and services across countries. Their calculation follows the ÉKS method (https://ec.europa.eu/eurostat/cache/metadata/en/prc_ppp_esms.htm). Prices of pharmaceuticals are collected by national statistical offices using different methods, from asking prices in pharmacies to retrieving scanner data. The sample is limited to 150 top-selling medicines, which are not available in all countries. Consequently, the PLIs (price level indices) and PPPs derived are sometimes based on only 50 pharmaceuticals. In a cooperation between Eurostat and EURIPID the PPP calculation was alternatively done with the EURIPID database for 28 countries.

Methods:

The study compared the PLIs/PPPs derived from the E20-2 ''Furniture and health'' survey (aka CGS) with those from EURIPID for 2018-2020. The main challenge was to identify comparable products from the 224,448 products in EURIPID. For this we grouped those that shared the same 1) ATC, 2) active substance(s) & strength(s), 3) pack size group and 4) dosage form group (e.g., oromucosal) resulting in 157,186 distinctive products compared to 1,928 included in CGS. We used the Gross Retail price (GRP) as defined in the Eurostat PPP manual.

Results:

The ranking of PPPs was similar in both approaches, with Switzerland and Iceland in the lead and Poland and Hungary in the end. Only for some countries, e.g. the Netherlands deviations were identified. The Pearson correlation between the 2020 PLI for the Euripid subsample using the asterisk method with all products marked as representative and the CGS results was 0,946.

Conclusions:

Results from EURIPID show the same trend as the CGS. It is possible to replace the national data collection by a central source. This would reduce the data collection burden on the statistical offices and allows a closer monitoring of the evolution of pharmaceutical prices (bi-annual PPP publication instead of current 3-year interval)

Key messages:

- To monitor affordability of medicines for all citizens it is important to compare prices on a regular basis with a simple tool as e.g. some products prices differed by 1000-times across countries.
- The EURIPID database (www.euripid.eu) allows detailed analysis of pharmaceutical prices in Europe and is available for free to non-commerical researchers.

A novel plot for the early alert of epidemic growth using regional targets: the doubling plot

Fabrizio Carinci

F Carinci[1,2], G Veltro[1], L Rocchi[1], D Mipatrini[1,3], D Mantoan[1], G Siccardi[1]
[1]Information and Communication Technologies, Italian National Agency for Regional Health Services, Rome, Italy
[2]Department of Statistical Sciences, University of Bologna, Bologna, Italy
[3]General Directorate of Health Prevention, Ministry of Health, Rome, Italy
Contact: fabrizio.carinci@unibo.it

Background:

During the pandemic, restrictions set by the Italian Government were primarily based on the regional level of key parameters including hospitalization and incidence rates. We aimed to build a specific plot to monitor trends and trigger early alerts, with daily updates publicly available on a National Portal.

Methods:

A multidisciplinary team conceived and implemented a new composite plot, developing ad hoc R scripts on top of a specialised database, built in collaboration with the Ministry of Health. We calculated the doubling time Td as log(2)/log(1+r/100), where r is the daily change of target parameters and Td ranges between (0,+-infinity), and not determined for constant or missing values. We calculated Td daily, as either doubling (growth) or halving (decrease) time. To visualize trends, we assembled two different types of graphs: a bivariate plot showing the path of each point (Td, target parameter) over time, and a line plot of Td over time. The Y axis was inverted for doubling times, as lower Td indicate higher alert in this case. The two graphs were arranged in lines, using cutoffs for excessive high values for doubling times and low values for halving times. A third line was included to display trends of the target parameter over time.

Results:

The plot was successfully realized and published on the Portal for all regions in February 2021 (https://www.agenas.gov.it/covid19/web/index.php?r = english%2Fdoubling&q = ITA&t = 0). Since July 2021, we used the doubling plot to monitor the three main parameters adopted to set restrictions for Covid-19: a) occupancy rates in intensive care; b) occupancy rates in medical wards; c) weekly incidence rates. The plot highlighted growth trends and early alerts, particularly in the initial phases of growth.

Conclusions:
The doubling plot can provide useful information to trigger early responses for pandemic control in decentralised governance. R code is available open source from AGENAS for free use.

Key messages:

- The doubling plot was conceived and implemented on a National Portal to trigger early alerts of Covid-19 progression in Italian Regions and Autonomous Provinces.
- The plot could be rapidly adapted to legislative parameters and can be useful in different situations to monitor epidemic growth and support public health policies.

Abstract citation ID: ckac129.345
Network analysis of a COVID-19 outbreak in the west of Ireland in February 2021

Catherine Timoney

C Timoney[1], *B Smyth*[1]
[1]Department of Public Health, HSE West, Health Service Executive, Galway, Ireland
Contact: catherine.timoney1@hse.ie

Notification and contact tracing systems of COVID-19 hold a vast amount of information on transmission chains of the virus. It can be hard to gain an understanding of these due to the number of individuals involved. Network analysis can be used as a method of visualising these systems, gaining understanding of transmission chains and as a potential tool for monitoring outbreaks. It can link cases together and show how far reaching initial infections were. Here, a system developed in the programming language R links the Irish infectious disease notification system and contact tracing system together and creates a network representation of the result. The system finds any cases or close contacts linked in any manner to the known cases. The result is a network from the earliest found case to the latest found case or contact related to the outbreak. A large outbreak of COVID-19 occurred in the student population in the West of Ireland in February 2021 with 449 cases linked to it by the Department of Public Health at the time. Using the system, 192 further positive cases were found to be linked to the outbreak. A total of 1,431 individuals were linked in some manner to it with 68% in the 19-24 age group and less than 1% in the 65+ age group. This takes a matter of seconds to run and highlights clusters within the outbreak, the largest of which had 96 cases and 121 not detected close contacts. Visualising the transmission chains also showed that there were no other large clusters outside of the outbreak at the time. A system such as this can link cases to outbreaks not previously linked, dramatically reduce the time taken to link cases together and visualise transmission chains to gain a deeper understanding of what is happening. This automated system frees up resources to allow for deeper investigation into cases and situations of concern. It also has the potential to link outbreaks together and spot previously unnoticed situations of concern.

Key messages:

- Network analysis is beneficial for the monitoring of the spread of an infectious disease like COVID-19.
- Here, 192 cases were found to be linked to an outbreak that was thought to have 449 cases in it.

Abstract citation ID: ckac129.346
Measuring Health Insurance Literacy in the Netherlands – first results of the HILM-NL questionnaire

Laurens Holst

L Holst[1], *JJDJM Rademakers*[1,2], *AEM Brabers*[1], *JD de Jong*[1,2]
[1]Healthcare System and Governance, NIVEL, Utrecht, Netherlands
[2]CAPHRI, Maastricht University, Maastricht, Netherlands
Contact: l.holst@nivel.nl

Background:
Many Western countries have healthcare systems that expect their citizens to make critical, well-considered decisions about which health insurance policy best fits their needs and preferences. There are indications that citizens struggle to fulfil this role due to the complexity of the healthcare systems and lack of skills, support or motivation. This can lead to citizens being sub-optimally insured, suffering inadequate coverage and facing unexpected costs. To understand how citizens choose and use a policy, the health insurance literacy measure (HILM) was developed in the US. It seems valuable to investigate the concept of Health Insurance Literacy (HIL) in other countries. This study aims to examine how HIL is distributed among citizens in the Netherlands; and to find out whether certain groups have more difficulty choosing and using a health insurance policy.

Methods:
We measured HIL using the HILM-NL questionnaire, a validated and translated version of the HILM. In February 2020, the HILM-NL was sent to 1,500 members of the Nivel Dutch Health Care Consumer Panel. The response rate was 54% (n = 806). Higher HILM-NL scores imply a higher self-assessed ability in choosing and using health insurance.

Results:
There is a wide variation in HIL among citizens in the Netherlands. The average total HILM-NL score is 55.14 (ranging from 21-84). Lower-educated citizens ($p<.04$) and citizens with lower income ($p<.01$) are relatively more likely to have lower HIL, than, respectively, higher-educated citizens and citizens with higher income.

Conclusions:
Citizens who completed less education or earn a lower income are relatively more likely to have difficulty choosing and using a health insurance policy. It is important to support these vulnerable groups, so that Dutch citizens in general will be better able to choose a policy that fits their needs and preferences. This should ensure that citizens are less likely have to deal with inadequate coverage and unexpected costs.

Key messages:

- There is a wide variation in HIL among citizens in the Netherlands.
- Citizens who completed less education or earn a lower income are relatively more likely to have difficulty choosing and using a health insurance policy.

6.A. Workshop: Strategies to build up health system resilience: Legacy of the COVID-19 pandemic

Abstract citation ID: ckac129.347

Organised by: Finnish Institute for Health and Welfare, Tampere University, Trinity College Dublin, University of Copenhagen, EUPHA-HSR
Chair persons: Ilmo Keskimäki (Finland), Johan Hansen (EUPHA-HSR)
Contact: ilmo.keskimaki@thl.fi

Health systems are the central part of infrastructure in societies and their smooth operation is important for the continuation of a wide range of critical operations in any country. The COVID-19 pandemic has actualised questions on health system resilience defined as the system's ability to prepare for, manage (absorb, adapt and transform) and learn from external shocks.. However, economic recessions as well as long- and short-term stresses related to aging, climate change and migration, and most recently a war have underlined that also in Europe the governments need to prepare their health systems to face different types of threats in order to guarantee effective protection to population health in their countries. The importance of the task to strengthen health system resilience has been comprehended at national and international level. International actors including WHO, OECD and World Bank have designed policy advice on strengthening health systems against external shocks, the European Union has launched programmes for preparing for future health emergencies, and individual countries are designing policy and system reforms allowing for health crises. In the workshop we address policies to strengthen health system resilience drawing on the experiences in three countries: Ireland which entered the COVID-19 pandemic with a legacy of the recent economic crisis hitting hard health care financing, Finland which has been implementing a major health care reform concomitantly with the pandemic, and Denmark which offers a case study on organisational learning from the pandemic within the hospital sector and chronic patient care. Based on these three case studies the workshop also contemplates whether learning from shocks is always helpful in terms of system transformation or whether they can also create path dependencies that weaken the systems' ability to prepare for unknown threats. The workshop will broaden the view by discussing the trends of health system reforms in European countries and considering international advice on system and policy reforms to strengthen health system resilience.

Key messages:

- Shocks create opportunities for reform and better performance and challenges through overloaded systems and fast decision-making.
- Assuming all shocks are like the last weakens preparedness and adaptability.

Abstract citation ID: ckac129.348
Strategies for developing preparedness and building legacy – learning from the experience of building Health System Resilience in Ireland

Stephen Thomas

S Thomas[1], *P Fleming*[1], *C O'Donoghue*[1], *A Almirall-Sanchez*[1]
[1]School of Medicine, Trinity College Dublin, Dublin, Ireland
Contact: thomassd@tcd.ie

Health system resilience to shocks is perhaps the biggest global challenge facing health systems in the 21st Century. Health systems face an increasing prevalence and likelihood of a broad range of shocks (including economic crises, pandemics, climate-related events, political upheavals, mass migration, conflicts and cyberterrorism) that can each undermine the ability of a health system to function well. In particular, the twin processes of dealing with the legacy of a health system shock and preparing for the next shock are distinct but related challenges that face policy makers today. In this presentation the authors will present key findings on improving preparedness and building a constructive legacy drawing from:

- the results of a recent systematic review on how health system resilience has been measured in high income countries over the last twenty years;
- the results of a recent realist review exploring the legacy of the economic crisis for the resilience of the response of the health system to COVID-19, and
- analysis of interviews with Irish policy makers, managers and analysts as they reflect on the different shocks encountered by the Irish system over the last fourteen years.

Triangulating these findings, the authors will reflect on the merits and challenges of measuring resilience and what the focus should be moving forward. Key strategies and approaches will be outlined to best prepare a system for a shock and to leave a positive legacy for the future.

Abstract citation ID: ckac129.349
Lessons and long-term implications of the covid-19 response in Denmark from a resilience perspective

Karsten Vrangbæk

K Vrangbæk[1]
[1]Department of Public Health, University of Copenhagen, Copenhagen, Denmark
Contact: kv@ifs.ku.dk

The paper focuses on crisis responses and resilience within hospitals. The study is based on structured expert interviews with medical directors in selected hospital departments in two of the five regions of Denmark and primary care physicians in the same regions. We investigate stage 3 (Shock impact and management) and stage 4 (Recovery and learning) within hospital organizations using Denmark as case country, and we pay particular attention to issues of ''organisational learning'', ''purchasing flexibility and reallocation of funding'', ''distribution of human and physical resources'' and ''motivated and well-supported workforce''. Particular attention is paid to care for patients with chronic care needs and lessons for the long-term resilience building in the health system. The study highlights strategic choices and lessons for the long-term resilience within hospitals. It demonstrates, how the initial strategy of organizing specific COVID-19 response units was abandoned relatively early, as it appeared more efficient to integrate COVID-19 patients in the regular specialized department structure. Emergency wards experienced increasing pressure during the pandemic as primary care clinics were referring (too) many patients suspected of COVID-19. This raises questions about capacity and relations between primary and specialized care in crisis situations. Management of human resources is crucial. While the initial phases of the pandemic response were characterized by flexibility and ''team-spirit'', there has been a negative long-term impact particularly among the nursing staff, where burnouts and attrition are major issues. Pandemic crises place significant strain on health systems and personnel. This raises issues about communication of strategies and principles for organizing efforts. The Danish health system managed the crisis adequately, but there are also lessons that should be learned regarding long-term implications and preparedness for future crises.

Abstract citation ID: ckac129.350
From COVID-19 to Health System Reform: Qualitative Insights on Resilience and Lessons Learned from Finland

Liina-Kaisa Tynkkynen

L-K Tynkkynen[1,2], L Kihlström[2], I Keskimäki[1,2]
[1]Faculty of Social Sciences, Tampere University, Tampere, Finland
[2]Welfare State Research and Reform, Finnish Institute for Health and Welfare, Helsinki, Finland
Contact: liina-kaisa.tynkkynen@tuni.fi

The pressure of COVID-19 on health system functioning has made policies to strengthen health system resilience a major theme of research. Accordingly, crises like COVID-19 can be seen as windows of opportunity for health system reforms to enhance health system resilience. In Finland, COVID-19 arrived on the eve of a major health system reform. In 2023 running health and social services will be transferred from 309 municipalities to 22 counties. While the reform was framed before the pandemic, we explore how lessons from COVID-19 matter for the future reform. Our results come from interviews of 53 top managers and civil servants in the year one of COVID-19, representing municipalities, municipal healthcare authorities and state agencies. The results offer a lookout to how national and local healthcare leaders view pandemic responses in connection to the future reform. Finland fared well in the pandemic compared to many countries e.g. in terms of excess deaths. However, our results reveal a tension between major issues in managing COVID-19 and implementing the reform. While the data suggest that dealing with a prolonged crisis proved challenging due to lack of trust, communication, and transparency between national and subnational actors in the health system, the dominant lessons learned and needs for reform among the interviewees build upon obvious fixes, such as ensuring supply of PPEs and ICU beds for the next pandemic. While being important in preparedness, these can build a legacy not tackling the root causes of lacking resilience and can be inconsistent with reform goals. The pandemic provides an opportunity to analyse the reformed system from a new viewpoint and may reveal weaknesses not considered in reform planning. Reforms can impact health system resilience in positive and negative ways. While different shocks may open new avenues for system transformation, they can also create path dependencies weakening the systems' ability to prepare for unknown threats.

6.B. Round table: Insights from COVID-19: Preparing for and responding to the next health emergency

Abstract citation ID: ckac129.351

Organised by: Institute for Health Metrics and Evaluation, Division of Country health Policies and Systems, WHO Europe
Chair persons: Maja Pasovic (USA), Elizabeth Serieux (USA)
Contact: mpasovic@uw.edu

The COVID-19 pandemic has stretched national health care systems to its limits, underscoring the importance of advance planning for health emergencies and the role of health data and evidence for informed policy interventions and actionable strategies. The experience with the pandemic has demonstrated the constraints of existing health information systems and the negative impacts that the lack of actionable and timely data can have on the implementation of rapid response measures during emergencies. This workshop aims to assist participants to become better prepared to deal with future health threats, such as pandemics, by exploring the role of trust in pandemic preparedness and response, effective communication strategies during a pandemic, and the use of qualitative research for evaluation of pandemic response. The specific objectives are to share and discuss: (a) results and conclusions derived from an online qualitative survey of experiences and lessons learned by member states across the WHO European Region; b) results and conclusions derived from an IHME study exploring the factors that contribute to / predict pandemic preparedness, and (c) lessons learned in the process of developing and disseminating scientifically valid, timely evidence across the globe, to assist policymaking during a pandemic. Together, these topics present and explore what countries and populations can do to effectively mitigate the negative effects of a pandemic or other health emergencies. These strategies and lessons learned include building trust, communicating clearly and succinctly, and using qualitative methods and data to evaluate pandemic response. Collectively, these are all geared at improving the capacity to address such threats and unexpected emergencies in the future. The panelists will also reflect on successful tools and strategies developed to aid policymakers and country governments in their response to the COVID-19 emergency. The workshop will be in the form of a 60-minute round table discussion with three panelists. Each panelist will make a brief presentation on their specific area of research, followed by a discussion between the panel members and audience.

Key messages:

- Trust, transparent communication, and reliable and timely data are critical aspects of both pandemic preparedness and response.
- The importance of qualitative evaluation for exploring what worked during the pandemic and what innovations should become part of an enhanced health information system in the future is essential.

6.C. The revised EU health security framework

Abstract citation ID: ckac129.352
Organised by: DG SANTE and ECDC
Chair persons: Isabel de la Mata (European Commission - DG Sante)
Contact: David.GORRIA-CARDESA@ec.europa.eu

As a response to the pandemic, the Commission's communication of 11 November 2020 proposed building blocks for a European Health Union (EHU) and advocated the strengthening of existing structures and mechanisms for better EU level protection, prevention, preparedness and response against human health hazards. It recommended a reinforced framework for cross-border cooperation against all health threats to protect better human lives and the internal market as well as to maintain the highest standards in the protection of human rights and civil liberties, and a strengthened EU role in international cooperation to prevent and control cross-border health threats and improve global health security. By upgrading the EU health security framework for cross-border health threats, the building blocks of the European Health Union bring greater overall impact while fully respecting the Member States' competence in the area of health. Concretely, before the end of 2022, two pieces of legislation will have been adopted: the upgrading of Decision 1082/2013/EU and the strengthened mandate of the European Centre for Disease Prevention and Control (ECDC) and the European Medicines Agency (EMA) that go hand in hand. The new Regulation on serious cross-border threats to health, the overarching legislative piece of the EU Health Union Package, aims at a stronger and more comprehensive legal framework for the Union to better prepare and respond to serious cross-border threats to health and public health emergencies. It better governs actions at Member States and Union level on prevention, preparedness and response, surveillance, risk assessment, and early warning. Further, it ensures better arrangements for joint procurement at EU level. With its revised mandate, the ECDC will be able to issue recommendations to Member States regarding preparedness and response, host a new network of EU reference laboratories and establish an EU Health Task Force for crisis preparedness and rapid public health interventions in case of a major outbreak. The regulation reinforcing EMA's role in crisis preparedness and management of medicinal products and medical devices puts some of the structures and processes established during the COVID-19 pandemic on a permanent footing. EMA is now responsible for monitoring medicine shortages, as well as reporting shortages of critical medicines during a crisis. It will also coordinate responses of EU / EEA countries to shortages of critical medical devices and in-vitro diagnostics in crises. The EU Health Security Framework will link up to IHR (where EU is requesting to become a contracting party) and the pandemic treaty, and the parallel developments to improve pandemic preparedness and response in G7 and G20 framework (also new global health strategy). The revised legislation addresses the weaknesses evidenced by the COVID-19 pandemic and support actions that can be financed via the EU4Health programme and other EU funding instruments. DG SANTE and ECDC will present the new legislation; two Member States will share their views on the newly adopted legislation. HaDEA will present the funding opportunities through EU4Health to support the implementation of th
e two new legislation.

6.D. Workshop: Strengthening awareness of obesity in Europe: from knowledge to action

Abstract citation ID: ckac129.353
Organised by: EUPHA-FN, EUPHA-CHR, WHO Europe
Chair persons: Iveta Nagyova (EUPHA), Licia Iacoviello (Italy)
Contact: giuseppe.grosso@unict.it

The obesity rates in Europe are constantly growing with a substantial input from the market towards unhealthy food products, a general carelessness or lack of knowledge of the general population, and a major drive of modern societies towards an obesogenic environment. With about half of European people having weight problems, strengthening the resources across institutions, scientific associations, and governmental bodies is highly warranted to try to counteract this major public health issue, which seems to have played a pejorative role over the last 2 years regarding the health risks related to the COVID-19 pandemic. Emerging evidence provides a more complex and multifaced understanding of obesity that it should be considered a disease far beyond the simple concept of excess of body weight, while characterized by a constellation of related comorbidities connecting chronic conditions. Excess body weight is considered a risk factor for cardio-metabolic diseases and certain cancers, but investigating the issue with a more holistic approach would add to this context also the psychosocial burden and a broader involvement of the immune system and inflammatory processes potentially responsible for most obesity-related chronic diseases. Scientific research is also investigating the role of diet-related nutritional and non-nutritional risk factors that may play a role in obesity and its health consequences, also in the context of European countries and the resulting differences depending on the traditional dietary patterns adopted. Moreover, current studies are exploring how dietary choices impact the environment aiming to a reform and a rethinking of the food systems, of citizen/customer preferences, and ultimately of dietary habits to invert the controversial long-term projections that put at risk the global environmental sustainability. The EUPHA Food and Nutrition Section, the Chronic Diseases Section, in collaboration with the World Health Organization (WHO), aim to propose a joint workshop to promote the current knowledge from the latest research on obesity and related chronic conditions, including an objective and more complex biological and societal examination of this public health problem, with a focus on diet-related risk factors and an analysis of how dietary choices may impact the environment. The workshop will have its focus on the presentation of the new WHO European Regional Obesity

Report accompanied with ground-breaking new research in the field. The experts will aim to provide new perspectives on a well-known public health issue, discussing about current strategies to tackle the obesity pandemic and possible scenarios for the near future.

Key messages:

- Obesity should be considered as a disease, not limited to excess body weight but investigated in a more complex context of comorbidities.
- Current research should also approach the study of obesity with a more holistic approach, including dietary factors and environmental impacts.

Abstract citation ID: ckac129.354
Key messages of the WHO European Regional Obesity Report

Kremlin Wickramasinghek

Obesity is a complex multifactorial disease defined by excessive adiposity and is linked to an increased risk for many noncommunicable diseases (NCDs). Overweight and obesity affect almost 60% of adults and nearly one in three children in the WHO European Region. Recent estimates suggest that overweight and obesity is the fourth most common risk factor for NCDs in the Region, after high blood pressure, dietary risks and tobacco. It is also the leading risk factor for disability and obesity is linked to greater morbidity and mortality from COVID-19. And obesity is considered a cause of at least 13 different types of cancer including cancers of the breast, colorectum, kidney, liver and ovary, multiple myeloma and meningioma. None of the countries in the Region are on track to achieve the obesity related target set in 2013. Early studies from a number of countries in the Region indicate that the prevalence of overweight and obesity and/or mean body mass index has increased in children and adolescents during the COVID-19 pandemic. This latest WHO European report on obesity examines the growing challenge and impact of obesity in the Region, building on past publications and aligning with initiatives to tackle cancer. The report focuses on managing obesity throughout the life course and tackling obesogenic environments; it also considers more recent challenges, including problematic digital marketing to children and the impact of the COVID-19 pandemic on obesity prevalence. Policy options to prevent obesity are outlined for consideration by Member States together with a suite of population-level approaches. The report highlights the importance of including prevention and control of obesity within measures to build back better in the wake of the COVID-19 pandemic. Whilst highlighting that single intervention will not be sufficient in any country, it examines the challenges faced by countries to implement known interventions to tackle obesity.

Obesity, body weight stigma and biomedical oversimplification: moving beyond BMI

Saverio Stranges

S Stranges[1]
[1]Department of Epidemiology and Biostatistics, Western University, London, Canada
Contact: saverio.stranges@uwo.ca

Body Mass Index (BMI) is one of the most important factors considered to analyse health status. High BMI scores are usually associated with physical or mental disorders, such as cardiovascular disease, diabetes, inflammation, dyslipidemia and depression. However, obesity is usually characterised by the presence of various comorbidities that should be addressed as part of a unique, more complicated picture. Emerging evidence suggests that a deeper acknowledgment of the complexity of obesity as disease, including its comorbidities, should take place in the near future. Overweight, obesity and related disorders have been associated with direct healthcare-related costs and the indirect costs of productivity loss, mostly due to the presence of comorbidities rather than to body weight in general. The belief that weight loss is the best recommendation for people with high BMI as the only path to health could be questioned. In fact, it would seem that weight loss in some subjects does not necessarily coincide with any health improvement. Thus, the relationship between weight status and health expenditure is complex with particular reference to the fact that costs of disease are higher in high-comorbid profiles independently of weight status. Over the last years, researchers have also studied some conditions, such as metabolically healthy overweight and obesity. Recent studies deal with alternatives to conventional weight-loss approaches that could be more effective in health terms. Conventional methods of weight loss are based on calorie restriction and increased energy expenditure instead of unconventional methods, such as the weight-neutral program, which is based on the crucial concept of ‘‘mindfulness’’ to underline the importance of intuitive eating, self-care, pleasurable exercise and size-acceptance. The health benefits related to such types of approaches include physical, psychological and behavioural improvements.

Nutritional and non-nutritional dietary factors affecting obesity and chronic related disorders

Giuseppe Grosso

G Grosso[1], M Bonaccio[2]

[2]Department of Epidemiology and Prevention, IRCCS Neuromed, Pozzilli, Italy
Contact: giuseppe.grosso@unict.it

There is convincing evidence that diet quality represents one of the most important public health targets to prevent non-communicable diseases. Dietary risks alone have been estimated to be responsible for about 10 million deaths due to cardiovascular diseases, metabolic disorders, and certain cancers worldwide, with trends not expected to decrease. Results from meta-reviews and expert assessments are quite in line with robust key messages to deliver to the general public. From a nutritional point of view, lack of fibre, vitamins and antioxidants, and unsaturated fatty acids together with high content in free added sugars, sodium, and saturated/trans fats represent key features for unhealthy dietary patterns and are responsible for most diet-related non-communicable diseases. While the role of animal-derived foods is still controversial due to the registered excess consumption and the environmental impact, a general low intake of plant-derived foods remains a major detrimental factor for health. The concept of diet quality should thus overcome the over simplistic calorie-count when coming to prevent obesity and related non-communicable diseases, while an adequate communication on this matter to the public is highly warrant. Together with these general dietary recommendations relying on nutritional aspects affecting human health, emerging evidence is now also exploring the role of non-nutritional dietary factors. The level of processing, the alteration of the food matrix, the presence of additives (such as flavor enhancers, colorants, emulsifiers, artificial sweeteners, thickeners, foaming/anti-foaming agents, and preservatives) have been demonstrated to play a role in metabolic health and inflammatory-related disorders. These aspects are currently under investigation, but they might represent an underrated concern for public health due to the food market drive and a perfect fit into the obesogenic modern society.

New frontiers in risk assessments related to diets, health and the environment

Marco Springmann

M Springmann[1]
[1]Nuffield Department of Population Health, University of Oxford, Oxford, UK
Contact: marco.springmann@ndph.ox.ac.uk

Based on the sustainable development goals agenda, public health experts should approach the study of planetary diets, environment, and health with a holistic approach that includes both human and planetary health. Modelling studies help in estimating priorities while attaining differences across countries. Future scenarios vary according to priorities to be set. When aiming only at fulfilling food-security objectives, studies suggest that reductions in premature mortality have few environmental co-benefits. In contrast, modelling studies that include environmental goals indicate the potential for reducing environmental impacts while improving diet quality and overall health outcomes, especially in high-income countries. The scenarios indicate that focusing on dietary changes towards healthy and balanced dietary pattern seems an ideal strategy to improve both mortality risk and the environmental impact, although the magnitude of the effects may vary across countries. Weight and dietary risk factors have traditionally been considered separate categories. A new approach can be proposed for attributing weight-related risks to food intake at global, regional, and national levels. When comparing current consumption patterns to diets that for each country minimise diet and weight-related risks, a total of 5 million weight-related deaths in 2019 were attributed to the overconsumption of refined grains, dairy, red and processed meat, sugar, and eggs, and to the underconsumption of oils, and legumes, among others. A large share of deaths attributable to high intake of animal source foods and imbalanced grain intake occurred in countries with the higher high human development index, while more than a third due to imbalanced sugar and oil intake occurred in medium ones. Attributing weight-related risks to food intake can inform food-based interventions for reducing the burden of preventable deaths associated with imbalanced weight levels.

6.E. Skills building seminar: 'Think global, act local'- using the Place Standard tool to support action on climate and health

Abstract citation ID: ckac129.358

Organised by: EUPHA-HIA, EUPHA-ENV
Chair persons: Odile Mekel (EUPHA-HIA), Peter Van Den Hazel (EUPHA-ENV)
Contact: patricia.tollmann@bzga.de

The global determinants of health act on our physical, social, and economic environments or ''places'', which impact on population health, wellbeing and inequalities. Climate change poses an increasing threat to health and equity. So tackling the consequences of the climate emergency is one of the most serious issues facing our places and it will lead to a transformation of people's lives. Good place-making is essential for designing a robust response to the climate emergency at a local level, such as taking local action to cut emissions (mitigation) and to increase resilience to local climate change impacts (adaptation). A place-based approach to addressing climate has the potential to deliver co-benefits to drive fair and just solutions that also support health, wellbeing, and equality. The Scottish Place Standard Tool (PST) is an effective and widely used tool originally created in a collaborative partnership between Public Health Scotland, Scottish Government, Architecture & Design Scotland, and Glasgow City Council for assessing a place, with a focus on health and wellbeing. As it syntheses complex evidence into 14 easily understood questions to develop a shared understanding of what matters in a place, it has proved to be an effective tool to facilitate a place-based approach, in which local communities, local government and third sector can work together to deliver improvements. Today it is used widely in Scotland, its application internationally has extended across 14 countries in Europe and worldwide it has been translated into at least 16 different languages. Whilst climate has been strengthened in the core content of the tool, both Scotland and Germany have recognised the need of additional support to really focus on climate issues and have embarked on separate simultaneous projects to enhance PST's ability to do so. The workshop aims to introduce the PST with a climate lens and share the different approaches from Scotland and Germany.

The objectives of the workshop are to:

- Provide a brief overview of the connection between climate, place, health and health equity.
- Introduce and compare recent work in Scotland and Germany, which both aim to build on the success of the original PST to strengthen climate considerations in the design and delivery of healthy and equitable places.
- Enable participants, through sharing learning from real-life examples gathered during piloting of the new PST climate resources, to consider how they might practically engage with climate and health through a place-based approach.

This will be achieved through an introduction to the key principles behind the PST, and presentations from Scotland and Germany on their respective approaches to strengthening the potential of the PST to address climate, health and equity, plus practical case study examples of climate action supported by the PST. Time will be provided at the end for practical involvement of the participants and for discussion.

Key messages:

- The climate emergency is one of the biggest challenges facing public health. The Place Standard Tool addresses the need to include climate change and health issues within a discussion about a place.
- Adding a ''climate lens'' to the Place Standard Tool offers the potential to maximise co-benefits to drive fair & just solutions that support health, wellbeing, & equality.

[5]Sustainable Scotland Network, Edinburgh, UK
Contact: kat.hasler@gov.scot

Since the launch of the Place Standard tool (PST) in Scotland in 2015 awareness has increased of the critical impact of the climate emergency on health and equity. A 2019 review of the PST, informed by emerging evidence and community and stakeholder feedback, confirmed the need to strengthen its contribution towards place-based climate action. This was partly achieved by integrating enhanced prompts within the PST itself, however with the increased focus of policy and action around climate adaptation and mitigation a knowledge and resource gap remained. So in 2020 PST partners* began work with experts from environmental organisations (Sniffer, Sustainable Scotland Network) and other partners to develop a ''Place Standard with a climate lens'' (PST CL). The PST CL toolkit was created through an iterative process integrating feedback from 10 pilot projects chosen to represent the varied communities, scales, landscapes and placemaking projects being undertaken across Scotland. It provides a suite of materials to use alongside existing PST resources to help placemaking conversations consider how climate change might play out in a local area. This ensures that local responses to climate change are designed holistically, delivered collaboratively, and helps achieve on other local priorities such as health, wellbeing and equity. This presentation will provide a brief overview of the project background, describe the Scottish PST with a climate lens, share case study examples from the piloting phases, and enable exploration of the learning from Scotland around the value of integrating health and climate in place-based approaches. While the Place Standard tool was not originally designed as a climate change tool, it is an effective method to support the design of local responses to the climate emergency. A ''climate lens'' can help us to plan the future of our places to maximise the health benefits and minimise the negative consequences of a changing climate.

Creating a German ''StadtRaumMonitor'' with a climate lens - The approach and design of the piloting

Patricia Tollmann

P Tollmann[1], O Mekel[2], M Mensing[2], T Claßen[2], T Sammet[3], R Boos[3], H Köckler[4], C Plantz[1]
[1]Department Q1, Federal Centre for Health Education, Köln, Germany
[2]NRW Centre for Health, Bochum, Germany
[3]Ministry of Social Affairs, Health and Integration, Stuttgart, Germany
[4]Department of Community Health, University of Applied Sciences, Bochum, Germany
Contact: Patricia.Tollmann@bzga.de

Based on the Scottish Place Standard tool (PST), the Federal Centre for Health Education (BZgA) adapted and piloted a German version called 'StadtRaumMonitor' from 2019-2021 as part of a Joint Action 'Health Equity Europe' (JAHEE) funded by the EU Commission. The 'StadtRaumMonitor' was developed in cooperation with the NRW Centre for Health Nordrhein-Westfalen and the Ministry of Social Affairs, Health and Integration Baden-Württemberg under the leadership of BZgA and with scientific support from the University of Applied Sciences in Bochum. Based on the piloting and the findings of the accompanying scientific research, some adjustments were made to the PST and the website was relaunched offering extended functionality to users. Building on the successes of the 'StadtRaumMonitor', a follow-up project started in 2021: Recognising the health impacts of climate change and the need to include climate change issues when assessing the quality of places, the BZgA started a pilot project with the same project partners to adapt the tool to the context of climate change. The ''StadtRaumMonitor'' with a climate lens aims to address municipal climate adaptation for health promotion. The tool is inspired by the Scottish PST with a climate lens and was developed based on a systematic literature research, focus groups with experts and with actors in municipalities, as well as in participative cooperation with municipal stakeholders. After pre-test and subsequent adjustments, the tool is currently being piloted in four German municipalities, and an evaluation of the application of the tool is taking place. This part of the workshop aims to provide an example of the approach to the further development of an existing tool, here within the context of municipal climate adaptation and on the basis of the ''StadtRaumMonitor'', and thereby build competencies in this field. Furthermore, early insights into the piloting of the German PST with a climate lens will be given.

6.F. Skills building seminar: Digital health and communication

Abstract citation ID: ckac129.361

Organised by: EUPHA-DH
Chair persons: Stefan Buttigieg (EUPHA-DH), Anthony Staines (Ireland)
Contact: anthony.staines@dcu.ie

Information has always been central to public health practice. As digital health develops it becomes increasingly central to health care delivery, health system management, and population health monitoring. Despite enormous investment, and great effort in collecting these data, much of the potential value of health care information is lost because of poor data architecture. Good design and interoperability are sometimes seen as obstacles to implementation. but in fact they are key to getting value out of health data systems. Tools and ideas developed over the last thirty years by bioinformaticians may be quite unfamiliar to public health practitioners. The intention of this seminar is to introduce some of these ideas, specifically syntactic and semantic interoperability, ontologies, and terminologies, and to show, using case studies, how these may fit into public health practice.

Key messages:

- It is necessary to have an excellent data architecture to get a good return on investment in healthcare ICT systems.
- Standards are key to interoperability, be that syntactic or semantic.

Abstract citation ID: ckac129.362
Case based approach to the application of standards and Interoperability in practice

Pamela Hussey

P Hussey[1], *S Das*[1]
[1]Centre for eIntegrated Care, Dublin City University, Dublin, Ireland
Contact: pamela.hussey@dcu.ie

Digital infrastructure and connectivity is layered and requires a number of defined viewpoints in order for safe data flow and use to occur. To address context specific challenges to support communication in health and social care, health informatics standards supporting interoperability are key. In this skills building seminar we will introduce participants to a standards based roadmap for interoperability. We will provide examples of projects and resources detailing the process of engagement to optimise system design for sustainability through a use case based approach.

Abstract citation ID: ckac129.363
How ontology can be used to achieve semantic interoperability in healthcare

Subhashis Das

S Das[1], *P Hussey*[1]
[1]Centre for eIntegrated Care, Dublin City University, Dublin, Ireland
Contact: subhashis.das@dcu.ie

Semantic interoperability allows machines to share, interpret and use data without ambiguity. Semantic Interoperability is a major concern in healthcare (c.f. the EU commission 2021 report on electronic record exchange formats). The lack of interoperability with regard to electronic health record (EHR) leads to fragmentation and a lower quality of cross-institution and cross-border healthcare. The simple choice of an interchange language (HL7, FIHR etc.)is not sufficient to ensure interoperability. Healthcare interoperability is associated with multi-level and multi-sectoral complexity, and this cannot be addressed without consideration of a range of people and needs, from application design to knowledge sharing. Each transaction needs to be defined in unambiguous details as part of a complete, consistent, coherent, and machine-readable set of specifications for interoperability between the machines to minimize any potential error. We propose a systematic process to achieve healthcare interoperability, working with healthcare professionals starting from design level to implementation level. In our seminar we will explain with examples how ontology can be used to achieve semantic interoperability in healthcare. Technical requirements, including the choice of tools (e.g. Protégé); data base (e.g. GraphDB); data model (i.e. Web Ontology Language 2 (OWL2); formal specification (i.e. Description logics (DL)); and the right syntax (RDF/XML). Will be introduced.

Abstract citation ID: ckac129.364
Terminologies matter - the case of ICNP and SNOMED-CT

Anthony Staines

A Staines[1], *P Hussey*[1], *S Das*[1]
[1]Centre for eIntegrated Care, Dublin City University, Dublin, Ireland
Contact: anthony.staines@dcu.ie

Terminologies can seem very abstract to end-users. While most health professionals will be familiar with some terminologies (for example MeSH (Medical Subject Headings), the controlled vocabulary thesaurus used for indexing articles for PubMed or ICD-10, WHO's terminology for disease coding), fewer will be aware of the depth and range of terminologies used in healthcare, nor of the central importance of multilingual standard terminologies in health care interoperability. Following a brief introduction to the use of terminologies, the integration of the International Classification for Nursing Practice (ICNP) the Systematized Nomenclature of Medicine - Clinical Terms (SNOMED CT) will be presented, as an example of the use of terminologies, and their ongoing curation, maintenance and development.

6.G. Workshop: The European Health Data Space 2: is Europe ready to maximise the re-use of health data?

Abstract citation ID: ckac129.365

Organised by: Sciensano (Belgium), Belgian Federal Public Health Institute Towards the European Health Data Space, PHIRI
Chair persons: Irini Kesisoglou (Belgium)
Contact: irene.kesisoglou@sciensano.be

The EU's Heads of State called in October 2020 to set up a European Health Data Space (EHDS): "The European Council welcomes the creation of common European data spaces in strategic sectors, and in particular invites the Commission to give priority to the health data space". As a response, multiple initiatives were set-up to engage the views and expectations from EU member states in the development of the upcoming legislative proposal on the EHDS for primary (EHDS1) and secondary use of health data (EHDS2). One of these was the launch of the Joint Action (JA) Towards the European Health Data Space (TEHDAS) in February 2021. The aim of TEHDAS is to support the European Commission (EC) and Member States (MS), identifying the challenges and providing concepts and options for the EHDS2. It is built on the needs and expectations of national and international stakeholders, citizens' engagement and existing infrastructure. The major expected outcome of this JA is a sustainable roadmap towards the EHDS2 implementation promoting the cross-border sharing of health data for secondary use. The EHDS2 will benefit population health by facilitating the timely exchange of and access to health data, improving not only the care of patients but also facilitating research, epidemiology, disease prevention and data-based policy decisions. This workshop aims to provide an overview of the preparedness of MS to join the EHDS for secondary use of health data, covering current state-of-play of health data management systems in the EU, barriers on the secondary use of health data, the ongoing work on the development and deployment of the EHDS2 infrastructure and finally, how population health research can benefit from the EHDS2. The workshop will begin with a short introduction on the TEHDAS JA, followed by a presentation on the outcomes of the TEHDAS country visits. In these country visits, the state-of-play of the health data management system and the preparedness to join the EHDS2 were mapped in 12 different EU MS. The next presentation will continue with the results from a study that collected more evidence on the barriers to cross-border sharing of health data for secondary use and options on how to overcome these. It will focus on the legal preparedness and barriers and will discuss how the options proposed by experts in the field align with the legislative proposal for the EHDS2. The audience will be able to give their opinion on the different options through an interactive voting poll during the session. Some of the options on how to overcome technical barriers will be taken further in the development of a pilot infrastructure for the EHDS2. Therefore, the last two presentations will focus on the development and deployment of this pilot infrastructure for the EHDS2 and the role and benefits that population health research will have in it. Throughout the workshop there will be discussion sessions between presentations to allow exchange of knowledge, experiences and opinions with the audience.

Key messages:

- The main outputs will support EU countries to prepare their health data management system for the EHDS2 based on the best practices and actions presented.
- The presentations will inform and align participants on the current work on the technical EHDS infrastructure that is being developed for secondary use of health data, the EHDS2.

Abstract citation ID: ckac129.366
Results from the TEHDAS country visits: State-of-play of 12 EU member states in relation to the EHDS2

Linda Abboud

L Abboud[1], *S Cosgrove*[1], *I Kesisoglou*[1], *P Bogaert*[1]
[1]EU Health Information Systems, Sciensano, Brussels, Belgium
Contact: Linda.Abboud@sciensano.be

Successfully launching a sustainable EHDS requires a clear understanding of the current situation in Member States, taking into account the existing diversity. With this in mind, country visits are being carried out in a group of 12 countries: Denmark, Belgium, Hungary, Netherlands, Estonia, Ireland, Portugal, Finland, Czech Republic, Slovenia, Sweden, Germany. The aim of the country visits is to map the state-of-play of health data management in different countries and explore their preparedness to join the EHDS. The topics explored include: the health data sources available, the health data infrastructure (storage, access and interoperability), data quality assurance mechanisms, data governance, as well as resource and training needs and opportunities. Another aim of the country visits is to explore needs and expectations at national level, and how the EHDS can respond to them. This presentation will include an overview of the health data management systems of the 12 countries mapped, providing a snapshot of the situation across Europe. It will then present the findings on their preparedness to join the EHDS. Preparedness takes into account a variety of factors, including political will, as well as legal and technical factors. The presentation will further share the lessons learnt and best practices highlighted from the country visits. Finally, based on these findings, the presentation will close with an overarching view on the preparedness across Europe to deploy the EHDS for the secondary use of health data, EHDS2, as well as planned actions that would facilitate the implementation of the EHDS2 in different member states.

Abstract citation ID: ckac129.367
Barriers on cross-border sharing of health data for secondary use and options to overcome these

Rosie Richards

R Richards[1]
[1]European Digital and Research Policy, NHS Confederation, Brussels, Belgium
Contact: Rosie.Richards@nhsconfed.org

Cross-border health data sharing is essential to facilitate vital health research into new treatments and to improve patient care and safety across Europe. The flagship European Health Data Space (EHDS) aims to promote better exchange and access to health data through the creation of a European-wide infrastructure. However, significant barriers to cross-border data sharing must first be resolved in order to fully ensure the successful functioning of the Data Space. To this end, the European Commission established a Joint Action (TEHDAS), as the policy development tool for the development of the EHDS. This presentation will be based around the findings of the recent TEHDAS report ‘Barriers to cross-border sharing of health data for secondary use and options to overcome them.’ The report draws on the results of a dedicated literature review, 133 case studies from across 23 countries and expert interviews to identify the primary barriers to cross-border data sharing and options to overcome these from the perspective of European data users (research and policymakers). The session will start with a concise presentation of the report methodology. The research team will then deliver an interactive presentation, in which they succinctly outline each barrier and policy option and ask participants to vote for their preferred policy option to overcome each barrier identified. EUPHA participants votes will inform the final TEHDAS recommendations on mitigations and solutions for barriers to cross-border data sharing which will be submitted to the European Commission for incorporation in the European Health Data Space legislative proposal.

EHDS2 pilot infrastructure for the secondary use of health data

Camille Cloitre

E Bacry[1], *M Jendrossek*[1]
[1]Health Data Hub, Paris, France
Contact: amille.cloitre@health-data-hub.fr

The EHDS2 Pilot consortium brings together 16 European partners (national platforms, research infrastructures, EU agencies and associations in the area of health) to respond to the EC’s call for projects to set up a test version of the future European Health Data Space (EHDS) for the secondary use of health data (EHDS2). It aims to build this pilot version of EHDS2 by interconnecting data platforms in a network of nodes, implementing and testing a first user journey for creating, deploying and running health data research projects at EU level. The network will investigate the technical tools and set up the standards allowing researchers to query the metadata of all nodes, to request selected data via a single application form and to analyze data across national nodes. To build this network, the EHDS2 Pilot will propose legal and technical frameworks based on use cases selected by the EC. These will also serve to illustrate the powerful impact of exploiting health data from several countries and address topics from population health to healthcare pathways, cancer, rare diseases and genomics. This presentation will give an overview of the planned activities by the coordinating team.

Abstract citation ID: ckac129.369
The role of PHIRI in the EHDS2

Enrique Bernal-Delgado

E Bernal-Delgado[1], *J Gonzalez-Garcia*[1], *P Derycke*[2], *N Schutte*[2], *P Bogaert*[2], *M Saso*[2]
[1]Data Science for Health Services and Policy Research, Institute for Health Sciences, IACS, Zaragoza, Spain
[2]EU Health Information Systems, Sciensano, Brussels, Belgium
Contact: ebernal.iacs@aragon.es

The Population Health Information Research Infrastructure (PHIRI) is setting the foundations for the design, implementation and deployment of a fully operative European research infrastructure on population health research in the next few years. In a nutshell, this effort represents setting up the principles and instruments for the governance of the reuse of data for research purposes in a number of aspects - the legal and ethical foundations for the mobilization of data, including sensitive data; how the different nodes in the infrastructure organize to respond multiple research questions in a federated manner; how to ensure high standards of data quality and data interoperability; and, how technological solutions can preserve a safe use of the data while enabling sound scientific outputs. PHIRI has been challenged to provide real-life solutions to each of these aspects. Acting as a demonstration project, PHIRI is currently providing solutions to researchers that are trying to solve their research questions. Building on this experience, in the future, PHIRI is expected to provide support and services to population health researchers that build their research on the secondary use of health data. Among those services: data discovery; data harmonization services (e.g., discovery and use of common data models and interoperability standards); technological services (e.g., playgrounds with synthetic data, secure process environments); research outputs archival (e.g., maintenance and dissemination of the knowledge base generated in the infrastructure); and, training and capacity building. Interestingly, PHIRI can be seen as a primer for the upcoming European Health Data Space for secondary use (EHDS2). In this workshop will be discussing how to line up PHIRI's vision and role within the EHDS2.

6.H. Workshop: Towards improved performance measurement and universal health coverage in oral health care

Abstract citation ID: ckac129.370

Organised by: European Observatory on Health Systems and Policies, Technische Universität Berlin, Radboud University, New York University
Chair persons: Ewout van Ginneken (Germany), Dimitra Panteli (Belgium)
Contact: juliane.winkelmann@tu-berlin.de

Oral diseases are increasingly recognized as one of the most prevalent conditions in Europe, affecting nearly half of the European population. They are the third most expensive diseases to treat in the EU and dental expenditures are set to rise substantially. Within EU countries, oral health policy and financing are most often separated from the general health system and vary considerably between countries with different public and private organisation structures providing oral health services, different levels of out-of-pocket payments for patients and a variety of financing models. Oral diseases are a main driver of unmet need and financial hardship in the EU and particularly affect poorer and marginalized groups. However, current provider payment systems prioritize expensive invasive and technology-based methods which drives public expenditure while disserving the healthcare system's central objective of better health outcomes and reducing waste. Moreover, broad and effective oral health promotion policy that spans various care settings and areas of life is not sufficiently implemented. Oral health care systems thus face complex challenges regarding efficiency, quality and integration of care which requires good evidence to steer oral health policy. However, current health information systems only collect few indicators on oral health and oral health care. There is thus need for an improved evidence base for more meaningful assessments and comparisons of oral health systems performance which would allow better informed policy decisions and enable more targeted and effective oral health interventions. In May 2021 the World Health Assembly approved an historic resolution on oral health which urges Member States to include oral health in universal health coverage (UHC) benefit packages and to shift from the traditional curative approach towards a preventive approach. Oral health and the urgent needs for improving the financing of oral health systems have thereby received increased policy attention also in Europe. In this workshop evidence from a cross-country comparison of oral health financing, access and provision in Europe will be presented and the lack of supportive information systems for oral health system performance assessment will be highlighted. Recent research activities will be discussed such as the Horizon Europe project DELIVER (DELiberative ImproVEment of oRal care quality) which aims to create a synergistic problem-solving ecosystem to improve oral health systems. Debates in oral health research and policy in Europe are influenced by global developments such as the WHO resolution. To this end, the recent call for urgent system reform and policy action to address the burden of oral diseases will be set in context and discussed.

Key messages:

- Oral care systems are still dominated by a traditional curative and technology-driven approach which fail to sufficiently encourage prevention and support holistic and integrated oral health care.
- Lack of harmonized data reporting on oral health and oral health system indicators impedes oral care systems performance monitoring and evidence-informed policy-making.

Global public health must end the neglect of oral health

Habib Benzian

H Benzian[1], S Loistl[2]
[1]College of Dentistry, New York University, New York, USA
[2]Radboud Institute for Health Science, Radboud University, Nijmegen, Netherlands
Contact: habib.benzian@nyu.edu

Oral diseases are among the most common health problems and constitute major public health challenges across countries and health systems worldwide. The main diseases dental caries, severe periodontal disease, oral cancer and toothlessness affect populations everywhere and show significant social gradients - poor, disadvantaged, rural, or otherwise vulnerable groups suffer from a much higher burden, while at the same time having more difficulties to access prevention and care. Similarly, low- and middle-income countries have the highest prevalence of oral diseases while their healthcare systems are ill-equipped to address the challenges. Due to the predominant clinical care model of dentistry that favours an interventionist approach requiring costly technology provided by a dentist, many health systems and large population segments are not able to afford even basic oral health care. Moreover, oral health has been largely absent from the global health arena for the last 20 years leading to faltering political priority and attention. This has changed recently with the convergence of several initiatives of global relevance, supported by advocacy of the wider oral health community. Following the first ever paper series on oral health in The Lancet, a Lancet Commission on Oral Health was established in 2019, which sparked a group of WHO member states to embark on a remarkable policy development process dedicated to oral health. We now have a Global Strategy for Oral Health and will soon have a Global Action Plan complemented by a comprehensive Monitoring Framework. In addition, work on defining Best Buys in Oral Health and other supportive workstreams are under way. The presentation will provide an introduction and overview to these global policy guidance frameworks that are shaping a new reform agenda for oral health as part of NCDs, Universal Health Coverage and the SDGs towards 2030. Particular implications for public oral health in Europe will be discussed.

Contact: juliane.winkelmann@tu-berlin.de

With growing awareness of the large burden of oral diseases and how limited coverage affects both access and affordability, oral health policy has been receiving increased attention in recent years. This culminated in the adoption of the WHO resolution on Oral Health in 2021, which urges Member States to better integrate oral health into their universal health coverage and noncommunicable disease agendas. This study investigates major patterns and developments in oral health status, financing, coverage, access, and service provision of oral health care in 31 European countries. While most countries cover oral health care for vulnerable population groups, the level of statutory coverage varies widely across Europe resulting in different coverage and financing schemes for the adult population. On average, one third of dental care spending is borne by public sources and the remaining part is paid out-of-pocket or by voluntary health insurance. This has important ramifications for financial protection and access to care, leaving many dental problems untreated. Overall, unmet needs for dental care are higher than for other types of care and particularly affect low-income groups. Dental care is undergoing various structural changes. The number of dentists is increasing, and the composition of the health workforce is starting to change in many countries. Dental care is increasingly provided in group practices and by practices that are part of private equity firms. Although there are early signs of a shift towards more prevention of oral diseases, dental care overall remains focused on treatment. A lack of data affects all areas of oral health care and impede to inform policy-making on the underlying causes and the prevalence of oral disease, as well as the effectiveness of community preventive activities and oral health services.

Horizon Europe: the DELIVER (DELiberative ImproVEment of oRal care quality) project

Paula Vassallo

P Vassallo[1,2]
[1]Radboud Institute for Health Science, Radboud University, Nijmegen, Netherlands
[2]Poliklinik für Zahnerhaltungskunde, Heidelberg University Hospital, Heidelberg, Germany
Contact: paulavassallo@gmail.com

Oral diseases and conditions affect more than 3.5 billion people worldwide. They are the 3rd most expensive diseases to treat in the EU and disproportionally affect vulnerable groups. In deviation from the UN and WHO goal of Universal Health Coverage, many EU citizens do not have access to quality oral care without financial hardship. To this end, the DELIVER (DELiberative ImproVEment of oRal care quality) project aims to enhance the quality of oral care through deliberative dialogue and action involving citizens, patients, providers, payers and policymakers. DELIVER will create a synergistic problem-solving ecosystem to convert deliberative dialogues into meaningful improvement of oral care quality. Using a mixed-methods research approach, DELIVER will co-develop and co-produce new quality improvement approaches in three phases. The 1st phase involves situational analysis, consenting of core quality indicators, and development of a EU-wide monitoring framework. The 2nd phase involves in-depth analysis of select quality improvement approaches: (i) PROMs/PREMs-based quality improvement in dental practices; (ii) community-based quality improvement for vulnerable groups; (iii) quality-oriented commissioning of oral health services. The regulatory determinants of oral care quality improvement will be scrutinized. In the 3rd and final phase, the knowledge gained in the 1st and 2nd phases will be merged into the DELIVER Quality Toolkit with manuals and digital tools for concretely actionable and context-adaptive approaches for oral care quality improvement. This presentation will give an overview of the DELIVER project and discuss how it can contribute to improving oral health systems.

6.J. Workshop: Precarious employment and its impact on social protections in the EU

Abstract citation ID: ckac129.374

Organised by: EUPHA-SSWH
Chair persons: Ute Bültmann (EUPHA-SSWH), Agnes Meershoek (Netherlands)
Contact: u.bultmann@umcg.nl

The changing nature of work, resulting from technology, globalization, shifts in demographics, and other economic and political forces, poses many potential problems for workers, employers, and society today and for the foreseeable future. Moreover, the COVID-19 pandemic has revealed the importance of social protection systems, e.g. income security for injured or sick-listed workers. The pace of work is increasing, driven by increasing productivity demands and greater use of technology. The nature of employer-employee relationships is also changing rapidly, best exemplified by increases in what has been termed ‘‘nonstandard employment arrangements’’, such as gig economy work and short-term contracts. However, what is viewed as greater employment flexibility by employers may represent a more precarious job for workers, as compared to pay, benefits and security for those with long-term employment arrangements. Nonstandard employment is typically shorter in duration, leading to more jobs over a lifetime, with the potential for exposure to multiple and simultaneous risks, some of them new, combined with the possibility of more time spent in periods of unemployment or underemployment. Precarious employment has been linked to adverse effects on worker health and well-being. Although these employment arrangements can affect workers of all education and income levels, they disproportionately affect workers in lower socioeconomic strata. One of the major consequences of nonstandard employment arrangements is the potential loss of social protections, including social security, yet this has not been well addressed. Our workshop focuses on the changing work life across different EU member states and beyond, examining different types of precarious employment and their effects on health and social security benefits.

Prof. Ellen MacEachen will focus on how laws, policies and collective agreements in six EU countries, New Zealand and Canada protect the health of low wage and digital platform workers. She will address occupational and public health interventions for these workers in light of health risks related to the COVID-19 pandemic.

Dr. Solveig Osborg Ose will focus on precarious work, sickness absence and risk sharing between employers, employees and social insurance in nine north-western EU countries. Moreover, she will discuss the adaptation of social protection systems to cover all types of employment to avoid increasing inequalities.

Two experts Dr. Anita Tisch and Prof. Angelique de Rijk will reflect on the findings and discuss with the presenters and the audience the challenges, policies and practices needed towards employment and occupational safety and health social protections of precarious workers.

Key messages:

- Precarious employment has been linked to adverse effects on worker health and well-being. Workers in lower socio-economic strata are disproportionately affected.
- A major consequences of nonstandard employment arrangements is the potential loss of social protections, including social security, yet this has to be addressed.

Abstract citation ID: ckac129.375
Health protection policies for digital platform and low wage workers

Ellen MacEachen

E MacEachen[1]
[1]School of Public Health Sciences, University of Waterloo, Waterloo, Canada
Contact: ellen.maceachen@uwaterloo.ca

Background:

In the context of the COVID-19 pandemic, shifting employment and occupational health social protections of low-wage and self-employed digital platform workers are described and compared. Specifically, we examine how, across advanced economy countries, laws, policies, and collective agreements protected the health of low wage (e.g., service workers) and digital platform workers (usually classified as self-employed) including during the first three waves (2019-2021) of the COVID-19 pandemic. The overall goal is to inspire conversation, comment, critique and new research questions to tackle the issue of the employment, work and health of low wage workers and self-employed digital platform workers.

Methods:

Taking a comparative focus on eight advanced economy countries, this paper identifies legal efforts to address employment misclassification and challenges related to employee definitions that vary by the legal act. Debates about minimum wage and occupational health and safety standards as these relate to worker well being are considered. Finally, we discuss promising changes introduced during the COVID-19 pandemic that protect the health of low-wage and self-employed workers.

Results:

Overall, we describe an ongoing ‘‘haves’’ and a ‘‘haves not’’ divide, with on the one extreme, traditional job arrangements with good work-and-health social protections and, on the other extreme, low-wage and self-employed digital platform workers who are mostly left out of schemes. However, during the pandemic small and often temporary gains occurred and are discussed.

Conclusions:

In the context of an evolving social contract during the COVID-19 pandemic, this paper provides views on avenues for policy reform and research from employment and occupational health specialists across eight advanced economy countries.

Abstract citation ID: ckac129.376
Precarious work, sickness absence and risk sharing between employers, employees and social insurance

Solveig Ose

S Ose[1]
[1]SINTEF Digital, Health Research, SINTEF, Trondheim, Norway
Contact: solveig.ose@sintef.no

Background:

The COVID-19 pandemic has revealed the importance of social protection systems including income security when health problems arise. Particularly the protection of those with precarious work felt short in some countries. For some time there has been an interest in the European variation in sick-pay schemes but still we still lack knowledge on country differences and similarities. This is particularly the case regarding precarious workers, while they have higher chances for sickness absence. Our aim is to understand, in the context of precarious work, the differences in risk sharing of sickness absence between employer, worker and social insurance.

Methods:

Data had been collected in a study on sickness absence follow-up regimes in nine countries (the Nordic countries (Sweden, Denmark, Finland, Norway and Iceland) and in Germany, the Netherlands, Belgium and the UK). Comparative statistics were collected and scholars familiar with their countries system were invited to answer a list of 51 questions on system characteristics. Data were re-analysed from the perspective of precarious work, using actor-network theory and insider-outsider theory of employment.

Results:

Countries with shorter employer periods of sick pay have stricter follow-up responsibility for employers as they are regarded gatekeeper except for The Netherlands. The tax-based systems that target all citizens offer more protection for precarious workers while the employee-focused systems define their target population more strictly, leaving precarious workers underserved. There is a large difference in how self-employed are supported or not.

Conclusions:

Despite small economic differences in the nine countries studied, the systems for dealing with sickness absence in the context of precarious work vary largely. Even though, in all systems those with secure jobs seem insiders and those with precarious work outsiders. Social protection systems should be updated to avoid an increasing inequality.

6.K. Workshop: Health Literacy in Health Care Settings in Europe: Practice experience, challenges and future needs

Abstract citation ID: ckac129.377

Organised by: Fulda University of Applied Sciences (Germany)
Chair persons: Katharina Rathmann (Germany)

Contact: katharina.rathmann@pg.hs-fulda.de

Health care organizations (e.g., hospitals, nursing homes, facilities for people with disparities) are increasingly required to create health literate structures and processes, to train staff in such a way that they make it easier for their users to behave in a health literate manner, to deal competently with health information and to navigate competently through facilities and the entire health care system. This approach is known as the concept of organizational health literacy (OHL). Meanwhile, different standards (fields of action) of organizational health literacy and assessment tools to measure health literacy on an organizational level are available, which address, among other issues, health literacy as part of the quality management system, the development of health-related information by involving users, or to facilitate navigation within and to health care facilities and through the health care system. In order to assess and to strengthen OHL in health care settings, an increasing number of projects in Europe and internationally conduct needs assessments and interventions to implement tools to strengthen OHL at the patient-/client-, staff- and organizational-level. The assessment and implementation is accompanied by different requirements, challenges and needs at different levels (i.e. clients, staff, management).

Thus, the workshop emphasizes the following objectives:

1. to present findings from OHL projects in European countries (Austria, Belgium, Germany, the Netherlands, Switzerland).
2. to present and to discuss methodological issues (e.g., needs assessment),
3. to highlight practical experiences when implementing measures to strengthen OHL, and
4. to discuss beneficial factors, challenges and helpful approaches (e.g., participatory or co-creation setups) for the implementation of OHL.

A total of five experts on the topic of 'health literacy in health care settings' will present and discuss the implementation of health literacy in health care settings in Central European countries.

Key messages:

- The Workshop highlights a synthesis of challenges and future needs that are evident for organizations and users at different levels (management, staff, clients).
- Beneficial factors are a supporting management and leadership staff, participatory approaches, communication tools, training staff in health literacy skills as well as clients/patients.

Abstract citation ID: ckac129.378
The Vienna self-assessment questionnaire for hospitals: Three explorative case studies in Belgium

Gilles Henrard

G Henrard[1], *J Rademakers*[1,2]
[1]Département de Médecine Générale, Université Liege, Liege, Belgium
[2]Hoofd Onderzoeksafdeling Nivel, Maastricht University, Maastricht, Netherlands
Contact: gilles.henrard@uliege.be

Background:

One way to develop adequate health literacy responsive policy and strategies in hospitals is the use of self-assessment tools to raise awareness, help prioritize action and mobilize stakeholders. In this study we have piloted the French version of the Vienna Health Literate Organisation (V-HLO-fr) tool in three hospitals to explore its feasibility.

Methods:

We performed explorative case studies in the three main hospitals of Liège (Belgium). Our mode of application of the V-HLO-fr was inspired by the 'RAND Appropriateness' method: first, individual members of an internal multidisciplinary panel filled out the questionnaire and then the results were discussed collectively in each hospital during a 'round table' meeting. The feasibility of the process was assessed by direct observation of the round tables and with semi-structured phone interviews

Results:

The V-HLO-fr tool was fully applied in the three targeted hospitals and the process seems to be acceptable, practicable and integrable. Its mode of application, formalized by taking inspiration from the RAND method, could be further improved, e.g. by paying more attention to recruiting and supporting participants. Strengths (e.g. the facilitation of patient navigation to the hospital) and weaknesses (e.g. the provision of easy to read, understand and act on health information materials) in terms of health literacy responsiveness have been highlighted.

Conclusions:

V-HLO-fr could be a suitable tool to create awareness and formulate targeted actions to further strengthen hospitals health literacy responsiveness.

Those explorative case studies give:

– an overall positive signal about the feasibility of the V-HLO-fr

– useful feedback to further formalize and refine its procedure of application.

Abstract citation ID: ckac129.379
Health literate settings in Austria

Lisa Gugglberger

L Gugglberger[1]
[1]Austrian National Public Health Institute, Gesundheit Österreich GmbH, Vienna, Austria
Contact: Lisa.Gugglberger@goeg.at

Issue/problem:

Health literacy (HL) depends largely on how easy or difficult it is in a given situation to find, understand, evaluate and apply health-related information. HL is thus an interplay between personal skills and organisational requirements.

Description of the problem:

In 2018 the Austrian platform for HL initiated the focal point 'organisational framework conditions for strengthening health literacy'. Since then the needs of organisations are being assessed regularly and several strategies and initiatives have been launched to support organisational HL.

Results:

To support organisations and settings with the implementation of HL a ''starter kit'' consisting of a general practical guide and several settings specific self-assessment tools (SAT) has been developed. SAT currently exist for hospitals, primary care units, businesses, open youth work, schools and municipalities. For the settings of primary care units as well as open youth work certification processes have been developed, based on the SAT, distribution of high-quality health information and proof of communication trainings. Currently tools for general practitioners are being developed.

Lessons:

Experiences from workshops and pilot testing have shown that organisations need a variety of different tools and measures to help with the implementation of HL. Any type of support needs to be flexible and customisable to different needs and have a low threshold. What is needed most - apart from financial incentives - are settings-based workshops and personal consultation to raise awareness of what health literate organisations can achieve.

Main messages: Settings and organisations are important to increase HL in the population. Several settings in Austria have started to implement HL and are at different implementation statuses.

Abstract citation ID: ckac129.380
A multi-component health literacy intervention addressing needs of kidney patients and professionals

Marco Boonstra

M Boonstra[1], SA Reijneveld[1], R Westerhuis[2], JM Tullius[1], JPM Vervoort[1], G Navis[2], AF de Winter[1]
[1]Department of Health Sciences, University Medical Centre Groningen, Groningen, Netherlands
[2]Department of Nephrology, University Medical Centre Groningen, Groningen, Netherlands
Contact: m.d.boonstra@umcg.nl

Background:

Limited health literacy (LHL) is associated with faster kidney deterioration. To maintain kidney function, health care professionals (HCPs) promote self-management. However, in chronic kidney disease (CKD) care organizations, patients with LHL report multiple communication and self-management barriers. The need for health literacy responsive organizations, and multi-component interventions targeted at patients and HCPs, is recognized. We aimed to determine the objectives and strategies of such an intervention, and to co-create and evaluate it.

Methods:

First, we performed a longitudinal qualitative study among CKD patients with LHL (n = 24) and HCPs (n = 37) from general practices and nephrology clinics to assess needs and barriers, and to identify promising intervention objectives. Second, we included patients (n = 19), HCPs (n = 15), educators (n = 3) and students (n = 4) in an Intervention Mapping (IM) process to co-create and evaluate the intervention.

Results:

Grip on Your Kidneys (GoYK) addresses the competences of patients with LHL to self-manage CKD on the long-term, and the communication competences of patients and HCPs. Based upon patients' preferences, GoYK encompasses a visually attractive website and brochures to optimize self-management and a card to contribute to consultations. With HCPs, we developed a training to optimize their competences to support patients with LHL. Evaluation revealed the intervention was useful, comprehensive and fitting needs.

Conclusions:

Mapping the needs of CKD patients and HCPs, combined with a process of intervention co-creation, resulted in a multi-component, positively evaluated intervention. Implementation of this type of interventions in organizations is promising to improve care for patients with LHL. However, the effectiveness of these interventions requires further assessment.

Abstract citation ID: ckac129.381
Strengthening the Swiss health system by improving organizational health literacy: a practice-approach

Saskia De Gani

S De Gani[1], AS Bilgeri[1]
[1]Careum Center for Health Literacy, Careum Foundation, Zuerich, Switzerland
Contact: Saskia.Degani@careum.ch

Issue:

Healthcare organizations represent vital points of contact and disseminators for people to find, understand, assess, and apply health information, and may thereby strengthen people's health literacy (HL). From a system perspective, healthcare organizations provide essential practices and structures to foster population health beyond their medical-based services.

Description of the problem:

Despite increasing research on the promising role of organizational health literacy (OHL) the current Swiss healthcare system provides insufficient support for healthcare organizations to address HL. In response, the Careum Foundation in Zurich recently launched a Center for Health Literacy to promote OHL - among other HL initiatives. A first step was a practice-oriented collaboration project with the Department of Health of the canton of Zurich, which started in 2019 to assess, implement, and improve HL in primary care organizations. Therefore, a self-assessment tool for OHL is being developed, implemented, and evaluated. In addition, the center started to shed light on HL in Switzerland, on HL and necessary competencies of health professionals. Moreover, it is investing in communication and expertise on OHL, and developing first ideas regarding health literate hospitals.

Results:

A first systematic evaluation of the self-assessment tool has demonstrated a significant potential to improve OHL, organizational development, and teambuilding processes in healthcare organizations. Connected through (inter)national networks, the Center for Health Literacy launches a practice approach to understand OHL as both medium and outcome of a health literate population.

Lessons:

We have learned that practice-oriented OHL initiatives can provide promising approaches to strengthen both population health and organizational development processes.

Abstract citation ID: ckac129.382
Organizational health literacy in health care: Results from a participatory project in Germany

Katharina Rathmann

K Rathmann[1,2], LD Salewski[1,2], LV Zelfl[1,2]
[1]Department of Health Sciences, Fulda University of Applied Sciences, Fulda, Germany
[2]Public Health Centre Fulda, Fulda University of Applied Sciences, Fulda, Germany
Contact: katharina.rathmann@pg.hs-fulda.de

Background:

Health care facilities (i.e., hospitals, care facilities and integration assistance) play an important role in providing health-related information and strengthening health literacy (HL) of patients/clients, staff and at the organizational level. The project ''Development of Health Literacy in Health Care Facilities (EwiKo)' aims at implementing tools to promote and strengthen organizational health literacy (OHL) in health care institutions in Germany. Objectives are 1) to assess needs for strengthening OHL in pilot facilities and 2) to examine factors that are beneficial to strengthen OHL in health care facilities.

Methods:

N = 6 pilot institutions (n = 2 hospitals, n = 2 care homes for elderly people, n = 2 facilities for people with disabilities) and their members of the ''working groups on HL'' filled in a self-assessment tool to assess the level of OHL, accompanied by focus group interviews (n = 6-9 persons per pilot facility). Regarding conducive and obstructive factors when implementing tools to strengthen OHL, focus group interviews (n = 6-9 persons per pilot facility) and semi-structured interviews (n = 1 coordinator per organization) were conducted.

Results:

Results of the self-assessment tool showed a need to strengthen OHL in all types of health care facilities, particularly in the fields of action 'training of employees in HL tools', ''communication'' and 'participatory development and testing of documents, materials and services on HL'. Results of the focus group interviews showed a special need to strengthen OHL in the area 'HL of employees'. Beneficial factors by implementing tools to strengthen OHL are, for instance a supporting management, resources, a participatory approach and trainings by the project team.

Conclusions:

Due to the ongoing corona pandemic and accompanying challenges (e.g., personnel resources), it is comprehensible that health care facilities emphasize a need for strengthening HL of employees.

6.L. Round table: Digitally literate health workforce for a resilient future

Abstract citation ID: ckac129.383

Organised by: Young Forum Gastein, EUPHAnxt
Chair persons: Matthias Wismar (European Observatory)
Contact: yfg@ehfg.org

Currently, health systems worldwide are experiencing an unprecedented challenge after the shock caused by the COVID-19 pandemic. However, there lies an opportunity for renewal to strengthen health systems. The importance of collaboration becomes imperative in times of health workforce (HWF) shortages and demanding working conditions. This workshop, organised in partnership by the Young Forum Gastein and EUPHAnxt, will focus on connecting generations to explore, discover and share best practices for HWF education and (re)training in digital skills to deliver better patient care. The COVID-19 pandemic has accelerated digitalisation across many sectors including healthcare. Yet it has also served to highlight the digital divide, which has the potential to hinder health experts in providing optimal care. Concurrently, the demanding working conditions of the HWF can be improved by making use of digital tools. It is high time to discuss how digital literacy can be improved across a multigenerational HWF and how to empower the next generation of healthcare leaders to re-imagine health services. The workshop will bring different perspectives to the table - policy-making, science & academia, and governance - on the approaches for better intergenerational collaboration by making use of digital literacy. At the end of the session, participants will understand the realistic potential of digital literacy and how it can be used to ensure effective communication across the HWF, support the resilience of health systems, and ultimately, safeguarding patient care.

Key messages:

- Digital literacy is not a stable level of knowledge - the health workforce needs opportunities to advance their knowledge and (digital) skills.
- Acknowledging the shortages in health workforce planning, it is essential to ensure adequate skills of the health workforce personnel.

Speakers/Panellists:
Natasha Azzopardi Muscat

6.M. Workshop: Models of care in prison: addressing infectious diseases during and after the pandemic in EU/EEA

Abstract citation ID: ckac129.384

Organised by: EMCDDA, WHO, UNIPI, EUPHA-PHPP, EUPHA-IDC
Chair persons: Sara Mazzilli (Italy), Sofia Ribeiro (EUPHA-PHPP)
Contact: sara.mazzill@gmail.com

According to the latest data, in 2019 about 497,000 people were held in prison on any given day in the EU. However, the number of people who pass through European prisons each year is considerably higher. Due to infrastructural and population characteristics, individuals in contact with the criminal justice system face multiple and complex health care issues, including a higher prevalence of communicable diseases than the general population, and severe clinical outcomes when infected. The high turnover of people coming from the most disadvantaged segments of the population, together with the daily inflow/outflow of prison staff and facilities characterized by overcrowding, poor ventilation increase the risk of air-borne virus outbreaks. People living in prison are substantially more likely to experience drug-related problems than their peers in the community. Incarceration is associated with increases in blood-borne diseases-related risk behaviour among people who inject drugs. People living in prisons, because of the scarcity or lack of availability of needles, syringes and condoms, often share injecting equipment, tattooing and shaving materials, and practice unprotected sex. Individuals in contact with the criminal justice system often come from marginalized groups of society with a higher burden of poverty and discrimination, and with limited access to healthcare. Despite tailored preventive interventions should be implemented among vulnerable groups at the community level. Prisons can represent a point of access to integrated prison-community healthcare and social services. Delivering health protection and harm reduction programmes in prisons not only benefits the prison population but also has the potential to reduce the risk of transmission of some infectious diseases in the community, intervening earlier in the natural history of disease. The WHO has long supported the concept of prison health as an inseparable component of public health. However, a number of challenges hampers the successful implementation of such a concept, including the need for evidence-based decision making, inter-sectoral partnerships and adequate monitoring systems. Due to structural and operational reasons, conducting solid research and monitoring activities in prison settings is challenging and often available studies are mono-centric. This workshop will provide attendees with a comprehensive overview at European level of infectious diseases prevalence in prison populations and health services provided in detention facilities. The discussion of three European project collecting successful models of care for hepatitis elimination and implementation of vaccination services in prisons will create the context for an in-depth analysis of key challenges for prison health implementation and may help promote awareness that targeted interventions are feasible and effective in reducing infectious diseases burden among people living in prison and the community at large.

Key messages:

- Existing European initiatives contribute to building the evidence for tailored prevention & control interventions in prison settings.
- Adequate and effective prisons healthcare contribute to achieving the UN's SDGs through improving health, reducing health inequalities and providing a fairer and safer society for all.

Abstract citation ID: ckac129.385
Burden of infectious diseases in prison settings and services offered

Filipa Alves da Costa

F Alves da Costa[1]
[1]WHO Regional Office for Europe, Copenhagen, Denmark
Contact: azevedof@who.int

Introduction:

The WHO Prison Health Framework was developed to assess prison health system performance and support Member States (MS) in improving their prison health systems. Moreover, it shall enhance MS capacity to evaluate: the impact of changes in governance models, progress in service provision and improvements of the health status of people in prison (PiP).

Methods:

The framework informed the 2021 data collection round of the Health In Prisons European Database Survey. Invitations were sent to all 53 MS of the WHO European Region. Those MS nominating a focal point and providing valid answers were included in the analysis.

Results:

Answers were obtained from 36 MS, representing a total of 613,497 PiP. Access to immunization was very good across all MS, with the highest for COVID-19 (90% of MS provide it in all prisons). Vaccination against HBV was only available in all prisons of 25 MS. Access in all prisons to HIV post and PrEP were reported, respectively, by 78% and 58% of MS. Screening for diseases at entrance was common for HIV, HCV and HBV. In all prisons of 35 MS soap was provided for free, while needles & syringes and lubricants were only provided free of charge, respectively, in 3 and 4 MS. 5 MS did not have therapeutic spaces to tackle drug problems in any prison, in 73% of those having, accessibility was restricted to some prisons. HIV prevalence ranged from 0-16% and treatment was accessible to 55-100% of those diagnosed. Prevalence of HCV ranged from 0-34%, with access to treatment ranging from 0-91%. The most common format of health records in European prisons was paper based (44%).

Conclusions:

Prison-based data collection systems resulted in limited capacity for extraction so that some countries were unable to provide any data on disease prevalence or treatments offered. Given the scarcity of data on this topic obtained from real-world and not from ad-hoc studies, this snapshot provides an important contribution to public health.

Introduction:

Prisons are high-risk environments for the transmission of drug related infections, due to over-incarceration of people who inject drugs; often inadequate healthcare, substandard prison conditions; and others. An overview of the availability and coverage of prison-based harm reduction interventions in Europe is presented.

Methods:

National Focal Points of the EMCDDA (30) collected 2019 data, which were integrated with findings from the European funded project HA-REACT (Joint Action on HIV and Co-infection Prevention and Harm Reduction).

Results:

Prison based harm reduction interventions are available in European countries, but only few of them are available in most countries and often with a low coverage (e.g. less than 10% of prison population in Opioid Substitution Treatment (OST) in most countries). Interventions available in most countries (20 or more) include: HIV, HBV, HCV testing (29), OST continued from community (29), Referral to HIV treatment upon release (28), HIV treatment (27), Referral to HCV treatment upon release (25), HCV antiviral treatment (25), Testing for TB (23), HBV antiviral therapy (25), OST initiated in prison (22), Treatment for TB (21), Vaccination for HBV (20). Interventions available in 10 to 19 countries are: condom distribution (19), OST (re)initiated before release (17), prison/community guidelines for implementation of OST (13).

Interventions provided in < 10 countries include: distribution of disinfectant (9), condom with lubricant (9), take-home naloxone (5), needles and syringes programs (3).

Conclusions:

Compared to the community, the availability and coverage of harm reduction interventions in European prisons are limited and large information gaps exist. Scaling up harm reduction in prison can achieve important individual and public-health benefits.

Viral hepatitis micro-elimination: models of care and barriers to implementation in 5 EU/EEA prisons

Thomas Seyler

T Seyler[1], *L Montanari*[1], *L Ceccarelli*[2], *E Torri*[2], *S Mazzilli*[2,3], *L Tavoschi*[2]

[3]Scuola Normale Superiore, Pisa, Italy
Contact: Thomas.Seyler@emcdda.europa.eu

Introduction:

Coverage of essential prevention and control services and adequate monitoring schemes for viral hepatitis are often suboptimal in prison settings. Yet, evidence shows that targeted interventions are feasible and effective in reducing viral hepatitis burden and decreasing virus circulation among people living in prison and the community at large. To promote transferability and improvement of prison health quality in EU/EEA the European Monitoring Centre for Drugs and Drug Addiction (EMCDDA) will identify and disseminate models of care for viral hepatitis elimination in prisons.

Methods:

The models of care were gathered using a data collection tool that has been designed for this purpose based on the literature review and agreed with an expert advisory group. Based on the results of the data collection, a survey for healthcare staff working in 5 selected prison institutions in the EU/EEA has been developed.

Results:

The following models of care were collected: HCV micro-elimination in prison; transitional care for HCV treatment or HBV prevention/treatment; HCV or HBV care services tailored to women living in prison; HBV or HAV/HBV vaccination in prison settings. Harm reduction and drug treatment services in the prison are essential at all steps of the prevention and continuum of care. Among barriers identified were: engagement of people living in prison and prison governance structure, availability of infrastructural and human resources, daily prison organisation, inter-sectorial collaboration within prison and between prison and community services, training for prison staff and lack of systematic monitoring.

Conclusions:

Evidence of effective and acceptable interventions in prison to prevent and control viral hepatitis is essential to foster inclusion of prison setting within national elimination programmes. Intra-EU benchmarking may help promote awareness, to allocate adequate resources, monitor of impact and ultimately the achievement of the elimination goal.

Introduction:

Vaccinations are one of the most powerful preventive tools discovered by modern medicine. Although expanded programmes of immunization are well established in EU/EEA, significant immunity gaps and suboptimal coverage are registered among specific populations, including people living in prisons (PLP). PLP are also at increased risk to vaccine-preventable diseases (VPD) with potential outbreak in prison, e.g. flu, COVID-19, as well as other VPDs such as HBV. The EU-funded project RISE-Vac, aimed at collecting models of care developed during the pandemic to design tailored vaccine delivery strategies that could be extended beyond the sole COVID-19 vaccine.

Methods:

Through a survey to healthcare staff working in prisons in six countries of the EU/EEA (Cyprus, France, Germany, Italy, Moldova, UK) we collected information on the implementation of COVID-19 vaccination program. The following areas were investigated: challenges & barriers encountered, workload distribution, education & training activities for prison staff and PLP, referral strategies after release, immunization information system.

Results:

The respondents reported that in prisons COVID-19 programs have been implemented efficiently. Strategies for optimal management of the vaccination campaign included: week-day dedicated to vaccination services when vaccines were delivered and immediately administered to overcome cold chain challenges; new staff recruitment & task shifting; administration of booster doses within prison premises for released individuals; distribution of informational material both to PLP & prison staff.

Conclusions:

Our results show that universal immunisation campaigns are feasible, acceptable and effective in places of detention when there is commitment to implementing them. Evidence from the pandemic situation may inform future provision of expanded immunization programmes.

What matters to families about the healthcare of preterm or low birth weight infants

Lisa Hurt

D Odd[1], M Mann[1], H Beetham[1], E Dorgeat[1], T Isaac[2], A Ashman[3], F Wood[1]
[1]Division of Population Medicine, Cardiff University, Cardiff, UK
[2]Paediatrics Department, Yeovil District Hospital, Yeovil, UK
[3]Specialty Training Programme, Public Health Wales, Cardiff, UK
Contact: hurtl@cardiff.ac.uk

Introduction:
Preterm and low birth weight (LBW) infants have complex long-term healthcare needs. The impact on families of caring for a sick infant is increasingly understood, with consequences for attachment and bonding and parental health and wellbeing immediately after birth and beyond. In this qualitative evidence synthesis, we aimed to understand what matters to families about the care provided to preterm or LBW infants in hospital and the community.

Methods:
We searched nine databases and the reference lists of included studies for eligible studies using qualitative methods examining the views of families on healthcare for preterm or LBW infants. We used the Critical Appraisal Skills Programme checklist for qualitative studies to assess study quality and the GRADE-CERQual approach to assess confidence in each review finding. Studies were sampled after data saturation, and thematic synthesis techniques were used for analysis.

Results:
203 studies were eligible for inclusion. We selected 49 studies from 25 countries for the analysis, based on methodological quality, data richness and on ensuring representation from settings with varying resources. Eight analytical themes were identified. Confidence in most results was moderate to high. What mattered to carers was a positive outcome for the child; active involvement in care; support to cope at home after discharge; emotional support for the family; the healthcare environment; their information needs were met; logistical support was available; and positive relationships with staff.

Conclusions:
Enabling a positive post-natal period for families of small and sick infants is difficult. Experiences of care for preterm or LBW infants vary, but we found high consistency in what matters to families. This information can be used to shape global recommendations on support for infants and carers. More research is needed on what matters to parents who receive community-based care, especially in low resource settings.

Key messages:
- We found high consistency across settings in what matters to families in the care of preterm infants.
- Understanding carers views and values ensures that care can be planned to meet the needs of infants and families.

Abstract citation ID: ckac129.390
Contraception free of charge for young women in Tuscany: an interrupted time series analysis

Amerigo Ferrari

A Ferrari[1], M Bonciani[1], I Corazza[1], C Tortù[1], M Vainieri[1]
[1]Management and Health Laboratory, Sant'Anna School of Advanced Studies, Pisa, Italy
Contact: amerigo.ferrari@santannapisa.it

The Regional Health Authority of Tuscany, ITALY, launched in November 2018 a public program providing all contraceptive methods free of charge to all young residing women after medical evaluation at free family counselling centres. We aimed to explore the effect of the regional program on five outcomes - abortions, contraception provision, access to family counselling centres, conception, and outpatient service utilization for six sexually transmitted diseases (STDs). These outcomes were retrospectively computed from January 2016 to December 2020 using regional administrative databases, and then expressed as both annual rates per 1,000 and monthly rates per 100,000 women aged 14 to 25 years and residing in Tuscany. We ran interrupted time series (ITS) models to analyze how the trends in monthly rates changed over time after the intervention (set in November 2018). The decline in annual abortion rates per 1,000 women doubled from 2016-2018 (-9%, from 7.0 to 6.4) to 2018-2020 (-17%, from 6.4 to 5.3). ITS models revealed a significant post-intervention decrease in monthly abortion rates (-0.61, -1.11 to -0.12) and a significant increase in both access rates to counselling centres (87.60, 77.77 to 97.43) and contraception provision rates (16.75, 0.31 to 33.19). Conception rates fell significantly just in under-18 women (-0.84, -1.39 to -0.28). A significant reduction in outpatient service utilization rates for STDs emerged for N. gonorrhoeae, HSV, and HPV. As a prime example of similar initiatives in Italy, the free contraception program of Tuscany promoted access to counselling and contraception services among young under-25 women, empowering the entire care pathway. As a result, abortion rates declined significantly in this group. The wider access to counselling centres to obtain free contraception and overall enhancement of the pathway might have fostered sexual education and reproductive health, leading to a reduction in teenage conception and STD spread.

Key messages:
- This study proves the effectiveness of the free contraception campaign of Tuscany in reducing abortions and empowering the entire care pathway, providing further evidence for policy accountability.
- Therefore, this study supports the maintenance of this program and suggests the potential benefits of implementing and promoting similar initiatives in other Regions.

Preventing HIV infection in pregnancy: a comprehensive ANC-based intervention in Western Uganda

Stefanie Theuring

S Theuring[1], LS Jahn[1], A Kengonzi[2], SN Kabwama[3], J Rubaihayo[2]
[1]Institute of Tropical Medicine and International Health, Charité-Universitätsmedizin, Berlin, Germany
[2]School of Health Sciences, Mountains of the Moon University, Fort Portal, Uganda
[3]School of Public Health, Makerere University, Kampala, Uganda
Contact: stefanie.theuring@charite.de

Introduction:
Pregnant women in sub-Saharan Africa represent a high-risk group for HIV infection, but most endemic countries including Uganda do not engage specific HIV prevention measures in pregnancy. This longitudinal study aimed to assess outcomes of a comprehensive, ANC-embedded strategy to prevent seroconversions during pregnancy in Western Uganda.

Methods:
HIV-negative ANC clients were administered an HIV risk assessment tool, followed by individual risk counselling. They received a fixed appointment for repeat HIV testing after three months. Those attending ANC without partners obtained

formal partner invitation letters. At follow-up after three months, women not attending repeat testing were reminded via text message. Post-intervention risk behavior engagement was captured. We analyzed uptake of the intervention, HIV incidence rate, and associations with risk behavior.

Results:

Of 1081 participants, 116 (10.7%) reported risk behavior engagement at first ANC visit, 148/1081 (13.7%) were accompanied by partners. The repeat test visit was attended by 848/1081 (78.5%) women, 42 (5.0%, $p < 0.001$) reported post-intervention risk behavior engagement, and 248 (29.4%, $p < 0.001$) were accompanied by partners. Seroconversion occurred in two women. In multivariable logistic regression, rural facility clients compared to urban ones (aOR 3.96; 95%CI 1.53-10.26), and women with positive or unknown partner HIV-status (aOR 2.86; 1.18-6.91) and partner alcohol abuse (aOR 2.68; 1.15-6.26) had increased odds for engagement in risk behavior despite the intervention.

Conclusions:

After our intervention, risk behavior in pregnancy was reduced by half, and partner attendance had doubled compared to baseline. Our cohort showed a 0.76/100 women-years HIV incidence rate compared to 2.85 in pre-intervention data from the same setting. Clients from rural settings and women experiencing precarious partner situations require special attention to reduce risk behavior engagement during pregnancy.

Key messages:

- HIV incidence in pregnancy in Western Uganda can be significantly reduced through a comprehensive, ANC-based counselling intervention.
- Pregnant women from rural settings and those experiencing precarious partner situations require special attention regarding sexual risk behavior.

Background:

Timely vaccination is essential to protect infants from vaccine-preventable diseases. The aim of the study was to evaluate the determinants of vaccination timeliness for hexavalent (HEXA) and measles-mumps-rubella (MMR) vaccines.

Methods:

The study is part of the PREHMO project funded by Tuscany Region, Italy. Data on the 2017 and 2018 full birth cohorts of Tuscany (N = 41,493) were retrieved from the Birth Registry and linked to those of the Vaccine Registry up to 24 months after birth. Sociodemographic and at birth characteristics of mothers and infants were retrieved. The primary outcome was the timeliness of HEXA 1st and 3rd doses, and MMR 1st dose. Timeliness was defined as the administration of the dose a day after the period recommended by the vaccination schedule. Multiple logistic regression models were performed.

Results:

For all the vaccines considered, a significantly increased risk of delayed vaccination was observed in preterm infants and in infants born in hospital of second level of newborn care, while infants conceived by assisted reproductive technologies and first-born infants showed a significantly decreased risk for delayed vaccination. Multiple births, small for gestational age status, maternal unemployment, and rural residence were significantly associated with an increased risk of delayed HEXA-1 vaccination (OR 1.31, 95%CI 1.13-1.51; OR 1.12, 95%CI 1.03-1.22; OR 1.06, 95%CI 1.01-1.13; and OR 1.1, 95%CI 1.03-1.16). As for MMR vaccination, a low maternal education was significantly associated with high risk of delay (OR 1.12, 95%CI 1.06-1.18), while rural residence, maternal foreign nationality and female sex were significantly associated with a decreased risk of delay (OR 0.91, 95%CI 0.87-0.96; OR 0.82, 95%CI 0.78-0.87; and OR 0.95, 95%CI 0.91-0.99).

Conclusions:

Several common and vaccine-specific predictors of vaccination timeliness were identified. Strategies to improve a timely vaccination should take into account these predictors.

Key messages:

- Several maternal and infants factors may influence vaccination timeliness of routine immunization in childhood.
- Tailored vaccination strategies are needed to improve vaccination timeliness in infants at high-risk of delayed vaccination.

Abstract citation ID: ckac129.393
An integrated care pathway for maternal and childcare: evidence from Ethiopia, Tanzania, and Uganda

Ilaria Corazza

I Corazza[1], *P Belardi*[2], *M Bonciani*[1], *F Manenti*[2], *D Abebe*[2], *S Santini*[2], *G Azzimonti*[2], *J Nsubuga*[2], *G Dall'Oglio*[2], *M Vainieri*[1]
[1]Health and Management Laboratory, Sant'Anna School of Advanced Studies, Pisa, Italy
[2]Doctors with Africa CUAMM, Padua, Italy
Contact: ilaria.corazza@santannapisa.it

Performance monitoring and evaluation are key to quality improvement in maternal and child healthcare in Sub-Saharan Africa. This study presents the experience of designing and implementing bottom-up and integrated performance evaluation tools for care pathway to monitor and manage maternity healthcare services. The research project involved four health districts and relative reference hospitals, supported by the NGO Doctors with Africa CUAMM in Ethiopia, Tanzania, and Uganda. The maternal and childcare pathway developed consists of 23 indicators, calculated at hospital and district level, relating to pregnancy, childbirth and first year of life phases. The authors developed staves and performance maps, as graphical representation tools, to display longitudinally integrated health services provision performance along the continuum of care. Substantial variation was observed between the phases of each maternal and childcare pathway and across the care pathways of the different analysed settings. The most impressive results across the four settings are: 1) regarding pregnancy phase, that women tend to attend more than four antenatal classes, still with a quite high drop-out rate, and are largely tested for syphilis, 2) with respect to childbirth, that there are varying percentage levels in terms of C-sections, episiotomies and peri/intra-partum asphyxia cases, and 3) as it regards first year of life, there emerges scope for improvement considering the vaccination coverages attained for pentavalent, measles and polio vaccinations. Thanks to the collaboration with local managers and health professionals, the maternal and childcare pathway allowed to monitor the changes in the quality of maternity services provided within the analysed contexts. The benchmarking approach encouraged local professionals to learn from other settings. The use of such tool allowed the development of targeted quality improvement actions, shared among all involved stakeholders.

Key messages:

- In collaboration with local professionals, we designed and implemented an integrated pathway for maternal and childcare, covering the phases of pregnancy, childbirth and first year of life.
- Benchmarking performance results encouraged collaboration among professionals and allowed the identification of actions to improve the provision of maternal and childcare services.

6.O. Workshop: Urban design interventions for fostering mental health and mental health literacy

Abstract citation ID: ckac129.394

Organised by: Darmstadt University of Applied Sciences (Germany)
Chair persons: Evangelia Chrysikou (EUPHA-URB)
Contact: helena.mueller@h-da.de

With roughly half of the global population living in cities and an expected rise up to 85 % by 2050, urban environments are central to public health. Yet, they are often perceived as health risk factors due to e.g., noise, pollution, crowding, and anonymity. Indeed, mental disorders show higher incidence in urban contexts compared to rural areas, generally increasing, e.g., due to the Covid19-pandemic as well as to climate change. However, we argue that there is also a rich potential of urban environments to act as resource for mental health and to address mental health issues in the public space. Design interventions such as urban furniture, art and information elements can act as perceived affordances, signifiers and situative stimuli to influence health behaviour, social discourse and individual mindsets regarding mental health. Furthermore, by considering their unique potentials and resources during the design process, the specific surroundings of these interventions can become an integral part of the actual design. As a result, this might change citizens' perspective on the urban setting as such. While there exists a large body of literature as well as case studies focusing on physical health promotion by urban design interventions, evidence regarding its mental correlate is still scarce. This workshop aims at collecting and elaborating on features in the urban space as potential resources to foster mental health as well as mental health literacy. To that aim, first, three seven-minutes-presentations introduce different disciplinary perspectives on the topic: Starting from a psychological point of view, the relationship between urban environments and mental health will be outlined. Based on insights from human geography, social determinants of urban settings will be elaborated and participatory approaches will be presented as a crucial method for designing effective intervention. Synthesizing these insights, the role of design to influence health behaviour will be discussed and afterwards illustrated using the example of a trail-based design concept as the backdrop for the interactive part. In the second part of this session, first, co-creation methods (such as mindmapping and brainwriting) will be applied together with participants to brainstorm relevant categories, features and potentials of the urban space to foster mental health and mental health literacy. Participants will then be asked to contribute their expertise from their specific field of work particularly with regards to increasing mental health literacy in citizens. This exercise will be highly valuable for participants to acquire interdisciplinary knowledge regarding the influence of urban design interventions and mental health and broaden their perspective and knowledge regarding urban mental health and the built environment. Learnings and variations of this exercise could be also applicable in other settings such as rural communities or semi-public spaces.

Key messages:

- This workshop aims at understanding how features of the urban space can be utilised to foster mental health and mental health literacy.
- By co-creatively sharing and elaborating on insights from various disciplines, participants broaden their horizons regarding the interrelations between the urban built environment and mental health.

Abstract citation ID: ckac129.395

Risk factors and potentials for fostering mental health and wellbeing in urban space

Helena Müller

H Müller[1]*, J Rehn-Groenendijk*[2]*, A Wasmer*[3]

People shape their physical environments - and vice versa. As such, cities provide both resources (e.g., job opportunities, cultural diversity) as well as stressors (e.g., crowding, noise pollution) to their residents and visitors. In this context, numerous studies illustrate a considerable influence of the built environment (townscape, architecture) on health and well-being of interacting people. This impact ranges from physical aspects (e.g., traffic safety, particulate matter) to psychological processes (e.g., stress, loneliness) and behavioral aspects (e.g., physical activity, social behavior). At the same time, phenomena such as homelessness, crime, or mental disorders (e.g., substance addictions, schizophrenia) occur more frequently in cities compared to rural areas, illustrating causal as well as selective processes in the relation of urban environment and mental health. Increasing overall incidences in mental disorders (especially anxiety disorders and depression), the short-term shortage of psychotherapeutic care as well as the long-term economic burden on the health care system ask for a twofold strategy in public health: a) an extension of preventive measures with low threshold, i.e., accessible by large shares of the population, b) an extension of mental health literacy, which will empower the population to be attentive to mental health issues in themselves and others and which in turn can help to reduce stigmatization. While urban green and blue spaces have been researched in terms of restorative environments - allowing to regenerate resources consumed during the day - the built environment is still a resource for this strategy that has received insufficient attention to date. Utilizing the urban built environment not only as restorative but also informative and engaging environments thus affords an opportunity to address and potentially foster mental health and mental health literacy in citizens across socioeconomic backgrounds.

Potentials of participatory approaches for urban mental health

Anna Wasmer

A Wasmer[1], *H Müller*[2], *J Rehn-Groenendijk*[3]
[1]Civil Engineering, Darmstadt University of Applied Sciences, Darmstadt, Germany
[2]Social and Cultural Sciences and Social Work, Darmstadt University of Applied Sciences, Darmstadt, Germany
[3]Design Research, Darmstadt University of Applied Sciences, Darmstadt, Germany
Contact: anna.wasmer@h-da.de

Aspects of mental health, society, space and environment share entangled relations being studied in health geography. Recreational spaces as well as places that are commonly perceived as strenuous, unsafe, or highly stressful are unevenly distributed within urban areas, which is also associated with spatial differences in mental disorders. Spaces in general represent social constructions that reflect power inequalities; they are filled with subjective emotional resonances and sometimes visualize stigmatization of specific groups. As such, the interplay of socio-demographic factors, socio-economic factors and built environment is complex. To capture these entanglements represented in heterogeneous user groups, participatory approaches promise valuable insights. Yet, despite their great potential for fostering mental health in urban space, participatory approaches are still less common in health geography. Therefore, critical voices question whether the limitations of marginalized groups have been sufficiently considered in this field of study so far. Similar challenges arise in urban planning processes: Specific (vulnerable) groups such as children, women, foreign residents, and people with disabilities or elderly people are insufficiently included in planning processes, leading to an underrepresentation of their needs in the resulting environments. To tackle this shortcoming, the approach of co-creation offers a process in which participants jointly develop a solution without being the object of research or interview partners, but creators. Using rather practical or creative (e.g., joint mapping of the built environment, photo-elicitation) than discursive techniques allows contributions from population groups otherwise often excluded from planning processes. Despite certain limitations, participatory approaches promise the possibility to develop appropriate and just solutions in urban mental health.

The design of objects, spaces and systems can have a profound influence on the behaviours as well as emotional and cognitive states of the people confronted with it. With regards to health behaviour, elaborating on Schwarzer's HAPA model (1992), the Design Model for Health Behaviour Change - DMHBC (Rehn, 2018) proposes the use of the built environment to act as situative barriers or opportunities to change health behaviours and overall health promoting mindsets. Regarding urban space and mental health, most environmental stimuli and related behavioural patterns focus on consumption (e.g. retail stores) or daily routines (e.g. commuting). Using objects such as specifically designed furniture, installations and other elements to act as perceived affordances and stimuli can affect both cognitive-emotional states as well as specific behavioural responses. For instance, based on the research on mindfulness, drawing people's attention towards their own bodily sensations (e.g. breath) by playful interactive installations or information signs can increase feelings of calm, appreciation and contentment. The same applies to design interventions that guide one's view towards otherwise overlooked urban features (e.g. natural scenery). While mindfulness and relaxation are powerful techniques for increasing mental health, many other approaches (such as physical activity, social interactions etc.) can be found to have similar benefits. In fact, the orchestrated combination of various forms of stimuli might prove to be more effective than the sum of the individual interventions as they create a subsequent chain of stimuli that form a coherent experience. This approach poses particular potentials to foster mental health in vulnerable groups that usually suffer most from urban environmental risk factors. Thus, providing public and open access stimuli and affordances in this way, can have a significant effect on overall urban public health and reduce social inequalities at the same time.

6.P. Skills building seminar: Children and young people: engaging the unheard stakeholder

Abstract citation ID: ckac129.398

Organised by: EUPHA-CAPH, EUPHAnxt
Chair persons: Hellen Skirrow (UK), Jinane Ghattas (EUPHAnxt)
Contact: s.saxena@imperial.ac.uk

Global shocks from the COVID 19 pandemic have disproportionately impacted children and young people (CYP) and their families. Underlying health disparities have widened as a result of disruptions to healthcare, education and economic impacts. There are compelling arguments to engage children and young people in rebuilding society and systems from emerging public health threats including the covid 19 pandemic, the climate crisis and conflicts. Children and young people like others in society have a right to be involved in decisions that impact their lives and health but are too often unheard. Engaging those affected most by health policy ensures relevance and can improve adoption of interventions. Involving children and young people in strategic decision making can also improve their citizenship skills and improve health literacy. Although many children and young people have contributed to debates and publicly demonstrated their collective views on a variety of issues such as climate change, movements including #timesup, #Blacklivesmatter and #Metoo, their voices are seldom heard in policy and decision making arenas. In 2021, EUPHA CAPH and EUPHANxt sections collaborated to host the inaugural Engaging the Unheard Stakeholder workshop, supporting 2 young people aged <25 to attend the EPH and lead the workshop. (links). CAPH is now committed to make this a regular feature as part of our action plan to support young voices in public health.

Learning outcomes:
- Develop insight into innovative ways to support and engage young people in public health policy making.
- Practise advocacy skills to facilitate young people's voices in research & policy

Activities:
Participants will hear from young people who are championing activism or have been involved in shaping public policy.
Interactive skills building breakout session involving role play and scenarios to challenge their unconscious bias and learn skills as 'active bystanders' to empower young people

Key messages:
- Despite major movements where children and young people have demonstrated their views on a variety of issues such as climate change, their voices are seldom heard in policy and decision making arenas.
- Public health professionals can advocate, support and engage children and young people in public health policy making but lack awareness and skills in advocacy to do this effectively.

6.Q. Skills building seminar: Integrating social inequalities in the burden of disease framework

Abstract citation ID: ckac129.399

Organised by: COST Action CA18218– European Burden of Disease Network
Chair persons: Brecht Devleesschauwer (Belgium)
Contact: Brecht.Devleesschauwer@sciensano.be

Driven by the influential Global Burden of Disease (GBD) study, the burden of disease (BOD) approach has gained wide interest at national and international level to quantify the state of health and health inequalities. Central to the BOD approach is the Disability-Adjusted Life Year (DALY) metric, which quantifies the health impact of diseases, injuries and risk factors as the number of healthy life years lost compared to a counterfactual scenario of perfect health all life long. The BOD approach offers a valuable platform to quantify social inequalities in health, i.e., differences in health status by socioeconomic and sociodemographic characteristics. This is highly relevant, as health inequalities penalising socially disadvantaged groups are one of the most consistent, and persistent, findings in epidemiology, for almost every health outcome and socioeconomic indicator. Monitoring social inequalities in health is therefore a key priority for national health authorities. There are different ways by which social inequalities can be integrated in the BOD framework, but all come with important data challenges. Individual-level stratification is a common approach for quantifying inequalities by age and sex, but is more challenging for other sociodemographic and socioeconomic indicators. Area-level stratification allows for ecological analyses between BOD estimates and indices of social deprivation. Social inequalities can also be assessed using comparative risk assessment, by which the relative risk for adverse health outcomes in function of social position is to be quantified. This skills building workshop will present the methods that have been applied in different national burden of disease studies to include social inequalities, including a discussion of their strengths and weaknesses. By providing a step-by-step presentation of how the methods have been applied, attendees will gain unique insights in the different ways by which social inequalities can be integrated in the BOD framework.

Key messages:
- The burden of disease framework offers a valuable platform to quantify and monitor social inequalities in health, which is a key priority for health authorities.
- Attendees will receive an overview of the different ways by which social inequalities can be integrated in the burden of disease framework, including a discussion of their strengths and weaknesses.

Substantial social inequalities in almost all non-fatal and fatal health outcomes are one of the most consistent and universal epidemiological findings. Therefore, monitoring social inequalities in health is considered a key priority for researchers and policy makers. The Global Burden of Disease Injuries, and Risk Factors Study (GBD) is the most comprehensive worldwide observational epidemiological synthesis of data to date. However, currently, the GBD Study does not include the potential to stratify associated metrics, such as the disability-adjusted life years metric, by different socioeconomic factors, such as education or income level. Although The GBD Study does include the Socio-Demographic Index, this measure is only useful when comparing between, and not within, countries or regions. We conducted a Cox regression analysis using a national longitudinal prospective cohort study design and registry-based data linked at the individual-level. We stratified on educational groups and investigated cause-specific mortality rates over a 30-year period, adjusting for age, sex and 5-year age cohorts. We also calculate years of life lost (YLLs) stratified by educational groups, standardised by age, and presented for specific years - to investigate trends over time. We discuss the benefits and limitations of this "individual-level" stratification approach as one possible solution to the integration of social inequalities into the GBD study or when using a burden of disease framework approach more generally.

In the context of increasing demand for evidence-based policy, attempts to address or mitigate the effects of disadvantage have been usefully informed by comprehensive indices of multiple deprivation. These indices combine indicators on a range of dimensions of deprivation to classify neighborhoods or localities. Through combining information on fatal and non-fatal health loss, burden of disease studies allow planners and policy-makers to have a better understanding of the contribution of different diseases and injuries to the total burden of disease. These estimates can be augmented through studies, stratified by investigating inequalities in the burden of disease due to area-based deprivation. Doing so, helps contribute to discussions about where prevention and service activity should be focused to address health inequalities. The Scottish Burden of Disease study uses the Scottish Index of Multiple Deprivation (SIMD) as means to report on of the extent of inequality in the burden of disease in Scotland between people living in the areas of greatest, and of least, multiple deprivation. The SIMD quantifies deprivation based on data zones, a geographical unit comparable to a postcode. Using pooled and weighted data from seven domains (employment, income, crime, housing, health, education and geographic access), each data zone is given a composite rank out of 6,505 data zones. The composite rank was then converted to a decile, with 1 assigned to the 10% most deprived data zones and 10 to the 10% least deprived. In this presentation we will show the key steps involved in undertaking an area-based analysis of health inequalities in the burden of disease in Scotland using results from the Scottish Burden of Disease 2019 study, and from our monitoring of COVID-19 disability-adjusted life years.

Reducing educational inequalities in mortality: a comparative risk assessment approach

Terje Andreas Eikemo

TA Eikemo[1]
[1]Centre for Global Health Inequalities Research, Norwegian University of Science and Technology, Trondheim, Norway

Contact: terje.eikemo@ntnu.no

Educational inequalities in mortality are increasingly recognized as one of the main challenges for health policy. Studies comparing European countries have shown that such inequalities are substantial almost everywhere, but that there are important variations between countries, suggesting great scope for reduction. However, identifying this scope is difficult because it requires comparative information about the educational distribution of mortality rates, risk factors and relative risks. In this presentation I show how this can be done, by quantifying the impact of a theoretical equalization of the distribution of several known risk factors for mortality, in a comparative risk assessment approach. Harmonized data set on mortality (from register data) and risk factors (from survey data) by educational level for 21 European populations in the early 2000s were applied. The impact of the risk factors on mortality in each educational group was determined using Population Attributable Fractions (PAF). The impact on inequalities in mortality was estimated applying two counterfactual scenarios: a theoretical upward levelling scenario in which it is assumed that inequalities in the risk factor were completely eliminated, and a more realistic best practice scenario, in which it is assumed that inequalities in a risk factor were to be reduced to those seen in the country with the smallest inequalities for that risk factor. The analysis shows how information on risk factors, mortality rates and relative risks can be combined from different data sources and provide a meaningful analysis of the European mortality burden that can be linked to educational inequalities in risk factors. The analysis also shows that upward levelling scenarios and best practice scenarios demonstrate a theoretical potential for reducing inequalities in mortality.

7.A. Round table: Sustainable health system responses to meet the chronic health care needs of refugees from Ukraine

Abstract citation ID: ckac129.403

Organised by: Centre for Global Chronic Conditions, LSHTM, WHO Europe, Observatory on Health Systems and Policies
Chair persons: Natasha Azzopardi Muscat (WHO Europe), Martin McKee (UK)
Contact: adrianna.murphy@lshtm.ac.uk

Background:

Since Russia's reinvasion of Ukraine on 24 February, more than 5 million people have fled the country. Most have gone to the neighbouring countries of Poland, Slovakia, Hungary, Romania, and Moldova. This vulnerable population has significant healthcare needs. Among the most challenging to address will be chronic non-communicable diseases (NCDs), including mental disorders, as these require long-term, continuous care and access to medicines. NCDs are already the biggest contributor to disease burden among Ukrainian adults. About a third have hypertension and 7% have diabetes. Refugees are also at increased risk of mental disorders due to exposure to trauma and ongoing daily stressors. Host country health systems are faced with the challenge of ensuring accessible and affordable care for NCDs and mental disorders to this population. There is no consensus on the most effective and sustainable approaches for achieving this.

Objectives:

This workshop will provide a platform for sharing knowledge to support host country health systems. The objectives of the workshop are to i) identify sustainable health system approaches to providing quality health care for NCDs and mental disorders to refugees from Ukraine, and ii) establish research priorities to support host country health system decision-making.

Format:

The workshop will consist of a panel with 4 speakers, followed by a roundtable discussion. Each panel member will make a short presentation (5 min) related to health system responses for NCDs and mental disorders in refugee populations. They will highlight challenges faced in the current crisis and evidence of approaches that have worked in other refugee contexts. The roundtable discussion will focus on the adaptation of evidence-based approaches to countries hosting refugees from Ukraine, and the research needed to support this. Interventions will be made by representatives from countries hosting refugees, including from WHO country offices, and from the WHO Europe Migration and Health Programme. All workshop participants will be invited to contribute. The discussion will be chaired by Natasha Azzopardi-Muscat, Director of the Division of Country Health Policies and Systems, WHO European Regional Office. A report on the conclusions of the workshop, including research priorities to support host country health systems, will be published.

Key messages:

- Health systems receiving refugees from Ukraine will face challenges in providing them long-term and affordable care for NCDs and mental disorders.
- Drawing on evidence, the workshop will help to identify sustainable health system responses to NCDs and mental disorders, and priorities for research to support host country health systems.

7.B. Workshop: Labor migration, the food supply chain and the COVID-19 syndemic: Germany, Netherlands, and the USA

Abstract citation ID: ckac129.404

Organised by: Bielefeld University (Germany)
Chair persons: Nora Gottlieb (Germany), Seth M Holmes (USA)
Contact: lforst@uic.edu

The agriculture and meat-processing sectors employ, largely, (im)migrant workers in Germany, the Netherlands, and the USA. Deemed "critical infrastructure," workers in the food supply chain (FSC) were particularly vulnerable to SARS-CoV-2 infection due to poor adaptation of policies and practices related to health, immigration, and work. The pandemic has shone a light on preexisting inequalities and risks related to precarious and hazardous work, particularly for (im)migrant workers. We conducted harmonized policy analyses in North-Rhine Westphalia, Germany, in the Netherlands, and in Illinois, USA on measures taken during the pandemic and how they affected migrant workers. These three regions host large businesses in meat-processing and agriculture. They saw significant COVID-19 outbreaks, with widespread health, social and economic repercussions. Public health effects included higher risk for all communities in the region; social effects included local lockdown measures; economic effects included food supply problems, euthanized animals, and financial losses due to the temporary closure of businesses. In our workshop, we will deliver three brief presentations on (im)migration, labor, and occupational safety and health policies during the COVID-19 syndemic in Germany, the Netherlands, and the USA. We present results of our analysis, highlighting similarities and differences between the EU-member states Germany and the Netherlands, on the one hand, and the US, related to the employment and exploitation of migrant workers from the global South/East in the global North/West. We highlight issues to be addressed in future global emergencies. The pandemic has prompted occupational safety and health measures in the FSC. However, agro-industrial sectors in Western Europe and the US heavily rely on precariously employed workers (e.g., seasonal, temporary and/or subcontracted workers). This may impact the extent to which preventive measures "work" for these populations: even when good policies are formulated, information exchange, collaboration, and enforcement by relevant agencies and immigration authorities is critical. Without such cooperation, the realization of stronger social protection of (im)migrant workers is are left to the good will of the employer. Structural drivers in the form of policies related to mobile labor, (im)migration and employment, superimposed on segmented labor markets and discriminatory practices, drove significant morbidity among (im)migrant workers. The following discussion will synthesize insights from the three contexts, and provide an opportunity to brainstorm with workshop participants to facilitate cross-national collaboration on this issue.

Key messages:

- Food supply chain workers are at the intersection of discrimination in health, employment, and migration.
- Comparative analysis provides a rich framework to guide management of vulnerable sectors, workers and workplaces during future pandemics.

Abstract citation ID: ckac129.405

Labor migration, the food supply chain and the COVID-19 syndemic: Germany, Netherlands, and the USA

Ingrid Junwirth

Contact: Ingrid.Jungwirth@hochschule-rhein-waal.de

In Germany, the COVID-19 syndemic has brought questions regarding precarious labor migration in the food supply chain (FSC) to the forefront of the public debate. An analysis of responses to COVID-19-related challenges in agriculture and meat-processing pinpoints similarities and differences between the two industries, offering lessons for workers' health and safety, and for the improvement of the FSC's systemic resilience. Agriculture and meat-processing were highlighted as ''essential'' during the COVID-19 syndemic in Germany. In agriculture, amidst lockdowns and border closures, special arrangements allowed permits for migrant workers to harvest seasonal and perishable produce, thus ensuring food supply and mitigating economic loss. Bilateral agreeements with countries neighbouring the EU were concluded to increase temporary labor migration for seasonal work; while COVID-19 specific occupational health standards were set. In meat-processing, which emerged as a hotbed for COVID-19 in Germany, the public debate problematized the contradictions between migrant workers' essential contribution to the economy on the one hand, and their poor working and living conditions on the other hand. Here, the pandemic led to new legislation, prohibiting subcontracting in the meat processing industry and requiring higher standards for the housing of temporary migrant workers. While the long-term outcomes of these reforms remain to be seen, enforcement of health standards and other social rights will need attention. The German case, thus, underscores the importance of structural changes for ensuring social protection and dignified working conditions for labor migrants, which can, in turn, improve fairness, sustainability and systemic resilience of the FSC.

Essential EU mobile workers in the Dutch food supply chain: occupational safety and health policies during and after the Covid-19 pandemic

Tesseltje deLange

T deLange[1], S Mantu[1], N Skowronek[1], L Berntsen[2]
[1]Faculty of Law, Radboud University, Nijmegen, Netherlands
[2]Research Institute for Dutch Labour Movement, De Burcht Institute, Amsterdam, Netherlands
Contact: tesseltje.delange@ru.nl

The pandemic has revealed the dependence of many labour markets on EU mobile ((im)migrant) workers, particularly in sectors designated as essential for national economies. Despite many EU workers falling under the label of 'essential workers', they are nonetheless vulnerable to unhealthy and unfair working and living conditions linked to the type of work they perform (manual), the conditions of their employment (highly flexible) and their lack of social networks that makes them dependent on their employers for housing and health. Taking EU mobile workers in the meat and distribution sectors, two specific Food Supply Chain sectors in the Netherlands, as a case study, this contribution discusses how in the Netherlands protection during the Covid-19 pandemic was organized for this group of workers in relation to protective measures at the work place, quarantining, pay during periods of quarantine and protection against job loss, and access to public health services (testing, vaccines), topics that generated a great deal of insecurity among EU mobile workers. The analysis is based on data provided by a survey among 153 EU mobile workers (May-July 2021), 35 interviews with Polish and Romanian workers, and 50 interviews with national stakeholders. The aim is to problematize the disjuncture revealed by the pandemic between an EU legal regime that prioritizes mobility and national arrangements around welfare and social protection that leave many mobile workers vulnerable. We argue that EU free movement of workers needs to be flanked by measures to ensure that the people who move do so under decent and fair conditions.

Health equity and worker justice: the food supply chain during the COVID-19 pandemic

Linda Forst

L Forst[1]
[1]School of Public Health, University of Illinois Chicago, Chicago, USA
Contact: lforst@uic.edu

The COVID-19 pandemic has brought into stark relief the health, safety and security threats facing people in the US and around the globe. As stay-at-home orders were instituted, most economic activities closed or required work from home; however, companies in the Food Supply Chain (FSC) continued to operate, considered ''essential businesses.'' The meatpacking and agriculture sectors in Illinois - 79,000 and 55,000 workers, respectively - are largely populated by (im)migrant workers, some on short-term work visas and many of whom are part of the informal (cash) economy. Only a tiny percentage of meatpacking and no agriculture businesses are unionized in Illinois or most of the USA. Initially, FSC workplaces were not re-configured for social distancing; sanitation and entry procedures were not instituted; workers were not offered personal protective equipment (PPE); and no plans were made for quarantine of infected workers or isolation of COVID-exposed workers. Lack of paid sick leave for these workers, who earn subsistence wages and whose employment is extremely precarious due to immigration status, added pressure for them to continue to work while infectious. Investigation and enforcement of health and safety was taken on by local health departments rather than the occupational safety and health enforcement agency. Finally, these workers, who live in congregate housing and share transportation, carried the virus from work to community and community to work. We review US laws related to immigration, labor, and occupational health and safety before and during the pandemic, as well as epidemiological data. We will highlight the changes required to address ''work'' in the web of contagion during an infectious disease epidemic. Protection of workers' rights, as well as a clearer understanding of the integral connection between workplace and community, will be a likely ''side effect'' of these efforts.

7.C. Workshop: Towards a true European Health Union: milestones, drivers and barriers

Abstract citation ID: ckac129.408

Organised by: European Observatory on Health Systems and Policies
Chair persons: Matthias Wismar (European Observatory)
Contact: wismarm@obs.who.int

European health system responses to the COVID-19 pandemic have also demonstrated that European integration in health and health systems add value beyond what individual Member States can do: ranging from the joint purchase of medicines to providing large budgets for building back better. With a true European Health Union we will strengthen our health systems beyond crisis preparedness and response, which is necessary as we are facing the evolving perma-crisis, We will need to strengthen our health systems in general always with a view to Universal Health Coverage and improving health system performance. The European Health Union can work to help strengthen health systems, which may include support for Member States research, learning from best practices, investment but also common solutions including new or extended EU mandates, new arms-length bodies, as well as more coordination or harmonization. It has also taught us that we cannot wait to strengthen our health systems as we are in Europe in a perma-crisis.

The panel will address the following questions:

- Where are we with our progress towards a true European Health Union?
- What policy change is needed to create a true European Health Union?
- What would be the role of the true European Health Union strengthening and supporting Member States?

We will zoom in on the 1) existing public health mandate of the EU, 2) the impact of other EU-policies on health and health systems, 3) the new economic governance and, 4) the role of the EU in global public health

Key messages:

- A true European Health Union will strengthen universal health coverage and health system performance.
- A true European Health Union goes beyond crisis-preparedness and respons.

Speakers/Panellists:

Scott Greer
University of Michigan, European Observatory on Health Systems and Policies, Ann Arbor, USA

Anniek de Ruijter
University of Amsterdam, Amsterdam, Netherlands

Eleanor Brooks
University of Edinburgh, Edinburgh, UK

Thibaud Deruelle
University of Lausanne, Lausanne, Switzerland

7.D. Workshop: Older adults' resilience and vulnerability to COVID-19: 2-years results of multicentric LOST project

Abstract citation ID: ckac129.409

Organised by: University of Pavia (Italy)
Chair persons: Anna Odone (EUPHA-DH, EUPHA-IDC), Silvano Gallus (Italy)
Contact: anna.odone@mail.harvard.edu

COVID-19 pandemic and consequent mitigation and containment measures greatly impacted people's daily life. Older adults, especially those with chronic conditions, have paid the highest price for the emergency. Indeed, they are the most at-risk of severe and deadly forms of COVID-19; they deal with unmet healthcare needs because of considerable pressure on healthcare systems; they are at higher risk of worsening lifestyles, mental and socioeconomic status. In this context, we designed and are currently conducting the multi-partner project LOckdown and lifeSTyles in Lombardia (LOST in Lombardia), funded by AXA and Lombardy region. We will present the design and outputs of a telephone-based cross-sectional study conducted in the fall of 2020 on a representative sample of adults aged more than 65 years living in Lombardy. Researchers from the University of Pavia, Mario Negri Institute of Pharmacological Research, Vita-Salute San Raffaele University, Insubria University, University of Genoa, Bocconi University, Health Protection Agency of Bergamo and Brianza are involved. This project aims to evaluate the COVID-19 pandemic impact and nationwide stay-at-home order on a wide range of behavioural and health-related outcomes among the older population and provide useful evidence to plan, implement, and evaluate targeted prevention programmes and welfare policies facing pandemic consequences.

The workshop will be structured as follows:

We will first set the scene by focusing on the determinants of SARS-CoV-2 infection in the older adult population.

The second panellist will discuss changes in healthcare services use and delivery during the pandemic. Sociodemographic, physical and mental health-related determinants' roles will be thoroughly analysed.

Data on the access to hospital in older adults with chronic conditions from two local health Units from the Lombardy region, Italy during the first wave of the pandemic wee also presented.

We will then provide two original contributions about lifestyle changes.

In the first one, we will present data exploring how Mediterranean diet adherence has changed. A Mediterranean COVID-19 Pandemic Score was computing by scoring modifications in the consumption of nine food groups and five diet-related behaviours, and predictors of favourable changes will be debated.

The fifth panellist will open up about the mental health burden. The prevalence of depression, anxiety, insomnia and hopelessness before and during the COVID-19 lockdown will be assessed, identifying subgroups at higher risk of mental distress due to pandemic-associated restrictions.

In the end, we will engage in a fruitful discussion with the audience on the data presented and practical public health implications, exploring how they can inform critical policy debates addressing health system resilience and health inequalities at the European and global levels.

Key messages:

- Public health management of older people and chronic patients represents a major challenge within and beyond pandemic times, as they have been disproportionally impacted by COVID-19.
- Evidence-based recommendations are needed for the post-pandemic phase, and the results on successes and failures from one of the worst-affected regions provide guidance for the rest of Europe.

Most COVID-19-related deaths occurred in older adults, however to date, evidence on determinants of SARS-CoV-2 infection in this population is limited and mostly based on case series without a comparison group. A telephone-based cross-sectional study was conducted in November 2020 on a representative sample of 4,400 people aged $\geq$65 years from the Italian region of Lombardy. We determined the prevalence of participants reporting a SARS-CoV-2 infection in the period between the onset of the pandemic and the time of the interview. To investigate the determinants of the infection, we estimated odds ratios (OR) and their corresponding 95% confidence intervals (CI) thorough unconditional multiple logistic models. We further evaluated if the infection was a determinant of a worsening in mental health wellbeing. Overall, 4.9% of participants reported a history of SARS-CoV-2 infection. No significant relationship between sex and infection was observed. SARS-CoV-2 infection was less frequently reported in subjects aged $\geq$70 (OR = 0.55; 95% 0.41-0.74) compared to 65-69 years. We didn't observe any trend after 70 years of age. Participants reporting at least one chronic condition had a lower infection rate compared to healthy subjects (OR = 0.68 95% CI: 0.49-0.93). Separated/divorced subjects more frequently reported infection than married/cohabiting ones (OR = 2.33 95% CI: 1.29-4.20). Self-reported history of SARS-CoV-2 infection resulted being a determinant of an increase in depressive symptoms (OR = 1.57; 95% CI: 1.17-2.10). In this large study - among the few assessing the determinants of SARS-CoV-2 infection in a representative sample of older adults -, the prevalence of a history of infection in November 2020 approached 5%. We found that persons aged 70 and above and those with chronic conditions, thus individuals with likely less social interactions, were less frequently exposed to SARS-CoV-2 infection.

The COVID-19 pandemic strongly impacted older people, not only in terms of clinical outcome but also in care provision. Investigating trends of changes in healthcare services access among older subjects during the pandemic, along with studying potential determinants, is of utmost interest to identify the most at-risk individuals. We used data from LOST in Lombardia, a cross-sectional study conducted on a representative sample of 4,400 older adults (aged 65 or more) in autumn 2020. Data were collected about lifestyles, mental health, and access to healthcare services before and during the pandemic. To investigate potential determinants of changes in healthcare access, we presented prevalence ratios (PRs) estimated through multivariable log-binomial regression models. Twenty-one per cent of the participants increased telephone contacts with general practitioner (GP), 9.6% specialist visits for a fee, while 22.4% decreased GP visits, 7.5% ED access, 6% hospitalisations, 12.3% outpatient visits, 9.1% diagnostic exams. The prevalence of the cancellation or delay of medical appointments by the patient's decision was 23.8%, with higher proportions among men, among individuals aged 75 or over as compared to those aged 65-74, and among individuals with a higher self-reported economic status (p-value<0.05). People with comorbidities more frequently cancelled or postponed visits, reduced ED access or hospitalisations. Moreover, individuals with worsened mental health status showed a higher prevalence to cancel or delay visits and to reduce ED access. The decrease in healthcare provision and consultations could result in mortality and morbidity excess. Our results should inform targeted intervention to bridge the gaps and overcome the health inequalities that the pandemic has deepened. Exploring the underlying reasons and determinants for healthcare avoiding or delaying among the most vulnerable groups is crucial for epidemic preparedness and planning future interventions.

Background:
Healthcare delivery reorganization during the COVID-19 emergency may have had a significant impact on access to care for older adults with chronic conditions.
Methods:
We investigated such impact among all adults with chronic conditions aged $\geq$65 years, identified through the electronic health databases of two local health agencies - ATS Brianza and ATS Bergamo - from the Lombardy region, Italy. We considered hospitalizations for 2020 compared to the average 2017-2019 and quantified differences using rate ratios (RRs).
Results:
Overall, in 2017-2019 there were a mean of 374,855 older adults with $\geq$1 chronic condition per year in the two ATS and 405,371 in 2020. Hospitalizations significantly decreased from 84,624 (225.8/1000) in 2017-2019 to 78,345 (193.3/1000) in 2020 (RR 0.86). Declines were reported in individuals with many chronic conditions and for most Major Diagnostic Categories, except for diseases of the respiratory system. The strongest reductions were observed in hospitalizations for individuals with active tumours, particularly for surgical ones. Hospitalization rates increased in individuals with diabetes, likely due to COVID-19-related diseases.
Conclusions:
Although determinants of the decrease in demand and supply for care among chronic older adults are to be further explored, this raises awareness on their impacts on chronic patients' health in the medium and long run.

The COVID-19 pandemic and the adoption of restrictive measurements to control the SARS-CoV-2 spread disrupted general population lifestyles including dietary behaviours. However, there is poor knowledge on potential socioeconomic and gender disparities in dietary changes. We conducted a telephone-based survey during fall 2020 on a sample of 4,400 participants representative of the population aged 65-99 years living in Lombardy, Italy. Changes in a Mediterranean lifestyle were assessed retrospectively by asking participants to report modifications in the consumption of nine food groups and five diet-related behaviours (e.g., consumption of organic and local foods) compared to the previous year (2019). We then computed a Mediterranean COVID-19 Pandemic Score (MedCovid-19 Score), reflecting changes during pandemic, ranging from -14 to 14, with increasing values indicating improvements in line with a Mediterranean lifestyle. Overall, 18.3% of the study participants worsened their Mediterranean lifestyle (MedCovid-19 Score <0), 35.1% remained stable (MedCovid-19 Score = 0), while 46.6% reported improvements (MedCovid-19 Score ≥1). Predictors of favourable changes toward a Mediterranean lifestyle were educational level (OR = 1.52; 95% CI 1.19-1.95 for postgraduate vs lower education), wealth (OR = 1.52; 1.14-2.02 for high vs low wealth), and skilled manual occupations (OR = 1.57; 1.28-1.92 vs white collars). Women were more likely than men to move away from a Mediterranean lifestyle (OR = 1.86; 1.58-2.21). In conclusion, improvements in line with a Mediterranean lifestyle prevailed in almost half of a large sample of elderly Italians surveyed during the COVID-19 pandemic. However, changes towards a Mediterranean lifestyle were disproportionately distributed across gender and socioeconomic strata. These findings were similar to those from the general population of the Moli-sani study, where it was observed that healthful dietary changes were associated greater wealth.

Italy was the first country to be hit by the 2019 coronavirus disease (COVID-19) in Europe holding one of the highest clinical burdens. Older adults are those paying the highest price for the COVID-19 emergency. Within the Lost in Lombardy project, a web-based cross-sectional study assessing the prevalence of depressive and anxiety symptoms, hopelessness and insomnia before and during the COVID-19 pandemic, was conducted on a representative sample of 4,400 older adults aged 65 years or more from the Lombardy region recruited between November 17th and 30th 2020. The prevalence of depressive symptoms increased by + 112% during the pandemic, anxiety symptoms by + 136%, insufficient sleep by + 12%, unsatisfactory sleep by + 15%. Feelings of hopelessness were more frequent among women compared to men (15.1% vs. 10.4%) and increased with increasing age. A worsening in each of the four specific mental health outcomes was more frequently observed in women (OR = 1.50, depression; OR = 1.31, anxiety; OR = 1.57, sleep quality; OR = 1.38, sleep quantity), in subjects who decreased their physical activity during the pandemic (OR = 1.64, depression; OR = 1.48, anxiety; OR = 2.05, sleep quality; OR = 1.28, sleep quantity), and with increasing number of pre-existing chronic diseases (p for trend<0.001 for depression and anxiety; p for trend = 0.010 for sleep quality; p for trend = 0.012 for sleep quantity). A worsening in depressive symptoms was more frequently observed in more educated subjects (p for trend = 0.008), while a worsening in anxiety symptoms in subjects living in main towns compared to outskirt with an economic status below the mean. The use of at least one psychotropic drug - mostly antidepressants/anxiolytics - increased by + 26% compared to pre-pandemic. The protection of the mental health status of this vulnerable segment of population needs to be recognized as a real public health priority.

[5]Department of Economics, University of Exeter Business School, Exeter, UK
[6]Exeter University Law School, Exeter University, Exeter, UK
[7]University of Exeter Medical School, Exeter, UK
Contact: nicolas.berger@sciensano.be

Background:
There has been increasing policy interest in changing dietary patterns to reduce diet-related diseases and improve

population health. Meanwhile, the food choices people make every day have a determining impact on the climate change, with food systems responsible for a third of global greenhouse gas emissions. Current policies focused on dietary health are designed, implemented and evaluated in relative isolation, and there is a critical open question concerning the extent of possible synergy with an additional focus on carbon removal.

Methods:

We analysed the changes in UK households' food purchases from an online, randomized control experiment (n = 3933) designed to contrast respondents' current food purchase behaviour with that under a range of potential tax and labelling policies targeting improvement in dietary health, alone or combined with those designed to reduce carbon emissions. We assessed changes in the healthiness of food baskets between interventions through indicators of: i) purchase of calories; ii) % of calories purchased from 23 food groups; and iii) relative changes in nutrient composition of food purchased.

Results:

Food labelling and fiscal measures for both health and decarbonisation have a positive impact on dietary health, by reducing the calorie content of food purchases ($p < 0.001$). Adding carbon reduction considerations into health policies achieves nutritional improvement by further reducing fat and increasing fibre, resulting in a reduction of up to 193 kcal/person/day (95%CI: 172-214).

Conclusions:

With an additional focus on planetary health, the combined (health + carbon) tax and food labelling policies could achieve a reduction in calorie content at a magnitude close to the Public Health England's estimate of average excess calories consumed by adults (195kcal).

Key messages:

- Policies focused on achieving both nutrition and carbon reduction goals could achieve greater improvements in food choices and produce win-win scenarios.
- There is a need for greater dialogue and policy development between public health and environmental researchers, practitioners and policy makers.

Abstract citation ID: ckac129.416
The ultra-processed food content of school meals and packed lunches in the United Kingdom (2008-2017)

Jennie Parnham

JC Parnham[1], K Chang[1], F Rauber[2,3], RB Levy[2,3], S von Hinke[4], AA Laverty[1], C Millett[1], EP Vamos[1]

[1]Public Health Policy Evaluation Unit, Imperial College London, London, UK

[3]Department of Preventive Medicine, University of São Paulo, São Paulo, Brazil
[4]School of Economics, University of Bristol, Bristol, UK
Contact: j.parnham18@imperial.ac.uk

Background:

British children have the highest ultra-processed food (UPF) intake in Europe, which is linked to adverse health outcomes. Schools are posited as a setting for dietary intervention, yet the level of UPFs consumed at schools is currently unknown. This study aimed to describe the UPF content of school food in the UK, explore the UPF content of school meals and packed lunches (food from home) and examine whether UPF differs by children's household income.

Methods:

A pooled cross-sectional analysis of primary (4-11 years, n = 1,895) and secondary schoolchildren (11-18 years, n = 1,408) from the UK's National Diet and Nutrition Survey (2008-2017) was conducted. Food diaries recorded student's meal-type (school meal/packed lunch). UPF intake was defined using the NOVA food classification system. Quantile regression models assessed the association between meal-type and lunchtime UPF intake (%kcal and % grams). Models were stratified by school phase (primary/secondary) and interacted meal-type with income.

Results:

Schoolchildren consumed most of their lunch as UPF, with higher median intakes in secondary schoolchildren than primary schoolchildren (77.8 %kcal vs 72.6 %kcal). School meals were associated with lower median UPF intake (%kcal) in both primary (-20 percentage-points[pp] [95% CI -22.2, -17.4]) and secondary schoolchildren (-11pp [-16.0,-7.0]) compared with packed lunches. Results were similar when UPF %g was analysed. Overall, income was inversely associated with UPF content. However, in primary schoolchildren there was no significant income gradient in the UPF(%g) content of school meals.

Conclusions:

In the first nationally representative study, we showed that on average UPF intake was high in all UK schoolchildren. Higher UPF intakes were observed in packed lunch consumers, secondary schoolchildren, and those with a lower income. Procurement policies must be revaluated to protect children from high UPF intake.

Funders: NIHR School for Public Health Research

Key messages:

- In the first study of ultra-processed food content of UK school food, we show that children consumed around three quarters of their energy as ultra-processed food at lunch.
- Children who were older, took food from home or were from a low-income household were more likely to consume higher levels of ultra-processed food. Regulation is needed to protect these children.

Abstract citation ID: ckac129.417
Changes in retail food environments around schools over 12 years in Flanders, Belgium

Vincent Smets

V Smets[1], S Vandevijvere[1]

[1]Lifestyle and Chronic Diseases, Sciensano, Anderlecht, Belgium
Contact: vincent.smets@sciensano.be

Background:

Food environments influence food preferences, in particular among children. Besides their homes, children spend most of their time in and around the school. This study mapped changes in retail food environments around primary and secondary schools in Flanders between 2008 and 2020. In addition, associations between those indicators and children's weight status were assessed.

Methods:

The food environment near primary and secondary schools was mapped using three spatial indicators: 1) The density of different types of food retailers within 1000m road distance from the school entrance, 2) the percentage of schools with at least one food retailer of a certain type within 1000m road distance from the entrance, and 3) the median walking distance from the school entrance to the nearest food retailer of a certain type. Associations between the density of convenience stores, as well as fast food outlets around the schools and the weight status of the schools' children were assessed using generalized linear models adjusted for level of urbanization, socio-economic status of children at school level and sex.

Results:

Food environments near schools in Flanders were found to be unhealthy, with a significant increase in fast-food outlets and convenience stores between 2008 and 2020. Food environments near schools with a higher proportion of children from a poor socio-economic background were found more unhealthy than those near schools with a lower proportion of such children, regardless of the urbanization level. A significant positive association was found between the density of fast food outlets as well as convenience stores around primary schools and the weight status of children aged <6 years and 6-12 years.

Conclusions:

Food environments around schools in Flanders became more unhealthy over time and were associated with children's weight status. The government therefor has the responsibility to create healthy food environments near schools to protect children's health.

Key messages:

- The food environment near schools became more unhealthy between 2008 and 2020.
- The food environment near schools was associated with younger children's weight status.

7.F. Pitch presentations: Applying eHealth solutions

Abstract citation ID: ckac129.418
Implementing an eHealth tool to improve referral services for obstetric emergencies in Sierra Leone

Stefanie Theuring

S Theuring[1], *A Lewally*[2], *J Shepherd*[2], *R Williamson Taylor*[3]
[1]Institute of Tropical Medicine and International Health, Charité-Universitätsmedizin, Berlin, Germany
[2]National School of Midwifery, Ministry of Health and Sanitation, Freetown, Sierra Leone
[3]Princess Christian Maternity Hospital, Ministry of Health and Sanitation, Freetown, Sierra Leone
Contact: stefanie.theuring@charite.de

Background:

Maternal health remains a major issue of concern in Sierra Leone. In the main referral maternity institution, Princess Christian Maternity Hospital (PCMH), up to 25% of maternal deaths occur during or shortly after transit from another health facility. There is an urgent need to improve referral systems between peripheral health units (PHUs) and PCMH. Our aim was to pilot and evaluate an eHealth tool facilitating referral of obstetric emergency cases through effective teleconsultation between PHUs and PCMH.

Methods:

A web application was designed to capture unclear or complicated delivery cases at PHUs and request respective telemedical counselling from the referral institution PCMH. The eHealth tool was piloted at 10 PHUs in Western area urban and rural in August 2021. Necessary devices were provided and delivery staff was trained to use the app. In December 2021, we conducted focus group discussion with 3-6 delivery staff at five PHUs and at PCMH to evaluate utilization and outcomes of the tool.

Results:

All participants perceived the eHealth tool as an improvement of referral procedures. Response time from PCMH after a request for counselling from a PHU was mostly <30 minutes. The main perceived advantage of the tool was the systematic documentation of obstetric complications and procedures. This relieved staff from fear of wrong treatment accusations, and recorded communication with PCMH made processes and responsibilities transparent. Another important benefit was PCMH staff being already prepared to receive a specific emergency case after use of the app, thus reducing the 'third delay' within the referral facility. As a major obstacle to smooth referral despite the eHealth tool, a lacking ambulance system was mentioned as a critical gap.

Conclusions:

Exceedingly positive user experiences with this simple tool seem to make an expansion to more PHUs worthwhile. Benefits of using the app in more remote districts in Sierra Leone should be further investigated.

Key messages:

- Delivery staff in Sierra Leone was capable of using a web app for telemedical counselling in a useful and effective manner.
- The eHealth tool was perceived as very helpful in systematically and transparently documenting emergency delivery cases and treatment procedures.

Abstract citation ID: ckac129.419
Attitudes and experiences towards the IMMUNI App among Sapienza university students: a pilot study

Maria Roberta De Blasiis

MR De Blasiis[1], *C Isonne*[1], *F Turatto*[1], *E Mazzalai*[1], *C Marzuillo*[1], *C De Vito*[1], *P Villari*[1], *V Baccolini*[1]
[1]Public Health and Infectious Disease, Sapienza University, Rome, Italy
Contact: mariaroberta.deblasiis@uniroma1.it

Background:

IMMUNI is an app that was created to help fight epidemics, starting with COVID-19. The app has a contact tracing feature but its diffusion in Italy was low. In this pilot study, we investigated university students' attitudes and experience towards the IMMUNI app.

Methods:

This cross-sectional study was conducted at Sapienza University of Rome between 14 April and 19 April 2021. An online survey was administrated to university students of medical area. A multivariable logistic regression model was built to identify app download's predictors. Adjusted odds ratio (aOR) and 95% confidence interval (CI) were calculated.

Results:

We collected 247 questionnaires (response rate: 78.2%). More than half of the students (65.0%) didn't download IMMUNI app mostly because of the belief that it was useless (30.0%). By contrast, the main reason for downloading was sense of duty (40.0%). Experience with the app was limited but the process was judged as lacking for the technical difficulties. As for hypothetical incentives, feedback on how the download could help against the pandemic was considered as the most effective (3.5 out of 5). In the multivariable analysis, higher likelihood of download was associated with higher fear of contagion for family and acquaintances (aOR:1.50, 95% CI: 1.01-2.23) and higher rating to the health management of the emergency (aOR: 1.33, 95% CI:1.00-1.76). The highest odds of download were found for participants who have been advised to download the app (aOR: 3.21, 95% CI:1.80-5.73). On the other hand, greater belief that the virus came from a laboratory was negatively associated with the download (aOR: 0.75, 95% CI: 0.60-0.93).

Conclusions:

Strategies aimed at raising students' awareness on the importance of health technologies, restoring confidence in health authorities, and limiting disinformation around SARS-Cov-2 should be devised. In addition, the app could be enriched with positive feedbacks for users, and some technical issues should be fixed.

Key messages:

- The spread of digital technologies for public health purposes is fostered by trust in health institutions and improving health literacy and user engagement.
- An efficient and user-friendly technology is recommended.

Abstract citation ID: ckac129.420
The Italian investment in telemedicine: a breakthrough model of care in primary care

Alice Borghini

A Borghini[1], *D Mantoan*[1], *S Paone*[1], *I Leta*[1], *G Siccardi*[1]
[1]National Agency for Regional Health Services, AGENAS, Rome, Italy
Contact: borghini@agenas.it

Issue/Problem:

Aging populations, worsening burden of chronic disease and recent pandemic has accelerated awareness and the importance of telemedicine in providing continuity of healthcare.

Description of the problem:

AGENAS is the public body responsible for the implementation of telemedicine investment (€1 billion) in the context of the NextGenerationEU plan. AGENAS has built up a working group expert panel to define the technical and informatics features of the investment. The project consists of the realization of the national telemedicine platform and the regional telemedicine services. Italian regions will implement telemedicine services based on the national guidelines defined by AGENAS, that will also monitor it through key performance indicators outlined on the basis of best practices and scientific evidence of multidimensional evaluation.

Results:

National telemedicine platform will improve, optimise and standardise telemedicine services throughout the Country, considering what may already be available in regional and local healthcare contexts. Regarding telemedicine services in regional context, that will be implemented within the NextGenerationEU, they will be focused on the telemonitoring of high prevalence conditions (i.e. cardiological, respiratory, diabetes, neurological and oncological) as well as other services such as televisit, teleconsultation and teleassistance. Connecting patient's home with healthcare system provide benefits for patients and their families, who will be able to interact with healthcare professionals, obtaining consultation and monitoring of their health.

Lessons:

The implementation of the investment, aiming at improving equity and integration of care, will contribute to provide real world evidence about usage, benefits and potential risk of the telemedicine in primary care for the management of chronic diseases.

Key messages:

- The investment under the Next Generation EU plan it is the lifetime chance to transform Italian healthcare service and draw a new framework to cope with the high demand in telemedicine.
- Improving telemedicine services will determine a breakthrough in management of patient with chronic diseases in the Italian primary care sector.

Abstract citation ID: ckac129.421
Mobile phone filmmaking in health promotion. Addressing problematic social media use in Swedish youth

Heléne Dahlqvist

H Dahlqvist[1], *K Gillander Gådin*[1]
[1]Mid Sweden University, Sundsvall, Sweden
Contact: helene.dahlqvist@miun.se

Background:

Digital media is an important part in the everyday lives of young people. However, hate, threats, and harassment on social media is becoming a global public mental health issue among youth. To promote mental health in this age group, this issue needs to be addressed, and community-based health promotion, in particular participatory interventions, are needed to make measures taken meaningful for youth. The aim of the study was twofold; to teach participatory mobile phone filmmaking to Youth Community Center (YCC) staff; and to investigate how they assess this method regarding feasibility, relevance, costs, resources needed, and time considerations.

Methods:

YCC staff participated in a two-day mobile phone filmmaking training. Group interviews that were recorded and transcribed verbatim were conducted and field notes were taken. Data was deductively analyzed in accordance with Elo and Kyngäs (2008).

Results:

YCC staff found the technology was easily accessible and the method needs limited extra resources. It has the potential to promote creativity and can be used as a means to involve young people in describing the issue in their own words, and to find a solution to the issue at hand. The method also has the potential to reach and engage the whole community as organizing a mobile phone film event is part of the process. Time consumption was not perceived as an issue, as staff is free to plan activities as they see fit.

Conclusions:

According to YCC staff, participatory mobile phone filmmaking has the potential to promote positive interactions on social media among youth. This in turn has the potential to promote wellbeing of young people. Recommendations are that this method is tested among young people and investigate if it is a helpful intervention to promote mental health in this age group.

Key messages:

- Participatory mobile phone filmmaking may be useful in youth mental health promotion.
- The method is cheap, easily accessible, and have the potential to involve the whole community.

Abstract citation ID: ckac129.422
Application of the patient navigation model with people experiencing homelessness: a scoping review

Alejandro Gil-Salmerón

I Grabovac[1], *C Carmichael*[2], *L Smith*[2], *E Aldasoro*[3], *A Gil-Salmeron*[3], *T Alhambra-Borras*[4], *A Donate-Martinez*[4], *R Seiler-Ramadas*[1]
[1]Department of Social and Preventive Medicine, Medical University of Vienna, Vienna, Austria
[2]Centre for Health, Performance and Wellbeing, Anglia Ruskin University, Cambridge, UK
[3]International Foundation for Integrated Care, Oxford, UK
[4]Polibienestar Research Institute, University of Valencia, Valencia, Spain
Contact: Alejandrogilsalmeron@integratedcarefoundation.org

Background:

Barriers in accessing healthcare services are a common issue that contributes to the disproportionately poor health outcomes in people who experience homelessness. A possible way to overcome these barriers and meaningfully engage with this under-served population is through the implementation of the so called patient navigation (PN) models. We conducted a systematic scoping review to gain a better understanding on how PN models are utilized with people experiencing homelessness and other comparable populations and to identify their features, barriers and facilitators to their implementation and their outcomes.

Methods:

A systematic scoping review was done based on a predetermined protocol. We conducted a search of Web of Science, PubMed/Medline and Scopus databases on the 15th of June 2021. A narrative analysis of the included studies was conducted.

Results:

Our search yielded 1203 hits, and after removing 475 duplicates, we were left with 728 publications of interest.

Finally, 21 studies have been included in the review, comprising of nine review articles and 12 individual studies, with most studies stemming from the USA. Results show that PN models are consistently associated with improvements in a wide range of health related outcomes, mostly with timely access to healthcare services. Implementation strategies and measurements used in assessing PN models show heterogeneity between studies. However, a number of consistencies were found including; a longitudinal approach, using of non-clinical navigators who share similarities to the participant groups and who engage as facilitators. Additional considerations for gender and age may further improve the outcomes.

Conclusions:

In order to improve on the success of the PN models and their application in removing barriers to healthcare access for people experiencing homelessness, more research is needed that focuses on the feasibility, acceptability and scalability of the approach outside the USA.

Key messages:

- People experiencing homelessness experience considerable barriers in accessing healthcare service leading to disproportionately larger burden of disease as well as lower life expectancy.
- Patient navigation models have a great potential in removing barriers and facilitating timely access to healthcare services in people experiencing homelessness.

Abstract citation ID: ckac129.423
mHealth platform improved health worker's compliance to WHO's IMNCI guideline in Nairobi, Kenya

Elsie Sang

M Shah[1], *E Sang*[2], *A Afeworki*[2], *M McLaughlin*[3], *B Finette*[3], *L Kwamboka*[4], *D Ogaro*[4]
[1]Global Health, Save the Children US, Washington DC, USA
[2]Health and Nutrition, Save the Children International, Nairobi, Kenya
[3]THINKMD, Vermont, USA
[4]Langata Sub-county Health Management Team, Ministry of Health, Nairobi, Kenya
Contact: elsienzale.sang@savethechildren.org

Poor access to quality health services, especially in urban slums, is a global challenge. Given similar challenges in Nairobi's Kibra informal settlement area, we collaborated with the Langata/Kibra sub-county health management team to conduct a pilot program for improving the quality of child health services delivered by health care providers (HCPs). The pilot introduced a digital mHealth platform to HCPs working in Kibra informal settlement area in Nairobi. This mHealth platform was compliant to WHO's recommended guideline for integrated management of newborn and child illnesses (IMNCI) and was designed to help sick child assessment, diagnosis and management by HCPs. We aimed to determine if using this digital platform, coupled with supportive supervision and community outreach, would lead to improve compliance to the IMNCI guideline for assessment, diagnosis and treatment of sick children. We conducted baseline (February 2019) assessment, trained selected HCPs on the mHealth platform on handheld android tablets, conducted end line (March 2020) and measured any change in HCP's compliance to IMNCI guidelines. Total 89 HCPs were the mHealth platform users during end line assessment. When asked about the choice of antibiotic for treating childhood pneumonia, we found proportion of HCPs who preferred Amoxycillin dispersible tablet, the recommended treatment for childhood pneumonia, increased from 3% at baseline to 38% at end line. Proportion of HCPs who were aware that antibiotics should NOT be used for the management of simple diarrhea increased from 14% (at baseline) to 50% (at end line). At end line, more than 90% HCPs were found compliant in their practice to IMNCI guidelines for sick child assessment, diagnosis and management. These results demonstrate the use of the IMNCI compliant mHealth platforms as a potential important effective way to improve capacity and compliance among HCPs who are serving communities like Kibra informal settlement in Nairobi, Kenya.

Key messages:

- WHO recommended IMNCI compliant mHealth platform enables health care providers to offer quality child health care.
- Using mHealth platform to ensure WHO's IMNCI guideline implementation by health care providers might have potential impact on saving sick children's lives from preventable deaths.

Abstract citation ID: ckac129.424
Digitalization-induced changes in health and social care work - perceptions of professionals

Anu-Marja Kaihlanen

A Kaihlanen[1], *J Nadav*[1], *E Kainiemi*[1], *T Heponiemi*[1]
[1]Finnish Institute for Health and Welfare, Helsinki, Finland
Contact: anu.kaihlanen@thl.fi

Background:

Digitalization has increased rapidly in health and social care and plays an increasingly important role in the daily work of health and social care professionals. The effects of digitalization are often viewed from the societal and economic perspectives, and less from the perspective of the changing health and social care work. This study examined how health and social care professionals perceive the effects of digitalization on their work.

Methods:

Eight semi-structured focus-group interviews were conducted in four Finnish health centers at the end of 2020. The participants ($n = 30$) were nurses, physicians, and social workers. Qualitative content analysis with inductive approach was used to analyze the data.

Results:

Four main categories emerged from the perceived effects of digitalization: 1) two-way changes in workload and pace (reduced/increased work, accelerated/slowed pace of work, duplication of work/saved employee resources), 2) changes in the content and nature of work (reallocation of work, emergence of new tasks, new skills needs, diversification of service provision), 3) changes in work community communication and interaction (improved interaction and communication, strengthened multidisciplinary collaboration, complicated remote interaction, reduced encounters) and 4) improved flow of patient information and information security (improved data transfer, patient monitoring and data protection).

Conclusions:

Digitalization-induced changes in health and social care work seem to be manifold and often two-sided. It has the potential to ease the work and offer other benefits, but at the same time it may complicate work in other respects, especially if the system does not support work tasks or the usability is poor. When implementing new digital services and pursuing benefits, more attention should be paid to assessing and considering the potential disadvantages to minimize additional strain among already burdened health and social care professionals.

Key messages:

- The perceived effects of digitalization on health and social care work are often two-sided and can contribute to the well-being of professionals.
- Monitoring the use of digital services and the experiences of professionals about them, as well as identifying their skills needs and training aspirations is crucial.

Abstract citation ID: ckac129.425
Presenting a Social Value Database and Simulator for Public Health

Andrew Cotter-Roberts

A Cotter-Roberts[1], *K Ashton*[1], *A Stielke*[1], *M Dyakova*[1]
[1]WHO CC, Public Health Wales, Cardiff, UK
Contact: Andrew.Cotter-Roberts@wales.nhs.uk

Background:
There is increasing recognition that Public Health Institutes need to build on the traditional value for money approach, to find ways to capture, measure and show the full range of their outcomes, impacts and related value. As part of a drive to measure value and impact in public health and demonstrate how investment in health can contribute to an Economy of Well-being, Public Health Wales has developed an interactive database to capture and illustrate the social value of public health services and interventions.

Methods:
Scoping reviews of both academic and grey literature were undertaken to populate a database of health economics evaluations of public health interventions, focusing on Social Return on Investment (SROI). In addition, a simulated methodology was developed which allows the evidence to be manipulated and made relevant to individual contexts to help inform investment decisions at a local level.

Results:
To date, the database has accumulated an excess of 50 SROI evaluations of various public health interventions, across areas including mental health, behaviour change, physical activity, nutrition, employment and primary care. The evaluations are based on European and International contexts, are published in both grey and academic sources, and are of varying quality.

Conclusions:
SROI is a credible method for measuring the value of wider social, economic and environment outcomes achieved from public health interventions. The Social Value Database and Simulator presents a collation of studies and analysis utilising innovative health economics methods.

Key messages:
- Public Health Wales' Social Value Database and Simulator collates economic evaluations of public health interventions, to be used by policy makers to enable improved investment in health and well-being.
- Social Return on Investment is a credible method for measuring the wider impact created by public health interventions.

Abstract citation ID: ckac129.426
Validity of self-reported diseases from health surveys: comparisons with registry data in Denmark

Heidi Rosendahl

H Rosendahl[1], *CJ Lau*[2], *M Davidsen*[1], *O Ekholm*[1], *AI Christensen*[1]
[1]Danish National Institute of Public Health, Copenhagen K, Denmark
[2]Center for Clinical Research and Prevention, Frederiksberg, Denmark
Contact: harj@sdu.dk

Background:
The validity of self-reported disease prevalence estimates in health surveys may be low when compared to data from medical records in administrative registers. Such discrepancies reflect a low content validity of the survey question, which may ultimately compromise the application of these survey data for public health purposes. The aim of the present study was to examine the agreement of self-reports of seven diseases with data from administrative registers, both overall and by sociodemographic characteristics.

Methods:
Prevalence estimates of self-reported current and/or previous diabetes, asthma, rheumatoid arthritis, osteoporosis, myocardial infarction, apoplexy, and cancer, respectively, were derived from the Danish National Health Survey in 2017 ($n = 183{,}372$ adults aged ≥ 16 years). Individual-level data were linked to registry data on the same diseases. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), kappa, and total agreement between self-reported and registry-documented prevalence estimates were examined.

Results:
For all included diseases, the specificity was >92%, and the sensitivity varied between 59% (cancer) and 95% (diabetes). NPV was >94% for all diseases and PPV varied between 13% (rheumatoid arthritis) and 93% (cancer). Total agreement varied between 91 % (asthma) and 99% (diabetes), whereas kappa was lowest for rheumatoid arthritis (0.21) and highest for diabetes (0.88). Sociodemographic variables were significantly associated with total agreement with sex, age, and educational level exhibiting the strongest associations.

Conclusions:
Overall, total agreement, specificity, and NPV between self-reported and registry-documented disease prevalence estimates are high, but PPV and kappa vary greatly between diseases. The latter findings reflect a low content validity of the applied survey question for specific diseases. This should be taken into account when interpreting similar results from surveys.

Key messages:
- The validity of self-reported disease prevalence estimates may be low when compared to data from medical records. We found positive predictive values and kappa to vary greatly between diseases.
- Future studies should aim at designing survey questions properly in order to ensure a high content validity of the applied question.

European HPC cloud infrastructure for managing SARS-CoV-2 data in compliance with GDPR

Chiara Dellacasa

C Dellacasa[1], *M Ortali*[1], *E Rossi*[1], *M D'Antonio*[1], *T Osmo*[2], *F Prasser*[4], *M Puskaric*[3], *E Rinaldi*[4], *Orchestra Working Group*[5], *G Scipione*[1]
[1]HPC Department, CINECA Consorzio Interuniversitario, Casalecchio di Reno, Italy
[2]CINES Centre Informatique National de l'Enseigneme, Montpellier, France
[3]High Performance Computing Center Stuttgart (HLRS), Stuttgart, Germany
[4]Berlin Institute of Health (BIH), Charité, Berlin, Germany
[5]ORCHESTRA Consortium, Verona, Italy
Contact: c.dellacasa@cineca.it

The Connecting European SARS-CoV-2 Cohorts to Increase Common and Effective Response to SARS-CoV-2 Pandemic (ORCHESTRA) consortium, led by University of Verona (Italy), brings together key European academic experts and research institutions in infectious diseases, data management and High Performance Computing (HPC) from 26 organizations (extending to 37 partners) from 15 countries. The project aims to create a new pan-European cohort built on existing and new large-scale population cohorts in European and non-European countries to significantly impact on the responsiveness to SARS-CoV-2. The integration and analysis of the very heterogeneous characteristics of SARS-CoV-2 data coming from many different sources such as EHR, retrospective and prospective patient registries, and related ‘omics’ data (incl. genomics, proteomics and transcriptomics) can benefit of data analytics enabled by HPC, where both high compute performance and fast storage capabilities are immensely important. During the first year of the project, a dedicated HPC cloud infrastructure have been designed and partially deployed to fulfill the functional requirements for data management ensuring healthcare data confidentiality/privacy, integrity and security in compliance with the European GDPR regulations. The result is an infrastructure for Data Management composed by three main layers: National Data Providers; National Hubs (one for each HPC center involved: CINECA - Italy, CINES - France and HLRS - Germany), to centralize data at national level and to support data storage, sharing and analysis on data ingested from the National Data Providers; ORCHESTRA Data Portal: the pan-European portal for sharing aggregated data and results. Currently data collection is on going; at the end of the project, clinical centers are expected to have enrolled more than 10.000 patients with about 50.000 samples for the prospective studies.

Key messages:

- The SARS-CoV-2 crisis made evident the need to manage and analyse very heterogeneous health data coming from many different resources across different countries.
- The HPC cloud infrastructure released for the Orchestra project can act as a model to manage future public health threats.

Abstract citation ID: ckac129.428
Cost-effectiveness of two psychological treatments for the reduction of alcohol consumption

Sergio Flores

S Flores[1], *I Feldman*[1], *F Sampaio*[1]
[1]Institute for Public Health and Caring Sciences, Uppsala University, Uppsala, Sweden
Contact: sergio.flores@pubcare.uu.se

Background:

Up to 7% of the Swedish population meets criteria for harmful use or alcohol dependency but only 10-20% seek treatment. One of the most recommended psychological treatments for controlled drinking is Motivational Enhancement Therapy (MET). Behavioural Self-Control Training (BSCT) is another treatment that is unique in that it is based on the psychology of learning and specifically focused on skills training. To our knowledge, no previous studies exist that evaluated the cost-effectiveness of BSCT for alcohol use disorders (AUD). The aim of this study is to assess the cost-effectiveness of BSCT compared to MET for patients with AUD aiming for controlled drinking over the longer-term from a societal perspective.

Methods:

We modelled a cohort of patients with AUD who aim for controlled drinking, over a 10 year time horizon, and estimated the expected costs and outcomes of BSCT and MET. The model reflects the epidemiological transitions between drinking states, which reflect different levels of daily alcohol intake. Each drinking state is connected to temporary or long-term complications attributable to alcohol consumption, different costs and utilities. The data was sourced from a randomized trial evaluating the effectiveness of MET vs BSCT. Risks for complications and associated costs, utilities and mortality were sourced from the literature.

Results:

Compared to MET, BSCT resulted in less total QALYs gained (4,7 vs 6,6 QALYs per patient). MET remains a cost effective treatment compared to BSCT [incremental cost-effectiveness ratio (ICER) = SEK 8497,79 per gained QALY] and a No Intervention scenario BSCT [incremental cost-effectiveness ratio (ICER) = SEK 16321,07 per gained QALY] at a threshold of 500.000 SEK per QALY.

Conclusions:

This study suggests that MET should remain the recommended treatment for AUD patients with a goal of controlled drinking in favor of BSCT.

Key messages:

- Motivational Enhancement Therapy should remain the recommended treatment for AUD patients with controlled drinking as their goal.
- A future study comparing Motivational Enhancemente Therapy to Behaivoral Self Control Training as recommended treatment in patients wanting to achieve abstinenece is suggested.

Abstract citation ID: ckac129.429
Personalised Medicine in shaping sustainable healthcare: a Delphi survey within the IC2PerMed project

Flavia Beccia

F Beccia[1], *FA Causio*[1], *S Farina*[1], *C Savoia*[1], *T Osti*[1], *M Di Marcantonio*[2], *A Morsella*[2], *C Cadeddu*[1], *W Ricciardi*[1], *S Boccia*[1,3]
[1]Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Faculty of Economics, Università Cattolica del Sacro Cuore, Rome, Italy
[3]Public Health Area, Fondazione Policlinico A. Gemelli IRCCS, Rome, Italy
Contact: flavia.beccia01@icatt.it

Background:

Personalised medicine (PM) has the potential to transform health systems and make them more sustainable, by making the population healthier and allocating resources efficiently. European Union and China have become world leaders in the field of PM, increasing collaborations worldwide. In this context, the EU Commission in 2020 launched the IC2PerMed (Integrating China in the International Consortium for Personalised Medicine) project to provide key solutions to enable the convergence of European and Chinese stakeholders toward a common approach in PM.

Methods:

From a mapping exercise of policies and programs in PM in EU and China, we identified 20 priority items for shaping sustainable healthcare. Such items were submitted to several Chinese and European experts in PM involved in a 3-round Delphi survey. Experts were asked to review the items’ content and rate their validity and relevance on a 5-point Likert scale. Priorities reaching a Content Validity Index of more than 79% were included, between 70 and 79% were revised, and less than 70% were excluded.

Results:

Of 20 priorities submitted, 9 reached consensus. The priorities hinge on the resources allocation, defining in advance priority investment, and identifying new payment models for public reimbursement, health technology impact, and assessment importance, while integrating end-user perceptions into the whole innovation process. In addition, the pivotal role of multidisciplinary and cross-sectorial collaborations emerged. Ethical, legal, and social implications and the related costs should be always considered in policymaking, evaluation, and management of technological innovation.

Conclusions:

Integrating resources and setting a clear agenda for the implementation of PM would lead to a faster and more efficient translation into clinical practice. Developing policies valuing all the stakeholders’ contributions would implement PM adoption.

Key messages:

- Healthcare systems sustainability is a priority and PM could make the population healthier and help allocate resources more efficiently, hence reducing the overall costs of healthcare.

- The inter-sectoral collaborations in healthcare are fundamental to achieving the best standard of care. All stakeholders and policymakers should engage to foster sustainability.

Abstract citation ID: ckac129.430
Validation of a national checklist for continuous service improvement in a decentralised framework

Michele Tancredi Loiudice

F Cardinali[1], *S Carzaniga*[1], *L Martini*[2], *M Loiudice*[1], *F Carinci*[1,3]
[1]Quality, Safety and Good Practices, Italian National Agency for Regional Health Services, Rome, Italy
[2]Continuous Medical Education, Italian National Agency for Regional Health Services, Rome, Italy
[3]Department of Statistical Sciences, University of Bologna, Bologna, Italy
Contact: m.loiudice@tiscali.it

Background:

Previous studies allowed defining a novel checklist for the participatory evaluation of person-centredness in hospital care using 243 items, grouped in 4 main areas, 12 sub-areas and 29 criteria. We aimed to validate a reduced set of core items that could be continuously used for service improvement in Italy.

Methods:

Validation was performed using data collected during the last national survey carried out in 2017-2018 in N = 387 acute care hospitals from 16 out of 21 Italian regions. Descriptive measures for each item were used to assess eligibility for factor analysis, applied separately on each of the 4 main areas originally identified. Varimax rotation with eigenvalues>1 was used to optimise factor structure. Items with an item-total correlation>0.30 and factor loadings>0.4 were attributed to individual factors. Items with inter-item correlation coefficient>0.70 were included in a list of candidate mergers, submitted to expert opinion. Cronbach's alpha was used to assess overall internal consistency.

Results:

A total of 183 out of 243 items included in the original checklist were submitted to factor analysis. Overall values of Cronbach's alpha ranged between 0.77-0.90, indicating a high consistency. A total of 67 items were finally attributed to 4 main areas, allocated as follows: 16 items in 4 sub-areas for 'Person-oriented organisational and care processes', 16 items in 4 sub-areas for 'Physical accessibility, livability and comfort of the facilities', 15 items in 3 sub-areas for 'Access to information, streamlining and transparency', and 20 items in 4 sub-areas for 'Taking care of the relationship with patients and citizens'.

Conclusions:

A simplified checklist including a manageable number of items that can be easily managed to evaluate hospital services was identified through an objective validation process. The national experience can provide valuable lessons for the application of participatory approaches of person-centred care.

Key messages:

- A standardised checklist has been validated using survey data collected through a participatory process in Italian regions.
- The checklist can be used to evaluate and improve person-centered hospital services through a manageable number of items and factors.

Burden of disease assessment for Germany and its regions – results from the BURDEN 2020 study

Michael Porst

M Porst[1], *E von der Lippe*[1], *A Wengler*[1], *J Leddin*[1], *A Anton*[1], *A Rommel*[1]
[1]Epidemiology and Health Monitoring, Robert Koch-Institute, Berlin, Germany
Contact: porstm@rki.de

Background:

Epidemiological measures such as incidence, prevalence, or deaths are essential for monitoring population health. However, evaluating them in isolation cannot adequately compare and assess the relative importance of different diseases. Assessments of the burden of disease (BoD) are therefore of growing importance in supporting health policy decisions. Using disability-adjusted life years (DALY) as a summary measure of population health, BoD integrates morbidity and mortality in a transparent approach.

Methods:

Within BoD methodology, deviations in the health of the population from an 'ideal' health status is quantified in the unit of life years. DALY are the sum of years of life lost due to death (YLL) and years lived with disability (YLD). While YLL describe the gap between age at death and statistical life expectancy, the indicator YLD quantifies years lived with a disability or disease. Calculations were based on different primary and secondary data sources for Germany, especially cause-of-death statistics, epidemiological survey data, and statutory health insurance data.

Results:

In Germany, there were about 12 million DALY in 2017, the equivalent of 14,584 DALY per 100,000 population. Coronary heart disease contributes the most to the overall burden of disease, followed by lower back pain and lung cancer. In women, headache disorders and dementias account for more DALY as compared to men. Men have a higher burden of disease from lung cancer or alcohol use disorders. Pain disorders and alcohol use disorders lead the DALY rankings for both sexes in younger adulthood. The burden due to cardiovascular disease, COPD, and diabetes mellitus increases with age and also varies by region.

Conclusions:

The results suggest age- and gender-specific prevention as well as regional health care needs. BoD studies therefore provide comprehensive data for population health surveillance and can support health policy decisions.

Key messages:

- The importance of specific diseases as measured by DALY differs greatly by age and gender, highlighting the need for targeted prevention measures.
- Regional patterns emerge for cardiovascular disease, COPD, and depressive disorders, among others, which may indicate health care needs.

7.H. Workshop: Lessons Learned Workshop from JAHEE- the importance of evaluation

Abstract citation ID: ckac129.432

Organised by: JAHEE
Chair persons: Raffaella Bucciardini (Italy), Bernadette Kumar (EUPHA-MIG)
Contact: raffaella.bucciardini@iss.it

Joint Action Health Equity (JAHEE) was a Joint Action financed by the Third Health Programme 2014-2020 of the European Union. It was developed in the period June 1, 2018 - November 30, 2021, and involved 24 countries. It represented an important opportunity for member states to work together to address health inequalities and achieve greater equity in health outcomes across all groups in society in all participating countries and in Europe at large. The results of JAHEE show that almost all participating countries have increased their level of action to address health inequalities and strengthened their capacities in some important policy domains. 76 actions to contrast health inequalities were started during the Joint Action and a final Consensus Policy Document was produced including a set of cross-cutting recommendations. The proposed workshop will discuss the 3-year JAHEE project in the European region and through presentations and active participation review JAHEE actions, results of internal and external evaluations and discuss the main lessons learned. The session will go beyond sharing information and disseminating results and focus on what the JAHEE evaluation has taught us and how it can help improve health equity interventions in the future.

We plan to have:
a) Presentations
1. Short introduction to JAHEE and Actions
2. Presentation Internal Evaluation
3. Presentation External Evaluation

After the presentations there will be opportunity for interactive sessions with the participants to further explore the case studies and issues raised around evaluation and equity

b) Interactive Group Discussion
- What do the JAHEE evaluations findings add?
- What aspects of the evaluation were missing? What could have been improved?
- How can the lessons learned from the evaluation be applied to interventions in equity/ migrant health?

3) Feedback from Groups
4) Summary and Conclusions

Key messages:
- No data no progress.
- Apply an equity lens: Evaluation in health equity actions is important for the sustainability of actions and contributes to the implementation of good practices.

Abstract citation ID: ckac129.433
Short introduction to JAHEE and Actions

Giuseppe Costa

G Costa[1]
[1]Piemonte Region, Turin, Italy
Contact: giuseppe.costa@epi.piemonte.it

Reducing health inequalities is on the agenda of many countries. Despite an increasing concern and awareness on health inequalities a wide gap exists in Europe in terms of political response. The main objective of JAHEE was to strengthen a cooperative approach among participating countries and implement concrete actions to reduce health inequalities. The partnership was composed of 24 countries including many strategically most relevant public health institutions in the European Union, which contributed with different backgrounds, skills and know-how to the achievement of the project objectives. The main results will be presented.

Abstract citation ID: ckac129.434
JAHEE internal evaluation

Apostolos Vantarakis

A Vantarakis[1]
[1]Department of Public Health Medical School, University of Patras, Athene, Greece
Contact: avanta@upatras.gr

The evaluation of the project for both the intermediate and the final report was based on an internal evaluation conducted by Work Package on Evaluation and on an external evaluation conducted by the Center for Global Health Inequality Research (CHAIN). The project evaluation as based on systematic and continuous monitoring of processes, outputs and outcomes indicators aimed to guarantee the achievement of the planned objectives and the identification of the lessons learned for future health inequalities programs. The main results will be presented.

Abstract citation ID: ckac129.435
JAHEE external evaluation

Mirza Balaj

M Balaj[1]
[1]Center for Global Health Inequality Research, Norwegian University of Science and Technology, Oslo, Norway
Contact: mirza.balaj@ntnu.no

The general aims and evaluation blocks concerned the extent to which JAHEE achieved its objectives, and the identification of lessons learned for future health inequalities programmes. More specific aims included: • Producing knowledge: to understand the outcomes of JAHEE and build knowledge on health inequalities. • Influencing decision-making: to produce results that can guide the development of policies and initiatives tackling health inequalities. • Accountability: to clarify responsibilities and outcomes of JAHEE. • Lessons learned: to provide recommendations for future initiatives.

The evaluation was grounded in five evaluation blocks: relevance, effectiveness and impact, sustainability, dissemination, and added value. The main results will be presented.

Abstract citation ID: ckac129.436
Interventions on health equity in the future

Terje Andreas Eikemo

TA Eikemo[1]

A final reflection on the importance of evaluation aspects will be proposed at the end of the workshop.

7.J. Pitch presentations: Occupational health and social support

Abstract citation ID: ckac129.437
Labor and social protection gaps impacting health of non-standard workers: An international study

Signild Kvart

S Kvart[1], *I Cuervo*[2], *V Gunn*[1,3,4], *S Baron*[2], *T Bodin*[1,5], *PWR Consortium*[1]
[1]Unit of Occupational Medicine, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden
[2]Commoner Center Health and Environment, Queens College, City University of New York, Flushing, USA
[3]Lawrence S. Bloomberg Faculty of Nursing, University of Toronto, Toronto, Canada
[4]MAP Centre for Urban Health Solutions, Li Ka Shing Knowledge Institute, Toronto, Canada
[5]Center for Occupational and Environmental Medicine, Stockholm Region, Stockholm, Sweden
Contact: signild.kvart@ki.se

Background:

Labor regulations and social protection structures are intended to protect workers, but the needs of those in precarious and non-standard employment (NSE) are often missed, which may negatively impact health and well-being. The aim of this research is to document how workers in NSE in six countries - Belgium, Canada, Chile, Spain, Sweden, and the US - with varying policy contexts experience aspects of employment that are linked to health.

Methods:

We employed a mixed methods approach for this study. To understand policy contexts, we analyzed country-level labor regulatory and social protection frameworks using 2019 Organization for Economic Cooperation and Development data. To understand the experiences of workers in NSE, we conducted 250 in-depth interviews with workers at different levels of employment precariousness between January and June 2021.

Results:

Overall, European countries have the most social expenditures and North American countries have the weakest labor market regulations. In all these varying contexts, workers in NSE reported multiple unmet needs, e.g., inadequate paid sick and parental leave and unemployment compensation. These unmet needs occur due to various barriers, including poor enforcement, legal loopholes, or required minimum employment time. Workers' living accommodations are also affected, as home financing or rental contracts are dependent on permanent employment. In response, they tended to rely disproportionately on individual or family resources for financial and social support rather than on government or employer resources.

Conclusions:

Findings suggested that diverse labor regulatory and welfare regime contexts are unsupportive of workers in NSE due to multiple gaps in policies essential to public health. The shifting of responsibility for key employment and social supports to individuals and their families is likely to increase health inequities for workers in NSE.

Key messages:

- Our study documents multiple policy gaps affecting key employment-related social determinants of health among workers in NSE.
- This occurred across diverse labor and social structure contexts in six countries.

Abstract citation ID: ckac129.438
The influence of onset of disease on exit from paid employment among workers in The Netherlands

Roos Hijdra

RW Hijdra[1], *SJW Robroek*[1], *A Burdorf*[1], *M Schuring*[1]
[1]Public Health, Erasmus Medical Center, Rotterdam, Netherlands
Contact: r.hijdra@erasmusmc.nl

Background:

This study investigates the influence of onset of disease on exit from paid employment, and whether this differs across diseases and sociodemographic groups.

Methods:

Register data from Statistics Netherlands on medication prescription was linked to information on employment status and demographics. Persons who were employed in 2009 and 2010, and who did not use medication for the selected disease in 2009 (n = 5,889,036) were followed-up during 9-years. Six diseases were identified based on medication prescription in 2010 and 2011: cardiovascular diseases, inflammatory diseases, diabetes mellitus, respiratory diseases, psychological disorders, and psychotic disorders. Four pathways out of paid employment were defined: disability benefits, unemployment, no income, and early retirement. Cause-specific Cox Proportional Hazards regression analyses were performed, with interaction terms for age, sex, and migration background.

Results:

Onset of disease increased the likelihood to exit paid employment, with strongest associations for psychotic disorders (HR 2.91, 95% CI 2.81-3.02) and psychological disorders (HR 2.01, 95%CI 1.98-2.04). Onset of disease was most strongly associated with disability benefits, followed by unemployment. The influence of psychological and psychotic disorders on disability increased until around middle-age, after which it decreased. The influence of mental health problems on exit from paid employment was stronger for persons with a non-native Dutch background and males.

Conclusions:

Onset of diseases, especially mental health disorders, is a risk for early exit from paid employment. Effective interventions are needed to enhance an inclusive workforce and prevent involuntary loss of paid employment.

Key messages:

- Onset of all diseases increased the likelihood of exiting paid employment, through disability benefits, followed by unemployment.
- Onset of psychological and psychotic disorder had the strongest association with exiting paid employment, especially among males and workers with a migration background.

Abstract citation ID: ckac129.439
Workplace social support, mental health and work functioning among young workers

Samira de Groot

S de Groot[1,2], *K Veldman*[1,2], *BC Amick III*[3], *U Bültmann*[1,2]
[1]Health Sciences, Community and Occupational Medicine, University of Groningen, Groningen, Netherlands
[2]Health Sciences, Community and Occupational Medicine, University Medical Center Groningen, Groningen, Netherlands
[3]Winthrop Rockefeller Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, USA
Contact: s.de.groot02@umcg.nl

Background:

Young adults with a history of mental health problems (MHPs) report lower work functioning (WF) compared to their peers without a history of MHPs. The identification of modifiable, protective workplace factors, such as workplace social support, is needed to increase WF.We examined the moderating role of workplace social support from supervisors and co-workers in the prospective association between MHP trajectories from childhood to young adulthood and WF among young adults.

Methods:

The most recent 2019/2020 data of N = 861 young workers, participating in the 18-year follow-up Dutch TRAILS (TRacking Adolescents' Individual Lives Survey) cohort study, was used. MHP trajectories for internalising and externalising problems included measurements at ages 11, 13, 16, 19, 22 and 26. Supervisor and co-worker social support were measured at age 29. WF was assessed at age 29. Logistic regression analyses were conducted to examine the moderating role of workplace social support in the association between MHP trajectories and WF.

Results:

Four trajectories were identified for both internalising and externalising problems. Young adults with high-stable MHP trajectories reported more often low WF (ORs 3.73 (95% CI 2.28-6.12) and 2.88 (1.78-4.65) for internalising and externalising problems respectively) than those with low-stable trajectories. Higher supervisor and co-worker social support were associated with a lower odds for low work functioning (adjusted ORs ranging from 0.67 (0.54-0.83) to 0.84 (0.71-1.00)). No moderating effect of workplace social support was found for the association between MHP trajectories and WF.

Conclusions:

Both supervisor and co-worker support were shown to be important for all young workers, regardless their history of mental health problems. Occupational health professionals should create awareness among employers and employees that workplace social support is beneficial for young adults' work functioning.

Key messages:

- Both supervisor and co-worker social support are important for all young workers' work functioning, regardless of their history of mental health problems.
- Creating awareness of the impact of workplace social support on young adults' work functioning among employers and employees should be a priority area for occupational health practice and policy.

Abstract citation ID: ckac129.440
Individual differences in sustainable working life: genetic and environmental contributions

Pia Svedberg

P Svedberg[1], *J Narusyte*[1,2], *A Ropponen*[1,3]
[1]Divsion Insurance Medicine, Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden
[2]Center for Epidemiology and Community Medicine, Stockholm County Council, Stockholm, Sweden
[3]Center of Work Ability and Working Careers, Finnish Institute of Occupational Health, Helsinki, Finland
Contact: pia.svedberg@ki.se

Background:

Previous research of aetiology of interruptions in working life have shown that both genetic and environmental factors contribute to individual differences in sickness absence (SA) and disability pension (DP). However, we still lack knowledge about etiological factors contributing to sustainable working life. The aim was to study the importance of genetics, shared (mainly childhood) environmental factors, and individual (unique) environmental factors for remaining in the work force over the life-course, i.e., having a sustainable working life.

Methods:

The study population include 108,275 twin individuals born 1930-1990 (53% women) with comprehensive national register data on social security, health, and demographic factors. We utilized two measures of sustainable working life: 1) employed at least two consecutive years (n = 21,348), without interruptions due to SA (>14 days), DP, or unemployment; 2) 22-years of sustainable working life, i.e., those who were employed all years from 1994 to 2016 (n = 12,931) without SA (>14 days), DP, or unemployment. Old-age pension, emigration, or death were censored. The final sample included same-sexed twin pairs of known zygosity; monozygotic pairs n = 11,403 and dizygotic pairs n = 13,354. Classical twin modelling was applied to estimate the relative contributions of genetic and environmental factors to individual differences in sustainable working life.

Results:

Individual differences for two consecutive years of sustainable working life were explained by genetics 36%, shared environment 8%, and unique environmental factors 56%. For 22-years of sustainable working life genetics accounted for 18%, shared environment 46%, and unique environmental factors for 37% of individual differences.

Conclusions:

Individual variation in sustainable working life is due to both genetic and environmental factors. Environmental experiences that twin siblings share while growing up is of importance, especially for long-term sustainable working life.

Key messages:

- Childhood environmental circumstances as well as environmental exposures later in life seem to outweigh genetic influences on long-term sustainable working life.
- From a public health perspective, the importance of family and surrounding environment on sustainable working life implies a potential for workplace or societal interventions, or individual support.

Abstract citation ID: ckac129.441
Sources of perceived social support and emotional difficulties in late adolescence

Viveca Östberg

V Östberg[1], *SB Låftman*[1], *J Raninen*[2,3]
[1]Centre for Health Equity Studies, Department of Public Health Sciences, Stockholm, Sweden
[2]Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden
[3]Centre for Alcohol Policy Research, La Trobe University, Melbourne, Australia
Contact: vostberg@chess.su.se

Background:

Late adolescence is a life phase when mental health problems are common. Social support is, however, associated with less problems. Social support stems from different sources with the family being the main provider in early life while friends gain in importance during adolescence. Using the Multidimensional Scale of Perceived Social Support (MSPSS), this study investigates the relative importance of different sources of support for emotional difficulties in girls and boys.

Methods:

Data was derived from the Swedish population-based cohort study Futura01 (girls: n = 2105, boys: n = 1673). Adolescents in the final year in compulsory school (aged 15-16 years) were sampled in 2017 and followed up in 2019 (aged 17-18 years). Perceived social support was measured at 17-18 years by the MSPSS scale. Emotional difficulties were measured at 15-16 and 17-18 years by the Strengths and Difficulties Questionnaire (SDQ) subscale. Linear regression analysis was used to study associations between support sources and emotional difficulties at 17-18 years, adjusting for all support sources, family type, upper secondary school program as well as prior emotional difficulties.

Results:

Among girls, emotional difficulties were associated with perceived support from family (b = -0.22; 95% CI -0.29; -0.15) and friends (b = -0.26; 95% CI -0.35; -0.18) but not significant others (b = 0.00; 95% CI -0.10; 0.11). Among boys, emotional difficulties were associated with support from family (b = -0.10; 95% CI -0.18; -0.02), friends (b = -0.17; 95% CI -0.25; -0.09) and significant others (b = -0.13; 95% CI -0.22; -0.04).

Conclusions:

The negative association between perceived social support and emotional difficulties, irrespective of prior emotional difficulties, suggests that support has a protective effect. In late adolescence, support from friends and, to a similar degree, the family seems to matter for mental health. Support from significant others did however not show a protective effect in girls.

Key messages:

- Adolescents aged 17-18 years with higher levels of perceived social support report less emotional difficulties.
- Efforts to increase family and friend support are relevant for adolescent mental health.

7.K. Workshop: The implementation of ''Good or Best Practices'': what can we learn from each other?

Abstract citation ID: ckac129.442

Organised by: RIVM (Netherlands), BZgA (Germany), Finnish Institute of Health and Welfare
Chair persons: Djoeke Dale Van (Netherlands), Christin Rossmann (Germany)
Contact: djoeke.van.dale@rivm.nl

Introduction:

The value of evidence-informed development and implementation of public health measures and practices - often called ''good'' or ''best practices'' - has been widely acknowledged in order to effectively address public health challenges. Yet information on such measures and practices remains insufficiently accessible to practitioners, policy and decision-makers. On a national level, several European countries have developed ''Best Practice Portals'' in order to support the uptake, implementation and dissemination of acknowledged public health best practices or policies.

Objective:

Six countries in Europe with a national ''portal'' have recently compared the rationale, structure, and processes used by their respective national portals, gaining first insights into how development and implementation of best practices can be further supported from a national level. The workshop will present these first insights, as well as further promising approaches to facilitate access to best practices, such as innovative digital tools which local public health actors, policy and decision-makers may use to inform selection of best practices for their contexts.

Methods:

The workshop starts with three presentations to introduce and to illustrate the topic. In the second half of the workshop we ask for an active contribution of the participants. For interaction, the open space method will be used.

Programme:

1. Three presentations of 10 minutes with 1-3 questions:
- The presentation of the results of a survey in Poland assessing the decision-makers' needs with regard to the implementation of best practices/evidence-informed policymaking
- A descriptive case comparison of six European program registries and the European Best Practice Portal, illustrating different approaches to support implementation of evidence-informed public health measures and practices
- Presentation of a digital tool to support evidence-informed planning and implementation of healthy and active environments by local public health actors

2. Discussion with the open space method (20 min)

In each of the four corners of one room, there is a flipchart with a moderator and a discussion question. Every participant is free to choose one of the flipcharts to discuss the topic with other participants who have chosen the same topic. The participant is free to go to another corner if he/she wants to join also other discussions. Discussion topics are:

- What are the advantages and limitations of national best practice portals in supporting the implementation of evidence-informed practices?
- What are other strategies to improve implementation and what makes them successful?
- How digital planning tool can be useful in evidence-informed planning and implementation??
- How can national portals collaborate with the EU Best practice portal?

3. Conclusion (10 min): every flip chart moderator reflects on their discussion, presenting 3 of the most important findings.

Key messages:

- National best/good practice portals have an important role to play in supporting the implementation of good/best practices.
- Different strategies should be employed to facilitate implementation of evidence-informed practices.

Abstract citation ID: ckac129.443
The way from stakeholders' needs research to the public health policy and practice

Katarzyna Lewtak

K Lewtak[1], L Sugay[1]
[1]Department of Health Promotion and Chronic Diseases, National Institute of Public Health – National Institute of Hygiene, Warsaw, Poland
Contact: klewtak@pzh.gov.pl

The implementation of the project ''ProfiBaza'' was the unique opportunity to effectuate a data set with the possibility to showcase for the first time in Poland which public health (PH) interventions are taken and whether they cover population health needs. In order to be forethoughtful to this challenge, the needs of stakeholders within the health system were investigated. Particularly, considering the widely recognised knowledge-practice gap in the PH field. We would like to demonstrate the results of a needs analysis related to: the accessibility assessment of the information about PH interventions; the need of establishing a good practices database regarding health promotion and disease prevention; the possibility to use research findings in PH practice. All those would be presented from the perspective of researchers, politicians, decision makers and PH institutions. This research was conducted as a questionnaire-based survey and focus group interviews. Researchers were asked to assess the compatibility between the PH research and the population health needs. The group of health sector decision makers were questioned about the usage of the information available in the ProfiBaza for the process of evidence-based decision making; local government politicians - to assess their readiness to implement health programmes, use the good practices database and build partnerships for health while representatives of various sectors - to assess the need of initiating a knowledge translation platform via the launched ProfiBaza system. The results of the research demonstrate that there is a need for: solidified collaboration between different types of PH stakeholders, mobilization, coordination, sharing experiences, creating networks of cooperating institutions, which will enable the effective response to emerging challenges and opportunities and to counteract the phenomenon of dispersion of efforts in improving health and reducing social inequalities in health.

Health promotion and disease prevention programme registries can play an important role in increasing transparency of ''good/ best Practices'' and promoting their implementation. In the EU, there are different approaches to how registries seek to support the implementation of practices. However, there is limited knowledge of the extent to which there are informative differences or overlaps in the mechanisms chosen for accreditation, capacity building and implementation. This presentation focuses on six national registries in the EU (Finland, Germany, Italy, Netherlands, Poland, Slovenia) and the European Public Health Best Practice Portal. Information was obtained through a working group on Good/ Best Practice Portals, established in 2019. Information on the process of adding good/best practices to the registry and on measures that promote implementation was gathered and evaluated through a descriptive case comparison. The comparison suggests that implementation can be promoted through different approaches for capacity building measures and incentives for implementation. The latter included funding resources, titling/ awarding of practice and professional feedback in only a few registries. Registries may be useful not only for transparency of good and best Practices but also for implementation through capacity building and several incentives. The information provided in this presentation may be informative in guiding development of similar resources elsewhere and a starting point for discussion on how to support best the implementation of good/ best practices.

Abstract citation ID: ckac129.445
Promotion of healthy living environments in communities: a digital planning tool for local public health actors

Annalena Busskamp

A Busskamp[1]
[1]Department for Cross Sectional Research, Federal Centre for Health Education Germany, Cologne, Germany
Contact: Annalena.Busskamp@bzga.de

In their function as overarching settings, communities have a controlling role and political competence for the development and implementation of healthy living environments in Europe. However, the establishment of health-promoting structures is often hampered by a lack of resources and know-how, and decisions in practice are mostly based on personal experiences or standard procedures, which are often not in line with scientific findings and evidence-informed decision making. In the area of physical activity and older people, a digital planning tool (''Impulsgeber Bewegungsförderung'') compromising tools for needs assessment, interventions and information on physical activity, process management, legal issues and funding is being built to support the implementation of practices by local public health actors. This presentation will introduce the digital planning tool and its process evaluation. A mixed-method approach was applied to answer the question of whether and how the application can succeed in community settings and which additional needs of local actors exist. Initial steps of the recruited socio-economically disadvantaged model regions were setting up local steering committees and needs assessment using the tool. The model regions confirmed the usefulness of the tool in their day-to-day work, but used it with varying frequency. Among others, the tool helps to raise awareness among key actors, to reflect on their own work, or to identify funding sources. Wider use of the digital tool may lead to more evidence-informed actions in health promotion and prevention. The evaluation of the digital planning tool in a small area of health promotion will provide initial insights into how to support the implementation of activity-promoting living environments on a local level.

7.L. Workshop: New roles and innovative skill-mix in nursing across Europe: trends and lessons for implementation

Abstract citation ID: ckac129.446

Organised by: WHO Europe, Technische Universität Berlin
Chair persons: Margrieta Langins (Canada), Claudia Maier (Germany)
Contact: c.maier@tu-berlin.de

Many countries in Europe are changing the roles and skill-mix of their nursing workforce. A sufficient and well-skilled nursing workforce has shown to be key for population health, most recently demonstrated during the Covid-19 pandemic. An increasing number of countries have introduced Master-level education for nurses to work in advanced practice nursing (APN) roles. These changes in the educational systems have implications on patients, clinical practice, teams and health systems. Moreover, many countries are re-orienting their health services from hospital to primary health care and prevention, driving new roles for nurses. The relevance of high-quality education and upskilling has been exemplified during the Covid-19 pandemic, where nurses had to quickly adapt to new treatment and caregiving situations in challenging work environments. Objectives of the workshop. This workshop will provide an overview of research and policy developments in Europe, drawing on recent research. First, an overview of innovative skill-mix changes in nursing will be presented and evidence on health outcomes, based on a study from the European Observatory on Health Systems and Policies. Second, research from Germany in five innovator hospitals will be presented, a country which is still at an early stage with integrating nurses in advanced roles. The panel discussion will address innovations in APN research, practice and policy lessons in Europe and with in-depth insights from four countries (Netherlands, Finland, Switzerland, Germany). In the Netherlands, the policy instrument "experimental law" has led to full practice authority for Nurse Practitioners, its impact on practice as well as barriers and enablers will be addressed. In Finland, the focus will be on recent evidence on the expanded role of nurse prescribers, the policy process and early evidence on impacts for nurses and patients. In Switzerland, the lack of regulation and reimbursement schemes restrict advanced practice, whereas drivers comprise changes in population needs, education (master and doctoral level) and reduced workforce availability. Developments at the national and cantonal level and the evaluation of innovative care models with APNs will be presented using case examples and recent research (e.g. university hospitals, primary care). The panelists will discuss implications for research, policy and nursing management, also taking into account the Covid-19 pandemic and other unexpected "health shocks" which have shown to impact considerably on nurses' roles in practice. Lessons will be shared on strategies for a well-qualified and -resourced nursing workforce integrated in systems. The format is 'regular workshop' with two presentations and a panel discussion with experts from four countries.

Key messages:

- Multiple innovative nursing skill-mix model exist, with promising outcomes for individuals and population groups if nurses are well trained and equipped.
- Implementation of APN roles requires enabling policy contexts, sufficient funding, clinical leadership, teams that are open to innovations, and strong nurses that take on APN roles.

Abstract citation ID: ckac129.447
Overview of innovative skill-mix changes in nursing across Europe

Claudia Maier

C Maier[1,2], *J Winkelmann*[1,2], *M Wismar*[2]
[1]Department of Healthcare Management, Technische Universität Berlin, Berlin, Germany
[2]European Observatory on Health Systems and Policies, Brussels, Belgium
Contact: c.maier@tu-berlin.de

Background:

Many countries in Europe and worldwide have implemented new professional for nurses or are in the process of implementation, yet, an overview of the evidence on skill-mix changes has been missing. This study has analysed skill-mix innovations in nursing, evidence on outcomes and lessons for implementation.

Methods:

An overview of systematic reviews, following a protocol plus country case studies, as part of an international study. The literature search was performed in six databases, with search terms covering skill-mix whereby the nursing profession played a key role. Screening was performed by three researchers after high interrater reliability rates were achieved. Analyses were performed for the nursing professions, a typology of skill-mix changes (task-shifting and role expansion) and evidence on outcomes.

Results:

A total of 42 systematic reviews were identified on nurses working in new roles. The roles varied considerably, ranging from nurse prescribing to advanced practice nursing and nurse-led clinics. Nurse-led chronic care programmes were frequently identified, with overall positive outcomes on several health outcomes, e.g., for patients with diabetes or cardiovascular diseases. Nurses were also working in advanced roles in health promotion and prevention, e.g., performing screening programmes, showing equivalent quality of care compared with doctors if adequately trained. Several skill-mix models to enhance care coordination and integration were identified, suggesting that when tailored to the needs of specific population groups, particularly for vulnerable groups, may improve health outcomes or access to services.

Conclusions:

The roles of nurses are increasingly diversifying and expanding internationally. Sharing country experiences on how to effectively educate the workforce to be prepared for these new roles and ensure smooth integration is critical.

Abstract citation ID: ckac129.448
Implementation strategies to integrate academically qualified nurses in German innovator hospitals

Julia Köppen

J Köppen[1], *J Kleine*[1], *CB Maier*[1]
[1]Department of Healthcare Management, Technische Universität Berlin, Berlin, Germany
Contact: julia.koeppen@tu-berlin.de

Background:

In Germany, the number of Bachelor and Master programs for nurses has increased significantly over the past 20 years but the recommended target of 10%-20% of academically qualified nurses has not yet been reached. In university hospitals, it was 3% in 2018. Major challenges for hospital managers are to attract and retain academically qualified nurses in clinical practice, with some hospitals doing better than others.

Methods:

In 2020, semi-structured interviews (n = 18) were conducted with chief nursing officers, nurse managers, nurses, and physicians working in five innovator hospitals, characterised by a high willingness to change the work environment, improve quality of care, and increase the number of academically qualified nurses. The interviews were recorded, transcribed, and analysed using Atlas.ti. Mayring's qualitative content analysis method was applied.

Results:

Recruiting, retaining, and integrating academically qualified nurses varied in the five hospitals studied but all provided time and/or financial support for nursing students. Those with a longer tradition of attracting academically qualified nurses were following a hospital-wide strategy. CNOs or other leaders motivated nurses to enrol in a degree program, provided close support for clinical projects (e.g., on the ward) and when starting a career (e.g., coaching), and fostered individual career planning. Specialised tasks for nurses with a master's degree were leadership roles or specialised patient care. Taking over additional clinical or scientific activities according to their qualification was seen as beneficial to integrate the nurses. Barriers were the limited acceptance of graduated nurses by nurses with a vocational training, low staffing levels, and limited political support.

Conclusions:

Recruiting and retaining graduated nurses takes efforts by hospitals in the current situation of a nation-wide nursing shortage. A hospital-wide approach can be a way to overcome this challenge.

7.M. Round table: Preparedness & response for emergency situations: joined forces of H2020projects in the PREPAREcluster

Abstract citation ID: ckac129.449

Organised by: PHIRI, Sciensano (Belgium), EUPHA-PHMR
Chair persons: Svetla Tsolova (Sweden), Petronille Bogaert (EUPHA-PHMR)
Contact: miriam.saso@sciensano.be

In recent years, there have been increasing instances of cross-border crises, including climate change, terrorism, international trade disputes and global health threats. These emergency situations require large-scale planning for preparedness and response in order for countries to be able to cope with unforeseen challenges. Especially the COVID-19 crisis had a huge impact on European countries and the daily lives of its citizens. The pandemic has proven to be more than a health crisis; it is a human, economic and social crisis, impacting people, societies and economies at their core. The European Commission has recently funded many projects (in the Horizon 2020 program, H2020) to work on different aspects of crisis management, many with a focus on managing pandemics. While each project has distinct aims and challenges, they all work towards a common goal. It is for this reason that thirteen EU-funded H2020 projects, with a combined funding of €72 million, have united to form the PREparedness and resPonse for emergency situAtions in euRopE (PREPARE) cluster. Each of the thirteen projects is tackling challenges specifically looking at the preparedness and response phases of crisis management and working together they aim to achieve stronger results and greater impact for their cause. Together CO-VERSATILE, COVID-X, COVINFORM, EUR3KA, LINKS, NO FEAR, PANDEM-2, PathoCERT, PERISCOPE, PHIRI, RISKPACC, STAMINA and STRATEGY will explore synergies, research opportunities and deliver joint activities to maximise impact. Through mutual support, the cluster will strengthen the response to the ongoing crisis and the aim to be better prepared for future health crises. In a round table discussion, a selection of these H2020 will briefly present their contribution to crisis preparedness and resilience of European countries (25 min). These brief presentations will be followed by a round table discussion (35 min), touching upon topics such as common findings (building trust, health inequalities, training and capacity building, addressing stakeholder diversity); and the dissemination and exploitation of the results to the general public, to researchers, to (public) health professionals and policy makers, Finally, as many of these projects end in 2022/2023, what are the next steps or threats, what should be the highest priority for future Horizon Europe projects? The audience will be able to provide their view on the different topics through an interactive voting poll during the session. Throughout the session, the exchange of knowledge, experiences and opinions with the audience will be facilitated by the chairs.

Key messages:

- The actionable outcomes of the major Horizon 2020 projects provide key-input for political decision-making in preparedness and response scenarios.
- The PREPARE cluster builds a sustainable structure for large-scale planning for preparedness and response for countries to be able to cope with unforeseen challenges.

7.N. Workshop: Mental health promotion is key to making a change for children and adolescents

Abstract citation ID: ckac129.450

Organised by: EUPHA-CAPH
Chair persons: Julia Dratva (EUPHA-CAPH), Jutta Lindert (EUPHA-PMH)
Contact: julia.dratva@zhaw.ch

The Covid-19 pandemic highlighted the already high burden in children and adolescents and has caused an increasing mental health burden in this age group. While provision of treatment is highly relevant, this alone is unlikely to make a significant difference in reducing the burden of poor mental health and mental illness. It is elemental to promote and strengthen mental health, also knowing this will not be the last crisis to tackle. Alongside of low threshold support and prevention, health promotion can strengthen individuals' resilience or coping mechanisms. Next to individual and target group interventions, health promotion interventions also follow a setting approach, according to which people are understood as part of the social systems in which they live and spend their time. This workshop is about mental health promotion in youth. We wish to point to the importance of health promotion in the overall aim to improve mental health. The first presentation will provide an overview of mental health promotion concepts and mechanisms, providing evidence-based arguments and examples. The second presentation focusses on the ABC-framework to develop and implement MHP initiatives developed by the WHO. The last two presentations address the setting-approach, school and family and their potential in mental health promotion. In the concluding discussion with workshop participants, we will address questions, experiences, and best practices in mental health. The aim of this workshop is three-fold:
1. Provide the back-drop and a theoretical & practical basis on mental health promotion.
2. Present both individual and setting-specific examples of mental health promotion.
3. Provide room for discussion on experience and best practice in mental health promotion in youth.

Key messages:
- Mental health promotion is an important element in reducing mental health burden in children and adolescents.
- Health promotion can effectively be implemented on an individual and structural level.

Abstract citation ID: ckac129.451
Central concepts in mental health promotion programs for children and adolescents: Evidence and examples from Switzerland

Frank Wieber

F Wieber[1,2], A Zysset[1], A von Wyl[3]
[1]Institute of Public Health, ZHAW Zürich University of Applied Sciences, Winterthur, Switzerland
[2]Department of Psychology, University of Konstanz, Konstanz, Germany
[3]Clinical Psychology and Health Psychology Section, ZHAW Zürich University of Applied Sciences, Winterthur, Switzerland
Contact: Frank.Wieber@zhaw.ch

Universal mental health promotion programs draw on a wide range of concepts to promote children's and adolescents' mental health. This presentation aims to provide an overview of the central concepts from health, developmental and social psychology, psychiatry, and public health/health promotion and to illustrate their application using examples from Swiss mental health promotion programs for children and adolescents. Concepts on internal, biological, psychological and psychosocial factors such as the ten life skills that are recommended by the WHO, self-efficacy, (mental) health literacy, and the resilience literature are looked at as well as concepts on external risk and protective factors such as social support (quality of attachment and relationships, positive family climate and peer relations) and the quality of educational institutions. Evidence on their effectiveness is reported and conceptual similarities and differences as well as the underlying mechanisms of action are explored from a health behavior change perspective using the behavior change wheel. Finally, implications for the design and implementation of mental health promotion programs are discussed

Abstract citation ID: ckac129.452
Implementing Mental Health Promotion Initiatives - Process Evaluation of the ABCs of Mental Health in Denmark

Lourdes Cantarero Arevalo

L Cantarero Arevalo[1], C Hinrichsen[1], VJ Koushede[2], K Rich Madsen[1], L Nielsen[1], ZI Santini[1], C Meilstrup[1]
[1]Danish National Institute of Public Health, University of Southern Denmark, Copenhagen, Denmark
[2]Department of Psychology, University of Copenhagen, Copenhagen, Denmark
Contact: Lou.Cantarero@sind.ku.dk

Treatment and prevention alone are unlikely to make a significant difference in reducing the burden of poor mental health and mental illness. Therefore, mental health promotion (MHP) initiatives are advocated. In 2014, the ABCs of mental health (ABCs) partnership was established in Denmark; in the partnership, partner organisations, e.g., municipalities and NGOs, use a research-based framework for MHP, the ABC-framework, to develop and implement MHP initiatives. This presentation has two aims: (1) to outline the overall characteristics of these MHP initiatives; and (2) to explore local coordinator and stakeholder perceptions of the implementation processes and the impact of the MHP initiatives. Questionnaire surveys, individual interviews and group interviews were conducted during 2017-2020. The MHP initiatives were grouped according to three strategies: building MHP capacity, campaign activities to promote mental health awareness and knowledge and establishing and promoting opportunities to engage in mentally healthy activities. The ABC-framework was positively received and viewed as providing relevant knowledge for working with MHP as well as fostering intersectoral and interprofessional collaborations. However, using a bottom-up approach to develop and implement MHP initiatives can be time-consuming and resource demanding, and it requires a deliberate balancing of local adaptability and concrete guidance when engaging stakeholders and implementers. Overall, using the ABC-framework to develop and implement MHP initiatives holds great promise for advancing and promoting MHP practice.

Abstract citation ID: ckac129.453

Challenges in school-to-work transition for marginalized groups - the need to strengthen structures for vulnerable youth (post pandemics) Findings from the German project ''Co*Gesund''

Maja Kuchler

M Kuchler[1]*, K Heid*[2]*, A Rademaker*[2]*, E Quilling*[1]

[1]Department of Applied Health Sciences, HS Gesundheit Bochum, Bochum University of Applied Sciences, Bochum, Germany

[2]Faculty of Social Sciences, FH Bielefeld, University of Applied Sciences, Bielefeld, Germany

Contact: maja.kuchler@hs-gesundheit.de

Objective:

The transition from school to work is a challenge for young people which is closely correlated with health and well- being. Promoting resilience factors contributes to adolescents' mental health and social and educational success. The aim of this study is to examine how especially vulnerable youth cope with the transition during the pandemic to identify which structural measures are helpful and which are a hindrance and to develop recommendations for action.

Methods:

First, a rapid review on the subject of young people's mental health during the pandemic was conducted. Based on this 30 interviews with professionals from schools and vocational education and two focus groups with young people from participating institutions follow in spring and summer 2022. Finally, recommendations for action will be developed together with both groups.

Results:

The results of the literature research illustrate the strong influence of the pandemic on the mental health of adolescents and, in particular, the increase in health inequalities along the social gradient. In relation to school and education, it is clear that young people lacked contact persons during this time. It is expected that the interviews and focus groups give insight, which resources of the young people can be strengthened in a low- threshold way and will provide further concrete indications on what structural development is needed to strengthen the resilience of young people.

Conclusions:

For the promotion of mental health it is necessary to rely not only on the resources of young people themselves, but especially on the resources available in their environment. Only in this way transition processes can be managed successfully by the young people and they can be strengthened for the future. To this end, solutions should be developed jointly and support systems should be improved

Abstract citation ID: ckac129.454

Family factors contribute to mental health conditions – a systematic review

Sarah Marth

S Marth[1]*, N Cook*[2]*, P Bain*[3]*, J Lindert*[1,4]

[1]Department of Social Work and Health, University of Applied Sciences Emden/Leer, Emden/Leer, Germany

[2]NHS Foundation Trust, Leeds and York Partnerships, Leeds/York, UK

[3]Countway Library of Medicine, Harvard Medical School, Boston, USA

[4]Brandeis University, Waltham, USA

Contact: sarah.marth@hs-emden-leer.de

Background:

Family functioning can have positive and negative mental health consequences. Positive relationships can boost mental health, the opposite is true for negative relationships. 1 in 4 individuals are affected by at least one mental health condition in their life. Family-based interventions can help prevent the onset of mental health conditions and mitigate its consequences.

Methods:

Following databases were systematically searched: Medline; PsychInfo, Web of Sciences and Cochrane, resulting in 3719 hits. After removing 12 duplicates, 3707 studies were screened. After exclusion of irrelevant studies, 362 studies were assessed for eligibility and 40 studies were included. Inclusion criteria were original studies with $\geq$100 participants, $\geq$18 years, general population, and family members. Exposure had to be family social cohesion or conflict, or social capital. The outcome had to be a mental health condition.

Results:

Most studies (n = 37) used a cross-sectional design. 37 studies included a measure of family functioning and 3 studies used one of family structure. Most used was the Family Adaptability and Cohesion Evaluation Scale (n = 17), followed by the Family Functioning Scale (n = 5). Family relationship quality was related to depression, anxiety, and substance use. All aspects family cohesion were related to mental health outcomes. Family conflicts are associated with an increase in mental health conditions.

Conclusions:

Family cohesion shows an association with positive mental health while conflict is associated with negative mental health. This is an indication, that interventions at the family level are useful to help prevent/mitigate mental health conditions over the life course. Main message: As mental health conditions are a big public health issue affecting at least 1 in 4 individuals, family-based interventions for mental health condition prevention could not only help individuals but the whole family to strengthen and maintain positive mental health.

Abstract citation ID: ckac129.455

Universal screening for postpartum depression? Inequalities and barriers among immigrant mothers

Maria Marti Castaner

M Marti Castaner[1]*, C Hvidtfeldt*[2]*, JM Møller Olsen*[1]*, M Nørredam*[1]*, S Fredsted Villadsen*[3]

[1]Health Services Section, University of Copenhagen, København, Denmark

[2]Research Unit, Rockwool Foundation, København, Denmark

[3]Social Medicine, University of Copenhagen, København, Denmark

Contact: maria.castaner@sund.ku.dk

Background:

Postpartum depression (PPD) is a serious public health concern affecting 12% of women globally. Early detection is necessary to provide timely support. In Scandinavian countries, universal screening is recommended. However, migrant women, who are at increased risk of PPD, seem to be screened less often. Still, there is limited knowledge about 1) how acculturation relates to screening, and 2) how healthcare providers navigate PDD screening with migrant women.

Aims and methods:

We used a mixed-methods approach to explore whether and why inequalities in PPD screening using the Edinburgh postpartum depression scale (EPDS) may exist in the context of universal PPD screening within the free home-visiting program in Denmark. Data from 77,694 infants and their mothers participating in the Danish home-visiting program

(2015-2018) was used to examine the prevalence of participation in PPD screening and its association with migrant status and acculturation factors. We interviewed 16 health visitors to examine qualitatively challenges and strategies used when assessing PPD among immigrant mothers.

Results:

Immigrant women were 80% more likely to lack screening (adj. RR 1.81-1.90). All factors indicating lower acculturation, such as shorter length of residence, older age at migration, and having studied abroad were independently associated with increased risk of lack of screening. Thematic analysis of qualitative data showed how cultural and linguistic differences and organizational constraints limit health visitors' ability to assess immigrant women's mental health needs. Although health visitors often used EPDS as an opener to talk about mental health, they did not use it as an 'assessment'.

Conclusions:

This study shows inequalities in PPD screening than may result in reduced use of mental health services among immigrant women. The experiences of health visitors shed light on how to improve the identification of PPD among immigrant mothers.

Key messages:

- Migrant women in Denmark, even those who have migrated as children, are at risk of being left out of PPD screening programs.
- Limited organizational support and cultural competences makes PPD screening among immigrant women not feasible for maternal health visitors.

Contact: julien.fakhoury@unige.ch

Background:

Resources are essential for mental health. In temporary stressful situations throughout life, people need to use a particular type of resources, their ''reserves'', to handle the stress. We do not know whether ''reserves'' (economic, cognitive, and relational) are more protective of mental health than ''conventional'' resources. Using a cohort of undocumented migrants experiencing a stressful transition in their life course (in the process of regularisation with local authorities), we will determine which resources, or reserves, and which types, better protect their mental health.

Methods:

A two-wave cohort study followed 362 undocumented migrants from 2017 to 2020, half of whom (48%) were involved in a regularisation process with the local authorities. Depressive symptoms were measured with the Patient Health Questionnaire, anxiety with the Generalized Anxiety Disorder. Economic reserves were measured at baseline and follow-up, cognitive and relational reserves at baseline only. Conventional economic and relational resources were assessed at both time points. The association between reserves and resources and mental health were examined using generalised estimated equations adjusted for age, sex and working hours per week, as well as the interactions between reserves/resources and regularisation status.

Results:

The indicators of economic and relational reserves were consistently and strongly associated with lower levels of anxiety and depressive symptoms. On the other hand, we found that mental health outcomes were marginally associated with conventional economic resources but independent of the relational resources indicators. We did not find strong evidence of interactions between reserves/resources and regularisation status.

Conclusions:

In a vulnerable population experiencing a stressful transition, reserves are more protective than resources. More research is needed in other vulnerable groups experiencing other stressful events.

Key messages:

- Undocumented migrants' economic and relational reserves protect their mental health.
- More research on the protective effect of reserves is needed in other vulnerable groups experiencing other stressful events.

Health empowerment and access to health coverage among immigrants in France: the Makasi intervention

Marwân-al-Qays Bousmah

M Bousmah[1,2]*, A Gosselin*[2,3]*, K Coulibaly*[1,2]*, A Ravalihasy*[1,2]*, A Desgrées du Loû*[1,2]
[1]Ceped, Université Paris Cité, IRD, INSERM, Paris, France
[2]CNRS, French Collaborative Institute on Migrations, Aubervilliers, France
[3]Ined, National Institute for Demographic Studies, Aubervilliers, France
Contact: qaysbousmah@gmail.com

Background:

The Makasi community-based research project offered an innovative health-related empowerment intervention to immigrants from sub-Saharan Africa living in precarious situations in the greater Paris area, to reduce their social vulnerability and their exposure to HIV. Our objective is to evaluate the impact of the intervention on access to health coverage in this population.

Methods:

Participants were recruited based on precariousness criteria in public places in Ile-de-France (squares, railway stations, markets, etc.) by mobile teams of social workers and health mediators. Following a stepped-wedge design, participants were randomised into two groups receiving the intervention sequentially (immediately in one group and 3 months later in the other). We evaluated the impact of the Makasi intervention on access to health coverage among 821 individuals observed at 0, 3, and 6 months, between 2018 and 2021. We implemented random-effects panel models - allowing for unobserved heterogeneity - using a Heckman selection approach to correct for attrition. Finally, we used seemingly unrelated regressions (SUR) to examine the extent to which the effect of the intervention was mediated by health-related empowerment.

Results:

Participants - 77% of which were men - had been living in France for 4 years on average. 44% of them had no health coverage at the time of inclusion. Our results provided evidence for a significant impact of the Makasi intervention on participants' access to health coverage, with an 18 percentage-point increase in the probability of accessing health coverage 6 months after having received the intervention ($p < 0.01$). The mediation analysis revealed that this effect operated partly through an empowerment process in terms of knowledge of social and health resources.

Conclusions:

We showed that a health empowerment intervention provided by social workers and health mediators largely favours access to health rights for immigrants in precarious situations.

Key messages:

- A health empowerment intervention improved access to health coverage among immigrants from sub-Saharan Africa living in precarious situations in France.
- Improvement in access to health coverage was found to be partly mediated by reinforcement of participants' health literacy in terms of social and health resources.

The income-mortality paradox among first- and second-generation immigrants in Sweden

Alexander Miething

A Miething[1], *SP Juarez*[1]
[1]Department of Public Health Sciences, Stockholm University, Stockholm, Sweden
Contact: alexander.miething@su.se

Background:
This study investigates mortality differences by income among first- and second-generation immigrants and the native ancestral population in Sweden. Despite immigrants' various vulnerabilities and the exhaustive evidence for a persistent inverse relationship between income and mortality in general Western populations, previous studies from outside Sweden demonstrated surprisingly weak income gradients in mortality among first-generation immigrants. Examining these associations among second-generation immigrants may help to understand this paradox.

Methods:
Swedish register data from 2002 to 2016 were used to study the association between individual income rank positions and all-cause mortality. The study population was restricted to ages 25-64 years. Based on 'relative indices of inequality' (RII) derived from Poisson regressions, we measured mortality differentials between the least and most deprived income rank positions stratified by nativity group and sex. Correspondingly, we assessed absolute differences in mortality between the most and least deprived by using 'slope indices of inequality' (SII).

Results:
Largest inequalities in mortality by relative income rank positions (based on RII) were found for the Swedish native ancestral population that showed on average a nearly doubled mortality risk for least compared to most deprived rank position. Immigrants disclosed weak or even nullified associations between relative income rank and all-cause mortality. Mortality inequalities by income among second-generation immigrants were substantially higher relative to first-generation immigrants but somewhat lower compared to the native ancestral population. These patterns were consistent between males and females, and confirmed by the use of SII.

Conclusions:
Distinct exposures to inequality structures but also first-generation immigrants' 'mortality advantage' likely contribute to the considerable mortality differences by income between the studied nativity groups.

Key messages:

- Despite their social and economic vulnerabilities, first-generation immigrants in Sweden disclose weak associations between relative income rank and all-cause mortality.
- Second-generation immigrants in Sweden show notably higher magnitudes in income-related mortality compared with first-generation immigrants.

7.P. Pitch presentations: Evidence for health policies

National taxation on sugar-sweetened beverages: a scoping review and time series analysis

Leonardo Villani

L Villani[1], *M Sassano*[2], *C Castagna*[1], *G Quaranta*[1,3], *R Pastorino*[3], *S Boccia*[1,3]
[1]Section of Hygiene, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Department of Medical and Surgical Sciences, Università di Bologna, Rome, Italy
[3]Department of Woman and Child, Fondazione Policlinico Universitario A. Gemelli, Rome, Italy
Contact: leonardovillani92@gmail.com

Background:
The intake of Sugar-Sweetened Beverages (SSBs) has increased around the world, leading to a growing burden of disease due to these beverages, such as obesity, diabetes, and heart disease. Taxation is a major action for comprehensive programmes aimed at reducing consumption of sugars. For these reasons, the aims of our study were to systematically summarize national tax legislation on SSBs and to assess the impact of these laws on the prevalence of overweight, obesity, and diabetes.

Methods:
We conducted a scoping review to summarize the landscape of national tax laws on SSBs implemented worldwide. We included any document reporting both currently into force and past national tax laws addressing SSBs. As to the time series analysis, data regarding the national prevalence of obesity, overweight, and diabetes were retrieved from WHO Global Health Observatory data repository.

Results:
As of July 2020, 34 countries worldwide implemented SSB taxation (amount-specific and ad valorem tax design), of which 17 (50.0%) in high-income countries, 12 (35.3%) in upper-middle income countries, and 5 (14.7%) in low-income countries. As for overweight, Hungary was the only country showing a slower rate of change after the taxation. Regarding obesity, France, Guatemala, Hungary and Panama showed a deceleration of the rates of change after the intervention. Eventually, Hungary and Tonga exhibited a one-time decrease of diabetes prevalence at the intervention point. Decelerating rates of change in the post-intervention period was also found for Guatemala and Fiji.

Conclusions:
Laws targeting SSBs showed, at least in part, to be an effective measure to reduce the prevalence of overweight, obesity, and diabetes. Less than one fifth of worldwide countries have implemented national taxation policies. Finally, while taxation might be effective to reduce SSB consumption, other types of Public Health interventions, such as educational initiatives, should not be neglected.

Key messages:

- Sugar-Sweetened Beverages (SSBs) are associated with obesity, diabetes, and heart disease. Taxation can be an important tool to reduce the consumption of SSBs.
- Prevalence of obesity, overweight and diabetes decreased in countries that adopted taxation. However, other strategies

such as educational programs should be implemented to reduce the intake of SSBs.

Citizens' perspective on 'the right care in the right place'

Laura Damen

L Damen[1], *JD De Jong*[1,2], *L Van Tuyl*[1], *JC Korevaar*[1]
[1]NIVEL, Utrecht, Netherlands
[2]Maastricht University, Maastricht, Netherlands
Contact: l.damen@nivel.nl

Background:
Healthcare systems around the globe are facing challenges, from increasing demand and costs to a diminishing health workforce. Without change, healthcare will become unsustainable. In the Netherlands, the government aims to organize sustainable healthcare by among others the policy 'the right care in the right place'. An important part of this policy is relocating healthcare, for instance, from the hospital to the general practitioner (GP) or from the GP to other healthcare providers or to citizens themselves. Relocation of care is expected to reduce costs and manpower shortages. There is, however, little known about how citizens think about this topic, although they are an important stakeholder. This research aims to investigate citizens' perspectives on the right place for care.
Methods:
A questionnaire was sent in December 2021 to 1.500 members of Nivel's Dutch Healthcare Consumer Panel, including 4 questions about the right care in the right place. The response was N = 796 (53%). In addition, two citizen platforms were organized in March 2022, to discuss the right care in the right place. A total of 23 citizens participated.
Results:
First results indicate that most citizens related expertise and accessibility to the right care in the right place. Participants said that non-complex care could be relocated from the hospital to the GP if the GP has the right expertise. Expertise was mentioned as the most important aspect of care delivery. According to participants, care could be shifted from the GP to other primary care professionals, to social services or to self-sustainability, given that citizens know who to visit or what to do with health problems/worries. More results will be available by November.
Conclusions:
Relocating care could be a possible solution to keep healthcare sustainable in the future in terms of costs and manpower. Among citizens, there seems to be support when certain conditions are met.
Key messages:
- Citizens support the substitution of non-complex care from hospitals.
- Citizens are willing to improve self-sustainability when they have the tools.

COVID-19 restrictions and NUTS-3 deprivation: multilevel approach in Italy during the second wave

Luca Dei Bardi

L Dei Bardi[1,2], *A Acampora*[1], *M Di Martino*[1], *M Davoli*[1], *N Agabiti*[1], *G Cesaroni*[1]
[1]Department of Epidemiology of the Lazio Region, Rome, Italy
[2]Sapienza University of Rome, Rome, Italy
Contact: l.deibardi@deplazio.it

Background:
To face the second COVID-19 wave, Italy implemented a tiered restriction system with different risk levels (yellow = low; orange = medium, red = high). It is unknown whether the effect of the tiers was equal among provinces with varying levels of socioeconomic deprivation (SED). At each restriction level, we analyzed the impact of the province's SED on the SARS-CoV-2 daily reproduction number (Rt).
Methods:
We considered the Rt (Nov 2020-May 2021) as the dependent variable and the SED as the independent variable. The Rt was estimated using daily incidence data from the Civil Protection Department as the instantaneous Rt. The province SED was measured using the percentage of individuals whose yearly income was less than 10,000€ (2019 data from the Ministry of Economy and Finance). We used multilevel linear regression models with random intercepts stratified by restriction level to estimate the effect of the SED on Rt (β) and its Standard Error (SE). Our analyses adjusted the estimates for the number of days into the tier first and then for other covariates.
Results:
We found different levels and trends of Rt by SED in every restriction. Days-adjusted models found a containing effect for the red and the orange tier, while the Rt had an increasing trend in yellow. Higher SED was associated with higher Rt: β was positive and significant in red ($\beta = 0.004$ SE = 0.001) and orange ($\beta = 0.002$ SE = 0.001) but not in the lowest tier ($\beta = 0.001$ SE = 0.001). We found a significant interaction between the number of days into the restriction and the SED in the complete models. Compared to less deprived, more deprived provinces had slower Rt reduction in the highest tier. However, they had steeper Rt reductions in orange and slower increasing trends in yellow.
Conclusions:
The highest restriction had milder effects in more deprived provinces, while lower tiers were more effective. These results underline the importance of accounting for SED when implementing public health measures.
Key messages:
- Area-level deprivation can modify the effects of public health measures.
- Socioeconomic characteristics of the areas should be considered when implementing policies aimed to prevent the spread of epidemics.

Abstract citation ID: ckac129.462
The role of public health scientists within the German political discourse on the COVID-19 pandemic

Julia Piel

M von Köppen[1,2], *J Piel*[1], *C Apfelbacher*[1]
[1]ISMHSR, Otto-von-Guericke-Universität Magdeburg, Frankfurt, Germany
[2]Gesundheitswissenschaften, Hochschule Fulda, Fulda, Germany
Contact: julia.piel@med.ovgu.de

Background:
During the COVID-19 pandemic politics was in search of scientific evidence to underpin decision making like never before. It is remarkable that voices from public health were less noticeable than those of virologists or immunologists. The aim of our ongoing study is to explore how public health scientists perceive their role in the relationship of their discipline and politics.
Methods:
We conducted 10 reflexive interviews with epidemiologists and public health scientists from Germany and collected documents (official statements and policy briefs of scientific societies). Data from both sources were analysed using situational analysis (Clarke, 2018), an approach used to map and analyse discourses in complex situations. To ensure data quality we used respondent validation.
Results:
According to participants, (1) improving population health was the top priority. Politicians tended to focus on short-term goals rather than long-term consequences. (2) Recognition of public health was increased by the pandemic in Germany. (3)

However, politicians favoured virology, biomedical and clinical perspectives. (4) The strong motivation of public health scientists to support politics at the beginning of the pandemic turned into disillusionment. (5) The composition of advisory boards was described as non-transparent. (6) Initiatives by the public health community were not sufficiently impactful. (7) Expectations of policymakers regarding future cooperation were not clear to participants.

Conclusions:

The results present different facets of a delicate relationship between public health sciences and politics. The pandemic increased the visibility and impact of public health in Germany on the one hand but also demonstrated that the realms of public health (science) and politics were not well connected. Involving scientific expertise in politics requires more transparency and the normative assumptions underlying the logics of science and politics need to be made more explicit.

Key messages:

- The potential of public health to address the covid-19 pandemic has not been sufficiently acknowledged by policymakers, and the involvement of its experts requires greater transparency.
- Reflecting on the normative assumptions underlying the different logics of public health sciences and politics can support their cooperation in the future.

Abstract citation ID: ckac129.463

Italian survey on the use of a multidisciplinary approach for age assessment of UAM

Alessandra Diodati

A Diodati[1], F Curtale[1], C Mirisola[1], G Costanzo[1]
[1]INMP, Rome, Italy
Contact: alessandra.diodati@inmp.it

Issue:

Many methods are used to assess the age of unaccompanied foreign minors (UAM). In Italy, in the frame of a new legislative asset, a multidisciplinary protocol has been adopted in July 2020 with the aim of ensuring that all UAMs are assessed uniformly throughout the country when their age is in doubt. The assessment is based on a multidisciplinary - social, psychological and physical - evaluation performed by a team of specialists. The local health authorities (ASL) carry out the assessment when requested by the Juvenile Court.

Description:

One year after the establishment of the protocol, INMP launched a national survey, through an online questionnaire, to investigate the formal adoption of the protocol by the ASL and their adherence in practice. The survey started on 10 January 2022 and closed on 8 March 2022.

Results:

Out of 118 ASL that were asked to participate, 102 (85%) answered. 37 declared to have a multidisciplinary team for age assessment. Of them, 18 use the formal protocol, 11 use an approach "in line" with the protocol and 8 have a forensic team, out of the rules of the protocol. Of the 65 that did not set up the team, 22 declared that they were ready to do so. 846 age assessment requests were reported and 687 were carried out. 398 migrants were recognized as minors, 222 migrants were not recognized as minors, and the age of 67 migrants remained uncertain.

Lessons:

The pandemic period prevented the effective adoption of the protocol by the ASL, that were strongly engaged in the COVID 19 response. There is still great variability in the way the age assessment of UAMs is conducted and in order to counteract the use of inadequate/outdated practices, it is necessary to actively promote and support the adoption of the protocol. In addition, a continuous comparison/dialogue between the multidisciplinary teams, the Juvenile Court, and the Police Headquarters is also needed, so that the procedure is requested only when necessary and carried out properly.

Key messages:

- In case of doubt, the age of all UAM has to be assessed in a uniform manner throughout the country.
- The adoption of the multidisciplinary protocol has to be actively promoted and supported to counter the use of inadequate or outdated assessment practices.

Action recommendations to support people living in precarious conditions during a pandemic

Zeliha Öcek

Z Öcek[1,2,3], AM Volkmann[4], V Klünder[1,2], A Basil[1], M Geise[5], M Coenen[1,2]
[1]Chair of Public Health and Health Services Research, Ludwig-Maximilians-University, Munich, Germany
[2]Pettenkofer School of Public Health, Munich, Germany
[3]Rachel Carson Center, Ludwig-Maximilians-Universität München, Munich, Germany
[4]University College London, London, UK
[5]NIVEL, Utrecht, Netherlands
Contact: zoecek@ibe.med.uni-muenchen.de

Background:

The COVID-19 pandemic has deepened pre-existing health inequalities. As members of an EU-funded research consortium (SoNAR-Global) tasked with assessing vulnerabilities in five European countries, we explored the impacts of the pandemic on vulnerable populations and identified concrete actions that strengthen resilience. Here, we present our action recommendation development process for populations living in precarious conditions such as refugees, migrants and those living below the poverty line in Munich, Germany.

Methods:

The process began by interviewing 82 people who were likely to face vulnerability mechanisms, followed by interviews with 19 community representatives. Based on this qualitative research data, we defined challenges and resilience factors, and matched these with a list of action recommendations. This list, named "Provision of social support to people living in precarious conditions in times of a pandemic", was considered by a panel with ten experts on migration, health, poverty, social support, and inclusion.

Results:

Through discussion, we eliminated one recommendation and re-defined three others and achieved consensus on six recommendations. They are: 1) work towards eliminating opportunity inequity in education, 2) streamline bureaucratic processes to improve access to care, 3) establish structures that allow for continuing social support even during a pandemic, 4) refrain from isolating socially vulnerable groups through blanket pandemic mitigation measures, 5) Hybrid (online and live) solutions for inclusion, 6) improving healthcare empowerment.

Conclusions:

Through an inclusive process that involved citizens, vulnerable populations, and health- and government experts we identified a set of actions that should be taken now to ensure an equitable and just approach to pandemic preparedness. Our panel identified feasible and achievable goals within those recommended actions.

Key messages:

- Vulnerability mechanisms are multi-layered. Therefore, policies that need to be developed should be based on comprehensive approaches, not selective interventions.
- Actions to mitigate vulnerabilities in pandemics must be ambitious in order to prevent further exacerbation of existing issues with potentially catastrophic long-term consequences.

[8]Department of Primary Care and Public Health, Imperial College of London, London, UK
Contact: palladino.raffaele@gmail.com

Background:

Most of the literature on conflict of interest (COI) has not focused on the role of academic editors and their possible COIs, although academic editors often hold senior faculty positions at universities, which might be considered a COI if this influences towards a more favourable processing to articles submitted by institutional colleagues. The current study aims to assess whether academic editor affiliation, a potential COI, can influence academic institution ranking as top contributor in the biomedical field.

Methods:

We conducted a cross-sectional analysis extracting publicly available data from the 2019 Clarivate InCites Journal Citation Reports for journals in the ''Medicine, General & Internal'' category and from each journal website. We constructed the following study outcomes: i) being a top 5 academic contributor for the peer-review journal of interest (yes/no), ii) being a top 10 academic contributor for the peer-review journal of interest (yes/no), and iii) ranking position as top 50 academic contributor for the peer-review journal of interest. Mixed-effect linear and logistic regression models were employed, as appropriate.

Results:

We included 114 journals in our analysis, 49% were open-access only. Sharing same affiliation of any of the editorial board members was associated with a 6.7 and 5.6 greater likelihood of being top 5 and top 10 contributors, respectively (95%CI 5.07-8.73 and 4.34-7.22). Similarly, sharing same affiliation was associated with being 12.1 places higher as top contributor (95%CI 10.35-13.81). When considering the editor in chief affiliation solely, association was even stronger.

Conclusions:

We found that academic editors sharing the same institutional affiliation with authors was strongly associated with the likelihood of that institution of being a top contributor. Shared institutional affiliations between editors and authors should be clearly stated as part of an open and transparent peer-review process.

Key messages:

- Editors sharing same affiliation with authors was strongly associated with the likelihood for the institution the editor was affiliated with of being top contributor for academic medical journals.
- Shared institutional affiliations between editors and authors should be clearly stated as part of an open and transparent peer-review process.

7.Q. Workshop: What population health researchers' need and how PHIRI federated research infrastructure can help

Abstract citation ID: ckac129.466

Organised by: PHIRI, EUPHA-PHMR
Chair persons: Enrique Bernal-Delgado (Spain), Martin Thißen (Germany)
Contact: ebernal.iacs@aragon.es

What population health researchers' need? The population health research community has a vast experience in the reuse of data for health monitoring and surveillance or healthcare performance assessment. However, there is a gap in the extensive reuse of individual sensitive data, particularly when mobilising these data requires the linkage of multiple data sources curated in different sites. The gap is greater when it comes to using sensitive data in cross-national research. The usual arguments to explain the scarce extensive and continuous mobilisation of sensitive data are data privacy and safety issues, the difficulty to discover data sources of value, complex accessing rules, uneven data quality (particularly, non-harmonized data), and limited capacity (personnel and dedicated resources). In InfAct Joint Action, Information for Action, we demonstrated at a very small scale that mobilising individual sensitive data is possible, it is compliant with the legal and ethical requirements, and it yields the expected outputs. The instrument used for such an achievement was the design, implementation and deployment of a very small-scale federated infrastructure, where we could pilot all the legal, organisational, data quality and technological issues related to the mobilisation of individual sensitive data. (https://doi.org/10.1186/s13690-021-00731-z). Building on those achievements In PHIRI (see here https://www.phiri.eu/wp7) we are paving the way for a large-scale research infrastructure where multiple population health researchers with multiple research questions will need the mobilisation of multiple data sources from multiple sites across Europe. The PHIRI enhanced infrastructure will have to be prepared to provide a variety of services for data discovery, data access, data analysis and research outputs FAIR publication, while improving the capacity of population health researchers community in the use of advanced computing tools. In this workshop we will start describing the PHIRI federated research infrastructure achievements, the governance step-wise approach and the technological solutions provided. The workshop will discuss how an enhanced PHIRI could improve its services for the community of population health researchers; in particular improving the analytical capacity and the associated technological solutions. Finally, the workshop will touch ground on the future developments, in particular, the interaction of the PHIRI infrastructure with existen European-wide services providers, as EGI, and research infrastructures.

Key messages:

- In the domain of population health sciences, the reuse of individual sensitive data for research purposes is very limited.

- The PHIRI federated research infrastructure is paving the way for population health researchers to enhance their research when reusing individual sensitive data.

Abstract citation ID: ckac129.467
What the PHIRI federated research infrastructure has achieved so far?

Juan Gonzalez-Garcia

J Gonzalez-Garcia[1]
[1]Biocomputing Unit, Institute for Health Sciences in Aragon, Zaragoza, Spain
Contact: jgonzalezgarc.iacs@aragon.es

PHIRI infrastructure follows a federated approach that is governed following the European Interoperability Framework. The vision of PHIRI is to create an infrastructure for individual level data processing following the privacy-by-design principle in a data-centric approach. As a basis to legal interoperability and compliance with the GDPR, the queries or algorithms are moved to the data instead of moving the data. So far, the PHIRI technological developments have focused on a client-server architecture. In this architecture a Coordinator Hub, the server, is in charge of orchestrating the deployment of the data-centric analysis solutions, in the form of R and Python scripts, that will be later executed in the partner nodes (data hubs), the clients. To perform the orchestration the Coordinator Hub encapsulates the scripts in software containers, using Docker images; all the outputs are published in Zenodo. The software containers are then deployed manually from Zenodo in the partner nodes and executed by its IT specialists using their own individual level data - the software containers have represented the technical interoperability layer. The data used on each partner has been previously adapted to a common data model (CDM) and the quality of the dataset has been assessed against the data model by each partner -this has represented the semantic interoperability layer. Finally, the outputs of the analysis's execution are aggregated data that are sent back to the Coordinator Hub to perform a comparative analysis. This stepwise approach has been tested in various research questions promoted by a leading researcher and agreed by the partner nodes who act as data hubs. A help-desk services and a developer's forum and a help-desk service have been set up to ease the implementation and deployment of the research queries - these both have represented the organisational interoperability layer

---

An enhanced version of the PHIRI infrastructure: improving the analytical services

Francisco Estupiñán

F Estupiñán[1]
[1]Data Sciences for Health Services and Policy, Institute for Health Sciences in Aragon, Zaragoza, Spain
Contact: festupinnan.iacs@aragon.es

The PHIRI federated approach has consisted of the development of four research queries (use cases) mobilising individual data from a number of data hubs (nodes in the federation). Methodologically speaking, use cases have required the creation of specific cohorts of patients, population subgroups or populations, and the identification of events of interest - over-time differences in health status and care healthcare utilisation before and during the pandemic. Technologically speaking, PHIRI infrastructure consists of a distributed end-to-end analytical pipeline containing the statistical analysis workflow, including data quality assessment at origin and the mathematical algorithms. Once datasets are prepared in each data hub, partners run the analyses and produce a research output (dashboards containing the research results and tables with aggregated data) that is shared for results compilation and comparative analysis. An enhanced version of the PHIRI infrastructure should allow more complex data distribution. The research questions covered so far are aiming inference on populations or providers, which implies a very simple distribution methodology, as described. However, when the research questions requires inference on the individuals (eg, quasi-experimental study on the effectiveness of a real-life intervention), when the inference requires a hierarchical approach (ie, part of the variance is at individual level and part at cluster level) or when, several rounds of training are needed (eg, validation of an artificial intelligence) the approach would require sharing coefficients, distances in n-dimensional spaces or models, and, some times various rounds of distribution. Finally, an enhanced version of the PHIRI infrastructure should generalise the current FAIR approach limited to the publication of the analytical pipeline in ZENODO, setting up the services and tools required for an improved version of the PHIRI open-science strategy.

Abstract citation ID: ckac129.469
An enhanced version of the PHIRI infrastructure: improving the technological solutions

Pascal Derycke

P Derycke[1]
[1]Sciensano, Brussels, Belgium
Contact: Pascal.Derycke@sciensano.be

The proof of concept tested by PHIRI consisted of the development of several research questions in multiple data hubs using a federated approach. It was possible to embed the use cases' analytical pipelines in a portable standalone (i.e. docker image) and distribute it in different health data hubs and technological environments sources for execution. The tested solution has the advantage of not moving sensitive data out of the silos and thus protecting privacy - the code meets data and not the opposite. Some precious lessons provide guidance on how to further develop the PHIRI infrastructure. 1) A deep knowledge on what data is available in the different data hubs of a federation is key since the basis for the development of a research query is the construction of a data model that is common to all the nodes in the federation. In an eventual enhanced PHIRI infrastructure, a solution will be implementing a semantic information system that allows the exchange of metadata using federated and interoperable metadata catalogues based on Semantic RDF graph databases, compliant with the W3C DCAT metadata standard and exposing the end-points of the SPARQL querying language of the Web of linked-data. 2) Making available training samples mimicking real-world data within the docker image has been of high added-value for the development of the use cases' analytical pipelines. In an eventual enhanced PHIRI infrastructure, a generalisation could consist of setting up a "knowledge hub" where synthetic data, twinning the population, data would allow any expert users to search and find data through federated queries and prepare and train their analytical pipelines; the "knowledge hub" would provide a computational environment (e.g. Jupyter as a service playground), the necessary tools (i.e. cookbooks and capacity building services) and training samples to answer research questions, with the advantage of using data that is anonymous by nature and open access.

Improving PHIRI performance and scalability: working within EGI-ACE

Gergely Sipos

G Sipos[1]
[1]EGI, Amsterdam, Netherlands
Contact: gergely.sipos@egi.eu

EGI-ACE is a 30-month H2020 project (Jan 2021 - June 2023) with a mission to empower researchers from all disciplines to collaborate in data- and compute-intensive Open Science, enabled by free-at-point-of-use services that are delivered through the European Open Science Cloud (EOSC). EGI-ACE delivers the EOSC Compute Platform (ECP), a federated system of compute and storage infrastructure extended with platform services to support diverse types of data processing and data analytics cases. The ECP currently includes High Throughput Compute (HTC) and Cloud Compute facilities, and will broaden its scope with High Performance Compute services later in 2022. The platform layer of the ECP provides assistance for single sign-on, transfer and federation of distributed data, interactive computing, management of large numbers of jobs, orchestration of compute clusters, AI and machine learning tasks. There are over 25 thematic services in EOSC that build on the ECP, and deliver scalable data analysis for different domains, from astrophysics, through life sciences, environmental sciences, to humanities. PHIRI participates in EGI-ACE as one of the 'Early Adopters' of the ECP. Under the EGI-ACE workplan PHIRI will explore reproducible population health workflows with the use of cloud computing, single-sign-on, Jupyter Notebooks and Binder services of the ECP. The tests will enable PHIRI to scale out existing data analysis notebooks to big capacity machines, to reproduce simulations and models across users, and to overall validate the technological and sustainability approaches of EGI-ACE. PHIRI will also advise the project on best ways to introduce secure processing capabilities within the ECP services.

8.A. Pitch presentations: Strengthening health systems

[2]The Nuffiled Trust, London, UK
[3]Panaxea, Amsterdam, Netherlands
[4]School of Social Work and Social Policy, University of Strathclyde, Glasgow, UK
Contact: josephine.exley@lshtm.ac.uk

Background:

Many countries are experimenting with novel ways of organising and delivering more integrated health and social care. Governance is relatively neglected as a focus of attention in this context but addressing governance challenges is key for successful collaboration.

Methods:

Cross-country case analysis involving document review and semi-structured interviews with 27 local, regional and national level stakeholders in Italy, the Netherlands and Scotland. We used the Transparency, Accountability, Participation, Integrity and Capability (TAPIC) framework to structure our analytical enquiry to explore factors that influence the governance arrangements in each system.

Results:

Governance arrangements ranged from informal agreements in the Netherlands to mandated integration in Scotland. Novel service models were generally participative involving a wide range of stakeholders, including the public, although integration was seen to be driven, largely, from a health perspective. In Italy and Scotland some reversion to 'command & control' was reported in response to the imperatives of the Covid-19 pandemic. Policies, budgets, auditing and reporting systems that are clearly aligned at all levels were seen to help with implementing innovations in service organisation. Where alignment was lacking, cooperation and integration was suboptimal, regardless of whether governance arrangements were statutory or not. There was wide recognition of the importance of buy-in. Enablers of greater engagement included visible leadership, time and long-standing working relationships. Lack of suitable indicators and openness to data sharing to measure integration hindered working relationships and thus the successful delivery of integrated services.

Conclusions:

Our study provides important insights into how to more effectively and efficiently govern service delivery structures within care systems. We will discuss approaches to governance that help support more resilient integrated care systems.

Key messages:

- Different governance arrangements face common challenges to greater integration of care. Enablers include strong leadership, inclusivity and openness to work across traditional boundaries.
- Meeting the governance challenges of integrated health and social care requires clear lines of accountability, aligned policies, budgets and reporting systems.

Abstract citation ID: ckac129.472

COVID-19 containment measures impact utilization and provision of healthcare in Europe

Julia Dratva

J Dratva[1,2], A Klein[1], S Marti[1], F Wieber[1]
[1]Institute of Public Health, Zürich University of Applied Sciences, Winterthur, Switzerland
[2]Medical Faculty, University of Basel, Basel, Switzerland
Contact: julia.dratva@zhaw.ch

Background:

The COVID-19 containment measures, implemented to curb the pandemic, impacted health of children and adolescents by numerous pathways. We present the impact on health care utilization and provision.

Methods:

A systematic review on secondary health impact is ongoing (PubMed, PsychInfo, Embase). Literature is screened (title, abstract, full-text) by 2 researchers, and data of interest extracted systematically.. Inclusion criteria are age (0 - 25 yrs.), exposure: containment measures, outcome: secondary health outcome, and European data origin.

Results:

Jan. 2020 - Aug. 2021 10112 studies were identified, 337 were included. n = 60 were on health care utilization and provision. Utilization studies relied on objective hospital or registry data, care provision studies more often on survey data (professionals, parents). Data yields a large but varying decrease in emergency department visits during the lockdown: Italy ~75%, Spain ~65%, France ~60%, and Germany ~64%, and a substantial change in case mix and severity compared to comparable pre-COVID. Specialized and primary pediatric practices report that elective interventions were postponed, state of the art diagnostics withheld, and rehabilitation services disrupted. Vaccinations in infants, children, and adolescents dropped during the lockdown inversely proportional to children's age. Studies repeatedly suggest patients' health services avoidance out of fear of infection and stay-at-home rules.Results on catch-up utilization and provision to follow (ongoing study).

Conclusions:

COVID-19 measures exerted a measurable impact on health utilization and provision in children and adolescents. The utilization was comparatively lower and service provision disrupted across Europe. So far little can be said about a potential recovery in terms of catch-up of visits, diagnostics, or treatments. Analyses of the long-term health impact of the observed effects is recommended and can serve to improve future pandemic preparedness.

Key messages:

- COVID-19 confinement measures had measurable secondary health impact on children and adolescents.
- Data on catch-up healthcare is important to establish long term impact and learnings.

Abstract citation ID: ckac129.473
Evaluation of opt-in HIV testing in the construction workplace using the socioecological framework

Holly Blake

H Blake[1,2]*, S Somerset*[3,2]*, W Jones*[1]*, C Evans*[1]*, C Cirelli*[3]*, D Mbang*[3]
[1]School of Health Sciences, University of Nottingham, Nottingham, UK
[2]NIHR Nottingham Biomedical Research Centre, University of Nottingham, Nottingham, UK
[3]School of Medicine, University of Nottingham, Nottingham, UK
Contact: holly.blake@nottingham.ac.uk

Background:

Late diagnosis of HIV remains a challenge and the construction workforce has several risk factors for HIV. In the Test@Work programme, we delivered HIV tests embedded within a general health check to construction workers, with high uptake and acceptability. Here, we report the experiences of construction managers and health professionals involved in Test@Work and explore the suitability of construction worksites as a venue for opt-in HIV testing.

Methods:

Qualitative interviews (n = 24) were conducted with construction managers who facilitated events (n = 13), and HIV/health check delivery partners (n = 11) at 21 Test@Work events held on construction sites. Interviews explored experiences of events and views towards workplace HIV testing. Event exit questionnaires (n = 107) completed by delivery partners provided qualitative data identifying facilitators and barriers to effective delivery. Thematic analysis identified themes that were mapped against a socioecological framework (individual, interpersonal, organisational, industry, public health).

Results:

Delivery partners reported high engagement of construction workers with workplace HIV testing, peer-to-peer encouragement for uptake, and value for accessibility of onsite testing. HIV professionals valued the opportunity to reach an untested population, many of whom had a poor understanding of their exposure to HIV risk. Managers valued the opportunity to offer workplace health checks to employees but some identified challenges with event planning, or provision of private facilities.

Conclusions:

The construction sector is complex with a largely male workforce. Providing worksite HIV testing and education to an untested population who have poor knowledge about HIV risk helped to normalise testing, increase uptake, and reduce HIV stigma. However, there are practical barriers to testing in the construction environment. This has global implications for delivery of HIV testing in construction workplace settings.

Key messages:

- Delivering workplace HIV testing as part of a general health check helps to normalise HIV testing and reduce HIV-related stigma.
- Workplace testing is convenient, accessible and reaches populations at risk for HIV, but there are some barriers to implementation of rapid tests on construction sites.

The Health and Quality of Life Development Plan as a policy advisory tool for municipalities

Rita Sequeira

R Sequeira[1]*, P Pita Ferreira*[1,2]*, S Carmezim Pereira*[1,3]*, G Quinaz Romana*[1,4]*, A Campos Fernandes*[1,5,6]*, P Sousa*[1,5,6]
[1]National School of Public Health, NOVA University, Lisbon, Portugal
[2]Public Health Unit of Oeste Norte, ARSLVT, Caldas da Rainha, Portugal
[3]Public Health Unit António Luz, ARSLVT, Lisbon, Portugal
[4]Public Health Unit Francisco George, ARSLVT, Lisbon, Portugal
[5]Comprehensive Health Research Center, National School of Public Health, NOVA University, Lisbon, Portugal
[6]Public Health Research Centre, National School of Public Health, NOVA University, Lisbon, Portugal
Contact: ri.sequeira@ensp.unl.pt

Issue:

In 2019, the Portuguese government established the autonomy of local authorities and the decentralisation of public administration. Consequently, a process that includes the transfer of health competencies from the central government to the municipalities began. The newly acquired competencies enable local governments to play a crucial role in defining health policies and strategic partnerships with special focus on disease prevention, promotion of healthy lifestyles and active ageing. That said, several municipalities established a collaboration protocol with the National School of Public Health (NSPH) for the development of the Health and Quality of Life Development Plan (HQLDP) as a contribution to their strategic planning.

Results:

NSPH has developed a solidified methodology for municipalities to substantiate their health planning and priorities, based on a deep health diagnosis, from existing demographic, economical, health and environmental data in a given timeline. HQLDP is a medium-term reference that will support strategic action in the area of health and social determinants. The general objective of the HQLDP is to contribute to the improvement of the health status, in the different stages of the life cycle, based on the evaluation of the health profile and social determinants and to define a set of strategic objectives that promote the reduction of inequalities, the promotion and protection of health and the prevention of disease. The developed plan also includes public and stakeholders' scrutiny, to define key areas of action in the health sector.

Lessons:

The HQLDP takes into account the vocation of local authorities to act on determinants through policies that intervene in the environmental, socio-economic, educational, urban planning and mobility contexts; assuming an active, influential and local role in health policies. Municipal intervention requires a strong and concerted local action and the definition of territorialized development strategies.

Key messages:

- HQLDP has a crucial role on the situational diagnosis and set of priorities of the quality of life and health indicators to assess the priorities at council level.

- HQLDP provides the knowledge for the development of public policies and interventions that comply with the population characteristics by reducing health inequalities and inequities.

[11]Center for Primary and Community Care, University of Lucerne, Lucerne, Switzerland
Contact: olena.bychkovska@paraplegie.ch

Background:

Despite having a high healthcare need, persons with complex conditions are less likely to receive comprehensive care. Individuals with SCI experience difficulties accessing services 2-4 times more than the general population. There is little agreement concerning the factors that influence these access restrictions. Few studies focus on health system impact on characteristics on access.

Objective:

To outline barriers and facilitators to service access among persons with SCI across 22 countries in terms of health system characteristics

Methods:

InSCI(2017): 1st community survey on experience of persons with SCI, 12591 participants, 22 countries (Australia, Brazil, China, France, Germany, Greece, Indonesia, Italy, Japan, Lithuania, Malaysia, Morocco, the Netherlands, Norway, Poland, Romania, South Africa, South Korea, Spain, Switzerland, Thailand, USA).

Data analysis:

1. Hierarchical cluster analysis based on Gower distance (to group systems by access restrictions: Acceptability, Approachability, Availability, Affordability, Appropriateness).
2. Generalized linear mixed-effects decision tree (to explore the association of system characteristics and access, including WHO and OECD system indicators (e.g. UHC index, expenditure, human resources). Missing values were imputed with missforest.

Results:

12% of persons with SCI reported having an access restriction, most of them (7%) with Availability. By country, the highest unmet needs were reported in Poland (25%), Germany, Lithuania, and Romania (13).

1. Cluster analysis: 7 health systems clusters (groups) were identified.
2. By June 2022, we will have the results of the second analysis: the association of system characteristics with access and how it is modified by socio-demographic and medical factors.

Expected conclusions:

The study identifies factors a country could modify in order to improve access and strengthen the system for persons with SCI/disability, that might be relevant to general population as well.

Key messages:

- Persons with SCI often experience similar access restrictions across countries, incl. those with high-performing health systems. System strengthening in this area is further required in all countries.
- Health systems are fragmented, e.g. healthcare quality and access inside a country differs by region, urban/rural setting etc., hence, the systems are challenging to classify.

Abstract citation ID: ckac129.476
How to involve 'hard to reach' population groups in research projects

Lilian van der Ven

LGL van der Ven[1], JM van Baar[2], RS Wispelweij[1], M Jambroes[1]
[1]Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands
[2]Trimbos Institute, Utrecht, Netherlands
Contact: l.g.l.vanderven-2@umcutrecht.nl

Issue:

Addressing and reducing health inequalities is a major challenge in public health. Actively involving the most vulnerable populations groups in research projects in order to assess and address their needs is an important step towards reducing health inequalities. However, the most vulnerable groups are often perceived as the most difficult to reach for researchers.

Description:

We conducted a research project to assess and address the health effects of the COVID-19 pandemic in vulnerable population groups. In three neighbourhoods, we identified the 2-3 most vulnerable population groups. We aimed to interview at least 20 participants per neighbourhood, evenly distributed among the groups, using creative and adaptive recruitment methods.

Results:

Successful strategies differed per group. Strategies that proved successful were: rewriting information and consent letters together with the target population to help make them more accessible and attractive; using simple language in texts and while interviewing; asking the target population what type of compensation for the interview they would find most attractive; identifying persons who function as social hubs in the neighbourhood, asking them to help recruit participants, and providing them with financial compensation for their time; asking professionals in care and welfare organisations to help recruit among their clients; interviewing people in the places they would normally go to; snowball sampling. We met our recruitment goals.

Lessons:

When working with 'hard to reach' populations, it takes researchers time, flexibility and creativity to find the right strategy to recruit participants while still respecting the boundaries set by GDPR and ethics committees. We recommend researchers to think about various possible recruitment strategies before starting a project, and to be prepared to change strategies during a project if necessary.

Key messages:

- 'Hard to reach' populations are not really hard to reach, they just require a different mindset and skillset from the researcher.
- We encourage researchers to be creative and flexible in finding the right recruitment strategies in their project, and to think about various possible strategies before starting a project.

Abstract citation ID: ckac129.477

Addressing the relational determinants of health

Alison McCallum

I Abdikarim[1]
[1]Public Health, Chaite UniversitatsMedizin, Berlin, Germany
Contact: alison.mccallum@ed.ac.uk

Problem:

The persistence of systemic discrimination and inappropriate responses to unmet need by institutions in response to current challenges (COVID-19, austerity, war) requires a fresh look at the gaps in our response to inequities. We found evidence of avoidable inequity and harm associated with the relationships between individuals, communities, organizations, and governance structures. These have been described as the Relational Determinants of Health.

Results:

We undertook a scoping review to find research and policy interventions to address this problem. The relationships between individuals, communities and institutions that underpin how health is experienced and lives are lived were rarely considered explicitly in the design and implementation of interventions to address inequalities other than at local level or in response to individual trauma. We found academic work co-created with indigenous peoples did address trauma experienced due to historical structural violence and discrimination. It recognised the importance of land, culture, ceremony, and language in the organization of inter-personal, community and institutional relationships, codified the relational determinants of health and tested interventions that changed them. By applying assemblage theory, relationships with individuals and communities that had been previously excluded and harmed were being redesigned. These promising findings, replicated in different settings, indicate that relationships between communities and authorities that appear structural, are not fixed but can be primed to be changed for the better.

Conclusions:

To reduce the scale of future inequalities, it is essential that we chronicle and quantify the impact of the Relational Determinants of Health. We present a model that will enable methods for gathering evidence for change to be established, and to support interventions that will improve our research, advocacy, and policy responses to this challenge.

Key messages:

- Discrimination and unmet health need are associated with the quality of relationships between individuals, communities and institutions.
- Attention to the Relational Determinants of Health can help institutions reduce exclusion and harm by working with communities to redesign relationships.

8.B. Workshop: The Dutch GOR-Covid-19 health monitor: a five-year research program to inform public health policy

Abstract citation ID: ckac129.478

Organised by: National Institute for Public Health and the Environment, GGD GHOR Netherlands, NIVEL, ARQ National Psychotrauma Centre (Netherlands)
Chair persons: Michel Dückers (Netherlands), Elske Marra (Netherlands)
Contact: m.duckers@nivel.nl

Societies can be confronted with disasters and major incidents that form a serious threat to population well-being, safety and health. The Covid-19 pandemic challenged governments at different levels in many countries across the world for over two years to address a variety of public health risks. This also applies to the Netherlands, a densely populated high income country in Europe with approximately 17 million citizens. Experience with previous crises - such as the Bijlmermeer Airplane Disaster in Amsterdam (1992), the Q fever outbreak (2007-2011), the MH17 airplane disaster in Ukraine (2014) and gas-mining induced earthquake problems in the north of the Netherlands (ongoing) - shaped the current Dutch public health response structure and knowledge base, designed to assist local and national authorities to anticipate disaster-related population health risks. During the Covid-19 pandemic this structure was used as a starting point to develop and implement a five-year monitoring program: the integrated GOR-Covid-19 health monitor; GOR stands for "Gezondheidsonderzoek bij rampen" (disaster health research). The main objective of the GOR-Covid-19 monitor is to collect and promote the uptake of reliable and timely monitoring information for the benefit of regional and national public health decision-making in the Netherlands, focusing on the public health impact of the Covid-19 crisis (virus infections and mitigation measures) among children and adolescents, adults and public mental health care, a potentially vulnerable group including homeless and former drug addicts. The monitor is carried out under coordination of the "Network GOR", comprised of the National Institute for Public Health and the Environment, GGD GHOR Netherlands (on behalf of the 25 municipal health regions), Nivel, and ARQ National Psychotrauma Centre. The current workshop consists of five presentations by members of Network GOR. The first contribution gives an overview of the research objectives and the outline of the study protocol of the monitoring program. The other contributions focus on particular study components, that are shaped and aligned during the timeline of the monitor. One presenter will share the findings from the first series of systematic literature reviews. Two contributions are based on a combination of surveys in representative samples and an analysis of primary care registry data: one with an emphasis on quarterly results (short-cycle monitoring), the other on (bi-)annual reports, which zoom in on long-term developments and differences between subgroups based on vulnerability factors and geography (long-cycle monitoring). The fifth contribution details the participatory stakeholder-engagement process designed and implemented to promote that monitor findings are used for local and national public health sense-making and decision-making.

Key messages:

- The workshop describes the background and design of a national longitudinal monitoring program to track the public health impact of the Covid-19 pandemic in the Netherlands.
- An overview is given of the first findings on the health impact of the pandemic for different populations and related vulnerability factors as well as the stakeholder engagement process.

[3]Impact, ARQ National Psychotrauma Centre, Diemen, Netherlands
[4]Centre for Environmental Safety and Security, RIVM, Bilthoven, Netherlands
[5]Faculty of Behavioural and Social Sciences, University of Groningen, Groningen, Netherlands
Contact: A.vanDuinkerken@nivel.nl

Introduction:
The global COVID-19-pandemic influences people's health, both directly through infection and indirectly through the protective measures taken by governments. Previous experience with health research after disasters/crises are generally limited to short-lasting, local disasters with direct consequences for those affected. The COVID-19-pandemic has a different nature: influencing everyone and lasting a longer time. A longitudinal, wide-reaching research-approach is needed to study the health effects of COVID-19. Therefore, the Network GOR-COVID-19, a research group consisting of different organizations, started a monitor on the health effects of COVID-19.
Methods:
The monitor consists of three main elements: yearly monitoring, quarterly monitoring and literature reviews. Where possible, existing data structures are used. For the quarterly monitoring, two data sources are used: general practitioners' [GP] registry data and data gathered from panels. The GP data is used for weekly surveillance, giving insight into the prevalence of health symptoms presented to the GP. The panel data is used to gain insight into current self-reported health and wellbeing of people. For the yearly monitoring, two data sources are used. The first is GP data which gives information about the prevalence, incidence and development of symptoms, complaints and diagnoses. It allows for comparison over time and among different population groups. The second is the corona health monitor questionnaire, an existing questionnaire on health and well-being. Finally, literature reviews are conducted annually to create an overview of international and national research about the effects of the COVID-19-pandemic on health.
Discussion:
Since most of our knowledge about the potential impact of the pandemic stems from research on short-term disasters, limited to specific places, this study is expected to provide valuable new insights.

Abstract citation ID: ckac129.480
The consequences of the COVID-19 pandemic on the health and wellbeing of the youth: a systematic review

Mark Bosmans

M Bosmans[1], *E Marra*[2], *C Baliatsas*[1], *M de Vetten-Mc Mahon*[2], *M Dückers*[1,3,4]
[1]Disasters and Environmental Hazards, NIVEL, Utrecht, Netherlands
[2]Centre for Environmental Safety and Security, RIVM, Bilthoven, Netherlands
[3]Impact, ARQ National Psychotrauma Centre, Diemen, Netherlands
[4]Faculty of Behavioural and Social Sciences, University of Groningen, Groningen, Netherlands
Contact: m.bosmans@nivel.nl

Introduction:
The coronavirus outbreak and resulting restrictive measures have a major impact on population health. Research results suggest that the impact on the youth is especially great. In this review of international literature we investigated the impact of the COVID pandemic on the health and wellbeing of the youth, with a special emphasis on identifying vulnerable groups.
Methods:
This review looked at the impact on five domains; physical health, (health)care needs, mental health, social effects and other effects. We also identified protective and risk factors. We searched the databases of Pubmed, PsychInfo and Embase for longitudinal empirical studies in May 2021.
Results:
For all topics together, 145 papers were included. Results show that the corona crisis had a negative impact on the physical and mental health of the youth. Many young people exercised less, ate less healthy and suffered more from depression, anxiety and loneliness. Young people who already had mental or physical health problems were more vulnerable and experienced more negative results of the corona crisis. The crisis worsened existing problems. Other factors that exacerbate problems are poverty and poor family functioning. The impact is the largest for youths with multiple problems. At the same time, young people seem resilient. Many had no or few health problems during the studied period (roughly the first year of the pandemic), or their health problems decreased when restrictions were lifted.
Discussion:
More attention is needed for preventive interventions that prevent health problems, promote health and that support the youth to maintain and build their resilience. Special attention should be paid to vulnerable groups when targeting these interventions.

Abstract citation ID: ckac129.481
The integrated GOR-COVID-19 health monitor: quarterly reporting ("short-cycle monitoring")

Mare Derks

M Derks[1], *C Baliatsas*[2], *M Dückers*[2,3,4], *M Bosmans*[2], *E Marra*[1]
[1]Centre for Environmental Safety and Security, RIVM, Bilthoven, Netherlands
[2]Disasters and Environmental Hazards, NIVEL, Utrecht, Netherlands
[3]Impact, ARQ National Psychotrauma Centre, Diemen, Netherlands
[4]Faculty of Behavioural and Social Sciences, University of Groningen, Groningen, Netherlands
Contact: mare.derks@rivm.nl

Introduction/objective:
Given the capricious nature of COVID-19, infections and accompanying restrictive measures to reduce spread of the virus are known to strongly vary over time. The impact of the corona crisis on the mental and physical health of the general population may fluctuate accordingly. The quarterly monitoring research line is aimed to monitor the health impact of the corona crisis over time on a high frequency basis.
Methods:
This is achieved through a multi-method approach, combining: a) survey data on perceived impact of corona measures and several health outcomes from two representative panels (~ 5.000 adolescents/young adults aged 12 and 25 years; ~ 5.000 adults aged 26+ years), and b) surveillance data of acute health problems from the Nivel Primary Care Database (~1,6 million patients from 380 general practitioners). Data collection started in September 2021 and continues during the five-year monitoring program. Panel data is collected every quarter; Nivel surveillance data is collected weekly. Our contribution to the EUPHA conference will include data up and until September 2022 (i.e. five rounds of survey and surveillance data).
Results:
Preliminary results from September 2021 through March 2022 indicate that adolescents/young adults reported worse mental and physical health outcomes compared to adults. Moreover, they experienced a more negative impact of corona measures. Accordingly, their mental health related problems, including suicide ideation, spiked between December 2021 and February

2022, a period characterized by highly restrictive COVID-19-measures.

Discussion:

The quarterly monitoring research line showcase the relevance and feasibility of integrating multiple data sources in understanding the short- and long-term effect of the corona crisis. The results increase our understanding in the potential adverse effects of corona-related restrictive measures on population health, potentially aiding policy making and health promotion.

Abstract citation ID: ckac129.482
The integrated GOR-COVID-19 health monitor: annual reporting (''long-cycle monitoring'')

Christos Baliatsas

C Baliatsas[1], A Meerdink[2], N Tak[2], M Dückers[1,3,4], P Geuijen[5], E Marra[5], M Bosmans[1]

[1]Disasters and Environmental Hazards, NIVEL, Utrecht, Netherlands
[2]GGD GHOR Netherlands, Utrecht, Netherlands
[3]Impact, ARQ National Psychotrauma Centre, Diemen, Netherlands
[4]Faculty of Behavioural and Social Sciences, University of Groningen, Groningen, Netherlands
[5]RIVM, Bilthoven, Netherlands
Contact: c.baliatsas@nivel.nl

Introduction:

Because of foreseeable COVID-19- related mental and physical health risks for the general population, a longitudinal health monitor was launched in the Netherlands. The monitoring program includes multiple methods. The current contribution places an emphasis on the so-called ''long-cycle'' monitoring activities at the national and regional level. The aim is to produce (bi-)annual reports on developments in health status of the general population and several potentially vulnerable subgroups (e.g. psychological and somatic comorbidities, lower socio-economic status).

Methods:

Primary care registrations and questionnaire data were used. Both depend on existing methods of data collection, cover a broad spectrum of health aspects and offer the possibility of pre-COVID-19-comparison. Primary care data were obtained from electronic health records of general practices in the Nivel Primary Care Database. Large-scale survey research with questionnaires was conducted in all the 25 health regions of the Netherlands among 2nd and 4th graders in high schools, adults, elderly and young adults (16-25 years old). Where possible, data were combined with data on socio-economic status and additional health aspects from Statistics Netherlands (CBS).

Results:

The first results from both data sources show that the COVID-19 pandemic undeniably had an effect on the mental health of youth. Compared to 2019, there was a general decrease in overall health and happiness in 2020 and a perceivable increase in social problems as well as health symptoms such as lack of smell and taste. Furthermore, a smaller groups of people experienced more psychological symptoms, serious problems like suicidal thoughts and PTSD symptomatology.

Discussion:

Adverse effects of the pandemic on youth are already visible in the first year after the outbreak. It is crucial to closely monitor the course of this health impact in the years to come, based on the combination of large, representative databases.

The integrated GOR-COVID-19 health monitor: research-informed policy-making through dialogue

Noor Jansen

N Jansen[1], E Marra[2], M de Vetten-Mc Mahon[2], M Dückers[1,3,4]

[1]Impact, ARQ National Psychotrauma Centre, Diemen, Netherlands
[2]Centre for Environmental Safety and Security, RIVM, Bilthoven, Netherlands
[3]Disasters and Environmental Hazards, NIVEL, Utrecht, Netherlands
[4]Faculty of Behavioural and Social Sciences, University of Groningen, Groningen, Netherlands
Contact: n.jansen@arq.org

Introduction:

Like in many other countries, the COVID-19 pandemic and the government restrictions introduced to contain the spread of the virus had major consequences for the health and wellbeing of the population in the Netherlands. To monitor the short and long-term public health impact, a nationally coordinated research program was initiated with the intention to guide decision-making by local and national public health authorities. This contribution presents the process to establish a continuous dialogue with end-users of information to add focus to the monitor, make sense of the findings and formulate policy recommendation and practical guidance, both at the national and regional level.

Methods:

To facilitate the translation and dissemination of research results among policy makers, practitioners and scientists, an ongoing series of dialogue sessions is organized during the monitoring program. Apart from the objective of evidence-informed public health decision-making, the dialectic process seeks to ensure multi-sectoral learning and co-creation and contribute to a broad sense of ownership among stakeholders. National and regional health participants serve as hub coordinators. New stakeholders are invited and will be actively approached wherever considered relevant.

Results:

At the EUPHA conference experiences with organizing the dialogue in app. the first two years of the program will be presented together with preliminary results and a reflection on factors that helped or hindered the implementation and uptake of findings.

Discussion:

Monitoring data collected using robust methods and analyzed in such a way that vulnerability factors are carefully considered, is invaluable for decision-making. However, in order to effectively serve as guidance to public health policy, whether in the context of the COVID-19 pandemic or in non-crisis situations, a constructive, ongoing exchange between end-users of the information needs to be facilitated.

8.C. Workshop: Networking for life: How European regions develop/strengthen cross-border health

Abstract citation ID: ckac129.484

Organised by: Healthacross Initiative, Health Agency of Lower Austria (Austria)
Chair persons: Julia Winkler (Austria), Bettina Menne (Denmark)
Contact: julia.winkler@healthacross.at

The WHO European Programme of Work (2020-2025) emphasizes the importance of ''supporting local living environments that enable health and well-being''. Through engaging with regulatory arrangements that support an environment that responds to citizens' concerns for safer, healthier and better living, the EPW intertwines with the aims of the EPH Conference to promote population health and to strengthen health systems. The Covid-19 pandemic shows that health threats do not stop at national borders. Different responses amongst cross-border regions, based on national policies in terms of Public Health and Social Measures (PHSM), may even weaken their effectiveness. The importance of cooperation across border is not only relevant in the framework of pandemic preparedness and responses, but in many other fields: healthcare cooperation, emergency medical care, medico-social cooperation and health promotion. All have shown to be beneficial to population health when developed at the subnational level across border regions. Consequently, cross-border health (care) gained importance in recent years and there are various border regions who showcase successful cross-border cooperation in the field of health. Projects are being implemented along neighbouring European regions, translating into improved access to healthcare for the border populations, promoting prevention and health education as well as increasing healthcare availability and equity. Via various health networks, border regions can learn to engage with neighbours and build up tailor-made health services for their citizens. More so, through active participation in various well-established public health networks, the exchange of ideas, knowledge and solutions to strengthen cross-border health becomes part of region's daily work. Through strong networks and partnerships, joint solutions for a strengthened citizens' health in rural areas could be found. Creating synergies between the healthcare capacities of the two sides of the border, collaboration between border area medical teams, access to equipment located one or other side of the border can make a positive impact on the users of health services and facilities. In this round table workshop, the role and impact of health networks on a sub-national level (regional) will be further examined. Based on selected well-established health networks, their work and value will be outlined.

The Keynote speech will be given by the Coordinator of the WHO Europe Regions for Health Network, Dr. Bettina Menne. Subsequently, 3-4 well-established health networks will take the floor with a short presentation (5 min) in order to present their 'business case' and value. The presentations will be followed by a short round table discussion in order to highlight the role and strengths European health networks can bring to regions in order to improve cross-border healthcare (WHO RHN, Healthacross /Lower Austria, euPrevent, AEBR, EUREGHA).

Key messages:

- Role and impact of health networking for cross-border health on a sub-national level.
- Outlining the benefits and challenges for border regions to participate in health networks in order to strengthen cross-border health (also during Covid-19).

WHO RHN Network

Bettina Menne

M Menne[1], *A Forcellini*[1]
[1]WHO Regions for Health Network, WHO Regional Office for Europe, Venice, Italy
Contact: menneb@who.int

The WHO European Office for Investment for Health and Development (Venice Office) works in the thematic areas of health equity, social and economic determinants of health, and investment for health in the context of the 2030 Agenda for Sustainable Development and the European Programme of Work. Within the WHO Venice Office, the the Regions for Health Network (RHN) works to place health and well-being high on the key political agendas, and advocates the needs of local and subnational authorities at the regional and international levels. RHN has been launched in 1993 to help regions to accelerate the delivery of improved population health, and currently has 34 members. It has developed over the decades into a forum that creates synergies between regions and stakeholders in the field of health (mutual learning); strengthens cooperation/collaboration between regional and local actors and international health institutions; increases understanding of the functioning of regional and local health systems; promotes the exchange of experience, and mutual learning. RHN positions itself at the forefront of innovative approaches and aims at becoming a cutting-edge network ready to capture and disseminate effective approaches, policies and strategies that improve population health at the regional level of governance. In past years, RHN has spearheaded collaborative efforts amongst cross-border regions, on different topics, and with technical guidance from WHO. These efforts have led to joint initiatives, publications, study trips, project collaboration and periodic and structured exchanges of experiences.

Healthacross initiative of Lower Austria

Julia Winkler

J Winkler[1]
[1]Healthacross Initiative, Health Agency of Lower Austria, St. Pölten, Austria
Contact: julia.winkler@healthacross.at

Lower Austria is by size the biggest province of Austria and located in the heart of Europe with a 414 km long border to the Czech Republic and Slovakia, and in close proximity to Hungary. Not only through its geographic location but also through its understanding to be a connected region as part of a strong European Union, cross-border health care plays an important issue at the provincial level. Led by the European spirit, all international and cross-border health activities are bundled under the umbrella of the 'Healthacross initiative''. The initiative is part of the Health Agency of Lower Austria (NÖ Landesgesundheitsagentur), which operates and manages all 27 public hospitals and around 50 care/nursing homes in the region. Via the ''Healthacross initiative'', Lower Austria is participating in four transnational networks and since 2008, conducted eight EU co-funded projects in cross-border healthcare, four of them currently running. Healthacross is the coordinator of this session, with support of WHO RHN network. Active networking in various European and international networks is part of the regional strategy of Lower Austria in order to gain excellence to improve the health and quality of life for citizens living in border regions. The premise is to enable equal access to health care services for citizens, regardless of their place of residence. The current epidemiological situation with the COVID-19 pandemic has not only impact on cross-border healthcare, but also on the life, health and well-being of citizens. With the closure of national borders, the exchange of healthcare services came to an interim halt; solely dialog remained - which was incredibly valuable for both commuters and citizens living in the border regions. Lower Austria will take care of the moderation of the session and will be represented by Julia Winkler.

euPrevent

Brigitte Van Der Zanden

B Van Der Zanden[1]
[1]euPrevent, Heerlen, Netherlands
Contact: vanderzanden@euprevent.eu

euPrevent is a non-profit organisation and a Euroregional network that wants to promote the quality of life of citizens in the border regions of the Netherlands, Germany and Belgium. Policy in the field of care and well-being is mainly organised at national level. This has a major impact on citizens in the border region who regularly cross the border for work or family reasons. We therefore focus on the establishment of sustainable, cross-border network connections between health organisations in the border region. Our cross-border cooperation is based on the following three frameworks, within we work: (1) Positive Health, (2) Health in All Policies (HiAP), and (3) Sustainable Development Goals. The network will be represented by Brigitte van der Zanden, the Director of euPrevent and a long standing expert in cross-border health issues.

Association of European Border Regions (AEBR)

Martin Guillermo Ramirez

M Guillermo Ramirez[1]
[1]Association of European Border Regions, Berlin, Germany
Contact: m.guillermo@aebr.eu

AEBR is one of the oldest regional associations in Europe (founded in 1971), with a hundred members (border and cross-border regions) in more than thirty European countries. AEBR works for the interest of border regions towards EU and national authorities, developing capacities, increasing awareness, organizing events and implementing projects. AEBR currently implements IVY (Interreg Volunteer Youth) on behalf of the European Commission's DG Regio, within the framework of the European Solidarity Corps, which has deployed more than 700 young Europeans in Interreg programmes and projects during the last four years. It also manages b-solutions to tackle cross-border legal and administrative obstacles and test possible solutions, and takes part in other projects in Europe and other continents. It has recently finished a study for DG SANTE on cross-border patients' flows in various EU cross-border areas. The association will be presented by it's Secretary General, Martin Guillermo-Ramírez.

European Regional and Local Health Authorities (EUREGHA)

Michele Calabro

M Calabro[1]
[1]European Regional and Local Health Authorities, Brussels, Belgium
Contact: michele.calabro@euregha.net

EUREGHA's vision is to ensure that the local and regional perspective is represented in EU health policy because local and regional authorities are the natural interface between citizens and European institutions, being the bridging bodies between policies and practices and the closest organizations to the concept of communities. We are the only European network prioritizing the representation of local and regional health authorities at EU level, as they fulfil a key role in improving efficiency, quality, and accessibility of healthcare systems and services. EUREGHA understands their specific needs and works tirelessly to represent regional and local health authorities in EU health policy, to amplify their voices as a means to improve European public health and healthcare. Through advocacy, policy monitoring, profile promotion, partnerships, and project development, EUREGHA facilitates and promotes collaboration between its members, EU institutions, pan-European health networks and other healthcare stakeholders. Network activities and projects are implemented upon a strategic background of "ways to make things happen" such as value based healthcare, smart specialization strategies and skills for innovation and digital transformation - on one side - and along thematic and field objectives such as cross-border healthcare, cancer, obesity, mental health and ageing - on the other side. Lower Austria is a long-standing member and Vice-Chair of EUREGHA.

8.D. Oral presentations: Diabetes and nutrition

Abstract citation ID: ckac129.490
Nitrites and nitrates dietary exposure from natural sources and additives and type-2 diabetes risk

Bernard Srour

B Srour[1], *E Chazelas*[1], *C Debras*[1], *N Druesne-Pecollo*[1], *C Agaesse*[1], *F Szabo de Edelenyi*[1], *L Sellem*[1], *E Kesse-Guyot*[1], *M Deschasaux-Tanguy*[1], *M Touvier*[1]
[1]EREN, Inserm, Inrae, Cnam, USPN, INSERM, Bobigny, France
Contact: b.srour@eren.smbh.univ-paris13.fr

Nitrates and nitrites occur naturally in water and soil and are commonly ingested from drinking water and dietary sources. They are also used as food additives. The epidemiological evidence linking exposure to nitrites/nitrates with type-2 diabetes (T2D) risk is scarce. We aimed to study these associations in a large population based prospective cohort study. Overall, 104,168 adults from the French NutriNet-Santé cohort study (median follow-up time 6.7 years) were included. Associations between intakes of nitrites and nitrates (evaluated using repeated 24h dietary records, linked to a comprehensive food composition database and accounting for details of commercial names/brands of industrial products) and risk of T2D were assessed using cause-specific multivariable Cox proportional hazard models adjusted for known risk factors (sociodemographic, anthropometric, lifestyle, medical history, and nutritional factors). During follow-up, 969 incident T2D cases were ascertained. Total nitrites and nitrites from natural sources were both positively associated with higher T2D risk (HRtertile 3 vs.1 = 1.29 (95% CI 1.06-1.56), Ptrend = 0.004, and 1.27 (95% CI 1.05-1.54), Ptrend = 0.01, respectively). Participants with higher exposure to nitrites from food additives (i.e. above the sex-specific median), and specifically those having higher exposure to sodium nitrite (e250) had a higher T2D risk compared with those who were not exposed to food additive nitrites (HRtertile 3 vs.1 = 1.58 (95% CI 1.28-1.94), Ptrend<0.001, and 1.59 (95% CI 1.30-1.96), Ptrend<0.001), respectively). There was no evidence for an association between nitrates of any source and T2D risk (all Ptrend>0.4). In this large prospective cohort, a higher dietary exposure to nitrites (from both natural sources and food additives) was associated with higher T2D risk. These results provide additional evidence in the context of current discussions about updating regulations on the use of nitrites as food additives.

Key messages:

- A high exposure to dietary nitrites (from both natural and food additive sources) is associated with an increased risk of type-2 diabetes.
- These findings support further regulations concerning the use of nitrites as food additives in processed meats.

Abstract citation ID: ckac129.491
Nitrites and nitrates from additives and natural sources and risk of cardiovascular outcomes

Bernard Srour

B Srour[1], *E Chazelas*[1], *C Debras*[1], *N Druesne-Pecollo*[1], *C Agaesse*[1], *F Szabo de Edelenyi*[1], *L Sellem*[1], *E Kesse-Guyot*[1], *M Deschasaux-Tanguy*[1], *M Touvier*[1]
[1]EREN, Inserm, Inrae, Cnam, USPN, INSERM, Bobigny, France
Contact: b.srour@eren.smbh.univ-paris13.fr

Nitrates and nitrites are used as food additives in processed meats. They are also commonly ingested from water and several foods. Evidence suggests a beneficial role of dietary nitrites and nitrates in lowering blood pressure. However, associations between exposure to nitrites and nitrates from natural sources and food additives, separately, and risks of hypertension and cardiovascular disease (CVD) have not been investigated. We aimed to study these associations in the French population based prospective cohort NutriNet-Santé. Overall, 104,817 adults were included. Associations between exposure to nitrites and nitrates (evaluated using repeated dietary records, linked to a food composition database accounting for commercial brands of industrial products) and risks of hypertension and cardiovascular disease were assessed using multivariable Cox proportional hazard models. During follow-up, 3810 incident cases of hypertension were ascertained, and 2075 cases of CVD, 1004 of cerebrovascular diseases and 1079 or coronary heart diseases were diagnosed. Participants with higher exposure to nitrites from food additives and specifically those highly exposed to sodium nitrite (e250) had a higher hypertension risk compared with those who are not exposed to nitrites from food additives (HR = 1.19 (95% CI 1.08-1.31), P = 0.002, and 1.19 (95% CI 1.07-1.31), P = 0.002, P < 0.001), respectively). There was no evidence for an association between total nitrites or nitrites from natural sources, or dietary nitrates with hypertension risk (all P-values>0.3). There was no evidence for associations between dietary nitrites, or nitrates with risks of cardiovascular, cerebrovascular or coronary heart diseases (all P-values>0.2). In conclusion, we found that higher exposure to nitrites from food additives was associated with higher risk of hypertension. Our results do not support a potential protective association between dietary nitrites or nitrates and cardiovascular outcomes.

Key messages:

- These results provide additional evidence in the context of current discussions about updating regulations on the use of nitrites as food additives.
- Our findings do not support any protective impact of nitrites and nitrates on cardiovascular health.

Skipping breakfast and late-night-eating have been associated with risk factors for type 2 diabetes (T2D). However, less is known about the link between daily timing and frequency of food intake and risk of developing T2D. The objective of the present study is to investigate the associations between circadian nutritional behaviours, defined by meal timings and frequency, and risk of T2D. 103,312 adults (79% females, mean age at baseline = 42.7) from the French NutriNet-Santé cohort were included. Participants' circadian nutritional behaviours were assessed using repeated 24 h dietary records. Associations of time of first and last meal of the day, meal frequency and of nighttime fasting duration with risk of T2D were assessed by multivariable Cox proportional hazard models adjusted for known risk factors. During a median follow-up of 7.3 years, 963 new cases of T2D were ascertained. Compared with subjects reporting on average a first meal before 8AM, those having a first meal after 9AM had a higher risk of developing T2D, HR = 1.59 (1.30 to 1.94). A late time of last meal (after 9PM) was associated with a higher risk of T2D, HR = 1.28 (1.06 to 1.54), but this association was no longer significant after adjusting for time of first meal. Each additional eating episode was associated with a reduction of the risk of T2D, HR = 0.95 (0.90 to 0.99), p-value = 0.01. Overall, nighttime fasting duration was not associated with risk of T2D, except in participants having breakfast before 8AM after a nighttime fasting duration of more than 13 hours (HR = 0.47, 0.27 to 0.82). In this large prospective study, circadian nutritional behaviours were associated with risk of T2D. Daytime nutritional behaviours and specifically an early first meal was associated with a lower risk of type 2 diabetes. If confirmed in other largescale studies, an early breakfast should be considered in preventive strategies for type 2 diabetes.

Key messages:

- If confirmed in other largescale studies, an early breakfast could be considered in preventive strategies for type 2 diabetes.
- Beyond nutritional quality of meals, meal timing could also be a risk factor for type-2 diabetes.

Abstract citation ID: ckac129.493
Cardiometabolic dysregulation and cognitive decline: potential role of depressive symptoms

Norbert Schmitz

N Schmitz[1,2], *S Deschenes*[3], *J McLeish*[2]
[1]Population-Based Medicine, Tuebingen University, Tuebingen, Germany
[2]McGill University, Psychiatry and Epidemiology, Montreal, Canada
[3]University College Dublin, Psychology, Dublin, Ireland
Contact: norbert.schmitz@med.uni-tuebingen.de

Background:

Previous studies have examined associations of cardiometabolic factors with depression and cognition separately.

Aims:

To determine if depressive symptoms mediate the association between cardiometabolic factors and cognitive decline in two community studies.

Methods:

Data for the analyses were drawn from the Rotterdam Study, the Netherlands (n = 2940), the Whitehall II study, UK (n = 4469) and the Canadian Longitudinal Study on Aging, Canada (n = 13,720).

Results:

Mediation analyses suggested a direct association between cardiometabolic factors and cognitive decline and an indirect association through depression: poorer cardiometabolic status at time 1 was associated with a higher level of depressive symptoms at time 2 (standardised regression coefficient 0.07 and 0.06, respectively), which, in turn, was associated with greater cognitive decline between time 2 and time 3 (standardised regression coefficient of -0.15 and -0.41, respectively).

Conclusions:

Evidence from three independent cohort studies suggest an association between cardiometabolic dysregulation and cognitive decline and that depressive symptoms tend to precede this decline.

Key messages:

- Cardiometabolic dysregulation and depression might increase cognitive decline.
- The association between cardiometabolic dysregulation and cognitive decline might be mediated by depression.

Abstract citation ID: ckac129.494
Modelling the impact of salt reduction policies on hypertension in Portugal

Nora Lorenzo i Sunyer

N Lorenzo i Sunyer[1,4]*, M Severo*[2]*, MJ Gregório*[3]*, C Lopes*[4]
[1]EPIUnit/ITR- Institute Public Health, University of Porto, Porto, Portugal
[2]Institute of Biomedical Sciences Abel Salazar, University of Porto, Porto, Portugal
[3]Food and Nutrition Science Faculty, University of Porto, Porto, Portugal
[4]Faculty of Medicine, University of Porto, Port, Portugal
Contact: noralorensu98@gmail.com

Salt reduction policies are identified as effective; however, the assessment of their impact in European countries has been underexplored. The aim of this study is to assess the impact of salt reduction policies on hypertension in Portugal, to ultimately guide future policies. Based on national data, the top five foods contributing to salt intake, their salt content, and daily consumption were determined. Food reformulation included current policies and proposed targets for future agreements. Food availability trend from the main contributors was estimated from national food balance sheets. For this study, we considered five counterfactual scenarios (CF) to estimate salt intake variation: (1) reduction of salt content of foods targeted by current policies, while assuming stable consumption of the primary contributors; (2) proposal to extend CF 1 to other food categories; (3) change in the principal contributor's consumption based on the trend, assuming stable salt content; (4) combination of CF 2 and 3; (5) CF 4 and assuming a reduction of "1 pinch of salt". Relative risk was estimated from regression coefficients to then calculate the potential impact fraction (PIF) and ultimately provide the hypertension cases prevented per year for each CF. The change in salt intake expected by each CF is -11.16%, -13.57%, +0.12%, -13.40% and 23,99%, respectively. For each CF, PIF and hypertension cases avoided per year was, as follows (mean (95%CI)): 9.46% and 46401 (44201;48925) for the first; 14.05% and 68921 (66149;72025) for the second; -1.24% and -6099 (-7636;-4763) for the third; 13.2% and 65125 (62286;67892) for the fourth; and, 15.58% and 76397 (73208;80021) for the last. This study suggests that if the salt content of main contributors was not reduced, its increasing food trend consumption might result in higher incidence of hypertension in Portugal. However, by combining current policies with targets on additional foods, more than 60,000 cases could be avoided annually.

Key messages:

- Salt content reduction policies are necessary if we want to reduce the incidence of hypertension among the Portuguese population.
- Assessment of the impact of salt reduction policies is crucial if we want to choose those that have a stronger impact on the health of our population.

8.E. Workshop: Climate crisis and public health: public health practitioners are key to successful litigation

Abstract citation ID: ckac129.495

Organised by: EUPHA-LAW, EUPHA-ENV, Faculty of Public Health (UK), Groningen Centre for Health Law (Netherlands)
Chair persons: Amandine Garde (EUPHA-LAW), Vlatka Matkovic (Belgium)
Contact: d.w.patterson@rug.nl

Encouraged by wins on asbestos and against Big Tobacco, the public health community and environmental advocates are turning to litigation to sue governments and private sector interests for public health harms from environmental pollution and climate change. Legal systems are as varied as health systems, yet there are principles common to all jurisdictions. In particular, the choice of legal forum is key: which court is best placed to hear a given case? Questions also arise regarding legal 'standing' - who can initiate legal proceedings? What is the most suitable legal basis for the claim? - it could be under a national constitutional protection of the right to life, a human rights treaty, or environmental or tort law. And, what evidence is required and what evidential standard should be met? Since 2020, four cases have been filed with the European Court of Human Rights in Strasbourg on States' responsibilities for the physical or psychological impacts of climate change on human health. Moreover, in May 2021, the Dutch District Court in The Hague ordered Shell to reduce CO2 emissions by 45% by 2030, globally. To reflect on these developments, in October 2021 EUPHA co-hosted a webinar on public health, climate change and strategic litigation which highlighted how strategic partnerships between public health practitioners, environmental advocates, legal experts and affected communities can win cases, raise public awareness and push governments to act. In March 2022 EUPHA-LAW co-hosted a webinar on climate change litigation at the European Court of Human Rights. Sound scientific evidence is as critical to successful litigation as to effective public health policies. Increasingly, public health practitioners are asked to testify in court about the known health impacts of environmental harms. Collecting this evidence requires foresight, meticulous record-keeping, peer-support, and the courage to withstand questioning of professional capacity. In response to this need the Faculty of Public Health (UK), EUPHA-LAW, the Groningen Centre for Health Law in collaboration with Lancet Countdown, will publish a training package and toolkit for public health practitioners on public interest litigation to address climate change and environmental pollution. The workshop will review the role of litigation in advancing public health, and the outline and proposed uses for the toolkit, building on collaboration with environmental and legal organizations such as Greenpeace International and ClientEarth. Opportunities to engage with public health practitioners in regions outside Europe will also be explored.

Key messages:

- Strategic alliances between public health practitioners, environmental advocates, legal experts and affected communities can use litigation and legal process to address common goals.

- Public health practitioners are increasingly asked to testify in court about the known health impacts of environmental harms. Relevant knowledge and skills must be strengthened.

Speakers/Panellists:

8.F. Round table: Digital Innovations in Health Financing: Experiences from sub-Saharan Africa

Abstract citation ID: ckac129.496
Organised by: DigitalUHC Consortium
Chair persons: Wilm Quentin (Germany), Catherine Kyobuutungi (Kenya)
Contact: wilm.quentin@tu-berlin.de

Background:
Universal Health Coverage (UHC) is key for reaching Sustainable Development Goal 3. Digital technologies for health financing (DTHF) may help countries in sub-Saharan Africa (SSA) make progress towards achieving UHC. DTHF are increasingly used to strengthen health financing systems across their three key functions, (1) raising revenues, (2) pooling resources, and (3) purchasing services.

Objectives:
To provide an overview of the potential role of DTHF, discuss country case-studies of DTHF, explore possible risks and challenges, and outline a future research agenda. Together with the participants, we intend to discuss policy options to enable maximising the benefits, while mitigating the risks and challenges.

Added value: The workshop will (1) identify potential benefits as well as risks and challenges of DTHF; (2) highlight the importance of politics and policies for reaping the benefits and minimizing their risks; and (3) establish the building blocks of a future research agenda on digital health financing technologies.

Coherence of workshop: Following a brief presentation of benefits and risks of DTHF from the perspective of the World Health Organisation (WHO), the workshop will present four case studies: (1) Rwanda, where a near universal coverage systems is supported by the digital Mutuelle Membership Management System (3MS) facilitating revenue collection through mobile money; (2) Ghana, where the National Health Insurance Scheme (NHIS) is using a Mobile Renewal system to increase coverage rates, and where an electronic claims management system has been recently introduced; (3) Kenya, where a wide range of digital innovations for revenue raising and purchasing were introduced in the private sector, which are now (partially) integrating the public coverage system; and (4) Madagascar, where experiences with private sector initiatives could support the development of national health insurance. Finally, we will outline the research agenda of the DigitalUHC consortium and collect input on salient topics for policy-makers and researchers.

Format:
The workshop is organised as a round-table panel discussion with panel members giving brief (5 min) introductory presentations before engaging in discussions with other panel members and the audience about cross-cutting issues, including (1) potential benefits of DTHF as well as risks and challenges; (2) the importance of politics and policies for reaping the benefits and minimizing the risks; and (3) the future research agenda. Several polling rounds will engage the audience and collect input on these topics, e.g. by asking participants about (a) examples of digital technologies that they know of, (b) their assessment of potential benefits, risks, and challenges, (c) necessary regulations in different countries, and (d) topics for future research.

Funding:
German Alliance for Global Health Research (GLOHRA) with funds from the Federal Ministry of Education and Research (BMBF).

Key messages:
- Digital technologies for health financing may help countries to achieve universal health coverage.
- Politics and policies are important to reap the benefits and minimize potential risks.

Speakers/Panellists:
Inke Mathauer
WHO, Geneva, Switzerland

Regis Hitimana
Rwanda Social Security Board, Kigali, Rwanda

Daniel Opoku
KNUST, Kumasi, Ghana

Diana Ratsiambakaina

APHRC, Nairobi, Kenya

8.G. Workshop: European Health Data Space: Dialogue on TEHDAS JA data quality & semantic interoperability proposals

Abstract citation ID: ckac129.497

Organised by: TEHDAS JA WP6
Chair persons: Enrique Bernal-Delgado (Spain), Persephone Doupi (Finland)
Contact: persephone.doupi@thl.fi

The EU Data Strategy foresees the development of shared European data infrastructures, enabling cross-border exchange and availability of comparable and high-quality data. The European Health Data Space (EHDS) is the first of these infrastructures to be launched, making use of the potential of health and social data for the purpose of advancing public health, research and innovation. Quality of digital health data has been the focus of research and debate for a long time and several proposals for improvement have been put forward. While these efforts are ongoing, secondary use or re-use of health data, combined with recent developments in data analytics, AI and real-world data (RWD), have raised new requirements on our understanding of data quality and the means for its assurance. Both the European Commission and Member States have underlined the need to support EU and national authorities, as well as the scientific community to agree on interoperability guidelines addressing data quality and semantic interoperability. The TEHDAS Joint Action has responded to these expectations through work undertaken in the context of WP6 - Excellence in data quality. With expected delivery deadline early 2023, the EUPHA conference offers an excellent platform to present the draft forthcoming proposals to the public health community and engage in meaningful dialogue with participants. Key members of the WP6 team will present the process through which the TEHDAS JA recommendations on data quality and semantic interoperability have been developed, the results achieved thus far and the remaining open questions. The workshop discussion section will allow the JA team to collect direct input and feedback for utilization in the production of the final version of the deliverables.

Key messages:

- Increased awareness and understanding of background and rational of forthcoming proposals on data quality and semantic interoperability in the European Health Data Space.
- Opportunity to raise concerns and proposals for improvement and thus have a direct impact on the final TEHDAS JA output on data quality.

Abstract citation ID: ckac129.498
A Data Quality Framework for the European Health Data Space for secondary use

A cornerstone in the development of the European Health Data Space for secondary use of data (EHDS2) is the design, implementation and assessment of a Data Quality Framework (DQF). Consistently, the Joint Action TEHDAS has a dedicated work program where, learning from others' experiences across Europe and abroad, the work package is building the concepts and methods for such a DQF. The scope of this work program is to provide recommendation to the Member States and the European Commission on the concept of DQF to foster, where (institutions) the DQF should be implemented, when in data life cycle, how should be implemented and by whom. In terms of the concept, the DQF raises the importance of quality assurance procedures at data processor level and the level of quality of the data collections in terms of reliability, relevance, timeliness, coherence, coverage and completeness. When it comes to when along the data life cycle, DQF is expected operate when data needs harmonization at data processor level (ie, the effective application of interoperability standards), in the publication of the data sources (ie providing users knowledge on the provenance of data and the content of data source); or, when data sources have to be integrated and sensitive data pseudonymized (ie, the quality of the linkage and losses after pseudonymisation). Finally, when it comes to the methodology, TEHDAS suggests a three-fold approach - some quality measures in the DQF could be translated into legislation (eg, the requirement of regular auditing for a data processor to be a trusted party in the EDHS2); some could be kept as good-practices (eg, recommendation of archival procedures when a research project finalizes); and, under the assumption of continuous data quality improvement, an assessment, benchmarking and promotion methodology (eg, a grading system at data processor level).

In the first phase of its work, WP6 has explored and synthesized existing knowledge and experiences on data quality assurance frameworks (DQAFs) in the context of cross-border sharing of federated secondary use health data. Our aim was to identify good practices within this area and develop a first set of corresponding recommendations. The recommendations reflect the synthesis of results from three parallel lines of work, each utilizing a different methodology: a) thematic workshops and partner meetings, b) analysis of existing data-sharing initiatives, and c) a scoping literature review. Our analysis of literature and existing health data initiatives suggest that currently deployed DQAFs cannot as such serve as platforms or models for an EHDS-wide data quality solution. There is an agreement in principle, that reliability, relevance, timeliness, coherence, coverage and completeness should be incorporated in a DQAF as measurable dimensions of data quality. We aim towards a working definition of data quality, which will be able to reflect the reality of the data, as well as its fitness for purpose from the perspective of potential users.

- We recommend focusing efforts on transparency at the level of data holder institutions across Member States in relation to adoption of regular audits, a well-developed DQAF and clear procedures with regard to processing the data.
- In the medium to longer-term EHDS nodes could promote and support the development of a benchmarking process, which will assist data managers and data holder institutions with alignment against a Europe-wide approach to measuring data quality within and across Member States.

WP6 has approached the target of supporting trustworthy secondary use of health and health care data through two operational objectives: developing the EHDS data quality assurance framework for real-world health data and developing the EHDS secondary use Semantic Interoperability Framework. For the latter objective, several interoperability standards were identified in accordance with the EHDS2 data life cycle and user's journey approach, hence focusing on data discoverability (at data source and variable levels), communication support across nodes and on development of common data models. Selection was based on active participation of WP6 leaders in various pertinent workshops and interactive activities, both in the framework of TEHDAS (Stakeholder and Project Forum meetings) as well as other relevant initiatives (e.g. the PHIRI project). Input was also sought from Commission representatives and EU-level regulatory authorities. In a first step, standards were catalogued based of features such as typology of interest, utility and application domains. In the next phase we organised virtual semi-structured interviews with key representatives of over 20 standards (incl. HL7, SNOMED, CDISC, DCAT, OMOP etc.). The focus of the interviews targeted experiences in standards' actual use, challenges in their implementation, issues of maintenance and sustainability, as well as undergoing collaborations and developments. Sessions were recorded and subsequently the transcripts of discussion extracted automatically. The process of analysing interview materials is presently ongoing, using an adapted version of the Common Assessment Method for Standards and Specifications (CAMSS) v.4.0.0. toolkit. Interim results will be discussed within the Joint Action meeting activities in June 2022, to produce a version for wider stakeholder dialogue later in the fall. Results and recommendations generated through this process will also be presented for discussion with the workshop audience.

8.H. Workshop: Health equity and Chronic diseases: Public health and Primary care roles

Abstract citation ID: ckac129.501

Organised by: Western University (Canada)
Chair persons: Saverio Stranges (EUPHA-CHR), Tatjana Makovski (France)
Contact: saverio.stranges@uwo.ca

Publicly funded health systems are based on the principle of universal access to care. However, significant gaps still exist between services needed and services received (i.e. unmet need for healthcare), especially in chronic disease management and prevention, particularly affecting marginalized groups in the society. Public Health and Primary Care should be working in integrated systems, as they are crucial in addressing health needs in the community and population at large. Several international organizations and leading scholars in the field have been advocating for the integration or primary care and public health to improve population health as well as to tackle complex issues such as multimorbidity. However, these two sectors are still working in silos across several countries, with a significant negative impact in terms of efficiency of the services provided and health care costs. The aim of this workshop will be to provide a global perspective on the issue of health equity in chronic disease management and prevention, with focus on marginalized population subgroups, such as elderly, immigrants and people from low socioeconomic status. We will discuss as well the determinants of unmet health needs for access to primary care in middle-aged and older adults, and examine the reasons for unmet need. We will further discuss about the need and strategies for enhanced integration between public health and primary care in chronic disease management and prevention.

Key messages:

- Public health systems are based on the principle of universal access to care. However, significant gaps still exist between services needed and services received (i.e. unmet need for healthcare).
- Public Health and Primary Care should be working in integrated systems to tackle complex issues such as multimorbidity.

Contact: cornelia.wagner@unifr.ch

Multimorbidity is the co-existence of two or more chronic conditions in the same individual and is highly prevalent in ageing populations. Inequity in multimorbidity in old age could have socioeconomic roots that can be traced across the life course. It is, however, unclear if adverse socioeconomic conditions (SEC) at different periods of the life course predict the occurrence of multimorbidity in later life. We reviewed, therefore, studies assessing the association between life course SEC, measured at min. two time points, and later-life multimorbidity. We identified four studies (25,209 participants) with the first measure of SEC in childhood. In these four studies, childhood SEC was associated with multimorbidity in old age, and the associations were partially or fully attenuated upon adjustment for later-life SEC. We identified five studies (91,236 participants) with the first measure of SEC in young adulthood, and the associations with multimorbidity in old age as well as the effects of adjustment for later-life SEC differed from one study to the other. In conclusion, SEC in early life could have an effect on multimorbidity, attenuated at least partly by SEC in adulthood. Our results suggest that interventions and health promotion aiming to reduce the risk of multimorbidity in old age should target early-life socioeconomic conditions.

Abstract citation ID: ckac129.503
Multimorbidity, low income and unmet need for healthcare: a national study of 41,135 older adults

Shehzad Ali

F Alemu[1], *J Thornton*[1,2], *S Ali*[1]
[1]Department of Epidemiology and Biostatistics, Western University, London, Canada
[2]Department of Family Medicine, Western University, London, Canada
Contact: shehzad.ali@uwo.ca

The aims of this study were: (1) to identify the determinants of unmet need for access to primary care in middle-aged and older adults; and (2) to examine the reasons for unmet need. We used data from the Canadian Longitudinal Study on Aging (CLSA), a nationally representative survey of adults aged 45 to 85 years. Respondents were asked if they 'needed health care during the last 12 months but did not receive it'. For those who replied 'Yes', the survey asked for the reason(s) for not receiving the needed care. Out of 41,135 respondents, 3,468 had unmet need for healthcare in the last 12 months. Among respondents with 0, 1, 2 and $\geq$3 morbidities, the proportion reporting unmet need was 2.5%, 5.3%, 5.1% and 9.1% respectively. After adjusting for covariates, the odds ratios (ORs) for unmet need for 1, 2 and $\geq$3 morbidities (compared to no morbidity) were 1.25 (95% CI: 0.87 to 1.78; $p = 0.23$), 1.57 (95% CI: 1.13 to 2.17; $p < 0.05$) and 2.03 (95% CI: 1.51 to 2.73; $p < 0.05$), respectively. For income groups, the ORs for unmet need (compared to >$150,000/year) were 0.94 (95% CI: 0.79 to 1.12) for $100,000-$150,000, 1.02 (95% CI: 0.87 to 1.20;) for $50,000-$100,000, 1.30 (95% CI: 1.09 to 1.55) for $20,000-$50,000, and 1.39 (95% CI: 1.08 to 1.78) for < $20,000. Other statistically significant determinants of unmet need included age (older adults were less likely to have unmet need), sex (females were more likely), having a family physician (less likely) and perceived physical and mental health (poor health more likely to be associated with unmet need). The most common reasons for unmet need were: 'long wait time' (52.1%) and 'doctor did not think it was necessary' (16.7%). Multimorbidity and low-income are associated with higher odds of unmet need among older adults. This disparity is partly due to not having a regular family physician and long wait time to see a doctor. Reducing these barriers are critical to reducing inequalities in health outcomes.

[4]Department of Readaptation and Geriatrics, University of Geneva, Geneva, Switzerland
Contact: cristian.carmeli@unifr.ch

Inequalities in premature mortality due to individual's attained education are well documented. Intergenerational educational trajectories, whereby both parental and individual education may affect mortality, have received less attention. Our aim was to assess the effect of intergenerational educational trajectories on sex- and cause-specific risks of chronic disease-related premature mortality in Switzerland. Data were from 695,972 individuals born between 1971 and 1980, who were followed from adolescence (10-19y) to mid-life (38-47y) in the Swiss National Cohort, a registry population-based study. Educational trajectories were categorized into four levels: High-High, High-Low, Low-High, Low-Low, which corresponded to the sequence of parental-individual attained education (exposure). Cause of death categories were cardiovascular disease (CVD), cancer, substance use and all other chronic diseases (outcome). We implemented a counterfactual-based framework to quantify inequalities and ran negative outcome controls to triangulate findings. Overall, inequalities were negligible for women and substantial for men, particularly in CVD and substance use deaths. Specifically, inequalities in CVD were negligible by age 30, while by age 45 inequalities due to a High-Low or Low-Low trajectory corresponded to 229 (95% confidence interval (CI): 99, 381) additional CVD deaths per 100,000 persons compared to a High-High trajectory. Inequalities in substance use deaths due to a High-Low trajectory corresponded to 106 (95% CI: 47, 208) additional deaths per 100,000 persons compared to a High-High trajectory by age 30, and increased afterwards. We identified sex- and cause-specific groups at high-risk of premature mortality, and life periods when inequalities due to both parental and individual education arise. Prioritization of prevention strategies in those life periods and groups may help reduce educational inequalities in chronic disease-related premature mortality.

Do Immigrants Use Less Health Care than Non-immigrants? A Population-based Study among People living with Multimorbidity in Canada

Saverio Stranges

C Talukder[1], *P Wilk*[1,2], *S Ali*[1], *S Stranges*[1,3]

[2]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland
[3]Department of Precision Health, Luxembourg Institute of Health, Strassen, Luxembourg
Contact: saverio.stranges@uwo.ca

Background:

Immigrants face unique health care barriers, which can negatively impact their health service use and overall health. Those with multimorbidity may face a particular challenge given its association with increased need for health care. The purpose of this study was to compare health care utilization, as measured by the number of visits to family physicians and specialists, between immigrants and Canadian-born individuals living with multimorbidity.

Methods:

A cross-sectional analysis was carried out using data from the 2015-2016 cycles of Canadian Community Health Survey (CCHS) on 9,014 study participants living with multimorbidity. The study utilized Andersen and Newman's behavioral model as a conceptual framework to identify quantifiable predictors associated with health service utilization. For the entire sample as well as for male and female subsamples, statistical models were fitted using negative binomial regressions to account for the count nature of the outcome variables.

Results:

After adjusting for relevant confounders, no statistically significant differences were observed between immigrants and Canadian-born respondents in the number of visits to family physicians or specialists. However, subgroup analysis revealed that female immigrants with multimorbidity had considerably fewer visits to family physicians than Canadian-born females (Incident Rate Ratio [IRR] = 0.86, 95% CI: 0.76-0.98), while for males these differences were not significant (IRR = 1.03, 95% CI: 0.87-1.21).

Conclusions:
Future research should focus on longitudinal studies to track the health status of immigrants over time, particularly those living with multimorbidity. Moreover, public health policies should be implemented to reduce cultural and social barriers to health care, with a special focus on female immigrants.

8.J. Workshop: Transfer and adoption of digitally enabled integrated care good practices: the JADECARE Joint Action

Abstract citation ID: ckac129.506

Organised by: Kronikgune Institute for Health Services Research (Spain)
Chair persons: Jon Txarramendieta (Spain)
Contact: jtxarramendieta@kronikgune.org

The ageing population and the burden of chronic conditions is increasing the demand for more comprehensive, efficient and smarter healthcare. The EU funded Joint Action JADECARE (Joint Action on implementation of Digitally Enabled integrated person-centred CARE) intends to reinforce the capacity of health authorities to successfully address the health system transition to digitally enabled integrated person-centred care. JADECARE involves 45 organisations from 16 different EU countries covering different funding systems (both Bismarck, Beveridge and mixed) holding different levels of penetration, adoption and maturity of integrated care. It focuses on the transfer and adoption of four original Good Practices (oGPs) to the contexts of 21 Next Adopters (NA). The project started on October 1 2020 and ends on September 30 2023. The oGPs that are being transferred in JADECARE concern integrated care, chronic conditions, self-care, prevention and population health. They are: The Basque Health strategy in ageing and chronicity: integrated care (Spain), the Catalan open innovation hub on ICT-supported integrated care services for chronic patients (Spain), the OptiMedis Model-Population-based integrated care (Germany) and the Digital roadmap towards an integrated health care sector (Denmark). Due to the heterogeneity of the NA, the transfer strategy of JADECARE enables them to customize the parts of the oGPs that will be transferred and adapted to its local context, considering its needs, local strategies and implementation goals. The JADECARE three-step implementation strategy has been designed to be appropriate from the scientific point of view, applicable considering data availability and feasible according to project's timeline and resources:

- Pre-implementation: definition of Local interventions and action plans.
- Implementation: roll-out and operation, based on two Plan-Do-Study-Act cycles.
- Post-implementation: result analysis, impact assessment and reporting on learnings.

By the end of 2022, the implementation phase will be completed, and all NA will start analyzing their results and reporting on learnings. Currently, NAs have defined their interventions and action plans for implementation and are finalizing the first of the two PDSA cycles that they will be performing within JADECARE. 3 of the NAs are implementing interventions at national level, 14 at regional level and 4 at local level. Most of the NAs implement interventions related to digitally enabled integrated care (36), 11 are related to risk stratification and 9 to patient empowerment. This workshop explores the key elements and challenges to be addressed when transferring Good Practices (GP) to heterogeneous health systems with different needs, aims and scopes. It will also highlight the experience of two NA: Marche region, in Italy and Olomouc, in Czech Republic and promote the discussion among speakers and attendees to highlight the challenges and key elements to enable the transfer of GPs.

Key messages:

- JADECARE will impact on EU health systems by implementing innovative solutions and helping to change the model of care provision. It will also settle the basis to implement them at large scale.
- The long-term effect of JADECARE is supported by involving stakeholders at regional and national levels to provide political support and commitment to sustained integrated care.

Contact: jtxarramendieta@kronikgune.org

In this group discussion, all speakers will participate in a group discussion. The moderator will launch questions to speakers, and attendees will be encouraged to make contributions to the group discussion.

8.K. Workshop: Pillars of health promotion and the role of Health literacy in the life course approach

Abstract citation ID: ckac129.511

Organised by: EUPHA-HP, University of Education (Germany), Polytechnic Institute of Coimbra (Portugal), CrAdLiSa
Chair persons: Luís Saboga-Nunes (EUPHA-HP), João Lima (Portugal)
Contact: saboga.nunes@gmail.com

Three pillars are considered today for the development of Health Promotion: Good Governance, Healthy Cities and Health Literacy (HL) (The Shanghai Declaration, WHO 2016). Good Governance and policies to make healthy choices accessible and affordable to all, will ensure that all have the right to health. Sustainable environments are critical to make whole of society collaboration real and it is relevant that Cities become healthier settings. For this, increasing knowledge and social skills to help people make healthiest choices and decisions, i.e. Health Literacy (HL), emerges as the third pillar of the health promotion agenda today. The 10th WHO World conference in 2021 emphasized the role of HL in Health Governance (Stewarding for a flourishing future) that ''... builds on co-design and makes full use of the digital transformation to achieve equitable benefits across populations, ensuring access and meaningful participation. This includes a high priority assigned to health literacy along the life course' (WHO 2021). This workshop discusses how this third pillar (i.e. HL) may be translated into the everyday practice of Health Promotion ''ensuring that people can cope with the challenges they face, through health literacy, ... to lead lives ... in harmony with Nature'' (WHO 2021). From the public health perspective the aim of this workshop is to share with the audience an opportunity to immerse in four different social contexts and explore their HL practices as tracer approaches. The first context is set in Brazil and the emphasis is on HL role in increasing health knowledge. The authors share the results of a large research and an ethnographic analysis of the role of HL in the development of health decisions in the context of public libraries. The second presentation will unveil one of the topics that is influencing health and well-being today: the struggle to counter misleading information. Therefore, a study case from Portugal will focus on HL impact of nutritional marketing on the preferences, attitudes and consumption of children from 6 to 10 years old. A third presentation will consider food sustainability & health, and how HL may be expanded using simple and integrative pedagogical strategies in usual kindergarten dynamics to promote legumeś consumption. Understand how children construct their HL and how influenced they are in this process is the aim of the 4th presentation, where an analysis will be proposed in the quest of exploring HL on those in the first years of schooling. This workshop offers a forum for researchers, practitioners and policy-makers interested in health promotion pillars (e.g. like health literacy). By dialogue and two-way communication lively interaction and vivid discussions will be facilitated. This will allow discussing results regarding their benefit for improving policy research, practice, and policy-making, support further synergies, facilitate networking and collaboration, and support international capacity building.

Key messages:

- Refinement of concepts and practices (e.g. on health literacy) from south-north cultural contexts is needed for wider health promotion implementation strategies.
- The third pillar of Health Promotion (i.e. health literacy) demands a wider reflection of theoretical integrative approaches of health paradigms like salutogenesis.

[2]Ufrgs, Federal University of Rio Grande do Sul, Rio Grande do Sul, Brazil
[3]Polytechnic Institute of Coimbra, Labinsaúde, Coimbra, Portugal
Contact: saboga.nunes@gmail.com

Introduction:

Health Literacy (HL) has received recognition of its role and is proposed as a key element of incrementing wellbeing in public health. In the south, this discussion is engaged but a dialogue north-south needs to be incremented to allow further comprehension and implementation of HL best practices. The BiblioSUS Network in Brazil engaged in this discussion while it aims to expand and democratize access to health promotion & HL best practices, disseminated through the virtual health libraries (BVS). As a distribution model of content production by the Ministry of Health in Brazil it reaches a large audience in the country.

Methods:

The target of this research includes BiblioSUS workers, representing the most diverse areas of knowledge and the community served by the Network. Data collection included an online survey on HL using the HLS-EU-BR instrument.

Results:

The study involved 717 members of the Network and community users of cooperating libraries. Inadequate (12%) and problematic (36%) HL levels revealed that 48% had low levels of HL. The analysis of the 12 variables to assess community's health information needs, showed that 83% of participants do not use the network for health promotion needs, 70.4% do not use for quality of life purposes, but that 41.4% use it for related diseases issues.

Discussion:

This research is the first of its kind and emphasize the need to promote health promotion and HL by several means (e.g. like BiblioSUS Network libraries). Communities need to be reached out to help them make decisions favorable to health in everyday life and settings (e.g. home, community, work). While health promotion and disease prevention are targeted, the Brazilian population need to have easier access to reliable health promotion information, in order to contribute to citizens' empowerment in health.

Contact: joao.lima@estescoimbra.pt

Introduction:

Childhood obesity is a natural response to the modern food environment. A daily consumption of sugar that exceeds the WHO recommendation by 40.7% of Portuguese children influence this condition. It is recognized that children spend more time watching television and youtube, absorbing commercials about food, being susceptible to these messages and negative health literacy. Nutrition marketing is involved in these ads and most of them promote foods high in fat, sugar and salt through persuasive techniques.

Purpose:

Assess implications of exposure to nutritional marketing through television and YouTube on preferences, attitudes and consumption of children from 6 to 10 years old and contribute to the increment of health literacy.

Materials and methods:

Data collection through two online questionnaires about television and youtube habits and children's food preferences, developed by the research team. Statistical analysis was performed using IBM SPSS Statistics software.

Results:

Forty-two students who were attending a private school, aged between 6 and 10 were evaluated. Access to youtube has led to less healthy choices for breakfast in 95% of students ($p = 0.038$). It was found that most children do not have TV in their room and have a more balanced breakfast (81%). Cereals, soft drinks and biscuits are foods groups that children see the most in the tv commercials ($p = 0.001$).

Conclusions:

Exposure to nutritional marketing influences children's preferences, consumption and preferences. An active strategy should be encourage to increment health literacy levels at the family level influencing therefore children's healthier choices.

Introduction:

Eating habits are a key aspect of a healthy lifestyle. This study focuses on the importance of consuming legumes - rich and accessible source of protein, and a healthy and sustainable option, in environmental terms - contributing to increment health literacy levels at the population level.

Objectives:

To design, implement and evaluate a program to promote the consumption of legumes - Beans4Life. Specifically, to assess its impact on the knowledge and frequency of consumption of the eight legumes (beans, grain, peas, beans, beans, lentils, chickpeas and lupins).

Methods:

Pre-test post-test analytical study, with three evaluation moments: 1) before the intervention; 2) after the intervention with the children and 3) after the intervention with the guardians (end of the intervention). Participants: 90 children from 3 to 6 years old (54.4% male) and their guardians. Instruments: questionnaire to assess knowledge and food preferences, questionnaire on eating habits and a questionnaire to evaluate sessions. The intervention had two components, the first with the children (4 food education sessions) and the second with the families (activities that facilitate the inclusion of recipes with legumes in the family's daily life).

Results:

Before the intervention, the results obtained show low levels of knowledge and frequency of consumption of legumes, influencing low health literacy. Peas and beans are the best known legumes (81.1% and 55.6%) and also preferred (77.8% and 73.3%). The results obtained in the second and third assessments show that there was a significant increase ($p < 0.05$) in the knowledge and frequency of consumption of most legumes.

Conclusions:

The objectives initially proposed were achieved and it will be pertinent to continue the present study, with larger samples, in order to increase health literacy awareness and the consumption of this food group in childhood, and provide more robust results that help to clarify the relationships found.

The salutogenesis perspective of Health Literacy

Luís Saboga-Nunes

L Saboga-Nunes[1], M Medeiros[2]
[1]Institute of Sociology, University of Education, Freiburg, Germany
[2]ISAMB, Institute of Environmental Health, Lisbon, Portugal
Contact: saboga.nunes@gmail.com

Introduction:

Health Literacy (HL) is the third pillar of Health Promotion and contributes to the sustainability agenda set earlier in Rio de Janeiro and latter in Shangai (e.g. WHO Shanghai Declaration, 2016). Nevertheless HL per se lacks consistency and structural modus faciendi implementation and practice.

Therefore it is proposed that a discussion be developed based in the salutogenesis embodiment of health literacy from the perspective of children's Sense of Coherence.

Methods:

A population cross-sectional study included (n = 725) children enrolled in the school year 2018/2019 of four schools in Santarem and Lisbon, Portugal. Indicators of anthropometric data, Health literacy (HL), water intake (WI) and nutrition status (NS) and their Sense of Coherence (SoC) levels (using the HLS-EU-PT questionnaire) were collected with the CrAdLiSa online self-administered questionnaire.

Results:

Preliminary results show that the instrument to measure HL (HLS-EU-PT) show satisfactory internal consistency (Cronbach's alpha coefficient 0,94) and association with SoC (Cronbach's alpha coefficient 0,89). The higher is HL levels the higher results are found in the Comprehensibility component of the SoC. The older the age, the amount of WI perception is adequate (p = 0.03); male children (p = 0,02) and children that attend schools in urban area (p = 0,01) drink more water; and have a higher SoC. Also the older the age, the lower the levels of HL (p = 0.000); children with higher levels of HL have greater WI (p = 0.01) as they have a broader perception of the adequate amount of water needed to be healthy.

Conclusions:

These results of CrAdLiSa study explore further on the theoretical perspectives influencing HL. They also showed the usability of the SoC and the HLS-EU-PT questionnaires adapted for children to assess their SoC and HL levels.

8.L. Round table: Breaking the barriers: gender equality and women empowerment in public health practice

Abstract citation ID: ckac129.516

Organised by: EUPHAnxt, EUPHA-PHPP, EUPHA SDG5WG
Chair persons: Sofia Ribeiro (EUPHA-PHPP), Jinane Ghattas (EUPHAnxt)
Contact: jinane.ghattas@uclouvain.be

Gender equality is an issue in the public health arena. Though women make 70% of the healthcare workforce, there is an average 28% pay gap. (WHO, 2019). Other barriers have been identified in the literature. (Lancet, 2019) Work-life balance, gender discrimination, sexual harassment or assault in the workplace are pointed out in research studies. Consequences of poor work-life balance include insufficient time with families, difficulties in handling work and all household responsibilities, affecting childbearing decisions. Women also decline leadership opportunities, such as promotions and committee chair positions, because of family obligations. Gender discrimination included feeling inferior and discouragement from promotions or leadership positions on the basis of gender. Another identified barrier was the lack of a safe and unbiased system for seeking help following harassment or assault. Issues related to work-life balance became even more apparent during the COVID-19 pandemic, which placed a disproportionate burden in female public health workers. In the recovery phase, we have an opportunity to rethink public health delivery in order to make it a more equal, less biased, and safe place for women. This should be a concerted effort, involving men and vulnerable populations such as trans women and underrepresented ethnic groups, to ensure that no one is left behind. As one of the leading public health organizations in Europe, the European Public Health Association is committed to join efforts to address this issue in the multiple public health arenas: public health practice, policy and research. This panel discussion is a collaboration between the EUPHA Working Group on gender equality and women's and girl's empowerment, the Policy and Practice section and EUPHAnxt, and is for any conference participant that is committed to reducing the gender gap in public health. The aim of this panel discussion is two-fold. First, we aim at discussing the barriers that female healthcare workers face on an everyday basis, and their impact on their careers. Secondly, we aim at discussing how institutions and individuals can address these barriers and contribute to enhanced gender equality in the public health arena. Following panelists' interventions (additional speakers have been invited and will be confirmed at a later stage), the audience will be invited to participate in a discussion on gender barriers they have experienced and how those could be addressed.

Key messages:

- Public health practice still faces several barriers to gender equality.
- Identifying barriers to gender equality and discussing strategies to overcome them is a step towards achieving gender equality in the workforce.

Speakers/Panellists:
Marie Guichardon
EUPHA

Marleen Bekker
EUPHA-PHPP

8.M. Round table: Health literacy and vaccine literacy as determinants of vaccine acceptance: a critical discussion

Abstract citation ID: ckac129.517

Organised by: EUPHA Working Group Health Literacy, EUPHA-HP, Technical University Munich, Public Health Austria, Careum Switzerland, Global Health Literacy Academy
Chair persons: Orkan Okan (EUPHA-HP), Kristine Sørensen (Denmark)
Contact: orkan.okan@tum.de

In 2019, Sars-Cov-2 caused the greatest pandemic the modern world has ever faced. The pandemic was unprecedented regarding its effects on all aspects of society. Since the outbreak, debates on vaccines have been elevated in public health. The pandemic also emerged into a game changer regarding health communication and information delivery. With digital communication technologies, the Internet and Social Media being the most important tools to discuss health matters, exchange health knowledge and get advice from peers, every human has been part of a global communication network discussing the pandemic, related policies and vaccines. The digital realm allowed everybody to contribute to the state of Covid-19 related health information and absorb them. Altogether, this led to an overabundance of accurate and false information circulating the digital world, which culminated into the information epidemic (infodemic). Early on in the pandemic, it became obvious that people need competencies enabling them to navigate digital information environments, manage (digital) health information and to use digital health services that were accelerated through Covid-19. While health literacy and vaccine literacy were undervalued at the time, policy makers and practitioners soon highlighted their critical role in mitigating the spread of coronavirus, for protection against infection and increasing adherence to public health emergency measures. In context of the Covid-19 pandemic, health literacy enables people to find, understand and critically appraise relevant information and use it for prevention behaviour. Since it empowers individuals to mitigate the effects of the pandemic, health literacy is seen as a social vaccines. Vaccine literacy is a sub-dimension about health literacy, which especially became important when global roll-out of Covid-19 vaccines began in 2021. Vaccine literacy helps people to understand what a vaccine is, why it is relevant to get vaccinated and how it protects oneself and others. In addition, vaccine literacy empowers people to find vaccine-related information and judge about vaccine claims. The purpose of this roundtable is to discuss research findings on health literacy and vaccine literacy in relation to Covid-19, the determinants of vaccine acceptance, vaccine hesitancy and vaccine attitudes, generated in different European studies: (1) the international trend study HLS-Covid-19 conducted in Germany, Austria and Switzerland, (ii) HLCA-Kids-NRW on coronavirus-specific health literacy in primary schoolchildren (Germany) and (iii) the HLS19 European Health Literacy Survey. While the roundtable aims at introducing empirical findings, each panelist will provide a statement related to the roundtable theme based on the findings of their study. Together with the audiences, we will discuss about lessons learned from the pandemic and how to utilize health and vaccine literacy to increase vaccine acceptance.

Key messages:

- Health literacy is a social vaccine and empowers people to manage health information and increase vaccine acceptance.
- Vaccine literacy is a sub-dimension of health literacy and in particular is useful when addressed as part of public health emergency strategies.

Speakers/Panellists:
Orkan Okan
Technical University Munich, Munich, Germany

Kristine Sørensen

The effect of active breaks on cognitive performance and classroom behaviour: the I-move study

Matteo Ricci

A Masini[1], M Ricci[1], S Marini[2], A Ceciliani[2], G Barone[2], D Gori[1], L Bragonzoni[2], A Sansavini[3], A Tessari[3], L Dallolio[1]
[1]Department of Biomedical and Neuromotor Sciences, Alma Mater Studiorum - University of Bologna, Bologna, Italy
[2]Department of Life Quality Studies, Alma Mater Studiorum - University of Bologna, Rimini, Italy
[3]Department of Psychology ''Renzo Canestrari'', Alma Mater Studiorum - University of Bologna, Bologna, Italy
Contact: matteo.ricci18@studio.unibo.it

Background:
Active Breaks (ABs) intervention involves short bouts of moderate to vigorous physical activity (MVPA) conducted during or between curricular lessons by the appropriately trained teachers. The aim of the Imola Active Breaks Study (I-MOVE study) was to evaluate the effect of an ABs intervention on cognitive function and classroom behaviour in primary school children.

Methods:
The study was quasi-experimental, and it involved two groups attending a primary school in Imola (Bologna, Italy). The Active Breaks group (ABsG) performed the I-MOVE protocol consisting in 10 minutes of ABs divided in warm up, tone-up with high intensity interval training and cool-down. This is

repeated three times a day for one year and half. The control group (CG) continued with regular lessons. The baseline assessment was conducted in October 2019 and the follow-up in May 2021. Cognitive performance was assessed using working memory test and classroom behaviour was monitored using an "ad hoc questionnaire".

Results:

Working memory performance increased significantly more in the ABsG (change: 1.30±1.17) than in CG (0.96±1.20), $p < 0.05$. Almost the entire sample of the children wanted to continue with this intervention in the next following year. Children reported improvements in their school-life quality, including feeling better in class (75.40%) and in school (82.50%) when using ABs. Improvements were also reported in children time-on-task behaviours: 52.90% said they work easily in class, 52.90% that they could listen more clearly, 58.80% reported they can stay seated easily, and 59.60% that they learned better and were more focused after ABs.

Conclusions:

In conclusion the program has proven to be very effective on the children's cognitive improvement and classroom behaviour. Since the ABs intervention demonstrates these positive effects, its implementation in schools can have a beneficial, sustainable and long-term impact on childhood health.

Key messages:

- ABs intervention represents a cost-effective strategy to be implemented in the school settings regardless of the age and sex differences, to make the school a more dynamic environment.
- Despite the pandemic difficulties, the ABs intervention proved to be sustainable, and to have a positive effect on classroom behaviour by improving children's concentration and attention in class.

Adolescent Binge Drinking in the West of Ireland: Associated Risk and Protective Factors

Ciara Kelly

C Kelly[1,2]*, Á McNamara*[2]

[1]Health Protection Surveillance Centre, Dublin, Ireland

[2]Department of Public Health, HSE West, Galway, Ireland

Contact: kellyc42@tcd.ie

This study aimed to examine potential risk and protective factors for binge drinking among a cohort of 15-16-year-old adolescents in the West of Ireland. This study was a cross-sectional secondary analysis of 4,473 15-16-year-olds who participated in the 2020 Planet Youth survey. Binge drinking was defined as ever consumption of five or more drinks in a two-hour period or less. Data were analysed using SPSS version 27. Multivariable logistic regression was used to examine independent associations between potential risk and protective factors and binge drinking. A p-value of < 0.05 was deemed statistically significant. The prevalence of binge drinking among participants was 34.1%. Female gender (aOR 0.55, 95% CI 0.46-0.67, $p < 0.001$) and non-White ethnicity (aOR 0.49, 95% CI 0.31-0.77, $p = 0.002$) were associated with reduced odds of ever binge drinking. Self-rated 'bad/very bad' mental health (aOR 1.61, 95% CI 1.26-2.06, $p < 0.001$), current cigarette use (aOR 4.06, 95% CI 3.01-5.47, $p < 0.001$) and current cannabis use (aOR 2.79, 95% CI 1.80-4.31, $p < 0.001$) were associated with increased odds of ever binge drinking. Parental supervision (aOR 0.80, 95% CI 0.73-0.88, $p < 0.001$) and negative parental reaction to adolescent drunkenness (aOR 0.51, 95% CI 0.42-0.61, $p < 0.001$) reduced the odds of ever binge drinking among participants. Getting alcohol from parents was associated with increased odds of ever binge drinking (aOR 1.79, 95% CI 1.42-2.25, $p < 0.001$). Adolescents with friends who drink alcohol had almost 5 times higher odds of ever binge drinking (aOR 4.59, 95% CI 2.65-7.94, $p < 0.001$). Participating in team sports was also associated with increased odds of ever binge drinking (aOR 1.30, 95% CI 1.07-1.57, $p = 0.008$ for 1-4 times/week, aOR 1.52, 95% CI 1.07-2.16, $p = 0.020$ for ≥5 times/week). This study highlights key influences of adolescents' social environment on their binge drinking, and a need for renewed public health efforts to protect adolescents from alcohol-related harm.

Key messages:

- This study identified a high prevalence of ever binge drinking among adolescents in the West of Ireland - this is highly concerning as adolescents are vulnerable to alcohol-related harm.
- This study identified factors in the social environment of adolescents associated with binge drinking. This can inform public health action to protect adolescents from alcohol-related harm.

Video game addiction among Tunisian adolescents in Sousse: A cross-sectional study in high schools

Sihem Ben Fredj

M Ouertani[1]*, S Ben Fredj*[1,2]*, R Ghammem*[1,2]*, N Zammit*[1,2]*,*
A Maatouk[1]*, W Ben Belgacem*[1]*, S Boujebha*[1]*, N Guesmi*[1]*,*
J Maatoug[1,2]*, H Ghannem*[1,2]

[1]Epidemiology Department, Farhat Hached Hospital, Sousse, Tunisia

[2]Faculty of Medicine of Sousse, University of Sousse, Sousse, Tunisia

Contact: benfredj.sihem@famso.u-sousse.tn

Background:

Addiction to video games is a theme regularly mentioned and associated with the risks that concern adolescents. This study aimed to determine the prevalence of video game addiction (VGA) among adolescents and identify its associated factors.

Methods:

We conducted a cross-sectional study within public high schools, in Sousse, Tunisia in 2019. The target population was high school students. A structured self-administered questionnaire was used to collect data about sociodemographic characteristics, lifestyle behaviors, and mental health disorders, and we used the 21-item Game Addiction Scale to objectify video game addiction. Statistical analysis was carried out using the program SPSS v.20.

Results:

A total of 1342 participants were recruited for the study,36.8% of whom were boys. The average age was 17.5 ±1.44 years. The analysis of mental health disorders showed that 67% were anxious, 66.8% were alexithymic, 65.4% were depressed and 39% had low self-esteem. The analysis of lifestyle behaviors showed that a lack of physical activity was reported by 57.6% of participants. Problematic use of the Internet (>2 hours per day) was reported among 72.4% of the students. The prevalence of video game addiction was 13%. Boys were more prone to be addicted than girls (66.2% versus 33.8%, $p < 0.001$). ≥17 years old students had a higher rate of VGA than those aged<17 years old (57.3% vs 42.7%, $p = 0.031$). VGA was higher among students who follow the non-scientific study section (69.4%, $p = 0.007$). Students who had moderate depression had the highest percentages of VGA (35.7%, $p = 0.005$). Students who had problematic use of the internet were more addicted to video games (80.3%) than those not having problematic use (19.7%), $p = 0.009$.

Conclusions:

This study allowed us to identify the students who are vulnerable to VGA. Also, a huge responsibility is accorded to school staff and parents to tackle this health problem by sensitizing their children and setting up some protective family rules.

Key messages:

- Several factors were significantly associated with video game addiction, especially problematic internet use.

- Further research is needed to understand the underlying mechanisms of video game addiction and to explore effective preventive or interventional strategies.

[6]University Clinical Centre of Serbia, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
[7]Clinic for Hematology, University Clinical Centre of Serbia, Belgrade, Serbia
Contact: milena.santric-milicevic@med.bg.ac.rs

Background:
The health and development of school-age children is a contemporary topic of various health policies and programs, which has become even more of a focus in critical situations such as the COVID-19 pandemic. The study aims to assess the prevalence of school-age children's participation in fights and bullying in Serbia, and to examine the relevance of students' socio-demographic characteristics and perceptions of school and relations with other students and professors for participation in fights and bullying.

Methods:
A secondary analysis of the original data of the 2017 HBSC study is performed on 3267 students in a nationally representative sample of primary and high schools in Serbia. Predictors of taking part in fights and taking part in bullying were examined by using univariate and multivariate logistic regression.

Results:
The main results show that 50.8% of boys and 17.1% of girls have taken part in fights, while 17.7% boys and 10.4% of girls have taken part in bullying. Students who felt a large and very large burden of school obligations were 1.43 times more likely to participate in bullying at least once, while they were 1.38 and 2.12 times more likely to participate in multiple fights and 4.04, 1.24, and 2.78 times more likely to participate multiple times in bullying. Fights among school-age children are significantly positively associated with living with relatives/legal guardians and poor quality of life.

Conclusions:
The prevalence of participating in at least one fight/bullying is higher than in multiple fights/bullying. These associations suggest a necessity to enhance the monitoring and control of peer behavior among school-age children. The findings of the study imply key enablers of protection, such as building relationships based on team spirit and work, friendly behavior, empathy, and help, which should be included in the value system of school and family activities in programs to combat fights and bullying in school-age children.

Key messages:
- In Serbia, every second boy and every fifth girl participated in fights, while less than every fifth boy and every tenth girl participated in bullying.
- Study results can inform school and healthcare actors' efforts to improve school-age children's development and health capacity for life.

Abstract citation ID: ckac129.522
Early childcare type and child development at age 3.5 years, data from the French ELFE cohort

Ramchandar Gomajee

R Gomajee[1], K Barry[1], M Melchior[1]
[1]Social Epidemiology Research Team, Sorbonne University, Pierre Louis Institute of Epidemiology and Public Health, Paris, France
Contact: ramchandar.gomajee@inserm.fr

Background:
Early childcare has been linked to child development in some countries. The aim of this study is to evaluate the impact of early childcare in the French context, where children can attend different types of childcare facilities prior to age 3 when they enter kindergarten, and development at age 3.5 years.

Methods:
10,683 children from the ELFE French national birth cohort were classified into 4 groups depending on their main type of childcare between birth and age three: childminder (n = 5,014), centre-based childcare (n = 2,583), informal childcare (n = 777) and parents only (n = 2,465). Children's development was measured with the short form of the Child Development Inventory (CDI) via parents-reports at age 3.5 years. The CDI score was transformed into a Development Quotient (DQ) taking into account the child's age, and global developmental delay was defined as DQ < 90. Missing data was imputed by Fully Conditional Multiple Imputation with 10 imputations. Multinomial analyses were carried out adjusted by Inverse Probability Weighting based on Propensity Scores calculated using main selection and confounding variables.

Results:
Compared to children who were cared for by parents only, children who were cared for by a childminder or in a centre-based childcare had a higher DQ (103.0 and 104.8 respectively) as well as a lower likelihood of global developmental delay (propensity-score weighted OR = 0.84, [95% CI 0.70-1.01] and propensity-score weighted OR = 0.54, [95% CI 0.44-0.66]) respectively.

Conclusions:
In the French context, early centre-based childcare attendance is significantly associated with a lower risk of global child delay. Policies should make centre-based childcare more accessible to a broader number of children.

Key messages:
- Early childcare type is linked to child development in France.
- Children in centre-based childhood had a lower likelihood of developmental delay compared to those looked after by parents only.

Abstract citation ID: ckac129.523
Implementation of resilience training programmes in children and adolescents: value and barriers

Claudio Pacillo

C Pacillo[1], W Malorni[1], U Moscato[1,2], LG Sisti[1,3]
[1]Center for Global Health Research and Studies, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Department of Woman, Child and Public Health, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy
[3]National Institute for Health, Migration and Poverty, Rome, Italy
Contact: claudio.pacillo01@icatt.it

Background:
Emotional distress increasingly represents a major burden in children and adolescents (C&A), especially in conflict zones where its prevalence is estimated to reach 70%. Resilience training programmes (RTPs) are interventions that seek to enhance resilience in individuals or groups pursuing mental distress prevention. Literature suggests RTPs be particularly effective in C&A; however, their effectiveness and value for public health are still unclear.

Methods:
A scoping review was performed in order to summarize evidence regarding the implementation and effectiveness of

RTPs in children and adolescents. A search string has been built according to the PICO model and launched on PubMed, PsycInfo, Academia databases. Additional references were identified by a hand-search in Google Scholar. Studies included were narratively summarized according to topics that emerged.

Results:

18 articles were finally included in the review. Main issues were 1) RTPs seem to be more effective in adolescents rather than in children; 2) COVID-19 pandemic has raised the attention towards RTPs in C&A; 3) beyond conflict zones their implementation is increasingly recognized in supporting C&A management of daily stressors and traumas also in C&A with disabilities; 4) school is identified as the key setting for RTPs; 5) the high heterogeneity in RTPs approaches, contexts and study samples limits a conclusive effectiveness assessment.

Conclusions:

Our findings highlighted how RTPs are increasingly recognized as a tool to improve C&A cognitive and behavioral functioning and resilience to external stressors, getting greater interest in the COVID-19 pandemic. Despite relevant theoretical support and promising study results, RTPs still lack strong evidence supporting their embracement by policymakers and effective implementation in public health policy. In order to not miss this chance, more efforts are needed in strengthening RTPs conceptualization and cost-effectiveness studies.

Key messages:

- RTPs are a promising tool to enhance the resilience of children and adolescents gaining increasing interest due to the COVID-19 pandemic.
- More studies are needed to provide a strong evidence base that supports their acknowledgment by policymakers and their implementation in public health policies.

Abstract citation ID: ckac129.524
Trust and emotional difficulties in adolescence: findings from a Swedish cohort study

Sara Brolin Låftman

S Brolin Låftman[1], *V Östberg*[1], *J Raninen*[2,3]
[1]Department of Public Health Sciences, Stockholm University, Stockholm, Sweden
[2]Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden
[3]Centre for Alcohol Policy Research, La Trobe University, Melbourne, Australia
Contact: sara.brolin.laftman@su.se

Background:

Trust is a key component of a socially sustainable society, and is typically divided into general trust (referring to trust in other people) and institutional trust (referring to trust in the public institutions of society). Trust tends to be developed and formed early in life. While a plethora of research has reported positive links between trust and health in adults, the aim of this study was to examine the associations between general and institutional trust and emotional difficulties in mid and late adolescence.

Methods:

Data were derived from the Swedish cohort study Futura01, using information collected amongst 3622 grade 9 students (~15-16 years, t1) who were followed-up two years later (~17-18 years, t2). General and institutional trust was measured by indices based on five items each at both t1 and at t2 (range 1-4). Emotional difficulties were measured by the Strengths and Difficulties Questionnaire (SDQ) subscale at both t1 and at t2 (range 0-10). Control variables included family type and cash margin at t1 and upper secondary school program (academic vs. vocational) at t2. Linear regressions were performed using the first difference (FD) approach, analysing the change in emotional difficulties (t2-t1) regressed on the change in general and in institutional trust (t2-t1), respectively.

Results:

Analyses simultaneously adjusting for change in both dimensions of trust showed inverse associations between the change in general trust and the change in emotional difficulties (b = -0.21, 95% CI -0.39, -0.04) and between the change in institutional trust and the change in emotional difficulties (b = -0.22, 95% CI -0.35, -0.09).

Conclusions:

Increases in general and in institutional trust between ages 15-16 and 17-18 years were associated with a corresponding decrease in emotional difficulties. The findings suggest that trust is a social determinant of emotional difficulties in adolescents. Endeavours to enhance trust in this age group are relevant.

Key messages:

- Changes in trust were inversely associated with changes in emotional difficulties in adolescents.
- The findings indicate that efforts to reinforce trust in adolescents are relevant.

Abstract citation ID: ckac129.525
Indoor metals pollution and metabolic outcomes among Italian children

Stefano Renzetti

S Renzetti[1], *M Schito*[1], *L Borgese*[1], *P Cirelli*[1], *G Cagna*[1], *A Patrono*[1], *M Peli*[1], *R Ranzi*[1], *RG Lucchini*[1,2], *D Placidi*[1]
[1]Università degli Studi di Brescia, Brescia, Italy
[2]Florida International University, Miami, USA
Contact: stefano.renzetti@unibs.it

Background:

Through this study, we aimed to test the association between the exposure to metals measured in indoor dust and metabolic outcomes among children living in areas with environmental exposure to metals.

Methods:

The project ''Health impacts of environmental exposure to airborne pollutants in the sites of Brescia and Taranto, Italy: increase knowledge to address preventive intervention of local and global relevance'' (ISEIA) enrolled 130 children aged 6 to 13 years (51.5% females) resident from pregnancy in highly industrialized areas of the Brescia province, Northern Italy. Metabolic outcomes including BMI, fasting blood glucose and blood creatinine were measured. The concentration of a mixture of 10 metals in indoor dust was determined through an X-ray fluorescence portable analyzer (p-XRF). Linear regressions and Weighted Quantile Sum (WQS) regression were applied to test for the association between metal exposure and metabolic outcomes. All models were adjusted for age, gender, socio-economic status and area of residence.

Results:

A significant association was observed between Cd and blood creatinine ($\beta = 0.01$; 95%CI = 0.001, 0.02; p-value = 0.028) when considering each individual metal separately in the model. WQS regression showed a positive significant association between the mixture of metals and fasting glucose ($\beta = 0.87$; 95%CI 0.14, 1.61; p-value = 0.023) identifying Mn, Cr and Cu as the elements with the higher weights, while a marginally significant association was found between the metal mixture and blood creatinine ($\beta = 0.01$; 95%CI = -0.001, 0.02; p-value = 0.075) where Cd and Ti showed the highest weight.

Conclusions:

We assessed the potential association between exposure to metals in indoor household dust and blood glucose and creatinine. Our results contribute to clarifying the role of metal exposure in the burden of non-communicable diseases although further studies are needed to better understand the relationship between metal exposure and metabolism.

Key messages:

- The metal mixture in indoor household dust is associated with an increase in fasting glucose.
- Cd concentration in indoor household dust is associated with an increase in blood creatinine.

8.O. Workshop: New challenges for suicide prevention in the context of Covid-19

Abstract citation ID: ckac129.526

Organised by: EUPHA-PMH
Chair persons: Johan Bilsen (EUPHA-PMH), Jutta Lindert (EUPHA-PMH)
Contact: johan.bilsen@vub.be

The recent COVID-19 pandemic confronted many societies with profound public health challenges. Although primarily a 'somatic' health concern, it becomes clear that Covid-19 and its aftermath also proved to have a substantial impact on mental health and wellbeing of the population in general and on vulnerable subgroups, such as young people and the elderly, in particular. An important public mental health concern in this context is the possible adverse influence of this pandemic on suicidality. Recent studies show that during the outbreak of the coronavirus disease the suicide mortality did not rise, rather on the contrary. However, the impact of the increased number of people with mental distress related to Covid-19 on suicidal ideation as well as the long-term impact on suicide rates is unclear. Also the long-term impact of the Covid-19 restriction measures greatly hindering adequate mental healthcare services and suicide prevention initiatives is uncertain. This workshop will focus on suicidality trends since the pandemic onset in different countries, suicide figures, experiences in the field of suicide prevention and on attitudes towards seeking help. Ann John from UK will talk about suicide trends during Covid-19 pandemic and will present suicide data of 35 countries collected by the international Covid-19 Suicide Prevention Research Collaboration. Fabrice Jollant will present data about the impact of Covid-19 pandemic on suicide attempts in France, and will discuss in this context the new national suicide prevention strategy. John Cachia will show the importance of a broad mental public health approach to suicide prevention in Malta. And finally, Saska Roskar from Slovenia will show how prevention of suicidality in individuals working themselves in the field of mental health can be hindered by self-stigma.

Key messages:

- We must remain vigilant about the possible long-term mental health impact (including suicidal behavior) of the Covid-19 pandemic.
- Pandemics like Covid-19 highlight certain weaknesses in suicide prevention strategies.

Introduction:

There was and still is much speculation about the COVID-19 pandemic impact on suicide rates. We aimed to assess the effect of the COVID-19 pandemic on suicide rates around the world.

Methods:

We sourced real-time suicide data from countries or countries areas through a systematic internet search (official websites of Ministries of health, police agencies, and government-run statistics agencies or equivalents), recourse to our networks (e.g. ICSPRC) and the published literature (a living systematic review). We used an interrupted time-series analysis to model the trend in monthly suicides before COVID-19 in each country or country area, comparing the expected number of suicides derived from the model with the observed number of suicides in the early months of the pandemic (from April 1 to July 31, 2020, in the primary analysis). We have now updated this work to cover the first 15 months of the pandemic and stratified analyses by age and sex and method. We will present findings from the new updated data (35 countries) at the conference.

Results:

Initially we sourced data from 21 countries (16 high-income and five upper-middle-income countries). Rate ratios (RRs) and 95% CIs based on the observed versus expected numbers of suicides showed no evidence of a significant increase in risk of suicide since the pandemic began in any country or area. There was statistical evidence of a decrease in suicide compared with the expected number in 12 countries or areas.

Conclusions:

This was the first study to examine suicides occurring in the context of the COVID-19 pandemic in multiple countries. Early on high-income and upper-middle-income countries, suicide numbers remained largely unchanged or declined compared with the expected levels based on the pre-pandemic period. We need to remain vigilant and be poised to respond as the longer-term mental health and economic effects of the pandemic unfold. We will present updated findings with more recent data.

Suicide prevention in France put to the test by COVID-19

Fabrice Jollant

F Jollant[1]
[1]Department of Psychiatry, Université Paris-Saclay and Bicêtre Academic, Paris, France
Contact: jollantf@gmail.com

Introduction:

Each year, nearly 9,000 people die from suicide in France, and more than 150,000 attempt suicide. In spite of a decrease for the last 30 years, rates of suicide in France remain higher than the European mean. Since 2018, a national suicide prevention strategy of the Ministry of Health has been in place. In 2020, this new strategy has been exposed to the COVID-19 pandemic.

Methods:

First, the different actions of the national suicide prevention strategy will be presented, followed by the results of the available data regarding the impact of COVID-19 on suicidal gestures. These data are 1) hospitalizations for self-harm (ICD-10 codes X60 to X-84) from the national health database; 2) calls to poison control centers and 3) visits to the emergency room for a suicide attempt. The latest figures available will be presented.

Results:

The analysis of these data compared to 2019 highlights two main periods. Between March and December 2020, a significant decrease in suicide attempts was observed (8.5%), with a rapid drop during the first week of the first confinement in mid-March 2020, in women and men, and in all age groups except old-aged people. Since January 2021, a significant increase in suicide attempts has been observed among teenage girls, including high-lethality acts. Moreover, among the young and the elderly, the figures are now similar to 2019. Only numbers for middle-aged adults continue to decline.

Conclusions:

The impact of the COVID-19 pandemic on suicide attempts appears to be variable over time, according to age and gender. The old-aged people and young people, especially adolescent girls seem to have suffered the most from this situation. It is still too early to know whether the new national suicide strategy has had any positive impact. However, the pandemic has highlighted certain weaknesses in the French system, in particular the lack of recent data on mortality by suicide, and the heavy dependence on a fragile mental health medical system.

Suicide Patterns in Malta: pathways for prevention

John M Cachia

J Cachia[1]
[1]Office of the Superintendent of Public Health, Ministry for Health, Valletta, Malta
Contact: john.cachia@um.edu.mt

Background:

Suicidal behaviour is the result of several risk factors, such as acute stress, severe depression, violence, sexual abuse, etc. A mental public health approach to suicide prevention needs to look beyond the demographic characteristics of deaths by suicide and to take into account specific country determinants. Available clinical information can help identify and quantify risk, analyse patterns of behaviour, explore links between risk and behaviour and generate possible suicide prevention pathways.

Methods:

162 deaths by suicide for the period January 2015 - June 2021 in Malta are analysed against available clinical information. Major sources of detailed clinical information include obligatory notifications to the Commissioner for Mental Health of all cases of persons involuntarily admitted to acute psychiatric services and other medical records held within the Maltese public mental health system.

Results:

81% of 162 deaths by suicide for the period under study were males, two-thirds of them between 25 and 54 years. The preliminary findings have confirmed that less than 50% of these deaths had previous contact with the public health system. The two main diagnostic criteria among deaths with recent psychiatric admission/s were acute stress reaction to personal life events and very severe mood disturbances, particularly depression. There seems to be increased risk among migrants and foreign workers residing and working in Malta. The frequency of prior admissions, age-related issues, the time-event relationships, and relevance of elicited clinical findings are still being evaluated and will be presented in more detail in the workshop.

Conclusions:

Exploring risk factors within the history of cases of suicide through available clinical information can contribute to the development of suicide prevention pathways, relevant to the specific context of local communities.

Abstract citation ID: ckac129.530
Self-stigma in suicide prevention of mental health professionals

Saska Roškar

S Roškar[1], *D Kralj*[1], *K Andriessen*[2], *K Krysinska*[2], *M Vinko*[1], *A Podlesek*[3]
[1]Public Health, National Institute of Public Health, Ljubljana, Slovenia
[2]Centre for Mental Health, University of Melbourne, Melbourne, Australia
[3]Department of Psychology, University of Ljubljana, Ljubljana, Slovenia
Contact: Saska.Roskar@nijz.si

Introduction:

Stigma is one of the main factors hindering help-seeking, which can have debilitating effects on mental health and even lead to suicidality. Stigma can affect the general public but also mental health professionals. In this study we examined mental-illness and help-seeking self-stigma as well as public stigma of suicidal behavior among suicidologists.

Methods:

Invitation to participate in the study was sent to 518 member of the Internat.l Assoc. for Suicide Prevention. 89 participants (55 female, 34 male; 17% response rate) completed the survey. We gathered sociodemographic data, data on personal history of mental illness and suicidal behavior and on different types of stigma. We hypothesized that help-seeking self-stigma is predicted by sociodemographic attributes and personal history of mental illness and that self-stigma related to mental illness and suicide act as mediators.

Results:

Personal experience with mental illness predicted mental illness self-stigma. There was no significant predictive value of other variables (age, gender, years working in suicidology) for self-stigma of mental illness and suicide behavior. Both types of self-stigma (mental illness and suicide behavior) were correlated. Mental-illness self-stigma was shown to be a stronger predictor of help-seeking self-stigma than self-stigma of suicide behavior, though the effect did not reach statistical significance. Self-stigma of suicide behavior showed no independent contribution to help-seeking self-stigma.

Conclusions:

Mental healthcare professionals represent a particularly vulnerable group for developing mental health issues and suicidality. However, due to fear of being perceived less competent by colleagues and the public, they often disguise their mental struggles and are reluctant to seek help. These pilot findings warrant further research to better understand self-stigma and its impact on help-seeking behavior in order to prevent suicidality in this population.

8.P. Skills building seminar: Design thinking: adopting a human-centred approach to tackling complex problems

Abstract citation ID: ckac129.531
Organised by: University College Dublin
Chair persons: Kate Frazer (Ireland), Thilo Kroll (Ireland)
Contact: kathleen.frazer@ucd.ie

The concept of wicked problems is recognised since the 1970s, and social determinants of health (SDOH) account for various difficulties. Fixing or solving wicked problems is challenging due to the complexity. The diverse nature of problems can mean that a solution for one group may result in unintended consequences for others. Healthcare itself is a complex adaptive system. An intersectionality lens may assist in navigating 'the messiness,' to reduce inequity and enable voices of those experiencing problems to be involved. COVID-19 amplified difficulties of marginalised populations including 'othering'. Homelessness is a complex global public health challenge, with limited reliable prevalence data and no universally agreed definition. Being homeless is associated with negative impacts on health and wellbeing, and an absence of belonging. Considering solutions requires a problem-solving focus. Design thinking is a human-centric problem-solving approach focusing on empathy, brainstorming ideas, and prototyping iterative solutions. Equity focused design thinking is a framework to develop people-centred solutions and reflect on the influence of own biases and beliefs on systems. Acknowledging the theme of the conference 'Strengthening health systems: improving population health and being prepared for the unexpected' we propose a 60-minute skills-building workshop. We will use a live design sprint format to facilitate collaborative learning for attendees, as an alternative to oral presentations, to explore the intersectionality of design thinking and equity using the Stanford D model. The value of this workshop is knowledge generation and dissemination using an equity lens to adopt creative methods for engagement to produce end-user solutions.

Objectives:

– To introduce design thinking approaches to consider solutions for homelessness.

– To facilitate an experiential approach to support learning and collaboration.

– To explore the application of design thinking using an equity focus as a tool to challenge mindsets and create problem-solving in public health.

Format:

Working in groups use Stanford D model equity-centred framework (Notice, Empathize, Define, Ideate, Prototype, Test, Reflect).

Introduction (10 min)
– Homelessness 'a wicked problem'
– Design thinking and equity focus explanation and plan for session
Phases of Design thinking (30-40 min)
– Noticing: awareness of own values, biases, assumptions
– Empathizing: Understanding homelessness from the perspective of the user
– Defining: The specific user challenge
– Ideate: Brainstorm solutions
– Prototype and test: Propose and pitch low fidelity solutions
Final reflection & summary (10 min)
– Insights and learning, networking, and collaboration.

Key messages:

- Equity focused design thinking methods provide approaches to increase awareness of the impact of biases and beliefs.
- Human-centred design is an agile approach to creating service and systems developments for marginalised populations.

8.Q. Workshop: WHO's activities to strengthen the evidence of public health and social measures

Abstract citation ID: ckac129.532
Organised by: WHO
Chair persons: Ramona Ludolph (Switzerland), Ryoko Takahashi (Switzerland)
Contact: ludolphr@who.int

Public health and social measures (PHSM) are key to reducing the spread of infectious diseases like COVID-19, especially in the early stages of an outbreak. PHSM include non-pharmaceutical actions that individuals, communities, and governments take to reduce person-to-person contact and/or make them safer. PHSM reduce the pressure on the health care system to allow for the continuation of essential services and buy time for the development and dissemination of treatments and vaccines. While a combination of PHSM has proven to be effective in reducing transmission during the COVID-19 pandemic, the evidence on the relative effectiveness and broader health, social and economic impact of individual interventions is still scarce. However, PHSM packages such as lockdowns can have severe unintended consequences for individuals and societies including economic hardship, decreased mental health and wellbeing and exacerbated social and health inequity; therefore, precision in PHSM decisions and implementation is needed. This requires a strengthened evidence base as well as tools that support countries in making balanced decisions about PHSM with the best possible cost-benefit ratio. WHO works with multisectoral partners to achieve effective and context- specific PHSM implementation while maximizing the benefits of PHSM and keeping their health, social and economic burden to a minimum and justifiable. In the WHO Regional Office for Europe, PHSM are a key pillar in the COVID-19 response. The office provides, amongst others, a PHSM monitoring dashboard to track the severity of implementation across all 53 Member States as well as a calibration tool and related capacity building to guide countries in their implementation decisions as the pandemic situation evolves. The WHO has further launched a global initiative in 2021 to measure the effectiveness and impact of PHSM and improve precision in future PHSM decisions and policies. The initiative aims at providing robust data and research evidence on PHSM through a global conceptual model and research agenda, a central research monitoring system and harmonized data collection mechanisms during health emergencies. It further seeks to integrate PHSM into emergency preparedness and response assessments and yield a decision-making tool to facilitate evidence-informed and context-specific PHSM implementation. This workshop will provide an overview of WHO's activities in advancing PHSM research and implementation for better decision-making during future emergencies. Three presentations by the WHO Secretariat at the regional and global levels will focus on the strategic approach and the main deliverables of the respective initiatives so far. The presentation by the University of Munich will provide in-depth insights into the conceptual model on PHSM. The workshop will actively solicit feedback from participants on planned activities and results gathered to-date.

Key messages:

- The lack of evidence on PHSM effectiveness and impact hampered an evidence-driven implementation approach during the COVID-19 pandemic.
- WHO works to achieve effective and context- specific PHSM implementation to maximize the benefits of PHSM while keeping their health, social and economic burden to a minimum and justifiable.

The WHO initiative to measure the effectiveness and impact of PHSM – key activities in 2022

Ramona Ludolph

R Ludolph[1]*, R Takahashi*[1]*, T Nguyen*[1]*, S Briand*[1]
[1]High Impact Events Preparedness Unit, WHO, Geneva, Switzerland
Contact: ludolphr@who.int

The presentation will focus on two main outcomes of the WHO initiative: a global research agenda to steer future evidence generation on PHSM, and a central monitoring system for PHSM research. In September 2021, a global technical consultation with over 60 global experts was organized to review the existing evidence on PHSM and identify the initiative's priorities. The consultation provided an opportunity to have an initial discussion on potential research priorities. This became the basis for an iterative online consultation process. The draft research agenda includes seven main research themes including effectiveness, unintended consequences, methodological challenges and implementation considerations affecting the uptake of and adherence to PHSM. Workshop participants will be invited to comment on the suggested themes and propose additional priority questions for the research agenda. The central research monitoring system will consist of a global repository of primary studies and reviews investigating the effectiveness and broader multisectoral impact of PHSM. Indexed studies will be mapped against the key themes of the research agenda, facilitating real-time monitoring and evaluation of its progress. An AI-based mechanism for automated updating of systematic reviews will complement the database. This one-stop shop will allow researchers and decision-makers worldwide to access the latest evidence on PHSM and keep track of the synthesized effectiveness and impact of different interventions and combinations. The platform will further provide a protected working interface. This monitoring system for PHSM research enables timely access to and utilization of evidence indecision-making processes during health emergencies and fosters international collaboration on the analysis and interpretation of data. Workshop participants will be invited to review the alpha version of the platform.

Abstract citation ID: ckac129.534
Public health and social measures during health emergencies such as the COVID-19 pandemic: an initial logic model to conceptualise and classify measures

Eva Rehfuess

E Rehfuess[1]*, J Burns*[1]*, R Ludolph*[2]*, A Movsisyan*[1]*, L Pfadenhauer*[1]*, B Strahwald*[1]
[1]Institute for Medical Information Processing, University of Munich, Munich, Germany
[2]High Impact Events Preparedness Unit, WHO, Geneva, Switzerland
Contact: rehfuess@ibe.med.uni-muenchen.de

Issue/problem:

In the context of the COVID-19 pandemic, public health and social measures (PHSM) are being implemented worldwide, but in very different ways. This is also due to a lacking common understanding of PHSM so far. As a result, there are limited insights regarding their components, implementation and effectiveness as well as impacts beyond health of PHSM.

Description of the problem:

The project contributes to the WHO PHSM initiative. A logic model is being developed that offers a shared language and understanding of how PHSM are intended to achieve transmission-related outcomes, but also that non-intended consequences need to be considered. The overall approach is informed by a system-based logic model template and a staged approach to logic modeling. The development process is making use of (i) existing COVID PHSM taxonomies and related literature, (ii) existing theoretical frameworks related to complex interventions in complex systems, (iii) consultations with WHO staff and the according PHSM steering group, and (v) iterative brainstorming within the working group.

Results:

The initial logic model is rooted in a complexity perspective which recognises that (i) all measures have both intended and unintended consequences for health and society and (ii) all elements within the logic model are interconnected and interact with each other. All PHSM operate through two basic mechanisms: reducing contacts and making contacts safer. Taken together, these two mechanisms work to reduce transmission-relevant contacts. Any specific PHSM is defined by a combination of the measure itself, the population and/or setting targeted and the mode of enactment. The central hub of the logic model connects and integrates all elements. The initial logic model was applied to school and travel measures as examples.

Main messages:

The PHSM logic model is a conceptual basis to facilitate research on PHSM, monitoring and evaluation of PHSM, and evidence-informed decision-making.

Implementing public health and social measures: an integral part of the health emergency management cycle

Tanja Schmidt

J Addo[1]*, D Cocciolone*[1]*, C Gapp*[1]*, A Latta*[1]*, S Lindmark*[1]*, L Owen*[1]*, J Sane*[1]*, I Perehinets*[1]*, T Schmidt*[1]*, C Wippel*[1]
[1]Country Health Emergency Preparedness and IHR, WHO Regional Office for Europe, Copenhagen, Denmark
Contact: schmidtt@who.int

Public health and social measures (PHSM) have been utilized as a tool to reduce the infection rates and disease burden throughout the COVID-19 pandemic and continue to play an important role even with vaccination campaigns well underway in preventing severe disease. In order to systematically track, analyze and report qualitative and quantitative data o PHSM implementation across the European Region and assist countries in the COVID-19 response, the COVID-19 Incident Management Support team at the WHO Regional Office for

Europe developed PHSM Severity Index and PHSM Dashboard. The PHSM Severity Index captures the types, severity and timing of PHSMs implemented by a country across six main indicators. By providing standardized data on PHSM implementation, the PHSM Severity Index can support and inform the development of policy at country and regional levels. PHSM data, severity methodology and policy tools developed throughout the COVID-19 pandemic should be adapted to provide a foundation for preparedness for future large-scale health emergencies. In addition, discerning the epidemiological impact of specific PHSM and their combinations currently is a priority for policy-makers and can guide countries' transition strategies. Analysing the impact of PHSM on COVID-19 transmission is of critical importance, especially as variants of concern bring new waves of COVID-19 cases and may challenge countries' vaccination and response strategies. Reference PHSM in Response to COVID-19 (who.int)

Contact: coccioloned@who.int

Public health and social measures (PHSM) are preventative measures taken by individuals, communities and government institutions at national and local levels to prevent and reduce transmission of an infectious disease - in this instance SARS-CoV-2. The decision to introduce, adapt or lift PHSM should be based primarily on a situational assessment of the intensity of transmission of SARS-CoV-2 and the capacity of the health system to respond to subsequent increases in hospital admissions, but must also consider the effects these measures may have on the general welfare of society and individuals. The WHO Regional Office for Europe developed an online public health and social measures (PHSM) calibration tool to assist Member States in decision-making relating to PHSM implementation during the COVID-19 pandemic. The tool, designed to be used primarily by policy-makers in national and local government authorities, provides guidance based on a situational-level assessment framework that is determined by the level of community transmission and the overall capacity of health systems and public health services within a country or region to respond. By using a combination of country-reported and user-input data, the tool automatically generates a situational assessment and corresponding PHSM guidance for users, summarized in a downloadable report.

Primary care management strategies and COVID-19 related hospitalization: a population-based study

Lucia Palandri

L Palandri[1], *A Ferrari*[1], *A Serafini*[2], *S Riccomi*[2], *G Ugolini*[2], *PP Kurotschka*[3], *F Bellelli*[2], *M Morandi*[2], *MS Padula*[1], *E Righi*[1]
[1]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy
[2]Department of Primary Care, Local Health Unit of Modena, Modena, Italy
[3]Department of Medical Science and Public Health, University of Wuerzburg, Wuerzburg, Germany
Contact: palandri.lucia@gmail.com

Background:

Due to SARS-CoV-2 rapid mutations, the ending of the pandemic is still proceeding at a slow pace and there is the need to strengthen and invest in health systems that avoid hospital overload and its consequences on patients' health. Most symptomatic infections have mild to moderate respiratory symptoms and patients are managed in the context of primary care. In Italy, literature on COVID-19 outpatients management by general practitioners (GPs) is scarce. This study explores the effect of GP active care and monitoring on COVID-19-related hospitalization in patients in the province of Modena (Italy) and investigates the possible determinants of GP's management.

Methods:

This is a retrospective cohort study of SARS-CoV-2 infected adult outpatients managed by their GPs from March 2020 to April 2021 in the province of Modena (Italy). Data on GPs' characteristics, management strategies (visits and remote monitoring), patients' socio-demographic characteristics, and hospitalization were extracted from the GP's electronic medical records and were analyzed using descriptive statistics and multiple logistic regression.

Results:

46 GPs agreed to participate, and 5340 patients were included in the analyses. 3014 (56%) patients received active daily remote monitoring and 840 (16%) were visited at home. Remote monitoring and home visits were both associated with a reduction of the probability of hospitalization rate of approximately 50% (respectively OR:0.52, 95%CI:0.33, 0.80 and OR:0.50, 95%CI;0.33, 0.78). Preliminary analysis of determinants showed that GPs' patient load, setting, age, and sex were significantly associated with management strategies.

Conclusions:

Active monitoring performed by GPs was effective in reducing the probability of hospitalization. Primary and hospital care integration can be effective for COVID-19 management. Studies on GPs' characteristics and patient load and their effect on their ability to care for patients are needed.

Key messages:

- Active remote monitoring and visits performed by Italian general practitioners effectively reduced hospitalization for COVID-19.
- Primary and hospital care integration can be effective for COVID-19 management.

The health system and health impacts of primary healthcare reform in China: A systematic review

Chang Cai

C Cai[1], *S Xiong*[2,3], *C Millett*[1,5], *M Tian*[2,4], *T Hone*[1]
[1]Public Health Policy Evaluation Unit, Imperial College London, London, UK
[2]The George Institute for Global Health, University of New South Wales, Sydney, Australia
[3]Global Health Research Centre, Duke Kunshan University, Kunshan, China

[4]School of Public Health, Harbin Medical University, Harbin, China
[5]National School of Public Health, NOVA University, Lisbon, Portugal
Contact: caichang0206@gmail.com

Background:
China has undergone a comprehensive primary healthcare(PHC) reform since 2009 aiming to deliver accessible, higher-quality, and equitable healthcare. However, there is limited understanding of the effectiveness of this reform. This systematic review synthesizes evidence on health system and health impacts of this reform.
Methods:
We searched 13 international databases and three Chinese databases for quantitative studies assessing the impacts of this reform published between January 2009 and March 2020. We searched for studies in English or Mandarin. Eligible study designs were RCTs, quasi-experimental studies and controlled before-after studies. We included studies that: assessed PHC policies since 2009; had geographical, temporal or population comparators; and assessed any outcome measures of health expenditures, health service utilisation, quality of care or health outcomes. Study quality was assessed using ROBINS-I, and results synthesized narratively. PROSPERO: CRD42021239991.
Results:
Of 35,480 titles, 37 studies were included (27 in English and ten in Mandarin). Eight were considered at low risk of bias. The 37 studies covered all major PHC policies since 2009, but mostly focused on the essential medicine (N = 15) and financing (N = 10). The quantity and quality of studies on service delivery policies(e.g., family physician and essential health services), were low(N = 3,with moderate or serious risk of bias). 17 studies found that the PHC reforms promoted primary care utilisation. Its impacts on quality and health improvement appear limited to people with chronic diseases(N = 11). Evidence on primary care costs and OOPs were not clear. Some evidence showed that the reforms were pro-equity with benefits accrued in disadvantaged regions and groups.
Conclusions:
Comprehensive PHC reforms can deliver some benefits related to utilisation and health for high-risk and vulnerable populations. Policymakers should continue to prioritize PHC to achieve Universal Health Coverage.
Key messages:
- The finding suggests that large-scale and comprehensive primary healthcare reforms can deliver benefits related to utilisation and health for high-risk and vulnerable populations.
- Future research should include more robust study designs and seek to better understand the impact of major PHC reforms on quality of care, health outcomes and equity.

[4]Research, Statistics Department, Italian National Statistical Institute, Rome, Italy
[5]National Outcomes Evaluation Programme, National Agency for Regional Health Services, Rome, Italy
Contact: gianfranco.damiani@unicatt.it

Background:
In Italy, primary care (PC) ensures universal health coverage while containing costs. However, the assessment of its quality still remains an issue. Evidence has shown that high-quality outpatient care, through timely interventions to prevent complications of "ambulatory care sensitive conditions", may avoid hospitalization. Aim of the study is to analyse the performance of PC in the Italian regions, using a composite and synthetic index of avoidable hospitalizations.
Methods:
Hospital discharge data from 119 Italian geopolitical areas were analysed for the 2017-2019 triennium and for 2020, separately. According to the "Italian National Outcomes Evaluation Programme" methodology, 9 avoidable hospitalization indicators covering 5 nosological fields (infectious, respiratory, metabolic, cardiovascular and mental diseases) were combined in a synthetic index, calculated as the weighted mean of their standardized scores (with equal weights for each field). Using "natural breaks" technique, the areas were grouped into 5 clusters: "high", "medium-high", "medium", "medium-low" and "low".
Results:
The analysis showed a marked heterogeneity at intra-regional level for the pre-pandemic triennium, with areas of homogeneity in regions with higher levels of hospitalization. The "medium" cluster, which is the widest, included 36 areas variously distributed across regions. The comparison with 2020 confirmed the geographical patterns observed for the previous triennium, despite a general reduction in hospitalizations due to the pandemic.
Conclusions:
As a proxy indicator of PC quality, this index can aid decision makers in prioritizing quality improvement actions. However, in order to obtain a comprehensive evaluation, a joint reading of this index with other healthcare indicators is recommended.
Key messages:
- High-quality PC is essential in maintaining appropriate hospitalization levels.
- The composite synthetic index proposed could aid PC quality assessment.

[3]Ospedale Policlinico San Martino IRCCS, Genoa, Italy
Contact: allegraferrari@virgilio.it

To assess how SARS-CoV-2 has changed the demand for in-person health care, we retrospectively analyzed data on access to the emergency department (ED) of San Martino Hospital, the referral acute-care center in the Liguria region (Northwest Italy). 181,699 records of patients diagnosed with an ICD-9 code between 2019 and 2021 were considered. In comparison to pre-pandemic levels, following the introduction of social distancing measures, the median number of ED visits declined by 41.4% in 2020 and by 28.1% in 2021. The period of maximum drop in access (-58.6%) corresponded to the 2020 11-12th calendar weeks and coincided with the highest rates of COVID-like illness - defined as either ILI or LRTI cases - identified through an operator-dependent syndromic surveillance system (+340%; 19.5% of total ED attendances). In terms of relative impact, in 2020 and 2021 non-urgent ED codes decreased (by 6.7% and 7.3%) and both urgent and emergency ED codes increased (by 4.8% and 3.8% the former; 5.5% and 8.8% the latter), even so, the absolute number of ED access fell drastically for all codes. Urgent codes, in particular, experienced the most severe decrease, shifting from a pre-pandemic value of 25,009 to 18,826 in 2020 and 19,528 in 2021. With

regards to diagnosis, in 2020, respiratory infections saw the highest increase (+3.3%) while traumas and eye diseases saw the highest decrease (-1.1% and -3.8%, respectively). This trend reversed in 2021 during which respiratory infections decreased (-2.2%) and traumas increased (+2.2%). Despite the admissions of males and the elderly being routinely lower, these categories experienced the greatest increase in access for respiratory infections: +3.9% and +10.1% in 2020; +2.8% and +7.4% in 2021. While reduction of non-urgent ED visits indicates that the high pre-pandemic access levels may have been avoidable, the significant decline in non-COVID-19 urgent accesses potentially points to an increase in delayed and missed care.

Key messages:

- During the COVID-19 pandemic – possibly due to fear and underestimation of symptoms – there was an overall reduction in ED accesses that potentially points to an increase in delayed or missed care.
- The reduction in non-urgent attendances indicates that high pre-pandemic accesses may have been avoidable and that a reduction in unnecessary ED visits is an attainable goal for healthcare systems.

Abstract citation ID: ckac129.541
COVID-19 incidence on Emergency Departments accesses. Health need and fear of infection, what wins?

Roberta Bosco

Contact: robertabosco0@gmail.com

Introduction:

The COVID-19 pandemic has changed the patterns of access to the Emergency Department (ED), but it is unclear whether this change was due to COVID-19 incidence or the lockdown imposed by law.

Aim:

To evaluate the association between trends of ED accesses and COVID-19 incidence in the period 1 January - 31 December 2020.

Material and methods:

The data of accesses to the ED per month and severity triage code of 14 hospitals in the Southeast Tuscany (Italy, Provinces of Siena, Arezzo, Grosseto) were obtained from hospitals data warehouses. Data on new cases of COVID-19 infection (obtained by the Ministry of Health) for the 3 provinces were used to calculate the incidence of infection. Hospitals were classified in 4 categories based on beds number, medical specialties offered, services provided. Differences in ED accesses by month, triage code and hospital type were investigated by a Kruskal-Wallis analysis of variance. Association between ED accesses and COVID-19 incidence was evaluated using a random effect panel data analysis adjusting for hospital type and triage code.

Results:

A total of 268,072 ED accesses have been studied. Their trends saw a strong decrease in correspondence of the first pandemic peak, subsequently they are increased and then decreased again until the minimum peak in November 2020. COVID-19 incidence appeared to overlap, but in the reverse direction, with ED admissions trends. Monthly differences of the ED accesses were significant ($p < 0.01$) except for most severity code. There is a statistically significant inverse association between ED accesses and COVID-19 incidence (Coef. = -0.074, $p < 0.001$) except for most severe cases (triage code 1: Coef. = -0.028, p = 0.154).

Conclusions:

ED admissions trends followed the COVID-19 incidence independently from the period of lockdown except for the most severe cases. The fear to contract the infection seemed to discourage patients to access ED for diseases that were perceived as not serious.

Key messages:

- The pandemic has changed the lifestyle of people worldwide, modifying even the perception that the patient has of own state of health and their access to Emergency Department.
- The decrease in accesses involved less severe cases. Reflect on both the adequacy of accesses in the pre-pandemic period and on what is the best setting to manage these cases in the pandemic period.

Characterizing post-covid conditions in a Turkish cohort: A prospective study

Öykü Turunç

AN Emecen[1], *O Turunc*[1], *N Sivye*[1], *AF Suner*[1], *E Basoglu Sensoy*[1], *S Keskin*[1], *B Unal*[1]
[1]Department of Public Health, Dokuz Eylul University, Faculty of Medicine, Izmir, Turkey
Contact: oykuturunc0@gmail.com

Background:

Investigating the people who suffer from post-COVID health conditions is necessary to accommodate the demand for accessing healthcare. This study aims to describe post-COVID health conditions within six months after diagnosis.

Methods:

This study was conducted at Dokuz Eylul University Hospital, a tertiary care hospital in Ä°zmir-Turkey. Participants aged $\geq$18 years who were diagnosed as SARS-CoV-2 RNA positive in the hospital from November 1st, 2020 to May 31st were interviewed by phone at one, three and six months after diagnosis. Symptom frequencies were stratified by demographic and clinical characteristics. The dependent variable was having post-COVID condition according to World Health Organization's definition. We estimated logistic regression models to identify associated factors for post-COVID condition in the patients who had symptoms at baseline.

Results:

A total of 5083 people completed the third month's interview. The prevalence of post-COVID condition was 21.8% (n = 1108). Tiredness/fatigue (10.2%), muscle or body aches (7.3%) and dyspnea/difficulty breathing (4.8%) were the most common symptoms. Older age (65-74 aged groups versus 18-24 aged group, odds ratio-OR:1.57, 95% confidence interval: 1.10-2.25), female gender (OR: 1.97, 1.71-2.28), bad economic status (OR: 1.44, 1.13-1.84), having more health conditions ($\geq$3 conditions, OR: 1.82, 1.28-2.55), having more symptoms (>5 symptoms, OR: 2.59, 2.20-3.07) and hospitalization (intensive care unit, OR: 1.98, 1.13-3.37) were found to be associated with reporting of post-COVID condition.

Conclusions:

This study identifies the prevalence and risk factors for post-COVID conditions in a large cohort of patients. The results of the study would guide the healthcare organizations in the planning of post-COVID management strategies.

Key messages:

- The prevalence of post-COVID conditions was 21.8%. Older age, female gender, having more health conditions, disease severity in the acute phase and bad economic status were risk factors.

- Clinical management strategies and country-specific healthcare planning should be devised for the post-COVID condition burden.

WICID 2.0: Integrating evidence and ethics in decisionmaking and guideline development on SARS-CoV-2

Jan Stratil

L Arnold[2], *S Bimczok*[2], *J Lehner*[2], *J Stratil*[1]
[1]Berlin, Germany
[2]Academy of Public Health Services, Angewandte ÖGD-Forschung und Transfer, Duesseldorf, Germany
Contact: stratil@posteo.net

Evidence-informed decision-making (EIDM) requires the balancing of numerous and often conflicting factors. During the SARS-CoV-2 pandemic, sound and fair EIDM procedures were challenged by time constraints and limited evidence. Beneficial effects had to be weight against public health impacts beyond COVID-19, broad societal consequences, or individual liberties. Evidence-to-decision (EtD) frameworks are neither able nor intended to replace stakeholder participation, but can serve as a tool to ensure the relevance and completeness of criteria to be considered for EIDM in public health and guideline development. Employing 'best-fit' framework synthesis, we used the WHO-INTEGRATE framework as a starting point to develop the WHO-INTEGRATE COVID-19 framework version 1.0. WICID 1.0 is based on a content analysis of comprehensive strategy documents to guide policy makers in implementing new or decrease existing measures to protect against COVID-19 in Germany. WICID 1.0 was validated by coding the framework against an updated set of the key strategy documents, and key strategy documents addressing non-pharmacological measures in long-term care facilities. In total, 12 key strategy documents were analysed to develop WICID 1.0, and 18 + 23 documents were analyzed for its refinement towards WICID 2.0. The revised framework consists of 11 + 1 criteria and includes implications for the health of individuals and populations due to and beyond COVID-19, infringement on liberties and fundamental human rights, acceptability and equity considerations, societal, environmental and economic implications, as well as implementation, resource and feasibility considerations. Validation found high consistency with minor revisions between WICID 1.0 and 2.0. WICID can be a tool to support researchers, practitioners, and policy makers to systematically integrate evidence and ethics and to balance of health, societal and other considerations when reflecting on PH interventions targeting COVID-19.

Key messages:

- Due to the rapidly developing pandemic, decision-making process often did not include the views of all affected stakeholders and did not adequately include all criteria and considerations of relevance.
- The WICID Framework can serve as a tool to support decision-makers in accounting for relevant considerations and criteria, even when not all stakeholders could be included.

[3]World Federation of Public Health Association, Geneve, Switzerland
[4]Center for Leadership in Medicine Research, Università Cattolica, Rome, Italy
Contact: angelicavalzgris@gmail.com

Background:

During the COVID-19 pandemic, several public health challenges were faced, requiring worldwide leaders able to direct, guide, and establish appropriate strategies. The aim of this review was to summarize evidence on public health leadership during the COVID-19 era.

Methods:

The systematic literature review was conducted according to the PRISMA 2020 checklist. A search of relevant articles was performed in the PubMed, Scopus, and Web of Science databases. Eligible articles were any type of publication, published between 2020 and 2022, that outlined one or more characteristics of effective public health leadership during the COVID-19 pandemic We excluded all articles that did not explicitly address the COVID-19 pandemic or had a different setting.

Results:

A total of 2499 records were screened, and 45 articles were included. We identified 93 characteristics, clustered in six groups, that were reported as fundamental to be an effective leader in public health crises worldwide. Emotional intelligence and human traits (reported by 46.67% of the articles) were considered essential to build trust in the population and ensure cooperation with working groups. Communication skills (47%) are considered necessary to enable people to understand and accept measures. A supportive, multidisciplinary team and accountability mechanisms (33,33%) were highlighted as central elements, especially in the international field, to ensure reliability and consistency in action. Management skills (35,56%), adaptability (44,44%), and evidence-based approach (33,33%) were reported as key capabilities to ensure a prompt and rapid response to the challenges created by the pandemic.

Conclusions:

The identification of the attributes of an effective public health leader conducted in this study is useful in choosing the key personalities who must lead public health today and in the training of tomorrow's European and worldwide leaders to be ready to face future threats.

Key messages:

- Effective public health leaders in crisis are empathetic and trustworthy people, who have developed management and communication skills, and are able to make timely and evidence-based decisions.
- In order to create leaders capable of facing future threats, more emphasis in the training of public health workforce on

soft skills and management competencies should be recommended.

Learning from COVID-19: The inclusion of vulnerable groups in COVID-19 responses across Europe

Jil Molenaar

J Molenaar[1], L Van Praag[1]
[1]Faculty of Social Sciences, University of Antwerp, Antwerp, Belgium
Contact: jil.molenaar@uantwerpen.be

Background:
More than two years into the pandemic, many European countries have begun to evaluate their COVID-19 public health responses and draw lessons for future preparedness. As the COVID-19 crisis has exacerbated intersectional social and health inequalities, it is pertinent to evaluate the extent to which COVID-19 responses have successfully responded to the diverse needs of various vulnerable groups. We present a comparative analysis of how evaluations of European COVID-19 responses have assessed efforts to adapt or tailor COVID-19 responses to vulnerable groups, focusing on public testing and tracing strategies and vaccination campaigns.

Methods:
We draw on data collected in the H2020 project COVINFORM. We combine insights from qualitative interviews conducted with public health policy- and decision makers in COVINFORM partner countries with a document review of available evaluations of COVID-19 responses published by both government and academic actors between March 2020 and June 2022.

Results:
Across countries, evaluations of COVID-19 responses show that efforts to adapt or target public health responses to specific vulnerable groups became more common as the pandemic stretched on. Differences across countries were observed in relation to which groups were considered particularly vulnerable; the types of responses considered successful; as well as the organisational/governmental level at which responses were coordinated. Analyses reveal that the heavy emphasis on medical vulnerability distracted from efforts to address broader, structural inequalities, complicating the development of tailor-made policies.

Conclusions:
The results inform ongoing policies that deal with the long-term consequences of the COVID-19 pandemic and aim to reduce disproportionate impacts faced by vulnerable groups. Our findings also add to a better understanding of how future preparedness structures should take into account how pandemic measures have unequal impacts.

Key messages:
- As the COVID-19 crisis has exacerbated intersectional social and health inequalities, it is important to learn from efforts to adapt or tailor COVID-19 responses to vulnerable groups.
- The findings demonstrate how across Europe, the combination of particular sets of country-specific COVID-19 responses, tailor-made or not, yield specific consequences for vulnerable groups.

Contact: anyavieira10@gmail.com

Brazil is one of the countries with the highest COVID19 mortality numbers. COVID19 deaths affected disproportionally different populations/communities, tending to be higher among more vulnerable ones. Brazil has a public-funded unified health system (SUS) built on the aegis of equity and social control. Its Primary Health Care (PHC) is organized by the Family Health Strategy (FHS) through Family Health Teams (FHT), which comprise a family doctor, a nurse, a dentist, nurse auxiliaries and Community Health Agents (CHAs). CHAs are individuals from the community trained to provide a range of services in the territories, including home visits, health promotion activities, and serve as liaisons between health units and communities. In this context, CHAs have the potential to play an important role in fighting the pandemic by working on contact tracing, collecting information on infected people, and providing guidance to them and the community in order to contain community transmission. However, not much is known about their readiness regarding the COVID19 pandemic in one of the Brazil's poorest regions. Thus, this study evaluated, though CHA perspective, aspects related to their preparedness for COVID19 in Brazil's northeast region. Questionnaires were applied to CHAs from 8 different municipalities - 4 capitals and 4 country-side municipalities. A total of 1935 CHAs were interviewed at their workplace in 2021. 77.8% said that they were acting in the COVID19 frontline, but only 16% referred to have received training for this function. Furthermore, only 13.7% mention to have had access to adequate individual protective equipment during their work, and 91.6% believe that they can get infected by SAR-COV-2 during their work duties. Additionally, 93.9% considered themselves a transmission vehicle due to work. Despite their potential in the fight against COVID19, CHAs did not received enough training, nor were equipped adequately during the COVID19 pandemic.

Key messages:
- CHAs did not received enough training, nor were equipped adequately during the COVID19 pandemic.
- Addequate trainning and work environment are essencial for proper work development.

Contact: milena.santric-milicevic@med.bg.ac.rs

Background:
Analysis of years of life lost (YLL) due to premature deaths during the COVID-19 pandemic can direct decision-makers towards specific public health recommendations in order to improve health and lives of people. Our study aimed to

examine the existence of age- and sex-specific patterns of the three most common causes of premature death in Belgrade during the first year of the COVID-19 epidemic.

Methods:

Mortality data disaggregated by age, sex and cause of death, as well as the estimated number of inhabitants and remaining life-expectancy by age-groups for Belgrade was provided by the Statistical Office of the Republic of Serbia. YLLs were calculated using the methods of the Global Burden of Disease Study, without garbage code redistribution. Mortality rates were standardized according to the European Standard Population. We acknowledge the support from the COST Action 18218 - European Burden of Disease Network.

Results:

In 2020 in Belgrade, according to the share in all-cause YLLs, cardiovascular diseases ranked first (36.2%), followed by neoplasms (25.7%) and COVID-19 (11.1%). However, on average, COVID-19 generated higher number of YLLs per death case (11.9) than cardiovascular diseases (9.2), but fewer than neoplasms (13.9). In total of 31,943 YLLs due to COVID-19, men had 1.7 times more YLLs than women. By age groups, the highest YLL share due to COVID-19 was among men aged 45-49 (16%) and 70-74 (16%) and among women aged 20-25 (33%) and 25-29. years (29%). In men, COVID-19 YLL rate was 2,488 per 100,000 and was higher after standardization (2,714). In women, COVID-19 YLL rate was 1346 per 100,000 and was lower after standardization (1,245).

Conclusions:

In Belgrade, COVID-19 was the third cause of premature mortality in 2020. The difference between COVID-19 YLL rates in men and women were even more prominent after standardization. Future research is needed to determine the synergistic impact of COVID-19 and other causes of premature death.

Key messages:

- In 2020, COVID-19 was among the top three causes of premature mortality among male and female contingents of the Belgrade population.
- Assessing the causes of premature mortality is important for determining community health priorities.

Abstract citation ID: ckac129.548
Covid-19 Vaccination and the issue of insurance status

Daniel Schröpfer

D Schröpfer[1], *R Fortunato*[1], *N Devaud*[1], *R Koppensteiner*[1]
[1]SAD, Stadt Zürich Stadtärztlicher Dienst, Zürich, Switzerland
Contact: daniel.schroepfer@zuerich.ch

Issue:

It is estimated, that 11000 - 14000 people that live in Zurich do not have health insurance. For the vaccination against Covid-19 in Switzerland one had to register oneself on a website (Vacme) with your address and a Swiss health insurance number was required. This systematically excluded any people without insurance or Sans Papiers.

Description:

To address this issue the city physician service Zurich organized a vaccination program for the uninsured from 14.06.2021 onward. To achieve this a code which could be used instead of the regular insurance number was organized and the staff recorded personal information of patients on site to remove language and technological barriers. Furthermore, the Police department was informed and agreed not to circulate the area of the vaccination service on vaccination days to minimize access-barriers for patients without legal residency.

Results:

Between 14.06.2021 and 19.02.2022, 880 people came for vaccination of which 603 were clearly identifiable as individuals from vulnerable populations with no insurance. After initial organization, other vaccination centers in Switzerland were able to use the substitute number to vaccinate people without health insurance as well..

Lessons:

There is a sizeable amount of people living without registration or/and health insurance. It is therefore critical not to forget these people when organizing public health measures, especially when addressing a pandemic or other infectious diseases (HIV, Hep C). Non-insurance is a known issue for universal access to care.

Acknowledgements: We would like to thank the hold crew of the ambulatorium kanonengasse at SAD

Key messages:

- When fighting a pandemic it is of utmost importance to reach as many people as possible.
- Acess must be possible also for vulnernable people.

Abstract citation ID: ckac129.549
Sharp Increase in Eating Disorders among University Students since the COVID-19 Pandemic

Marie-Pierre Tavolacci

M Tavolacci[1,4], *J Ladner*[2,4], *P Déchelotte*[3,4]
[1]CIC 1404, CHU Rouen, Rouen, France
[2]DEPS, CHU Rouen, Rouen, France
[3]Department of Nutrition, CHU Rouen, Rouen, France
[4]INSERM 1073, Université Rouen, Rouen, France
Contact: Marie-Pierre.Tavolacci@chu-rouen.fr

Background:

The COVID-19 pandemic has caused stress, required lockdowns, curfews and social restriction and thus may have altered physical activity and eating habits among university students. The objectives were to determine the impact of the COVID-19 pandemic on Eating Disorders (ED) among university students.

Methods:

Between 2009 and 2021, five repeated on line cross-sectional studies were conducted among university students. ED were identified using the French version of the five-item “Sick, Control, One stone, Fat, Food” (SCOFF) questionnaire. The ExpaliTM-validated algorithmic tool, combining SCOFF and body mass index, was used to screen EDs into four diagnostic categories: bulimic, hyperphagic and restrictive ED.

Results:

With the five studies, 8981 university students were included in total, 67.3% female with a mean age of 20.7 years. The prevalence of ED was stable between 2009 and 2018 and significantly increased from 31.8% in 2018 to 51.8% in 2021 for women (p trend < 0.0001), and from 13.0% in 2009 to 31.3% in 2021 for men (p trend < 0.0001). Lower food security scores were associated with a higher risk for all ED categories. Depression and academic stress due to COVID-19 were associated with ED regardless of category. Regarding health behaviors, a high adherence to the National nutrition recommendation was a protective factor for the risk of bulimic ED, hyperphagic ED and restrictive ED. A lower frequency of moderate and vigorous physical activity was associated with a higher risk of hyperphagic ED.

Discussion:

Our study has shown a high screening of ED among the students of a French university fourteen months after the beginning of the COVID-19 pandemic. By disrupting academic learning, jobs and social life, the COVID-19 pandemic could have exacerbated existing ED or contributed to the onset of new ED. Initiatives to reinforce early screening of ED to implement targeted interventions in the student population are urgently needed.

Key messages:

- This finding underlines the need to extensively screen for ED in students population and identify vulnerable individuals at risk of ED.
- By disrupting academic learning, jobs and social life, the COVID-19 pandemic could have exacerbated existing ED or contributed to the onset of new ED.

Abstract citation ID: ckac129.550
Real-life effects of nudging and pricing strategies in the supermarket to promote healthy diets

Josine Stuber

JM Stuber[1], JD Mackenbach[1], J Lakerveld[1], JWJ Beulens[1]
[1]Epidemiology and Data Science, Amsterdam UMC, Amsterdam, Netherlands
Contact: j.stuber@amsterdamumc.nl

Background:

Unhealthy dietary patterns pose a major public health challenge. Individual-level efforts to promote heathy diets (e.g. nutrition education) have limited effect on the long term. Context-specific interventions focussing on point-of-purchase may create opportunities for sustainable dietary changes. We evaluated real-life effects of nudging and pricing strategies in supermarkets on dietary intake.

Methods:

In this parallel cluster-randomised controlled trial, we randomized 12 Dutch supermarkets in socially deprived neighbourhoods to a control group (n = 6), or intervention group (n = 6). Healthy food nudges were implemented in intervention stores across 13 food groups, combined with healthy product price decreases and unhealthy product price increases. Eligible participants were aged 30-80 years and regular shoppers at participating stores. The primary outcome was dietary guideline adherence measured via an index score (0-150), at baseline and after 3, 6 and 12 months. Secondary outcomes included parameters of cardiometabolic health (HbA1c, lipid profile, and waist circumference), the percentage of healthy food purchases in the supermarket, socio-cognitive factors, and supermarket customer satisfaction. Effects were analysed with linear mixed models.

Results:

This study included 173 participants from intervention clusters and 220 from control clusters. Preliminary evaluation of the 3-month follow-up data revealed no effectiveness of the nudging and pricing strategies compared to the control supermarkets in terms of dietary guideline adherence (β -0.8, 95%CI -4.2; 2.7). Results on all outcomes will be available at time of the conference.

Conclusions:

This novel supermarket trial is the first to evaluate real-life long-term effects of nudging and pricing strategies based on a comprehensive set of study outcomes and using a strong methodological design. Findings can direct future design of context-specific interventions focussing on the promotion of healthy diets.

Key messages:

- Context-specific interventions focussing on point-of-purchase may create opportunities for sustainable dietary changes.
- Findings from this supermarket trial testing real-life and long-term effects of nudging and pricing strategies can direct future design of context-specific interventions focussing on healthy diets.

Meal timings and daily night-time fasting periods can synchronise the circadian system, which regulates the cardiovascular system. The present study aims to evaluate the prospective associations between circadian nutritional behaviours, defined by meal timing and frequency, and the risk of cardiovascular diseases. We used data from 103,389 adults (79% females) in the French NutriNet-Santé study, 2009-2021. Circadian nutritional behaviours were assessed using repeated 24h food records during the first two years of follow-up. We examined the associations between circadian eating behaviours and risk of cardiovascular, coronary heart and cerebrovascular diseases by multivariable Cox proportional hazard models. During a median follow-up of 7.2 years, 2036 incident cardiovascular diseases were diagnosed. A later first meal of the day was associated with a higher risk of cardiovascular diseases (HR per hour increase = 1.06, 95% CI 1.01 - 1.12). A later last meal of the day was associated with a higher risk of cerebrovascular diseases (HR per hour increase = 1.08, 95% CI 1.01 - 1.15). Among women, a later last meal was also associated with a higher risk of cardiovascular disease (HR per hour increase = 1.08, 95% CI 1.01 - 1.15). We found no evidence for an association between night-time fasting duration nor meal frequency, with risk of cardiovascular diseases. This study suggests that the habit of eating a later first meal, and a later last meal (in women) could be associated with a higher risk of developing circulatory diseases. These results need to be confirmed in other largescale studies before they can be transferable to clinical practice.

Key messages:

- Beyond nutritional quality of meals, meal timing could also be a risk factor for cardiovascular disease.
- If confirmed in other largescale studies, early breakfast and dinner could be considered in preventive strategies of cardiovascular diseases.

Background:
The Southern European Atlantic Diet (SEAD) is the traditional diet of Northern Portugal and North-Western Spain, but it may resemble that of other European countries. Higher adherence to SEAD has been associated with lower risk for myocardial infarction and all-cause mortality, but its relationship with mental health is uncertain. We examined the association between SEAD and depression incidence in Southern, Central, and Eastern Europe.

Methods:
We used data from participants $\geq$45 years from the Seniors-ENRICA-2 and HAPIEE cohorts, who were followed for a median time of 3.6 years. SEAD comprised fresh fish, cod, red meat and pork products, dairy, legumes and vegetables, vegetable soup, potatoes, whole-grain bread, and wine. Depressive symptoms were assessed with the GDS 10 and the CES-D 10 (participants with scores $\geq$4 were considered depression cases). Statistical analyses were performed among the 14675 participants who were depression-free at baseline.

Results:
Higher adherence to SEAD was preliminarily associated with lower depression incidence in the pooled sample (fully adjusted odds ratio [95% confidence interval] per 1-SD increment in the SEAD = 0.93 [0.89,0.98]). Results were consistent in Spain (odds ratio [95% confidence interval] 0.86 [0.68,1.08]), Czechia (0.92 [0.82,1.04]), Poland (0.94 [0.88,1.01]), and Russia (0.93 [0.87,1.00]). The association of SEAD with depression in the pooled sample was similar to that found for the Alternate Healthy Eating Index (odds ratio [95% confidence interval] per 1-SD increment = 0.94 [0.89,0.99]) and the Mediterranean Dietary Score (0.94 [0.90,0.98]).

Conclusions:
Adherence to SEAD was preliminarily associated with lower depression incidence in Spain, Czechia, Poland, and Russia. These findings may support the development of mental health guidelines for Southern European Atlantic populations based on their traditional diet, and for Central and Eastern European countries based on the food components of SEAD.

Key messages:
- Adherence to the Southern European Atlantic Diet (traditional diet of Northern Portugal and North-Western Spain) was associated with lower depression incidence in Spain, Czechia, Poland, and Russia.
- Mental health guidelines for Southern European Atlantic populations may reference their traditional diet, while those for Central and Eastern Europe could benefit from including its food components.

Ultra-processed food intake is associated with worse mental health in Southern Italian individuals

Giuseppe Grosso

G Grosso[1], J Godos[1], A Micek[2]
[1]Department of Biomedical and Biotechnological Sciences, University of Catania, Catania, Italy
[2]Department of Nursing Management and Epidemiology, Jagiellonian University, Krakow, Poland
Contact: giuseppe.grosso@unict.it

Background:
A growing body of literature suggests that inclusion of ultra-processed foods (UPFs) in the diet may be associated with various non-communicable diseases, including obesity, cardiometabolic diseases, and increased mortality. However, one of the most underrated research topics is represented by the potential role of diet for mental disorders. The aim of this study was to explore whether there was an association between UPF consumption and mental health outcomes in a cohort of southern Italian individuals.

Methods:
Demographic and dietary data from 1572 adults living in southern Italy was collected. Food items were categorized by the level of processing according to the NOVA classification. Multivariate logistic regressions were used to calculate odds ratios (ORs) and 95% confidence intervals (CIs) for the association between UPF intake and mental health outcomes, including sleep quality and depressive symptoms.

Results:
Individuals in the highest quintile of UPF intake were more likely to have low sleep quality compared to those with the least intake (OR = 1.54, 95% CI: 1.02-2.34). Among the main component of sleep quality, high UPF intake was associated with sleep latency and efficacy individually. No apparent associations were found between UPF intake and depressive symptoms. However, when considering different age groups, younger individuals (age <40 y) consuming more UPF were more likely to have depressive symptoms than low consumers (OR = 3.50, 95% CI: 1.53-7.99).

Conclusions:
These findings show a potential association between UPF consumption and mental health outcomes. Further studies are needed to understand whether the retrieved relation depends on alteration of the physiological feeding patterns leading to food-anticipatory and binge-type behaviors or on nutritional (i.e., high sugars and unhealthy fats) and non-nutritional factors (i.e., additives) triggering pro-inflammatory pathways.

Key messages:
- Ultra-processed food consumption is associated with worse sleep quality and depressive symptoms in Italian adults.
- The detrimental associations between ultra-processed food consumption and depressive symptoms seem stronger among younger individuals.

Gambling disorder and chronic diseases in Finland: a nationwide register study

Tanja Grönroos

T Grönroos[1,2], AH Salonen[1,3], TA Latvala[1], A Kouvonen[2,4]
[1]Department of Public Health and Welfare, The Finnish Institute for Health and Welfare, Helsinki, Finland
[2]Faculty of Social Sciences, University of Helsinki, Helsinki, Finland
[3]Faculty of Health Sciences, University of Eastern Finland, Kuopio, Finland
[4]Centre for Public Health, Queen's University Belfast, Belfast, UK
Contact: tanja.gronroos@thl.fi

Background:
Previous register-based studies on comorbidity have mainly focused on gambling disorder (GD) and psychiatric disorders. However, knowledge on somatic health of persons with GD is

also needed. This nationwide register-based study aims to examine the gender-specific prevalence rates of chronic diseases and conditions among the Finnish adults with GD.

Methods:

This study utilizes aggregated data of persons aged 18 and over with GD diagnosis (corresponding to pathological gambling, ICD-10; F63.0) in 2011-2020. The data were retrieved from the Finnish nationwide health registers: Register of Primary Health Care visits and Care Register for Health Care, including specialised outpatient and inpatient health care, and inpatient social care. All diagnostic groups were included. Corresponding figures for the total population with same age range were presented as reference numbers.

Results:

The preliminary results showed that 2,617 persons with the median age of 33.5-36.0 were diagnosed with GD (men n = 1,858; women n = 759). Despite the fact that the prevalence rates of the general population were not age-adjusted, many chronic diseases and conditions were more prevalent among persons with GD compared with the general population. The prevalence rates of psychiatric disorders (87.5% vs 29.2%) and nervous system diseases (23.9% vs 15.2%) were particularly high. Musculoskeletal diseases (61.6% vs 55.8%) and digestive diseases (30.2% vs 27.6%) were also slightly more prevalent. Memory disorders (1.1% vs 5.3%), cardiovascular diseases (25.3% vs 41.0%), and cancer (15.6% vs 24.4%) were less prevalent. Among persons with GD, all comorbid diseases were more prevalent among women than among men.

Conclusions:

Psychiatric disorders and nervous system diseases are exceptionally prevalent in persons with GD. These findings highlight the need for health and social care professionals to recognize that persons with GD may additionally have other disorders that need attention.

Key messages:

- Mental disorders are the most common comorbidity among persons with GD, however, many somatic chronic diseases are also common.
- Comorbidities are more common among women with GD than among men with GD.

Abstract citation ID: ckac129.555
Smoking cessation at diagnosis and cancer survival: systematic review and meta-analysis

Marco Del Riccio

M Del Riccio[1], *G Bonaccorsi*[1], *C Lorini*[1], *V Vettori*[1], *S Gandini*[2], *S Caini*[3]
[1]Department of Health Sciences, University of Florence, Florence, Italy
[2]Department of Experimental Oncology, European Institute of Oncology, IRCCS, Milan, Italy
[3]ISPRO, Florence, Italy
Contact: marco.delriccio@unifi.it

Stopping smoking can considerably cut one's risk of developing cancer compared to continued smoking (i.e. up to 50% after 5 years for esophageal cancer and after 10 years for lung cancer). Much less is known about whether quitting smoking may bring a survival advantage to people who are active smokers at the time of cancer diagnosis. We conducted a systematic review and meta-analysis of the studies that examined the prognostic effect of quitting smoking at or around diagnosis among cancer patients. We searched MEDLINE and EMBASE for articles published until 30th March 2022 that reported the impact of quitting smoking at or around diagnosis on cancer patients' survival (any type). Separately for each cancer site, study-specific data were pooled into summary relative risk (SRR) and corresponding 95% confidence intervals (CI) using random effect meta-analysis models, investigating sources of heterogeneity and bias. Forty-three articles were included, including 20 for lung cancer (LC), 16 for head and neck cancer (HNC), and less than 10 for bladder, breast, gastrointestinal tract, and other sites. Quitting smoking at or around diagnosis was associated with longer overall survival (SRR 0.71, 95% CI 0.64-0.80) in LC patients (consistently for non-small cell and small cell LC) as well as HNC patients (SRR 0.80, 95% CI 0.70-0.91). No significant publication bias was found. For the other body sites, the studies were limited in number, which prevented meta-analyses, but results were generally consistent with a beneficial effect of smoking cessation on survival. Quitting smoking at or around diagnosis is associated with a significantly improved overall survival of smokers diagnosed with LC and HNC and shows beneficial effects in patients with other cancers. Physicians should offer smoking cessation counselling to smokers who start diagnostic workup for suspected cancer, and smoking cessation strategies should arguably become part of standard multidisciplinary oncological care.

Key messages:

- Smoking cessation at or around diagnosis is associated with a significantly improved overall survival of smokers diagnosed with different types of cancer.
- Smoking cessation strategies (and counselling) should become part of standard multidisciplinary oncological care.

Abstract citation ID: ckac129.556
Rapid systematic review of smoking cessation interventions for people who smoke and have cancer

Kate Frazer

K Frazer[1], *N Bhardwaj*[2], *P Fox*[1], *V Niranjan*[2], *S Quinn*[2], *C Kelleher*[2,3], *P Fitzpatrick*[2,3]
[1]Nursing, Midwifery and Health Systems, University College Dublin, Dublin, Ireland
[2]Public Health, Physiotherapy, Sports Science, University College Dublin, Dublin, Ireland
[3]Department Preventive Medicine and Health Promotion, St Vincent's University Hospital, Dublin, Ireland
Contact: kathleen.frazer@ucd.ie

Background:

Higher rates of cancer are reported in smokers compared to non-smokers, and continued smoking following a cancer diagnosis is associated with reduced health outcomes and survival. Despite international evidence of increased risks, a substantial percentage of people with a cancer diagnosis continue to smoke. Patients may be unaware of the additional risks associated with continued smoking, and health care professionals may not engage with quit supports. As part of a larger feasibility study to develop a smoking cessation pathway in cancer services in Ireland, a rapid review of the evidence was completed.

Methods:

Systematic searches of PubMed, Embase, and CINAHL 2015 to December 2020 were conducted; with studies restricted to adults with a cancer diagnosis [lung, breast, cervical, head and neck] and published in English. No restriction was placed on study designs. 6404 studies were identified and uploaded into COVIDENCE platform, Cochrane's systematic review methods were adopted throughout, PRISMA reporting guidelines were used, and narrative data synthesis was completed (CRD 42020214204).

Results:

The twenty-three-studies report evidence from USA, Canada, England, Lebanon, and Australia. The setting for all interventions was hospitals and cancer clinics. Evidence identifies high dropout rates, inconsistencies in approaches and duration of smoking cessation interventions with varied outcomes. A wide-ranging number of critical components emerged associated with optimal quit support- including the timing of and frequency of quit conversations, use of electronic records, in-person support meetings, provision of nicotine replacement therapy and extended use of Varenicline, smoking cessation services embedded in oncology depts, and engaging with families wanting to quit at the same time.

Conclusions:

Developing tailored smoking cessation interventions are needed for smokers diagnosed with cancer to enable engagement.

Key messages:

- Continued smoking following a cancer diagnosis is associated with reduced health outcomes.
- Smoking cessation programmes for cancer patient should be tailored to meet needs.

[8]Veterinary Public Health and Food Safety, Ghent University, Ghent, Belgium
Contact: vanessa.gorasso@sciensano.be

Background:

According to WHO, approximately one in three people worldwide live with a chronic, painful musculoskeletal (MSK) disorder. Low back pain (LBP), neck pain (NKP), osteoarthritis (OST) and rheumatoid arthritis (RHE) are among the most disabling MSK disorders. According to the Global Burden of Disease (GBD) study, LBP was the leading global cause in terms of years lived with disability and OST showed an increase in prevalence and is predicted to be one of the leading future causes. Our study aimed to analyse the burden of these MSK disorders in Belgium, providing a summary of morbidity and mortality outcomes from 2013 to 2018.

Methods:

Prevalence and disability-adjusted life years (DALY) were computed using data from the Belgian health interview surveys from 2013 and 2018, the INTEGO database (Belgian registration network for general practitioners) and GBD study 2019. Mortality data was retrieved from the Belgian statistical office for people dying from RHE. Following GBD methodology, LBP, NKP and OST were assumed to not generate any deaths.

Results:

The prevalence of MSK disorders increased from 2013 to 2018 with OST being the disorder with the highest number of cases (1.7 million cases in 2018). The burden was higher in women and the gender disparities increased with age. Women died also more frequently due to RHE compared to men. In total MSK disorders contributed to 180,746 comorbidity-adjusted DALYs for female and 116,063 comorbidity-adjusted DALYs for men in 2018, with LBP being the largest contributor (140,031 DALY).

Conclusions:

The burden of MSK disorders has increased over the years. In 2018, 2.5 million Belgians were affected by at least one MSK disorder that resulted in almost 300,000 DALY. Our study provides valuable information of a part of the health burden that is known to have a great impact on the total burden of disease but that is sometimes disregarded by public health institutions.

Key messages:

- MSK disorders represent a major health problem in Belgium.
- Acting on risk factors associated to these disorders is crucial to mitigate their burden.

Healthcare use among cancer survivors during the COVID-19 pandemic

Ana Rute Costa

AS Pimentel[1], AR Costa[1,2,3]
[1]EPIUnit, Instituto de Saúde Pública da Universidade do Porto, Porto, Portugal
[2]ITR, Laboratório Investigação Integrativa e Translacional em Saúde Populacional, Porto, Portugal
[3]Departamento de Ciências da Saúde Pública e Forenses, Educação Médica, Faculdade de Medicina da Universidade do Porto, Porto, Portugal
Contact: arcosta@ispup.up.pt

Background:

The COVID-19 pandemic and the restrictive measures applied to prevent and control this disease have led to a substantial shift in healthcare systems, with a redefinition of priorities and essential care, causing a serious impact in the oncological care. Therefore, we aimed to estimate the association of a previous cancer diagnosis on healthcare use during the COVID-19 pandemic among European and Israelis cancer survivors (CS).

Methods:

This cross-sectional study was based on data from the Survey of Health, Ageing and Retirement in Europe (SHARE), including the SHARE COVID-19 Survey, which was conducted in the summer of 2020, in 27 countries. All CS (n = 6,490) were country-, sex-, age- and education-matched (1:2) to non-cancer individuals (NC). Odds ratios (OR) and 95% confidence intervals (95%CI) were computed using logistic regression.

Results:

Overall, CS were more likely to refer that they forwent medical appointments due to fear of COVID-19 (OR = 1.29, 95%CI:1.19-1.41), than NC, particularly those who lived with their partner and other relatives (OR = 1.79, 95%CI:1.39-2.30). Likewise, CS reported the occurrence of postponements more often (OR = 1.54, 95%CI:1.44-1.64); this association was stronger among CS who lived with their partner and other relatives (OR = 1.96, 95%CI:1.63-2.36), who reported higher economic difficulties (OR = 1.73, 95%CI:1.50-2.00) and those with no multimorbidity (OR = 1.85, 95%CI:1.62-2.11). CS were also more likely to refer that they were unable to book an appointment (OR = 1.43, 95%CI:1.26-1.63), particularly those who reported that a person close to them died due to COVID-19 (OR = 2.72, 95%CI:1.47-5.01).

Conclusions:

CS were more likely to forgo medical treatment and to report healthcare postponements and to be unable to book an appointment than NC, which highlights the importance of closely monitoring the long-term impact of the COVID-19 pandemic along the cancer care continuum.

Key messages:

- During the COVID-19 pandemic, a previous cancer diagnosis was associated with a more frequent report of appointment cancellations, postponements or denials.
- The first months of the COVID-19 pandemic led to changes in healthcare provided to cancer survivors, which may have a deleterious impact in their care and prognosis.

Abstract citation ID: ckac129.559
Gender bias in cardiovascular practice guidelines: the example of ischemic heart diseases

Kathleen Bastian

K Bastian[1], JL Rohmann[2,3], M Piccininni[2,3], M Kelly Irving[4], N Bajos[1]
[1]IRIS - EHESS - U997 INSERM, Interdisciplinary Institute of Social Issues IRIS, Aubervilliers, France
[2]Institute of Public Health, Charité - Universitätsmedizin Berlin, Berlin, Germany

[3]Center for Stroke Research Berlin, Charité - Universitätsmedizin Berlin, Berlin, Germany
[4]CERPOP-UMR1295, Université de Toulouse III, Toulouse, France
Contact: kathleen.bastian@inserm.fr

Background:

Despite declines in cardiovascular disease mortality, evidence suggests women have a higher mortality and worse prognosis after ischemic events compared with men. This work investigates to what extent clinical recommendations made by cardiovascular guidelines might include sex and gender biases.

Methods:

We reviewed the primary literature base underlying the 2019 European Society of Cardiology guidelines' recommendations on chronic coronary syndromes focusing on sex and gender sensitivity aspects pertaining to ischemic heart diseases. We applied an adapted Cochrane Collaboration appraisal checklist and only included recommendations with direct citation to literature evidence. We used beta regression to model the association between the proportion of female participants within the study population and the year of publication (modeled as cubic polynomial), impact factor, and sex of the first/last author.

Results:

In the 20 recommendations that quoted the literature, gender-sensitive propositions were fully absent, while 4 included sex-sensitive statements. Sex- or gender- specific study design or a priori statistical considerations were largely absent in the included publications. The term "gender" was used exclusively to denote biological sex. The included studies published between 1991 and 2019 comprised of more than 2.1 million individuals (29% female). Representation of women as study participants undulated over time. Female sex of first (OR = 1.84, 95%CI = 1.30-2.60) or last (OR = 2.27, 95%CI = 1.31-3.92) author were statistically significantly associated with the probability of having more female study participants.

Conclusions:

Methodological sex- and gender-sensitive considerations are largely missing in the evidence base used to guide cardiovascular care decision-making in Europe. Women remain underrepresented in the studies from which the guidelines are derived. Studies with female first or last authors were more likely to have better representation of women.

Key messages:

- Though differences in morbidity are well-described, current European cardiovascular recommendations lack sex and gender sensitivity, and women remain underrepresented in the underlying evidence base.
- To what extent the clinical cardiovascular recommendations may or may not be valid for groups not well-represented in the underlying evidence base remains unknown.

Abstract citation ID: ckac129.560
Social environment and cardiometabolic health outcomes: systematic review and meta-analysis

Taymara Abreu

TC Abreu[1], JWJ Beulens[1], LJ Schoonmade[2], JD Mackenbach[1]
[1]Department of Epidemiology and Data Science, Amsterdam UMC, Amsterdam, Netherlands
[2]University Library, VU, Amsterdam, Netherlands
Contact: t.c.abreu@amsterdamumc.nl

A number of studies investigated the relationship between the social environment (SE) (i.e., the social relationships and social context in which groups of people live and interact) and lifestyle behaviours. However, to what extent this relation extends to cardiometabolic disease (CMD) outcomes is unknown. This systematic review and meta-analysis summarizes the available evidence. We systematically searched PubMed (Medline), Scopus, and Web of Science from inception to 16 February 2021. Outcomes of were type 2 diabetes mellitus and cardiovascular diseases and determinants were SE factors. We assessed the quality of the studies with Newcastle-Ottawa Scale (NOS). We meta-analysed exposure-outcome combinations when ≥ 3 associations from high quality papers were available. Results are expressed as OR, 95%CI. From 7,671 records screened, 208 were included. Of these, 92% were conducted in high income countries, 58% were cross-sectional studies, and 20% were of poor quality. Among the 208 studies, 746 relevant associations were investigated. The largest number of associations investigated was on the dimension Economic and Social Disadvantage (ESD; 59%), followed by Social Relationships and Norms (21%) and Discrimination and Segregation (9%). Less evidence was found for the remaining dimensions. Meta-analysis of 14 exposure-outcome combinations indicated that worse SE was associated with increased odds of CMD outcomes. Despite this tendency, only the association between ESD and heart failure was statistically significant (1.58, 1.11-2.27; n = 4; I2 = 92%). Generally, heterogeneity was high. In conclusion, higher levels of ESD seem to contribute to increased risk of heart failure. The existing literature is highly heterogeneous and varies notably in terminology. Moreover, the dimensions Social Cohesion and Social Capital, Crime and Safety, Civic Participation and Engagement and Disorder and Incivilities are underexplored in relation to CMD. (PROSPERO-ID: CRD42021223035).

Key messages:

- Worse SE was associated with increased odds of CMD outcomes, with higher levels of Economic and Social Disadvantage being statistically significantly associated with increased risk of heart failure.
- The existing literature is highly heterogeneous and varies notably in study design and terminology.

[6]Department of Clinical, Surgical Sciences, University of Sassari, Sassari, Italy
[7]National Heart and Lung Institute, Imperial College, London, UK
Contact: ilaria.toccotussardi@gmail.com

Background:

Early life conditions are associated with lung function and the development of respiratory and non-respiratory illnesses. The relationship with birthweight (BW) is however conflicting. We examined associations of BW with lung function and respiratory diseases within the GEIRD (Gene-Environment Interaction in Respiratory Diseases) study.

Methods:

GEIRD is an Italian multi-centre, multi-case control study of people aged 20-84 from the general population conducted from 2008 to 2014. The study included cases of COPD, asthma, allergic rhinitis and controls. Multinomial logistic regression was performed with case/control status (control/COPD/asthma/allergic rhinitis) as response variable, and BW as main determinant adjusting for sex, age and smoking status.

Results:

Of 2,287 reporting BW, 6.4 % (n = 147) had low BW (<2500 gr), and this proportion was greater in women than men (7.8% vs. 5.1%; p = 0.006). Lung volumes were significantly lower in individuals with low than normal BW.

Median FEV1 was 3.01 L (p25-p75 = 2.60-3.45 L) versus 3.16 L (2.65-3.86 L) (p = 0.019) and median FVC was 3.68 L (3.19-4.34 L) versus 3.91 (3.34-4.81 L) (p = 0.003). However, FEV1 and FVC were not affected by BW when expressed as percent predicted. Of note, both men and women with low BW were shorter than those with normal BW (mean±SD: 160.2±5.5 vs. 162.6±6.5 cm in women, p = 0.009; 172.4±6.1 vs. 174.8±7.2 cm in men, p < 0.001). FEV1/FVC expressed as absolute ratio or as percent predicted, was not affected by BW. In multinomial analysis, BW was not associated with respiratory diseases in adulthood. However, those with low BW had a higher risk of self-reported hospitalisation for lung disease before age 2 (10.3% vs. 4.1%) and severe respiratory infection before age 5 (16.9% vs. 8.8%) (p = 0.003).

Conclusions:

BW was not associated with lung function in adulthood, when controlling for sex and height. Low BW was a risk factor for respiratory diseases in childhood, not in adulthood.

Key messages:

- Low birthweight was associated with respiratory diseases in childhood but not in adulthood.
- Although spirometrically-assessed lung volumes were lower in adults with low birthweight, this is likely explained by associations of low birthweight with sex and height.

Covid-19 pandemic in north-west Italy: the potential role of meteorology, air pollution and pollens

Giulia Squillacioti

G Squillacioti[1], *G Scaioli*[1], *C Cassardo*[2], *G Arduino*[3], *C Siniscalco*[4], *R Siliquini*[1,5], *R Bono*[1]
[1]Public Health and Pediatrics, University of Turin, Turin, Italy

[3]DIR Environment, Energy & Territory, Piedmont Region, Turin, Italy
[4]Life Sciences and Systems Biology, University of Turin, Turin, Italy
[5]A.O.U., City of Health and Science of Turin, Turin, Italy
Contact: giulia.squillacioti@unito.it

Background:

Italy was the first western country severely affected by the Covid-19 pandemic attesting more than 16 million cases since the outbreak began. Po Valley regions have been most afflicted, with Piedmont ranking sixth at 25,899 cases/100,000 inhabitants. Within this area, air dispersion is hampered making Po Valley a recognised air pollution hotspot. We aimed to explore the potential association between the environment and Covid-19 incidence.

Methods:

Daily key air pollutants (NO2, NO, CO, O3, PM10, and PM2.5), meteorological parameters (temperature, %humidity, wind speed and solar radiation), pollens and Covid-19 cases were collected from 01/01 to 31/12/2021 in Turin, Italy. This ecological study preliminarily tested correlations (Spearman) between air pollutants and Covid-19 cases.

Results:

The Covid-19 pandemic followed a seasonal trend with the highest number of cases (/100,000 inhabitants) in winter and spring (3.1) followed by autumn (1.3) and summer (0.5) (KW test $p < 0.0001$). Likewise, all air pollutants showed peaks in winter and autumn and sensibly decreased during spring and summer apart from pollens and O3. O3 follows the photochemical processes reaching its peak in the sunniest periods, while pollens undergo their natural vegetative process. Daily Covid-19 cases were positively correlated with daily-averaged NO2 (0.50, $p < 0.0001$), NO (0.48, $p < 0.0001$), CO (0.81, $p < 0.0001$), PM10 (0.36, $p < 0.0001$), PM2.5 (0.39, $p < 0.0001$), pollens (0.15, p = 0.073) and inversely with O3 (-0.44, $p < 0.0001$). We plan future analyses to test the hypothesized association by enhanced models with lagged air pollution variables, with demographic characteristics and meteorological data as potential confounders.

Conclusions:

Results from ecological studies may support researchers' preliminary understanding of the interplay between environment and Public Health issues, including pandemics. A multidisciplinary approach is mandatory to deepen the complexity of this topic across European regions

Key messages:

- The Covid-19 pandemic may be associated with environmental conditions and air pollution but further research is needed.
- Atmospheric particulate matter, including aeroallergens, can favour many airborne-related diseases by acting as immune suppressor and/or carrier, but these hypotheses deserve future research.

Contact: l.vandenbrekel-2@umcutrecht.nl

Background:

Air pollution (AP) contributes to a large disease burden and some populations are disproportionately exposed. It is unclear to what extent AP exposure differs across ethnic groups in the Netherlands and how this intersects with socioeconomic position (SEP). First, we identified differences in AP exposures between ethnic groups in the Netherlands. Second, we examined the interrelationships between ethnicity and SEP in relation to AP exposures.

Methods:

We assessed AP exposures for residents of the Netherlands in 2019 (N = 17,251,511). Home address AP levels were estimated by dispersion models of the National Institute of Public Health and the Environment (RIVM). We linked exposure estimations of particulate matter <10 or $< 2.5\,\mu m$ (PM10, PM2.5), nitrogen dioxide (NO2), and elemental carbon (EC) to demographic data gathered by Statistics Netherlands. Absolute and relative differences in AP levels across ethnic groups were assessed. We conducted multivariable linear regression analyses and estimated marginal mean exposures to evaluate differences by ethnicity, SEP, age and sex within urban and rural areas. We tested for interactions and stratified accordingly.

Results:

For the 40 largest minority ethnic groups (N > 18,314 per group), exposure to all pollutants was higher than for ethnic Dutch, with up to 1.5-fold differences for NO2. After stratification for urbanity and SEP, ethnic exposure inequalities persisted. For ethnic Dutch and some migrant groups, we found the lowest AP exposures in the middle SEP group (i.e. U-shaped trends), while we found linear patterns in other large migrant groups, with higher exposures at lower SEP.

Conclusions:

Exposure to PM10, PM2.5, NO2, and EC was consistently higher in minority ethnic groups compared to ethnic Dutch. The association between SEP and AP levels showed different patterns between the majority ethnic Dutch and some of the largest minority ethnic groups. Further research is needed to define the equity and health implications.

Key messages:

- Minority ethnic groups in the Netherlands are consistently exposed to higher levels of air pollution (PM10, PM2.5, NO2, and EC) than the ethnic Dutch population.
- Depending on the ethnic group, the association between SEP and air pollution exposure was either linear (i.e. lower exposures at higher SEP) or U-shaped (i.e. lower exposures in the middle SEP group).

Policies out of sync – are healthy ageing agendas fit for the future?

Angelique Mavrodaris

A Mavrodaris[1,2]*, L Lafortune*[1]*, C Brayne*[1]
[1]University of Cambridge, Cambridge Public Health, Cambridge, UK
[2]Department of Health and Social Care, Office for Health Improvement and Disparities, London, UK
Contact: amavrodaris@gmail.com

Background:

In both scale and impact, population ageing has far reaching implications for our planet, not least as a major driver of population growth and the ever-increasing human demands on natural resources and ecosystems. This fundamentally impacts sustainable development efforts to eradicate poverty, achieve food security, build inclusive and resilient communities, and ensure sustainable consumption. The overarching connections between global ageing and sustainability are clear: a focus on sustainable healthy ageing is fundamental to a healthy planet. Our responses to date have however largely been disconnected. To progress this dual agenda, our work aims to i) assess whether current national/international strategies addressing healthy ageing include a strategic focus on sustainability; ii) present the evidence for such alignments; and iii) develop a framework of sustainable actions and aligned policy.

Methods:

A mixed-methods approach using content and applied thematic analysis was utilised to examine strategy documents, and develop an analytical framework derived from relevant theory to guide quantitative and qualitative analysis of the resultant data. Evidence themes were developed iteratively during analytical phases. Findings informed the development of the framework.

Results:

We identified and analysed 36 strategies published from 2000 to 2021 containing over 600 wide-ranging policies. No strategies and only a minority of policies included a strategic sustainability focus. A larger subset made reference to links between ageing and sustainability or environmental elements yet these were largely theoretical and not carried through in the key strategic approaches or resulting polices.

Conclusions:

This work provides valuable insights into strategic approaches to foster sustainable healthy ageing and identifies levers for greater alignment and sustainable action. The recently declared 2021-30 UN Decade of Healthy Ageing provides an ideal platform for action.

Key messages:

- While the evidence for strong alignment is unequivocal, global healthy ageing and sustainability agendas are largely disconnected.
- By strengthening the links between healthy ageing and sustainability agendas, stakeholders across sectors can reinforce and design approaches that meet human needs while protecting our planet.

Abstract citation ID: ckac129.565
Identifying cross-sectoral cooperation for urban health

Kaija Matinheikki

K Matinheikki[1]*, A Liinamo*[2]
[1]School of Rehabilitation and Examination, Metropolia University of Applied Sciences, Helsinki, Finland
[2]Health Promotion, Metropolia University of Applied Sciences, Helsinki, Finland
Contact: kaija.matinheikki@metropolia.fi

Empirical evidence for collaborative health promotion practices is still limited. The Cross-Sectoral Cooperation Self-Assessment Tool (CroCo SA) presented here provides a tool for cities to assess their current commitment to promote urban health and well-being across sectors. The SA tool was validated by co-operating with 9 pilot cities and seven countries in the framework of the Healthy Boost project funded by Interreg Baltic Sea Region (2019-2022). Addressing the current complexity, interdependence and emerging challenges of health promotion requires cross-sectoral cooperation and tools to assess cross-sectoral processes and make their impact visible. A digitized CroCo SA tool was developed and validated. An SA evaluation matrix was created, including 162 cells of options for reflective and guiding responses according to 6 scale x 27 items used in the SA tool. After submission of the electronic form, respondents can view anonymized results in a digital form on the Healthy Boost platform. The feedback report summarizes the results for respondents and provides, both numerical and descriptive, verbal feedback on the state of the assessed city's capacity for cross-sectoral cooperation, based on each assessment. The steps the respondents could take in their respective cities to improve cross-sectoral cooperation are outlined. Recommendations are based on the evidence found to be the prerequisites for effective cross-sectoral work for health promotion. SA can be conducted in many languages offered by the Google translation programme. Guiding feedback of CroCo SA defines areas for improvement in strategies and actions, allowing respondents also to do benchmarking and learn from other cities and countries. Self-assessment itself is a learning process.

Key messages:

- The CroCo SA tool offers a method for gathering information about the state of cross-sectoral cooperation for urban health promotion.
- By identifying strengths and weaknesses in cooperation, the city can build capacity for cross-sectoral cooperation.

Abstract citation ID: ckac129.566
To what degree are health insurance enrollees aware of the restrictive conditions of their policies?

Frank van der Hulst

FJP Van der Hulst[1]*, L Holst*[1]*, AEM Brabers*[1]*, JD De Jong*[1,2]
[1]NIVEL, Utrecht, Netherlands
[2]Maastricht University, Maastricht, Netherlands
Contact: f.vanderhulst@nivel.nl

Background:

Over recent decades, many Western countries have added market incentives to their health systems. In a system of managed competition, health insurers are supposed to be prudent purchasers of health care on behalf of their enrollees. They can contract healthcare providers selectively. Enrollees who choose a health insurance policy with restrictive conditions, will have to make a co-payment if they consult a non-contracted provider. If the co-payment is unexpected, it may cause a problem for the enrollee. This study aims to gain insight into enrollees' awareness of the conditions of such health insurance policies in the Netherlands.

Methods:

In August 2020, an online questionnaire was sent out via health insurers to enrollees with restrictive health plans. In total 13,588 enrollees responded. Descriptive statistics and logistic regression analyses were performed on various outcome measures relating to enrollees' awareness of the restrictive conditions.

Results:

One fifth (19%) of the respondents appeared to be totally unfamiliar with the policy conditions. Men, younger people, people with a low level of education, a lower income, a poorer health status, and non-care users were found to be less familiar with the conditions ($p = 0.00$ for all). 62% who wanted to visit a healthcare provider whose care was not fully reimbursed, still went to that provider. Of those who had to pay extra because hospital care was not fully reimbursed, 62% did not know this in advance and 30% indicated that paying extra was a serious problem.

Conclusions:

Not all enrollees who choose a policy with restrictive conditions are aware of the consequences of receiving care from a non-contracted provider. There seems room for improving the information provision, in particular for people with a low income and people with a poorer health status, as these groups more often reported unawareness about having to pay extra and more often faced financial problems.

Key messages:

- Not all enrollees are well informed about their policy with restrictive conditions.
- Selective contracting does not always affect enrollees' choice of a healthcare provider.

Abstract citation ID: ckac129.567
Let's not forget those who forget! Participatory design in the context of dementia built environment

Evangelia Chrysikou

Dementia is a major cause of disability and dependency among older people worldwide. Eco-bio-psychosocially supportive design can significantly reduce agitation and depression while improving mobility and daily activities. For this we need to include dementia patients as experts while understanding the neurological changes and functional impairments associated with the progression of the disease over time. How can we support dementia patients to participate? What tools/processes can we use to involve them in the design process? The aim of this project was to map and evaluate co-design methods for dementia and neurodiversity, in order to create an eco-bio-psychosocially supportive environment. Mixed methods were used comprising a systematic literature review on co-design techniques for spaces for dementia, three workshops: a 3-day one with seven early career researchers translating patient involving methodologies to the dementia context, a round table Patient and Public Involvement and Engagement with six service providers and stakeholders cross three countries and a cross-sectoral international day conference with four academics, four early career researchers and eight stakeholders and a series of co-design workshops for dementia and neurodiversity, which were then classified according to applicability so as to generate co-production methods for living environments for dementia. This transdisciplinary project highlighted the challenges of participatory design in the context of dementia built environment. The importance of the topic was highlighted by clinicians and staff but there are still significant limitations in terms of research and methodologies. The workshops outcome was an inclusive code of conduct for participatory design and research for dementia patients, which will help to improve home and care environments for people with dementia. The framework involved aspects such as time, space, equipment in relation to people involved (carers, patients, proxies).

Key messages:

- The project created a framework to support dementia patients' involvement for built environment decision making that considers aspects such as time, space and equipment to foster communication.
- The framework described the phases and the tools/methods in order to build trust and enable fluidity to accommodate dementia patients' needs.

Abstract citation ID: ckac129.568
Exposure to phthalates, potential endocrine disruptors, in an infant cohort in Modena, Italy

Camilla Lugli

C Lugli[1]*, L Palandri*[1]*, A Ferrari*[1]*, R Barbieri*[1]*, V Trevisani*[2]*, E Passini*[2]*,*
L Lucaccioni[2]*, F Facchinetti*[2]*, E Righi*[1]

Contact: camillaluglimd@gmail.com

Phthalates are pollutants ubiquitous in the environment. Human exposure to phthalates and their endocrine disrupting effects have been widely studied. Therefore, the European Union forbids phthalates in toys, cosmetic and kitchenware manufacturing. However, phthalate metabolites can still be found in human biological matrices. The purpose of this study is to investigate phthalate exposure over time in a group of Italian healthy newborns. In a prospective cohort study, we enlisted 187 women who gave birth in the University Hospital of Modena, Italy, between January 2019 and May 2020. Urine samples from women after delivery and from their infants at birth, 3 and 6 months were collected and 8 metabolites of 6 phthalates were analysed. Descriptive statistics were calculated and preliminary correlation coefficients tests were performed. Monoethylphthalate (MEP) was always detectable in urine samples. MEP, monomethylphthalate and diethylhexylphthalate metabolites showed an increasing trend over time, while monobutylphthalate and monobenzylphthalate showed decreasing levels over time. Associations between levels of phthalates metabolites in mother and infant pairs at birth were found for a few metabolites, while metabolites in infant samples at 3 and 6 months appeared often significantly associated. Infants' phthalate exposure in Modena is still high and prolonged over time, even to those more toxic and strictly regulated. As phthalates presence in indoor environment can be a risk factor especially for the most fragile groups of population, such as children, public Health campaigns addressing childbearing age women should stress about the risk posed by these substances and how to avoid their exposure. Moreover, regulatory actions and a stricter legislation should be considered.

Key messages:

- In Italy infant exposure to phthalates, including those strictly forbidden, appears still high and continuous over time.
- Public heath intervention and stricter regulatory actions should be considered.

[3]Azienda Unità Sanitaria Locale della Romagna, Rimini, Italy
[4]AUSL Diabetes Unit Romagna, Ravenna, Italy
Contact: francesco.sanmarchi@studio.unibo.it

Background:

Plenty of literature reported the applicability and usefulness of telemedicine and teleassistance (TMTA) services in the management of diabetes and other chronic conditions. Specifically, TMTA proved to be effective for conditions that require radical lifestyle modifications, tailored pharmacological interventions, and periodic monitoring of clinical health status. The purpose of this study is to investigate the individual and contextual determinants of the perceived quality (PQ) of the telemedicine and teleassistance (TMTA) services and the willingness to continue (WC) with them among patients with diabetes using TMTA during the COVID-19 pandemic in one large region of Italy (Emilia-Romagna).

Methods:

A structured survey was administered to patients with type 1 and 2 diabetes who used TMTA services during the first wave of the COVID-19 pandemic. The questionnaire was comprised of questions on TMTA service experience and participants' socio-demographic characteristics. Multiple regression models investigated the independent factors associated with PQ (score 1-100) and WC (yes/no).

Results:

The final analysis included 569 patients with diabetes (54.7% female), with an average age of 58.1 years. TMTA services' PQ and WC were high. A higher education (OR = 1.83; 95%CI 1.04, 3.31) and being unemployed (OR = 2.57; 95%CI 1.17, 6.02) were factors associated with an increased WC. Older age was negatively related to PQ (b = −3.6; 95%CI −6.8, −0.29). Perceived support from TMTA service was positively associated with PQ (b = 10.1; 95%CI 5.1, 15) and WC (OR = 2.03; 95%CI 1.07, 3.85). Perceived increase in disease self-management was positively associated with PQ (b = 5.3; 95%CI 0.24, 10) and WC (OR = 7.11; 95%CI 4.04, 12.8).

Conclusions:

Our study identified several determinants of PQ and WC. These socio-demographic and patient-perception related factors should be considered in the implementation of care pathways integrating in-person visits with TMTA services.

Key messages:

- Socio-demographic factors play a crucial role in TMTA acceptance and should be taken into due consideration when implementing health pathways integrating in-person visits with TMTA services.
- Health workers should always try to improve patients' self-management skills and should always make patients feel supported. This is also true in the digital health era.

Abstract citation ID: ckac129.570
Specchio-COVID19: a digital cohort study to improve public involvement in epidemiological research

Helene Baysson

H Baysson[1,2], F Pennacchhio[2], A Bal[2], N Pullen[2], J Lamour[2], C Semaani[2], ME Zaballa[2], C Graindorge[2], I Guessous[1,2], S Stringhini[1,2]
[1]Faculté de Médecine, Universite de Genève, Geneve, Switzerland
[2]Unité D'épidémiologie Populationnelle, Hôpitaux Univesitaires de Genève, Geneve, Switzerland
Contact: helene.baysson@unige.ch

Background:

To manage the sanitary crisis and rapidly assess the seroprevalence of anti-SARS-CoV-2 antibodies in the canton of Geneva, we invited previous participants of an annual health survey of the general population to a first serological test. As the pandemic progressed, it become clear that there would be a significant longer impact on health and wellbeing of population. Moreover, there was a need to assess the adherence of the population regarding COVID-19 prevention measures, over time, as well as to provide scientific knowledge about antibodies dynamics and protection from new infections. For all these reasons, a long-term follow-up has been settled via the dedicated digital platform Specchio-COVID19 and on-line questionnaires and repeated serological tests.

Methods:

Several measures were designed to maintain high retention and involvement, including regular electronic newsletters with links to a ''News'' webpage, a ''Research'' webpage for dissemination of publications and the organization of webinars specifically dedicated to participants. A specific email address and a dedicated hotline were set up so that participants can get in touch with the Specchio-COVID19 team.

Results:

Specchio-COVID19 was launched in November, 2020. Up to February 2022, 10'946 individuals (57% women, median age 48) joined the project. Over time, participation rate remains around 65% for each release of questionnaire. 550 participants (5%) definitely dropped out.

Conclusions:

Our digital cohort facilitates participants' involvement, allowing participation from remote locations, organizing webinar, promoting news and scientific information via newsletters and specific webpages and enabling interaction between researchers and participants.

Key messages:

- When designing the Specchio-COVID19 digital cohort, the purpose was not only to collect data.
- But to establish a reciprocal exchange of information between researchers and participants, fostering long-term involvement and health empowerment.

Abstract citation ID: ckac129.571
Effect of a mobile app on breastfeeding among cesarean deliveries: A randomized controlled trial

Doan Duong

TT Duong Doan[1,2], *C Binns*[2], *A Lee*[2], *N Minh Pham*[2,3], *T Phuong Hoa Dinh*[1], *Y Zhao*[2], *TT Ha Bui*[1]
[1]Population and Reproductive Health, Hanoi University of Public Health, Hanoi, Vietnam
[2]School of Population Health, Curtin University, Perth, Australia
[3]Thai Nguyen University of Medicine and Pharmacy, Thai Nguyen, Vietnam
Contact: dttd@huph.edu.vn

Aim:

Cesarean section has negative impacts on breastfeeding rates. This study is to evaluate the effect of a mobile application on breastfeeding outcomes among mothers who had cesarean section using a randomized control trial in Vietnam in 2020 - 2022.

Methods:

A triple-blinded randomized trial of a mobile application was conducted. The mobile application was tailored to Vietnamese culture with two separate versions for the intervention and the control group. The intervention version auto-generated three messages per week and linked the information in the library content to improve breastfeeding while the control version sent messages on maternal and child health care. Pregnant mothers were recruited during their antenatal visits and randomly assigned to two groups. Outcomes of interest included early initiation of breastfeeding and exclusive breastfeeding rates.

Results:

A total of 275 mothers in the control and 293 in the intervention group who had undergone a cesarean section were included in the analyses. Significant increases were observed for early initiated breastfeeding within two hours (aOR = 1.51, 95%CI: 1.01 to 2.27) and exclusive breastfeeding during hospital stay (aOR = 1.59, 95%CI: 1.02 to 2.49).

Conclusions:

Our results support the use of a theory-based design mobile phone application as a part of a promising intervention to improve breastfeeding outcomes.

Key messages:

- A mobile phone application could be a widely accessible, acceptable, and effective intervention to improve breastfeeding outcomes.
- To improve exclusive breastfeeding rates, comprehensive interventions at different levels of sociocultural and market contexts, settings, and individuals are needed.

Abstract citation ID: ckac129.572
Content related with preschool children's health on Facebook: a study of parental informational needs

Indre Liepinaite

I Liepinaite[1], *D Austys*[1]
[1]Department of Public Health, Institute of Health Sciences, Faculty of Medicine, Vilnius University, Vilnius, Lithuania
Contact: indre.liepinaite@gmail.com

Background:

Little is known how Lithuanian mothers use social networks to seek information about preschool children's health. This study aimed to identify health topics of the posts, characteristics of the most engaging posts, and practices shared in the comments.

Methods:

This study included all accessible posts published in 2021 on one Facebook group with more than 21 000 Lithuanian mothers. In total, 1674 posts and 3192 comments on the most engaged group of posts (gastrointestinal disorders) were analysed. Number and type of reactions to posts, categories of health topics, aim, form, tone, and structure of the posts, also practice type on comment were registered.

Results:

Among all posts, 72.9% were related to children's health. The most common health topics included injuries (17.1%), healthcare (15.1%), gastrointestinal disorders (9.7%), allergies and skin diseases (9.7%), nutrition, physical activity and health promotion (9.3%), nurture (8.9%). The most common form was text only (48.7%), repetitive aim was to ask about personal experience (47.5%), and recommendations (35.5%). Larger numbers of reactions achieved posts with sensitive tone, including appeal, child's health description, gratitude in advance, and written in Lithuanian ($p < 0.05$). Comments with healthy lifestyle recommendations, recommendations for medication, also recommendations to treat children by themselves, to visit physicians accounted for 73.6%, 26.4%, 36.0% and 10.8% respectively.

Conclusions:

Main topics of children's health on Facebook for Lithuanian mothers are injuries, healthcare, gastrointestinal disorders, allergies, skin diseases, nutrition, physical activity, health promotion, nurture. Posts with sensitive tone, appeal, situation description, gratitude, written in Lithuanian achieve the largest number of reactions. Comments most frequently include advices to treat children at home, also healthy lifestyle recommendations.

Key messages:

- Lithuanian mothers most frequently seek advices regarding preschool children's injuries, healthcare, gastrointestinal issues, allergies and skin diseases, and nurture.
- Publication of posts including text only, sensitive tone, greetings, situation description, and gratitude might help to promote health more effectively.

[7]Department of Medical Education, Faculty of Medicine, Marmara University, Istanbul, Turkey
[8]School of Social Work, Columbia University, New York, USA
Contact: ok2267@columbia.edu

Issue/problem:

Young refugees often face barriers in accessing youth-friendly health information and care. Differing cultural norms, languages, laws, financial difficulties, gender disparities, and stigma pose additional challenges for youth in forced migration settings.

Description of the practice:

REACH is a regional initiative of Columbia University, which aims to bridge the gap in health literacy and health care access among refugee and disadvantaged youth in Turkey, Lebanon, and Jordan, which are heavily affected by the Syrian conflict. Supported by TaiwanICDF, Blue Chip Foundation, and Columbia University, the REACH Project uses a community-based participatory action research approach and aims to assess the impact of mHealth technologies on improving health literacy and health care access among youth in host countries. With a strong adult-youth partnership, the project includes stakeholder meetings, mixed-methods studies with youth, health service providers and policy makers, in addition to health advocacy, communication and dissemination activities such as photo exhibitions, panels, and production of policy briefs and scientific publications. REACH has been working with youth, software developers, health professionals, academia, and I/NGOs to develop the multilingual and freely available REACH4Health app to promote youth health.

Results:

Findings from three countries show that mHealth technologies have the potential to provide innovative, youth-friendly and widely used solutions to address the health education, health communication, and health care needs of disadvantaged and marginalized youth.

Lessons:

Youth-adult partnerships, working with mixed groups of refugee and local youth, using community-based participatory research, peer-to-peer methodologies, and co-design approaches, as well as using social media tools contribute to the overall success of mHealth and health promotion interventions for disadvantaged youth in countries affected by forced migration.

Key messages:

- mHealth technologies have a strong potential to improve health literacy and health care access of refugee and disadvantaged youth in countries affected by forced migration.
- Youth-adult partnerships, working with mixed groups of refugee and local youth, using participatory approaches and peer-to-peer methodologies significantly contribute to youth health interventions.

[6]National School of Public Health, NOVA University of Lisbon, Lisbon, Portugal
[7]On a personal capacity, Portugal
Contact: ppita.ferreira@gmail.com

Background:

Last year Europe registered >365 000 excess deaths, most from preventable causes. In order to timely track deaths, the Portuguese Directorate-General of Health developed a deep neural network that codifies ICD-10 causes of death (AUTOCOD) by analyzing free text in a death certificate (DC). While the performance of AUTOCOD has been demonstrated, it was not clear if it was sustained during excess mortality periods, when text quality could be lower due to the increased pressure on health services.

Methods:

We performed a sensitivity analysis comparing the ICD-10 classifications of 330 098 Portuguese DC by AUTOCOD and by human-coders, from 2016 to 2019. Excess mortality was defined using the EuroMOMO methodology and a sub-analysis in periods of extreme excess (+4 and +6 SD). We compared the periods without excess mortality with the periods of excess and extreme mortality by chapter. The same analysis was performed for ICD-10 blocks, for the three most common chapters (neoplasms; diseases circulatory and respiratory system). The confusion matrixes allowed us to calculate AUTOCOD's performance metrics, like sensitivity.

Results:

AUTOCOD showed high sensitivity ($\geq$0.75) in 10 chapters, with values above 0.90 for the three most common ones. The weighted-average of sensitivity showed no difference between periods without excess mortality and periods of excess mortality, a difference of 0.01 for periods of extreme mortality (+4 SD) and a difference of 0.04 for periods of extreme mortality (+6 SD). For the block classification, performance was similar.

Conclusions:

Even in periods of excess and extreme mortality, AUTOCOD accurately predicts the classification of the cause of death. Meaning that it is not affected by a potential loss in text-quality due to pressure in health services. This allows for the use of AUTOCOD for real time mortality surveillance and it highlights the importance of Artificial Intelligence as an advisory tool for Public Health policies in emergencies.

Key messages:

- Artificial Intelligence algorithms like AUTOCOD can predict the ICD-10 cause of death with very high sensitivity, during periods with and without excess mortality.
- Artificial Intelligence algorithms like AUTOCOD can be used for real-time cause specific mortality surveillance, providing valuable information for policy making during periods of excess mortality.

9.G. Workshop: Health in all Policies: key driver for better health still awaiting of greater governing stewardship

Abstract citation ID: ckac129.575

Organised by: EUPHA-HIA, EUPHA-PHPP, EUPHA-ECO, EUPHA-LAW
Chair persons: Piedad Martin-Olmedo (EUPHA-HIA), Monica O'Mullane (Ireland)
Contact: piedad.martin.easp@juntadeandalucia.es

Healthy public policies are those that take accountability of all possible health impacts, acknowledging the causal pathways resulting from the modification of upstream health determinants (e.g. transport strategies, etc.), and related risk factors downstream (e.g. air pollutants). The strategy of Health in All Policies (HiAP), promoted by the World Health Organization (WHO) and adopted by the European Union (EU) in 2006, reinforced the need to reduce inequalities and improve health and wellbeing as essential pillars for a sustainable economic development. Central to HiAP is the notion that health is not only the responsibility of the health sector, but also a shared responsibility with many other sectors. In this context, Health impact Assessment (HIA) was proposed as the combination of methods to support HiAP implementation by providing scientific evidence on the positive and negative effects that any new proposal may have on health and health equity. The COVID-19 pandemic, and the climate change threat, are two of the main challenges that emphasise the need of integrated responses across many sectors to mitigate not only effects on health and inequalities, but also in the economy. However, HiAP and HIA implementation remains almost at a conceptual level, with a few remarkable exceptions in Europe. One of the most relevant reported barriers contributing to this uneven HiAP implementation is the lack of political stewardship and commitment. The difficulties in applying the guiding principles of HiAP (and consequently of HIA) at local, regional, or national governance level are in many cases linked to a conflict between the right to work and mobilization of the economy, with the right to health and reduction of inequities. This is where the role and drive of public health actors comes across, as HiAP requires public health professionals to build partnerships and engage meaningfully with the sectors affecting the social determinants of health and health equity, external to the health sector. A good proxy example to HiAP implementation, facilitating local and regional initiatives with communities, is the WHO initiative of Healthy Cities. The present panel discussion intends to analyse, from different perspectives, why HiAP has not gained a meaningful place within governing contexts, the current and future status of the intersectoral approach, and the advocacy role of public health in this context. The session is scheduled with a first overview presentation followed by a debate framed around the following aspects:

– Different perceptions regarding the concrete implementation of HiAP at all political levels.

– Perceived barriers or trade-offs for a broader implementation of HiAP.

– Role of public health actors in the implementation of HiAP at a strategic, policy level, and how it could gain a more prominent role.

– Level of understanding and awareness of the utility of HIA for HiAP implementation by public health actors.

Key messages:

- HiAP, a recognised approach requiring all sectors to address decisions' health and equity implications for reaching better global health, has not yet been implemented with an overarching vision.
- Public Health actors can disentangle political and technical aspects, seeking for synergisms, and clarifying to non-health sectors the complexity and interrelatedness of social health determinants.

Abstract citation ID: ckac129.576
Health in All policies: what do we mean and where are we now?

Liz Green

L Green[1,2]
[1]HIA, Public Health Wales, Wrexham, UK
[2]Healthy Urban Environments, University of West of England, Bristol, UK
Contact: Liz.Green@wales.nhs.uk

This presentation sets what HiAP is and is not, and its evolution since it was conceived. It also addresses how HiAP can be mobilised in practice via the use of tools such as HIA and the key role that enabling structures and contexts - both politically strategic and locally operational- to ensure that health, wellbeing and equity is promoted in the European region. It discusses the enabling context of Wales, with the Future Generations (Wales) Act 2015, which provides political leverage for the implementation of HiAP in practical terms, enabling addressing health considerations intersectorially by non-health policies and projects. This Act along with supporting documents, guidance and legislation implicitly incorporates the principles of HiAP so the rest of non-health sector understand (and also have the statutory obligation) to address the health considerations of policies and plans. It does this by requiring all public bodies in Wales to strive to maximise 7 Well-being Goals - which include 'A healthier Wales', 'A more equal Wales' - and requires that they do so by working with other agencies in order to prevent negative impacts and promote participation, long-term thinking and integration to ensure that inequalities are minimised. These are key public health principles from which to have conversations. Wales also provides a good example with its advocacy and policy in respect to Economies of Wellbeing - a critical challenge for HIAP is that HiAP is, by its nature, political, and may challenge some policy proposals. Although the focus is on identifying 'win:wins' and co-benefits, sometimes there is a conflict between health and other outcomes. There may be a need to balance health gains against economic growth or other policy aims. The following debate intends to discuss the challenges and enablers to achieve that aim, and how public health can make its voice heard.

Alternative routes to HiAP implementation

Marleen Bekker

M Bekker[1,2]
[1]EUPHA-PHPP

Contact: marleen.bekker@wur.nl

From a public health political science perspective there are alternative routes to HiAP. Besides the 'classic' HiAP approach seeking government internal departmental alignments, facilitating and rewarding bottom up social initiatives by communities, or marketed health innovations by commercial health-related consultancies and enterprises, and regional (socio-) economic innovation networks that after a developmental stage can start to pressure multi-level governments for action. A final route lies along the litigation path (Think of climate agreements and governments being held accountable by the judiciary to comply with agreed emissions reductions etc.)

COVID-19 pandemic response was an opportunity to advocate for HiAP as everyone developed opinions on how policies could affect the different dimensions, including health and economy. Health planning, from the local to the international level, is the main setting where we still need to advocate for the inclusion of all political sectors and actors in order to ensure an effective HiAP implementation. From a more technical perspective, there is still a lot to do when it comes to implementing and improving economic evaluations, including on data on costs, valuing benefits or using cost-effectiveness approaches.

9.H. Workshop: Understanding the institutional context of health inequalities. A life stage approach

Abstract citation ID: ckac129.579

Organised by: Research Unit FOR2723(Germany)
Chair persons: Irene Moor (Germany), Dennis Jepsen (Germany)
Contact: irene.moor@medizin.uni-halle.de

Background:
The health of young people is strongly linked to their socioeconomic background. However, there is little systematic research on the complex mechanisms underlying the association between family socioeconomic position and health among young people, particularly regarding contextual factors at the (intermediate) meso-level. Several institutional contexts are relevant for young people's lives: the family, kindergarten, primary and secondary school, higher education system, vocational school and training, workplace and the healthcare system. Previous studies demonstrated that characteristics of these institutional contexts are associated with young people's health and well-being. It is unclear, which role they play regarding health inequalities. The aim of the workshop is to analyse the role of institutional characteristics, such as compositional (which people are found in an institution) and contextual (the structural characteristics of an institution) factors for the development or existing health inequalities.

Methods:
The research unit FOR2723 analyses the role of meso-level, institutional characteristics regarding health inequalities considering the whole period of early life based a common conceptual framework. The results are based on empirical analyses of various secondary data, such as the National Educational Panel Study (NEPS) or the German Health Interview and Examination Survey for Children and Adolescents (KiGGS). Bodymass index (BMI) and the subjective self-assessment of health are considered as outcomes.

Results:
We found substantial social inequalities in health and health behaviour at any life stage investigated. In each life stage we found meso-level characteristics of the family (family investment, family stress, family atmosphere, and parental health behaviour and well-being), the kindergarten (the association between ECEC centre focus and family SEP on pre-school children's BMI), the school (composition of the school in terms of education, income, and occupational prestige of the students' parents), the institutions and labour market states involved in the school-to-work transition (vocational training places, universities, workplaces, unemployment spells) as well as the health care system (regional health policy), which are associated with social inequalities in young people's self-rated health, subjective well-being and BMI.

Discussion:
In addition to micro-level determinants, meso-level characteristics of important institutions that young people are exposed to (family, kindergarten, school, school-to-work-transitions, healthcare system) are relevant for their health and reinforce health inequalities. More research is needed to understand how institutional contexts contribute to health inequalities and which institutional changes are needed to reduce inequalities.

Key messages:
- The role of institutional characteristics, such as compositional and contextual factors for health inequalities is unclear.
- Meso-level characteristics of institutions in young people (family, kindergarten, school, school-to-work-transitions, healthcare system) are relevant for their health and reinforce health inequalities.

Contact: RattayP@rki.de

Background:
Although health inequalities in adolescence are well documented, the underlying mechanisms remain unclear. Few studies have examined the role of the family in explaining adolescents' health inequalities. The study aimed to explore whether the association between socioeconomic position and self-rated health (SRH) was mediated by familial determinants.

Methods:
Using data from wave 2 of the KiGGS study (1,838 female and 1,718 male 11- to 17-year-olds), linear regression analyses were conducted to decompose the total effects of parents' education, occupation, income, socioeconomic position index, and adolescents' subjective social status on SRH into direct effects and indirect effects through familial determinants (family cohesion, parenting styles, parental well-being, stress, obesity, smoking and sporting activity).

Results:
A significant total effect of all socioeconomic position indicators on SRH was found, except for income in male adolescents. In female adolescents, more than 70% of the total effects of each socioeconomic position indicator were explained by familial mediators, whereas no significant direct effects remained. The most important mediator was parental well-being, followed by family cohesion, parental smoking and sporting activity. In male adolescents, the associations of parental education, the socioeconomic position index and subjective social status with SRH were also mediated by familial determinants (family cohesion, parental smoking and obesity). However, a significant direct effect of subjective social status remained.

Conclusions:
The family appears to play an important role in explaining health inequalities, particularly in female adolescents. Reducing health inequalities in adolescence requires policy interventions, community-based strategies, as well as programs to improve parenting and family functioning.

Abstract citation ID: ckac129.581
Do family characteristics explain a social gradient in overweight in early childhood?

Stephanie Hoffmann

[7]Heinrich-Heine University Düsseldorf, Child Health Services Unit, Düsseldorf, Germany
Contact: stephanie.hoffmann@b-tu.de

Background:
Children's overweight is associated with many factors, including their living situation, in particular their family's socioeconomic position (SEP) and family characteristics. Research on the extent to which family characteristics account for a social gradient in overweight in early life is scarce. This study evaluated whether family characteristics explain SEP differences in the risk of overweight in early childhood.

Methods:
The study used baseline data of 3-6 year-old children (n = 1,116) from the intervention 'Ene mene fit' conducted at kindergartens in Baden-Württemberg, Germany. Data included overweight (body mass index > 90 percentile) and parents' reports on their education and family characteristics associated with overweight (child consumes: sweets in front of TV, soft drinks; family joined time: outdoor, breakfast, sports; cooking; child sets table; role model). Model-based single mediation analyses decomposed the total effect of highest parental education on overweight into direct (unmediated) and indirect (mediated) effects (OR, 95% CI).

Results:
Girls and boys with low parental education had higher odds for overweight than children with high/medium education. Among boys, low education influenced the risk of overweight via indirect effects of i. 'sweets consumption in front of TV' (OR = 1.31, 1.05-1.59) and ii. 'no joined sports' (OR = 1.14, 1.00-1.44). The direct effect of low education only remained significant when 'no joined sports' was considered (OR = 2.19, 1.11-5.19). Among girls, family characteristics measured here did not explain SEP differences in overweight.

Conclusions:
The family characteristics 'sweets consumption in front of TV' and 'no joined sports' contribute to inequalities in overweight among boys, but not among girls. Therefore, more gender-sensitive research is needed to identify family risk and protective characteristics that explain health inequalities among both boys and girls.

Abstract citation ID: ckac129.582
A sport focus of ECEC centres appears especially health-promoting for boys from lower socio-economic background

[6]Technical University of Munich, Department of Sport and Health Sciences, Munich, Germany
Contact: Alena.Mayer@medma.uni-heidelberg.de

Background:
Pediatric overweight is considered one of the 21st century's most serious public health challenges. Many studies investigated individual level determinants of children's body mass index (BMI), yet studies measuring determinants at the meso-level are sparse. As there is a lack of theoretical and empirical knowledge about the role of child care facilities, the aim was to examine the combined effects of family socio-economic position (SEP) and the meso-level variable early childhood education and care (ECEC) centre with sport focus on the BMI of pre-schoolers.

Methods:
We used data from the German National Educational Panel Study (NEPS) and included 1,891 children from 224 ECEC centre groups. Multilevel mixed-effects linear regressions were applied to calculate the main association of ECEC centre focus and family SEP, as well as their interaction on children's BMI. All analyses were adjusted for age, migration background, number of siblings, and employment status of parents and were stratified by gender.

Results:
Boys attending an ECEC centre with a sport focus have on average a lower BMI than boys from ECEC centres not having this focus. Interactive effects between family SEP and ECEC centre focus were found. Considering predictive margins, boys with low family SEP not attending a sport focused ECEC centre had the highest BMI while boys with low family SEP attending a sport focused ECEC centre had the lowest BMI. For girls, no association regarding ECEC centre focus or interactive effects emerged. Girls in the high family SEP tertile had the lowest BMI in both ECEC centre types.

Conclusions:
Our analysis shows the social gradient towards a higher BMI for children from lower SEP families. Considering meso-level factors, we provide evidence for the relevance of ECEC centre characteristics for BMI in boys, whereas for girls the association of family SEP with BMI remains. The ECEC centre focus appears to lower the association of family SEP with BMI for boys.

Abstract citation ID: ckac129.583
The impact of the school-to-work transition on self-rated health & subjective well-being in Germany

Marvin Reuter

M Reuter[1], M Herke[2], M Richter[2,6], K Diehl[3,4], S Hoffmann[5], CR Pischke[1], N Dragano[1]

[5]Brandenburg University of Technology, Department of Public Health, Senftenberg, Germany
[6]Technical University of Munich, Department of Sport and Health Sciences, Munich, Germany
Contact: marvin.reuter@uni-duesseldorf.de

Background:
During the school-to-work transition (STWT), young people enter different states as vocational training, university or unemployment that may have immediate or long-term effects on health. Since research has not paid much attention to this, we investigate the development of self-rated health (SRH) and subjective well-being (SWB) during the STWT.

Methods:
We used data from Starting Cohort 4 of the German National Educational Panel Study (NEPS), a nationally representative

cohort of 11,098 ninth graders (50.5% girls) followed over nine years. Linear panel regression analysis with fixed-effects (FE) was used to explore intra-individual changes in SRH and SWB when moving between different STWT states (school, prevocational program, vocational training, university, employment, unemployment, inactivity). FE impact functions were used to compare trajectories of SRH and SWB by states reached after school-leave. Time-varying control variables were age, household composition, and residential area.

Results:

School-leave was linked to increases in SRH and SWB, whereas no impact was found for job entry after vocational training or university. Upward transitions (e.g. from a prevocational program to vocational training, from vocational training to university or from unemployment to employment) increased SRH or SWB, while downward transitions (e.g. from vocational training or employment to unemployment) were related to decreases. Over the years after school-leave, we found a decline in SRH and SWB, which was faster in case of transitions to unemployment or prevocational programs directly after school.

Conclusions:

Findings suggest that a smooth STWT is key for good health in youth and adulthood. Health and labour market intervention programs should focus on the time after school-leave, especially on those who are not able to find an academic or vocational training position.

Abstract citation ID: ckac129.584
The role of regional health policy for socioeconomic inequality in health services utilization

Wiebke Schüttig

[5]Martin Luther University Halle-Wittenberg, Institute of Medical Sociology, Halle, Germany
[6]Heinrich-Heine University Düsseldorf, Child Health Services Unit, Düsseldorf, Germany
Contact: wiebke.schuettig@tum.de

Background:

“J1” is a preventative routine examination in Germany recommended for adolescents at the age of 12-14 years. In contrast to the well-established U1-U9 examinations for younger children, with participation rates above 90%, the attendance of the J1 examination is approximately only 40%. The most frequent reason for not attending J1 is the unawareness of this examination. “Ticket to J1” is an intervention including an information leaflet introduced in Bavaria in 2017 to inform adolescents about J1. The aims of the present analysis are to investigate (1) if the regional policy was effective in increasing the attendance in J1, (2) if the effects vary by family socioeconomic status (SES), and (3) which meso-level characteristics of the healthcare system correlate with attendance rates in J1.

Methods:

We used anonymised data of a large statutory health insurance in Germany for the timeframe of 2016-2018. To investigate the effect of the policy, a difference-in-differences design at the individual level was used. Assuming a parallel trend at the level of federal states, the likelihood of attendance in J1 of 13- and 14-year-olds was compared between Bavaria and other federal German states before and after policy introduction. All analyses were additionally stratified by SES.

Results:

The introduction of “Ticket to J1” increased participation in J1 by 1% after controlling for all confounders. Furthermore, the effect was stronger for children from families with lower SES (an increase of 5%). Density of pediatricians was positively significantly correlated with participation in J1.

Discussion:

Regional health policy intervention had a significant positive impact on attendance of J1 and appears to have the potential to reduce socioeconomic inequalities in healthcare utilization. Informing adolescents about J1 seems to increase the attendance, in particular for children from families with lower SES.

9.J. Round table: Experiences on infodemic management in public health authorities in Europe and internationally

Abstract citation ID: ckac129.585

Organised by: PHIRI, EUPHA-PHMR, EUPHA-LAW, WHO
Chair persons: Petronille Bogaert (EUPHA-PHMR), Tim Nguyen (WHO Europe)
Contact: tina.purnat@gmail.com

The COVID-19 pandemic and current recovery efforts have been complicated by a parallel infodemic, an overwhelming amount of information, including mis- and disinformation, accompanying emergencies as individuals and communities struggle to separate scientific facts and guidance from manipulative, emotionally charged or inaccurate content. The infodemic has manifested itself in the rapid spread of questions, concerns and misinformation that can affect population attitudes and behavior harmful to health-from promoting stigma and discrediting science, to promoting alternative, non-recommended treatment and cures to politicizing public health programs and eroding trust in healthcare personnel and health system. Since the beginning of the COVID-19 pandemic, major advances in the nascent field of infodemiology and the practice of infodemic management have been made, with over 80% of WHO Member States reporting in a pulse survey that they are tracking COVID-19 misinformation and doing infodemic management work. Infodemic management, analogous to epidemic management, is an evidence-based practice in detecting, characterising, responding and managing the infodemic and its harmful effects. It is a leading area of concern for Ministries of Health, who have established infodemic management teams and insights units to help inform programmatic and communications shifts in face of a constantly evolving infodemic. During the COVID-19 crisis and ensuing recovery efforts in face of competing health priorities, public health authorities have been challenged in the way they engage with the public. Advances in social media and media consumption that have eased information sharing between people and communities have also become areas for infodemic risk, such as closed messaging apps, minimally regulated social media platforms, a noisy media environment and under-resourced communications and community engagement functions of MoH and IPH staff who are not versed in technology. The Population Health Information Research Infrastructure (PHIRI) generates and supports their partners in the generation of evidence for research on health and well-being of populations impacted by COVID-19. It supports exchange of expertise across Europe in the area of infodemic management as well.

This workshop aims to share the experiences with infodemic management during the pandemic and key learnings to take forward during recovery and future health systems strengthening and pandemic preparedness efforts. It will be organised as a round table, where speakers will present on how their health systems have built infodemic management capacity, what lessons they have learned and plan to apply to future efforts. Common themes from the participants will become a frame for the Q&A and for audience members to submit questions and their own lessons learned for discussion on these themes through an interactive interface.

Key messages:

- Infodemic management is growing from nascent science into full-fledged and more integrated public health practice ripe for innovation and application to health topics beyond COVID-19.
- Implementation science and evaluation of what works and doesn't in infodemic management must be systematically used for preparedness and response and improvement of routine health service delivery.

A gamification-based intervention to encourage active travel

Marc Harris

M Harris[1]
[1]Intelligent Health, Cardiff, UK
Contact: marcashleyharris@yahoo.com

Purpose:

'Beat the Street' is a community-wide intervention which aims to increase active travel by turning an area into a 6-week game. Residents earn points and prizes by walking and cycling and tapping a smartcard on RFID readers called 'Beat Boxes' placed on lampposts at half-mile intervals. To-date, over 1 million people have taken part in the intervention, however, the impact of the program on adult active travel is yet to be explored.

Methods:

In Autumn 2019, Beat the Street was delivered throughout the London Borough of Hounslow. Prior, and immediately following the intervention, residents were invited to complete a self-report questionnaire (Sport England Active Lives Survey-SF) to assess changes in physical activity. Time-stamp data generated through Beat Box activity provided an objective measure of intervention engagement and a traffic survey camera was used to measure the number of cars travelling along 1 target road between 1-week pre- and 1-week post-intervention.

Results:

28,219 people took part in the six-week game. Between pre- and post-intervention there was 7% decrease in adults reporting less than 30mins of activity per week and a 13% rise in adults reporting 150+ mins ($n = 346$, $p < 0.01$). Beat box data ascertained that 25% of total taps at all Beat Boxes were made between 08:00-08:59am and a further 28% were made between 3:00-3:59pm, typical travel to school/work periods. Further, traffic camera data showed that between the week before and week following Beat the Street, 1199 and 705 fewer cars and 130 and 36 fewer vans were observed travelling along Cambridge Road between 07:00-09:30am and 2:00-4:30pm, respectively.

Conclusions:

These data sources, in combination, suggest gamification may be an encouraging approach to increasing levels of active travel at a community-wide level.

Key messages:

- Gamification based intervention increases physical activity.
- Gamification encourages active travel to school and work.

Abstract citation ID: ckac129.587
Quality changes of workplace health promotion in Austrian companies over time

Gert Lang

G Lang[1], *C Heigl*[2], *P Jiménez*[3]
[1]Austrian Health Promotion Fund, Austrian National Public Health Institute, Vienna, Austria
[2]Austrian Health Insurance Fund, Austrian Network for Workplace Health Promotion, Linz, Austria
[3]University of Graz, Institute of Psychology, Graz, Austria
Contact: gert.lang@goeg.at

Background:

Workplace health promotion (WHP) is effective when it is implemented in a high-quality and sustainable manner. Companies in the Austrian quality management system can apply for a WHP quality certificate every three years. More and more companies are integrating WHP into their regular operations. This work investigates the WHP quality system and how the companies develop over time.

Methods:

WHP quality is measured using 15 holistic quality criteria, which are assessed by an external, independent institute. For the period 2014-2021, evaluations from $n = 570$ companies with two and from $n = 278$ companies over three measurement points in time are available (initial and renewal awards). The (potential) change of the WHP quality is examined with a longitudinal design by the means of confirmatory factor analyses and autoregressive models with latent variables.

Results:

The measurement of WHP quality shows acceptable to good measurement accuracy (internal consistency-reliability: $\alpha = 0.85\text{-}0.89$), validity (convergent and discriminant validity) and metric measurement invariance over time. At structural level, relative stability of WHP quality can be demonstrated for the measurement points ($\beta = 0.40\text{-}0.52$, $p < 0.001$). Both the quality of WHP and the temporal stability differentiate significantly according to the firm size and the experience of the company with WHP structures and processes.

Conclusions:

The use of the criteria allows a reliable, valid and objective quality assessment of WHP quality due to the concept of the assessment process. WHP quality is a relatively stable characteristic of the company, which, however, varies according to temporal, structural and process-related aspects. Company size moderates to a lesser extent of quality changes over time. This is in line with expectations, but also indicates that small companies should be clearly motivated and supported for their WHP measures. The insights help to further develop quality assurance in WHP and public health.

Key messages:

- The criteria used allow a reliable, valid and objective assessment of WHP quality.
- Because firm size moderates the change in WHP quality, small firms should be continuously encouraged and supported.

Abstract citation ID: ckac129.588
Assisted Reproductive Technology: Gaps in young adults' perceptions and information from clinics

José Miguel Carrasco

M López-Toribio[1], *J Melovska*[2], *V Dimitrievska*[2], *A Dostálová*[3], *M Novotná*[3], *V Rozée*[4], *K Hens*[5], *S March*[1], *F Güell*[6], *JM Carrasco*[1]
[1]Research and Transfer, APLICA Cooperative, Madrid, Spain
[2]Qualitative Research, Healthgrouper, Skopje, Republic of North Macedonia

[4]Sexual and Reproductive Health and Rights, Institut National d'Etudes Démographiques, Paris, France
[5]Department of Philosophy, University of Antwerp, Antwerp, Belgium
[6]Mind-brain Group, Institute for Culture and Society ICS-UNAV, Pamplona, Spain
Contact: jmcargi@gmail.com

Background:

Around 186 million individuals are facing infertility worldwide, with a huge impact on their wellbeing. Fertility care is considered a key element to promote reproductive health. This study aims to explore young adults' knowledge, perceptions and concerns about infertility and Assisted Reproductive Technology (ART), and to contrast it with the information provided by ART clinics.

Methods:

A multi-country qualitative study was conducted in Albania, Belgium, Slovenia, Spain, Italy, Kosovo, North Macedonia and Switzerland within the H2020 B2-INF project (Grant Agreement 872706). In 2021, 10-15 semi-structured interviews were conducted in each country with participants aged 18-30, childless and non-ART users. Additionally, 3-5 clinics' websites in each country were explored. Data was collected in native languages and translated into English. A thematic analysis was carried out.

Results:

In total, 98 interviews were conducted and 38 clinics' websites were explored. Three themes emerged from the analysis of the interviews: 1. Parenthood and (in)fertility; 2. Young people's perception on ART; 3. Information and publicity of ART. Parenthood was described as a relationship beyond biological ties and infertility as a social taboo. Most participants perceived ART positively and would use it if needed, although knowledge on ART was low. Participants considered information on ART as scarce and suggested that government-led information campaigns should be launched to raise awareness on it. Concerning clinics, the websites provided information on infertility and exhaustive technical descriptions of ART techniques, although it may be difficult for the general population to understand. Data offered on success rates were unclear and heterogeneous.

Conclusions:

Gaps in citizens' expectations and needs and the information provided by ART clinics were identified. Awareness campaigns are needed to diminish social taboo on infertility and ART and to promote reproductive health.

Key messages:

- Assisted Reproductive Technology is positively perceived by young adults, though their knowledge of it and infertility is low. Information campaigns are thus needed to raise awareness among the young.
- ART clinics have room for improvement in aligning the information provided on their websites with young people's perceptions and needs, and to show it in a more accessible and understandable way.

Leo&Giulia: a cartoon series to promote health and prevention in primary school-aged children

Anna Odone

R Vecchio[1], *A Meloni*[1], *L Gentile*[1], *M Gaeta*[1], *C Signorelli*[2], *A Odone*[1]
[1]Department of Public Health, University of Pavia, Pavia, Italy
[2]School of Medicine, Vita-Salute San Raffaele University, Milan, Italy
Contact: anna.odone@mail.harvard.edu

Background:

Coronavirus (COVID-19) pandemic control measures actively involved people who were called to adopt new and unusual lifestyles. In this context, children had to stay home from school for weeks, had to adapt to new teaching methods and give up socializing. In many countries, not much attention was paid to the educational sector, and, ultimately, to children's physical and psychological well-being.

Objectives:

In this context, we developed an innovative health education audio-visual model to teach children about public health, empower them to adopt preventive behaviours and limit the risk of infection transmission in schools and in the community.

Results:

We designed and produced the animated cartoon series ''Leo&Giulia'' to convey solid scientific content and key public health messages related to the ongoing COVID-19 pandemic to primary school-aged children. Contents and dialogues were validated by a scientific committee composed of experts in the fields of public health, paediatrics, infectious diseases, and neuroscience, as well as communication experts. The first episode of Leo&Giulia focused on COVID-19 and explained to children what SARS-CoV2 was, its transmission and why schools were closed. Endorsed by the European Commission, it was broadcasted by national public and private television channels and went viral on social media. The second episode of Leo&Giulia, funded by the Italian Ministry of Research, was launched in April 2022 and focused on vaccines and immunization explaining to children how vaccines work and why herd immunity is important for collective health.

Conclusions:

Leo&Giulia is an innovative health education project to help children to better understand how to cope with COVID-19 as a public health challenge. More broadly, the series aims to increase youth engagement by promoting public health values and healthy behaviours.

Key messages:

- Health promotion targeting children is important and contributes to societal health and wellbeing.

- Cartoon series are an innovative digital health education tool that effectively increase youth engagement on public health values.

Abstract citation ID: ckac129.590
Are French local health contracts promising in addressing determinants of diet and physical activity?

Yann Le Bodo

Y Le Bodo[1]*, D Diallo*[2]*, H Hudebine*[3]*, C Harpet*[1]*, F Jabot*[1]*, E Breton*[4]
[1]ARENES - UMR 6051, University Rennes, EHESP, CNRS, Rennes, France
[2]SHS, EHESP, Rennes, France
[3]LABERS, Université de Bretagne Occidentale, Brest, France
[4]Arènes - UMR 6051, RSMS - U 1309, University Rennes, EHESP, CNRS, Inserm, Rennes, France
Contact: yann.lebodo@ehesp.fr

Background:
There is a consensus on the need to transform the built, economic and socio-cultural environments to promote healthy eating (HE) and physical activity (PA). Yet, limited capacity and the biomedicalisation of public health are often blamed for steering investments towards individual risk factors. In France, local health contracts (LHCs) agreed between a regional health agency (RHA) and a local government could improve health promotion strategies. We examined how LHCs take into account the environmental determinants of HE and PA.

Methods:
Using the CLoterreS national census, we analysed a stratified random sample of 53 LHCs with a view to identify if actions target individual (knowledge, skills, etc.) or environmental (interpersonal, organisational, community or political) determinants. To this end, we developed an instrument drawing from different typologies of action and consensus documents to assess the integration of the socioecological approach in programmes. We ran a series of interviews with RHA staff (n = 39) and local actors (n = 23) to put into context our results.

Results:
Out of 53 LHCs, 42 included at least one action on HE or PA. For these topics, there was a higher proportion of actions targeting individuals (83% and 76% per contract, respectively) than environments (51% and 58%). For the latter, actions on interpersonal determinants (e.g. family) were the most common. However, we also found instances of actions on more distal ones (e.g. to improve nutrition standards in school canteens and walkability). Contextual factors such as local priorities, past experience with health promotion and the involvement of local actors in needs assessment and action planning may influence such orientations.

Conclusions:
LHCs constitute a promising avenue to address the environmental determinants of health-related behaviours. A key feature of this instrument is its capacity to develop intersectoral strategies. Further research will show if LHCs deliver on their action plan.

Key messages:
- Local health contracts facilitate the mobilisation of a broad diversity of NGOs and agencies.
- This makes it a promising device for addressing the environmental determinants of HE and PA, provided adequate resources are devoted to stakeholder engagement and local government capacity-building.

9.L. Workshop: A motivated, healthy and high-performing workforce: Innovation in health workforce research in Europe

Abstract citation ID: ckac129.591

Organised by: Technische Universität Berlin
Chair persons: Reinhard Busse (Germany)
Contact: c.maier@tu-berlin.de

Background:
Hospitals and their health care staff were severely impacted by the Covid-19 pandemic. Many health professionals faced high levels of stress and burn-out due to unfavorable work environments, limited staffing and highly pressured workloads. Yet, even prior to the pandemic, health professionals in many countries faced challenging work environments with often limited resources and support. At the same time, the roles of health professionals are changing across Europe, with new roles, task-shifting and sharing happening in teams, also driven by the Covid-19 pandemic. From a health system and management perspective, recruitment and retention is critical to ensure that there is a sufficient and well-educated health workforce capable to perform high-quality care. Multiple innovations have been implemented across Europe, these will be presented and discussed with a view towards evaluating complex interventions, sustaining innovations, ensuring the scalability and transferability of proven interventions for the benefit of health professionals and wider society.

Objectives:
This workshop will address innovative strategies at the micro (team level), meso (healthcare setting) and macro level (policy) to ensure that health professionals are motivated, perform high-quality care in teams and are sufficiently supported by enabling work environments and recruitment and retention policies. Innovations to improve work environments, task-shifting as well as recruitment and retention will be discussed, based on the findings from four EU-funded research projects: Magnet4Europe, H-Work, TASHI and METEOR. The format is a ‘round table’ with 5 panel discussants. The Magnet4Europe project focuses on the reorganization of hospital work environments for nurses and physicians in hospitals in five European countries. Innovative elements include a system-, inter-professional, organization-wide change management, structural empowerment of clinical staff and one-on-one twinning of European hospitals with U.S. twinning partners.

Innovations in the EU projects:
The H- WORK project aims to design, implement and validate psychosocial interventions to promote mental health and well-being in SMEs and the public sector. Innovative elements are the evaluation of interventions at multiple levels (individual, team, manager and organisational level) and the development of the H-Work innovation platform with toolkits, policy briefs and novel digital solutions. The TaSHI project provides a novel and up-to-date knowledge on task shifting and transferability of good practices in implementation. Through a cross-national and -sectoral perspective, the focus is on task shifting as an innovation towards more effective organisation of care and workforce, to improve efficient and sustainable systems. METEOR aims to enhance scientific knowledge on the predictors of job retention for healthcare workers and develops

evidence-based policy recommendations through stakeholder engagement and co-creation workshops.

Key messages:

- Innovations to improve work environments include system-wide, integrated approaches spanning individual, team, management and organisational levels.
- Elements of effective implementation of innovations are effective leadership at highest level, empowerment, evidence-informed action and tailored strategies on recruitment and retention of staff.

Role of surfaces and sinks in the control of multiresistant bacteria in Intensive Care Unit

Elvira Marin Caba

E Marin Caba[1], *I Guerrero Fernandez de Alba*[1], *E Soler Iborte*[1], *M Rivera Izquierdo*[1], *C Valero Ubierna*[1]
[1]Preventive Medicine, Clinico San Cecilio Hospital, UGC PPV, Granada, Spain
Contact: emarincaba@gmail.com

Background:

Control of multiresistant bacteria (MRB) outbreaks in the Intensive Care Unit (ICU) is a challenge of Public Health. There is strong evidence that surfaces, and sinks are reservoirs of MRB. In 2020, because of isolation of Klebsiella type IMP, OXA-48 and VIM in moist reservoirs in ICU of Clinico San Cecilio Hospital and another carbapenemase-producing Enterobacteriaceae (CPE) outbreak, it arises our aim, which is to highlight the relevance of periodic control of humid reservoirs and surfaces in ICU to prevent MRB transmission.

Methods:

Retrospective, descriptive study from March to June 2021. Due to a rise of cases of a CPE outbreak in our ICU in Granada, samples of surfaces and taps of different boxes were taken, after discharging patients and their corresponding terminal cleaning, whether they were CPE-colonised patient or not.

Results:

Samples of 20 boxes were taken (N = 325). CPE OXA-48 was isolated in 7,38% of the samples which correspond to 40% of the boxes, most of them Enterobacter cloacae. 25% of the positive samples isolated two types of resistance, OXA-48, and VIM. 79,2% of the positive samples were found in March. The rest of them in April and May, after establishing control measures in surfaces. CPE was isolated in blood pressure monitor, pulse oximeter, electrocardiogram and stethoscope from 6 boxes. 3 CPE humid reservoirs were found in the tap and drain sinks of 2 boxes, one of them with CPE colonised patient.

Conclusions:

We have observed the existence of carbapenem-resistant plasmids in surfaces and the persistence of humid reservoirs in our ICU, despite of establishing control measures of an outbreak. In conjunction with classical monitoring measures such as observation and training of hand hygiene, we recommend the use of disposable materials, systematic disinfection of reservoirs, appropriate use of gloves, chlorination of sinks and the goal of an ICU without water should be fundamental elements in the prevention of MRB transmission.

Key messages:

- Multifactorial approach for the control of multiresistant bacteria outbreaks in the Intensive Care Unit.
- Intensive Care Unit without water to avoid humid reservoirs of multiresistant bacterias.

Abstract citation ID: ckac129.593

Prevalence of unnecessary antibiotic use in European hospitals – a systematic review

Lea Tyllack

L Tyllack[1], *A Renz*[1], *S Runge Ranzinger*[1], *VR Louis*[1], *A Deckert*[1], *P Dambach*[1], *O Horstick*[1], *M Lowery Wilson*[1]
[1]Research to Practice Group, Heidelberg Institute of Global Health, Heidelberg, Germany
Contact: Lea.m.Tyllack@med.uni-giessen.de

Background:

Antibiotics (AB) are essential to modern day medicine as prophylaxis and therapy. Yet, unnecessary use has various negative effects on individual and global health, such as antimicrobial resistance (AMR) and contribution to high greenhouse gas (GHG) emissions of the healthcare sector. This systematic review provides an overview of unnecessary AB use in European hospitals in order to present possible ways forward.

Methods:

The systematic review followed PRISMA guidelines, included as databases were: Embase, ProQuest Environmental Science Collection, PubMed, ScienceDirect, Scopus and Web of Science. Studies conducted among adult in-patients in EU/EEA countries were included if they provided assessment methodology, included a clear standard of measurement and chart reviews were used as evaluation basis.

Results:

Fifty-six included studies were categorised into the following three groups: (1) Studies using an established evaluation method; 20 studies belong to this group, 18 used the same, established approach. Eleven of these studies performed an observational audit, while the interventions in the remaining studies were of educational or advisory nature. Unnecessary AB use ranged from 1.5% to 51% of all observed prescriptions. Outcomes of interventions showed great variation of effects on unnecessary use (-34.7% - +11.6). (2) Studies using a newly developed, clearly stated evaluation method (4 studies); (3) Studies which conform with established evaluation methods but the processes were not specified (32 studies). Results are subject to further analysis.

Conclusions:

The studies included reported a great range of unnecessary AB use in adult in-patients, for both prophylactic and therapeutic indications. Evaluation methods of unnecessary AB use vary greatly between studies. In future research, comprehensive application of established approaches is essential for better overview and identification of key areas for AMR and GHG emission reduction activities.

Key messages:

- Unnecessary antibiotic use varies greatly among studies conducted in European adult in-patients.
- In future research, wider application of established evaluation methods will improve comparability and targeting of interventions.

Abstract citation ID: ckac129.594
Impact of sepses caused by three Multi-Drug Resistant bacteria in a tertiary hospital in 2018-2020

Jacopo Garlasco

J Garlasco[1], I Beqiraj[2], C Bolla[3,4], EMI Marino[4], C Zanelli[5], A Rocchetti[6], MM Gianino[1]

[3]Department of Infectious Diseases, SS. Antonio e Biagio e Cesare Arrigo Hospital, Alessandria, Italy
[4]Infection Prevention and Control Unit, SS. Antonio e Biagio e Cesare Arrigo Hospital, Alessandria, Italy
[5]Quality and Management Accounting Unit, SS. Antonio e Biagio e Cesare Arrigo Hospital, Alessandria, Italy
[6]Department of Microbiology and Virology, SS. Antonio e Biagio e Cesare Arrigo Hospital, Alessandria, Italy
Contact: jacopo.garlasco@unito.it

Background:

Healthcare-associated infections represent a major health issue, particularly if caused by multi-drug resistant (MDR) microorganisms, with additional hospitalisation days and relevant costs besides illness and deaths. This study aimed at evaluating the economic impact of healthcare-related sepses caused by three MDR Gram-negative bacteria (Acinetobacter baumannii, Klebsiella pneumoniae and Pseudomonas aeruginosa) in a tertiary hospital.

Methods:

An observational, retrospective-cohort analysis was based on data related to patients admitted to the ''SS. Antonio e Biagio e Cesare Arrigo'' Hospital in Alessandria (Italy) between 2018 and 2020. Starting from the microbiology laboratory database, the set of patients developing sepses from the examined species was selected, by also checking that the relevant antibiogram provided evidence of resistance to ≥ 2 antimicrobial classes indicated by the European Centre for Disease Prevention and Control. Data were retrieved from patients' medical records and from the hospital's computer-based application.

Results:

In years 2018-2020, 174 patients developed septic infections from the examined species, the majority of which (88, i.e. 50.6%) in 2020 only. Altogether, these cases were responsible for 3,295 additional hospitalisation days (median 14 days, mean 19 days), with 901 imaging and 7,365 laboratory exams being reasonably ascribable to the septic episodes. Sepsis-related costs could be estimated in around 3 million Euros, about 85% of which (≈2.5 million Euros) were due to the actual cost of extra hospital stay. Specific antimicrobial therapy accounted for around 11.2% of the total (≈336,000 €).

Conclusions:

The results of this study pointed out that MDR sepses were responsible for conspicuous costs, largely grounded on the extra length of hospital stays but also due to the use of highly-expensive new-generation antimicrobials. Further research is needed to explore costs of septic episodes in different contexts.

Key messages:

- MDR sepses entailed high costs (around 3 million Euros in three years only in a single hospital), due to extra length of hospital stays and use of highly-expensive new-generation antimicrobials.
- In order to provide wider-scale estimates of the economic impact of sepses, further research is needed to explore costs of septic episodes in different sanitary systems and contexts.

Abstract citation ID: ckac129.595
Trends in mortality associated with surgical site infections: a cohort study in Italy, 2009-2019

Giovanni Paladini

G Paladini[1], HSMA Elhadidy[1], AR Cornio[1], V Bordino[1], C Vicentini[1], CM Zotti[1]
[1]Department of Public Health Sciences, University of Turin, Turin, Italy
Contact: giovanni.paladini@unito.it

Background:

Surveillance programs have proven to be effective in reducing surgical site infection (SSI) rates. In 2008 Piedmont joined the Italian national surveillance system. The aim of this study was to evaluate mortality rates and trends associated with SSIs in Piedmont from 2009 to 2019 for the two most frequently performed surgical procedures, hip arthroplasty (HPRO) and colon surgery (COLO).

Methods:

Data were collected through the national surveillance system, which includes 42 hospitals in Piedmont who participated in the surveillance program from 2009 to 2019. Procedure-specific SSI rates, overall mortality rates and case fatality rates (CFR) associated with SSIs were calculated, overall and per year. Trends were evaluated using the chi-squared test for trends. Analyses were performed using Epi Info v. 7.2.

Results:

A total of 33438 surgical procedures (21645 HPRO, 11793 COLO) were monitored over the study period from the hospitals participating in the network. 1215 SSIs (293 HPRO, 922 COLO) were observed and 617 deaths were registered (222 HPRO, 395 COLO). For HPRO procedures, an overall SSI rate of 1.35% was found, with an overall mortality of 1.03% and a CFR of 3.75%. No significant trend was observed. Considering COLO interventions, an overall SSI rate of 7.82% was found, with an overall mortality of 3.35% and a CFR of 6.94%. There was a statistically significant downward trend in SSI and overall mortality rates ($p = 0.046$ and 0.005, respectively).

Conclusions:

Considering HPRO, it is possible that the lack of significant trends could be due to the already low SSI and overall mortality rates, with the protective effect of surveillance having reached a plateau. Regarding COLO procedures, a significant reduction in SSI and overall mortality rates was observed during the study period. The reduction in mortality could be due to the decrease in SSI rates, however other factors not analysed in our study could have contributed.

Key messages:

- This study brings further evidence to the protective effect of surveillance, attributable to an improvement in healthcare quality and patients' safety.
- A significant decrease in COLO mortality rates was observed, which could be due to the decreasing trend in SSI rates.

Abstract citation ID: ckac129.596
Aetiology of influenza-like illnesses in the pre-COVID-19 season 2019-2020: role of coronaviruses

Irene Amoruso

I Amoruso[1], M Fonzo[1], C Bertoncello[1], V Baldo[1], T Baldovin[1]
[1]Hygiene and Public Health Unit, DCTVSP, University, Padua, Italy
Contact: irene.amoruso@unipd.it

Background:

Only a proportion of seasonal influenza-like illnesses (ILIs) can de facto be attributed to influenza viruses. This study investigated the aetiology of ILIs to estimate the prevalence of human coronaviruses (CoVs) and to analyse their clinical-epidemiological traits.

Methods:

A sample of 613 outpatients (253 adults, 360 children) with ILI in Veneto Region, Italy, was included. ILI was defined according with the EU Decision 2018/945. Sigma-Virocult nasopharyngeal swab were used. Nucleic acids were extracted with the QiaAmp Viral RNA Mini Kit (Qiagen). Molecular detection of respiratory viruses was performed with commercial One-step RT qPCR reagents (Allplex® Respiratory Panels, Seegene). Information on age, sex, symptoms, co-infections and comorbidities was collected.

Results:

CoVs were the 3rd most frequent pathogen in adults (7.5%, after influenza and rhinovirus) and the 4th in children (4.7%, after influenza, rhino- and adenovirus). Subtype distribution was similar, with OC43 the most frequent. Probability of CoV involvement was twice in males (AOR = 2.16; 95%CI: 1.05-4.39), whereas no association with age was noted. Co-infection with other viruses was frequent in children (65% of cases). CoV symptoms were not peculiar, although respiratory tract involvement was less likely than influenza (AOR = 0.13; 95%CI: 0.04-0.41). Among CoV outpatients, 36% had one or more chronic diseases, compared with 5.6% among influenza (p = 0.001).

Conclusions:

Even before the COVID-19 pandemic, CoVs had a substantial role in ILI aetiology: 1 case of CoV every 3 influenza infections in adults. The higher prevalence of comorbidities among CoV positives compared to influenza indirectly shows the benefits of flu vaccines in individuals at higher risk. Careful surveillance of the viruses responsible for ILI continues to be desirable, including, but not limited to, detecting a possible change in the aetiology of ILI after the administration of SARS-CoV-2 vaccines in the population.

Key messages:

- Pre-pandemic virological surveillance of influenza-like illnesses (ILIs) reveals how seasonal coronaviruses were the third most frequent respiratory pathogen in adults.
- Prevalence of comorbidities was significantly higher in patients with a coronavirus-related ILI compared to influenza, supporting the benefits of flu vaccination for high risk groups.

Abstract citation ID: ckac129.597
Flu vaccination coverage in healthcare workers during a 3-year period in the context of the pandemic

Giuditta Scardina

G Scardina[1], L Ceccarelli[1], V Casigliani[1], S Mazzilli[2], M Padovan[3], A Petillo[3], L Tavoschi[1], R Foddis[3], G Privitera[1], A Baggiani[1]
[1]Translational Research in Medicine, University of Pisa, Pisa, Italy
[2]Scuola Normale di Pisa, Pisa, Italy
[3]Occupational and Preventive Medicine, University of Pisa, Pisa, Italy
Contact: giudittascardina7@yahoo.it

Background:

Vaccination of healthcare workers (HCWs) against seasonal influenza is considered the most effective way to protect HCWs and maintain essential healthcare services during influenza epidemics. With the present study we aimed to evaluate the efficacy of measures implemented during the three flu campaigns of 2018/19, 2019/20 and 2020/21 in a university hospital in Pisa, Italy, through the assessment of vaccination coverage (VC) in HCWs and to assess attitudes toward flu vaccination.

Methods:

Flu VC was stratified according to sex, age, job and vaccination status for each season and the association between each variable and vaccination status was explored. In 2020, a survey collecting data on knowledge and attitudes on flu vaccination was distributed.

Results:

Starting from the 2018/19 campaign, an increasing flu VC rate was registered: contained in 2019/20 (from 11.6% to 14.3%, $\Delta\% = 23.1$) and significant (VC = 39.6%, $\Delta\% = 177.6$) in 2020/21 as compared with the previous year. Physicians were the professionals most willing to get vaccinated during all seasons. Considering age the situation changed greatly over the study period, with VC rising in 2020/21 in those age groups marked by low VC in previous years (<30 and 41-50 years old, $\Delta\% = 293$). Having been vaccinated in the previous year represented the most important variable to predict likelihood of accepting flu jab. However, while previously vaccinated HCWs were 13 times more likely to get the flu jab in 2019/20 compared with the others; in 2020/21 they were only 3 times. Only half of HCWS considered themselves at higher risk of contracting influenza compared to the general population, while 71% totally agreed that receiving the flu jab in 2020/21 was more important than the previous years due to COVID.

Conclusions:

A significant increase in VC was observed in 2020/21, especially among those sub-groups with consistently lower uptake in previous years, due to the COVID pandemic that positively influenced vaccination uptake.

Key messages:

- This study evaluates the impact of subsequent flu vaccination campaigns implemented in a large university hospital in Italy through the assessment of flu VC among HCWs.
- A significant increase in flu VC among HCWs was observed in 2020/21, especially in those categories characterized by lower VC rates in the previous years, more likely due to the COVID-19 pandemic.

[6]High Intensity Internal Medicine Unit, Careggi University Hospital, Florence, Italy
[7]Department of Health Sciences, University of Florence, Florence, Italy
Contact: vgallinoro@gmail.com

Problem:

Inappropriate antibiotic use contributes to the emergence and spread of multidrug-resistant organisms that are responsible for life-threatening infections. Furthermore, overprescription of antibiotics is associated with an increased risk of adverse effects and higher costs.

Description of the problem:

Careggi is a tertiary care teaching hospital in Italy, with nearly 1,200-bed units, involved since 2015 in antimicrobial stewardship (AMS) programs. Despite implementation programs, carbapenems (CAR) consumption rates remained higher than the national average; for this reason, the AMS hospital team started a project aimed at improving the appropriateness of this type of drug.

Results:

The project started in October 2021 and involved 10 hospital Units selected as the major prescribers of CAR. The strategies were planned by a multi-professional and multi-disciplinary team of experts in AMS and were set in place by a multimodal approach focused on information technology (IT) functions implemented in the electronic medical record such as:

- time-out alerts at 72 hours inviting physicians to evaluate if the prescribed antimicrobial is still warranted or effective against the identified organism(s);
- interactive and customizable prescribing algorithms to support physicians in empirical and targeted therapies;
- electronic dashboards viewable by physicians and the AMS team to daily monitor and review CAR prescriptions.

These functions were complemented by a series of training sessions for prescribing physicians aimed to promote a more rational and appropriate antimicrobials use. Six months after the project began, an overall reduction in the prescription of CAR was observed: from 6.2 DDD/100 patient-days to 4.9 DDD/100 patient-days.

Lessons:

AMS programs use different interventions to influence the behavior of prescribers toward more appropriate use of antimicrobials. IT functions represent complementary and useful tools to promote antimicrobial stewardship programs.

Key messages:

- Antimicrobial stewardship programs aim at optimizing antibiotic use and reducing inappropriate antibiotic prescriptions.
- Information technology systems represent useful tools within AMS programs.

Abstract citation ID: ckac129.599
A systematic review of randomized clinical trials on quadrivalent influenza vaccines for adults

Andrea Pellacchia

A Pellacchia[1], *A Mannocci*[2], *R Millevolte*[1], *M Chiavarini*[1], *C de Waure*[1]
[1]Department of Medicine and Surgery, University of Perugia, Perugia, Italy
[2]Faculty of Economics, ''Universitas Mercatorum'' University of Rome, Rome, Italy
Contact: andrea.pellacchia@hotmail.it

Background:

Vaccination is the most effective intervention to prevent influenza. Adults at risk of complications are among the targets of annual vaccination campaigns and can receive different types of quadrivalent influenza vaccines (QIV). To assess the immunogenicity of different QIVs we performed a systematic review of available randomized controlled trials (RCTs) with the aim of indirectly compare them through a network meta-analysis.

Methods:

The systematic review was conducted in accordance with PRISMA-NMA guidelines. We systematically searched RCTs conducted in adults aged 18-64 years that assessed the immunogenicity, namely seroprotection and seroconversion rate (SPR and SCR), of any QIV compared to any comparator. The literature search was performed on three databases (Medline, Cochrane Library and Scopus) until March 30th, 2021.

Results:

Twenty-four RCTs were included in the systematic review. A network meta-analysis was not possible: the assumption of transitivity was not satisfied. Therefore, we decided to combine data on immunogenicity and efficacy of each QIV through single meta-analyses in the presence of at least two studies. Live attenuated QIV showed the worst results in terms of both SCR and SPR. Standard dose egg based, low dose adjuvanted, cell based, recombinant and intradermal QIV showed similar SCR in respect to influenza strain A, whereas low dose adjuvanted QIV showed an overall better profile in respect to B lineages. Regarding SCR, the better results were issued by standard egg based, cell based, recombinant, and low dose adjuvanted QIVs.

Conclusions:

Albeit an indirect comparison among different QIVs was not possible, the assessment of SCR and SPR provided an overview of their respective potentiality and criticality in adulthood. In particular attention should be paid to new generation influenza vaccines that can have an antigen sparing effect and to the collection of real world data to make comparison among different QIVs possible.

Key messages:

- Available evidence does not allow to perform indirect comparison of the quadrivalent influenza vaccines for adults.
- Some QIVs, including new generation ones, elicit a better antibody response.

9.N. Workshop: It Takes Two To Improve European Child Health (Care)

Abstract citation ID: ckac129.600

Organised by: EUPHA-CAPH
Chair person: Danielle Jansen (EUPHA-CAPH)
Contact: julia.dratva@zhaw.ch

Many societal developments have an impact on health care in general and on child health care, in particular. Internationally challenges include an aging population, more cultural diversity and a rising prevalence of chronic diseases among children and adolescents, revealing potential risks for child health care. A strong focus must be placed on prevention strategies that are effective, sustainable and equitable. Planning and implementing prevention strategies may require shifts in the organization of care, such as the forging and strengthening of interdisciplinary and intersectoral partnerships within a country. A promising example of such partnerships is the collaboration of public health with paediatrics. Both professional groups acknowledge the call for greater integration since prevention strategies can only be achieved and sustained by working together.

The objectives of this workshop are to:

- Provide a selective overview of three partnerships and plans for cooperation between public health and paediatrics.
- To exchange experiences and possibilities with the audience to pave the way for further successful partnerships.

In this workshop, we outline the partnership and plans for cooperation between public health and paediatrics in three European countries: Netherlands, Finland and Switzerland. In the first presentation, Danielle Jansen and Károly Illy will share the new vision towards the year 2030 of the Dutch Paediatric Society in which building blocks are presented to guarantee accessible, high-quality, timely and effective care for every child. One of the building blocks to be highlighted is the interprofessional collaboration between paediatricians and public health professionals. In the second presentation, Julia Dratva and Susanne Stronski from Switzerland will present a shared paediatric and public health vision of a digital child health booklet. The digital booklet will empower parents and adolescents, provide access to personal health irrespective of place or time, improve sharing health information among care professionals, thus ensuring continuity of care and limiting redundancy of investigations and in addition, and provide data for public health research and monitoring. Challenges and solutions will be shared with the audience. In the third presentation, Silja Kosola from Finland will present a Finnish vision for school health care where professionals trained in public health and medicine collaborate with each other as well as with teachers for the benefit of children and adolescents. This multidisciplinary collaboration across governing bodies is especially important as Finland undergoes a national reform of social and health care services. After the three presentations, we engage the audience by asking for their experiences and sharing the examples of collaborations between public health and paediatrics, as well as barriers and facilitators. At the end of the workshop, we would like to summarize the results of the workshop in an overview of preliminary best practices.

Key messages:

- Global climatic, societal and politic developments reveal potential risks for child health cand health care, which must be countered effectively, sustainably and equitably.
- Greater integration of prevention across sectors is elemental and can be achieved through interprofessional partnerships.

Abstract citation ID: ckac129.601
The vision of Dutch paediatric care until the year 2030: prevention and collaboration as key ingredients

Danielle Jansen

D Jansen[1], *K Illy*[2]
[1]Department of General Practice and Elderly Care Medicine, University Medical Center Groningen, Groningen, Netherlands
[2]Dutch Paediatric Society, Utrecht, Netherlands
Contact: d.e.m.c.jansen@umcg.nl

There are many societal developments in The Netherlands that have or will have an impact on Dutch paediatric care. These developments both reveal potential risks in paediatric care and require future improvement of paediatric practices to achieve the best possible outcomes for Dutch children. To realise this, the Dutch Paediatric Society decided in their renewed vision to have a closer focus on prevention and on building partnership with public health, by implementing a building block 'Interprofessional Collaboration between Paediatricians and Other Health Care Providers'. This building block formulates the wish of the Dutch Paediatric Society to work together in networks with other domains of care, such as public health. Preferably, it will be a flexible network in which the disciplines involved align the needs of the specific child. In order to develop and participate in such a network, pediatricians and public health professionals actively have to invest in connecting, establishing, and further developing professional networks (including patient societies). A first precondition for the development and successful functioning of such a network is the implementation and use of a joint electronic medical record in which all diagnostics, treatment plans and positive health aspects of the child are collected, and which is accessible to all professionals involved. A patient record which guarantees a barrier-free exchange of medical and non-medical information between paediatricians and public health professionals within the framework of the current privacy legislation. A second precondition regards an improvement of the paediatric training curriculum in which the paediatrician of the future will gain knowledge of positive health and integrative medicine. The future paediatrician must be trained to function in networks and to make connections. In this presentation we present an update of the implementation of this building block: what is already realised and how.

Public health, paediatrics as well as other health professionals share the interest in providing services and improving conditions to ensure life-long health and well-being of children and adolescents. In this interprofessional setting and aim, parents are central partners, as are adolescents when they take over the responsibility of their own health. Ensuring the availability of health data for parents and adolescents at any given time and place is a key factor to empower and improve health management and literacy, providing continuity of health information along the care chain, and analysing health data of healthy and sick children is of high importance. The digital booklet will have a positive impact on sharing of health information among care professionals, thus ensuring continuity of care and limiting redundancy of investigation, and in addition provide data for public health research and monitoring of health and determinants. The Swiss Society of Paediatrics, the ZHAW/Institute of Public Health and the Kollegium of Hausarztmedizin (general practices) founded an association to digitalize the current paper child and adolescent health booklet with the aims:

1. Empower parents as 'owners' of health data to take responsibility and have greater autonomy in managing their child's health and illness
2. Provide a digital infrastructure for
   - low-threshold and reliable source of advice
   - easy update of data/information, digital communication with parents
   - sharing of data with professionals and non-professionals involved in care of child.
3. Monitoring of children's health data (parental consent provided)

The speakers with present their collaboration and project, its current status, as well challenges and solutions found.

Ethnic differences in COVID-19 deaths across various waves of Coronavirus pandemic in Netherlands

Felix Chilunga

FP Chilunga[1]*, L Stoeldraier*[2]*, C Agyemang*[1]*, K Stronks*[1]*, H Harmsen*[2]*, AE Kunst*[1]
[1]Public and Occupational Health, Amsterdam UMC, Amsterdam, Netherlands
[2]Demography Group, Central Bureau of Statistics, Den Haag, Netherlands
Contact: f.p.chilunga@amsterdamumc.nl

Background:

It is not known how ethnic differences in COVID-19 deaths in the Netherlands evolved throughout the pandemic, especially after introduction of ethnicity-oriented COVID-19 prevention measures. We investigated associations between ethnicity and COVID-19 deaths across first wave of the pandemic, inter-wave period, and second wave in the Netherlands.

Methods:

We obtained multiple registry data from Statistics Netherlands spanning from 01 March 2020 to 14 March 2021 comprising of 17.4 million inhabitants. We estimated incidence rate ratios (IRRs) for COVID-19 deaths among ethnic groups using Poisson regression models and adjusted for relevant sociodemographic factors. We used similar models to estimate IRRs for non-COVID-19 deaths among ethnic groups.

Results:

Ethnic minority populations exhibited higher risk of COVID-19 deaths than the Dutch origin population throughout various study periods. The most elevated risk of COVID-19 deaths was in populations originating from low- and middle-income countries, especially those with Turkish, Moroccan, and Surinamese background. The elevated risk of COVID-19 deaths among ethnic minority groups (as compared to Dutch origin population) was higher in inter-wave period (4 times higher) and second wave (2 times higher) when compared to the first wave (1.5 times as higher). Ethnic differences in COVID-19 deaths were larger compared to non-COVID-19 deaths.

Conclusions:

Ethnic differences in COVID-19 deaths persisted across first wave, inter-wave period and second wave in the Netherlands despite introduction of ethnicity-oriented prevention measures. Research on explanatory mechanisms and novel prevention measures are needed to address the ongoing differences in COVID-19 deaths across ethnic groups.

Key messages:

- Ethnic differences in COVID-19 deaths persisted in the Netherlands despite introduction of ethnicity-oriented prevention measures.We therefore call for better prevention measures.
- Well known drivers of SARS-CoV-2 infection such as household wealth, did not explain our findings calling for an in-depth understanding of drivers of ethnic differences in COVID-19 deaths.

Abstract citation ID: ckac129.605
Unseen abilities – how refugee women with disabilities experience social participation

Sarah Scheer

S Scheer[1]*, M Mondaca*[2]
[1]Health and Social Science, IB University of Applied Health and Social Science, Berlin, Germany
[2]Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden
Contact: sarah.scheer@ib-hochschule.de

Background:

In the European context, refugee women especially those with physical disabilities are confronted by many unequal conditions that have an impact on their health and social wellbeing. To address these, it is important to understand refugees' social participation and integration process. Furthermore, the purpose of the study is to identify refugee women's resources and their strengths in their everyday life that are related to current problems and needs.

Methods:

This research project is embedded in occupational science theories which include the effect of social and environmental issues on an individual's health and wellbeing. An ethnographic, longitudinal study using visual and narrative methods was used to explore the phenomena of the everyday life and social participation possibilities of five refugee women with physical disabilities living in Stockholm, Sweden. Moreover, to illustrate the process of meaning-making, the frame of intersectionality was used within the whole research process.

Results:

Through the lens of intersectionality, it was possible to determine gender, ableism, religion, and ethnicity issues as influencing factors concerning health and social participation. The women's narratives illustrate accessibility, e.g. public transport as a big resource in comparison to the country they came from. Still, to be a woman, a refugee, and having a disability at the same time is a challenge for social participation. One reason is less consideration of disabilities in the integration process. Having faith was mentioned as a safe place and using the public transport to independency. However, the women stress, that they want their abilities to be used instead of experiencing being limited by their disabilities.

Conclusions:

In conclusion, the women emphasize being engaged in the hosting community. Health and social policymakers should consider the refugee women's voices to develop integration strategies with and not for refugee women with disabilities.

Key messages:

- Through the lens of intersectionality, refugee women's narratives bring new insights about social participation.
- Refugee women with a disability want to engage in the hosting society and become active members.

Which effects had the pandemic in migrants' health and well-being? A mixed-methods approach

Ana Gama

A Gama[1,2], MJ Marques[3,2], AR Pedro[1,2], LV Hoffmeister[1,2], F Rodrigues[3], JS Ribeiro[3], S Dias[1,2]
[1]NOVA National School of Public Health, PHRC, Universidade NOVA de Lisboa, Lisbon, Portugal
[2]Comprehensive Health Research Center, Lisbon, Portugal
[3]NOVA National School of Public Health, Universidade NOVA de Lisboa, Lisbon, Portugal
Contact: anafgama@gmail.com

Background:
The COVID-19 pandemic affected populations' health, with a disproportionate impact on those most socially vulnerable such as migrants. The way these populations experienced the pandemic lockdowns and its effects on daily life are yet to be known. This study aimed to understand the effects of the pandemic on health and well-being of migrants in Portugal.

Methods:
In a mixed-methods approach, a survey was conducted with a community-based sample of 1126 migrants in the Lisbon Metropolitan Area, assessing sociodemographics, migration-related characteristics and the perceived impact of the pandemic on health. In addition, n = 12 migrants purposively recruited were invited to participate in a photovoice study, sharing photographs about their daily life during the lockdowns. Following semi-structured interviews were conducted. Quantitative data were analysed using multivariable analysis and qualitative data were analysed through content analysis.

Results:
A fifth of the participants perceived having worse health condition since the pandemic, which was more likely among women (OR = 1.58, CI95% 1.13-2.20), those >45 years old (OR = 1.78, CI95% 1.02-3.16), with lower education (Basic education: OR = 1.57, CI95% 1.01-2.47) and with lower monthly income (<EUR 650: OR = 1.69, CI95% 1.18-2.44). Two themes emerged from the photovoice: effects of the pandemic lockdowns on daily life (routines, social relations, work) and on health and well-being (eating habits, physical exercise, leisure). Strategies to cope with the adverse effects included social activation and changes in lifestyles.

Conclusions:
The pandemic had disproportionate effects on some migrant groups, intensifying social and health inequalities, with consequences for their well-being. Participatory methods can contribute to further understand migrants' experiences while involving and empowering them for health promotion.

Key messages:
- The pandemic had adverse effects on migrants' health and well-being, disproportionately affecting most socially vulnerable migrant groups.
- Participatory research methods as photovoice are valuable to gain access to individual experiences and perspectives, while involving and empowering participants.

Abstract citation ID: ckac129.607
Resilience in Syrian refugee youth

Cecilie Dangmann

C Dangmann[1], Ø Solberg[2], AK Myhrene Steffenak[1], S Høye[1], PN Andersen[3]
[1]Faculty of Health and Social Sciences, Inland Norway University of Applied Sciences, Elverum, Norway
[2]Department of Health Science, Swedish Red Cross University, Stockholm, Sweden
[3]Department of Psychology, Inland Norway University of Applied Sciences, Elverum, Norway
Contact: cecilie.dangmann@inn.no

Background:
The importance of resilience factors in the positive adaptation of refugee youth is widely recognised. However, their actual mechanism of impact remains under-researched. The aim of this study was therefore to explore protective and promotive resilience mechanisms on both negative and positive mental health outcomes. Promotive resilience is seen as a direct main effect and protective resilience as a moderating effect.

Methods:
Cross-sectional study with 160 Syrian youth aged 13-24 years, who recently resettled in Norway. A multi-dimensional measure for resilience was used to explore the potential impact of resilience factors on pathways between potentially traumatic events from war and flight (PTE), post-migration stress, mental distress and health-related quality of life (HRQoL). Analyses included regression, moderation and moderated mediation using the PROCESS macro for SPSS.

Results:
A direct main effect of resilience factors (promotive resilience mechanism) was found for HRQoL and general mental distress, but not for post-traumatic stress disorder (PTSD). No moderating effects of resilience factors (protective resilience mechanism) were found. Post-migration stressors mediated the effects of PTE, and this indirect effect was present at all levels of resilience. Relational and environmental level resilience factors and combined amounts had more impact than individual level factors.

Conclusions:
Despite high risk exposure and mental distress, resilience was also high. The direct main effect of resilience factors and less impact on PTSD, suggests universal resilience building interventions may be beneficial, compared to exclusively targeting groups with high symptom levels. These interventions should target relational and environmental resilience factors as well as individual coping techniques. Additionally, reducing current stress and symptoms could increase the efficacy of resilience factors already present.

Key messages:
- Refugee youth may have both high levels of risk and high resilience.
- Universal resilience interventions should focus on relational and environmental support, as well as individual resilience.

Abstract citation ID: ckac129.608
Elevated stress during pregnancy in women of Turkish origin: Results from a prospective cohort study

Laura Scholaske

L Scholaske[1], S Entringer[2], O Razum[3], J Spallek[4]
[1]Research Cluster Data - Methods - Monitoring, DeZIM-Institute, Berlin, Germany
[2]Institute for Medical Psychology, Charité - Universitätsmedizin Berlin, Berlin, Germany
[3]School of Public Health, University of Bielefeld, Bielefeld, Germany
[4]Department of Public Health, Brandenburg University of Technology, Senftenberg, Germany
Contact: scholaske@dezim-institut.de

Background:
Ethnic health disparities exist in the context of pregnancy and childbirth, suggesting that women of Turkish origin (i.e., they or their parents born in Turkey) in Germany have higher risks for some adverse maternal health and child developmental outcomes. Stress is believed to be a relevant pathway by which migration may be associated with these risks. In this study, we tested associations of Turkish origin with stress biology and psychological stress experiences during pregnancy.

Methods:
140 pregnant women (33 of Turkish/26 of other origin) participated in a prospective cohort study that was carried out in Bielefeld and Berlin (Spallek et al., 2020). Inflammatory markers CRP and IL-6 from venous blood samples and diurnal cortisol profiles from salivary cortisol samples were derived and participants completed the Perceived Stress Scale (PSS) and Center for Epidemiologic Studies Depression Scale

(CESD) at two study visits during pregnancy (T1: 20-25 weeks of gestation, T2: 30-35 weeks of gestation). Multilevel models were conducted to account for the nested data structure due to repeated measurements.

Results:

Compared to non-migrant women, women of Turkish origin had significantly higher inflammatory levels (b = 0.28, SE = 0.14, p = .052) (Spallek et al., 2021), a blunted cortisol awakening response (b = -0.21, CI = -0.38–0.03, p<.05), a flatter diurnal cortisol slope (b = 0.02, CI = 0.00-0.04, p<.05), and higher PSS (b = 0.46, SE = 0.13, p< .001) and CESD scores (b = 0.29, SE = 0.08, p<.001) during pregnancy after adjusting for socioeconomic factors.

Conclusions:

The results of our study suggest higher stress at the biological and psychological level in pregnant women of Turkish origin. Stress is a risk factor for pregnancy complications and poor birth and child developmental outcomes. To reduce such unequally distributed risks, interventions for stress reduction are needed that are tailored to women of Turkish origin.

Key messages:

- Women of Turkish origin in Germany have elevated psychological and biological stress levels during pregnancy compared to non-migrant women.
- This finding underscores the need for targeted interventions to reduce stress in this high-risk group.

Abstract citation ID: ckac129.609
Stressful life events as predictors of refugee adolescents' subjective mental health need

Alexandra Fretian

Y Namer[1], *A Fretian*[1], *D Podar*[1], *O Razum*[1]
[1]School of Public Health, Bielefeld University, Bielefeld, Germany
Contact: fretian@uni-bielefeld.de

Background:

Asylum seeking and refugee (ASR) adolescents fleeing armed conflict have lived through stressful events. Although not all stressful life events are experienced as post-traumatic stress, they may still lead to subjective need for mental health support. In this study, we assessed which stressful events predicted subjective need.

Methods:

We collected and analysed cross-sectional data (February 2019-November 2020) from ASR adolescents aged 11-18, coming from Syria, Afghanistan and Iraq (n = 216). Subjective mental health need was measured with the question "Do you think you have emotional difficulties that you need help with?" and stressful life events (SLE) by the SLE Checklist, a self-report screening tool that asks if participants experienced stressful events in three categories: separation from family, witnessing armed conflict, experiencing violence. Binary logistic regression was run to assess the relative contribution of stressful life events to subjective need.

Results:

30.1% of participants reported subjective need for mental health support. Most commonly encountered events were witnessing armed conflict (53.2%) and experiencing the death of a loved one (51.9%). Only one stressful event significantly predicted subjective need for mental health support: separation from family or relatives against one's will (e.g., by police or military) [OR = 6.32, 95%CI(1.79,22.31)].

Conclusions:

ASR adolescents who have been separated from their family by force report subjective need for mental health support. It is important to supplement diagnostic tools with subjective report of needing mental health care. ASR adolescents who have experienced separation from famil by force should be given spaces to talk about their need for mental health support. Public health interventions could focus on creating or utilising such spaces where mental health support is available. Crucially, bureaucratic and legal burdens that impede speedy family reunification should be reduced.

Key messages:

- ASR adolescents who have been separated from their families by force are more likely to report subjective need for mental health support.
- The higher reported need highlights the importance of reducing bureaucratic and legal burdens that impede fast family reunification.

Abstract citation ID: ckac129.610
Training peer researchers for CBPR on racism in health care in Germany

Tanja Gangarova

T Gangarova[1]
[1]National Discrimination and Racism Monitor, DeZIM-Institut, Berlin, Germany
Contact: gangarova@dezim-institut.de

For many affected by ongoing coloniality, research is not neutral or objective, but is part of the colonial violence inflicted through disciplines as diverse as medicine and ethnography. Against this background, choosing Community-based Participatory Research (CBPR) as research strategy for researching racism in health care can be seen as a way of challenging existing epistemologies of ignorance by embracing diversity of knowledge production. 'Community Perspectives on Racism in Health Care' is a participatory research project carried out in the frame of the National Discrimination and Racism Monitor which aims to improve the involvement of people affected by racial injustice in the research process, collect data on and generate theory about healthcare-related racism. It is conducted by DeZIM-Institut in collaboration with different racialized communities. Community members were trained as peer researchers and supported to conduct CBPR-projects. Two CBPR-projects were conducted: 1) digital focus groups with people marked as Muslims 2) digital focus groups with Black people. 'Racial' health disparities were identified on three levels: differential access to health care, differential care within the system and differences in exposures. The theory was built inductively, while drawing on existing theoretical concepts from the disciplines of public health, postcolonial and decolonial studies. Racialized people used the opportunity to be trained as peer researchers. They conducted CBPR projects tailored to the needs of their communities and conceptualized racism in the broader context of health care. Suggestions were made for improving health care services. Including those most impacted by racial injustice as peer researchers enables us to widen the "we" who constitute the researchers and to harvest the wisdom of situated knowledges. However ongoing challenges have been faced raising the question of the (im)possibilities of democratic knowledge production in German academia.

Key messages:

- Including those most impacted by racial injustice as peer researchers enables us to harvest the wisdom of situated knowledges.
- Ongoing challenges have been faced by trying to establish democratic knowledge production in German academia.

9.P. Pitch presentations: Mental health policies

Abstract citation ID: ckac129.611
Reform of the mental health care system in the Republic of Croatia

Danijela Stimac Grbic

D Stimac Grbic[1,2]
[1]Croatian Institute of Public Health, Croatian Public Health Association, Zagreb, Croatia
[2]University of Zagreb, School of Medicine Andrija Stampar, Zagreb, Croatia
Contact: danijela.stimac@hzjz.hr

Issue/problem:

The pandemic and earthquakes that hit Croatia have increased the need to develop an effective community based mental health care system.

Description of the problem:

In Croatia, the hospitalization rate for depression has doubled in the last 20 years, and the growing needs are mainly related to the mental health of children and young people. The average length of hospital stay due to mental disorders is higher than the EU average, as is the suicide rate. Due to insufficient recognition at the primary level of health care, inadequate treatment and stigma, people with mental disorders rarely seek help.

Results:

Croatia is in the process of adopting the Strategic Framework for Mental Health 2022-2030. The Action Plan for community based mental health service and the Action Plan for mental health promotion, the early detection and treatment of mental disorders are being developed. Emphasis is on intersectoral cooperation, reorientation of the mental health system to community-based care, empowerment, especially of young people, through social emotional learning in school programs, peer support and involvement of young people in decision-making processes. Increasing the mental health literacy, destigmatization, empowering people with mental health disorders to participate in designing interventions, establishing multidisciplinary mobile teams to provide community services and the cooperation of all sectors in mental health care are emphasized. The national program for improvement mental health literacy of educational staff was launched. Telemedicine services have been developed, and the pilot project Providing psychosocial services by mobile multidisciplinary teams have been implemented.

Lessons:

Comprehensive, multidisciplinary and multisectoral action is needed to effectively address the problems in the mental health care system.

Key messages:

- Community based mental health care is client oriented care.
- People with experience of mental disorder and their families must be involved in the decision-making process.

Abstract citation ID: ckac129.612
Self-cutting in bullying victimized adolescents is mediated by depression and dissociation

Manisha Hamal

M Hamal[1,2]*, V Kekkonen*[1,2]*, S-L Kraav*[2,3]*, P Kivimäki*[1]*, M-L Rissanen*[4,5]*, J Hintikka*[6,7]*, T Tolmunen*[1,2]
[1]Department of Health Sciences, University of Eastern Finland, Kuopio, Finland
[2]Department of Adolescent Psychiatry, Kuopio University Hospital, Kuopio, Finland
[3]Faculty of Social Science, University of Eastern Finland, Kuopio, Finland
[4]University of Applied Sciences, Savonia University, Kuopio, Finland
[5]Faculty of Social Sciences, Health Sciences, University of Tampere, Tampere, Finland
[6]Department of Psychiatry, Päijät-Häme Central Hospital, Lahti, Finland
[7]Faculty of Medicine and Health Technology, University of Tampere, Tampere, Finland
Contact: hamal.manisha07@gmail.com

Background:

Bullying victimization is a universal public health threat with numerous negative mental health consequences, including anxiety, depression, and dissociation.

Aims:

We explored 1) firstly whether bullying victimization is associated with self-cutting in Finnish adolescent population and, 2) if the possible association is mediated by dissociation and/or depression.

Methods:

We used cross-sectional questionnaire data from 13-18- year-old Finnish students (N = 4214; boys n = 1942; girls n = 2229).

Results:

Bullying victimized adolescents were older, more likely to come from single-parent families and to take drugs and drink alcohol, had a poorer relationship with parents and siblings, as well as poorer school performance compared to non-bullied adolescents. According to logistic regression analysis the association between bullying and self-cutting remained significant despite adjustments for age, gender, fear of going to school, school performance, social network-related factors, family-related factors, lifestyle related factors, and dissociative symptoms, but not for depressive symptoms. In mediation analyses we found that both depression and dissociation mediated the effect of bullying victimization on self-cutting.

Conclusions:

Self-cutting is more common in adolescents who have been bullying victimized. The association is mediated by depressive and dissociative symptoms. More studies are needed to clarify the exact mechanisms how of depressive and dissociative symptoms interact with the association between bullying and self-harm.

Key messages:

- Bullying victimized adolescents are associated with self-cutting.
- Depression and dissociation mediate the mentioned association.

Abstract citation ID: ckac129.613
Evaluating Mood and Anxiety Disorders in Canada Through a Gender-Based Analysis Plus (GBA+) Lens

Shant Torkom Yeretzian

ST Yeretzian[1]*, Y Sahakyan*[1,2]*, L Abrahamyan*[1,2,3]
[1]Turpanjian College of Health Sciences, American University of Armenia, Yerevan, Armenia
[2]Toronto Health Economics and Technology Assesment, University Health Network, Toronto, Canada
[3]Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, Canada
Contact: shantyeretzian@outlook.com

Background:

The prevalence of mental disorders continues to increase worldwide. We assessed the prevalence and associated factors of mood and anxiety disorders in the Canadian population using a Gender-Based Analysis Plus (GBA+) lens on a nationally representative survey.

Methods:

A secondary analysis of the 2017-2018 Canadian Community Health Survey (CCHS) - Annual Component was conducted using a GBA+ lens, an analytical process to incorporate sex, gender, and other intersecting identity factors into research, programs and policies. Sampling and bootstrap weights were applied to account for complex sampling design. Chi-square test and multivariable logistic regression models were used to assess associated factors of mood and anxiety disorders.

Results:

2017-2018 CCHS included 113,290 observations, representative of 98% of the Canadian population over the age of 12. Mood and anxiety disorders were more prevalent among females than males (11.0% vs 6.4% and 11.6% vs 6.3% respectively, $p < 0.001$). Logistic regression analyses revealed higher odds for both disorders for those who were female, unemployed, smokers, homosexual or bisexual, had low education and income levels, suffered from food insecurity or had disabilities. Statistically significant interactions were observed between sex and factors such as age, income, employment and sexual orientation. Of those who had a mood or anxiety disorder, 5.0% reported having unmet mental health care needs compared to 1.0% of the general population ($p < 0.001$). Those reporting unmet mental health care needs were more frequently younger, females, single parents, with disabilities, lower income and food insecurity.

Conclusions:

Females in Canada continue to be affected by mood and anxiety disorders at higher rates than males. Strategies for preventing mental health disorders and improving mental health care must be tailored towards the needs of specific groups. We recommend the use of GBA+ as a guide in both research and policymaking.

Key messages:

- This study provides estimates of the present state of mood and anxiety disorders in the Canadian population using secondary data from a cross-sectional, nationwide survey conducted through 2017-2018.
- The application of Gender-Based Analysis Plus (GBA+) helps with the systematic evaluation of healthcare disparities and development of targeted strategies to address gaps in mental health.

Abstract citation ID: ckac129.614
Mental health problems, low economic capability, and social marginalization among 28,047 adults

Siri Havas Haugland

SH Haugland[1], A Topor[1], JG Friesinger[1]
[1]Department of Psychosocial Health, University of Agder, Grimstad, Norway
Contact: siri.h.haugland@uia.no

Background:

Mental health problems and low economic capability increase the risk of social marginalization. However, few larger studies with a broad age group have investigated how the cumulative effect of having both these difficulties may affect social life. The purpose of this study was to examine the associations between having mental health problems or having low economic capability or reporting both, and social marginalization.

Methods:

The study is based on responses from 28 047 adults (> 18 years old) from the general population participating in The Norwegian Counties Public Health Survey 2019. The study had a cross-sectional design and included respondents' evaluation of own economic capability, mental health problems (HSCL-5) and social marginalization measured as lack of social support, low participation in organized social activities, low participation in other activities, missing someone to be with, feeling excluded and feeling isolated. Multivariable logistic regression was adjusted for sex and age.

Results:

Findings showed that having mental health problems or low economic capability were both associated with various measures of social marginalization with odds ratio [OR] 95% confidence interval [CI] ranging from OR 1.33; CI 1.23-1.43 to OR 12.63; CI 10.90-14.64. However, the odds of social marginalization strongly increased for respondents having both mental health problems and low economic capability compared to respondents without both these difficulties, with OR ranging from OR 2.08; CI 1.90-2.27 to OR 29.46; CI 25.32-34.27. Findings are preliminary.

Conclusions:

Having both mental health problems and low economic capability strongly increases the risk of social marginalization, far beyond the effect of each factor alone.

Key messages:

- Having both mental health problems and low economic capability strongly increases the risk of social marginalization, far beyond the effect of each factor alone.
- Services should aim to develop multi-faceted approaches to meet multiple life-challenges to prevent social marginalization.

Abstract citation ID: ckac129.615
Low-quality employment trajectories and mental health disorders among Swedish and migrant workers

Roxana Pollack

R Pollack[1,2], B Kreshpaj[2], J Jonsson[2], T Bodin[2,3], V Gunn[2,4,5], C Orellana[2], P Östergren[6], C Muntaner[7], N Matilla-Santander[2], PWR Consortium[2]
[1]MRC/CSO Social and Public Health, University of Glasgow, Glasgow, UK
[2]Unit of Occupational Medicine, Karolinska Institutet, Stockholm, Sweden
[3]Centre for Occupational and Environmental Medicine, Stockholm Region, Stockholm, Sweden
[4]MAP Centre for Urban Health Solutions, Unity Health Toronto, Toronto, Canada
[5]Lawrence S. Bloomberg Faculty of Nursing, University of Toronto, Toronto, Canada
[6]Social Medicine and Global Health, Lund University, Lund, Sweden
[7]Dalla Lana School of Public Health, University of Toronto, Toronto, Canada
Contact: roxana.pollack@gmail.com

Aim:

This study aims to examine the effects of low-quality employment trajectories on severe common mental disorders (CMD) according to Swedish and foreign background.

Methods:

This is a longitudinal study based on Swedish population registries (N = 2,703,687). Low- and high-quality employment trajectories observed across five years (2005-2009) are the exposure with severe CMD as outcome (2010-2017). Adjusted hazard ratios (HR) were calculated using Cox regression stratified according to background (first-generation (i) EU migrants, (ii) non-EU migrants, (iii) second-generation migrants, (iv) Swedish-born with Swedish background) and sex. The reference group were Swedish-born with Swedish background in a Constant high-quality employment trajectory.

Results:

Second-generation migrants had an increased risk of CMD compared to Swedish-born with Swedish background when following low-quality employment trajectories (e.g., male in Constant low-quality HR: 1.53, 95% CI: 1.41-1.68). Female migrant workers, especially first-generation from non-Western countries in low-quality employment trajectories (e.g., Constant low-quality HR: 1.65, 95% CI:1.46 - 1.87), had a higher risk of CMD compared to female Swedish-born with Swedish background. The confidence interval for CMD risk showed little differences between migrant groups (1st and 2nd generation) compared to the reference group.

Conclusions:

Low-quality employment trajectories appear to be determinants of risk for CMD, having a differential impact according to background of origin and sex. We observe a higher risk for severe CMD across migrant groups, especially second-generation migrants, compared to Swedish-born with Swedish background. Further qualitative research is recommended to understand the mechanism behind the differential mental health impact of low-quality employment trajectories according to foreign background.

Key messages:

- First and second-generation migrants in low quality employment have higher risk of severe common mental disorders compared to Swedish born with Swedish background workers in low quality employment.
- Policies targeting working conditions in low-quality employment and promoting workers mental well-being are essential to reduce this higher risk for developing CMD, especially for migrant populations.

Contact: helga.urke@uib.no

Background:

School climate is recognized as important for adolescent mental wellbeing. However, there is a lack of longitudinal studies, and most research focus on school climate as an antecedent of mental wellbeing while the relation could be in the opposite direction or bidirectional. Further, no study has examined this relation with analyses that separate between- from within-person variability to properly assess intraindividual developmental processes.

Methods:

Using a random-intercept cross-lagged panel model we investigated the longitudinal reciprocal relations of perceptions of a caring school climate and mental wellbeing across three time points (T1, T2, T3) in adolescence, and if socioeconomic position (SEP) predicted perceptions of a caring school climate and mental wellbeing at each time point. The sample consisted of 1508 Norwegian adolescents (60.7% female; baseline mean age = 16.33, SD = .62).

Results:

Results showed positive cross-lagged effects at the within-person level from mental wellbeing to later perceptions of a caring school climate across all time points (T1->T2 b = .12* [.01, .22], T2->T3 b = .12* [.01, .23]), but no similar effects in the opposite direction. Positive concurrent effects from SEP were observed at one time point for mental wellbeing (T1 b = .10* [.01, .19]), and all time points for perceptions of a caring school climate (T1 b = .12* [.02, .22], T2 b = .11* [.02, .20], T3 b = .12* [.02, .22]), indicating SEP to be related to intraindividual fluctuations mainly in perceptions of a caring school climate.

Conclusions:

The findings support a unidirectional temporal relationship from mental wellbeing to perceptions of a caring school climate and underscore the importance of investigating the subject longitudinally and as a function of within-person fluctuations. From a public health view, the findings support the importance of systematic efforts to promote mental wellbeing to facilitate positive school experiences of adolescents of all social classes.

Key messages:

- The study found a unidirectional temporal relation at the within-person level in adolescents where mental wellbeing predicted perceptions of a caring school climate, but not the other way around.
- The findings underline the importance of systematic public health efforts to promote mental wellbeing as one avenue to facilitate positive school experiences of adolescents of all social.

Contact: nerbaydar@gmail.com

Aim:

Femicide is the women's murder by men for misogynistic reasons. This research aims to determine the characteristics of femicides in Turkey.

Methods:

In this cross-sectional study, 13 news sites were scanned using keywords related to femicides between 2000-2019, and 1744 cases were included. In the study, the murdered women, the perpetrators', and the femicides' characteristics were determined and the percentages, central tendency, and distribution measures were calculated.

Results:

The mean age of the murdered women was 33.2 (SD = ±13.2); 55.5% who were married or cohabitated had at least one child (Mean = 2.2±1.4), and 977 children lost their mothers due to femicide. Of the women killed, 19.1% of them filed for divorce, 10.0% of them applied to law enforcement before, and 4.5% were pregnant. Of the perpetrators, 53.1% were husbands/ex-husbands. The mean age of perpetrators was 38.3±13.4 and 10.8% had criminal records. Of the perpetrators, 12.1% had threatened the women before, and 6.2% of them had been detained. Of the femicides, 80.4% were committed in urban areas. According to the news, 34.7% of the perpetrators were in the prosecution and detention process, 25.6% were on trial, 16.2% committed suicide. Of those whose sentences have been finalized, 26.6% of them were given aggravated life imprisonment and 36.3% of them to life imprisonment. Sudden quarrels, desire for divorce, jealousy, and honor/custom were the most cited reasons. Firearms or sharps were the most frequently used weapons.

Conclusions:

Women were killed by men who were close to them. Women's desires for separation/divorce or to make their own decisions for their lives posed a threat to traditional masculinity. The fact that one out of every ten perpetrators had a criminal record in femicides showed that violence was a way of life for some men. In addition, the ease of access to firearms led to their frequent use in femicides.

Key messages:

- Improve gender equality.
- Access to firearms should prevented.

9.Q. Skills building seminar: Redistribution of ill-defined deaths: a methodological conundrum

Abstract citation ID: ckac129.618

Organised by: COST Action CA18218– European Burden of Disease Network
Chair persons: Brecht Devleesschauwer (Belgium)
Contact: Brecht.Devleesschauwer@sciensano.be

Today, several countries are conducting national burden of disease (BOD) studies, calculating Disability-Adjusted Life Years (DALYs) for a variety of diseases, injuries and risk factors. The DALY metric is composed of a morbidity component, the Years Lived with Disability (YLDs), and a mortality component, the Years of Life Lost (YLLs). The calculation of YLLs typically starts from national cause of death data, which are coded using the International Statistical Classification of Diseases and Related Health Problems (ICD). National BOD studies however often follow (a modified version of) the cause hierarchy of the Global Burden of Disease (GBD) study, which applies coarser categories, and does not contain unknown or ill-defined causes. This implies that not all ICD codes can be mapped to one specific BOD cause, giving rise to so-called ''ill-defined'' or ''garbage'' codes. To include all deaths in a national BOD study, it is therefore necessary to redistribute the ill-defined deaths to specific BOD causes. Several methodological approaches exist for redistribution of ill-defined deaths, ranging from the use of fixed redistribution proportions to advanced redistribution algorithms based on multiple cause of death data. The choice of the methodology needs to depend on the nature of the available cause of death data, and as a consequence, methodologies are typically tailored to the specific data at hand. The absence of a single best methodology, and the methodological heterogeneity across applications, has made redistribution of ill-defined deaths into a methodological conundrum. This skills building workshop will present the redistribution methods applied in different national burden of disease studies, including a discussion of their strengths and weaknesses. By providing a step-by-step presentation of how the methods have been applied, attendees will gain unique insights in the different redistribution methods currently applied.

Key messages:

- Redistribution of ill-defined deaths is an essential part of national burden of disease studies, but is methodologically challenging.
- Attendees will receive an overview of the redistribution methods applied in different national burden of disease studies, including a discussion of their strengths and weaknesses.

Redistribution down under—dealing with ill-defined deaths in the Australian Burden of Disease Study

Richard Juckes

M Dunford[1], W Ho[1], K Bishop[1], M Gourley[1], R Juckes[1]
[1]Population Health Group, Australian Institute of Health and Welfare, Canberra, Australia
Contact: richard.juckes@aihw.gov.au

Burden of disease analyses measure the healthy years of life lost due to living with and dying prematurely from disease and injury. It is now the global standard for comparable policy-relevant evidence on the impact of disease, injuries, and risks on a population. The Australian Burden of Disease Study (ABDS), undertaken by the Australian Institute of Health and Welfare, uses Australian-specific data and methods (based on the Global Burden of Disease Study, adjusted to suit the Australian context) to quantify disease burden for Australia. Despite the high quality of deaths registration data in Australia, in burden of disease analyses not all coded causes of death are considered appropriate or valid to estimate years of life lost (YLL). Therefore, these 'ill-defined deaths' are redistributed to one or more diseases on the ABDS disease list according to a more probable underlying cause of death. In the latest ABDS, almost 1 in 10 deaths in 2018 was an ill-defined death. Most of these were redistributed to other diseases using one of three methods developed for the Study:

1) direct evidence on more plausible causes of death from data linkage studies or other sources
2) redistribution algorithms based on the distribution of underlying causes of death where the ill-defined cause was recorded as an associated cause of death
3) reassignment of deaths across a specified range of target diseases according to patterns of causes of death observed in the mortality data for the ABDS disease list.

Expert advice was also received on the redistribution of deaths from septicaemia and deaths coded to ICD-10 code X59 Exposure to unspecified factor. Overall, 8.5% of the years of life lost for Australia in 2018 came from ill-defined deaths. These deaths generally followed age-specific all-cause mortality patterns. It is important to consider methods and target diseases when redistributing ill-defined deaths to appropriately quantify their contribution to disease-specific burden.

Burden of disease (BoD) studies are an established method of quantifying health loss across - and within - a population. They aim to combine the impact of living with, and dying from, various health conditions to allow for comparability of conditions in an equitable manner. A key component of this is the calculation of the loss of years of life arising from premature death (Years of Life Lost (YLL)). Most high-income nations have robust death registration systems which ensure that deaths are routinely recorded, the causes are medically certified and the age at death is accurate. However, even in these situations the recording of ill-defined death (IDD) causes remains widespread and to some extent unavoidable, in that it is not always appropriate to undertake extensive investigation to establish an exact cause of death or the cause of death recorded does not map directly to disease groupings used routinely in BoD studies. The Scottish Burden of Disease (SBoD) uses cause of death data from the National Records of Scotland. These patient-level records include one underlying cause of death and up to 10 supplementary causes of death, all coded using ICD classifications. Around 12% of these deaths do not map directly to a BoD cause group and could therefore be considered ill-defined. The SBoD study have developed a 9-step hierarchical methodology for the redistribution of ill-defined deaths, utilising uses a mix of fixed and proportional redistribution and focusses on exploiting the data recorded on the death certificate at both an individual and population level.

In this presentation we will describe the methodology used to redistribute ill-defined deaths in the Scottish study - the development, the application and the strengths and weaknesses of our approach. We will also discuss the example of COVID-19 and how competition between the underlying cause of death is likely to impact how we need to approach IDDs in the future.

Redistributing ill-defined deaths in the German Burden of Disease study BURDEN 2020

Annelene Wengler

A Wengler[1], *E von der Lippe*[1]
[1]Epidemiology and Health Monitoring, Robert Koch Institute, Berlin, Germany
Contact: wenglera@rki.de

Having valid information on mortality within a country is of great importance for public health planning. This includes knowing the causes of death (CoD) within a population. However, these data are not always suitable for Burden of Disease calculations from the start and hence, need some realignment in advance. The CoD statistics in Germany include a relatively high share (26% in 2017) of ill-defined deaths (IDD) - using the definition of the Global Burden of Disease Study. Additionally, only the underlying CoD is included in the national statistics and no multicausal data are available yet. As part of the German Burden of Disease project BURDEN 2020 we redistributed IDD to valid CoD using a process of proportional redistribution. To do so, we made use of the distribution of the valid ICD-codes in the data. In the proposed presentation, we use examples of stroke, diabetes, and heart failure to illustrate how IDD were reallocated. After redistribution, the largest increases for both women and men were seen for lower respiratory infections, diabetes mellitus, and stroke. The numbers of deaths for these causes more than doubled after redistribution. Within this project, we carried out the first comprehensive redistribution of IDD for German CoD statistics.

Information on years of life lost (YLLs) due to premature mortality is necessary to assess the fatal impact of disease, crucial for the calculation of Belgian disability-adjusted life years (DALYs). This study presents a novel method to redistribute cause of death data. Belgian cause of death data are obtained from Statistics Belgium (Statbel). After mapping the ICD-10 codes defining the underlying cause of death to the GBD cause list, we redistributed ill-defined deaths (IDDs) to specific causes using a four-step probabilistic redistribution process developed to fit the Belgian context: internal redistribution, redistribution using predefined ICD codes, redistribution using multiple causes of death data, and redistribution to all causes. Finally, we used the GBD 2019 standard life expectancy table to calculate the years of life lost at age of death. In Belgium, between 2004 and 2018, IDDs increased from 31% to 34% of all deaths, reflecting increases in the average age at death. The majority was redistributed using predefined ICD codes (13%), followed by the redistribution using multiple causes of death data (10-11%). The total number of YLLs decreased from 1.83 to 1.77 million. In 2018, the top causes of YLLs were ischemic heart disease and lung cancer with a share of 8.4% each, followed by dementia and cerebrovascular disease with a share of 5.5% each. All results are stratified by age, sex, region, and year, and can be explored via an online tool: https://burden.sciensano.be/shiny/mortality.

10.A. Workshop: Integrated primary care: reform experiences from Estonia, Poland, and Slovenia

Abstract citation ID: ckac129.623

Organised by: European Observatory on Health Systems and Policies
Chair persons: Ewout Van Ginneken (Germany), Katherine Polin (Germany)
Contact: katherine.polin@gmail.com

The rising burden of multiple chronic diseases requires countries to change the reactive approach of their health systems, originally designed to cure acute illness, to a proactive approach that scales up preventive interventions and integrates cure (health care) and care (long term care and social care). This requires a central coordination role for primary health care (PHC). PHC is the foundation for delivering health services to the population. It mainly encompasses the first level of professional health care and includes PHC practitioners and other health workers. Together, PHC providers can satisfy most curative and preventative health needs, ideally providing integrated services. In this way, PHC has the potential to agilely respond to population health needs; help individuals navigate their way to good health and stay healthy; prevent disease by identifying risk factors; and manage chronic disease outside of hospital settings. Yet PHC in many countries is not designed to fully realize these promises and ongoing reforms aim to strengthen it. Meanwhile, this potential was on display in several countries during the COVID-19 pandemic, when primary care doctors played a key role in making an early diagnosis; helping vulnerable people cope with their anxiety about the virus; reducing the demand for hospital services; and delivering vaccinations-all while reaching out to vulnerable patients and maintaining access to essential (non-COVID) services for the wider population using new in-person protocols or new digital solutions. This workshop will update the audience on recent PHC reforms across the EU and provide insights from three key examples-Estonia, Poland, and Slovenia. An introductory presentation sets the stage by putting PHC reforms in a wider context of reforms introduced across the 31 countries of the Health Systems and Policy Monitor network of the European Observatory on Health Systems and Policies between 2018 and 2021. A second presentation describes how Estonia has introduced a series of PHC reforms over time and used financial incentives to encourage multidisciplinary care. A third presentation looks to Poland, which from mid-2018 through 2021 piloted a multi-professional model of PHC organization in around 40 PHC practices, with an emphasis on care coordination and disease prevention. A final presentation highlights Slovenia, where a multidisciplinary, community-based, prevention-oriented service delivery model is being expanded to play a larger role in the prevention and management of chronic diseases as well as the country's COVID-19 response. The workshop concludes with an audience discussion on lessons learned from the three case studies and potential implications for other countries.

Key messages:

- Strengthening primary health care is a key priority of many countries as they seek to improve integration of care.
- Implementation of primary care reforms in shaped by the legacy of care delivery and requires a strong workforce, ongoing financial support, sustained policy focus, and collaborative governance.

Trends in health reforms in the Health System and Policies Monitor network: increasing interaction of primary health care and care coordination

Katherine Polin

K Polin[1,2], *W Quentin*[1,2]
[1]Department of Health Care Management, Technical University Berlin, Berlin, Germany
[2]European Observatory on Health Systems and Policies, Technical University Berlin, Berlin, Germany
Contact: katherine.polin@gmail.com

Since 2018, the Health System and Policy Monitor (HSPM) network of the European Observatory on Health Systems and Policies has tracked health reform activity in its countries. Top three reforms are identified by national experts yearly and classified across 11 policy clusters. Efforts inform a standardized overview of healthcare development. 337 reforms have been assessed for 31 (mainly EU) countries over 4 years, with clear trends like the converging of PHC and care coordination. Main reform areas were primary/ambulatory care, governance, and hospital care (2018-2019); coordination, governance, and digital health (2020); and care coordination, governance, and insurance coverage/resource generation (2021). For PHC, this suggests a shift from leveraging innovations to support existing delivery mechanisms to transforming PHC. Some PHC reforms in 2018-2019 introduced elements of integrated care, but more focused narrowly on specific levers, e.g., gatekeeping. Early care coordination reforms focused on certain patient groups or care delivery across the system. Separately, PHC and care coordination have long been reform priorities. Since 2020, they are increasingly linked to one another, and to multidisciplinary care. This suggests a recognition that multidisciplinary processes/staffing are key to realizing the promises of PHC-to coordinate the care of patients and ensure comprehensive and continuous care over time for most health needs. This vision is underpinned by the UN SDGs and COVID-19, which highlighted the need for health systems to be set up for and with the resources to respond to crises while maintaining core functions. The overview of HSPM health reforms identifies reform trends and opportunities for cross-country learning. More research is needed for policymakers to benefit fully from reform experiences abroad. Case studies with in-depth analysis of reform design and implementation processes can help inspire or support future health reforms elsewhere.

Estonia has a historical legacy of large hospital networks and municipality-owned specialist clinics, with a low emphasis on primary health care (PHC). Since the 1990s, a transition towards PHC has occurred, delivering PHC in family physician practices rather than in specialist clinics. The transition has been underpinned by a series of comprehensive healthcare system reforms starting in the late 1990s. The most recent reforms, although lacking a legal basis, have been accompanied by financial incentives including EU structural funds to encourage change. These financial incentives were designed to improve quality of care, encourage working in remote areas, and more. A key focus of PHC reforms has been an emphasis on multidisciplinary care, and the reforms have aimed at increasing the involvement of home nurses, midwives, and physiotherapists in PHC. The reforms have also prioritized PHC centres, with multiple practicing physicians, over single physician practices. Although EU structural funds have supported building the infrastructure for expanded scope of services at PHC level, the uncertainty of long-term funding of expanded services remained a key challenge limiting the success of the reform. Further, the supply of family physicians will be problematic in the future, as the number of permanently vacant positions has quadrupled in the last five years and almost half are 60 years of age or older. As the PHC reform process in Estonia continues until today, it can serve as a case study for other countries interested in strengthening their PHC systems.

Poland, like many other former eastern bloc countries, inherited a health system dominated by narrow medical specialties, a large number of hospital beds and relatively weak primary health care (PHC). Since early 1990s, efforts have been made to strengthen the role of PHC, starting with the introduction of specialization training in family medicine. With privatization of PHC practices the standard of PHC care has improved. However, national audits have repeatedly found PHC to still be inadequate, with the key weaknesses including shortages of family medicine specialists, insufficient provision of preventive services, and limited use of diagnostics, which led to inappropriate referrals and long waiting times for specialist consultations. Between mid-2018 and the end of 2021, a new model of PHC organization was piloted in around 40 PHC practices across Poland that met the model's requirements. The pilot, supported by the World Bank, put much emphasis on health promotion and disease prevention by including health educators and dieticians in PHC teams and by introducing periodic check-ups. It also aimed to reduce referrals to specialist care by allowing PHC doctors to order extensive diagnostic and laboratory tests and, if needed, consult with a range of cooperating specialists. It also sought to increase the role of PHC doctors in the management of chronic conditions by introducing disease management programmes (DMPs) for 11 most prevalent conditions. PHC teams were made responsible for coordinating patients' care pathways, including post-hospital treatment, and a new role of care coordinator was introduced to that end. After the pilot was concluded, all PHC practices were mandated to hire care coordinators. Implementation of other solutions tested in the pilot remains uncertain, mainly due to the lack of financial and human resources, and the dominance of small PHC practices that struggle to meet the ambitious requirements set out in the new model.

[4]Health Promotion and Prevention, Ministry of Health, Ljubljana, Slovenia
Contact: Pia.Vracko@nijz.si

Primary health care (PHC) in Slovenia is delivered mainly by a network of 63 public community-based primary health care centres (CPHCs), serving as entry points to the health system. Here, multidisciplinary teams provide an array of preventative, diagnostic, therapeutic, palliative, and health promotion services under one roof. Since 2011, several reforms in PHC highlight integrated care. A national scale-up of Family Medicine Practices is underway, where all family medicine teams include a 0.5 FTE registered nurse to improve prevention, early diagnosis and care coordination of chronic patients. Health promotion centers (HPCs) are being introduced in CPHCs to support people in healthy lifestyle, with currently 28 HPCs managed by CPHCs and supported operationally by the National Institute of Public Health. New mental health centers facilitate access to comprehensive mental health care. In 2020, dedicated temporary COVID-19 units in CPHCs played a key role in treating mild/moderate cases and shielding hospitals from overburden. Regarding implementation, pilots have been critical to creating a strong evidence base to enable sustainable (sometimes external) financing, while innovations capitalize on existing links between Slovenia's primary care and public health functions and the Ministry of Health for governance and the flexibility of the multidisciplinary, multiple-practice care model represented by CPHCs. Though this has eased their initial introduction into existing structures, challenges remain. These include dissatisfaction among family physicians due to high administrative burden and an outdated CPHC governance model that limits managers' authority as well as workforce shortages in public health and primary care. Financial incentives, task shifting, and adjustments to education and training have been used to mitigate these issues. Slovenia's experience may serve as a case study for countries interested in improving their primary healthcare services.

10.B. Round table: Shelter in place: lessons from policy making during the COVID-19 pandemic in three countries

Abstract citation ID: ckac129.628

Organised by: University of Augsburg (Germany)
Chair persons: Verina Wild (Germany), Angus Dawson (Australia)
Contact: angus.dawson@sydney.edu.au

The key aims of the workshop are: (1) to engage in early discussion of the findings of this timely project and gain critical feedback from the EUPHA audience, (2) discuss and debate with the audience comparable and contrasting experiences from across Europe. This workshop will outline and discuss results from a project, funded by the Volkswagen Foundation, about the experience of decision-making and the implementation of non-pharmaceutical public health measures (such as social distancing, school closures, lockdowns etc) in the early stage of the response to COVID-19 (the pre-vaccine phase) in three countries (Germany, Israel and Australia). The project combines both empirical research in the form of qualitative interviews with key stakeholders as well as theoretical and conceptual ethical analysis. These methods are integrated to propose a comprehensive ethics assessment building upon the resources of public health ethics to improve the capacity for ethically sensitive decision-making in the future. Key objectives will be: (1) to record some of the relevant values that are explicitly appealed to by stakeholders, (2) to record any implicit values visible in the decision-making process, (3) discuss some of the value conflicts that arose during decision-making, (4) tentatively suggest lessons to be taken into account in future pandemic policy making. The format of this workshop will be a roundtable with a series of short (5 minute) presentations from five panellists, all part of the project, as set out below (25 mins). The chair will then invite questions on matters of clarification arising (max. 10 mins) before inviting members of the audience to provide short comments documenting and reflecting upon their similar or contrasting experiences in their countries (20 mins) before a brief conclusion (5 mins).

Key messages:

- Ethical values are implicitly or explicitly used to justify proposed and actual policy choices, even during a pandemic. Discussion of such values is useful for refinement of future pandemic policy.
- It was common to assume that everyone had the same access to information and ability to respond etc. However, a great, more explicit focus on disadvantaged or vulnerable groups would be beneficial.

10.C. Round table: Is public health just science?

Abstract citation ID: ckac129.630

Organised by: UK Faculty of Public Health, EUPHA-ETH, EUPHA-PHPP
Chair persons: Farhang Tahzib (EUPHA-ETH)
Contact: farhang.tahzib@gmail.com

Politicians and policy makers often assert that they are following the science and the evidence in their decision making. Public health is proud of its rigorous scientific and evidence-based approaches and providing the numbers and facts. It is clear though that such numbers and facts, as during the pandemic, have resulted in diverse policies in different countries. Some commentators have noted that public health has lost its way, arguing that its leadership is failing, lacks courage and not sufficiently concerned with issues about social reform and political accountability and change. Is providing facts and the science sufficient to fulfil our mandate and obligations in public health? What should be our role in advocacy and engagement in politics and policy-making to promote and protect the public's health and tackle health inequalities? The purpose of the roundtable is to explore questions of whether public health is ''just science'': is it built merely on a scientific skillset; or is it about justice-promoting science? This question goes to the heart of public health's mandate, with direct implications for public health practice. The questions will be considered largely from the perspective and evidence from the Covid pandemic. There will be presentations by senior distinguished academics and public health practitioners and leaders who have been researching and advising policy makers on wide range of public health issues. They will share their research and experience in particular from membership of the UK Independent Scientific Advisory Group (Indie_ SAGE) for the pandemic and on the Pandemic Ethics Accelerator, as well as other groups advising the government and public organisations on the analysis and implementation of policy options during the pandemic. This will be followed by reflections and discussion with the workshop participants and their reflections and insights on these critical questions.

Key messages:

- Public health is not merely a technical, scientific discipline; it incorporates norms and values, and operates in a political environment where value-judgments are fundamental to decision making.
- Public health practitioners and leaders need to consider advocacy and engagement, and the moral foundations of public health, as key to their mandate and professional obligations.

Contact: mpapadakaki@hmu.gr

Globally, injuries cause over 4.3 million deaths per year with incalculable costs for the health, legal, and social systems. Burden of disease analyses are being conducted across the world in order to map the health status of injured population, run comparisons and enable prioritization of preventive and interventional measures. Metrics of injury burden are therefore important indicators of population health that are increasingly being incorporated into national and international health information systems. To prevent injuries and their disabling health consequences, and to effectively reduce injury burden, it is essential to provide policy makers and health system planners with detailed measurements and assessments that allow them to focus resources where they are most needed and areas where more targeted policy attention might be required. However, efforts to fully understand the health outcomes of trauma patients remain inconsistent and insufficient, specifically for certain injury populations and health outcome domains. A wide variety of measures are available to track outcomes after injury in various health domains. Reaching consensus is an important step in benchmarking of outcomes across institutions and injury types to improve quality and advance the field of injury care. Modern, validated measures that are feasible and usable in both research and clinical contexts are needed to facilitate the improvement of quality and comparability of research. The workshop aims to discuss trends and variation of injury burden, which is critical to health system planning. The high human and societal costs as well as inequalities of injury mortality and burden will be highlighted based on comparisons with long-term trends. The workshop will discuss the latest developments in injury severity classification and disability measurement. The most efficient measures to calculate the valid burden of injuries will be presented and comparative measurements across EU countries will be promoted. Limitations of injury classifications and factors introducing uncertainty and potential bias in estimation of disability, will be identified. The workshop will contribute to the identification of evidence-informed tools and measurements of injury burden.

Key messages:

- Some injury outcomes are responsible for huge individual and societal burden but are still difficult to measure.
- Multiple measures are developed to assess severity and outcomes: e.g. AIS/ ISS/New ISS/ ICD-10. Efficient prevention and quality care requires validated and easy to use measures.

Abstract citation ID: ckac129.632
Severity in a Norwegian hospitalized injury material (N = 177,663) by two severity measures: threat-to-life and threat of disability

Johan Lund

C Madsen[1], *J Lund*[1]
[1]National Public Health Institute, Oslo, Norway
Contact: johan9lund@gmail.com

We conducted a registry-based cohort study of all individuals aged 25-64 years residing in Norway by 1st of January 2008 (N = 2,535,213). This cohort was followed from 2008 through 2014 using inpatient registrations for acute hospitalizations due to all-cause injuries, getting 177,663 cases of hospitalized persons (incidence rate of new cases: 102.1 pr 10,000 person-years at risk). We derived two measures of severity: threat-to-life using the International Classification of Disease-based Injury Severity Score (ICISS) (Stephenson et al 2004; Gedeborg et al 2014), and threat of disability using long-term disability weights (DW) from the Injury-VIBES project (Gabbe et al 2014), also based on the ICD-codes. We found the following distributions of the hospitalized persons (N = 177,663): 1) Threat to life (ICISS): High threat to life: 4,186 (2.4 %); Lower threat to life: 173,477 (97.6%). 2) Threat of disability (Injury Vibes DW): High probability of long-term disability (DW-score < 0.807): 36,573 (20,6 %); Medium probability of long-term disability (DW-score 0.807-0.947): 97,590 (54,9 %); low probability of long-term disability (DW-score >0.947): 43,530 (24.5 %). Correlation between ICISS-score and the Injury Vibes disability weight score was moderate ($r = 0.418$, $p < 0.001$). The presentation will end up in a discussion on which of these two severity measures could be used for comparing burden of injuries across countries.

Methodological considerations when assessing the Burden of Disease due to injuries

Robby De Pauw

R De Pauw[1]
[1]Sciensano, Brussels, Belgium
Contact: Robby.DePauw@sciensano.be

Measuring the burden of disease due to injury is a similar process compared to the disease burden. However, burden calculations for injuries impose an extra complexity for the non-fatal burden, as it is important to consider both the ‘cause’ and the ‘nature’ of the injury. Cause of injury (e.g., road injuries, falls, drowning) have historically been used for assigning cause of death as opposed to the ‘nature’ of injury, which more directly specifies the pathology that resulted in death or disability. However, precisely estimating the disability as a result of an injury requires a mapping of, for example, individuals that have suffered a fracture hip (‘nature’ of the injury) because of falling (‘cause’ of the injury). This process would require a matrix of the nature-cause relation of injuries, which are only scarcely available, because they required dual-coded data registers. The presentation will zoom into the differences between disease and injury estimations and will appraise the methodological considerations for the estimations of injury-related burden of disease estimates.

Quantification the cost of injuries

Juanita Haagsma

J Haagsma[1]
[1]Department of Public Health, Erasmus MC, Rotterdam, Netherlands
Contact: j.haagsma@erasmusmc.nl

The population health impact of injuries can be measured with a range of metrics. ranging from incidence and mortality to disability adjusted life years and cost-of-illness. Cost of illness gives insight into the societal burden of injury, and factors and characteristics that are associated with higher costs. Assessment of the economic burden of health care is important, because this information allows us to understand main cost drivers of health care and to monitor the impact of injury prevention and interventions. However, comparability of cost-of-illness is hampered by differences in included and excluded health care resources, the perspective and time horizon that is applied in the cost-of-illness studies and inclusion or exclusion of productivity costs. Productivity costs refer to that are caused by work absence. In our injury cost of injuries studies, we found that, among working age injury patients, productivity costs are a significant contributor to the total costs related to injury. We also found that there is a lot of variety in the health care and productivity costs in injury patients, and these costs are not solely dependent on injury severity. In this presentation, we will discuss data sources that can be used to assess the cost of illness of injuries, methodological choices that can be made and risk factors for high health care and high productivity costs.

10.E. Round table: Climate emergency, health and equity education: policy and practice recommendations for Europe

Abstract citation ID: ckac129.635

Organised by: ASPHER, Ecorys (Netherlands), EUPHA-ENV
Chair persons: Rana Orhan (ASPHER), Marija Jevtic (EUPHA-ENV)
Contact: rana.orhan@aspher.org

Climate change continues to be the biggest challenge of the 21st century, with profound and growing negative consequences on public health. While the public health and wider healthcare sector faces the health risks and consequences of climate change, it is also an important actor as producer of carbon footprint. There is therefore a need for public health and healthcare professionals to be prepared to address the climate emergency and its inequitable impacts across vulnerable populations. Climate resilience and climate-health-equity and political literacy should be built to enable public health and healthcare professionals to gain a deeper understanding of the needed changes and communicate the direct and indirect environmental impact of our health system, institutions and daily lives. This round table discussion will be framed by the joint statement ''Moving towards the right to 'health for all' by training the public health workforce on climate change and health'' issued by a network of public health stakeholders under the EU Health Policy Platform. Endorsed by more than 75 organisations from the global, European and national level, the statement calls actors in public health to bring climate change and health concerns to the forefront of the debates. During the round table, 4 panellists will touch on evidence, solutions and guidance to address the climate emergency from the different perspectives of ASPHER, EuroHealthNet, Ecorys and EHESP French School of Public Health. The added value of the round table is conveying the different views of the panellists, bringing together European CSOs and partnerships of public health authorities, academia and a research-based consultancy company, and laying out possible ways of how working together could steer the EU and national multidisciplinary policy and decision-making on the intersection of climate, health, social justice, and education. After setting the need for action, the round table will seek to produce recommendations from public health actors to address the climate emergency, bringing the dialogue parallel to COP27. This workshop will explore how different actors from inside and outside the public health domain can contribute to climate mitigation and adaptation actions. The discussion will cover: investing in climate-health training for public health and healthcare professionals; investing in public health research; designing and monitoring mitigation programmes (e.g., sustainable and resilience-enhancing healthcare policies); building climate-health-equity literacy; and providing space for dialogue for those communities who will be most harmed by an inadequate public health response. From a policy perspective, the workshop will help prepare recommendations for actions related to COP27 and will reflect on strategic processes taking place at the European level (including the Conference on the Future of Europe, the European Health Union, the Strategic Foresight, and the Recovery and Resilience Plans).

Key messages:

- Climate change poses an immediate threat to planetary health, and the co-benefits of climate change mitigation and adaptation actions to health and social justice should be highlighted in policies.
- The workshop provides public health actors the opportunity to produce recommended actions from public health actors to address the climate emergency at the European and national level.

Speakers/Panellists:

10.F. Pitch presentations: Communicating public health messages

Abstract citation ID: ckac129.636

Storytelling to communicate public health messages during the COVID-19 pandemic; A systematic review

Priyamvada Paudyal

P Paudyal[1], *S Ozkosar*[1]
[1]Primary Care and Public Health, Brighton and Sussex Medical School, Brighton, UK
Contact: p.paudyal@bsms.ac.uk

Background:

Storytelling has been increasingly used in public health to disseminate health messages in a format that is more understandable and engaging. This project aims to summarize the findings from the studies that used storytelling approach for conveying health messages during the COVID-19 pandemic.

Methods:

The protocol for this systematic review is registered in PROSPERO (CRD42021281957). Studies were identified via electronic databases; EMBASE, Ovid MEDLINE and EBSCO using variations of the search terms 'COVID-19' and 'storytelling'. Studies that used storytelling interventions in COVID-19 and published in English after 2020 were eligible for inclusion. Data from eligible full text article was collated in a summary table. Quality of included studies were assessed using Joanna Briggs Institute Checklists.

Results:

Of the 4562 studies identified in the electronic search, 11 were eligible for inclusion. Participant numbers in each study varied from 14 to 3746. Eight of the 11 studies included were set online, looking at virtual forms of storytelling. This included online surveys and social media campaigns within hospitals, and online meetings with patients at home. Overall, studies showed that storytelling intervention increased engagement in health communication and has the potential to be used as an effective public health communication tool, for changing health behaviours. Studies were small, six out of 11 were of poor quality.

Conclusions:

Storytelling is a widely accepted intervention and has the potential to positively impact communication, empathy and health behaviour. As there is no standardized definition of storytelling, and studies into this area are new, it is important to continually re-evaluate data to enhance understanding and provide standardized guidelines for storytelling in the COVID-19 context.

Key messages:

- Storytelling has been increasingly used in public health to disseminate health messages.
- Storytelling has the potential to positively impact communication, empathy and health behaviour.

Abstract citation ID: ckac129.637
Effectiveness of a health literacy intervention targeting kidney patients and professionals

Marco Boonstra

MD Boonstra[1], MS Gurgel do Amaral[1], GJ Navis[2], ME Stegmann[3], R Westerhuis[2], AF de Winter[1], SA Reijneveld[1]

[1]Department of Health Sciences, University Medical Center Groningen, Groningen, Netherlands

[2]Department of Nephrology, University Medical Center Groningen, Groningen, Netherlands

[3]Department of General Practice and Elderly Cawre, University Medical Center Groningen, Groningen, Netherlands

Contact: m.d.boonstra@umcg.nl

Background:

Chronic kidney disease (CKD) patients with limited health literacy (LHL) experience a faster kidney decline. To counteract this, we developed Grip on your Kidneys (GoyK). This intervention targets patients' communication and self-management. It trains health care professionals (HCPs) competences to support patients with LHL. This study aims to test the effectiveness of GoyK on patients' health and self-management, HCPs' communication competences, and the quality of consultations.

Methods:

A clustered and non-blinded quasi-experimental study was conducted, including 161 patients with mild to severe CKD and 48 HCPs from Dutch general practices and nephrology clinics. Patients (n = 77) and HCPs (n = 30) in the intervention group received GoyK. In the control group, patients (n = 76) had routine visits with HCPs (n = 19). Between March 2021 and June 2022, data were collected with questionnaires and from patient records at baseline (T0), 4 months (T1) and 9 months (T2). Primary outcomes were patients' self-management and HCPs' use of health literacy communication strategies.

Preliminary results:

At T1, the intervention improved the days per week patients exercised (B = 1.00, 95% confidence interval, CI = 0.35-1.65, P = 0.003), and Likert-scale reported (1-4) fluid intake (B = 0.37, CI = 0.10-0.63, p = 0.006). The intervention had a positive effect on several outcomes related to how patients perceived the consultation quality, and improved the reported use of communication strategies by HCPs at T1 (B = 0.68, CI = 0.35-1.01, p = <0.001). We found no effects on other patient outcomes, like activation for self-management or salt intake.

Conclusions:

Our health literacy intervention, targeting CKD patients with LHL and HCPs, improved lifestyle behaviors of patients and the quality of consultations. A further strengthening of other self-management behaviors and on HCPs' competences is needed, also to reach sustainable effects in the care for patients with LHL.

Key messages:

- A health literacy intervention, targeting patients and professionals simultaneously, improved the patients' self-management and care consultations.
- Training of HCPs improved their competences to support patients with LHL, and care organizations and studies need to implement education on this topic.

Abstract citation ID: ckac129.638
The risk and safety profile of electronic nicotine delivery systems (ENDS): An umbrella review

Taghrid Asfar

T Asfar[1], W Maziak[2]

[1]Public Health Sciences, University of Miami, Miller School of Medicine, Coral Gables, USA

[2]Department of Epidemiology, Florida International University, Miami, USA

Contact: tasfar@med.miami.edu

Background:

Balancing electronic nicotine delivery systems (ENDS) health communication between limiting the harm for new users while offering current smokers the benefits of reduced-risk products is challenging. This umbrella review aims to summarize the evidence about ENDS risk and safety health profile to inform ENDS health communication strategies.

Methods:

Six databases were searched for systematic reviews presenting evidence on ENDS health effects. Ninety reviews divided into 5 categories were included: toxicity = 20, health effects = 40, smoking cessation = 24, transition to combustible cigarettes (CCs) = 13, and industry claims = 4. Findings were summarized narratively. Meta-analyses were conducted when appropriate. Quality assessment was conducted using the Measurement Tool to Assess Systematic Reviews. The Institute of Medicine's Levels of Evidence Framework was used to classify the evidence into high-level, moderate, limited-suggestive, and limited-not-conclusive.

Results:

We found high-level evidence that ENDS exposes users to toxic substances; increases the risk of asthma; leads to nicotine dependence; causes serious injuries due to explosion or poisoning; increases smoking cessation in clinical trials but not in observational studies; increases CCs initiation; and exposure to ENDS marketing increases its use/intention-to-use. Evidence was moderate for ENDS association with mental health and substance use, and limited-not-conclusive for its association with cardiovascular, cancer, ear, ocular, and oral diseases, and pregnancy outcomes.

Conclusions:

Currently, ENDS communication can focus on high-level evidence related to ENDS association with toxicity, nicotine addiction, respiratory disease, ENDS-specific harm (explosion, poisoning), and anti-ENDS industry sentiment. Further research is needed to assess the full spectrum of ENDS health profiles.

Key messages:

- Further research is needed to establish the risk and safety health profile of ENDS with consideration of the wide variety of ENDS, their frequency of use, and different segments of the population.
- More prospective cohort studies that take place over longer time periods and with larger sample sizes are necessary to gauge accurately the short- and long-term health-related risks of ENDS.

Abstract citation ID: ckac129.639
Improving the quality of translation for patients with language barriers

Rebecca Newell

R Newell[1], S George[1], M Patel[1], H Dawe[1], M Roelas[1], F Wedmore[1], M Morris[1]
[1]Acute Medicine, Barts Health NHS Trust, London, UK
Contact: rebecca.newell1@nhs.net

Background:

Patients with language barriers have worse health outcomes. To promote equitable care, efforts must be made to ensure effective communication with patients, including providing professional translation. In a busy, overstretched health service this can be difficult to achieve. Language translators can reduce barriers, improve safety and ensure impartiality.

Description of the Problem:

Aims - To understand the quality of translation and explore interventions that could improve this in a busy diverse hospital in East London.

Methods:

A quality improvement project in the Medical Admissions Unit of the Royal London Hospital was completed over two years. Patients with language barriers were identified, methods of translation were analysed and interventions to improve access to independent translation were introduced.

Results:

Cycle 1- All medical admissions over a two-week period were analysed. 36 patients had documented evidence of a language barrier with 7 (19.4%) having independent professional translation. 20 (55.6%) patients had family members providing translation, for 4 patients limited English was used and previous documentation was used for 3 patients.

Cycle 2- Posters and information leaflets were disseminated regarding how to access translation services. There was no improvement in the types of translation used. Only 1 patient had impartial professional translation, out of 43 patients identified.

Cycle 3- Advocates (Bengali speaking professional translators) were made available on the ward twice a week. Results showed no significant improvement, with only 6 (10%) identified having impartial professional translation. However staff and patient feedback has been positive.

Lessons:

Impartial professional translation is essential in reducing barriers and delivering equitable health care. This can be difficult to achieve in busy healthcare services. Education alone is not enough. Good accessibility to translation services is paramount in promoting usage.

Key messages:

- Healthcare services often fall short of providing impartial professional translation.
- Education alone is not enough. Good accessibility to translation services is paramount in promoting usage.

Abstract citation ID: ckac129.640
Health literacy, consciousness, and locus of control in relation to vaccine hesitancy and refusal

Alexandros Heraclides

K Kouvari[1], A Hadjikou[1], I Heraclidou[2], A Heraclides[1]
[1]Health Sciences, European University Cyprus, Nicosia, Cyprus
[2]Psychology, University of Cyprus, Nicosia, Cyprus
Contact: a.heraclides@euc.ac.cy

Background:

About 35% of adult Europeans remain not fully vaccinated against COVID-19. Health literacy (HL), health consciousness (HC), and health locus of control (HLC) have been linked to different health behaviors, yet their role in COVID-19 vaccination uptake remains unclear. Here, we report preliminary findings from a cross-sectional survey conducted in Greece and Cyprus, aiming to elucidate the aforementioned associations.

Methods:

Participant recruitment for the current analysis took place from January to June 2022, following proportional quota sampling. The current sample comprises 190 participants, with full information on COVID-19 vaccine hesitancy (composite scale outcome) and refusal (binary outcome), as well as HL (European Health Literacy Survey Questionnaire-Q16), HC (Health Consciousness Scale-G), and HLC (Multidimensional Health Locus of Control Form B). Linear and logistic regression analyses were used to determine associations between the aforementioned factors, using the standardized versions of the independent variables.

Results:

After adjusting for sociodemographic factors and other predictors of vaccination status, HL (β, 95% CI: -2.56, -3.76; -1.36), 'internal' HLC (-2.76, -3.79; -1.73) and 'health professionals' HLC (-2.64, -3.66; -1.63) were strongly and negatively associated with vaccine hesitancy, while HC showed a weaker association in the same direction (-1.46, -2.58; -0.35). In contrast, 'chance' HLC was strongly and positively associated with vaccine hesitancy (4.40, 3.37; 5.43). Similar results were detected when vaccine refusal was used as a binary outcome.

Conclusions:

Health literacy and locus of control and to a lesser extent health consciousness, are independent predictors of COVID-19 vaccine hesitancy and refusal. Increasing vaccination uptake via programs aiming at enhancing health literacy and shifting health locus of control, can have a significant impact on COVID-19 pandemic management internationally.

Key messages:

- Health literacy, locus of control and to a lesser extent consciousness, are novel predictors of vaccine hesitancy and refusal in two Eastern Mediterranean European populations.
- Increasing health literacy and shifting health locus of control could render programs aiming to increase COVID-19 vaccine uptake more targeted and effective, internationally.

Abstract citation ID: ckac129.641
Designing a bilingual health prevention website: challenges of using a participatory approach

Johann Cailhol

S Jaroof[2], H Cordel[1], B Badoro[1], B Felix[4], M Rolland[5], C Bourovali-Zade[1], J Cailhol[1,2,3]
[1]Infectious Diseases Department, Paris Seine Saint Denis University Hospital, Bobigny, France
[2]Laboratoire Education et Promotion de la Sant, Sorbonne Paris Nord University, Bobigny, France
[3]Institut Convergences Migrations, ICM, Aubervilliers, France
[4]Centre régional de Prévention en Santé, CRIPS, Pantin, France
[5]Paris, France
Contact: johann.cailhol@aphp.fr

Issue/problem:

For some migrants, specific health information tools are needed in order to counterbalance lack of access to information both in countries of origin and of destination.

Description of the problem:

Migrants originating from Pakistan and newly arrived in France are highly affected by for instance hepatitis C. Many of them have a low level of litteracy, including health litteracy. We decided to create a bilingual Urdu/French website, to provide information on hepatitis C, but also on sexual and mental health. The project was conceptualized in a participary manner, in order to fit the targeted population needs. The project started in June 2021 and the website is expected to be launched by September 2022. We report here some of the key challenges which emerged when working with such hard-to-reach community.

Results:

The participatory approach involving community members consisted of 3 steps. In step 1, we confirmed content needs, and assessed preferences in terms of type of media to be used and media styles. About 30 themes were prioritized and the preferred media was video with formal style. After writing scripts, we organized focus-groups discussions to create culturally-appropriate messages. A third and last step will be the selection of titles and keywords for internet search, after shooting videos.

Lessons:

Despite working closely with a Pakistani cultural association and urdu-speaking health professionnals, recruitment of community members for participating in the website design happened to be extremely difficult. Despite initial enthusiasm, interests in the project tended to decrease according to sometimes hidden motivations. Focus groups dynamics were at times affected by significant differences in social situations between participants. Despite these challenges, the participatory process allowed us to reshape part of the content according to the community's communications codes, in order to enhance the efficiency of the messages.

Key messages:

- Working with socially disadvantaged community members is crucial in order to reduce social inequalities in health.
- However, caution is needed to anticipate and decrease unfulfilled expectations.

Abstract citation ID: ckac129.642
A novel stream of collaborative National portals to enhance preparedness and informed choices

Fabrizio Carinci

F Carinci[1,2], *C Vicario*[1], *N Zamperini*[3], *F La Valle*[1], *L Rocchi*[1], *G Veltro*[1], *G Siccardi*[1], *D Mantoan*[1]
[1]Information and Communication Technologies, Italian National Agency for Regional Health Services, Rome, Italy
[2]Department of Statistical Sciences, University of Bologna, Bologna, Italy
[3]Gnoti Lab srl, Rome, Italy
Contact: fabrizio.carinci@unibo.it

Issue/problem:

AGENAS supports the implementation of health policies in direct collaboration with Italian Regions and Autonomous Provinces. To improve public reporting, we aimed to complement the production of technical reports with new forms of timely communication, using National Portals.

Description of the problem:

Between October-December 2020, we designed and implemented the Covid-19 National Portal, including a suite of targeted indicators, fully automated via ad hoc scripts written in php and R on top of a relational database using internal and external data sources. Targeted information was widely communicated and continuously updated. Dedicated sections on forecasting and resilience were delivered in collaboration with specialised academic institutions. In 2021, we deployed the Portal for the Transparency of Health Services, broadly oriented towards health issues, the location of services and performance indicators.

Results:

Pre-post comparisons of web analytics for Jan-Apr 2020-2022 showed clear advantages of Covid-19 Portal. By Apr 2020, Italy had introduced national lockdown, while AGENAS covered the topic traditionally, recording 48,122 users overall, with daily peaks below 5,000 sessions. In 2021-2022, the number of users skyrocketed at 436,280, with daily peaks of 100,000 sessions, and 421,123 respectively, with daily peaks of 150,000 sessions. Visits to the Transparency Portal were considerably more limited.

Lessons:

To be widely used, public health information needs to be relevant (responding to personal need close to home), understandable, accurate and timely. National Portals can gain efficiency through the mediation of search engines, enhanced by: targeted naming (url), coherent semantic perimeter (third level domain in a highly referenced institutional website), continuous updating, and impact factor (linked by authoritative websites). The Transparency Portal will take stock of these lessons to succeed in a new funded program of NextGenerationEU.

Key messages:

- Relevant, understandable, accurate and timely dissemination for different types of audience may be effectively organised through National Portals.
- Productive collaboration between health specialists and communication experts can enhance usability and actionability of National Portals for public health.

10.G. Oral presentations: Health information and infodemic management

Abstract citation ID: ckac129.643
Semi-Automatic Knowledge Extraction from COVID-19 Scientific Literature: the COKE Project

Davide Golinelli

D Golinelli[1,2], *AG Nuzzolese*[3], *F Sanmarchi*[1], *L Bulla*[4], *M Mongiovì*[4], *A Gangemi*[3], *P Rucci*[1]
[1]DIBINEM, Department of Biomedical and Neuromotor Science, Bologna, Italy
[2]Research and Policy Unit, AUSL Romagna, Ravenna, Italy
[3]STLab, (ISTC)-CNR, Rome, Italy
[4]STLab, (ISTC)-CNR, Catania, Italy
Contact: davidegolinelli@gmail.com

Background:

The COVID-19 pandemic highlighted the importance of rapidly updating scientific information. However, the guidelines' drafting process is highly time- and resource-consuming. The COKE Project aims to accelerate and streamline the extraction and synthesis of scientific evidence. To do so, the Project used deep learning to implement a semi-automated system that enhances the systematic literature review processes. We aim to show some preliminary results on the automatic classification of abstract sentences in papers related to COVID-19.

Methods:

The tool is based on Natural Language Processing algorithms to detect and classify PICO elements and medical terms and organize abstracts accordingly. We built a BERT + bi-LSTM language model. The tool was trained on a corpus of 24,668 abstracts unrelated to COVID-19. We assessed the tool performance in a specific topic related to COVID-19 that has not been covered during training. To carry out manual validation, we randomly selected 50 abstracts. Abstract sentences were classified by 2 domain experts into 7 types: Aim (A), Participants (P), Intervention (I), Outcome (O), Method (M), Results (R), and Conclusion (C). The performance of the tool was compared with that of the experts in terms of precision, recall, and F1.

Results:

The classifier proved to have a 76% overall accuracy. Precision, recall, and F1 were above 75% for all types of sentences except I, M, and P.

Conclusions:

The results indicate a promising ability of the semi-automated classifier to predict expert-validated labels on abstracts of different topics. Our proposed tool is expected to significantly reduce the effort for producing medical guidelines and therefore have a strong, positive impact, particularly in emergency scenarios. The COKE Project also represents a call-to-action for similar initiatives, aimed at enhancing the information extraction process in medicine.

Key messages:

- A rapidly changing healthcare requires fast decisions supported by scientific evidence. This is not compatible with the human limits in cognitive skills that reduce the ability to extract information.
- The COKE Project aims to speed up the creation of healthcare guidelines, semi-automating parts of the workflow, and supporting the human-performed process of extracting and analyzing contents.

Abstract citation ID: ckac129.644
Infodemic management for public health practitioners: landscape analysis and practical tools

Atsuyoshi Ishizumi

A Ishizumi[1], T Purnat[1], R Ludolph[1], S Cecchini[1], B Yau[1], C Bertrand-Ferrandis[1], S Briand[1], T Nguyen[1]
[1]Epidemic and Pandemic Preparedness and Prevention, WHO, Geneva, Switzerland
Contact: ishizumia@who.int

Issue:

Infodemics (i.e., overflow of information in physical and digital spaces that makes it difficult for people to make good health decisions) can undermine emergency response, but capacity for infodemic management has been limited in countries thus far. Specifically, there is a need to build capacities in the field with practical and scalable tools.

Description of the problem:

WHO has developed tools and trainings to quickly build and enhance infodemic management (IM) capacity at the country-level, such as tools for rapid generation of IM insights and a framework for conducting landscape analyses to establish sustainable IM capacities. These were developed in collaboration with multidisciplinary experts who provided feedback. We sought to create tools that can be a basis for introducing evidence-generation in health information systems to inform emergency preparedness and response, and mainstream methods into routine infodemic diagnostics activities.

Results:

The tools and trainings provide a comprehensive framework for diagnosing and addressing infodemics, such as a public health taxonomy to guide digital intelligence analysis and integrated analysis methods for generation of actionable insights. Additionally, the landscape analysis framework outlines steps for assessing strategic needs and assets for routinizing IM functions as part of existing public health systems and programs.

Lessons:

The tools and trainings will be deployed in the field to evaluate utility. Feedback from users in the global WHO infodemic manager community will be systematically captured.

Key messages:

- Field responders need practical tools and trainings that guide quick infodemic response during health emergencies.
- These tools and trainings can be used to diagnose and intervene on infodemics, even in settings where infodemic insights units are not yet established.

Delivering actionable infodemic insights and recommendations for the COVID-19 pandemic response

Tina Purnat

TD Purnat[1], A Ishizumi[1], B Yau[1], B White[1], C Bertrand-Ferrandis[1], S Briand[1], T Nguyen[1]
[1]Epidemic and Pandemic Preparedness and Prevention, WHO, Geneva, Switzerland
Contact: tina.purnat@gmail.com

Issue:

The COVID-19 pandemic and current recovery efforts have been complicated by a parallel infodemic. The infodemic has manifested itself in the rapid spread of questions, concerns and misinformation that can affect population attitudes and behavior harmful to health -promoting stigma and discrediting science, non-recommended treatments and cures, politicizing health programs and eroding trust in health workers and health systems.

Description:

WHO's COVID-19 Pillar 2 (risk communication, community engagement and infodemic management) developed an integrated public health infodemic insights methodology for weekly analysis of social media, traditional media and other data sources to identify, categorize, and understand the key concerns and narratives expressed, and inform risk communication and response activities.

Results:

The infodemic characterization, integrated analysis and insights generation consisted of a 3-step mixed-methods approach. First, data was collected from publicly available social and news media and categorized into categories of conversations by a COVID-19 public health taxonomy. Second, the dataset was analyzed and compared week-on-week to identify changes in narratives and conversation sentiment. Third, the digital infodemic intelligence was reviewed by a group of subject matter experts and triangulated with other data sources to derive infodemic insights and provide recommendations for action for the week. The methodology has been applied to inform COVID-19 response, COVID-19 vaccine demand promotion, and preparing for mass gatherings or mass immunization campaigns.

Lessons:

The methodology for infodemic intelligence generation and integration has introduced evidence-based analytical practices for generation of infodemic insights and recommendations for action into the work of WHO. It must be further adapted for use by different health programmes and preparedness functions, and is described WHO Field Infodemiology Manual.

Key messages:

- Health authorities can use infodemic insights to respond to people's concerns, questions and information deficits in a timely and effective manner.
- An evidence-based methodology has been developed and validated to generate infodemic insights and recommendations for action during an acute health event or emergency.

Abstract citation ID: ckac129.646
PHIRI Rapid Exchange Forum (REF): A key tool for cross-country exchange in times of crisis

Claudia Habl

C Habl[1], C Pries[1]
[1]International Affairs and Consulting, Gesundheit Österreich GmbH - Austrian National Public Health Institut, Vienna, Austria
Contact: claudia.habl@goeg.at

The COVID-19 pandemic demanded a quick exchange between experts and institutions supporting national governments in the crisis response literally from the first day onward to provide evidence-based information. There was no such regular cross-country forum established in the field of population health in the beginning of the crisis. Thus, devoted members of the Joint Action on Health Information started already in April 2020 to meet regularly online to foster cross-country exchange. In these meetings, partners could approach each other for questions and shared views in a trusted environment. The European Commission recognized this achievement and supported this exchange as part of the Population Health Research Infrastructure (www.phiri.eu), allowing a quick exchange of data, indicators, good practices and experiences in the COVID-19 crisis response in an efficient manner. Till May 2022 34 REF meetings have taken place, involving project partners, national advisors to ministers/heads of agency, representatives of expert networks (e.g. Healthy Cloud), EU services (ECDC, JRC) and different health stakeholders (e.g. ELIXIR). The bi-weekly 1 hour online meetings cover in a moderated, structured format pre-agreed COVID-19-topics that are proposed by the participating countries and chosen via a survey ex-ante to each meeting). Responses by the countries (backed up by national reports, andguidelines that are briefly presented in the meetings) are compiled and shared immediately after the meeting via the Corona-Corner of the Health Information Portal (www.healthinformationportal.eu/rapid-exchange-forum).

Topics covered reach from a discussion on suitable non-pharmaceutical interventions and their application especially prior to the availability of vaccines to child vaccination strategies and overall testing regimes to the most suitable communication tools. In average, 25 to 30 delegates from different, mainly EU member states attend each exchange.

Key messages:

- The PHIRI Rapid Exchange Forum demonstrated its importance for regular decision making in the field of population health not only in times of crisis.
- The Rapid Exchange Forum is an integral part of the European Health Information Portal (www.healthinformationportal.eu) which shall be transformed into a sustainable infrastructure.

Effect of a client-accessible record on autonomy of parents and adolescents in Dutch care for youth

Janine Benjamins

J Benjamins[1,2], A Haveman-Nies[2,3], E de Vet[2]
[1]Icare JGZ, Meppel, Netherlands
[2]CHL, Wageningen University and Research, Wageningen, Netherlands
[3]GGD NOG, Warnsveld, Netherlands

Contact: j.benjamins@cjgnoordveluwe.nl

Background:

In the Netherlands, since 2015, a paradigm shift towards client-centred 'care for youth' initiated a focus on client autonomy, enabling clients to make informed decisions in their care process. Client autonomy is assumed to positively correlate with mental and physical health and can be strengthened by autonomy-supportive behaviour from professionals. Aiming for client autonomy, three organizations developed an electronic health record (EPR-Youth), accessible for parents and adolescents. Although research shows that patient-accessible records contribute to patient autonomy, limited research is available about use of such records among adolescents. We investigated whether use of EPR-Youth in 'care for youth' contributed to experienced autonomy among adolescents and parents, and what role professional autonomy-supportive behaviour played.

Methods:

A mixed methods design combined baseline and follow-up questionnaires with focus group interviews, over a two-year period. Clients completed a questionnaire about experienced autonomy and portal use at baseline (1202 parents, 202 adolescents) and after one year (914 parents, 89 adolescents). Professionals completed questionnaires about autonomy-supportive behaviour at baseline (N = 100), after 5 months (N = 57) and 24 months (N = 110). After 14 months, focus group interviews were held with a purposive sample of parents (N = 8), adolescents (N = 4) and professionals (N = 12).

Results:

Twelve months after introducing EPR-Youth, higher autonomy scores were found among parents ($\Delta = 0{\cdot}23$; 95%CI = 0·18-0·28; $p < 0{\cdot}001$) and adolescents ($\Delta = 0{\cdot}53$; 95%CI = 0·34-0·73; $p < 0{\cdot}001$). Portal users showed higher scores than non-users. Focus group members reported a positive effect of portal use on client autonomy, which was strengthened by professional autonomy-supportive behaviour.

Conclusions:

The use of EPR-Youth was associated with increased autonomy among parents and adolescents. Autonomy-supportive professional behaviour enhanced this effect.

Key messages:

- The possible contribution of EPR-Youth to client autonomy is promising, but follow-up research is needed to strengthen evidence.
- Implementation of client-accessible records with the aim to enhance client/patient autonomy needs to address autonomy-supportive professional behaviour to increase impact.

10.H. Round table: Access, equity and the relevance of the Pandemic Treaty: lessons from the COVID-19 response

Abstract citation ID: ckac129.648

Organised by: EUPHA-HTA, EUPHA-LAW, European Association of Health Law
Chair persons: Dineke Zeegers Paget (EUPHA), Elena Petelos (EUPHA-HTA)
Contact: elena.petelos@med.uoc.gr

Access to medicines, equity and fair pricing have been intensely debated in the context of EU policies and global health priorities for many years prior to the COVID-19 pandemic. To this effect, there have been efforts to develop mechanisms to jointly assess health technologies (HTA Regulation) and to establish cross-border partnerships for price negotiation and procurement. Although TFEU (art.168) is limiting the scope of activities and decisions to be taken at the EU level for public health matters, the Commission has also played an active part in global health discussions in the G20 and in the G7 since 2010, and there is explicit commitment to SDGs, and in particular UHC (SDG3.8) 'leaving no one behind' (2019). Indeed, according to its commitments "the EU advocates equitable, universal and high-quality healthcare coverage and promotes fair, effective financing of research to benefit the health of all [and] it is working to ensure that new products are safe, effective, accessible and affordable.'' In the context of the COVID-19 pandemic, the EU came together in solidarity within and beyond its borders, including through joint procurement of countermeasures. At the same time, different instruments were developed to combat the pandemic globally, such ACT-Accelerator deploying the diagnostic and medicinal products, including, vaccines, and its COVAX Global Vaccines Facility to scale up production and establish consensus on the international allocation of these products. In this transitional phase, issues that arise are:

What is the role of the EU in shaping European public health and global health? What are the fundamental principles enshrined in legislative and non-legislative instruments determining EU policies and actions of global health impact? Is such EU policymaking informed by evidence? Are the necessary interdisciplinary and intersectoral partnerships in place to generate the necessary evidence?

Which instruments and mechanisms have been the most efficient and effective in combating the COVID-19 pandemic? Are they relevant for future pandemics and for increasing preparedness and resilience? What has been the role and contribution of the EU in these initiatives? What are the values and fundamental principles determining EU action and policy, and to what degree are EU policies evidence-informed? Will the EU's efforts be determined by G20 decision-making, interests and priorities?

Each panel member will briefly (5 min) present work conducted to inform European public health and global health policies. The panel will then discuss EU public health and global health policies, assessing the extent to which they are evidence-informed and the degree to which they reflect the fundamental principles of the Union. There will be two rounds of questions/statements, the first elucidating the role of the EU, the second examining it in the context of the COVID-19 pandemic and future pandemics, incl. in the context of the development of the Pandemic Treaty.

Key messages:

- Sound governance, transparency and implementation monitoring is required for all instruments and mechanisms to combat the COVID-19 pandemic and ones, with due consideration to sustainability and UHC.
- The EU's role in global health needs to be strengthened via interdisciplinary and intersectoral collaboration for evidence-informed policies, and in a manner consistent with EU fundamental principles.

Speakers/Panellists:

Dimitra Lingri
National Organization for Health Care Services Provision, Athens, Greece

Rosa Castro
European Public Health Alliance, Brussels, Belgium

Tom Buis

Diabetic ketoacidosis among patients admitted to a general hospital in Ethiopia: a spatial analysis

Roberto Benoni

E Paiola[1], *A Sartorello*[1], *G Andreani*[2], *A Tsegaye*[2], *S Tardivo*[1], *F Manenti*[2], *R Benoni*[1]
[1]Department of Diagnostics and Public Health, University of Verona, Verona, Italy
[2]Doctors with Africa CUAMM, Padua, Italy
Contact: roberto.benoni90@gmail.com

Non-Communicable diseases are rapidly increasing in low- and middle-income countries. The number of patients with diabetes is estimated to reach 4.7 million in Ethiopia by 2045. Ensuring access to care is critical to improving the management and clinical outcome of diabetic patients. The study describes the characteristics of patients with diabetic ketoacidosis (DKA) and evaluates the relationship between the severity of clinical presentation and the travel time to the hospital. A retrospective cohort study was conducted on the charts of patients admitted for DKA at St. Luke Catholic Hospital (SLCH), Wolisso, Oromia Region (Ethiopia), between 01/01/2021 and 31/08/2021. Demographic and clinical data were collected. Negative binomial regression was used to explore the relationship between the incidence of admissions for DKA and travel time to the hospital. Logistic regression was used to estimate the odds of insulin treatment. Results were presented with 95% confidence intervals. During the study period, 651 patients were admitted, including 77 (11.8%) for DKA (33 females (42.9%) and 44 males (57.1%)), with no differences based on diabetes type ($p = 0.258$). The mean age was 35 years (IQR 19.0-52.0). Mean BMI was 18.4 kg/m2 (IQR 15.6-19.5), with no differences based on diabetes type ($p = 0.639$). Cumulative incidence of hospitalizations was significantly correlated to travel time to the hospital ($p = 0.039$) with an Incident Rate Ratio of 1.01%[1.00-1.02]. The cumulative incidence ranged from 7.0%[4.5-10.3] in Wolisso to 30.8%[14.3-51.8] in Ameya, the most distant district. The relative probability of insulin treatment was higher with increasing time to SLCH (OR 1.11[1.02-1.21] $p = 0.027$). The hospitalization rate for DKA was significantly correlated with the travel time to the hospital. Access to care is therefore a key factor for health that should be taken into account by improvement programs and the spatial analysis of travel time could help focus on priority areas.

Key messages:

- Spatial analysis can be a robust tool to tailor population healthcare needs on its own topography.
- Health policies must consider that accessibility can influence the severity of clinical presentation.

Abstract citation ID: ckac129.650
health service utilization among older population in a terai region of nepal

Baburam Subedi

B Subedi[1]
[1]USAID's SSBH Activity, Abt.Associates.Inc, Rupandehi, Nepal
Contact: baburamsub@gmail.com

Introduction:
The world is heading towards a larger proportion of older population, indicating an increased risk of diseases, disability, and advanced ageing before death as well as the demand for the health system.

Methods:
This study is a community based cross-sectional study, total 329 older people aged 60 years and above were surveyed. Two stage cluster-sampling technique was used. Semi structured questionnaire was used for data collection.

Results:
Current study showed that 63.3% of the older population have utilized health services in the past one year. Multivariate analysis showed that, respondents with basic education and secondary education are 0.3(AOR: 0.31, 95% CI: 0.17-0.56) and 0.14 (AOR: 0.14, 95% CI: 0.83-0.26) times less likely to utilize health services, respectively. Similarly, respondents reporting current personnel income above forty thousand are 2.8 (AOR:2.81 95% CI:1.84-4.31) times more likely to utilize health services. Respondents at risk of malnutrition are 2.1(AOR: 2.18, 95% CI: 1.14-4.17) times more likely to utilize health services, similarly undernourished respondents are 3.3 (AOR:3.35,95% CI:1.50-7.51) times more likely to utilize health services as compared to respondents with normal nutritional status. Respondents with chronic disease condition are 11.8 (AOR: 11.89, 95% CI: 6.81-20.74) times more likely to utilize health services as compared to those with no chronic disease condition when holding other variables constant.

Conclusions:
There is urgent need to highlight the problems faced by the older population as regards health service utilization and dealing with the identified factors associated with health service utilization among the older population should receive high priority.

Key messages:
- Municipality and health facilities should create enabling environment for older population to get necessary health services.
- Awareness program targeting the underprivileged ethnic groups and poor houses are recommended.

Abstract citation ID: ckac129.651
Health facilities readiness to provide primary cardiometabolic healthcare in Burkina Faso, 2012-2018

Kadari Cissé

K Cissé[1,2], *F Kirakoya*[2]
[1]Biomedical and Public Health, Research Institute of Health Sciences, Ouagadougou, Burkina Faso
[2]Ecole de Santé Publique, Université Libre de Bruxelles, Brussels, Belgium
Contact: cisskad4@gmail.com

Background:
Cardiovascular diseases (CVD) and diabetes, referred to as "cardiometabolic diseases" (CMD), are a growing health issue in developing countries like Burkina Faso. As the first contact point with the national health system, primary health care must play a crucial role in CMD prevention and control. This study aimed to analyse the primary health care (PHC) system readiness for CMD prevention and treatment in Burkina Faso from 2012 to 2018.

Methods:
We performed repeated cross-sectional data analysis from health facility-based surveys, conducted in 2012, 2014, 2016, and 2018. These surveys were conducted using the World Health Organisation (WHO) Service Availability and Readiness Assessment (SARA) tool. The readiness of PHC for CMD was defined according to the SARA manual.

Results:
A total of 586 healthcare facilities were included in 2012, 659 in 2014, 567 in 2016, and 653 in 2018. Between 2012 and 2018, the percentage of healthcare facilities providing CMD specific care significantly increased (66.2% to 92.0% for CVD and 39.4% to 46.6% for diabetes). However, the mean readiness index of the PHC system to manage CVD decreased from 26.0% to 21.6% (p for trend<0.001). For diabetes, the overall readiness index increased significantly (from 34.2% to 37.5%, p = 0.005). The readiness index of PHC for CVD significantly decreased in all health regions particularly in the Sahel region (from 31.7% to 20.8%, $p < 0.001$). While, for diabetes, it increased in all the health regions excepted the Centre-Sud region (from 37.8% to 32.2%, $p < 0.001$).

Conclusions:
There is a low level of preparedness of PHC system to provide CMD in Burkina Faso. Although improvements for diabetes, this is not enough (80% availability of affordable basic technologies and essential medicines recommended by the WHO). Strengthening of the primary healthcare system considering the geographical disparities is urgently required for early detection and management of CMD.

Key messages:
- There is a low level of readiness of PHC system to provide cardiometabolic healthcare in Burkina Faso.
- Public health policy makers must pay more attention to strengthening of the primary healthcare system to address the rising burden of CMD.

Abstract citation ID: ckac129.652
Socio-demographic determinants of infectious disease knowledge in Armenia

Zhanna Sargsyan

Z Sargsyan[1], *Z Grigoryan*[1], *S Sahakyan*[1], *K Kelenjian*[1], *V Hayrumyan*[1], *A Agopian*[1], *T Harutyunyan*[1]
[1]Turpanjian College of Health Sciences, American University of Armenia, Yerevan, Armenia
Contact: zhsargsyan@aua.am

Background:
There is substantial evidence that infectious disease knowledge (IDK) predicts people's behavioral intentions and preventive practices. Since level of IDK varies across socio-economic contexts and imposes a substantial burden on vulnerable groups, we aimed to assess the relationship between socio-demographic factors and IDK in the adult population of Armenia.

Methods:
A cross-sectional nationwide phone survey was conducted in the capital Yerevan and all Armenian provinces in 2021, using a stratified two-stage cluster sampling to complete a sample of 3,483 respondents. The questions on socio-demographic characteristics and IDK were included in a multi-domain structured survey questionnaire. Four questions measured IDK; a summative IDK score (0-4) was used in bivariate and multivariate linear regression analysis.

Results:
Females constituted 71.0% of the sample. The mean age was 49.5 years. About 68% of the study participants had some vocational (12-13 years) or university degree education and 54.4% were employed. About one fifth of the respondents reported family monthly expenditures of less than 100,000 Armenian drams (AMD) $\approx$ \$200, while the majority reported spending 101,000AMD to 400,000 AMD per month. The mean IDK score was 2.48. In the adjusted analysis, being female, holding a higher education level, being employed, having younger age and higher family monthly expenditures were positively associated with IDK score.

Conclusions:

Our findings suggest that there is a gap in IDK affecting specific population groups such as older people, those with incomplete or secondary education, unemployed and financially disadvantaged people. Educational interventions and campaigns should target these groups to minimize the gap and ensure even prerequisites for good health.

Key messages:

- Gender, age, education level, employment status and income level all independently influence population's infectious disease knowledge.
- Health communication campaigns on infectious disease knowledge should particularly target males, older people and socially disadvantaged groups.

Abstract citation ID: ckac129.653
Mortality among internal and international migrants in the 100 Million Brazilian Cohort

Julia Pescarini

JM Pescarini[1,2]*, E Goes*[1]*, P Scaff*[1]*, B Schindler*[1]*, LC Rodrigues*[2]*, EB Brickley*[2]*, L Smeeth*[2]*, ML Barreto*[1]
[1]Centre of Data and Knowledge Integration for Health, Oswaldo Cruz Foundation, Salvador, Brazil
[2]Faculty of Epidemiology and Population, LSHTM, London, Brazil
Contact: juliapescarini@gmail.com

Background:

There is limited evidence on the health of migrant populations in low and middle-income countries (LMICs). Here, we investigated the patterns of mortality risk in migrants and non-migrants in women and men over the life course.

Methods:

We linked socioeconomic and mortality data from 1st Jan 2011 to 31st Dec 2018 in the 100 Million Brazilian Cohort. We calculated all-cause and cause-specific age-standardised mortality rates according to individuals' migration status. Using Cox regression models, we estimated the age- and sex-adjusted mortality hazard ratios (HR) for internal migrants (i.e., people born in Brazil but living in a different Brazilian state to their state of birth) compared to Brazilian-born non-migrants; and for international migrants (i.e., people born in another country) compared to Brazilian-born individuals.

Results:

We followed 45,051,476 individuals, of whom 6,057,814 were internal migrants and 277,230 were international migrants. Internal migrants had a similar overall risk of all-cause mortality compared to Brazilian non-migrants (aHR = 0.99, 95%CI = 0.98-0.99), with lower mortality from some causes but higher mortality for some non-communicable diseases (NCDs). Compared to Brazilian-born individuals, international migrants had a lower risk of all-cause mortality (aHR = 0.82, 95%CI = 0.80-0.84), with up to 50% lower risk of death attributed to interpersonal violence among international migrant men (aHR = 0.50, 95%CI = 0.40-0.64), but a markedly higher risk of death by avoidable causes related to maternal health among young migrant women (aHR = 2.17, 95%CI = 1.17-4.05).

Conclusions:

Overall, internal migration was not associated with excess all-cause mortality, while international migration into Brazil was associated with lower all-cause mortality. Mortality patterns among migrant populations in Brazil show marked variation for specific causes of death, and risks varied by age and sex.

Key messages:

- Non-communicable diseases and maternal mortality are disproportionally higher among internal and international migrants, respectively.
- Further investigation of the underlying factors associated with higher maternal mortality among international migrant women is key to informing the targeting of social and health interventions.

Abstract citation ID: ckac129.654
Inequalities in adverse birth outcomes and survival in early childhood: birth cohort in South Korea

Minjin Jo

M Jo[1,2]*, H Chung*[2,3]
[1]Department of Public Health Sciences, Graduate School of Korea University, Seoul, South Korea
[2]BK21FOUR Learning Health Systems, Korea University, Seoul, South Korea
[3]School of Health Policy and Management, Korea University, Seoul, South Korea
Contact: minjinjo@korea.ac.kr

Background:

Adverse birth outcomes (ABOs) are considered the most common factor of deaths in early childhood. Inequalities in child mortality occur due to interactions between intrinsic and socio-environmental factors related to socioeconomic disadvantage. There are, however, few studies investigating the impact of ABOs on mortality in terms of parental SEP.

Methods:

Using the Under-5 Infant Birth-Death Cohort Data in Korea, a pooled retrospective birth cohort of all children born in 2012-2014 was built (N = 1,356,584). We analyzed neonatal, post-neonatal, and childhood mortality by ABOs and with the interaction of parental SEP using the Cox proportional hazard regression model for survival analyses. We further stratified the analysis both by parental SEP and child age. Multiple logistic regression was performed to confirm the social inequalities in ABO itself.

Results:

After adjusting for covariates, children born with ABOs presented higher risk of mortality for all periods. For post-neonatal period, lower maternal education showed significant interaction effect with LBW (HR = 0.57; 95% CI = [0.39-0.85]), PTB (HR = 0.53; 95% CI = [0.33-0.86]), LBW & PTB ([HR = 0.67; 95% CI = [0.54-0.83]) while lower paternal education (HR = 0.67; 95% CI = [0.54-0.82]) and maternal unemployment (HR = 0.80; 95% CI = [0.63-0.99]) showed significance for babies with LBW & PTB. However, stratification analyses suggested that the impact of ABOs on mortality was greater for children born to lower parental SEP in neonatal period. Meanwhile apparent social inequalities in ABOs were suggested from regression analyses.

Conclusions:

We confirmed social inequalities in the incidence of ABOs as well as mortalities from ABOs. However, the difference in mortality between babies with and without ABOs was greater for advantaged children. Policies to reduce the mortality of children with ABOs as well as those of healthy children among socioeconomically disadvantaged families are required.

Key messages:

- Social inequalities in mortality from ABOs were apparent especially in the neonatal period while the incidence of ABOs itself was greater among children from disadvantaged families.
- Disadvantaged children are more likely to die not only from ABOs but also from other socio-environmental determinants, especially in the post-neonatal period than their counterparts.

10.K. Workshop: School health during the COVID-19 Pandemic. Perspectives from the COVID-HL school principal study

Abstract citation ID: ckac129.655

Organised by: EUPHA Working Group on Health Literacy, COVID-Health Literacy Network, Fulda University of Applied Sciences, Technical University Munich (Germany)
Chair persons: Kevin Dadaczynski (Germany), Orkan Okan (EUPHA-HP)
Contact: kevin.dadaczynski@pg.hs-fulda.de

The COVID-19 pandemic is associated with far-reaching challenges for the educational system, which impact the health of all involved in the school context, making it a critical public health topic. Consequences include school-closures, a switch from face-to-face classroom learning to homeschooling via online learning, resulting in uncertainty, stress and an increased risk of reinforcing already existing inequalities. Since the pandemic started, some research has been conducted in child and adolescent populations. However, there is very limited research available exploring the effects of the pandemic on school principals, who are responsible for all aspects of the school life and therefore have to cope with particularly high demands as a result of the COVID-19 pandemic. Pre-pandemic research shows that school principals report high work-related stress and more frequently psychological and physical burden compared to other professional groups (Dadaczynski et al., 2020; Phillips et al., 2008). Moreover, little attention has been paid to what health promotion activities are implemented by schools during pandemic times and what the schools' needs are in this area. To provide empirical evidence on that matter, a school principal survey was conducted within the international COVID-Health Literacy Research Network (www.covid-hl.org), that aimed to assess (1) work-related stress and strain, (2) corona-specific health literacy among school principals and (3) the implementation status of activities in school health promotion during the COVID-19 pandemic. This workshop aims to present and discuss findings of the COVID-HL school principal study from Germany, Italy, Poland, Switzerland and Wales, which have used the same instrument and study design. The first presentation will focus on the pandemic as a potential disruptive event impeding the implementation of holistic activities on school health promotion and prevention. In their presentation, Chiara et al. analyse beliefs about vaccines among principals and its associations with COVID-19 information satisfaction. The third presentation originates from Poland and will introduce findings regarding work-related coping behavior and its association with mental health of school principals. While the fourth presentation from Switzerland focus on the relationship between health literacy and health promoting activities implemented by schools, Marchant et al. explores the effects of the COVID-19 pandemic on senior leaders experiencing high job demands. Each project will be given ten minutes to present their findings, including questions, which will be followed by Q&A and an open discussion with the audiences. This workshop offers a forum for researchers, practitioners and policy-makers interested in school health promotion and school staff health. By dialogue and two-way communication, vivid interaction will be ensured, allow building synergies, and facilitate networking and capacity building.

Key messages:

- School leaders should be systematically supported as 'gate-keepers' of school health promotion.
- School principals represent a largely neglected target group for school health promotion.

Abstract citation ID: ckac129.656

The COVID-19 pandemic as an disruptive event in school health promotion. Survey results from Germany

Kevin Dadaczynski

K Dadaczynski[1,2]*, M Messer*[3]*, O Okan*[4]
[1]Department of Health Science, Fulda University of Applied Sciences, Fulda, Germany
[2]Center for Applied Sciences, Leuphana University of Lueneburg, Lueneburg, Germany
[3]Department of Nursing Science, Trier University, Trier, Germany
[4]Department of Sport and Health Sciences, Technical University Munich, Munich, Germany
Contact: kevin.dadaczynski@pg.hs-fulda.de

Background:

This study examines the extent to which schools implement activities on health promotion and prevention during the COVID-19 pandemic. Moreover, potential differences with regard to demographic variables, school type, state, and participation in state public health and health promotion initiatives are determined.

Methods:

As part of the international COVID-Health Literacy Research Network, an online-based cross-sectional study was conducted from March to April 2021 with 2,186 school principals from three German federal states. The implementation status of COVID-19 related school health promotion was assessed using a self-developed instrument. After examining the factorial structure of the instrument, univariate and bivariate data analyses were performed.

Results:

Three dimensions of implementing school health promotion can be identified (1. COVID-19- related support for pupils, 2. Health promoting design of teaching, learning and working conditions, 3. Principles of Health Promoting School). A low level of implementation can be observed for aspects of teaching, learning and working conditions (31%) as well as for participation (52%) and cooperation with community stakeholders (42%). Significant differences can be determined with female, older and primary school principals reporting a higher implementation status while for federal state mixed results are found. Stratified by participation in state health promotion initiatives, only schools with a certificate in health promotion show a higher level of implementation.

Conclusions:

The results indicate that the COVID-19 pandemic is a disruptive event for schools, impeding the implementation of holistic activities on health promotion and prevention. In addition to systematic support for school principals in the area of health promotion and prevention, it should be ensured that existing initiatives are provided with sufficient resources, especially in times of crisis.

Beliefs about vaccines and information about coronavirus, COVID-19 and the pandemic. Findings from Italy

Chiara Lorini

C Lorini[1]*, V Velasco*[2]*, P Zanobini*[1]*, L Vecchio*[2]*, G Bonaccorsi*[1]
[1]Department of Health Science, University of Florence, Florence, Italy
[2]Department of Psychology, University of Milano-Bicocca, Milan, Italy
Contact: chiara.lorini@unifi.it

Introduction:

In Italy, COVID-19 vaccination campaign for school personnel started in February 2021 and began mandatory from 15th December 2021 to all the people who work within schools. Here we described Italian school principals' beliefs about vaccines and its association with feelings about information regarding coronavirus, COVID-19 and the pandemic.

Methods:

Data collection started in October 2021 and is ongoing. Beliefs about vaccines were investigated both for COVID-19 vaccination and for vaccination in general.

Results:

A total of 726 questionnaires were analyzed so far. The majority feels to be well informed about the coronavirus or the pandemic (75%) and not at all nor a little confused about COVID-19 information (89%). Only 2% disagree/strongly disagree with the statement ''vaccination is compatible with my attitudes or religious beliefs''. Beliefs regarding vaccines in general are correlated with those regarding COVID-19 vaccines. When different beliefs are described, we observed a trend towards considering COVID-19 vaccines less safe and effective, but more important to protect themselves and their family than other vaccines. Moreover, beliefs about vaccination in general and regarding COVID-19 are associated with how well they feel informed about the coronavirus or the pandemic, and whether they feel confused about COVID-19 information. In particular: the better they feel informed about the coronavirus and the related pandemic, the higher the perception of vaccines in general and COVID-19 vaccine as important, safe, and effective; the less they feel confused about COVID-19 information.

Conclusions:

School principals showed a high level of confidence on vaccines. The association between beliefs in vaccinations and the characteristics of information about COVID-19 supported the effectiveness of Italian vaccination policy and information campaigns.

Life-work balance of school-principals during the COVID-19 pandemic in Poland

Karina Leksy

K Leksy[1], *K Borzucka-Sitkiewicz*[1], *R Muster*[1]
[1]University of Silesia, Katowice, Poland
Contact: karina.leksy@us.edu.pl

Background:

The health crisis caused by the COVID-19 pandemic has severely affected the education sector and its whole community. Due to their responsibility for organizing schoolwork, school managers were in an extremely challenging position. The main objective of the present study is to reveal the extent to which school principals in Poland put aside their own needs in favor of fulfilling their professional duties during the COVID-19 pandemic.

Methods:

The results come from an online survey among school principals in Poland, which is part of the international COVID-19 Health Literacy School Principals Survey. The survey was conducted in 8 out of 16 provinces in Poland between June 2021 and December 2021. 1899 school principals participated in the survey, of which 928 completed the questionnaire.

Results:

The study revealed that 68,3% of school principals often and very often worked longer than contractually agreed and 71,3% reported to be available for their colleagues, pupils, and parents in their free time. Most of them also had to give up leisure activities in favor of work (67,9%), work extra hours in their spare time (60%), waive breaks during working hours (57,3%), and did not get sufficient sleep in favor of work (50,5%). Devoting more time to work and high stress levels during the pandemic were associated with somatic complaints among respondents (e.g. muscle pain (neck, shoulder, or back) and headache).

Conclusions:

The results suggest that Polish school principals worked at the expense of their free time and health during the COVID-19 pandemic. As such, findings emphasized a lack of life-work balance and the need to raise their awareness of the consequences of self-exploitation in work in challenging times. The ability to set healthy boundaries between work and private life among managers is one of the health promotion tasks in demanding times.

School health promotion during the COVID-19 pandemic: Associations with school leaders' health literacy

Simona Betschart

S Betschart[1], *A Sandmeier*[1], *G Skedsmo*[1]
[1]Schwyz University of Teacher Education, Goldau, Switzerland
Contact: simona.betschart1@phsz.ch

Background:

School leaders are credited with an important role when it comes to school health promotion. During the COVID-19 pandemic, much health-related information was available and had to be interpreted and acted upon by school leaders. Therefore, it is crucial that they have sufficient health literacy as the ability to gain access to, understand and use health-related information. A study in Germany showed that limited health literacy among school principals was associated with low levels of health promotion activities. This paper explores the association between school leaders' health literacy and school health promotion in Switzerland, addressing the following questions: 1. What is the relationship between health literacy of school leaders and the implementation of school health promotion? 2. Does health literacy explain variance above and beyond other antecedents, such as principals individual mental health and attitudes?

Methods:

The quantitative analysis is based on an online survey conducted among school leaders in the German- and French speaking parts of Switzerland in June 2021 as part of the project ''COVID-19 health literacy school principals survey''. The final sample comprised N = 339 school leaders. The data were analyzed using stepwise regression with health literacy, stress, wellbeing and attitudes toward school health promotion as antecedents and COVID-19 related school health promotion as the outcome.

Results:

The results show that health literacy of school principals has played an important role in the implementation of school health promotion during the COVID-19 pandemic. It explains additional variance beyond other antecedents.

Conclusions:

One way to promote implementation of school health promotion is to strengthen the health literacy of school leaders.

Abstract citation ID: ckac129.660
The COVID-19 HL School Principal Survey (Wales) linked to routinely collected anonymised health data

Emily Marchant

E Marchant[1], *M Seaborne*[1], *S Brophy*[1]
[1]Swansea University Medical School, Swansea University, Swansea, UK
Contact: e.k.marchant@swansea.ac.uk

Background:

Evidence before the pandemic suggests that school headteachers report high work-related stress and psychological/

physical burden compared to other professional groups (1). There is an evidence gap exploring the effects of the COVID-19 pandemic on senior leaders in schools who have experienced high demands as a result of COVID-19. This is important because in the UK, teacher retention is policy priority.

Methods:

The COVID-19 HL: School Leadership Survey aimed to explore the burden and stress that school leaders in Wales, UK experienced during COVID-19, part of a global study with the COVID-HL network (3). 172 school leaders (62% female) from 130 primary (age 3-11) and 30 secondary schools (age 11-16) completed an online survey between July-Nov 2021, exploring topics such as work-related stress and mental health. A unique aspect is the use of data linkage using the SAIL (Secure Anonymised Information Linkage) Databank. SAIL is data repository containing individual-level, anonymised population-scale data for Wales.

Results:

Initial descriptive findings show 54% of senior leaders have depression (WHO-5), and lower wellbeing scores compared to other UK professions. 83% report moderate-high perceived stress (Perceived Stress Scale) and physical (38%) and mental (57%) work exhaustion. The next stage of this study is to perform data linkage of survey responses to health records and administrative data. Logistic regression analyses will examine wellbeing and work-related stress with outcomes including mental health (e.g. anxiety/depression) diagnosis and time off work.

Conclusions:

Preliminary results show high levels of stress, exhaustion and low wellbeing amongst school leaders in Wales. The next part of this study will examine this in greater detail using data linkage of routine records. Data linkage allows this sample to be extrapolated to population level to theorise work-related stress for all school leaders in Wales.

10.L. Round table: Health literacy in health professionals – conceptualising and piloting a new measuring instrument

Abstract citation ID: ckac129.661

Organised by: Careum Center for Health Literacy (Switzerland), Gesundheit Österreich GmbH (Austria), University of Bielefeld (Germany)
Chair persons: Doris Schaeffer (Germany), Saskia De Gani (Switzerland)
Contact: haarmann@hertie-school.org

Background:

Studies have shown that the population's health literacy is low in many countries, including Austria, Germany, and Switzerland. In order to improve the health literacy of patients and the population, health professionals have an essential role to play. However, as most studies have been conducted either outside of Europe or among health professionals in training, there is a lack of a clear definition, clear-cut concept, and reliable data on the professional health literacy of the healthcare workforce in Europe so far.

Approach of the Pilot Study:

The present study is a pilot study that aims to remedy this shortcoming. The underlying notion of health literacy is based on the definition by the HLS-EU Consortium and the HLS19-study. Following these definitions, a joint concept of professional health literacy was developed. It is comprised of the following complexes: a) communication with patients and users, b) dissemination of health related information with patients in a comprehensible manner, and c) dealing with relevant professional knowledge by health professionals. Based on this conceptual reflections, a quantitative survey was developed and conducted among health professionals in Austria, Germany, and Switzerland. This process revealed some challenges and limitations of a standardised questionnaire, as national discourses vary and different professions require distinctive vocabulary and frameworks of reference. Moreover, differences in professional qualifications and training challenge the comparability of both sample and results.

Objectives of the Workshop:

The objective of this workshop is threefold.

a. The first is to present the working group's concept, its experience with, and reflections on this first of its kind study in Europe - all before the backdrop of previous endeavours to examine professional health literacy. This is the more important as interest in professional and organisational health literacy is growing.

b. The second objective includes the presentation of the survey instrument, its development, and preliminary results (the analysis of the study's data will not be completed by the time of the workshop).

c. The third objective is to provide a platform for discussion about the study as well as the challenges and potential limitations of a wider international comparison across a larger variety of health professions.

Added Value of the Workshop:

The workshop will provide an overview of the general context, the approaches in the field of professional health literacy, and the concept. This combination offers a unique opportunity to discuss the study, its questionnaire, and preliminary results, while considering aspects and issues in this field of research in general. This discussion is essential, as it supports identifying opportunities and limitations in order to develop solutions in this field of research - and contribute to the possible progress in the development of the role of health professionals.

Key messages:

- Professional health literacy is essential to improve patients' health literacy.
- This workshop discusses potentials, challenges, and potential limitations examining this field.

Speakers/Panellists:

Robert Griebler

[2]Kazakh National Medical University, Almaty, Kazakhstan
[3]Department of Pediatrics and Psychiatry, Columbia University Irving Medical Center, New York, USA
[4]University of International Business, New York, USA
[5]Columbia University School of Social Work, New York, USA
Contact: gaukhar.mergenova@gmail.com

Background:
COVID-19 vaccine hesitancy is a major problem worldwide that impedes vaccine uptake. We explored factors associated with vaccine hesitancy in Kazakhstan.

Methods:
We conducted a cross-sectional face-to-face survey of 991 adults in Kazakhstan in July 2021, using quota sampling of respondents over 18 years old reflecting the distribution of gender, age, residence type, and geographical regions of Kazakhstan, according to the 2020 census.

Results:
Over two third (68.4%) of the sample was vaccine hesitant; 22.11% - received a vaccine (18.6%-Sputnik V, 2%-Hayat-Vax, 0.9%-QazCovid and 0.6%- CoronaVac). We used logistic regression to explore factors that were associated with vaccine hesitancy, adjusting age, education, employment, type of residence, self-reported COVID-19. The odds of not being vaccine hesitant were higher among those who had a higher perception that the COVID-19 vaccine was important for health OR = 2.66 (95%CI:2.24,3.17), higher belief in vaccine safety/effectiveness OR = 3.16 (95%CI:2.57,3.89), higher trust in government/health providers OR = 3.32 (95%CI:2.72,4.05), higher trust in official sources of information OR = 1.16 (95%CI:1.12,1.21), higher adherence to preventive measures OR = 1.05 (95%CI:1.03,1.08), knew someone diagnosed with COVID-19 OR = 1.36 (95%CI:1.01,1.82), or who died of COVID-19 OR = 1.47 (95%CI:1.04,2.08), had been ever tested for COVID-19 OR = 1.75 (95%CI:1.30,2.35), had ever received flu vaccine OR = 2.16 (95%CI:1.62,2.88), among health professionals OR = 2.76 (95%CI:1.38,5.51), and who had lower vaccine conspiracy beliefs OR = 0.48 (95% CI:0.40,0.58).

Conclusions:
Vaccine accepting individuals held positive beliefs about the COVID-19 vaccine, had greater trust in government/official sources of information/health care workers, had greater exposure to COVID-19. Interventions aimed at reducing vaccine hesitancy need to address sources people find credible and may need to target individuals who have had limited exposure to the risks of COVID-19.

Key messages:
- Strategies to increase trust in government/ health care workers and official sources of information can be an effective approach to reduce COVID-19 vaccination hesitancy.
- Interventions to reduce COVID-19 vaccination hesitancy should target individuals who have had limited exposure to the risks of COVID-19.

Abstract citation ID: ckac129.663
Development of a strategy to control COVID-19 in hard-to-reach migrant communities

Annalisa Rosso

A Rosso[1,2], A Rinaldi[2], D Coluzzi[2], F Perrelli[2], PA Napoli[2], P Villari[1]
[1]Sapienza University of Rome, Rome, Italy
[2]Migrants' Health Unit, Local Health Unit Roma 2, Rome, Italy
Contact: annalisa.rosso@uniroma1.it

Issue/Problem:
The risk of SARS-Cov-2 infection and its adverse health effects proved to be higher among socially disadvantaged groups, including migants and ethnic minorities. Hard-to-reach (HTR) migrants, such as undocumented people, those living in informal settlements (e.g squats) or roma people have experienced severe barries to access COVID-19 information, testing and vaccination services.

Description of the problem:
During 2020 and 2021, the Migrants'Health Unit of Roma 2 Local Health Unit (ASL) developed different strategies to control the COVID-19 epidemics in HTR communities, addressing both the containment of clusters in informal settelments and access to COVID-19 vaccination for these population.

Methods:
A multicomponent and multidisciplinary strategy was implemented, based on a strong collaboration of different services across the ASL and with Non Governmental Organizations (NGOs). Starting from a mapping of the settlements and the identification of the main critical issues for the control of the epidemic in the target populations, interventions were carried out that included the involvement of NGOS in active surveillance, reporting of suspected cases of COVID-19 to the ASL and information to the communities, and the reorganization of health interventions (eg, swabs, epidemiological investigations, COVID-19 vaccinations) directly in HTR communities' life places.

Results:
In the period from April 2020 to February 2021, 15 outbreaks were controlled, for a total of over 4500 persons reached, and 265 COVID-19 cases identified. From July to November 2021, vaccinations were offered in outreach or with dedicated vaccination sessions, which reached 1664 people. The intervention model, based on a deep context analysis, strong multisectoral collaboration, community involvement, lays the foundations for the design of public health strategies, not only aimed at HTR populations.

Key messages:
- Controlling COVID-19 in Hard- to- reach migrant populations was possible thanks to a strong collaboration between public health services and NGOs.
- Public health interventions addressed complex groups should envisage intersectoral collaborations, reorientation of services in order to meet target groups' need and community involvement.

Abstract citation ID: ckac129.664
Impact of COVID-19 vaccination on risk perception: a cross- sectional study on vaccinated people

Valentina De Nicolò

V De Nicolò[1], P Villari[1], C De Vito[1]
[1]Department of Public Health, Sapienza University, Rome, Italy
Contact: studiosservazionalecovid19@gmail.com

Background:

High risk perception and perceived threat of COVID-19 had played an important role on public attitudes toward vaccination and protective countermeasures acting as motivational factors to perform behaviors that facilitated disease prevention. To explore COVID-19 vaccination influence we conducted a cross-sectional study on vaccinated people (18-80 years old).

Methods:

Partecipants, randomly selected, were recruited during the vaccination campaign in the Hub of Cosenza, Calabria Region, Italy, at the end of the 2nd wave of pandemic (Jul-Aug 2021). A multivariable logistic regression model was built to calculate odds ratios (OR) and 95% confidence intervals (95% CI) comparing risk perception and preventive measures confidence pre vs. post vaccination.

Results:

Globally 625 partecipants fully responded; 51.4% women, mean age 40.5 years (SD +/-15.36). Infection risk perception and protective measures adherence significantly decreased after the vaccination even if a significant gender gap was present; women were always more worried and respectful than men. More prudent partecipants had a significantly higher mean age. 64.2% of participants believed that compliance with social distancing was yet absolutely necessary after the immunization and about half of them believed that also the use of masks was yet necessary. Results of multivariable analysis confirmed that risk perception decreases after vaccination in different contexts: workplace (0.65; 95% CI 0.44-0.94); sport activities (0.60; 95% CI 0.39-0.95); bars and restaurants (0.51; 95% CI 0.33-0.80); means of transport (0.32; 95% CI 0.19-0.50) as well as handwashing practice (2.23 95% CI 1.20-4.12).

Conclusions:

The research shows that COVID-19 vaccination significantly decreases self-perceived risk and adherence to preventive measures. Public Health communication strategies could underline that COVID-19 vaccination is indispensabile but not sufficient to protect the World against this devastating catastrophe.

Key messages:

- Public Health should promote consciousness and strengthen the importance of health-protective measures in order to further reduce risk of human-to-human transmission after immunization.
- Even after vaccination, extra precautions are still required and necessary to do not nullify vaccination protective effect, mostly in more exposed and less careful groups like young people.

Abstract citation ID: ckac129.665

How to deal with COVID-19 vaccine hesitancy in pregnant and breastfeeding women? A meta-analysis

Francesco Paolo Bianchi

FP Bianchi[1], P Stefanizzi[1], MC Di Gioia[1], N Brescia[1], S Lattanzio[1], S Tafuri[1]
[1]Interdisciplinary Department of Medicine, University of Study of Bari, Bari, Italy
Contact: frapabi@gmail.com

Background:

Pregnant and breastfeeding women are at an increased risk of severe illness from COVID-19 compared to people who are not pregnant. Therefore, the CDC recommends COVID-19 vaccination for women who are pregnant, breastfeeding, and trying to become pregnant or who may become pregnant in the future. Despite this, low vaccination coverages are reported in this population sub-group. The purpose of this study is to estimate the proportion of pregnant and breastfeeding women expressing hesitation to the COVID-19 vaccine worldwide. Determinants of vaccine compliance and options suggestedto address vaccine hesitancy were also analyzed.

Methods:

Forty-six studies were included in the meta-analysis and systematic review, selected from scientific articles available in the MEDLINE/PubMed, Google Scholar, and Scopus databases between January 1, 2020 and February 6, 2022. The following terms were used for the search strategy: (adherence OR hesitancy OR compliance OR attitude) AND (covid* OR SARS*) AND (vaccin* OR immun*) AND (pregnan* OR post-partum OR breastfeeding OR lactating).

Results:

The vaccine hesitation rate was 48.4% (95%CI = 43.4-53.4%). In a sub analysis by study period, the pooled prevalence of vaccine hesitation was 40.0% (95%CI = 31.6-46.6%) considering surveys administered in 2020, 58.0% (95%CI = 48.9-66.9%) considering surveys administered in the first semester of 2021, and 38.1% (95%CI = 25.9-51.2%) considering surveys administered in the second semester of 2021. The main reasons for vaccine hesitation were lack of information about vaccination, opinion that the vaccine is unsafe, and fear of adverse events for both mother and fetus/child.

Conclusions:

In order to achieve high vaccination coverage, a multifactorial approach is needed, requiring major social, scientific, and health efforts. The success of the vaccination campaign in this population depends on the capillarity and consistency of the interventions implemented.

Key messages:

- Vaccine hesitancy can be a determining factor in the success (or otherwise) of the anti-COVID-19 immunization campaign.
- Vaccine hesitancy in pregnant and breastfeeding women is a genuine public health concern worldwide.

Abstract citation ID: ckac129.666

Impact of booster vaccination on COVID-19 outcomes in Portuguese population aged 80 or more years old

Irina Kislaya

I Kislaya[1,2,3], AP Rodrigues[1], S Silva[1], AJ Santos[1,2], C Matias Dias[1,2,3], B Nunes[1,2,3], A Machado[1,2,3]
[1]Department of Epidemiology, National Institute of Health Doutor Ricardo Jorge, Lisbon, Portugal
[2]Public Health Research Centre, Universidade NOVA de Lisboa, Lisbon, Portugal
[3]Comprehensive Health Research Centre, Universidade NOVA de Lisboa, Lisbon, Portugal
Contact: irina.kislaya@insa.min-saude.pt

Background:

Vaccination is essential to control SARS-CoV-2 transmission and complications. The study aimed to estimate the number of SARS-CoV-2 infections, COVID-19 hospitalizations and deaths averted by booster vaccination in Portuguese population aged 80 or more years old.

Methods:

We developed an ecological study for the period of the Omicron variant of concern predominance (week 2 to week 16, 2022). Data on vaccine coverage and effectiveness, and number of events of different severity reported to the national COVID-19 surveillance system were used to estimate the number of averted events, prevented fraction and number needed to vaccinate. Uncertainty intervals (UI) were obtained using Monte Carlo simulations.

Results:

By week 2 2022, vaccination coverage in the target population reached 91.2%. Booster vaccine effectiveness was 4.1% (CI95%: -0.1 to 9.0), 87.5% (CI95%: 84.9 to 89.7) and 83.2 (CI95%: 80.3 to 85.7) against infection, hospitalization and death, respectively. During the study period, 70862 SARS-CoV-2 infections, 2697 COVID-19 hospitalizations and 2106 deaths were reported. Booster vaccination averted 2731 (UI95%: -298 to 5838) infections, 10629 (UI95%: 9173 to

12127) hospitalizations and 6608 (UI95%: 5725 to 7546) COVID-19 related deaths among individuals aged 80 years or more resident in Portugal. Prevented fractions were 3.7% (UI95%: 0 to 7.6%), 79.7% (UI95%: 77.3 to 81.7%) and 75.8% (UI95%: 73.2 to 78.1%), respectively. It would require to vaccinate 59 individuals (UI95%: 52 to 69) to prevent one hospitalization and 94 individuals (UI95%: 82 to 109) to prevent one death in the target population.

Conclusions:

The booster vaccination strategy had considerable impact on preventing severe outcomes in the Portuguese population aged 80 and more years old.

Key messages:

- High vaccine coverage combined with high vaccine effectiveness resulted in considerable reduction of severe COVID-19 outcomes.
- Information on number of outcomes of different severity levels averted by COVID-19 booster vaccination allows to strength public health communication.

Abstract citation ID: ckac129.667
A dynamic transmission model to calculate vaccination coverage needed to control COVID-19 in Germany

Maria Waize

M Waize[1], S Scholz[1], N Schmid-Küpke[1], J Koch[1], S Vygen-Bonnet[1], T Harder[1], O Wichmann[1]
[1]Vaccination Unit, Robert Koch-Institute, Berlin, Germany
Contact: waize.maria@gmail.com

Background:

Control of the 2019 coronavirus disease (COVID-19) pandemic in Germany and return to pre-pandemic behaviour can only be achieved through natural or vaccine-induced immunity. Sufficient vaccine capacity promotes interest in the necessary and feasible target vaccination coverage.

Methods:

An age and risk group stratified SEIR transmission model was used to assess the impact of vaccination coverage ranging 65%-95% for 12-59-year-olds and 90%-95% for $\geq$ 60-year-olds on COVID-19 incidence and intensive care unit (ICU) utilization between 01.07.2021-31.03.2022. Separate implementation of licensed vaccines allows to consider different efficacies, delivery rates and age-specific national vaccination recommendations. The analysis was conducted under different assumptions about contact behaviour during summer, reduction of daily contacts with increasing number of cases, daily vaccination uptake and the dominant variant. Data from the COVIMO study (N = 3004, data collection: 17.05.-09.06.2021) were used to define the population percentage willing to be vaccinated.

Results:

The COVIMO study indicates an achievable vaccination compliance rate of 83.9% among 12-59-year-olds and 94.8% among those $\geq$ 60-year-olds. Maximum incidence or ICU utilization during observation period decreases from 385 to 61 and 6220 to 2800, respectively, with an increase in vaccination coverage from 65% to 95% of 12-59-year-olds, 90% vaccination rate among $\geq$ 60-year-olds, compared to pre-pandemic reduced contact behaviour in summer and reduction of contacts as case numbers increase.

Conclusions:

The vaccination campaign should be continued at high intensity until at least 85% of 12-59-year-olds or 90% of $\geq$ 60-year-olds are fully vaccinated against COVID-19. Based on the population's willingness to be vaccinated, this goal seemed feasible.

Key messages:

- Mathematical modeling was used to determine an evidence-based target vaccination coverage of $\geq$ 85%.
- Expertise in modeling should be further strengthened.

Contact: irina.kislaya@insa.min-saude.pt

Introduction:

Vaccination is the primary pharmacological measure to reduce SARS-CoV-2 transmission and its complications. Timely information on vaccines effectiveness in a context of novel variants of concern (VOC) emergence is essential for public health policies. This study aimed to provide a measure of comparative vaccine effectiveness between Omicron (BA.1) and Delta (B.1.627.2) VOC according to vaccination exposure (complete primary regimen or booster dose) for Portuguese population aged 12 or more years old using routinely collected data from electronic health records.

Methods:

We used a case-case study design linking national electronic vaccination registry and surveillance data on 13,134 SARS-CoV-2 RT-PCR laboratory-confirmed cases notified in Portugal during weeks 49-51 of 2021. Notified cases were classified as Omicron or Delta based on whole-genome sequencing or S-gene Target Failure (SGTF) status using the RT-PCR TaqPath^{TM} Covid 19 CE IVD Kit (Thermo Scientific^{TM}) assay. The odds of vaccination was compared between Omicron cases and Delta cases using logistic regression adjusted for age group, sex, region and week of diagnosis and laboratory of origin.

Results:

The odds of vaccination were higher in laboratory-confirmed cases infected by Omicron (BA.1) VOC compared to Delta (B.1.627.2) VOC for both complete primary vaccination (Odds ratio (OR) = 2.1; 95% Confidence Interval (95%CI): 1.8 - 2.4) and booster dose (OR = 5.2; 95%CI: 3.1 - 8.8), indicating vaccine effectiveness reduction against Omicron.

Conclusions:

We found significantly higher odds of vaccination in Omicron cases compared to Delta, suggesting lower effectiveness of the primary vaccination and the booster dose in preventing infections by Omicron. Case-case study design has proven to be feasible approach to rapidly compare vaccine effectiveness between VOC in context of novel VOC emergence to timely inform public health stakeholders.

Key messages:

- Reduction of vaccine-induced protection against SARS-COV-2 infection with the Omicron compared to Delta after primary and booster vaccination.
- Continuous monitoring of COVID-19 vaccine effectiveness is essential to support public health policies in context of novel VOC emergence.

Background:
The nature of the relationship between maternal tobacco smoking during pregnancy and the occurrence of children's behavioural problems is still a matter of controversy. We tested this association using data collected among a sample of children followed from pregnancy to early adolescence (age 11.5 years), accounting for multiple parents', children's and family characteristics.

Methods:
Data come from 1424 mother-child pairs participating in the EDEN mother-child cohort set up in France. Using repeated measures (3, 5.5, 8 and 11.5 years) of the mother-reported Strengths and Difficulties Questionnaire, we estimated trajectories of children's emotional and behavioural difficulties. Two aspects of maternal smoking were studied: the timing and the level of use (cigarettes/day) during the first trimester of pregnancy. Multinomial regression models controlled for confounding factors including maternal mental health and socioeconomic characteristics using propensity scores with the overlap weighting technique.

Results:
Contrary to bivariate analyses, in propensity score-controlled regression models, maternal smoking throughout pregnancy was no longer significantly associated with offspring emotional or behavioural difficulties. Maternal heavy smoking ($\geq$10cigarettes/day) remained significantly associated with intermediate levels of overall emotional and behavioural difficulties (OR 1.64, 95%CI 1.04-2.58) and conduct problems (OR 3.05 95%CI 1.22-7.61), as well as with high levels of conduct problems symptoms (OR 2.82 95%CI 0.88-9.06) - although the latter did not reach statistical significance.

Conclusions:
The association between maternal smoking in pregnancy and offspring emotional and behavioural difficulties appears to be largely explained by women's other characteristics. However, maternal heavy smoking appears to be related to offspring behavioural difficulties beyond the role of confounding characteristics.

Key messages:
- The association between maternal smoking in pregnancy and offspring emotional and behavioural difficulties seem largely explained by the family's socio-demographic and behavioural characteristics.
- Maternal heavy smoking appears to be related to offspring behavioural difficulties beyond the role of confounding characteristics.

The impact of conscientious objection on voluntary abortion in Italy in the last two decades

Emanuele Koumantakis

L Charrier[1], *M Bo*[2], *E Koumantakis*[1], *CM Zotti*[1]
[1]Public Health and Pediatrics, University of Torino, Turin, Italy
[2]Hospital Medical Direction, Local Health Authority Torino 5, Chieri, Italy
Contact: emanuele.koumantakis@unito.it

Background:
Italian Law 194/1978 legalized voluntary abortion during the first 90 days of pregnancy. Healthcare professionals can claim conscientious objection (CO), but regional governments must guarantee women's rights. In recent years, international human rights authorities argued that access to safe abortion was limited in Italy due to widespread CO.

Methods:
An ecological study was conducted using 1997-2019 ministerial data on the number of gynecologists registered as conscientious objectors, the proportion of abortions performed timely (within 14 days of the request), and within 8-10 weeks of pregnancy. The extra workload for non-objecting gynecologists was calculated as the ratio between the workload for non-objectors and the (theoretical) workload for each gynecologist on duty. The correlation between the extra workload for non-objectors and the proportion of abortions performed within 14 days of the request or beyond 21, as well as the correlation between waiting time and gestational age at the time of the procedure. Data were analyzed for Italy and stratified for its 21 Regions.

Results:
CO among gynecologists turned out to be stable around an average of 70% (median 69%, IQR 64-71%) in the last decades, with 62% of abortions performed within 14 days and 82% of procedures performed by the 10th week of pregnancy. In 13 regions (statistically significant in 5) the increase in workload for non-objectors was inversely correlated with abortions performed within 14 days, and directly correlated with those performed later than 21 days. In all regions (statistically significant in 18) a direct correlation was found between procedures performed timely and those performed within 8 weeks of pregnancy.

Conclusions:
Data from the last 20 years confirm previous findings and CO still seems to have a strong impact on women's right to access safe and timely abortion in Italy. More efforts are needed to narrow the gap between the provisions of the law and its implementation.

Key messages:
- A high proportion of objecting staff makes it difficult to guarantee women's rights to access timely and safe abortion.
- Effective organizational strategies and a proper legal framework are needed to cope with the high percentage of conscientious objectors among health professionals.

Contact: ecapitani89@gmail.com

Background:

The first 1000 days are crucial for the health of the baby and the well-being of the mother-baby dyad, which forms a single complex organism with its co-metabolism expressed through sophisticated neurobiological, epigenetic and microbiome development mechanisms. This study aims to investigate how much social support can influence the path of pregnancy and motherhood.

Methods:

The retrospective observational study was conducted on a sample of mothers enrolled through social networks who were administered a questionnaire from July to September 2021. The questionnaire consisted of 37 questions: 11 analyzed sociodemographic variables, 20 were on current / any previous pregnancies and breastfeeding, and 6 were used to calculate the Maternity Social Support Scale (MSSS-Webster et al.). STATA 14 was used for statistical analysis.

Results:

Our sample consisted of 3447 women. 88.0% wanted the pregnancy, and 63.5% planned it. The average of the Maternity Social Support Scale (MSSS) was 23.91 points. A low MSSS score correlates with a higher risk of cessation of breastfeeding before 6 months of age, a higher risk of not having spontaneous labour, a higher risk of cesarean section and a higher risk of not having a spontaneous birth. On the other hand, a higher MSSS total score is a protective factor concerning breastfeeding duration, which is more likely to be longer-lasting (>6 months), to have spontaneous onset labour with a higher probability of spontaneous delivery.

Conclusions:

The results showed that most of our sample have good friends who support them, can often count on their family, and receive help from their partner/husband. The outcomes of pregnancy, childbirth and motherhood are strongly influenced and conditioned by the social context in which they occur and the support the woman can receive. The presence or lack of this support can affect the health of newborns.

Key messages:

- The first 1,000 days is a vulnerable phase in which parents, institutions and health professionals should create early interventions for the proper development and promotion of good health.
- the outcomes of pregnancy, birth and motherhood are strongly influenced and conditioned by the social context, but especially by the presence or lack of support that can affect the health of newborns.

Future in Pediatrics: prevention in maternal child chronic diseases in the first 1000 days

Barbara Hugonin-Rao

B Hugonin-Rao[1]
[1]Maternal Newborn Child Health, Azienda USL Toscana Centro, Florence, Italy
Contact: barbarahugoninrao19@gmail.com

Introduction:

The screening and management of obesity, metabolic chronic conditions conditions and genetic predisposition, before and during pregnancy, improve the effects of therapies and reduce the rate congenital diseases, metabolic fetal disorders and early chronic diseases during first 1000days. The maternal child health promotion program 'Future in Pediatrics' is dedicated to women in preconception and in early pregnancy, with three steps: 1) a specific survey, 2) a personalisated plan 3) the management of chronic conditions (diabetes, hypertension, overweight, metabolic disorders) and surveillance during the first maternal child 1000 days. Encouraged results

Methods:

In 2019-2021, FUTURA project involved 460 women (before,during and after pregnancy) into 2 groups: group 1 of 280 women, with overweight/ obesity, metabolic conditions, malnutrition, and hypovitaminosis, group 2 of 180 women without chronic conditions, but physical inactivity, high level of homocysteine (60 to 100 µmol/L) and with predisposition for cardiovascular diseases. We have involved the patients in a survey of 100 questions about health, lifestyle, habits, sleep and in a daily diary. In the second time we have realized a personalised and educational program for diet, supplementations sleep, physical activities, health routine.

Results:

The 2 groups of women improved the quality of their health and the management of weight, chronic and metabolic conditions, with impact on reproductive and perinatal health, reduction of inflammatory status and metabolic parameters.We have observed a great influence on cardiovascular health in both groups and decreased of homocysteine levels in the 2nd group. During first 1000 days 393 women, involved into the program, continued with the healthy and preventive routine with zero cases of weight and metabolic chronic disorder in their children.

Conclusions:

This research that the prevention in perinatal health influences the children's health.

Key messages:

- The origins of chronic and metabolic conditions are in uterine life before the conception. The unhealthy lifestyle influenced fertility, cardiovascular health and child health.
- The cardiovascular health and metabolic chronic conditions are influenced by first 1000 days health and habits.

Abstract citation ID: ckac129.673
Household deprivation, comorbidities and COVID-19 hospitalization in 690,115 children/adolescents

Nico Dragano

N Dragano[1]*, O Dortmann*[2]*, J Timm*[3]*, M Mohrmann*[2]*, R Wehner*[2]*, CJ Rupprecht*[2]*, M Scheider*[2]*, E Mayatepek*[4]*, M Wahrendorf*[1]
[1]Institute of Medical Sociology, University Hospital Duesseldorf, Düsseldorf, Germany

[3]Institute of Virology, University Hospital Düsseldorf, Düsseldorf, Germany
[4]Department of General Pediatrics, Neonatology and Pediatric Cardiology, University Hospital Düsseldorf, Düsseldorf, Germany
Contact: dragano@med.uni-duesseldorf.de

Background:

Studies document that adults in disadvantaged socio-economic positions have elevated risks of a severe course of COVID-19, but it is unclear if this holds true for children. We investigate in this population-based study whether young people from socio-economically disadvantaged households in Germany had a higher risk of COVID-19 hospitalization compared with more affluent counterparts. We also examined if differences were related to comorbidities that predict severe courses in children.

Methods:

We included data from all 690,115 children and adolescents (0-18 years) enrolled in a statutory health insurance carrier. Daily hospital diagnoses of COVID-19 were recorded from 1.1.2020 to 13.7.2021. Logistic regressions were used to compare children from households with an indication of poverty (e.g. long- or short-term unemployed) with children from households with insurance holders in regular employment. We also assessed socio-economic characteristics of the area of residence. We controlled for age, sex, days under observation, nationality, and comorbidities (e.g. obesity).

Findings:

A COVID-19 hospital diagnosis was a rare event (n = 1637). Children of long-term unemployed parents had a 1·36 times (95% CI 1·21-1·51) higher adjusted odds of hospitalization compared with those of employed parents. Elevated odds were also found for short-term unemployed or low-wage employment. Those living in poor areas had a 3·02 (1·81-5·22) higher odds of hospitalization than those in less deprived areas. Comorbidities were strongly related to hospitalization, but their adjustment did not change main estimates for household deprivation.

Discussion:

Results suggest that children from poor households are at higher risk of severe courses of COVID-19 than their affluent counterparts. This underlies the need to implement effective Public Health strategies to protect deprived children from COVID-19 and other infectious disease even in high income countries such as Germany.

Key messages:

- Children and adolescents from poor families seem to be at higer risk for sever courses of COVID-19.
- Comorbidities were no key mediating factor in this study.

10.O. Workshop: Developmental and School-Based Factors Shaping Sexual and Gender Minority Youth Mental Health

Abstract citation ID: ckac129.674

Organised by: EUPHA-SGMH, EUPHA-CAPH
Chair persons: Arjan van der Star (EUPHA-SGMH), Richard Ma (UK)
Contact: arjan.van.der.star@ki.se

Research from across the globe has consistently shown that young sexual and gender minority individuals (e.g., those identifying as lesbian, gay, bisexual, and/or transgender [LGBT+]) are at a higher risk for depression, anxiety, and suicidal thoughts and behaviors when compared to heterosexual youth, including during early childhood and later adolescence. A sizeable body of research has attributed the elevated risk to increased exposure to specific social stressors related to navigating a stigmatized minority identity, including stressors such as victimization and other interpersonal and social difficulties in, for example, the school environment. Yet, relatively less is known about the early developmental timing of such disparities in childhood and how LGBT+ youth navigate school climates. As a sensitive developmental period, childhood and adolescence may be a particularly challenging time for sexual and gender minority youth to navigate cisnormative and heteronormative school contexts. Exposure to oppressive norms, particularly in school environments, has only recently become the subject of research. Additionally, research has been limited on how supportive school climates may be protective but stigmatizing school environments may drive LGBT+ trajectories towards suicidal behaviors and shape how they may navigate self-disclosure of cooccurring identities and mental health status in school settings, particularly when such stigmas may prevalently intersect. This workshop aims to further explore these novel aspects around developmental and school-based risk and protective factors shaping the mental health of sexual and gender minority children and adolescents. This workshop includes five empirical presentations that span from examining the developmental timing of mental health disparities, the role school-based experiences play in shaping and driving these disparities, to how sexual and gender minority youth may navigate their school context and how supportive climates may be protective for mental health. First, Arjan van der Star will present longitudinal evidence on how sexual identity formation precedes the onset of sexual orientation-based mental health disparities and the role that peer difficulties play in driving these as early as pre-teen years. Next, Niolyne Jasmin Bomolo will present findings from a qualitative study that unravel how school-based experiences shape individual trajectories toward suicidal attempts among LGBT+ adolescents. Third, Wouter Kiekens will explore how normative cultures in school environments may drive sexual attraction-based mental health disparities among a large sample of adolescents. Fourth, Lourdes Cantarero Arévalo will present findings on how LGBT+ adolescents living with mental conditions navigate self-disclosure in school environments. Finally, Sandra Sevic will present results on how supportive school environments may be protective for gender minority mental health.

Key messages:

- Negative school-based experiences put sexual and gender minority youth at elevated risk for adverse mental health as early as middle childhood.
- Intersecting stigmas around minority identities and mental health problems may further complicate how sexual and gender minority children and adolescents navigate their school environments.

Sexual orientation and mental health disparities in US pre-teens: A longitudinal mediation study

Arjan van der Star

BA Feinstein[1], A van der Star[2], KD Dorrell[1], AJ Blashill[2,3]
[1]Department of Psychology, Rosalind Franklin University of Medicine and Science, North Chicago, IL, USA
[2]Department of Psychology, San Diego State University, San Diego, CA, USA
[3]Joint Doctoral Program in Clinical Psychology, San Diego State University, UC San Diego, San Diego, CA, USA
Contact: arjan.van.der.star@ki.se

Background:

Sexual minority children are at increased risk for psychopathology compared to their heterosexual peers, but longitudinal studies are needed to determine whether sexual minority identification precedes (rather than co-occurs with) mental health disparities and what may drive these disparities during childhood. The current study examined the longitudinal associations between sexual orientation and mental health over two years in a cohort of U.S. pre-teens with two potential mediators (increased social problems and decreased perceived school safety).

Methods:

We used data from Waves 1-3 (2016-2020) of the U.S. Adolescent Brain Cognitive Development study. Multiple linear regression and auto-regressive cross-lagged mediation models were used to examine longitudinal associations and mediation. Analyses accounted for customized sampling weights to correct for attrition and missing data.

Results:

The analytic sample included 5,574 children (46.0% assigned female at birth, 55.1% non-Hispanic White). Across waves, beginning to identify as gay/bisexual (0.6-2.7% of sample) was associated with increased internalizing and externalizing problems, and consistently identifying as gay/bisexual (3.4-5.0% of sample) with increased internalizing problems, compared to consistently identifying as heterosexual. For those who consistently identified as gay/bisexual, the widening disparities in internalizing problems were partially explained by increased social problems and decreased perceived school safety.

Conclusions:

The health disparities affecting sexual minority children include internalizing and externalizing problems, and are partially explained by increased social problems and decreased perceived school safety. These findings demonstrate that sexual minority identification precedes increases in mental health problems relative to heterosexual children, driven by peer difficulties and feelings of unsafety at school experienced by sexual minority children.

Abstract citation ID: ckac129.676
Suicide attempts in LGBTQ+ youth in Switzerland: Qualitative insights in school-based risk factors

Niolyne Jasmin Bomolo

NJ Bomolo[1,2]*, N Koschmieder*[2]*, A Gavin*[3]*, S Kupferschmid*[4]*,*
C Bourquin[3]*, L Michaud*[3]*, A Pfister*[1,2]
[1]Institute of Public Health, ZHAW Zurich University of Applied Sciences, Winterthur, Switzerland
[2]School of Social Work, Lucerne University of Applied Sciences and Arts, Lucerne, Switzerland
[3]Psychiatric Liaison Service, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland
[4]Integrated Psychiatry Winterthur, Winterthur, Switzerland
Contact: niolyne.bomolo@hslu.ch

Background:

Studies show that the LGBTQ+ population is particularly vulnerable to suicidal thoughts and behavior. This vulnerability is even more pronounced in the younger population. However, in Switzerland, qualitative studies on this topic are missing. Our study investigates the processual dynamics and background of suicide attempts of LGBTQ+ youths while looking into their subjective meaning. Here, behaviors of help-seeking are also from interest. In addition, the burdens and resources associated with being LGBTQ+ are explored. By better understanding the process of suicide attempts, we can identify relevant contexts of the respondents' experiences and illustrate how to enhance suicide prevention strategies. We are referring here to the school context.

Methods:

From 2021 until 2024, we interview LGBTQ+ youths in the German- and French-speaking parts of Switzerland who have tried to end their lives between the ages of 14 to 25 (max. three attempts). Applying a multi-perspective approach, we interview persons from their social environment if agreed. Recruitment is based on 'theoretical sampling'. Data collection and analysis follow the grounded theory methodology. As of July 2022, the sample consists of 18 persons: 3 bisexual women, 1 lesbian woman, 2 gay men, 7 transgender persons, and 5 persons with fluid identities.

Results:

Through preliminary analysis, the school context could be identified as one relevant burdening context in the respondents' experience and suicide attempt process. In this respect, respondents experienced complicated social relationships: e.g., bullying, social exclusion, and pressure to conform. Moreover, the school environment was experienced by some as LGBTQ+ hostile.

Conclusions:

Our current findings support the necessity to integrate schools as important stakeholders in suicide prevention but highlight a need for LGBTQ-specific and LGBTQ-sensitive orientations to suicide prevention strategies.

Abstract citation ID: ckac129.677
Sexual attraction-based disparities in adolescent mental health: The role of school norms

Wouter J Kiekens

WJ Kiekens[1]*, L Baams*[2]*, GWJM Stevens*[3]
[1]Department of Sociology, ICS, University of Groningen, Groningen, Netherlands
[2]Department of Pedagogy and Educational Sciences, University of Groningen, Groningen, Netherlands
[3]Department of Interdisciplinary Social Sciences, Utrecht University, Utrecht, Netherlands
Contact: w.j.kiekens@rug.nl

Purpose:

Few researchers have explained disparities in mental health between sexual minority and heterosexual adolescents by focusing on structural forms of stigma as, for instance, heterosexist school or classroom norms. Addressing this gap, our paper aimed to study disparities in life satisfaction, psychosomatic complaints, and emotional problems between sexual minority and heterosexual adolescents and examine the moderating role of heterosexist norms in the classroom and school.

Methods:

We used data from the 2013 and 2017 Dutch Health and Behaviour in School-Aged Children (HBSC) study (N = 12,756; M age = 14.02; SD = 1.54). Separate multi-level analyses for life satisfaction, psychosomatic complaints, and emotional problems were conducted in which cross-level interaction effects between sexual attraction and school and classroom-level heterosexist norms were estimated.

Results:

Same-sex attracted, both-sex attracted, and adolescents unsure about their sexual attraction reported lower life satisfaction, more psychosomatic complaints (not for unsure adolescents), and more emotional problems than their other-sex attracted peers. Stronger school-level heterosexist norms were associated with higher life satisfaction and fewer psychosomatic complaints and fewer emotional problems. Stronger classroom-level heterosexist norms were associated with less emotional problems. Few moderating effects of classroom and school-level heterosexist norms were found. Contrary to expectations, disparities in life satisfaction between same-sex attracted and other-sex attracted adolescents decreased when classroom-level heterosexist norms were stronger.

Conclusions:

Although our findings suggest pressing health disparities between heterosexual and sexual minority adolescents, heterosexist norms at the school- and classroom-level hardly contributed to these health disparities.

Envisioning supportive and safe learning environments: A dialogical study with LGBTQ+ adolescents living with chronic conditions or diagnoses

Lourdes Cantarero Arevalo

L Cantarero Arevalo[1]*, A Skov Nielsen*[2]*, L Slyngbord*[2]
[1]Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark
[2]Faculty of Humanities, University of Copenhagen, Copenhagen, Denmark
Contact: lou.cantarero@sund.ku.dk

Background:

LGBTQ+ adolescents living with mental conditions are affected by stigma based on their health status, sexual orientation, and/or gender identity/expression (SOGIE), especially when navigating their learning environments. Our aim is to gain detailed insights into how LGBTQ+ adolescents living with mental conditions vision their learning environments so that they can feel safe and supported enough to freely disclose their SOGIE and health status, and hence thrive.

Methods:

Aware of the participants' vulnerabilities, a dialogical narrative-based approach was used to gather thick descriptions and deep insight, while applying the "seven C's": conversation, curiosity, context, complexity, challenge, caution, and care (Frank, 2019). Recruitment was done through LGBTQ+ Denmark and via networks of networks. Two LGBTQ+ young adults living with chronic conditions held the dialogues. Mode of communication was chosen by the participants (either face-to-face, via internet or via telephone). Data analysis was conducted via the "analysis grid" (Roest et al. 2021).

Results:

Nine dialogues lasting from 20 to 50 minutes were held with youth from 14 to 24 years old during spring 2022. According to their narratives, supportive and safe learning environments would: respect for change of names and pronouns, update learning materials, allow for flipped classrooms (hybrid teaching tested under COVID lockdowns), have separate neutral change rooms/bathrooms and create safe private spaces to take medications. They would also permit higher absenteeism rates for those living with chronic conditions or getting hormonal treatments, allow for more breaks/slower version of the pensum, and show proactive healthy curiosity and respect for "invisible diseases", fluid SOGIEs and neurodiversity/neurodivergent profiles.

Conclusions:

The differing participants' narratives provide innovative ways to create safe and supportive inclusive learning environment that embrace and enhance diversity.

Structural and school factors, affirmation and well-being among gender minority youth across Europe

Sandra Sevic

S Sevic[1], K Klasnic[1], DM Doyle[2]
[1]Department of Sociology, University of Zagreb, Zagreb, Croatia
[2]Department of Psychology, University of Exeter, Exeter, UK
Contact: ssevic1@ffzg.hr

Background:

Previous research has shown that structural-level factors (discriminatory laws and policies) result in impaired health and well-being for transgender and gender diverse (TGD) adults. This study aims to assess if structural stigma is associated with school bullying/victimization and well-being among TGD youth and if more LGBTI supportive school environments, as well as social, physical, and legal gender identity affirmation ameliorate the effects of both structural stigma and experiencing violence.

Methods:

The study was conducted online in 2019 in 27 EU Member States and in the UK. We analyzed data from TGD students, aged 15 to 24 years, who at most had completed lower secondary education (n = 2,714). Well-being indicators used in the analyses included one-item measures of life satisfaction, depression, and considering leaving or changing school.

Results:

School environment, but not structural-level stigma, was associated with school bullying/victimization. Similarly, the effects of structural-level stigma, along with physical and legal gender identity affirmation were inconsistently related to students' well-being across the multilevel models, whereas a more positive school environment and especially experiences of social identity affirmation were related to greater life satisfaction, better mental health, and lower odds of considering leaving or changing school; even though the negative effects of school bullying/victimization remained statistically significant across all models.

Conclusions:

This study's results suggest that compared with distal factors, more proximal factors - better school environment and social identity affirmation - have a greater impact on TGD students' well-being. Given the inconsistency of our findings, more research is needed to understand the role of structural stigma and legal and physical gender identity affirmation in TGD students' well-being.

10.P. Round table: Public health of the future: innovations in surveillance, communication and knowledge translation

Abstract citation ID: ckac129.680

Organised by: SESPAS, EUPHA-PHPP, ASPHER
Chair persons: Enrique Bernal-Delgado (Spain), Gabriela Barbaglia (Spain)
Contact: mgbarbag@aspb.cat

The social, ecological, economic and health crises exacerbated by COVID-19 pandemic are challenges of extraordinary magnitude and complexity for global public health. Moreover, the context in which the pandemic emerged was characterized by underinvestment in public health and growing distrust in institutions. Public health responses were often fragmented and failed to make use of existing resources and expertise. Nearly 3 years after the start of the COVID-19 pandemic much has been learned and much is still to be learned. Accordingly, European national public health agencies have been pushed to their limits and currently face an urgent need to be renovated incorporating innovations in surveillance, communication and knowledge translation. National agencies should network and collaborate at the EU level. EUPHA may play an important role in this effort.

On the one hand, there is the need of improving surveillance of harmful effects of the pandemic, specifically the health inequalities aggravated at local, national and global levels; and, on the other, to improve the availability of this knowledge to policymakers. Public Health communication needs to be further developed as it has been a crucial piece of national and international efforts to protect and promote health in the pandemic and so will be in the future. With this workshop proposal, we would like to bring up for discussion how could we further improve surveillance, communication and knowledge translation to policy makers and citizens in our European national public health agencies. Innovative and updated public health agencies will help regaining trust and strengthening public health institutions. National and European Public

Health further development is essential and should be strengthened to protect and promote European populationś health.

The objectives of the workshop are:

– To discuss key innovations to implement in national public health agencies to improve surveillance, communication and knowledge transfer to policy makers and citizens.

– To reflect on supranational European coordination mechanisms that would allow for efficient surveillance and a rapid and adequate response to different public health challenges, including social inequalities in health.

– To manage public health intelligence in the European Health Data Space and the role of public health in this data lake design.

Key messages:

- COVID19 pandemic has revealed the challenges of creating strong trustworthy national public health institutions to ensure the integrity of public health science and information dissemination.
- Structures to facilitate timely and efficient monitoring requires national and supranational coordination mechanisms, including data and experience sharing.

Speakers/Panellists:

Robert Otok
ASPHER, Brussels, Belgium

Sofia Ribeiro
EUPHA-PHPP

Manuel Franco
University of Alcalá, Madrid, Spain

10.Q. Workshop: Imbalance in use and impact of public psychotherapy – A Finnish working-age population register study

Abstract citation ID: ckac129.681

Organised by: Finnish Institute of Occupational Health
Chair persons: Ari Väänänen (Finland), Sanna Selinheimo (Finland)
Contact: sanna.selinheimo@ttl.fi

Mental disorders are globally among the leading causes of disability in the working-age population. Psychotherapies have proven to be effective in the improvement of mental health. The current evidence on the benefits of psychotherapies is mainly based on randomized control trials and patient-reported outcomes, whereas the potential impact of long-term psychological therapy on work disability and income is not so well known. This emphasizes the need for longitudinal studies on the effects of psychological therapies in a 'real-world study setting', and on the distribution of the availability and the use of psychological therapies in different populations. In Finland, rehabilitative psychotherapy is the major single form of publicly provided psychological therapy. It is targeted at those aged 16 to 67 who are at risk of disability or not being able to study because of mental health problems. It is granted an annual period (maximum three years), a maximum of 80 sessions per year and 200 sessions per 3 years. From 2011 on this psychotherapy has been statutorily granted to all at risk of work disability due mental health disorders. The number of annual users has increased from 15 757 (2010) to 56 682 (2020). This workshop presents the results from a research project investigating the use and real-world effects of long-term psychotherapy in the Finnish working-age population in the 2010s. It shows 1) whether the use of psychotherapy is associated with subsequent work disability and labour market outcomes (income, employment), 2) how the use of long-term psychotherapy differed between socio-demographic groups in the 2010s in Finland, and 3) the extent to which state-subsidized psychotherapy is linked to the distinctive profiles of mental health problems in the population. The five presentations offer new results from the Rise of Mental Vulnerability in Work Life Study drawn from the national registers. The presentations are mostly based on three randomly selected population cohorts which each included 33% of the 18-64-year-old permanent Finnish residents at the baseline. These data were sampled (sampling years: 2010, 2013, 2016) by and derived from the Population Register maintained by Statistics Finland and included information on various socio-demographic characteristics (e.g., gender, occupation class, region, income). These were linked to the national health registers. Information on reimbursed psychotherapy and mental health indicators (sickness absence, psychotropic drugs, disability benefits) were obtained from the Social Insurance Institution of Finland and complemented by the disability pension data from the Finnish Centre for Pensions. The data provide a unique opportunity to observe how the use of state-subsidized long-term psychotherapy was distributed across population groups in the 2010s, and to the extent to which disability trajectories and economic outcomes have developed in different groups during and after psychotherapeutic treatment.

Key messages:

- Psychotherapy is likely to decrease the risk of work disability and improve labour market outcomes.
- The provision of long-term psychotherapy is related to social inequality in the working population.

Abstract citation ID: ckac129.682

Psychotherapy and change in mental health-related work disability - A prospective population level register-based study in Finland

Johanna Kausto

J Kausto[1], K Gluschkoff[1], S Selinheimo[1], J Turunen[1], A Väänänen[1]
[1]Finnish Institute of Occupational Health, Helsinki, Finland
Contact: johanna.kausto@ttl.fi

Introduction:

Mental disorders are a major cause of work disability among working age population. Psychotherapy has been shown to be an effective treatment for mental disorders, but the evidence mainly comes from small scale randomised trials with a relatively short follow-up.

Objectives:

We used population-based register data to examine the association between statutory rehabilitative psychotherapy and change in depression or anxiety related work disability using a quasi-experimental interrupted time series analysis.

Methods:

All those who started rehabilitative psychotherapy in 2011-2014 comprised the study group. The study group included

10436 participants who were followed from three years prior to four years after the onset of rehabilitative psychotherapy, resulting in 83488 observations. Annual total number of mental health related work disability months was calculated based on total number of annual compensated sickness absence and disability pension days.

Results:

The onset of rehabilitative psychotherapy marked a decline in depression or anxiety related work disability as compared to the counterfactual trend. Specifically, a 20% decrease in the level (incidence rate ratio, IRR 0.80; 95% CI 0.76-0.85) as well as a 48% decrease in the slope (IRR 0.52; 95% CI 0.50-0.54) of work disability was detected. The decline was steepest in the oldest age-group

Conclusions:

Providing statutory psychotherapy may decrease work disability at the population level. Further evidence for causal inference and the potential heterogeneity of the association is required.

Psychotherapy – A Sound Investments In (Mental) Health Capital?

Jarno Turunen

J Turunen[1], *K Gluschkoff*[1], *J Kausto*[1], *S Selinheimo*[1], *A Koskinen*[1], *A Väänänen*[1]
[1]Finnish Institute of Occupational Health, Helsinki, Finland
Contact: jarno.turunen@ttl.fi

Introduction:

The concept of health capital views health as a form of capital that produces healthy time to individual. This stock of capital - health that is - can decrease or increase. The potential of psychotherapy as individual's investment to (mental) health capital has been rarely studied in population level.

Objectives:

The aim of our study is to shed light on the returns on individual-level investments in health capital. We consider the use of psychotherapy as an investment in health capital. This investment offers potential returns for individual as a higher level of subsequent income. However, these returns are potentially heterogenous: we aim to show to whom the use of psychotherapy is a sound investment in health capital.

Methods:

We model the effects of mental health, and subsequent treatments such as the use of psychotropics and psychotherapy on income using two-way fixed effects regression.

Results:

Preliminary results show that different parts of working-age population seem to have different potential returns related to the use of psychotherapy. These heterogenous effects are related to previously reported socioeconomic status related disparities: the level of human capital i.e. income and education play a role in the profitability of the individual level investment made in the health capital by the use of psychotherapy.

Conclusions:

The use of psychotherapy has heterogenous effects on the income of individuals. The potential of this investment to produce health capital varies with education, the level of income prior to the use of psychotherapy.

Socioeconomic factors affecting psychotherapy use rates

Sanna Selinheimo

S Selinheimo[1], *K Gluschkoff*[1], *J Turunen*[1], *J Kausto*[1], *A Väänänen*[1]
[1]Finnish Institute of Occupational Health, Helsinki, Finland
Contact: sanna.selinheimo@ttl.fi

Objectives:

Previous studies indicate socioeconomic inequalities in psychotherapy utilization. The aim of this study was to assess the associations of individual annual incomes with the utilization of long-term rehabilitative psychotherapy during nine-year follow-up in men and women. As secondary analyses we assessed the association of main activity with the utilization of psychotherapy.

Methods:

For this study, we selected those from a random sample of the working-age population (18-55 years) with information about income at each time point during the follow-up from 2011 to 2019 (N = 736 613). Psychotherapy usa during the follow-up period served as dependent variable and sosiodemographic variables, annual incomes and main activity (employed, unemployed, studying, other) were used as independent variables. To examine change in the psychotherapy use rates over time, we used sex-stratified generalized estimating equations logistic regression models with predicted marginal probabilities.

Results:

Psychotherapy use rate was constantly higher among women than in men (in 2011 0.8% and 0.2%) and increased from 2011 to 2019 among both genders and income quartiles (among women 174% - 231% and among men 213% - 248% increase between quartiles). Among men, psychotherapy use rate was highest among lowest income quartile throughout the study interval. Among women such difference was not observed. Among women, studentś psychotherapy use increased significantly when compared to other groups from 2011 to 2019 (299% increase vs 89% - 210% increase among other groups). A similar pattern was seen among studying men versus other groups.

Conclusions:

Between 2011 and 2019 the probability of having psychotherapy increased among both genders. Unexpectedly, pro-rich psychotherapy use rate was not observed. The highest probability to use psychotherapy in lowest income quartile might be linked with differences in health care systems for students and for other.

Occupational class, gender, mental distress and use of psychotherapy

Sanna Selinheimo

L Kokkinen[1], *K Gluschkoff*[2], *J Kausto*[2], *S Selinheimo*[2], *A Väänänen*[2]
[1]Faculty of Social Sciences, Tampere University, Tampere, Finland
[2]Finnish Institute of Occupational Health, Helsinki, Finland
Contact: lauri.kokkinen@tuni.fi

Introduction:

Previous studies have shown the effects of occupational class and gender on mental distress and use of psychotherapy. However, less is known about the mental distress-based use of psychotherapy in different occupational classes.

Objectives:

The aim of our study is to show how the prevalence of mental distress and the use of long-term psychotherapy correlates in different occupational classes by gender.

Methods:

Data were drawn from the Rise of Mental Vulnerability Study (psychotherapy) and FinHealth 2017 Study (mental distress). Adjusting for age, we calculated GHQ caseness, psychotherapy use rate, and the ratio between GHQ caseness and psychotherapy use rate in three occupational classes (upper non-manual employees, lower non-manual employees, and manual workers) separately for men and women. Age-adjustment was performed through regression analysis by using model generated predicted values of GHQ caseness and psychotherapy use rate at the average sample age of 40.

Results:

In the group of upper non-manual men there were 10 persons with severe mental distress for every single person having used psychotherapy. For lower non-manual men and manual male workers the numbers were 14 and 31, respectively. In the group of upper non-manual women there were six persons with severe mental distress for every person having used psychotherapy. For lower non-manual women and manual female workers these numbers were nine and 18, respectively.

Conclusions:

We found differences in the mental distress-based use of state-subsidized long-term psychotherapy between occupational classes. For upper non-manual workers, the use of therapy best meets their mental distress. The opposite is true for manual workers. We also found differences between men and women, but these findings should be confirmed with larger datasets.

Distinctive mental health profiles in the working population: A nation-wide study from Finland

Ari Väänänen

A Väänänen[1], J Kausto[1], K Gluschkoff[1], L Kokkinen[2], S Selinheimo[1]
[1]Finnish Institute of Occupational Health, Helsinki, Finland
[2]Faculty of Social Sciences, Tampere University, Tampere, Finland
Contact: ari.vaananen@ttl.fi

Introduction:

Studies on mental health inequalities are usually based on limited sets of mental health indicators.

Objectives:

Using a large number of mental health indicators, we explored whether it is possible to identify similar hierarchical rankings regardless of mental health indicators (incl. psychotherapy) among employees representing different socio-demographic statuses, and which groups of employees have the highest mismatch between mental health symptom and treatment.

Methods:

Employees representing different occupational classes and employees from four different areas of Finland were studied and compared. We used national register data to define psychotropic medication (purchases), sickness absence for mood disorders, and the use of psychotherapy between 2017 and 2019 and national survey data from the FinHealth 2017 Study to define the level of psychological symptoms (BDI, GHQ). We assessed the risk of each outcome by population group separately for men and women, and estimated the mismatch between symptoms (BDI/GHQ caseness) and treatment (psychotropic drugs/therapy).

Results:

In all the studied groups, the prevalence of mental health indicators was mostly considerably higher among women than men. The risk of register-based mental health indicators was typically higher among lower non-manual employees. In the case of some mental health indicators, we observed significant interactions between occupation class and region. Some stark mismatches were detected between symptoms and treatment in some populations, whereas at the other end of the spectrum, the correspondence between symptoms and the mobilization of care was rather high.

Conclusions:

Although gender is strongly linked to mental health indicators, occupational class and region influence mental health profiles in the population. There are considerable inequalities between populations in the level of professional care associated with mental health problems.

11.A. Workshop: Leveraging meso-level data to advance population health in Europe: further directions

Abstract citation ID: ckac129.687

Organised by: Montpellier University Hospital (France)
Chair persons: Gregoire Mercier (France)
Contact: gregoire_mercier@hotmail.com

Health services and public health researchers provide timely and critical evidence to answer real-world policy questions and work extensively with policymakers at the macro, meso and micro levels of government. One goal shared by researchers and policymakers is to foster evidence-informed policy and program development to ensure that policy initiatives provide the greatest benefit possible to individuals and society. Among other sources of data, meso-level datasets are usually comprising contextual data aggregated at various geographical areas such as cities, counties, and regions. Although meso-level data are sometimes used as proxies for individual level data, they can also be used to explore complex questions at the population level. This workshop aims to provide a unique, interprofessional, European conversation about how to translate meso-level research evidence into meaningful insights or recommendations. It brings together a group of high-level people from academia, think tanks, and companies who are involved in generating, transferring, or using meso-level evidence to inform public health and health care policy in Germany and France. In the first presentation, Schüttig et al. use district-level data from Germany to suggest that increased spending and improved continuity of care may be effective ways to reduce the rate of potentially avoidable hospitalizations among patients with type 2 diabetes. Then, Mercier et al. analyze department (district)-level data from France to quantify the impact of the population-based prevalence of diabetes and psychiatric conditions, of air pollution, of socio-economic variables, and of meteorological factors on the spread of COVID-19 during the first lockdown. Rodts et al, in a collaboration between a think tank and a small company, use a broad set of district-level variables to classify French 'departements' into homogeneous clusters in terms in needs and explore the discrepancies between total health care spending and needs at the population level. Finally, Mâlatre-Lansac et al. build on these studies to discuss how data can be used to inform public health and health care policy making in Europe. In addition, they suggest future directions to improve meso-level data-driven policy at the local, national, and European levels. Beyond methodological points, the discussion will address ethical issues in the use of meso-level data, and how to improve the availability of data, and the ability of local, regional, and national policymakers to use research evidence efficiently. It is designed as a regular workshop with 4 presentations (10 minutes each), ample audience interaction through Q&A after each presentation and one freehand poll in the introduction of each presentation.

Key messages:

- Meso-level data can be efficiently leveraged to inform health care policy.

- Further efforts need to be taken to address the information needs of policymakers.

Meso-level ambulatory care and ambulatory care sensitive hospitalizations in Germany

Wiebke Schüttig

W Schüttig[1], *L Sundmacher*[1]
[1]Health Economics Department, Technische Universität München, Munich, Germany
Contact: wiebke.schuettig@tum.de

Ambulatory care sensitive hospitalizations are widely considered as important measures of access to as well as quality and performance of primary care. In our study, we investigate the impact of spending, process quality and continuity of care in the ambulatory care sector on ambulatory care sensitive hospitalizations in patients with type 2 diabetes. We used observational data from Germany's major association of insurance companies from 2012 to 2014 with 55,924 patients, as well as data from additional regional data sources. We conducted negative binomial regression analyses with random effects at the district level. To control for potential endogeneity of spending and physician density in the ambulatory care sector, we used an instrumental variable approach. In doing so, we adjust for a number of known risk factors for hospitalizations among this patient group. We undertook a Shorrocks-Shapley decomposition to investigate the relative contribution of groups of regressors to the pseudo R2. The results of our analysis suggest that spending in the ambulatory care sector has weak negative effects on ambulatory care sensitive hospitalizations. We also found that continuity of care was negatively associated with hospital admissions. Patients with type 2 diabetes are at increased risk of hospitalization resulting from ambulatory care sensitive conditions. The results of the decomposition analysis for groups of variables indicate that ambulatory care characteristics account for 9.8% of the pseudo R2, morbidity of patients (including gender and age groups) for about 85.5%, and system-related factors of health provision for 4.7%. Our study provides some evidence that meso-level factors such as increased spending and improved continuity of care while controlling for process quality in the ambulatory care sector may be effective ways to reduce the rate of potentially avoidable hospitalizations among patients with type 2 diabetes.

The impact of various environmental, socio-economic, and epidemiological factors on COVID-19 transmission and severity is well-known. However, there is little evidence about the respective role of these factors at the population-level at a national scale. The objective was to identify the environmental and contextual factors that influenced the spread and the severity of COVID-19 at the French department level during the first national lockdown. We performed a national, population-based, retrospective analysis. The cumulative rate of patients admitted for COVID-19 to any public or private acute care hospital from March 31st, 2020 to May 25, 2020 was modelled at the 'departement' (hereafter county) level. We used spatial regression models to quantify the aggregated effect of population health status, air pollution, meteorological, and socioeconomic factors. 57,356 patients were admitted to an acute care facility for COVID-19 over the period of interest. At the county level, the age and sex-standardized rate of admission ranged from 0.07 to 3.24 admissions per 1,000 people. After adjustment on the pre-lockdown COVID-19 hospital admission rate, the standardized cumulative rate hospital admission for COVID-19 during the period of interest was significantly and positively associated with the prevalence of diabetes, with the prevalence of mental conditions, and with high cumulative exposure to atmospheric ozone values. It was significantly and negatively associated with high cumulative exposure to ultraviolet radiation. These results suggest that several population-based epidemiological and meteorological factors could have played a role in COVID-19 spread in France. They provide potentially useful insights to design and implement geographically differentiated public health policies.

Aligning health care spending with population needs is a goal shared by many public health and health care systems. However, most modelling approaches have proven deceptive and ineffective. We propose a novel data-driven, population-based approach to help policymakers explore the discrepancies between spending and needs in France. We leveraged several national open data sources covering demographics, social deprivation, epidemiology, environment, health-related behaviors, and all-payer health care spending (hospital inpatient, prescription medicines, ambulatory events, and dental care). We classified the French "departements" (hereafter counties) into clusters that are homogeneous in terms of health care needs, based on a multidimensional framework. Then, we calculated all-payer per capita health care spending to analyze its within- and between-cluster variation. Based on these findings, we designed a web-based, interactive mapping tool dedicated to French policymakers and payers. The analysis shows 7 clusters of French counties differing in terms of health care needs and spending. The higher-needs/lower-spending and lower-needs/higher spending clusters suggest considerable room for improvement through a regional distribution of spending at least partially based on needs. Most interestingly, the data we used is publicly available, but policymakers lack expertise and time to undergo such analyses themselves. We plan to develop a dynamic and more granular version of the tool to allow policymakers to accurately design and evaluate health care policies.

Data-driven policy making: a key step for the healthcare system

Angele Malatre

A Malatre[1], *E Ros*[1], *L Millet*[1]
[1]Institut Montaigne, Paris, France
Contact: amalatre@institutmontaigne.org

The work presented in this workshop suggest important room for improvement in data-driven health policy making in France and in Germany. We identify data generated by healthcare systems can be mobilized to inform four different aspects of public health and health care policy making:

1. Supporting patient-centered evaluation of healthcare services: micro-level data collection is key to developing evaluation tools which can be used to improve quality of care and patient experience, as evidenced by the development of PROMS and PREMS.
2. Adapting care supply to population needs: meso-level data collection enables local and national policy makers to design and implement healthcare programs and investments which fit population needs.
3. Developing targeted prevention policies: meso-level data collection can also be used to identify health hazards, improve population safety and limit health impact of exposure to sanitary and environmental risks, allowing local and national policy makers to articulate prevention strategies.
4. Informing healthcare research: patient and meso-level data are invaluable resources for health and life-sciences research, supporting identification of biomarkers and development of diagnostic tools and treatment.

Additionally, we identify that all four of these aspects of data-driven policy have implications at a local, national, and European level. In light of this, Institut Montaigne strongly advocates for a population-based approach, as implemented in Canada, relying on multiple datasets as well as individual and collective responsibility. We also stress the need for coordination at a European level, aware the current implementation of the European Health Data Space is an opportunity to leverage information from EU-wide databases. Data-driven public health and health care policy is a tool of public value and its use is critical to ensuring resilience of current health systems and addressing future crises.

11.B. Round table: From Science to Policy Making: Lessons learned from ASPHER's COVID-19 Task Force

Abstract citation ID: ckac129.692

Organised by: ASPHER
Chair persons: Nadav Davidovitch (Israel), Ines Siepmann (Belgium)
Contact: r.hrzic@maastrichtuniversity.nl

ASPHER, the Association of Public Health Schools in the European Region, convened a COVID-19 Task Force (TF) at the start of the pandemic. The TF has involved over 60 experts, 30 member schools, more than 20 countries across four continents, supported by young professionals (YPs). The COVID-19 TF became a unique expert forum for mutual support, sharing, reviewing, and presenting evidence on epidemiological, technical, societal, and political dimensions of the COVID-19 pandemic across Europe. Working with European and national health authorities and non-governmental organisations (NGOs), it also prompted and supported the coordination of policy responses across the WHO European Region. Drawing on members' collective knowledge and expertise, the TF produced a significant body of work that speaks to different public health aspects of the pandemic and gaps in responses. Since its inception in early 2020, the TF has produced more than 30 peer-reviewed publications, regular position statements and reports on topics from personal to planetary protection including: face masks, testing, tracking, vaccination, health inequalities, protecting vulnerable groups, safe schools, advocacy for wider social protection and global vaccine equity. The panel will reflect on key lessons learned over two years of TF work. First, that effective cross-country comparative work was made possible by the group's independence, interdisciplinarity, and high trust between its members. This mix of characteristics allowed for unencumbered weekly sharing of ideas, utilisation of data, insights available in local languages, and unique access to the front-line experience of members, those with positions in health authorities or advising national or regional governments. The second lesson is the importance of a flexible, bottom-up organisation, which allows the members to pursue individual research, education, and advocacy agendas while acting in concert. Cooperation between ASPHER Schools of Public Health existed before the pandemic, but the TF strengthened these relationships and made inter-school collaborations more frequent. Lesson three is a successful combination of policy advocacy, with shaping public health education and providing training opportunities for YPs. Thirteen YPs have been involved in the work of the COVID-19 TF since its inception, playing a critical role by preparing weekly situation reports, a horizon scanning exercise, surveys of ASPHER members, and contributing an early-career perspective to the groups' outputs. Involving young public health professionals effectively in expert forums provides crucial training opportunities in knowledge transfer and leadership that should be more widely available. The panel will also reflect on how to set-up, build, scale-up, and sustain collaborations with wide geographic, cultural, linguistic, and political-administrative coverage to support the capacity and preparedness of public health institutions during future challenges.

Key messages:

- The panel will recount key lessons from ASPHER's COVID-19 Task Force: fostering independence, interdisciplinarity, and trust; a flexible, bottom-up organisation; and involving young professionals.
- The panel will reflect on setting up collaborations across cultural and political-administrative boundaries to strengthen the advisory capacity of public health institutions during future challenges.

Preschool children's temperament and its associations with energy intake

Riikka Pajulahti

R Pajulahti[1,2], C Ray[1,2], K Salmela-Aro[3], L Korkalo[1], R Lehto[2], H Vepsäläinen[1], K Nissinen[4], E Roos[2,5], M Erkkola[1]
[1]Department of Food and Nutrition, University of Helsinki, Helsinki, Finland
[2]Folkhälsan Research Center, Helsinki, Finland
[3]Faculty of Educational Sciences, University of Helsinki, Helsinki, Finland
[4]Seinäjoki University of Applied Sciences, Helsinki, Finland
[5]Department of Public Health, University of Helsinki, Helsinki, Finland
Contact: riikka.pajulahti@helsinki.fi

Background and objectives:
Child's temperament dimensions have been linked with different weight outcomes as well as dietary factors such as consumption of fruit and vegetables, sugar-rich foods and drinks and an overall dietary quality. Links between temperament dimensions and energy intake, however, remain underexamined. This study expands the literature by investigating associations between child's temperament dimensions and energy intake.

Methods:
Altogether 505 Finnish children aged 3-6 years provided data for the analyses. The data is a part of the DAGIS (Increased Health and Wellbeing in Preschools) study conducted in 2015-2016. Child's energy intake was measured with 3-day food records. To be included, children had to 1) have food record for two preschool days and one weekend day and 2) to have consumed both lunch and an afternoon snack in the preschool on the two preschool days. The very short form of Children's Behavior Questionnaire was used to measure child's temperament dimensions. Concurrent associations between three temperament dimensions (surgency, negative affectivity, and effortful control) and energy intake were examined using linear regression models adjusted for child's age, sex, mother's highest education, and moderate-to-vigorous physical activity.

Results:
Surgency, temperament dimension referring to characteristics such as impulsivity, high activity level and high approach, was positively associated with energy intake. Effortful control or negative affectivity were not associated with energy intake.

Conclusions:
The findings imply that temperamental surgency may be one relevant determinant of energy intake among preschool children. The result is in line with previous studies linking child's surgency as well as its specific facets, such as impulsivity, with weight outcomes and food approach behaviors. Considering child's individual temperament dimensions when counselling families in eating issues could be beneficial.

Key messages:
- Surgency, a temperament dimension referring to characteristics such as impulsivity, high activity level and high approach, was positively associated with energy intake.
- When promoting children's balanced eating, tailored support for parents acknowledging child's temperament could be beneficial.

Abstract citation ID: ckac129.694
Trans fatty acid intake and risk of type 2 diabetes in the NutriNet-Santé prospective cohort

Gaëlle Wendeu-Foyet

G Wendeu-Foyet[1,2], A Bellicha[1,2], V Chajes[2,3], I Huybrechts[2,3], C Debras[1,2], B Srour[1,2], L Sellem[1,2], L Fezeu[1], M Deschasaux-Tanguy[1,2], M Touvier[1,2]

Contact: g.wendeufoyet@eren.smbh.univ-paris13.fr

Type 2 diabetes (T2D) is one of the most common noncommunicable diseases worldwide, with an increasing prevalence and a considerable global health burden. Substantial evidence has linked consumption of trans fatty acids (TFAs) to an increased risk of cardiovascular disease. However, the effects of T2D remain unclear. We aimed to investigate the associations between different types of TFAs (total, ruminant, industrial and corresponding specific isomers) and risk of T2D in the NutriNet-Santé prospective cohort. Overall, 105,551 participants aged 18 years or older from the French NutriNet-Santé cohort (2009-2021) were included (mean age at baseline = 42.7y (SD = 14.6y), 79.2% women). Dietary intake data, including usual TFA intake, were collected using repeated 24-hour dietary records (n = 5.7 [SD = 3.1]). Associations between sex-specific quartiles of dietary intake of TFAs and type 2 diabetes risk were assessed using multivariable Cox proportional hazard models adjusted for known risk factors. A total of 969 incident type 2 diabetes cases occured during follow-up. Total TFAs was associated with higher T2D risk (HRfor quartile 4 versus 1 = 1.38; 95% CI = 1.11-1.73; Ptrend<0.001). This association, specifically observed for industrial TFAs (HR = 1.45; 95% CI = 1.15-1.83; Ptrend<0.001), was mainly driven by elaidic acid (HR = 1.37; 95% CI = 1.09-1.72; Ptrend<0.001) and linolelaidic acid (HR = 1.29; 95% CI = 1.04-1.58; Ptrend = 0.07). In contrast, ruminant trans fatty acids were not significantly associated with the risk of T2D. In this large prospective cohort, higher dietary intakes of total and industrial TFAs were associated with increased T2D risk. These findings support WHO's recommendation to eliminate industrially-produced TFAs from the food supply worldwide. As such, consumers should be advised to limit the consumption of food products containing partially hydrogenated oils (main vector of iTFAs) as this, specifically, may contribute to lower the substantial global burden of T2D.

Key messages:
- Higher dietary intakes of total and industrial trans fatty acids were associated with increased type 2 diabetes risk.
- Our findings support WHO's recommendation to eliminate industrially-produced TFAs from the food supply worldwide.

The path to evidence-based guidelines for food insecurity during pregnancy

Fiona McKay

F McKay[1], P van der Pligt[2,4], J Zinga[1,3], R Lindberg[2], A Dickson[2]
[1]School of Health and Social Development, Deakin University, Burwood, Australia
[2]Institute for Physical Activity and Nutrition, Deakin University, Burwood, Australia

[3]Royal Women's Hospital, RWH, Parkville, Australia
[4]Department of Nutrition and Dietetics, Western Health, Footscray, Australia
Contact: fiona.mckay@deakin.edu.au

Background:

Food insecurity has negative health implications during and after pregnancy, however, identifying and then assisting women who are food insecure is complex. Successful screening programs are often embedded in practice guidelines that include referral and treatment guidance. Screening for food insecurity is vital to address food insecurity, however, it is not present in Australia, nor are there any guidelines for healthcare settings. This presentation will describe the steps taken to gather evidence to inform the development of practice guidelines.

Methods:

The creation of practice guidelines for screening and responding to the needs of food insecure pregnant women was informed by 1) qualitative interviews with food insecure pregnant women, and 2) qualitative interviews with clinicians about their experiences of assisting hungry and food insecure pregnant women, 3) quantitative research with a cross-section of pregnant women about their experiences managing their food supply, 4) a systematic review describing the existing interventions addressing food insecurity during pregnancy, and 5) a modified Delphi to gather the opinions of experts on the best ways to address food insecurity in pregnancy.

Results:

This work highlight the potential effectiveness of a food insecurity screening tool in the antenatal setting, the readiness of clinicians to respond to this need, the breadth and depth of current interventions to address food insecurity, and the opinions of experts on how this issue needs to be addressed. The combined impact of these 5 studies is the identification of a number of responces to food insecurity and hunger during pregnancy.

Conclusions:

Given the lack of screening, standard care, and treatment of food insecurity in a clinical setting in Australia, it is essentail that guidelines are created that standardise patient care and control costs through efficient use of health care resources.

Key messages:

- Food insecurity during pregnancy has significant implications for both mother and baby.
- Creating supportive evidence-based mechanisms to address food insecurity will lead to positive outcomes.

[3]Department of Life Sciences, University of Nicosia, Nicosia, Cyprus
Contact: demetriou.chri@unic.ac.cy

Childhood obesity is a public health crisis. Even though appetite traits in infancy were associated with childhood adiposity, whether early weight gain can influence later appetite has not been researched. Our aim was to prospectively examine the bidirectional association between growth and appetite traits during the first year of life. We followed up 450 healthy term infants for 12 months (m). Appetite traits at 4 weeks (wk), 6m and 12m were assessed using the Baby and Child Eating Behaviour Questionnaires. Infant feeding, anthropometric, socioeconomic and demographic data were also collected. Infant weight-for-age z-scores (WFAZ) were calculated using the WHO 2006 growth reference. Growth was assessed as conditional WFAZ change (cWFAZc) by saving the residuals from linear regression models of WFAZ at each successive time point versus WFAZ at the earlier time point. Multivariable linear regression was used to analyse bidirectional associations between cWFAZc (0-4wk, 4wk-6m, 6-12m) and appetite traits Enjoyment of Food (EF), Food Responsiveness (FR), Satiety Responsiveness (SR) and Slowness in Eating (SE) at 4wk, 6m and 12m. All models were adjusted for relevant confounders. At 4wk, SR score was associated with lower (β:-0.16; 95% CI:-0.28,-0.03), and FR score with higher (β:0.10; 95% CI:0.01,0.19) cWFAZc from 4wk to 12m. SR score at 6m was inversely associated with cWFAZc from 6-12m (β:-0.09; 95% CI:-0.16,-0.01). Conversely, higher cWFAZc between 4wk-6m was associated with higher EF (β:0.10; 95% CI:0.01,0.19) and FR (β:0.16; 95% CI:0.04,0.29) scores at 12m. cWFAZc between 6m-12m was inversely associated with SR at 12m (β:-0.18; 95% CI:-0.35,-0.01). Our results suggest that the growth acceleration hypothesis, where faster growth in infancy leads to later obesity, may be mediated by an up-regulation of appetite traits at 12m. This highlights the public health importance of avoiding growth acceleration in infancy as a way to curb the childhood obesity epidemic.

Key messages:

- Weight gain in early infancy impacts appetite regulation in the first year of life and up-regulation of appetite traits at 12 months predisposes to childhood obesity.
- Avoiding growth acceleration in infancy can decrease the risk for childhood obesity.

[5]Faculdade de Ciências Medicas, NOVA Medical School, UNL, Lisbon, Portugal
Contact: rica.cane@gmail.com

Background:

Globally, anemia prevails as a public health issue, being also a concern in Mozambique, where about two-thirds of children 6-59 months of age are affected by anemia. We carried out this study to estimate anemia prevalence and evaluate structural determinants and hematological parameters association among children aged 6 to 59 months attending pediatric inpatient and outpatient services in a Quaternary Health Facility in Maputo City Province, Mozambique.

Methods:

From August 2021 to January 2022, we conducted a cross-sectional study at the 'Maputo Central Hospital' where we collected data from 397 inpatients or outpatients who attended pediatric consultations. The cut-off values for anemia were: mild (10g/dL≤Hb≤10.9g/dL), moderate (7g/dL≤Hb≤9.9g/dL), severe ($Hb < 7.0g/dL$). We used SPSS 28.0 software to perform descriptive analyses and Chi-Square tests.

Results:

Our preliminary findings show that the total rate of positive cases was 30.0% moderate anemia (119/397), 23.9% mild anemia (95/397), and 7.3% severe anemia (29/397). Anemia frequencies were higher in male patients unregarding the type (54.2% moderate, 62.1% mild, 67.9% severe). Anemia prevalence was higher among children aged 24-59 months (41.2% moderate, 47.4% mild, 51.7% severe; $p < 0.05$). The rate of all anemia types was higher in children from rural areas and Maputo City province relative to those from urban areas and other country provinces. The level of education of the child's companion to the consultations was associated with anemia ($p \leq 0{,}05$), with higher rates observed in secondary level education. We observed no association between iron or serum ferritin values to anemia.

Key messages:

- Children aged 24-59 months, children from rural areas, and who are male are more vulnerable to suffering anemia than their peers, thus needing more monitoring during their growth.
- Nutritional-anemia-specific interventions targeting the first 1000 days of life may be helpful to its reduction in children.

Understanding eating-related health outcomes: connections between anxiety and eating behavior

Felix Hussenoeder

FS Hussenoeder[1], I Conrad[1], M Löbner[1], M Löffler[2], A Tönjes[3], M Sturmvoll[3], A Villringer[4], S Riedel-Heller[1]

[2]IMISE, Leipzig University, Leipzig, Germany
[3]Medical Department III, Leipzig University, Leipzig, Germany
[4]Human Cognitive and Brain Sciences, Max-Planck-Institute, Leipzig, Germany
Contact: felix.hussenoeder@medizin.uni-leipzig.de

Background:

Research shows that anxiety is connected to a variety of mental health outcomes, and that it is widespread among the population. In the light of the great personal and societal costs of obesity and eating disorders, we want to understand the connection between anxiety and different dimensions of eating behaviors that have a strong empirical link with negative eating-related health outcomes.

Methods:

We used data from the population- based LIFE-Adult-Study (n = 5019) to analyze the connection between anxiety (GAD-7) and the three dimensions of eating behaviors: Cognitive Restraint, Disinhibition, and Hunger (FEV, German version of the Three-Factor-Eating-Questionnaire). We controlled for sociodemographic variables, smoking, physical activity, personality, and social support.

Results:

Multivariate regression analyses showed significant positive associations between anxiety and Disinhibition ($\beta = 0.23$, $p \leq 0.001$), Hunger ($\beta = 0.21$, $p \leq 0.001$) and Cognitive Restraint ($\beta = 0.04$, $p \leq 0.01$). After adding control variables, analyses revealed significant positive associations between anxiety and Disinhibition ($\beta = 0.15$, $p \leq 0.001$) as well as Hunger ($\beta = 0.14$, $p \leq 0.001$), but not between anxiety and Cognitive Restraint ($\beta = 0.03$, $p = 0.076$).

Conclusions:

There is an empirical connection between anxiety and two factors of eating behavior, i.e., Disinhibition and Hunger. If future research strengthens the assumption of a causal direction from anxiety to those factors, interventions that help individuals to better regulate and cope with anxiety, could be one potential pathway to reducing eating disorders and obesity in the population.

Key messages:

- There is a significant connection between anxiety and eating behavior.
- Interventions that address anxiety could reduce problematic eating-related health outcomes like eating disorders and obesity.

11.D. Workshop: Depression comorbidity in prediabetes and diabetes: evaluating risk factors and outcomes

Abstract citation ID: ckac129.699

Organised by: Tuebingen University (Germany)
Chair persons: Norbert Schmitz (Germany)
Contact: norbert.schmitz@med.uni-tuebingen.de

Depression is a common comorbidity in prediabetes and diabetes. Evidence for the interaction of depression and behavioural and biological risk factors for (pre-) diabetes and diabetes-related outcomes will be presented and discussed using longitudinal data from the Lifelines Cohort, the Canadian Longitudinal Study on Aging, and the Cartagene study. In addition, digital phenotyping will be discussed as an alternative approach for the assessment of mobility and behaviour in people with diabetes.

Key messages:

- Behavioural, psychosocial and biological risk factors might increase the risk of poor diabetes outcomes in a synergistic way.
- Prevention program for diabetes and diabetes realted outcomes should focus on behavioural, psychosocial and biological risk factors simultaneously.

Abstract citation ID: ckac129.700

Childhood trauma, depression, and the risk of incident prediabetes in young adults: findings from the Lifelines Cohort Study

Sonya Deschenes

S Deschenes[1], F Nearchou[1], A McInerney[1], N Schmitz[2,3], A Nouwen[4]
[1]University College Dublin, Psychology, Dublin, Ireland
[2]Tuebingen University, Population-Based Medicine, Tuebingen, Germany
[3]McGill University, Psychiatry & Epidemiology, Montreal, Canada
[4]Midlesex University, Psychology, London, UK
Contact: sonya.deschenes@ucd.ie

Background:

Childhood trauma and depression have been shown to increase the risk of type 2 diabetes. However, many studies have focused on middle-age and older adults, with less known on the role of these variables in early glucose dysregulation. The goal of the study was to examine childhood trauma, depression, and their interactions, as risk factors for the onset of prediabetes in young adults.

Methods:

Data were from the Dutch Lifelines Cohort Study. N = 8,650 adults (61% female) between 18-35 years without prediabetes/diabetes at baseline (2007-2014) were included. Childhood trauma was assessed using the Childhood Trauma Questionnaire. Depression was assessed using the Mini International Neuropsychiatric Interview. Prediabetes at follow-up (2014-2017) was considered by haemoglobin A1c levels between 5.7%-6.4%. Logistic regressions examined associations between depression and childhood trauma with the risk of incident prediabetes. Odds ratios (OR) and 95% confidence intervals (CI) for unadjusted analyses and analyses adjusted for age, sex, education, ethnicity, body mass index, smoking, and alcohol use (reduced adjusted sample size; n = 7,186) are presented.

Results:

244 participants (2.8%) developed prediabetes. In univariate analyses, childhood trauma (OR = 1.02, CI = 1.01-1.03, p = .006) and depression (OR = 2.08, CI = 1.01-4.29, p = .048) predicted incident prediabetes. When childhood trauma subscales were examined, only sexual abuse significantly predicted incident prediabetes. In adjusted analyses, only childhood trauma, specifically sexual abuse, significantly predicted incident prediabetes (OR = 1.06, CI = 1.01-1.12, p = .021). No multiplicative interaction between depression and childhood trauma was found.

Conclusions:

Young adults who have experienced childhood trauma, particularly sexual abuse, may be at risk of glucose dysregulation in early adulthood. Early targeted preventive care may help attenuate or halt glucose dysregulation and the development of type 2 diabetes.

Abstract citation ID: ckac129.701
Systemic inflammation and the risk of depression in people with type 2 diabetes

Norbert Schmitz

N Schmitz[1,2], *E Graham*[2], *S Deschenes*[3]
[1]Tuebingen University, Population-Based Medicine, Tuebingen, Germany
[2]McGill University, Psychiatry & Epidemiology, Montreal, Canada
[3]University College Dublin, Psychology, Dublin, Ireland
Contact: norbert.schmitz@med.uni-tuebingen.de

Background:

Depression is a common co-morbidity in diabetes. The mechanisms underlying the association between depression and diabetes are poorly understood. Although risk factors, such as poor lifestyle behaviours, obesity, and stress have been identified, emerging evidence suggests that systemic inflammation may play an important role in the pathogenesis and recurrence of depression in people with diabetes. The aim of the present study was to evaluate if the inflammatory marker C-reactive protein (CRP) is associated with an increased risk of major depression episodes in people with type 2 diabetes.

Methods:

A prospective, community-based study was conducted in Quebec, Canada. Individuals were recruited from the CARTaGENE (CaG) cohort, a population-based survey of Quebec residents aged 40 to 69 years. Our sample included 719 individuals with type 2 diabetes and 1423 individuals without diabetes. Individuals were assessed at baseline and 5 years after baseline. Major depression disorders were assessed using a clinical interview (CIDI). Inflammatory markers were assessed from blood samples. Elevated CRP levels were defined as ≥ 3 mg/L.

Results:

Participants with both diabetes and elevated CRP levels had the highest risk of major depressive episodes (adjusted OR = 1.90, 95% CI 1.45, 2.50), compared to those without diabetes and without elevated CRP levels. The risk of major depressive episodes in individuals with diabetes without elevated CRP episodes was lower (adjusted OR = 1.21, 95% CI 0.85, 1.73) and similar to the risk of those without diabetes and elevated CRP levels (adjusted OR = 1.15, 95% CI 0.94, 1.39).

Discussion:

The study highlights the interaction between diabetes, inflammatory makers, and depression in a community sample. Early identification, monitoring, and management of elevated inflammation levels might be an important depression prevention strategy in people with type 2 diabetes.

Depression, diabetes and change in cognitive functioning: results from the Canadian Longitudinal study on Aging

Mahdieh Shojaa

M Shojaa[1], *S Deschenes*[3], *J McLeish*[2], *N Schmitz*[1,2]
[1]Tuebingen University, Population-Based Medicine, Tuebingen, Germany
[2]McGill University, Psychiatry & Epidemiology, Montreal, Canada
[3]University College Dublin, Psychology, Dublin, Ireland
Contact: Mahdieh.Shojaa@med.uni-tuebingen.de

Background:

Individuals who ultimately receive a diagnosis of dementia typically have an observable accelerated cognitive decline (ACD) many years prior to diagnosis. Depression in combination with diabetes is an emerging risk factor that is associated with cognitive problems. Using data from the Canadian Longitudinal Study on Aging, the objective of the present study was to investigate the longitudinal association between depression, diabetes, and cognitive decline in an elderly cohort.

Methods:

Baseline and follow-up data from a population-based study in Canada were used. The sample consisted of 18161 adults between 45 and 85 years of age without diabetes. Cognitive functioning was assessed at baseline and after 4 years using six measures: the Rey Auditory Verbal Learning Test (RAVLT), the Mental Alternation Test (MAT), the Animal Fluency Test (AF), the Controlled Oral Word Association Test (COWAT), the Stroop Test, and the Prospective Memory Test. Depression was assessed using the CES-D10. Regression analysis was conducted to evaluate interactions between depression, diabetes and cognitive decline.

Results:

The mean age of participants was 61 years. Participants with a comorbidity of depression and diabetes had an accelerated cognitive decline (g-factor) compared to those with depression without diabetes and those with diabetes without depression (regression coefficients ß = -0.145 (0.036), ß = -0.076 (0.011), and ß = -0.053 (0.021), respectively).

Conclusions:

This study suggests that depression and diabetes might increase the risk of cognitive decline in a synergistic way.

Introduction:

Societal restrictions due to COVID-19 have had a profound effect on our ability to connect with one another and limited our personal mobility. There is evidence that loneliness, social isolation, and psychological distress increased during restrictions for people with diabetes. Fluctuating restrictions provide a unique opportunity to utilise continuous GPS data from personal smartphones (digital phenotypes) to explore the relationship between time-at-home and psychosocial health for people with diabetes. This study aims to (1) describe the digital phenotypes of time-at-home during varying societal COVID-19 restrictions for people with and without type 2 diabetes and

(2) to explore associations between these digital phenotypes and loneliness, social support, and other psychosocial factors and compare for people with and without type 2 diabetes.

Methods:

Data come from a longitudinal observational study in the Republic of Ireland that ran between March and August 2021. Participants are seventy-four adults (64.8% female; median age-group = 50-54) with (N = 40) and without (N = 34) diabetes. Continuous GPS data were recorded for 2 months through the Beiwe smartphone application. Loneliness (UCLA-3), social support (MSPSS), diabetes stigma (DSAS-2; diabetes cohort only) as well as other demographic, psychosocial, and lifestyle questionnaires were assessed at baseline, 1 month, and 2 months follow-up.

Analysis:

GPS data are being processed. The GPS-derived features of time-at-home, overall movement, and location variance will be computed. Associations between these digital phenotypes and psychosocial factors will be explored and changes over time examined using multilevel modeling.

Conclusions:

We expect this study to be the first to describe and compare the digital phenotypes of people with and without diabetes during varying societal COVID-19 restrictions, providing new insights into the effects of such policies on the psychosocial health of people with diabetes.

11.E. Workshop: Urban Green Spaces, Built Environment and Urban - Mental - Environmental Health outcomes

Abstract citation ID: ckac129.704

Organised by: EUPHA-URB, EUPHA-PMH, EUPHA-ENV
Chair persons: Stefano Capolongo (EUPHA-URB), Marija Jevtic (EUPHA-ENV)
Contact: andrea.rebecchi@polimi.it

Environmental sustainability, especially in an era of growth health inequality, is one of the most important challenges facing Public Health systems around the World. Environmental sustainability is responsibly interacting with the planet to maintain natural resources and not jeopardize the ability for future generations to meet their needs. The SDGs put environmental sustainability at the center of sustainable development. Environmental Health is the branch of Public Health concerning all aspects of the natural and built environment affecting human health. It is targeted towards preventing disease and creating health-supportive environments. It encompasses the assessment and control of those environmental factors that can potentially affect health, such as pollution, poverty and inadequate energy solutions. Urban Health is an intersectoral arena that links both the public health and the urban planning sectors, mainly captured by SDG3 (including Mental health) and SDG11. Both during the first waves of the Covid-19 pandemic period and in contemporary cities, urban environments were stressed; the resilience of our cities were tested, highlighting the strengths and weaknesses of the urban contexts, not always capable to pro-mote and protect the population health status. Urban Green Spaces (UGS) have proved essential role as ‘‘tools’’ to improve Urban Public and Mental Health. Unfortunately, the heterogeneous distribution of UGS inside the contemporary cities, together with the disparity in quality of such spaces, led to some exclusion phenomena. Evidence/experience-based research strongly demonstrated the positive effects on Public Health of the UGS, and for this reason, they are now becoming the strategic and challenging issue of many urban regeneration programs. The importance of UGS as a key infrastructure has generated the necessity of developing new health-centered design criteria able to conform to their new role in urban environments. The augmentation of UGS surface alone, does not necessarily make cities more livable. An increase in area and surfaces does not translate in ease of accessibility from all social groups or from all the cities' neighborhoods, or not does it give data on the qualities of such areas, like potential for social engagement or Physical Activity.

Aim of the Workshop - organized by the three EUPHA Section URB+MEN+ENV - it would like to be to build the capacity and knowledge between participants about the main topics and urban features capable to have relevant Urban Public, Mental and Environmental Health outcomes. Additional scope is to collected case studies and research experiences considered virtuous at the international level, analyzed in detail to highlight the main urban and architectural features of those healthy experiences and the related health outcomes, such as sedentary lifestyle reduction, increase of the attractiveness of places, reduction of air and noise pollution.

Key messages:

- Promotion of healthy places - with particular reference to the green spaces - that enhance the experience and Mental Health needs to be part of green and inclusive recovery at all levels.
- Policy Makers, Public Health experts, civil societies & citizens are driving forces to implement the development equation, allowing cities to become greener, inclusive, safer, resilient & sustainable.

Abstract citation ID: ckac129.705

Bridging Epidemiological Data with Features of the Urban Context: An experience of Urban Public Health within the City of Milan, Italy

Andrea Rebecchi

A Rebecchi[1], AA Johnson[2], A Brambilla[1], M Buffoli[1], AG Russo[3], S Capolongo[1]
[1]Design & Health Lab, DABC - Politecnico di Milano, Milan, Italy
[2]Columbia University, Vagelos College of Physicians and Surgeons, New York, USA
[3]ATS della Città Metropolitana di Milano, Milan, Italy
Contact: andrea.rebecchi@polimi.it

Referring to the Research Project ‘‘Enhancing Healthcare and Well-Being Through the Potential of Big Data: An Integration of Survey, Administrative, and Open Data to Assess Health Risk in the City of Milan with Data Science’’ the Authors present preliminary results regarding a survey distributed to a sample of citizens across all neighborhoods of Milano city. This survey sought to collect data regarding health risk factors of this population, including both individual (e.g. socio-demographic characteristics, behaviors, etc.) and community (e.g. environmental/morphological features, available social services, etc.) data. A digital survey was designed to collect information on the health conditions, risk factors, and lifestyle characteristics of a representative sample of the Milanese population at the neighborhood level, with reference to the census tracts and Local Identity Units (NIL). Collected survey data are entered into a system containing corresponding individual health information acquired from the Local Health Authority databases, creating a synthesized information profile with each respondent's state of health, including existing conditions, health services used, and drug therapies. The disseminated survey was developed from comparisons with similar experiences at the national/international level and divided into 60 multiple choice questions (6 for Sociodemographic profile; 8 for Context of residence; 12 for Functional limitations; 25 for Behaviors and lifestyles; 9 for Access to health services). The data from urban analysis conducted on the NIL of the City of Milan are assessed with particular reference to the theme of bicycle-pedestrian accessibility (Walkability) in the urban context and repercussions on the adoption of Healthy Lifestyles. The models developed through this research are expected to provide critical insight for designing health promotion, health protection, and disease prevention interventions aimed both at individual and community level.

Nature deprivation under COVID-19 lead to reduced well-being. Urban design interventions were also identified as an important contributor to the restoration of community confidence, choice, and safety. Factors related to sociodemographic, housing and lockdown were linked to changes in exposure to nature during the pandemic lockdown. Changes in exposure to nature and mental health outcomes during the COVID-19 lockdown were strongly linked. Especially young people had an increased number of mental health problems. Children and youth were more bored and worried in comparison with the pre-pandemic period. The educational institutions worldwide were closed or changed to online education during the pandemic, leading to great disturbance in students' education and outdoor events. All ''green infrastructure'' (GI) resources (including parks, gardens etc.) received great attention as ''essential infrastructure'' supporting well-being. But, the quality, functionality and position of GI in urban areas showed inequality in distribution. Frequently, societies with greater ethnic diversity, lower income and larger health inequality suffered from unsatisfactory or lack of access. GI is important in decision-making to address inequality. This work will also present an open-air activity for all generations: A reflective walk through the oldest part of Novi Sad (EU Capital of Culture 2022), as a part of Project Reflective citizens in Novi Sad. This walking tour was led by pupils from primary school - where all generations spend useful time in open space and a safe atmosphere walking tour, learning and listening about the cultural history of the oldest part of the city. It is vital to enhance urban planning and design practices in making healthier and more resilient communities. It is necessary to underline the importance of planning green spaces that need time to form in urban areas, and which have proven to be very important for mental health in the midst of the pandemic crisis.

Abstract citation ID: ckac129.707
Green space availability and mental health – results from a cross-sectional study in Northwestern Germany

Felix Sisenop

F Sisenop[1]*, J Lindert*[1]
[1]University of Applied Sciences Emden/Leer, Brandeis University, Emden, Germany
Contact: felix.sisenop@hs-emden-leer.de

Background:
A relationship between green space and health has been shown in several epidemiological studies. The impact of different types of green space is still relatively unknown. To start filling this gap, we looked at associations between different green space types and health outcomes (depression and mental health).
Methods:
Data are obtained from a cross-sectional study (n = 479). Depression (assessed with PHQ-9) and mental health (assessed with GHQ-28) are dependent variables. Availability of green space in the surrounding neighborhood was assessed as independent variable by the percentage of green space (> = 1ha) within a 250m radius participants residence. Survey data were analyzed using IBM SPSS 26 and Geo data using QGIS 3.18.0.
Results:
N = 479 participants of a cross-sectional study in 2018 provided data (49.4%, n = 240 women; 49.6%, n = 239 men). Participants had a mean age of 57.55 years (SD: 18.80, min-max:18-95), majority (75.2%, n = 360) were married or partnered, had a lower educational qualification than A-levels equivalent (56.8%, n = 272), were not employed (53%, n = 254), had a net household income of at least 3. 000€ per month (40.1%, n = 192) and at least sometimes financial worries (51.4%, n = 246). Green areas without agricultural areas show an association with frequency of depression (B(SE) = 0.056(0.024), p = 0.018). This contrasts with green spaces including agricultural areas, where there is no statistically significant association (B(SE) = 0.007(0.012), p = 0.564).
Discussion:
We found an association between type of green space and depression. Further studies are needed to establish a grid for assessing characteristics and quality criteria of green spaces. However, it can already be assumed that there is an association between quality of green spaces and psychosocial outcomes.

How breaks in nature can affect the users' wellbeing: an experience based survey during the lockdown

Marco Gola

M Gola[1]*, M Botta*[2]*, AL D'Aniello*[3]*, S Capolongo*[1]
[1]Design & Health Lab, DABC - Politecnico di Milano, Milan, Italy
[2]Monica Botta Architects, Novara, Italy
[3]HUB 4 MIND, Varese, Italy
Contact: marco.gola@polimi.it

Background:
In the occasion of COVID-19 pandemic in Italy, the life of citizens was greatly disrupted - from healthcare professionals to the smart workers - and consequently also the state of mood. On the basis of the scientific evidences in relation to the relationship between the built environment and health, a research group has promoted an investigation on the benefits that greenery can have on the psychophysical state of the users, especially healthcare staff and users at home.
Objectives:
The methodology adopted is the Profile of Mood States, which provides experiential activity in nature - without any technological distraction- to evaluate the benefits on mood. The methodology adopted refer to the shorter version

(34 items) designed by prof. Grove at the University of Western Australia. In relation to the COVID-19 pandemic, the experience based questionnaire is differentiated for healthcare staff and general users. The questionnaire is composed of a few questions, to be completed before and after an experience in nature of 20/30 minutes. The investigation requires to be carried out in private gardens, balcony and/or terrace with greenery, public green areas, etc.

Results:

300 participants (subdivided into 225 general users and 75 healthcare professionals) took part in the investigations. Data analysis highlighted the higher performances in anxiety, depression, anger, force, fatigue and confusion, in particular for users who had the experience in garden (-50/70%), and among the healthcare staff the best outcomes are related to who did the investigation during or after the workshift (-60/-90%).

Conclusions:

Although it is well-known the benefits that nature affects positively on well-being and stress level of users, the investigation underlines that brief breaks in the nature - especially in period of great stress such as pandemic - can influence the well-being and mental health of users.

11.F. Workshop: Can digital health literacy act as a protective factor for students in times of crisis?

Abstract citation ID: ckac129.709

Organised by: University of Graz (Austria), EUPHA Working Group on Health Literacy
Chair persons: Barbara Gasteiger-Klicpera (Austria), Michaela Wright (Austria)
Contact: michaela.wright@uni-graz.at

As mental health related issues become more and more prevalent across all ages and social groups around the globe, the identification of protective factors related to well-being is of high importance. In times of the COVID-19-pandemic, this proves to be even more crucial. Young adults and especially students were particularly burdened by social isolation and missing opportunities for personal exchange and supporting relationships during the pandemic. Within this workshop we will discuss the significance of a possible protective factor for the promotion and strengthening of well-being: digital health literacy (DHL). It involves the ability to search for health-related information, to add self-generated content, to evaluate the reliability of health information, to determine the relevance of health information and to protect one's privacy. Findings suggest that it plays a vital part as a protective resource when it comes to maintaining or promoting well-being. This might be particularly the case when the possibility of accessing health-related information is restricted due to reduced social contact. Since important sources for health information are available within the digital space, digital competencies are becoming important to access such information and to conduct a successful and healthy life. The competence of adequately dealing with digital health information, in particular, became more relevant during the COVID-19-pandemic. DHL can be seen as a two-dimensional construct. On the one hand, it refers to the ability to use digital resources to gather health information and, on the other hand, it refers to critical information literacy. Critical information literacy is the ability to collect, understand, evaluate and apply information. Within the proposed workshop, findings of a university survey, conducted within the global COVID-HL network, will be presented. Presentation 1 seeks to address the role of individual factors for the interaction between well-being and DHL. It will further examine the importance of being able to properly assess the relevance of health information. Presentation 2 sheds light on actions, such as adding self-generated health content, when it comes to mental health promotion. It will also take up the relevant individual factors that mediate the relationship between DHL and well-being. Presentation 3 highlights the ability of students to search for health-related information and to use it as a factor to improve their well-being. Presentation 4 provides insight into the importance of DHL for future health professionals in a health sector that is under digital transformation. Lastly, presentation 5 argues for the necessary enhancement of DHL and sense of coherence of students and stresses the need for health promoting and target group specific interventions. In a second step, the audience will be encouraged to ask questions and to engage in a discussion about the suggested conclusions and implications.

Key messages:

- It has been shown internationally that there is a strong relationship between digital health literacy and students' well-being.
- Individual factors are relevant mediators in the relationship between well-being and digital health literacy.

Abstract citation ID: ckac129.710
Digital health literacy and well-being of university students in Austria during the pandemic

Franziska Reitegger

F Reitegger[1], M Wright[2], B Gasteiger-Klicpera[1,2]
[1]Institute of Education Research &Teacher Education, University of Graz, Graz, Austria
[2]Research Center for Inclusive Education, University of Graz, Graz, Austria
Contact: franziska.reitegger@uni-graz.at

Background:

Previous findings suggest that depressive and anxiety-related symptoms have doubled among students since the beginning of the pandemic. Digital health literacy can act as a protective resource to strengthen well-being.

Objectives:

This paper analyzes the relationship between digital health literacy, socioeconomic status and well-being and future-anxiety among students in Austria.

Methods:

480 students from Austrian higher education institutions were surveyed via online questionnaire during the second wave of the Corona pandemic. Sociodemographic data, students' self-assessments of well-being, fears regarding future development and perspectives, and digital health literacy were collected. Variance and regression analyses were used for the evaluation.

Results:

About 50% of the students reported low scores in well-being and distinct fears about the future. A higher socioeconomic status correlated with higher well-being as well as lower fears about the future.Regarding digital health literacy, the ability to assess the relevance of information showed the highest correlation with well-being.

Conclusions:

Individual factors such as gender or the study-program are relevant for the interaction between well-being and digital health literacy. The assessment of the relevance of information and its connection with one's own life reality seems to be important factors in promoting well-being.

The relationship between well-being and digital health literacy in university students from Romania

Marius-Ionut Ungureanu

M Ungureanu[1,2], *MA Coman*[1,2]
[1]Department of Public Health, Babes-Bolyai University Cluj-Napoca, Cluj-Napoca, Romania
[2]Center for Health Workforce Research & Policy, Babes-Bolyai University Cluj-Napoca, Cluj-Napoca, Romania
Contact: marius.ungureanu@publichealth.ro

Background:

Digital Health Literacy (DHL) gained traction in recent years in the health promotion and well-being field as a possible protective factor.

Methods:

A cross-sectional survey was conducted using a self-reported web-based questionnaire on students enrolled at a university from Romania between December 2020 and February 2021. Descriptive statistics, correlation tests, and logistics regressions were employed to analyze the relationship between DHL, well-being, subjective social status (SSS), and future anxiety among students.

Results:

The data set included 1381 valid surveys (out of 1877 total surveys) completed by students aged between 18 and 39 years (mean = 21.9, SD = 3.701), the majority (69%) being males. Most of the students were studying at Bachelor level (83%), while the rest were Master or PhD students. Responses showed that 49% of the students expressed low well-being, 48% expressed a high level of future-anxiety and 59% considered they have a low SSS. For the DHL subscale of evaluating the reliability of the information, 56% of students had limited DHL, while for the subscale of determining the relevance of information, 64% of students presented limited DHL. The DHL subscale of adding self-generated content showed the highest correlation with well-being, followed by the determining relevance of the information subscale. Sufficient DHL was associated with higher levels of well-being when controlling for age, gender, and study program.

Conclusions:

Well-being is influenced by actions such as adding self-generated health content, determining the relevance of health information, and anxiety for the future, all being important actions in health promotion. Individual factors such as age and gender are also relevant in mediating the relationship between DHL and well-being.

Digital health literacy and well-being of students at Sofia University – Bulgaria

Ioannis Patias

I Patias[1], *K Kaloyanova*[1]
[1]Department of Computer Informatics, Sofia University, Sofia, Bulgaria
Contact: patias@fmi.uni-sofia.bg

Background:

During the Covid-19 pandemic the students in the Faculty of Mathematics and Informatics at Sofia University 'St. Kliment Ohridski' applied their abilities for searching health-related information and use it as a factor to improve their well-being.

Methods:

The study used the Questionnaire developed by Dadaczynski, K., Okan, O. & Rathmann, K. in 2020 as COVID-19 Health Literacy Survey: University Students (COVID-HL Survey), and the respective Scale Documentation under the Public Health Centre Fulda (PHZF) at the Fulda University of Applied Sciences & Interdisciplinary Centre for Health Literacy Research at Bielefeld University. 216 students, almost 13% (12.78%) of 1.690 students approached, participated.

Results:

There is a correlation as our students reported Very easy or easy to the question how easy they deal with the coronavirus information on the Internet - with 71% choosing from all the information they find, 91% using the proper words to find the information, and 71% finding the exact information. Those results were achieved as our students reported feeling over the last two weeks 27.12% very low, 18.08% low, and only 54.80% high (>50) well-being, measuring the dimensions of psychological general well-being by the WHO-5.

Conclusions:

Our students reported they can search and retrieve the appropriate information on the coronavirus or related topics, and they are satisfied with the information found. Our students' abilities to search and retrieve health-related information are applicable even under the pandemic pressure, where they contribute to the improvement of their well-being feelings. [This research is supported by the National Scientific Program ''eHealth'' in Bulgaria.]

Digital health literacy and well-being of health sciences students from MU-Sofia during the pandemic

Nikoleta Leventi

N Leventi[1], *A Vodenicharova*[2], *K Popova*[3]
[1]Department of Health Technologies Assessment, Medical University – Sofia, Sofia, Bulgaria
[2]Department of Bioethics, Medical University – Sofia, Sofia, Bulgaria
[3]Department of Social Medicine, Medical University – Sofia, Sofia, Bulgaria
Contact: n.leventi@foz.mu-sofia.bg

Background:

The aim of the study is to demonstrate the Digital health literacy and the well-being of the students from different faculties in Medical University - Sofia during the pandemic.

Methods:

To achieve the purpose of the study a web-based questionnaire was distributed among health sciences students from the Faculty of Public Health and the Medical College -Sofia, as well as medical students from the Faculty of Medicine all from Medical University -Sofia in Bulgaria. Data was collected between February and April 2022, and all respondents participated anonymously and voluntarily. Established statistical methods were used in data analysis.

Results:

Completed questionnaires were received from 239 students. Data collected show that among participants the majority (81,4%) were females, and 73,3% were studying in a Bachelor's programme. Among the respondents 87.7% found it easy, or very easy to use the proper words or search query to find the information they were looking for about coronavirus or related topics. Finally 29,3% of health sciences students expressed low to very low well-being during the last two weeks and the rest 70,7% expressed high well-being.

Conclusions:

The presented results draw attention to the fact that during the pandemic health sciences students demonstrate the appropriate skills in searching and acquiring the information about coronavirus or related topics. In addition, translating and applying the information could contribute to benefit the psychological well-being of the students. In a digitally transformed health sector it is significant for future health professionals to obtain competencies including digital health literacy to promote health and well-being of the patients and provide better outcomes for them. The necessity of digital competences was underlined and thus we need further more, and in depth education in ICT, and digital technologies to all students, starting from the beginning of their studies.

Digital health literacy and well-being in university students in Germany

Kevin Dadaczynski

K Dadaczynski[1]*, M Messer*[2]*, K Rathmann*[1]*, O Okan*[3]
[1]Department of Nursing and Health Sciences, Fulda University of Applied Sciences, Fulda, Germany
[2]Nursing Science, Trier University, Trier, Germany
[3]Department of Sport and Health Science, Technical University Munich, Munich, Germany
Contact: kevin.dadaczynski@pg.hs-fulda.de

Background:
Digital communication technologies had a crucial role during the COVID-19 pandemic, with the internet and Social Media as highly frequented sources for retrieving health information. University student's health and well-being were highly affected and most interaction with peers and professionals migrated to the digital realm, which made digital health literacy (DHL) a key competence to navigate digital health environments. The main goal of the study was to explore DHL of students in Germany.

Methods:
A cross-sectional online survey among students (N = 14916) from 130 universities in Germany was implemented as part of the global Covid-HL Network, collecting data on DHL, physical and mental health, SoC and sociodemographics. Data was analyzed using univariate, bivariate and regression analyses.

Results:
Assessing the reliability of information (5964/14,103, 42.3%) and determining commercial interest of information posed the most difficult tasks (5489/14,097, 38.9%). Difficulties were revealed for finding information (4282/14,098, 30.4%). Female students reported lower DHL and social media use was associated with lower judgment skills. 38% of all students reported low and very low well-being and 29% reported at least two health complaints weekly, while health outcomes follow a social gradient (lower SES and gender). Regression analysis showed significant association between SoC and well-being (OR: 1.2-2.03) and health complaints (OR: 1.58-1.71). Higher future worries were with low well-being (OR: 2.83) and multiple health complaints (OR: 2.84).

Conclusions:
There is an urgent need to enhance DHL and SoC of students and implement health promotion strategies, using target group specific intervention. Gender and socioeconomic differences must be taken into account and interventions could be delivered within the university. Measures should also address student mental health.

11.G. Round table: Resilient health systems: harnessing health information to improve population health

Abstract citation ID: ckac129.715

Organised by: EUPHA-PHMR, EUPHA-HSR, EUPHA-ECO, Sciensano (Belgium), PHIRI
Chair persons: Petronille Bogaert (EUPHA-PHMR), Johan Hansen (EUPHA-HSR)
Contact: Shona.Cosgrove@sciensano.be

Health systems are built to improve the health of the population. When the COVID-19 crisis hit Europe, the sustained performance of these health systems was challenged. The resilience of these health systems, defined as the ability to absorb, adapt, and transform to cope with shocks (Observatory, 2021), was found to be different in the many European countries, leaving some important lessons to be learned and best practices to be showcased to help countries assess their own response to the COVID-19 pandemic and support efforts to strengthen health systems in Europe. A common denominator is health information; the data and information that is needed to monitor the health of patients as well as the general population. Especially in times of crisis, the availability and trustworthiness of these data is of utmost importance. The COVID-19 pandemic showed that within a substantial number of European countries, health information systems were not always equipped to accommodate the data and information flows that were needed in order for researchers to provide the best available evidence to underpin health policy decisions. Ad-hoc surveillance and monitoring systems were set up (under emergency legislation) and clear governance of health information was lacking. In addition, sharing data and information across European borders and ensuring comparability of data and indicators proved to be difficult in a timely manner during the COVID-19 crisis. This resulted in a European landscape with different national and federal health policies, based on sometimes poor scientific findings. However, when the crisis progressed, numerous national and international initiatives were set up aiming to harmonize the available health information and as of now, many of these initiatives are forming a solid foundation of the health systems, rendering their performance sustainable for the future. In this workshop, which is organized as a round table discussion, we will discuss the resilience of health information systems in European countries, with regards to lessons learned from the COVID-19 crisis, barriers to sharing health information within and across borders, best practices and future perspectives. The topic will be highlighted from multiple perspectives, bringing together experts from different backgrounds, including the European level (European Commission and European Observatory on Health Systems and Policies), the country level, and the perspective of European projects. The audience will be able to provide their view on the different topics through an interactive voting poll during the session. Throughout the session, the exchange of knowledge, experiences and opinions with the audience will be facilitated by the chairs.

Key messages:
- Population health information plays a key role in times of crisis, with trustworthy information flows facilitating evidence-informed policies and decision-making.

- Sharing and harmonising health information is key to building resilient healthcare systems that are prepared for the future.

11.H. Round table: Timely access to quality-assured medicines worldwide

Abstract citation ID: ckac129.716

Organised by: EUPHA-HTA, EMA, WHO
Chair persons: Elena Petelos (EUPHA-HTA), Dineke Zeegers Paget (EUPHA)
Contact: elena.petelos@med.uoc.gr

A key aspect of achieving UHC and reducing health inequity is ensuring the timely access to high-quality, safe and effective medicines across the world. The regulatory approval of such products in countries with limited regulatory resources can be lengthy, often compromising patients' timely access to much-needed medicines. This resource-demanding process extends well beyond marketing authorisation, incl. for post-approval changes. The WHO Collaborative Registration Procedure uses the Stringent Regulatory Authorities' medicines evaluations (SRA CRP), a procedure that allows National Regulatory Authorities (NRAs) to leverage the work performed by Stringent Regulatory Authorities (SRAs) on scientific evaluations to decide on medical products approvals within their jurisdiction, through the concept of reliance. Reliance allows an authority to leverage the work performed by other authorities, such as scientific evaluations, to decide on medical products approval within their jurisdiction. This reduces duplication of regulatory efforts, resources and time, while maintaining national sovereignty. In the context of these processes, multi-agency partnerships and cross-border collaboration the role of European bodies, and specifically that of the European Medicines Agency (EMA) as a Stringent Regulatory Authority will be explored. The SRA CRP and its pilot has been evaluated, based on data and stakeholders' perceptions. The evaluation indicates that the procedure delivers on expected objectives and benefits, including shortened timelines (from submission to approval), reduced duplication of efforts and resources (human and financial). It also shows significant and long-term positive impact for the LMICs involved. Additional benefits include greater application of international harmonized standards, an added capacity-building component and an informed and high-quality decision-making at the NRA. The impact of the procedure can be seen through 59 approvals for 16 medicines in 23 countries. The key areas for improvement and recommendations include greater collaboration, communication and transparency between NRAs, applicants, SRAs and WHO, to facilitate interactions and regular sharing of information between stakeholders. It is key to optimise resource utilisation and to leverage synergies, and to this end, a centralized, live platform could be developed to share the status, progress and challenges of applications in real time including information related to post-approval changes. This panel will present the SRA CRP pilots and its evaluation, bringing together experts from regulatory agencies and multilateral bodies to elucidate the current degree and extent of collaboration, whilst attempting to role of the EU and of the EMA in these processes. The panelists will also have an opportunity to take questions from the audience and to discuss the contribution of the EU to global health, incl., timely access for people across the world.

Key messages:

- The SRA CRP facilitates and accelerates the regulatory approval of quality-assured, safe and effective medicines by reliance on SRAs, while maintaining decision-making national sovereignty.
- The EU, via the EMA and the EUM4all and SRA CRP mechanisms, promotes international collaboration and reliance pathways for earlier access to medicines and contributing to global public health and UHC.

Speakers/Panellists:
Victoria Palmi
European Medicines Agency, Amsterdam, Netherlands

Mariana Roldão Santos
WHO, Geneve, Switzerland

Richard Pilsudski
Sanofi, Paris, France

11.J. Workshop: Enabling participation of vulnerable groups in primary health and long-term care

Abstract citation ID: ckac129.717

Organised by: Bielefeld University (Germany)
Chair persons: Kerstin Haemel (Germany), Anja Dieterich (Germany)
Contact: kerstin.haemel@uni-bielefeld.de

Enabling individual and collective participation or vulnerable people in health and social care is fundamental to achieving equitable, people-centered care. However, for vulnerable groups and clients, unfolding opportunities for participation in their care is closely related with experiences of empowerment and disempowerment. The workshop focuses on primary health and long-term care, as those are the pillars of resilient health care systems able to meet the complex care needs of vulnerable people. From a public health perspective, the facets of participation range from providing access to comprehensive services for people in need, to developing a shared understanding between clients and health professionals regarding clients' everyday and care preferences, to sharing decision-making on health and care matters. In this workshop, we will discuss how helpful public health interventions between individual, professional and systemic-structural approaches should or could be designed, to (better) enable participation of vulnerable groups in primary and long-term care. The workshop presentations draw on empirical research with members of vulnerable groups, health professionals and key informants in care policy and practice conducted in Brazil, Germany, India, and Spain. By focusing on different primary and long-term care settings as well as vulnerable groups (undocumented persons, older people in need of care, people living with chronic illnesses) we will address and discuss the following questions:

- What ideas can we find to strengthen participation of vulnerable groups in primary and long-term care settings?
- Which opportunities and barriers are involved?
- How can individual, professional, and structural approaches 'fit together' to enable greater participation of vulnerable groups in their (self-)care?

Key messages:

- Practitioners' efforts to enable participation have to be accompanied by qualification- and governance-oriented public health approaches to achieve patient oriented health and social care systems.
- Present barriers and opportunities for vulnerable groups are instructive indicators for broader challenges towards comprehensive people-centered care.

Abstract citation ID: ckac129.718
Relevance and limits of patient surveys within humanitarian primary health care in Germany

Anja Dieterich

A Dieterich[1,2]
[1]Catholic University of Applied Social Science, Berlin, Germany
[2]Alice-Salomon-University of Applied Sciences, Berlin, Germany
Contact: Anja.Dieterich@KHSB-Berlin.de

Background:

In Germany, distinct parts of the population, such as undocumented persons, uninsured German nationals, EU citizens without employment and asylum seekers, do not have adequate access to health care. Civil society organisations provide humanitarian medical aid for these individuals. However, the offered care is not comprehensive, but depends on volunteers and is restricted to acute conditions. The local initiatives are often underfinanced. To receive funding, they experience increasing pressure to provide evidence of the impact of their work.

Methods:

The applied research project was conducted in cooperation with a German medical Non-Government Organization. A routine patient survey, including items on patient satisfaction and patient reported outcomes, was developed and implemented. The NGO aimed to use it as an instrument for patient participation as well as to strengthen their impact assessment.

Results:

Survey results show high satisfaction levels and a reported increase in health status and system competence. They provide valuable answers for organisational development and fundraising but do not correlate with the extent of care provided.

Conclusions:

Patient surveys are particularly helpful in humanitarian care to legitimize the efforts of compensatory initiatives. Since the affected persons still suffer from undersupply, results are not a valid measure of care standards but rather demonstrate appreciation for the mere existence of volunteer help. For an effective participation, one should not confound involvement in surveys with access to care. To illuminate existing barriers, alternative methodical approaches such as qualitative multi-level case studies are promising, as they allow data on local support settings to be linked with individual care histories and underlying institutional frameworks.

Abstract citation ID: ckac129.719
Primary mental health care in India for older people: stigmatization and community-orientation

Tom Kafczyk

T Kafczyk[1], *K Hämel*[1]
[1]Health Services Research and Nursing Science, School of Public Health, Bielefeld University, Bielefeld, Germany
Contact: tom.kafczyk@uni-bielefeld.de

Background:

In India, older persons are among the fastest growing population groups that are particularly vulnerable to an impaired mental health. Strengthening public primary mental health care (PMHC) has been one of the political priorities in recent years, including efforts to provide more old age-inclusive care. Many factors play a role in shaping equitable access to PMHC. In this study, we focus on how social norms and perceptions of mental health in old age on the community-level facilitate or hamper access to inclusive PMHC.

Methods:

Semi-structured interviews with key informants ($n = 14$) from the fields of mental health and old age policy and practice have been conducted and analyzed.

Results:

The interviewees describe barriers and opportunities towards old-age inclusive and community-oriented PMHC that go beyond the availability of services. The stigmatization of mental health - especially in old age - is a major barrier that is deeply rooted within the family and community care system. While experts stress the relevance of relatives in fostering mental health of older people, a lack of awareness of facets of mental health and a fear of stigmatization within communities prevents older persons and their family caregivers to seek formal mental healthcare. Moreover, experts describe an increasing disintegration of family support systems in rural and urban areas. Therefore, a more prominent role for outreach-support provided by community health workers (CHWs) is suggested. However, according to experts, transforming the scope of practice of CHWs to include mental healthcare for older persons is still predicted to be a major challenge.

Conclusions:

To improve equitable access to and participation of older persons and their families in PMHC, the perceptions and attitudes towards mental health and old age need to be considered.

Abstract citation ID: ckac129.720
Participation in vulnerable old age? Barriers and opportunities in nursing homes in Germany

Susanne Kuempers

S Kuempers[1], D Hahn[1], M von Köppen[2]
[1]Fulda University of Applied Sciences, Fulda, Germany
[2]IMHSR, Otto von Guericke University of Magdeburg, Magdeburg, Germany
Contact: Susanne.Kuempers@pg.hs-fulda.de

Background:

Nursing homes in Germany are still often associated with the idea of a daily routine determined by the institution, linked to losses of self-determination and participation. Residents, as well as carers and caregivers, perceive chances for co-determination and co-creation as limited.

Methods:

The research project PaStA (Participation in Inpatient Care for Older People) examined and analyzed opportunities and limits of improved participation in nursing homes in Germany with the help of a participatory action research design. Experiences and findings with participatory research processes in two nursing homes are presented.

Results:

Access to people both living and working in nursing homes is demanding and time-consuming. Building a trusting cooperation requires commitment and resources. However, if a research team - including residents - is successfully installed, the participatory process enables all those involved to explore, try out and shape participation possibilities. The reflection that takes place in the process leads to learning processes that (can) result in empowerment.

Discussion:

However, there is a danger that participatory research may primarily reach people better provided with resources for participation based on life-long circumstances (participation dilemma), highlighting the need for responsibly designed access. Likewise, the question of impact must be critically discussed. Sustainability must be considered from the beginning.

Conclusions:

Participatory action research is a worthwhile endeavor, even in settings that are rather unfamiliar with participation, such as residential care for older people. However, researchers should not underestimate the time and commitment required, because preconditions and resistance of people and structures can compromise progress.

Abstract citation ID: ckac129.721
Participation and chronic illness: Nurses' perceptions in primary care in Brazil, Germany, and Spain

Marcus Heumann

M Heumann[1], G Röhnsch[2], E Zabaleta-del-Olmo[3], B Rosana Gonçalves de Oliveira Toso[4], L Giovanella[5], K Hämel[1]
[1]Health Services Research and Nursing Science, School of Public Health, Bielefeld University, Bielefeld, Germany
[2]Qualitative Social and Education Research, Freie Universität Berlin, Berlin, Germany
[3]IDIAP JORDI GOL, Barcelona, Spain
[4]Centre for Biology and Health Research, Western Paraná State University, Cascavel, Brazil
[5]National School of Public Health, Oswaldo Cruz Foundation, Rio de Janeiro, Brazil
Contact: mheumann@uni-bielefeld.de

Background:

Many chronically ill persons are challenged by integrating the illness in everyday life and making 'competent' decisions on their life and care. In multiprofessional primary care, promoting clients' self-management and strengthening their abilities to participate in everyday life is increasingly recognized as a nursing task. This study investigates facilitating and inhibiting conditions that nurses experience when exercising this task.

Methods:

Drawing upon a phenomenological approach, we conducted guided interviews with 34 practicing nurses and 23 key informants with advanced knowledge of primary health care nursing practice in Brazil, Germany, and Spain. The interviews were analysed using structuring content analysis.

Results:

The interviewees see competencies of nurses to establish trusting relationships with chronically ill clients as key to greater client participation. Nurses, however, state that bonding with clients can be time-consuming and exhausting. They consider it fundamental that physicians and other professionals value nurses' efforts towards stronger client participation as a way forward to reach for person-oriented primary care. They criticize that especially physicians value biomedical tasks more than enabling participation. Referring to primary health care organisation, nurses experience that pressure of time through a growing number of routine and administrative tasks inhibits their efforts to strengthen clients' participation.

Conclusions:

To promote the participation of clients with chronic illnesses in their everyday life and in care, relationship building with clients and self-management support needs to be acknowledged as an important scope of practice approached by nurses. To be able to unfold the potentials nurses need to be equipped with sufficient time and skills.

11.K. Pitch presentations: Barriers and enablers in health promotion behaviours

Abstract citation ID: ckac129.722
Health literacy time trends in Germany

Eva-Maria Berens

D Schaeffer[2], J Klinger[1,2], E-M Berens[2], K Hurrelmann[3]
[1]Institute for Sociology and Social Psychology, University of Cologne, Köln, Germany
[2]Interdisciplinary Centre for Health Literacy Research, University Bielefeld, Bielefeld, Germany
[3]Hertie School Berlin, Berlin, Germany
Contact: eva-maria.berens@uni-bielefeld.de

Background:
Health literacy (HL) is becoming increasingly important in the European public health sector. Since the Health information landscape is changing constantly there is a need for monitoring HL regularly in order to observe the influence of these changes, to enable trend statements and to obtain precise information on the societal and individual factors. For the first time, this has been done for the population in Germany.

Methods:
Cross-sectional data collected in the adult population in Germany in 2014 (n = 1.940) and 2020 (n = 504) was used. The instrument HLS-EU-Q47 was used to measure HL in the domains of health care, disease prevention and health promotion. Changes between time points were analysed on the population level as well as in several population groups.

Results:
The HL of the German population has become lower within the observed six years. This is evident in all three domains but is most pronounced in health promotion literacy. This trend is particularly visible among people with low social status and financial deprivation. Single health information tasks that are precepted as more difficult involve the evaluation of information and handling information from the media.

Conclusions:
Over time, dealing with health and disease-related information has become more difficult. As this development is mainly driven by socioeconomically disadvantaged population groups, it has apparently increased social inequality in the health sector. Due to more complex and demanding health information, which lately result in an ‘infodemic’, it seems that these groups in particular are overburdened and cannot raise the resources and skills to adequately engage with health information.

Key messages:
- HL interventions should focus on socioeconomically disadvantaged population groups to counteract the increasing health inequality.
- Monitoring HL should be included in public health surveillance to determine needs and challenges for health policies as well as achievements of interventions.

Abstract citation ID: ckac129.723
Health literacy among migrants in Germany – results of the quantitative cross-sectional HLS-MIG study

Eva-Maria Berens

E-M Berens[2], J Klinger[1], S Carol[3], D Schaeffer[2]
[1]Institute for Sociology and Social Psychology, University of Cologne, Köln, Germany
[2]Interdisciplinary Centre for Health Literacy Research, University Bielefeld, Bielefeld, Germany
[3]School of Sociology, University College Dublin, Dublin, Ireland
Contact: eva-maria.berens@uni-bielefeld.de

Background:
Health literacy (HL) is considered an important prerequisite for health. HL research often identifies migrants as vulnerable for low HL. However, in-depth data on HL among migrants and its determinants are still scarce, especially in Germany. Therefore, the analysis presents first time data on HL among migrants in Germany, specifically in the domains of health care, disease prevention and health promotion, considering migrant-specific and universal factors, such as social and psychological aspects.

Methods:
Around 1.000 first- and second-generation adult migrants from two of the largest migrant groups in Germany, from Turkey and former Soviet Union (FSU), were interviewed face-to-face in German, Turkish or Russian in late summer 2020. HL was measured using the HLS19-Q47 instrument. Bi- and multivariate statistical analyses were conducted.

Results:
More than half of the migrants have limited general HL on average. HL in disease prevention and health promotion was lower than in health care. Low social status, financial deprivation, low literacy skills and low self-efficacy were negatively correlated with each HL domain. Social integration, by contrast, goes along with a higher HL. Duration of stay in Germany and country of origin were only partly associated with HL.

Conclusions:
Our study goes beyond existing studies by analyzing HL in its domains and including the explanatory power of self-efficacy and social integration for migrants’ HL. Moreover, we reveal that migrants can’t generally be considered as vulnerable, as oftentimes outlined. There is need for targeted interventions, e.g. enhancing usability of health information, for the above-mentioned subgroups regarding differences in domains.

Key messages:
- HL among migrants varies across domains and is only partly linked to migrant-specific features but mainly associated with universal aspects.
- Measures to increase HL should consider differences in domains and address vulnerable subgroups including targeted interventions, respectively.

Abstract citation ID: ckac129.724
Language barriers for primary care access in Europe: a systematic review

Priyamvada Paudyal

R Evenden[1], N Singh[1], S Sornalingam[1], S Harrington[1], P Paudyal[1]
[1]Primary Care and Public Health, Brighton and Sussex Medical School, Brighton, UK
Contact: p.paudyal@bsms.ac.uk

Background:
A recent increase in migration both inside Europe and from non-European countries has expanded the language profile of many European countries. As a result, there has been a significant increase in barriers to healthcare access experienced by linguistic minority migrants. This systematic review aims to explore language barriers in primary care, focusing on the experiences of linguistic minority migrants living in Europe.

Methods:
PubMed, Embase, Scopus and Global Health were searched to identify studies published in English until May 2021. Qualitative and mixed methods studies on either linguistic minority migrants or healthcare workers working with linguistic minority migrants, exploring the impacts of language barriers in a primary care setting published were eligible. The studies were analysed using a Braun and Clarke’s thematic analysis approach. Quality of the studies were assessed using the Mixed Methods Appraisal Tool.

Results:
16 studies from 14 different European countries were eligible. Participants in the studies included four groups: linguistic minority migrants (n = 11), healthcare workers (n = 10), interpreters (n = 1) and administrative staff (n = 1). Barriers identified included a lack of interpreters, limited cultural competence of practitioners, a lack of practitioner training and knowledge, a lack of accessible information for migrants, difficulties expressing emotions and building patient-practitioner relationships, and risks to women's bodily autonomy resulting from language barriers.

Conclusions:
Linguistic minority migrants living in Europe face a number of barriers when accessing primary care. These barriers can risk patient safety, reduce the likelihood of seeking healthcare services, and impact patient experiences of healthcare services. There is a need for improved interpreter services, practitioner training, and information accessibility for both migrants and healthcare staff.

Key messages:
- Linguistic minority migrants experience significant barriers to primary healthcare access across Europe.
- There is a need for improved interpreter services, practitioner training, and information accessibility for both migrants and healthcare staff.

Abstract citation ID: ckac129.725
Exploring the involvement of representatives of migrant groups in health research

Elin Lampa

E Lampa[1], A Sarkadi[1], F Osman[2], A Tökés[1], N Johansson[1], G Warner[1]
[1]Child Health and Parenting, Uppsala University, Uppsala, Sweden
[2]School of Health and Welfare, Dalarna University, Borlänge, Sweden
Contact: elin.lampa@pubcare.uu.se

Background:
Public involvement in research is increasingly utilised, but has been problematised for lack of diversity. Involving representatives from seldom-heard groups, such as the migrant population, has the potential to transform health research for some of Europe's most disadvantaged groups.

Methods:
We have explored involvement of migrants in health research projects in Sweden, through a three-year longitudinal qualitative study with migrant contributors involved in a child mental health trial, and a series of behavioural observations of research meetings in several projects with migrant contributors.

Results:
The migrant contributors were initially hesitant to trust the researchers. However, through relationship-building and time, mutual trust was established. The contributors gained a social network in each other and the researchers, and their motivation for involvement changed over time, from focussing on individual benefits to societal change. They viewed their role as sharing their experiences, but saw researchers as in control of the final research decisions. Behavioural observations identified barriers to contributors' access to information in the meetings, such as academic terminology and difficulties in language interpretation. Enabling factors included balancing the presence of experts in the meeting as well as flexibility towards contributors' needs and initiatives. Additionally, transparency around the research process and providing feedback to the contributors functioned as enablers for involvement.

Conclusions:
This longitudinal qualitative inquiry paired with behavioural observations, revealed that when involving migrants as public contributors in research, time and resources should be focused on relationship building, to increase mutual trust and understanding, and careful planning undertaken to make the research process transparent and accessible for the contributors.

Key messages:
- Involving migrants in research has great potential – but requires careful planning and consideration.
- Awareness of barriers and enablers can assist researchers in attaining meaningful involvement.

Abstract citation ID: ckac129.726
Public knowledge of chronic kidney disease in Portugal: a quantitative approach

Ana Rita Pedro

AR Pedro[1,2], FG Avelar[1], B Raposo[1], A Boleu[3], S Silva[3], S Henriques[3], H Martinho[3]
[1]Public Health Research Centre, National School of Public Health, Lisbon, Portugal
[2]Comprehensive Health Research Centre, Lisbon, Portugal
[3]Astrazeneca, Barcarena, Portugal
Contact: rita.pedro@ensp.unl.pt

Background:
Chronic kidney disease (CKD) has increased progressively worldwide, however evidence on public awareness highlights gaps for a comprehensive public health strategy. This study aims to evaluate public knowledge and possible lack of awareness about CKD in Portugal.

Methods:
Cross-sectional study conducted through community based online survey (n = 1209). It was applied the CKD Knowledge Questionnaire and a score was calculated from 24 items categorized in 5 dimensions. Bivariate analyses was performed using one-way ANOVA and independent T-tests, at a 5% significance level, to compare the effect of independent variable and score.

Results:
A total of 1209 respondents with mean age 50 years (±15.1), 74.1% of female, 62.6% married or living with a partner, 55,7% at least university level. The mean (SD) public knowledge of CKD score was 14.30 (±3.4). The dimension "Functions of kidneys perform in the body" presented the lowest percentage of correct answers (48.9±19.5) while "Following are commonly used to determine health of the kidney" the highest percentage (71.3±22.4). Results of the bivariate analysis showed significant associations with gender ($p < 0{,}001$), marital status ($p = 0{,}019$), education ($p < 0{,}001$), high blood pressure ($p = 0{,}020$), personal history of kidney disease ($p < 0{,}001$), familiar history of kidney disease ($p < 0{,}001$), access to healthcare ($p = 0{,}049$), follow-up with a healthcare professional ($p = 0{,}023$), use of urgent care or hospital urgency ($p = 0{,}020$) and use of medical specialty appointments ($p < 0{,}001$).

Conclusions:
People living in Portugal revealed a middle knowledge level. Knowledge higher scores were observed in female, people with higher level of education, with experience imposed by health condition (e.g., risk factors or history disease), and access to health services. Future health education focused on 'Functions of kidneys perform in the body' might be an important contribution to increase health literacy about CKD.

Key messages:
- Social vulnerabilities may be associated with lower levels of public knowledge of Chronic Kidney Disease.
- The evaluation of population's knowledge about CKD is an important instrument for public health policy-making.

Abstract citation ID: ckac129.727
Evaluation of pediatric dentists' approaches to oral health literacy

Nevra Karamüftüoğlu

N Karamüftüoğlu[1], D Atabek[2], A Uğraş Dikmen[3], F Semanur Korkmaz Öner[3], S Özkan[3]
[1]Dentistry Faculty, Pedodontics, Cyprus International University, Lefkoşa, Cyprus
[2]Dentistry Faculty, Pedodontics, Gazi University, Ankara, Turkey
[3]Public Health, Gazi University, Ankara, Turkey
Contact: nvrserbest@hotmail.com

Aim:

In the study;it is aimed to determine the knowledge,attitudes,behaviors and educational needs of pediatric dentists about oral health literacy(OHL).

Methods:

The study was carried out with 100 pediatric dentists across Turkey between 20/06/2021-20/07/2021 on the online platform.In the questionnaire form;there are 14 descriptive,25 approaches to OHL in a 5-point Likert format and 8 questions about communication barriers in individuals with insufficient OHL.

Results:

The mean age of the participants was 34.4±7.9 years.92.0%(n = 92) of the participants did not receive OHL training.63%(n = 63) of the participants stated that it is necessary to carry out studies to improve OHL and to develop programs.The mean OHL approach scores of the participants were 3.81±0.61;the mean score of evaluating communication barriers in individuals with insufficient OHL level was 4.06±0.62.60%(n = 54) of the participants think that the health information in the media is very effective in misleading patients.As the age of the participants increased,the OHL approach score increased($r = 0.204$;$p = 0.042$).As the number of daily outpatient clinics of the individuals participating in the research increases,the evaluation scores of communication barriers decrease($r = -0.304$;$p = 0.004$).Among the participants,those who work in private institutions,those who know their rights while providing oral health services and those who are satisfied with the profession have higher scores for evaluating the OHL approach,the difference is statistically significant($p < 0.05$).

Conclusions:

As a result,positive benefits will be provided to the professional satisfaction of pediatric dentists and the quality of oral health services with in-service trainings to be organized before and after graduation on the evaluation of communication barriers in individuals with inadequate OHL approach and level.

Key messages:

- Oral health literacy is a new concept and is becoming increasingly important in dentistry.
- The importance of oral health literacy in pediatric dentistry is that both children and parents are affected.

Abstract citation ID: ckac129.728
An update on national recommendations for the use of the adjuvanted recombinant zoster vaccine

Romy Weller

R Parikh[1], R Widenmaier[2], R Weller[3], N Lecrenier[1]
[1]Global Medical Affairs, GlaxoSmithKline, Wavre, Belgium
[2]Global Medical Affairs, GlaxoSmithKline, Rockville, USA
[3]Global Medical Affairs, GlaxoSmithKline, Munich, Germany
Contact: romy.x.weller@gsk.com

Background:

The adjuvanted recombinant zoster vaccine (RZV), first approved in 2017, has high, long-lasting efficacy against herpes zoster (HZ) and a clinically acceptable safety profile. In addition to the prevention of HZ in adults aged $\geq$50 years, the non-live RZV can be used from age 18 years in individuals with immunocompromised (IC) conditions. We reviewed the evolving landscape of national recommendations for RZV use.

Methods:

National health authority and vaccination committee websites of countries where RZV is approved were searched in March 2022.

Results:

Of 41 countries where RZV is licensed, 14 (Australia, Austria, Canada, Czech Republic, Germany, Ireland, Italy, Netherlands, New Zealand, Saudi Arabia, Spain, Switzerland, UK, US) provide national recommendations related to RZV; the majority are preferential to RZV or only recommend RZV. Overall, seven and seven countries recommend immunisation from age 50 years or 60/65 years, respectively. Of the seven countries that recommend immunisation from age 60/65 years, five recommend immunisation in individuals from age 50 years with comorbidities/IC conditions. Five countries recommend immunisation from age 18/19 years in individuals at increased risk of HZ due to immunosuppressive disease/treatment. In addition, six national recommendations refer to RZV safety and nine address prior HZ vaccination and/or infection. All recommendations outlined the RZV administration schedule.

Conclusions:

Although national recommendations can inform decision making in clinical practice, RZV recommendations are not available in all licensed countries. The recommendations highlight a trend in favour of the use of RZV for the prevention of HZ in older individuals and those with IC conditions.

Main messages: An increasing number of countries are providing recommendations for the use of RZV for the prevention of HZ in older individuals and those with IC conditions.

Key messages:

- An increasing number of countries are providing recommendations for the use of RZV for the prevention of HZ in older individuals.
- An increasing number of countries are providing recommendations for the use of RZV for the prevention of HZ in IC conditions.

11.L. Pitch presentations: Providing services to diverse populations

Abstract citation ID: ckac129.729
Ethnicity and paediatric healthcare utilisation: Improving the quality of quantitative research

Claire Zhang

CX Zhang[1], MA Quigley[1], C Bankhead[2], T Bentley[3], C Otasowie[3], C Carson[1]
[1]National Perinatal Epidemiology Unit, University of Oxford, Oxford, UK
[2]Department of Primary Care Health Sciences, University of Oxford, Oxford, UK
[3]Medical Sciences Division, University of Oxford, Oxford, UK
Contact: claire.zhang@ndph.ox.ac.uk

Background:

The COVID-19 pandemic highlighted the stark health inequities affecting minority ethnic populations in Europe.

However, research on ethnic inequities and healthcare utilisation in children has seldom entered the policy discourse. A scoping review was conducted in the UK, summarising and appraising the quantitative evidence on ethnic differences (unequal) and inequities (unequal and unfair or disproportionate to healthcare needs) in paediatric healthcare utilisation.

Methods:

Embase, Medline and grey literature sources were searched for studies published 2001-2021. Studies that found differences and inequities were mapped by ethnic group and healthcare utilisation outcome. They were appraised using the National Institute for Health and Care Excellence appraisal checklists. The distribution of studies was described across various methodological parameters.

Results:

Of the 61 included studies, most found evidence of ethnic variations in healthcare utilisation (n = 54, 89%). Less than half attempted to distinguish between ethnic differences and inequities (n = 27, 44%). Studies were concentrated on primary and preventive care and hospitalisation, with minimal evidence on emergency and outpatient care. The quality of studies was often limited by a lack of theory underpinning analytical decisions, resulting in conflation of difference and inequity, and heterogeneity in ethnic classification. The majority of studies examined children's ethnicity but overlooked parent/caregiver ethnicity, and also didn't investigate patterns across age, year or location.

Conclusions:

To improve the validity, generalisability and comparability of research on ethnicity and paediatric healthcare utilisation, findings from this scoping review were used to develop recommendations for future research. These lessons could be applied more broadly across the European context to improve evidence generation and evidence-based policy-making to reduce inequities in healthcare.

Key messages:

- Quantitative studies of ethnicity and paediatric healthcare utilisation in the UK lack the use of sound theoretical frameworks, and often do not distinguish between ethnic differences and inequities.
- The quality of future studies can be improved with greater attention to how ethnicity is classified and analysed, alongside specific considerations for examining healthcare utilisation in children.

Abstract citation ID: ckac129.730
Racially discriminatory experiences among older chronically ill people of Turkish origin in Germany

Hürrem Tezcan-Güntekin

H Tezcan-Güntekin[1,2]
[1]Alice Salomon University of Applied Science, Department of Health and Education, Berlin, Germany
[2]Charité Berlin, Berlin School of Public Health, Berlin, Germany
Contact: tezcan@ash-berlin.eu

Background:

Racism in health care is rarely clearly identified as such in Germany. Barriers to access are more often addressed, but people's experiences of discrimination rarely receive attention (Schellenberg & Tusch 2021, Kristiansen 2016). Internationally, racism is recognized as a determinant of health and there is a discourse that it must be addressed in order to achieve health equity (Weil 2022). This qualitative secondary data analysis focuses on racially discriminatory experiences among older chronically ill people of Turkish origin in the context of medical and drug care in Germany.

Methods:

11 expert interviews and 11 problem-centred interviews with chronically ill people of Turkish origin and their relatives in Germany were conducted in the MedikaMig-Project with regard to care practices, continuity of drug care and polypharmacy and analysed with structuring qualitative content analysis (Mayring 2015).

Results:

The analysis yielded 7 superordinate categories and 27 subcategories, identifying racial discrimination in access to care, the treatment situation and communication, and in the consideration of transnational lifestyles. Patients are often helpless, sometimes trying to put their experiences into perspective or to be treated by Turkish doctors in order to avoid these discriminatory experiences.

Conclusions:

Racial discrimination is pervasive in health care and should not be hidden behind other terms that mask discrimination. An intersectional approach allows us to understand which individuals are particularly affected and what they need to be protected from racism in health care.

Key messages:

- Structural racism in health care needs to be clearly named and examined from an intersectional perspective in further research projects.
- Elderly patients with Turkish origin need empowerment and contact persons after racist experiences to find ways to deal with discriminating experiences that are sometimes perceived as traumatic.

Diversity competence: what should be prioritised in an online course? An adapted delphi study

Janne Sorensen

J Sorensen[1], *C Michaëlis*[1], *JM Møller Olsen*[1], *A Krasnik*[1], *K Bozorgmehr*[2,3], *S Ziegler*[3]
[1]Danish Research Centre for Migration, Ethnicity and Health, University of Copenhagen, Copenhagen, Denmark
[2]Department of General Practice and Health Services Research, Heidelberg University Hospital, Heidelberg, Germany
[3]School of Public Health, University of Bielefeld, Bielefeld, Germany
Contact: jans@sund.ku.dk

Background:

Population diversity is a reality in our societies and requires health systems and health professionals to adapt to the needs of diverse patient groups, including migrants and ethnic minorities. This study aims to investigate topics and methods that should be prioritised in an online course on diversity competence in healthcare delivery to improve health care encounters and provide health services that meet the unique needs of all patients in order to reduce health disparities.

Methods:

The study uses an adapted Delphi method including two rounds, combining some open-ended questions with predefined items, asking 31 European academic experts and health professionals within the field of migrant health to rate training content and teaching methods. Consensus for training topics was set to 80% and for teaching methods 70%.

Results:

The only item reaching 100% consensus as being important or very important to include was 'health effects of migration (pre-, mid- and post-migration risk factors)'. Other high-scoring items were 'social determinants of health' (97%) and 'discrimination within the healthcare sector' (also 97%). A general trend was to focus more on reflective practice since almost all items in the reflection section reached consensus. 'Reflection on own stereotypes and prejudices' reached the highest consensus in this section (97%).

Conclusions:

Experts' prioritisations of teaching content and methods for diversity training can help the design of short online trainings for health professionals and reduce extensive course content, thereby fostering professional development and enabling diversity competence trainings to be implemented in cases of scarce resources.

Key messages:

- Trend toward more focus on 'diversity' and less focus on 'culture, and the inclusion of social determinants of health and awareness of stereotypes and bias in training of health professionals.
- Diversity competence training should use reflective exercises and activities as teaching methods in online training.

Abstract citation ID: ckac129.732
Foreign-born people and covid-19 in Sweden - the effect of co-morbidity

Sharareh Akhavavn

S Akhavavn[1]
[1]National Board of Health and Welfare, Stockholm, Sweden
Contact: sharareh.akhavan@socialstyrelsen.se

Foreign-born people who live in Sweden, especially those who were born in low- and middle-income countries, were at higher risk of developing severe covid-19. It has previously been found that morbidity and mortality in covid-19 were associated with country of birth, level of education, income and type of housing. The aim of this study was to map differences between foreign and Swedish-born (18 years and older) with severe covid-19 regarding co-morbidity. This was a register -base study. Register data were gathered from the Patient Register, the Swedish Intensive Care Register, the Cause of Death Register and information on socio-economic variables from Statistics Sweden. Results shows that co-morbidity with severe covid-19 was generally higher for Swedish-born than foreign-born. On the other hand, co-morbidity with diabe-tes and obesity was slightly higher for foreign-born than for Swedish-born. The results also indicate that a higher risk of developing severe covid-19 remains despite the fact that we have controlled a number of factors that affect the relationships such as residential region, demography and socioeconomics. The conclusion of this study is that there is a need for strengthening public health surveillance systems for information such as diagnoses from primary care, the stage at which a person who has become infected has sought care, how the possible differences were in care seekers between foreign and Swedish-born and what the care chain looked like from the time the patient received first symptoms until she/he ended up in inpatient or intensive care.

Key messages:

- Co-morbidity with severe covid-19 was generally higher for Swedish-born than foreign-born.
- There is a need for strengthening public health surveillance systems in primary health care for explaining the reasons of higher risk of developing severe covid-19 among foreign-born people in Sweden.

Abstract citation ID: ckac129.733
Health Service Experiences of Transgender Individuals from Foreign Backgrounds in Finland

Mercédesz Czimbalmos

M Czimbalmos[1], *S Rask*[1]
[1]Equality-unit, The Finnish Institute for Health and Welfare, Helsinki, Finland
Contact: mercedesz.czimbalmos@thl.fi

Background:

Internationally, an increasing body of scholarship has focused on the experiences of transgender individuals when accessing gender-affirming healthcare. However, the experiences of transgender individuals who belong to the foreign background population in Finland have rarely been studied. This study aims to fill the gap in research and contribute to the understanding of the experiences of acquiring gender-affirming healthcare among those, who fall into the intersections of transness and also identify of foreign origin in Finland.

Methods:

Fourteen semi-structured qualitative interviews were conducted and analyzed with reflexive thematic analysis (RTA), through the framework of intersectionality. The interviews were part of a broader sample of qualitative data, collected about the experiences of sexual and gender minorities among the foreign origin populations in Finland.

Results:

The analysis showed two main interconnected themes. Firstly, perceived barriers when accessing gender-affirming care. In this theme, the intersections of transgender identity, foreign background, class, and age affected the experiences of the individuals. Secondly, the necessity of "performing identities:" the intersections of class, transgender identity, and race affected those.

Conclusions:

The findings of the current study suggest that the intersectional aspects of individual identities create structural inequalities in the Finnish gender-affirmation healthcare system. To tackle these inequalities, further research is needed on the healthcare experiences of gender minorities in Finland both within and outside the scope of transgender-specific healthcare.

Key messages:

- Intersectional aspects of individual identities create structural inequalities in accessing gender-affirming healthcare.
- Further research is needed on the healthcare experiences of gender minorities that examines health and wellbeing using an intersectional lens.

11.M. Workshop: Vaccination hesitancy in the Western Balkans and inclusive governance

Abstract citation ID: ckac129.734

Organised by: EURO HEALTH GROUP (Denmark), School of Public Health & Health Management (Serbia)
Chair persons: Michele Gross (Denmark), Ulrich Laaser (Germany)
Contact: ulrich.laaser@uni-bielefeld.de

Vaccine hesitancy has been identified as one of the crucial contributors to the global decline in vaccination coverage for several well-established vaccines in previous decades and is listed by the World Health Organization as one of the top ten threats to global health. In developing countries, the leading reasons for under-vaccination appear to be the lack of access, low education and socio-economic status. In developed countries psychological, social, and contextual factors are defined as main drivers of vaccine hesitancy. With the COVID-19 pandemic the threat of vaccine hesitancy has become more evident and is now in the focus of strategies and efforts to improve and strengthen the interventions to combat vaccine hesitancy and increase vaccination coverage. Despite the availability of multiple effective vaccines against COVID-19, only 40% of population of Wester Balkans in average has been completely vaccinated (with a complete initial protocol), which is far below the world average (56%). Vaccine hesitancy largely jeopardizes the achievement of heard immunity, postponing the end of the pandemic. To explore reasons of vaccine hesitancy, the cross-sectional and quasi-experimental studies were performed from July to September 2021 in five countries of the Western Balkans: Albania, Bosnia-Herzegovina, Montenegro, North Macedonia, and Serbia. The results will be presented and discussed from a policy perspective. The first presentation will introduce to the actual debate around vaccination hesitancy; the second presentation describes the survey design and key results related to societal factors (confidence in political and health authorities, science, and pharmaceutical companies), social responsibility (personal sense of responsibility in achieving collective immunity and contagion prevention) and the credibility of information sources about COVID-19 vaccines; the third presentation will discuss components of credibility (expertise, trustworthiness, and caring/goodwill) after respondents' exposure to messages with narratives on COVID-19 vaccine decisions. The fourth presentation is going to identify promising policy options. The objective of the workshop is to present and discuss the results of the Western Balkans study, relate them to corresponding studies in Europe and beyond, and propose effective interventions. The audience is invited to discuss the findings and the practicability of strategies to improve the acceptance of qualified information in the population, how to enhance trustworthy, how to improve vaccination rates. The discussion will focus on the following questions: a) What are the main drivers of vaccination hesitancy? b) Which messaging format is most convincing and trustworthy? c) Why is the global dimension essential?

Key messages:

- Vaccine hesitancy is a serious threat and reason for the insufficient vaccination coverage and suboptimal herd immunity in the Western Balkans.
- Vaccination policy has to enhance information trustworthy and source credibility at the national level and argue for fair resource distribution in the global dimension.

Abstract citation ID: ckac129.735
Global decline in vaccine coverage; COVID-19 Vaccine Hesitancy

Ulrich Laaser

U Laaser[1]
[1]Bielefeld School of Public Health, Bielefeld, Germany
Contact: ulrich.laaser@uni-bielefeld.de

Vaccine hesitancy is a relatively new concept, developed by WHO's Strategic Advisory Group of Experts (SAGE) on Immunization in 2014 as a response to the growing awareness of the decline in global confidence in vaccination. Vaccine hesitancy is a context-specific behavioural phenomenon whose occurrence ranges between full acceptance and complete refusal of vaccines. Several studies have explored factors that influence people's decision to get vaccinated and in 2018 WHO and UNICEF conducted a joint study to explore the reasons for vaccine hesitancy. The study aimed to determine the reported rate of vaccine hesitancy across the globe and the reasons for hesitancy. In most studies three top reasons were identified. 1) vaccine safety concerns, 2) lack of knowledge and awareness of vaccine importance, and 3) religion, culture, gender and socio-economic issues regarding vaccines. Other factors contributing are negative perception of vaccine efficacy, safety, convenience, and price. Some of the consistent socio-demographic groups that were identified to be associated with increased hesitancy included: women, younger participants, and people who were less educated, had lower income, had no insurance, lived in a rural area, and self-identified as a racial/ethnic minority. Vaccine hesitancy is associated with the global crisis of trust in science and institutions, namely lack of political trust, which can be defined as public judgment that the system and its representatives are responsive and reliable. Furthermore, distrust in one institution is related to distrust in other, indicating the unidimensional phenomenon. This kind of distrust is exemplified by the appearance of infodemic - an overabundance of information. In addition, support for conspiracy theories related to COVID-19 which correlates with the scepticism towards vaccination has significantly higher rates among Balkans' populations.

Abstract citation ID: ckac129.736
COVID-19 vaccine hesitancy in five Western Balkan countries

Sanja Matovic Miljanovic

S Matovic Miljanovic[1], *S Cvjetkovic*[2], *V Jeremic-Stojkovic*[2], *S Mandic-Rajcevic*[3]
[1]Public Health, Euro Health Group, Copenhagen, Denmark
[2]Department of Humanities, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
[3]Institute of Social Medicine, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
Contact: smatovic@ehg.dk

Background:

The vaccine hesitancy is a matter of global concern with inadequate global uptake postponing the moment of reaching herd immunity and bringing the COVID-19 pandemics under control. Countries in the Western Balkans struggle with vaccine hesitancy, trying to bring vaccine acceptance and ways to improve it into the focus.

Methods:

A cross-sectional study on vaccine hesitancy was conducted from July to September 2021 and included adult population from Albania, Bosnia and Herzegovina, North Macedonia, Montenegro and Serbia (1605 individuals). Convenience sampling was applied using anonymized online questionnaire (shared through social media) measuring, among others, trust in societal factors, social responsibility and, the credibility of information sources about COVID-19 vaccines.

Results:

The highest degree of trust in societal factors was found in North Macedonia (M = 3.65, SD = 1.06), followed by Montenegro (M = 3.50, SD = 1.19) and Serbia (M = 3.24, SD = 1.26). In Albania 44.7% respondents believed in reluctance of pharmaceutical companies to publish detailed research reports on the risks of adverse reactions to COVID-19 vaccines. The view that the health authorities when they encourage vaccination do so with the best intentions supported 66,3% respondents in North Macedonia and 49% in Albania and Serbia. The highest level of social responsibility (M = 4.12, SD = 1.09) was revealed in North Macedonia. Primary care physicians, health professionals in media, webpages of public health institutions, and scientific literature are the most trusted sources of information about COVID-19 in all countries.

Conclusions:

The study demonstrated moderate trust in societal factors and moderately high level of social responsibility in all countries. The health professionals enjoy the greatest trust, which implies that medical doctors, especially physicians in primary health care should have a pivotal role in promoting vaccination and educating the general public in the Western Balkans.

Abstract citation ID: ckac129.737
Does it matter who addresses whom in vaccination promotion campaign?

Smiljana Cvjetkovic

S Cvjetkovic[1], *V Jeremic- Stojkovic*[1], *S Mandic-Rajcevic*[2], *J Jankovic*[2]
[1]Department of Humanities, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
[2]Institute of Social Medicine, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
Contact: smi13smi@yahoo.com

Background:
A vaccine promotion campaign is primarily grounded on the selected message features, namely, a carefully chosen information source. People holding diverse views towards vaccination could experience the same information source differently, and it is the comprehension of these diversities that is important to tailor effective interventions. The aim of this study was to determine differences in perceived source credibility between the vaccinated and unvaccinated.
Methods:
Overall 172 adults aged 18 and older from Western Balkans both vaccinated and unvaccinated, voluntarily after obtaining informed consent, were randomly assigned to one of four message interventions. The messages were developed combining two prototypical COVID-19 vaccine decision narratives (determined vs. hesitant) with two communication sources (physician vs. lay peer), resulting in four conditions: determined physician, hesitant physician, determined peer, hesitant peer. After the message exposure, participants evaluated three components of source credibility - expertise, trustworthiness and, goodwill. Two-way ANOVA was applied.
Results:
Compared to the vaccinated, the unvaccinated judged the source as less trustworthy ($p < 0.01$), regardless of the message they have been exposed to. Although not statistically significant ($p = 0.064$), the unvaccinated evaluated all sources with the exception of hesitant physician as having a lower level of good intentions. Vaccinated perceived the determined physician as a source with most expertise, while unvaccinated attributed highest expertise to the hesitant physician (without significant difference ($p = 0.719$)).
Conclusions:
The unvaccinated are generally less likely to experience the information sources as goodwill and trustworthy. In order to perceive the source as more competent the focus should be on the objective characteristics of the communicator, as well as on the congruency in attitudes between the communicator and the audience.

Abstract citation ID: ckac129.738
Inclusive governance: Enhance health literacy to reduce vaccine hesitancy

Vesna Bjegovic-Mikanovic

V Bjegovic-Mikanovic[1]
[1]Institute of Social Medicine, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
Contact: vesna.bjegovic-mikanovic@med.bg.ac.rs

Background:
The COVID-19 pandemic placed a call for action worldwide. Based on scientific investigation, governments need to assess strategic priorities. Health system capacity constraints and failures in response to the pandemic have social, medical, productivity, and economic implications. It compounds health equity issues and confronts with excess mortality, higher chronic disease prevalence, and risk factors. Despite initial progress in vaccination against COVID-19 and attempts to speed up vaccination, the Western Balkan lags behind. Infodemic and low trust in institutions are among the main factors associated with low success and adverse effects on other vaccination programs. This presentation aims to shed light on the importance of health literacy in resilient communities supported by inclusive governance.
Methods:
A narrative review based on literature on inclusive governance, health literacy, and resilient communities during COVID-19 and other emergencies. Primary sources are databases, scientific articles, Health System Response Monitor, and observations by ECDC and OECD.
Results:
Results show that characteristics of resilient communities in possessing knowledge and ability to assess risk, manage an emergency, monitor change, and address threats stand out. Many studies highlight the interconnectedness of community members with the wider external environment and their participation in decision-making to improve health services. Examples include interventions for developing future vaccination programs in program planning, conducting sound evaluations, transferring results to those who need to know, and receiving feedback. The key to this success is enhancing digital and health literacy.
Conclusions:
COVID-19 requires cross-sectional strategies to reinforce collaborative gains and build resilient communities, ready to apply population strategies for prevention. Inclusive governance and a bottom-up approach will be essential to optimize the response to future challenges.

11.N. Workshop: School-based sexual health education: from evidence to implementation and evaluation

Abstract citation ID: ckac129.739

Organised by: University of Pisa (Italy), Federal Centre for Health Education - WHO Collaborating Centre for Sexual and Reproductive Health, EUPHA-IDC
Chair persons: Lara Tavoschi (Italy), Johanna Marquardt (Germany)
Contact: lara.tavoschi@unipi.it

Sexual and reproductive health (SRH) is a key dimension of health and well-being of individuals. Sexuality Education (SE) is one of the most important means of promoting sexual well-being of youth and a key component of HIV and sexually transmitted infections (STIs) prevention. International treaties and global health organisations explicitly urge governments to take the necessary measures to ensure the provision of SE, that should: be age-appropriate, start as soon as possible, promote mature decision-making, be directed towards improving gender inequalities and engage young people in all phases of activities. It is widely recognised that school plays a central role in learning about health and health promotion skills, including sexuality and sexual health. Although school-based SE (SBSE) alone may not be enough to ensure the rights of young people to SRH and prevent STIs, school programs are a very cost-effective way to contribute to these goals. Moreover, addressing these topics in schools is a thematic indicator for monitoring the UN Education Agenda 2030. Existing evidence indicates a great variability in the offer of school-based SE throughout the world. GEM report (2016) reveals that basic school curricula and educational standards rarely include SE programs, and multi-country reviews show limited progress in developing national strategies for the implementation of SE or in developing high-quality programs implemented on a large scale. Theoretical and research evidence indicate that SE, and in particular Comprehensive Sexuality Education (CSE), positively impacts the behaviour of young people, improving SRH outcomes by reducing risk-taking. UNESCO in 2018 defined CSE as ''a curriculum-based process of teaching and learning about the cognitive, emotional, physical and social aspects of sexuality. It aims to equip children and young people with knowledge, skills, attitudes and values that will empower them to: realize their health, well-being and dignity; develop respectful social and sexual relationships; consider how their choices affect their own well-being and that of others; and, understand and ensure the protection of their rights throughout their lives''. In 2022, Italy is one of a few European countries that still lacks a comprehensive approach to SE that is coherently and equally implemented across the country and SE is not yet included in Italian schools' curricula. As a consequence, several studies conducted on Italian young people report that they have poor sexual health knowledge, a low and inconsistent use of condoms and contraception, very little access to SRH services such as youth sexual health clinics and high levels of gender-based violence and homotransphobia. Moreover, 20% of all STIs detected in Italy affect young people. Yet, according to Italian students, school has clearly been pinpointed as the most appropriate place to receive information about SE.

Key messages:

- Some European countries, including Italy, do not include SE in national school curricula. Often, available SBSE programs lack a comprehensive approach, with limited coverage across the countries.
- Including CSE in national school curricula is an action urgently needed in order to provide young people with evidence-based, age-appropriate and accurate information on SRH and wellbeing.

School-based sexuality Education in Europe and Central Asia

Johanna Marquardt

J Marquardt[1]
[1]Federal Centre for Health Education, Berlin, Germany
Contact: Johanna.Marquardt@bzga.de

Introduction:

In 2016, the BZgA and the European Network of the International Planned Parenthood Federation initiated an extensive survey regarding the development and current status of sexuality education (SE) in Europe and Central Asia, which included 25 selected countries of the European WHO Region. Since 2000, remarkable progress has been made in the region in developing and integrating SE curricula in school settings. The majority of the surveyed countries teach basic elements of SE in schools. Yet, in about half of the countries, there is still some reticence in understanding the benefits of SE for the health and well-being of young people. In countries with fully developed comprehensive SE programmes, the school is the main source of information on sexuality for young people. In the other countries young people tend to rely on information from friends or peers and the internet. The findings also showed a gap in teacher training on sexuality education.

Methods:

The Survey included a detailed questionnaire, among member associations of IPPF EN and government agencies responsible for SE. A random sample was drawn from the 50 states of the region which is considered representative for the entire region. All 25 IPPF EN members and 16 of the 25 government agencies responded.

Results and discussion:

Remarkable progress has been made in developing and integrating SE in formal school curricula. In 11 of the 21 countries, SE is a mandatory teaching subject, and in six additional countries it is partly mandatory. In four additional countries it is optional. Despite the progress, there are still shortcomings and gaps in providing the full spectrum of SE.

Conclusions:

If provided, SE tends to focus primarily on the biological aspects and prevention of HIV/STIs and unwanted pregnancy. There is a need to broaden the spectrum of topics that are addressed to include gender equality, sexuality, violence and sexual abuse, human rights and empowerment.

Introduction:

School-based sexuality education (SBSE) is the most effective way to positively impact young people's behaviour and attitude towards sexuality. This study describes the development of a SBSE pilot activity targeting lower secondary schools (LSS) within the context of EduforIST project funded by the Italian Ministry of Health.

Methods:

A desk review was carried out to collect information about national policies, international literature and guidelines on SE and STIs prevention. An online survey was developed to collect information on SBSE activities implemented in Italy during 2016-2020. Focus groups among project partners and open consultations with a multisectorial expert advisory board were organised. SBSE pilot activity was developed by an interdisciplinary team of pedagogists, public health and SE experts, educators.

Results and discussion:

The SBSE was structured in: a) 5 interactive interventions of 2 hours each with students (4 theoretical and practical modules; 1 final intervention for students-led discussion and evaluation); b) introductory and closing meetings with teachers and with parents. The modules addressed the following dimensions: changes in adolescence; emotions and relationships; sexual identities and diversity; sexual consent, STIs/pregnancy prevention, sexual health services. Additional materials were developed: a. pre/post evaluation tools for educators and students; b. pre-implementation checklist for schools; c. materials for teachers' and parents' engagement before/after the SBSE activity.

Conclusions:

This pilot activity represented a first step towards the development of a standardised, evidence-based and comprehensive approach to SBSE, for future implementation across the country.

Introduction:
This study describes the preliminary results of a School-based sexuality education (SBSE) pilot activity developed and implemented within EduForIST project, funded by the Italian Ministry of Health.

Methods:
The pilot activity (5 modules of 2 hours each delivered per classroom) targeted lower secondary schools students. A total of 20 schools located in 4 different Italian regions participated. The educators were staff of several HIV/AIDS civil society organisations operating in Italy. A 2-days intensive workshop for educators was performed. Pre and post tests were conducted.

Results:
At the time of submission, pre-test results were available from 14 classrooms of 5 schools within 2 Italian Regions, for a total of 266 students. Among these, 37,4% were unsure that personal identity is built through social comparison; 21,8% reported that emotions don't get more intense during adolescence, while 18,1% were unsure about the response; 42,1% reported a higher level of uncertainty concerning the definitions of gender identity, sexual orientation and stereotype. The highest level of uncertainty were reported for STIs symptoms (58,7%), impact of treatment on HIV+ people (61,9%) and efficacy of contraceptive pills in preventing STIs (43,4%). The post-test results were available for 153 students. Pre/post analysis showed an increase of correct answers ($p < 0.05$) for 12 of 15 items investigated. A total of 102 students responded to the satisfaction questionnaire, with preliminary positive results.

Conclusions:
Since activities are ongoing, further data will be soon available for more exhaustive analyses. Early pre/post evaluations suggested that the pilot experience was effective in enhancing knowledge and decreasing uncertainty in the different domains addressed in the pilot. Evidence collected through this study shall raise awareness among decision makers on the urgency of introducing CSE in Italian school curricula and inform future policy options.

How to evaluate a sexual health education intervention: experience from an Italian pilot project

Marco Ubbiali

M Ubbiali[1], L Mortari[1]
[1]Università di Verona, Verona, Italy
Contact: marco.ubbiali@univr.it

Introduction:
Evaluation is an essential dimension of every educational activity, however it is a very crucial and problematic aspect to be considered. It is necessary to focus on some fundamental concepts: the idea of 'measurement', the definition of expected goals for the educational activity, whether they are measurable, and if not, how they can be evaluated. Finally, effectiveness may be assessed only after longer periods of time and by adopting coherent instruments. Outcomes of educational activities on sensitive themes such as sexuality education, are challenging to evaluate through causal relationships. So a fundamental question is: what is really possible to evaluate in the field of sexuality education (SE)?

Methods:
A desk review was carried out to collect information about national policies, international literature and guidelines on SE evaluation. A literature review was performed to collect and collate reported field experience and evaluation data.

Results and discussion:
In literature it is possible to find a consistent number of studies aimed at evaluating SE programs (in particular inspired by the models 'abstinence-only' and 'abstinence-plus'), whose goal is to understand their impact on adolescents sexual health. Most of the studies reported limited evidences on SE efficacy on sexual health-related outcomes. This may be attributed to two different causes: methodological - evaluation instruments are epistemologically difficult to develop; and theoretical - the underlying philosophical frameworks they refer to may not fully reflect the complexity of sexuality education for adolescents.

Conclusions:
Based on the findings, evaluation instruments were developed to collect experiences from educators performing school-based sexuality education within the context of EduforIST project funded by the Italian Ministry of Health. Analysis of the collected data were still ongoing at the time of submission.

Background:
Studies on mental health changes during the COVID-19 pandemic report no change or increasing prevalence of mental

health problems in general, but less is known on changes in potentially disadvantaged groups over time. We investigated changes in anxiety and depression symptoms during the first year of the pandemic in France, Germany, Italy, the Netherlands, Spain, Sweden, and Australia by prior mental disorders and migration status.

Methods:

Overall, 4,674 adults answered a web-based survey in May-June 2020 and were followed by three repeated surveys up to February 2021 in these countries. Information on socio-demographic, living conditions, psychosocial factors, diagnosis of mental disorders before, depression and anxiety symptoms during the pandemic and migration status (being a resident or not) was collected. Weighted general estimation equations modelling was used to investigate the association between prior mental disorders, migration status, and symptoms over time.

Results:

Most participants were <40 years old (48%), women (78%), and highly educated (62%) with some variations across countries. The baseline prevalence of depressive and anxiety symptoms ranged between 19%-45% and 13%-35% respectively. In most countries, prevalence remained unchanged throughout the pandemic and was higher among people with prior mental disorder than without even after adjustment for socioeconomic, psychosocial, living and health factors. We observed interactions between previous mental disorders and symptoms of anxiety or depression over time in Germany (p = 0.01) and in Spain (p = 0.04). No prevalence difference was noted by migration status.

Conclusions:

Depression and anxiety symptoms were worse among individuals with prior mental disorders than without, but there was no clear trend of mental health worsening in the observed groups during the first year of the pandemic. Still, monitoring mental health should be continued in the long-term, with special focus on vulnerable groups.

Key messages:

- Depression and anxiety symptoms were higher in individuals with prior mental disorders during the first year of the pandemic in an international sample of six European countries and Australia.
- There were no clear trends of mental health worsening in any of the observed groups in neither of the countries between May-June 2020 and February 2021.

Background:

Evidence about how population mental health has evolved from before and over the COVID-19 pandemic remains mixed, with impacts on mental health inequalities being unclear. We investigated changes in mental health and sociodemographic inequalities from before and across the first year of the pandemic.

Methods:

Data from 11 UK longitudinal population-based studies with pre-pandemic measures of psychological distress were analysed, estimates pooled, and stratified by age, sex, ethnicity, country and lone household status. Trends in the prevalence of poor mental health were assessed before the pandemic (TP0) and across the pandemic at three time periods (initial lockdown (TP1), easing of restrictions (TP2), and a subsequent lockdown (TP3)).

Results:

In total, 49,993 adult participants were analysed across the 11 cohort studies. There was an overall worsening in mental health from pre-pandemic scores across all three pandemic timepoints, (TP1 Standardised Mean Difference: 0.15 (95% CI: 0.06 - 0.25); TP2 SMD: 0.18 (0.09 - 0.27); TP3 SMD: 0.21 (0.10 - 0.32)) with no evidence of improvement during the period of eased lockdown restrictions in summer 2020. Changes from pre-pandemic psychological distress were higher in females during the pandemic (TP3 SMD: 0.23 (0.11 - 0.35)), amongst those with degree-level education (TP3 SMD: 0.26 (0.14 - 0.38)), and adults aged 25-44 years. We did not find evidence of changes in distress differing by ethnicity, lone household status or UK nation.

Conclusions:

The substantial deterioration in mental health seen in the UK during the first lockdown did not reverse when lockdown lifted and a sustained worsening was observed across the pandemic. Mental health declines have been unequal across the population and these results have implications for policy, including the need for specific investment for support for those most affected to mitigate the effects of the pandemic and measures to reduce inequalities within these specific groups.

Key messages:

- A sustained deterioration in mental health was observed from before the start of the COVID-19 pandemic, and did not recover when social restrictions were eased.
- Deterioration in mental health varied by sociodemographic factors, namely age, sex, and education, and highlights a need for improved mental health care provision to minimise widening inequalities.

Contact: pierre-julien.coulaud@bccsu.ubc.ca

Background:

To mitigate the adverse effects of the COVID-19 pandemic on financial resources, governments provided financial support (e.g., emergency aid funds) as well as family via personal assistance. This study aims to assess the moderating effect of financial support from the government or from family on the association between income loss and depression among young adults.

Methods:

Two online cross-sectional surveys among young adults (18-29) living in Canada and France were conducted in October-December 2020 (n = 4511) and July-December 2021 (n = 3329). Depressive symptoms were measured using PHQ-9 score+10. Two logistic regression models were performed for each survey with an interaction term between income loss and financial support (government or family modeled separately), controlling for demographics (e.g., country, age, gender, income, living conditions).

Results:

In the total sample, half reported depressive symptoms (2020/2021: 53%/46%), and over a third lost income (2020/2021: 10%/12% all income, 38%/22% some income). In 2020, 41% received government financial support (2021: 18%) while family/friends support was constant (12%). In both surveys, among those who received government support, income loss was associated with depression, whether participants lost all income (2020: AOR 1.75 [1.29-2.44]; 2021: AOR 2.17 [1.36-3.44]), or some income (2020: AOR 1.31 [1.17-1.81]; 2021: AOR 1.46 [0.99-2.16]). However, among those who received family support, income loss was no longer significantly associated with depression, whether participants lost all income (2020: AOR 1.37 [0.78-2.40]; 2021: AOR 1.51 [0.88-2.56]), or some income (2020: AOR 1.31 [0.86-1.99]; 2021: AOR 1.10 [0.67-1.81]).

Conclusions:

Association between income loss and depression was moderated by receipt of family financial support but not by receipt of government support. Financial support may help to mitigate the negative effects of income loss on young adults mental health during public health crisis.

Key messages:

- Financial support may help to minimize risk of depressive symptoms among youth who lost income related to the COVID-19 pandemic.
- Financial support through personal assistance (e.g., family, friends) appears to have a greater impact on youth mental health than COVID-specific government assistance funds.

Abstract citation ID: ckac129.747
The effects of the Covid-19 pandemic on the stress and depression levels of new mothers

Cristina Florea

C Florea[1], J Preiß[1], M Angerer[1], M Schabus[1]
[1]Psychology, Paris-Lodron University of Salzburg, Salzburg, Austria
Contact: cristina.florea@plus.ac.at

Background:

New mothers are a particularly vulnerable group during the COVID-19 pandemic, due both to the higher depression and stress levels associated with early child care and to the risk of a COVID-19 infection. We investigated the effects of the pandemic on the childbirth experience, stress and depression levels in this population.

Methods:

This cross-sectional, explorative study included 1964 Austrian and German mothers who gave birth between 16.03.2020 and 01.07.2021 and completed an online survey between 18.05.2021 and 01.07.2021. This contained the Childbirth Experience Questionnaire (CEQ2), the Edinburgh Postnatal Depression Scale (EPDS), and the Perceived Stress Scale (PSS), as well as three custom-made scales: a birth risk score (risk factors for a poor birth outcome), a pandemic repercussions score (perceived effects on different aspects of personal life), and a social support score (how emotionally supported they feel). We computed post-hoc multilinear regression models to evaluate which factors can predict the CEQ2, PSS and EPDS scores.

Results:

Mothers had a worse birth experience, perceived less stress and had more depressive symptoms during the pandemic than previously reported cohorts. The CEQ2 was predicted by the birth risk (negatively), the access to a midwife (positively) and the perception of sufficient access of the visitors in the hospital (positively) (adjusted R2 = 0.26, F(4, 1738) = 155.64, $p < 0.001$). The PSS was predicted by the pandemic repercussions (positively), the social support (negatively), and the presence of a coping mechanism (negatively) (adjusted R2 = 0.28, F(4, 1959) = 195.1, $p < 0.001$). The EPDS was similarly predicted by the same factors as the PSS (adjusted R2 = 0.28, F(4, 1959) = 189.59, $p < 0.001$).

Conclusions:

Social support and strong coping mechanisms can lower the stress and depression scores. Instructing the population about how to improve these factors might be a target for future social policies.

Key messages:

- Compared to historical cohorts, mothers who gave birth during the pandemic had a worse birth experience, and, postnatally, perceived less stress but had more depressive symptoms.
- The visitors' access to the hospital and the mother's access to a midwife impacted the birth experience, while the social support and the coping mechanisms affected the stress and depression scores.

Abstract citation ID: ckac129.748
Reactive surveillance of suicides during the COVID-19 epidemic in France, 2020- March 2022

Anne Fouillet

A Fouillet[1], D Martin[2], I Pontais[1], C Caserio-Schönemann[1], G Rey[2]
[1]Division of Data Sciences, Santé Publique France, Saint-Maurice, France
[2]CépiDc, Inserm, Kremlin-Bicêtre, France
Contact: anne.fouillet@santepubliquefrance.fr

Background:

Mitigation actions during the COVID-19 pandemic, in particular lockdowns and curfews, may impact mental health and suicide in general populations. We aimed to analyse the evolution in suicide deaths from January 2020 to March 2022 in France.

Methods:

Using free-text medical causes in death certificates, we built an algorithm, which aimed to identify suicide deaths. We measured its retrospective performances by comparing suicide deaths identified using the algorithm with deaths which had either an ICD10 code for 'intentional self-harm' or for 'external cause of undetermined intent' as underlying cause. The number of suicide deaths from January 2020 to November 2021 was then compared with the expected number estimated using a generalized additive model. The analysis was stratified by age group and gender. Analysis from December 2021 to March 2022 was conducted using electronic death certificates only.

Results:

The free-text algorithm demonstrated high performances. From January 2020 to November 2021, suicide mortality declined during France's three lockdowns, particularly in men, and remained quite comparable with expected values between and after both of the country's lockdowns. Provisional results based on electronic death certificates suggest that suicide mortality remained stable until March 2022.

Conclusions:

Monitoring suicide mortality is possible in France with a 4-month delay; this will be reduced to two days when electronic death certification is fully deployed. This study highlighted the absence of an increase in suicide mortality during France's COVID-19 pandemic, and a substantial decline during lockdowns periods, something already observed in other countries. Further studies are required to explain the factors for this decline.

Key messages:

- In the absence of reactive coding of medical causes of deaths, the study proposed an approach to reactively identify suicide based on free-text medical causes from death certificates.

- Our findings provide reassurance that the COVID-19 pandemic has not had a negative impact on the general population in terms of suicide in France from March 2020 to September 2021.

Self-reported anxiety and depression among COVID-19 patients: A prospective cohort study from Turkey

Öykü Turunç

N Şiyve[1], AN Emecen[1], S Keskin[1], E Başoğlu[1], Ö Turunç[1], AF Süner[1], C Cimilli[2], B Ünal[1]
[1]Department of Public Health, Dokuz Eylul University Faculty of Medicine, Izmir, Turkey
[2]Department of Psychiatry, Dokuz Eylul University Faculty of Medicine, Izmir, Turkey
Contact: oykuturunc0@gmail.com

Background:
It has been shown that COVID-19 can cause symptoms and diseases such as insomnia, depression, and anxiety. This study aimed to describe prevalence of feeling anxious or depressive among COVID-19 patients in six months of follow-up time and its association with baseline independent factors.

Methods:
This prospective cohort study included patients aged ≥18 years who tested positive for SARS-CoV-2 at Dokuz Eylul University Hospital, Turkey between November 1, 2020 and May 31, 2021. Participants were interviewed by telephone calls on the 1st, 3rd and 6th months after diagnosis. The dependent variable of the study was self-reported moderate or severe anxiety or depression based on EQ-5D-3L general quality of life scale. Generalized estimating equations were used to identify the factors associated with feeling anxious and depressive after SARS-CoV-2 infection.

Results:
In total 5446 patients agreed to participate in the study. Frequency of feeling anxious or depressive at the 1st, 3rd and 6th months after diagnosis were 18.5%, 17.9% and 15.4%, respectively. Older age (≥65 years; odds ratio-OR:1.17, 95% confidence interval-CI: 0.95-1.44), female gender (OR:1.76 (1.58-1.96)), bad economic status (OR: 1.62 (1.34-1.97)), having more symptoms (4-5, OR:1.48 (1.21-1.81); ≥5, OR:1.65 (1.35-2.01)), having more underlying health conditions (1-2, OR:1.35 (1.19-1.54); ≥3: OR:1.50 (1.13-1.99)), intensive care unit admission (OR: 2.58 (1.70-3.90)) were associated with self-reported anxiety and depression.

Conclusions:
Feelings of anxiety and depression are common in COVID-19 patients and may persist in the long term. Anxiety and depression were associated with gender, economic status and disease severity. Determination of vulnerable groups for anxiety and depression after COVID-19 can be helpful for early diagnosis and initiation of mental care services.

Key messages:
- As a consequence of Covid-19, anxiety and depression in Covid-19 survivors are common generally. It shouldn't be overlooked or underestimated for the public mental well-being.
- Covid-19 mental effects on the population have a correlation with social determinants of health. Therefore, determining vulnerable groups is a key to planning mental care services.

Abstract citation ID: ckac129.750
Longitudinal rate of change in depression symptoms from pre- to post-COVID-19 onset among US mothers

Julie Kapp

J Kapp[1], D Coble[2], A Kemner[3], B Hall[3]
[1]Health Management and Informatics, University of Missouri School of Medicine, Columbia, USA
[2]Division of Biostatistics, Washington University in St. Louis, Saint Louis, USA
[3]Parents as Teachers National Center, Saint Louis, USA
Contact: kappj@health.missouri.edu

Background:
The extent of the psychological impact of the pandemic is still unfolding. Despite existing literature, most studies lack rigor. We assessed the longitudinal rate of intra-individual change in maternal depression symptoms from before to after COVID-19 onset among US mothers enrolled in a home visiting program with robust adjustment for family contextual factors. We hypothesize that the rate of change in maternal depression symptoms increased after the pandemic onset.

Methods:
Eligibility included mothers with ≥1 depression assessment both prior to and after March 16, 2020; thresholds of ≥ 13 on the Edinburgh Postnatal Depression Scale and ≥10 on the Patient Health Questionnaire-9 identified probable depression. We used a generalized linear mixed effects longitudinal model with a random intercept and random slope for time (years) to analyze probable depression (event='Yes') pre- and post-COVID. Covariates for model estimation were based on the literature and theory.

Results:
Our cohort of 3,431 mothers included 43% non-Hispanic White, 21% non-Hispanic Black, and 31% Hispanic races/ethnicities; 58% from rural/small towns, 18% Spanish-speaking, 63% with one child, median age of 29 and median 2 years follow-up. Households included: 82% low income, 24% low education, 10% insecure housing, 29% single parents, 21% mental illness, 10% substance abuse, and 8% domestic violence. Fourteen percent screened positive for depression pre-COVID, and 10% post-COVID. Depression was significantly higher pre- versus post-COVID, with no significant difference in the rate of change over time. Significant variables ($p < 0.05$) associated with depression included race/ethnicity, region of the country, number of home visits, mental illness, substance abuse, and domestic violence.

Conclusions:
After controlling for family contextual factors, we did not find a significant increase in maternal depression post-COVID-19. Additional research is needed to examine subgroups and the timing of events.

Key messages:
- The extent of the psychological impact from the pandemic is still unfolding.
- It is difficult to fully articulate its effects without rigorous, longitudinal research designs.

Abstract citation ID: ckac129.751
Establishing Covid-19 Research in UK Care Homes – Infrastructure Challenges for Trial Design

Paul Leighton

P Leighton[1], K Sprange[1], K Robinson[1], C Rick[1]
[1]University of Nottingham, School of Medicine, Nottingham, UK
Contact: paul.leighton@nottingham.ac.uk

Background:
The Covid-19 pandemic brought into sharp relief the role that long-term care facilities play in health and social care of an aging population. It also cast a spotlight upon the need for high-quality research to assess the effectiveness of any care home interventions. The Prophylactic Therapies in Care Homes (PROTECT-CH) trial was one such study (funded by the UK National Institute for Health and Care Research). PROTECT-CH was designed to collect data in 200 care homes (approximately 6,400 residents), and whilst the changing epidemiology of Covid-19 in the UK (due to vaccination take-up) made this unfeasible other insights were gained about establishing large-scale research in care homes.

Methods:
An iterative process evaluation of the set-up phase of a large, platform trial testing prophylactic measures in long-term care facilities. Including a documentary review of the PROTECT-

CH working groups and an online survey of working group members.

Results:

Documents were reviewed from 24 working groups, which in a hub and spoke model represented the PROTECT-CH trial infrastructure; representative of 20 of these groups completed an online survey about their organisation and working. Data demonstrated the number and organisation of individuals required to set up a large-scale care-home trial - 91 individuals representing a mix of academic, clinical, and methodological contributions from 25 organisations. Data demonstrated working groups specific to care home research, and activities designed to address the specific challenges of researching in care homes. PROTECT-CH produced dedicated training materials and reporting templates for care home research. PROTECT-CH established novel mechanisms for prescribing and clinical oversight in care home research.

Conclusions:

PROTECT-CH has highlighted the complexity of establishing large, scale RCT research in long-term care facilities. It has produced resources which might be of use in subsequent care home research.

Key messages:

- Infrastructure is required to support high quality research in long-term care facilities.
- RCTs in long-term care facilities pose specific challenged to researchers.

11.P. Workshop: Tobacco control policy strategies to contribute to the EU's tobacco-free generation goal

Abstract citation ID: ckac129.752

Organised by: Tilburg University, Amsterdam UMC, University of Amsterdam (Netherlands)
Chair persons: Andrea Rozema (Netherlands), Mirte Kuipers (Netherlands)
Contact: m.a.kuipers@amsterdamumc.nl

In 2021, the European Union's (EU) 'Europe's Beating Cancer Plan' set the goal to achieve a tobacco-free generation in Europe by 2040, which means that less than 5% of people will use tobacco. The EU proposed policies to address internationally relevant issues such as tobacco taxation, cross-border purchases, packaging, flavours, and online advertising. However, many tobacco control policies need to be adopted and implemented at the national or local level. It is therefore important to exchange research findings and insights on national tobacco control policies. In this workshop we present results mainly from the Netherlands. With a 21% smoking prevalence and scores 53 out of 100 points on the Tobacco Control Scale, it may therefore be considered an average European country in terms of its tobacco control. However, the Netherlands has progressed its tobacco control policies in recent years, in part due to the 2018 National Prevention Agreement. This Agreement included the same goal as the European tobacco-free generation goal. Achieving a tobacco-free generation requires the prevention of smoking initiation among young people, but also smoking cessation among those who already smoke. This is especially important among lower socioeconomic groups, as the smoking prevalence in these groups is higher both in adults and adolescents. Therefore, smoking and tobacco products need to be less visible and available in the environment, and easily accessible smoking cessation support needs to be provided. With this workshop, we cluster very recent evidence on the EU's tobacco-free generation goal. We will present evidence on four policy strategies for the smoke-free generation, in which their potential impact and challenges in implementation will be discussed. These presentations will be followed by a plenary discussion on the implications and the relevance of the four strategies taking into account differences between international settings.

The presentations will focus on four policy areas:

- Policies to reduce smoke-exposure in and around sport clubs
- Policies to reduce availability of tobacco products in the retail environment
- Policies to reduce smoke-exposure in hospitality venues and homes
- Policies to increase access to smoking cessation

The objectives of the workshop are:

1. Present evidence of four tobacco control policies strategies
2. Discussion of the international relevance and implications of the results

Key messages:

- We present on multiple settings that can be further capitalised on to achieve a non-smoking norm, including sports clubs, retail outlets, hospitality venues, and the home environment.
- The majority of European countries currently does not have strong tobacco control policies in the presented settings, and the potential of such policies throughout Europe will be discussed.

Abstract citation ID: ckac129.753

Diffusion of smoke-free policies at outdoor sports clubs in the Netherlands

Rixt Smit

HH Garritsen[1], AE Kunst[1]
[1]Department of Public and Occupational Health, Amsterdam UMC, University of Amsterdam, Amsterdam, Netherlands
Contact: r.a.smit@amsterdamumc.nl

Background:

Although outdoor smoke-free policies (SFPs) at sports clubs represent an important new area of tobacco control, the majority of sports clubs are not smoke-free. This study aims to assess diffusion patterns of outdoor SFPs at sports clubs in the Netherlands, which may inform national strategies aimed at making all outdoor sports clubs smoke-free.

Methods:

Using a retrospective, registry-based design, an inventory was made of football, field hockey, tennis, and korfball clubs that became smoke-free between 2016-2020. We determined the type of sports, number of members, and proportion of youth members. The degree of urbanization and density of smoke-free sports clubs were measured at the municipality level. The association between sports clubs' characteristics, degree of urbanization, and SFP adoption was analysed using multilevel regression analysis. Horizontal diffusion was tested by analysing the association between the density and annual incidence of smoke-free sports clubs.

Results:

Since 2016, the number of sports clubs with an outdoor SFP increased from 0.3% to 26.4%. Field hockey [OR compared to football 6.00 95% CI 4.46-8.07] and korfball clubs [OR 6.65 95% CI 4.98-8.87] and clubs with many (youth) members [OR 8.75 95% CI 6.20-2.35] were more likely to be smoke-free. SFPs spread from the most urbanized to less urbanized municipalities, which could mostly be attributed to sports clubs' characteristics. A higher density of smoke-free sports clubs within municipalities was associated with an increased incidence of new SFPs in the following year.

Conclusions:

Outdoor SFPs at sports clubs in the Netherlands diffused across horizontal and hierarchical lines. National strategies for smoke-free sports should monitor clubs that are more likely to stay behind, such as football and tennis clubs, smaller clubs, and clubs in less urbanized areas.

Abstract citation ID: ckac129.754

Policies to reduce availability of tobacco products in the retail environment

Tessa van Deelen

AE Kunst[1], B van den Putte[2], EM Veldhuizen[3], MAG Kuipers[1]
[1]Department of Public and Occupational Health, Amsterdam UMC, University of Amsterdam, Amsterdam, Netherlands
[2]Amsterdam School of Communication Research, University of Amsterdam, Amsterdam, Netherlands
[3]Department of Geography and Planning, University of Amsterdam, Amsterdam, Netherlands
Contact: t.r.d.vandeelen@amsterdamumc.nl

Background:

After implementation of a tobacco vending machine ban in 2022 and a supermarket sales ban in 2024, the Dutch government intends to further phase out tobacco sales after 2030 by prohibiting sales in petrol stations and small outlets. This study aims to understand 1) the impact of these policies on tobacco outlet availability, and 2) differences in tobacco outlet availability by area socioeconomic status (SES) in the Netherlands.

Methods:

Between September 2019 and June 2020, all potential tobacco retailers in four Dutch cities (Amsterdam, Eindhoven, Haarlem, and Zwolle) were visited and mapped using Global Positioning System (GPS). Expected reductions in tobacco outlet availability were calculated per policy measure. Tobacco outlet density was calculated using ESRI ArcMap version 10.4.1. The association between neighbourhood SES and tobacco outlet availability was estimated with linear and logistic regression model.

Results:

We identified 870 tobacco outlets and an outlet density of 6.2/10.000 capita. The potential sales bans in petrol stations and small outlets would reduce the number of outlets (resp. -7% and -43%) and the outlet density (resp. -0.4 and -2.7). In Eindhoven, Haarlem, and Zwolle, neighbourhoods with high-SES compared to low-SES were less likely to contain a tobacco outlet (OR:0.71, 95%CI:0.59-0.85) and had a lower outlet density (ß:-1.20, 95%CI:-2.20;-0.20). In Amsterdam, the associations were inverse (OR:1.22, 95%CI:1.05-1.40; ß:3.50, 95%CI:0.81;6.20).

Conclusions:

The availability of tobacco outlets varies within and between cities depending on the distribution of the built environment. Future tobacco control policies targeting the retail environment should focus on limiting the overall number tobacco outlets and especially small outlets, which may benefit low SES neighbourhoods in mid-sized cities most.

Abstract citation ID: ckac129.755

Impact of smoke-free policies in hospitality venues and the home environment on smoking behaviour and exposure to second-hand smoke: results of two systematic reviews

Heike Garritsen

YY da Costa Senior[1], AD Rozema[2], AE Kunst[1], MAG Kuipers[1]
[1]Department of Public and Occupational Health, Amsterdam UMC, University of Amsterdam, Amsterdam, Netherlands
[2]Tranzo, Tilburg University, Tilburg, Netherlands
Contact: h.h.garrtisen@amsterdamumc.nl

Background:

Smoke-free policies (SFPs) have proven to be effective in protecting people from exposure to second-hand smoke (SHS) and lowering smoking rates. Our aims were to assess the impact of SFPs in hospitality venues (e.g. bars) on smoking behaviour of young people and to assess the impact of SFPs in the home environment on smoking behaviour and exposure to SHS.

Methods:

Two reviews were conducted. The first was conducted in June 2020. We searched PubMed, Embase, and Scopus for studies that assessed the association between any form of SFPs in hospitality venues and a measure of smoking behaviour among young people (aged 10-24 years). The second review will be conducted in June 2022. Searches will be conducted in PubMed, Embase, Web of Science, PsycINFO and CENTRAL. We will search for studies that assess the association between any form of SFPs in the home environment (e.g. multi-unit housing) and a measure of smoking behaviour (e.g. initiation) or SHS exposure.

Results:

Nine studies (publication years 2005-2016) were included in the first review, of which the majority used a quasi-experimental design. Four studies evaluated SFPs in hospitality venues specifically. Two studies reported that strict, but not weaker, SFPs decrease progression to established smoking. Two other studies provided mixed results. Five studies also included other workplaces, of which three studies found significant decreases in current smoking, smoking frequency, and/or smoking quantity. The results of the second review will be presented in detail during the workshop, however an exploration suggests that SFPs in the home environment may prevent smoking and SHS exposure.

Conclusions:

Most studies of the first review found that SFPs in hospitality venues are associated with a decrease in smoking behaviour among young people. Their results indicate the need for strict smoke-free legislation without exemptions. The conclusions of the second review will be presented during the workshop.

Abstract citation ID: ckac129.756

Implementing a smoking cessation training for lower socioeconomic groups into local policy in Amsterdam, the Netherlands: Identifying preconditions and barriers among multiple stakeholder groups

Judith Visser

J Harting[1], MAG Kuipers[1]
[1]Department of Public and Occupational Health, Amsterdam UMC, University of Amsterdam, Amsterdam, Netherlands
Contact: j.e.m.visser@amsterdamumc.nl

Background:

Socioeconomic inequalities in smoking prevalence are high, partly because smoking cessation programs are insufficiently accessible and suitable for smokers with a lower socioeconomic position (SEP). To make it easier for this target group to access suitable smoking cessation programs, it is necessary to structurally implement such programs into local policies.

The study aims to identify preconditions and barriers for the implementation of smoking cessation programs for people with low SEP from the perspective of key stakeholders.

Methods:

The Feel Free! Smoking cessation rolling group training has been previously developed for people from lower socio-economic groups and was implemented in Amsterdam Noord. Semi-structured interviews were held with 25 stakeholders consisting of participants, trainers, professionals in the neighbourhood and stakeholders of the municipality. The interviews were audio-recorded, transcribed verbatim and analysed using a thematic approach. The Implementation Framework of Fleuren will be used to structure the presentation.

Results:

The main preconditions found are effective recruitment of participants by local professionals, having a central coordinator for implementation within the neighbourhood network, and offering a smoking cessation program with a clear added value for participants. The main barriers found are challenges in setting up a sustainable financial structure, allocation of organizational tasks, and high participant absences and dropout. More results will be presented in detail.

Conclusions:

This study shows that action is required from various stakeholders to facilitate the implementation process. These findings can inform policy makers and implementers to choose strategies to implement suitable smoking cessation programs into local policy.

11.Q. Pitch presentations: Monitoring the burden of disease

Abstract citation ID: ckac129.757
The global burden of neglected zoonotic diseases: current state of evidence

Carlotta di Bari

C di Bari[1], *N Venkateswaran*[2], *D Pigott*[2], *C Flastl*[1], *B Devleesschauwer*[1,3]
[1]Epidemiology and Public Health, Sciensano, Brussels, Belgium
[2]Department of Health Metrics Sciences, Institute for Health Metrics and Evaluation, Seattle, USA
[3]Department of Translational Physiology, Infectiology and Public Health, Ghent University, Ghent, Belgium
Contact: carlotta.dibari@sciensano.be

The majority of emerging infectious diseases are zoonoses, most of which are classified as ‘‘neglected’’. By affecting both humans and animals, zoonoses pose a dual burden. The disability-adjusted life year (DALY) metric quantifies human health burden using mortality and morbidity. This review aims to describe and analyze the current state of evidence on the burden of neglected zoonotic diseases (NZDs) and start a discussion on the current understanding of the global burden of NZDs. We identified 26 priority NZDs through consulting the CDC One Health Zoonotic Disease Prioritization Exercise, the Joint External Evaluation reports, and the WHO roadmap for NTDs. A systematic review of global and national burden of disease (BoD) studies for these priority NZDs was conducted using pre-selected databases. Data on diseases, location and DALYs were extracted for each eligible study. A total of 1887 records were screened, resulting in 72 eligible studies (58 national or sub-national, 12 global, and 2 regional studies). The highest number of BoD studies was found for non-typhoidal salmonellosis (23), whereas no estimates were found for West Nile, Marburg and Lassa fever. Geographically, the highest number of studies were found in the Netherlands (11), China (5) and Iran (4). The number of BoD studies retrieved mismatched the perceived importance in national prioritization exercises. For example, anthrax was considered a priority NZD in 73 countries, but only one national estimate was retrieved. By summing the available global estimates, these diseases would cause at least 10 million DALYs in total. The burden of NZDs at the global level remains scattered, and trends were challenging to identify. There are several priority NZDs for which no burden estimates exist, and the number of BoD studies does not reflect national disease priorities. To have complete and consistent estimates of the global burden of NZDs, these diseases should be integrated into larger global BoD initiatives.

Key messages:

- There is a mismatched between the estimated retrieved in the search and the perception of the importance of these disease. This amplify the need for a comprehensive program.
- No complete list of zoonoses exist, and the definition used is vague. A stricter definition of zoonoses and what defines them will help provide a clear view of dealing with and controlling them.

Abstract citation ID: ckac129.758
The changing landscape of food deserts and swamps in Flanders, Belgium

Vincent Smets

V Smets[1], *S Vandevijvere*[1]
[1]Lifestyle and Chronic Diseases, Sciensano, Anderlecht, Belgium
Contact: vincent.smets@sciensano.be

Introduction:

For decades, people’s body weight has been increasing at alarming rates, leading to a worldwide obesity epidemic. One of the main causes of this obesity epidemic is poor diet quality. The food environment has been suspected to be one of the principal drivers of poor diet quality. Older people and families with a poor socioeconomic background can be disproportionately affected.

Methods:

This study maps the food environment in Flanders between 2008 and 2020 by using the concepts of food deserts and food swamps. Food deserts have been defined as neighborhoods that lack access to some or all foods that are required for a balanced, nutritionally adequate diet. Food swamps refer to places where there is an abundance of unhealthy food options relative to healthy food options. A spatial analysis using population- and retail density datasets yielded the change in food deserts and swamps between 2008 and 2020.

Results:

Food deserts in Flanders are found to be small in area and very localized. While food deserts in areas with the two highest deciles of people older than 65 years increased from 1.3% to 1.6% of total surface area in Flanders between 2008 and 2020, the food deserts in areas with the two lowest deciles of low income families decreased from 4% to 2.4%. Food swamps in

Flanders on the other hand, are ubiquitous. In 2020, 42.9% of the residential area examined contained no healthy food retailers and 77.7% of the area can be considered a severe food swamp. Areas with a high number of vulnerable groups are healthier than Flanders as a whole because these areas are mostly found in dense urban centers where the ratio of healthy food retailers to all retailers is higher.

Conclusions:

Food deserts are a relatively small problem in Flanders in comparison to the widespread occurrence of food swamps. These food swamps exacerbates the obesity epidemic in Flanders and lead to a shorter health span of the affected individuals and to increased medical costs for society.

Key messages:

- The food environment in Flanders is generally unhealthy, making it easy for individuals to buy unhealthy foods.
- Food swamps are a major problem in Flanders, where unhealthy retailers drown out healthy retailers.

Abstract citation ID: ckac129.759
The prevention indicator system of the German Federal States – a tool to monitor prevention policies

Jonas D Finger

JD Finger[1], *S Oberwoehrmann*[1], *J Zeiher*[1], *M Haftenberger*[1], *S Hermann*[1]
[1]Department of Health, Senate Department for Health, Berlin, Germany
Contact: Jonas.Finger@SenWGPG.berlin.de

In 2015 the German Prevention Act was implemented. The National Prevention Conference published the first National Prevention Report in 2019 to evaluate the health promotion activities. The second National Prevention Report is planned for 2023. Development of a harmonized prevention reporting system for the German Federal States is needed to form the basis for the contribution of the Federal States to the next National Prevention Report. A working group mandated from the sub-national health authorities has developed a harmonized prevention reporting system for the German Federal States since 2018. The Robert Koch Institute collaborated as representative of the national level during the process. Subject areas for indicators were selected based on a survey in which all 16 State Ministries of Health participated. Indicator subgroups developed indicators for each subject area based on predefined indicator selection criteria. Final set of indicators was adopted by indicator rating and majority voting process. The German Health Ministers Conference acknowledged the indicator system in June 2021. The conceptual framework is adapted from the health determinants model of Dahlgren and Whitehead. The indicator system is divided into 14 subject areas categorized into upstream, midstream and downstream level of prevention indicators. Seventy-three prevention indicators were included as a whole. The indicator short list consists of 32 Core indicators. An overview of the prevention indicator system will be given. First results of a pilot data collection will be shown. Health promotion and prevention reporting tools are needed to monitor prevention policies and evaluate health promotion measures. The prevention indicator system of the German Federal States will be used for the National Prevention Strategy in Germany of which one component is the next National Prevention Report 2023.

Key messages:

- The prevention indicator system of the German Federal States is a useful tool to monitor prevention policies.
- The indicator system will form the basis for the German Federal States' contribution to the National Prevention Report 2023.

Abstract citation ID: ckac129.760
Monitoring the burden of disease in Scotland and the contribution of risk factors

Ian Grant

E Fletcher[1], *I Grant*[1]
[1]Data Driven Innovation Directorate, Public Health Scotland, Edinburgh, UK
Contact: ian.grant@phs.scot

Background:

The Scottish Burden of Disease (SBoD) Study monitors the contribution of over 100 diseases and injuries to the population health in Scotland, in the context of disability-adjusted life years (DALYs). Providing robust estimates of burden is the first step in identifying areas of prevention which could have the biggest impact on health; including identification of modifiable risk factors and changes in the underlying risk factor prevalence. Our aim was to estimate DALYs for 2019, to describe the current burden in Scotland and as a baseline for future burden scenarios.

Methods:

The SBoD 2016 study estimated the burden using routine data and patient-level record linkage. For this update, years lived with disability were estimated using 2016 age-sex-deprivation specific rates, assuming no change in disease prevalence from 2016, but taking account of changes to the population structure. Years of life lost were calculated from 2019 observed deaths and the application of the Global Burden of Disease (GBD) aspirational life table. Population attributable fractions (PAFs) were sourced from the GBD 2019 and risk factor prevalence from the Scottish Health Survey.

Results:

In 2019 the leading causes of burden were ischaemic heart disease (IHD), Alzheimer's/other dementias, lung cancer, drug-use disorders and cerebrovascular disease, representing over a quarter (27%) of the total DALYs in Scotland. Application of PAFs shows that a proportion of the burden for each of these causes can be attributed to modifiable risk factors.

Conclusions:

IHD continues to be the leading cause of health burden in Scotland in 2019. However recent years show an increase in burden of social causes and diseases affecting the ageing population. Application of PAFs demonstrate the importance of continuing to monitor both the burden of disease in Scotland and the prevalence of risk factors, to provide robust evidence for planning of local and national services.

Key messages:

- The Scottish Burden of Disease continues to monitor the population health landscape of Scotland.
- Ischaemic heart disease continues to be the leading cause of burden in Scotland.

Abstract citation ID: ckac129.761
Evaluation of the quality of cause of death statistics of the last decades in the European Union

Lluís Cirera

L Cirera[1], *M Ballesta*[1,3], *V Uroz*[1,4], *D Sameron*[4,2]
[1]Department of Epidemiology, Consejeria de Sanidad, Murcia, Spain
[2]CIBERESP, Epidemiology and Public Health, Madrid, Spain
[3]Department of Social and Health Sciences, University of Murcia, Murcia, Spain
[4]Center of Legal Medicinen, Ministry of Justice, Almeria, Spain
Contact: lluis.cirera@carm.es

Introduction:

The European Union (EU) do not publish the quality of cause-of-death statistics, when is possible to assess quality by reliability. Quality does not present consolidated indicators. Ill-defined and other inaccurate causes have presented different groupings.

Objective:

To assess the quality of official cause-of-death statistics of the European Union by member states from 2006 to 2020.

Methods:
Cases and population were from the WHO repertory. We selected causes in EU27 countries by up to fourth code-character of ICD10 -on the EuroStat website were not available-. Case counts were grouped into ill- defined, unspecific, less specific (the latter two, in inaccurate), and judicial (inaccurate external causes) categories, based on literature and expertise. We calculated age-adjusted rates to the Standard European Population by country, sex, period (2006-, 2011- and 2016-2020), and quality category. We tested the Comparative Mortality Ratio (CMR) of each country to the European Union median by a Bayesian approach, at 5% statistical significance. We plotted the rates proportion of each quality category in its all causes.

Results:
We included 25 countries. Some did not report all years. Six countries showed >19% for ill-defined causes and 3 member states had <5% in both sex and last period. In inaccurate, for the same time period and sex, average pointed 10% with a range of 3-19%. In the same period, CMR exceeded significantly the EU median in 19 and 18 countries for women and men, respectively; and exceeded in unspecific causes in 12 countries for women and men.

Discussion:
Literature showed that incorrect causes of death were random distributed. Probably major causes were biased and underestimated.

Conclusions:
Quality of cause of death is a useful indicator of mortality statistics reliability. Quality indicators targeted national gaps across EU. We need a new EU task force on statistics of causes of death in accordance with the XXI century.

Key messages:
- Quality indicators of causes of death statistics targeted national gaps across the European Union.
- The statistics of death causes underestimated the main causes of death in the European Union.

Abstract citation ID: ckac129.762
Undetected hypertension in primary care – a public health iceberg?

Lauren Young

L Young[1], H Bibi[1], R Rasheed[1]
[1]Medical Education and Research, Rigg Milner and Corringham Health Centre, East Tilbury, UK
Contact: lauren.young10@nhs.net

Background:
Hypertension is largely asymptomatic and contributes to considerable lifetime cardiovascular morbidity and mortality, costing the NHS £2.1 billion annually. The national prevalence of hypertension is 13.7 % and lack of a national screening programme, despite meeting aspects of the Wilson Junger criteria, adds to delays in detection and treatment. Earlier detection could mitigate future cardiovascular risk. We wanted to understand the potential of detection of prehypertension in primary care to see if this fits the Wilson and Junger criteria for a screening programme.

Methods:
GP records of adult patients n = 2178 with a known diagnosis of hypertension on the hypertension register from a practice population of 10,000 patients (prevalence is 22%.) were analysed for the prevalence of prehypertension systolic 120-139 mm hg and diastolic bp of 80-89. The average length of prehypertension, the time delay in detection and treatment were assessed, alongside the prevalence of clinical and therapeutic inertia.

Results:
A retrospective analysis of a sample size of 1809 patients out of 2178 patients (83.1%) with known hypertension across 3 primary care sites over 20 years was undertaken. Of these 1809 patients, we found that 1095 patients (60.5%) were prehypertensive prior to being diagnosed. The mean time interval between detection of prehypertension to a formal hypertension diagnosis was 10.6 years, with a standard deviation of 7.89 years with no variation with age or sex. However, 588 patients (32.5%) did not have readings within the prehypertensive ranges prior to diagnosis and were opportunistically detected. 51 patients (2.82%) never had readings recorded within the prehypertensive range.

Conclusions:
Prehypertension predates hypertension by an average of 10.6 years. Offering annual screening nationally to patients of risk groups e.g., those with a family history, obesity, and alcohol excess, would enable earlier detection, treatment, and considerable cost saving.

Key messages:
- Prehypertension predates hypertension; therefore, hypertension meets the Wilson Junger criteria for earlier detection by a screening programme, which is lacking in the UK.
- Offering a national scheme to screen for hypertension to those at a higher risk, can only be considered a benefit to the public and should be implemented.

1.R. Strengthening health system

Abstract citation ID: ckac130.001
Community-based health professionals in face of crisis – a practice example from Bremen, Germany

Dirk Gansefort

D Gansefort[1], T Altgeld[1], N Tempel[1], M Wächter[1], J Sterner[1], I Lettau[1], L Focke[1]
[1]Association for Health Promotion Lower Saxony, Hannover, Germany
Contact: dirk.gansefort@gesundheit-nds.de

At the end of 2020, a district-based analysis of Covid-19-infection rates in Bremen uncovered differences between socially deprived and ‘‘better off’’ areas. The first analysis conducted on a district level in Germany revealed a social gradient in the Covid-19-affectedness with deprived areas having above-average incidences. These areas are characterized by poor living conditions, high migrant population, low education and health literacy levels, language barriers and precarious job situations. Bremen's Health Senator acted on this challenge early on, initiated and financed the deployment of community-based health professionals (CHP) in disadvantaged areas to tackle the rising Covid-19-rates while reducing social inequalities and promoting health literacy. The CHPs' work is coordinated by the Association for Health & Academy for Social Medicine Lower-Saxony. The 14 CHP are multilingual, with a background in health professions, social work and public health. They cooperate with local partners in 18 disadvantaged districts in Bremen and Bremerhaven. In 2021, work focused on outreach work, low-threshold provision of multilingual information (e.g., on regulations, vaccination) and the support of local vaccination campaigns. Bremen currently has the highest vaccination coverage in Germany (87,5% of population with primary series, national average: 76,2%; 07/2022).

Since 2022, CHPs' work has shifted to health promotion activities aimed at mitigating the effects of the pandemic, e.g., physical inactivity, mental stress. Bremen was the first German city to pilot a large-scale implementation of CHP in socially disadvantaged areas. Due to their continuous presence, CHP quickly became people of trust and are integrated into local structures. Their work has received huge attention both in professional contexts and public media. The low-threshold outreach-work and close cooperation with local partners has high potential to address other health challenges in disadvantaged communities.

Key messages:

- Community-based health promotion with CHP is an effective way of reaching citizens in local settings and is able to adapt to unexpected social and health-related challenges.
- CHP strengthen the health literacy in the community and the communication of health regulations.

Abstract citation ID: ckac130.002
Improve service coordination and delivery in community hubs serving homeless and at-risk populations

Hala Shamaa

H Shamaa[1], W Sun[1], V Peters[1], L Martignetti[1], E Valant[2], D Sparks[3]
[1]Faculty of Health Sciences, Ontario Tech University, Oshawa, Canada
[2]Social Services, Regional Municipality of Durham, Oshawa, Canada
[3]Office of the Regional Chair and CAO, Regional Municipality of Durham, Whitby, Canada
Contact: hala.shamaa@ontariotechu.net

Background:

Two community hubs are currently located in Durham Region, Ontario, Canada, to provide a single point of access to a wide range of support services for individuals experiencing homelessness and other at-risk populations. The community hub in Oshawa is formally known as the Back Door Mission for the Relief of Poverty and the community hub in Ajax is formally known as the Ajax Hygiene Hub. It is unclear if these two community hubs are effective in addressing the needs of individuals experiencing homelessness and how the COVID-19 pandemic continues to impact these services amongst this population. This study was conducted to identify gaps and barriers within the community hub models as well as provide recommendations to improve the coordination and delivery of services serving individuals experiencing homelessness and other at-risk populations.

Methods:

A mixed methods approach was utilized in this study, which included surveys for individuals experiencing homelessness, through open-ended and close-ended questions to assess their experiences at either one of the two community hubs. A total of 75 surveys were completed by the study participants (40 surveys in Oshawa and 35 in Ajax). Thematic analysis was performed for all the open-ended survey responses. A literature review was also conducted to evaluate the community hub models as well as best practices for the implementation locally, nationally, and internationally.

Results:

Data analysis for the open-ended survey responses revealed the need for housing support, increased resources for medical services, and the expansion of programs provided by the community hubs.

Conclusions:

Homelessness is a major public health issue however community hubs play a pivotal role in addressing this concern in Durham Region. The equitable access to a diverse range of services that are co-located in a community hub is imperative for individuals experiencing homelessness, especially during the COVID-19 pandemic.

Key messages:

- The needs of homeless populations, program outcomes, service gaps, partnership collaboration, and best practices were explored to help inform the development of new community hubs in Durham Region.
- Study highlighted the effectiveness of community hubs in addressing the needs of homeless populations, whether it should become a permanent solution, and be developed in Durham Region and beyond.

Abstract citation ID: ckac130.003
A capital-based approach to understand health inequalities: empirical explorations

Yuwei Qi

Y Qi[1], JC Vrooman[2,3], J Almansa[1], P Ots[1], S Brouwer[1], SA Reijneveld[1]
[1]Health Sciences, University Medical Center Groningen, Groningen, Netherlands
[2]Department of Sociology, ICS, Utrecht University, Utrecht, Netherlands
[3]The Netherlands Institute for Social Research, SCP, Den Haag, Netherlands
Contact: y.qi@umcg.nl

Background:

The persistence of health inequalities may not be merely driven by education and income, but also by other economic and non-economic factors. In this study we investigated how the association between single-dimensional health and socioeconomic status (SES) changes when including health-related person capital, economic capital, social capital, cultural capital and non-health related person capital.

Methods:

The present study proposes a capital-based approach to understand health inequalities. It presumes intertwined relationships between a wide notion of health ('health-related person capital') and embodied resources ('non-health related person capital') on the one hand, and non-person capital, i.e. economic, social, and cultural resources on the other. We used cross-sectional data on 152,592 participants from the Dutch Lifelines cohort study. Correlations between capital constructs were estimated using partial least squares structural equation modelling.

Results:

The correlation between health-related person capital and SES (r = 0.15) was higher than the correlations between single-dimensional health (physical and mental health) and SES (r = 0.12, r = 0.04, respectively). Non-person capital, combining economic, social and cultural capital, showed a correlation of 0.34 with health-related person capital. This was higher than the correlation between health-related person capital and economic capital alone (r = 0.19). Lastly, the correlation between health-related person capital and non-person capital increased when non-health (personality and attractiveness) and health related person capital were combined into person capital construct (from r = 0.34 to r = 0.49).

Conclusions:

This exploratory observational study shows the empirical interconnectedness of various types of resources. Our findings corroborate the idea of considering health as a multidimensional concept, and to extend conventional SES indicators to a broader measurement of economic and non-economic resources.

Key messages:

- A wide notion of capital may be key to a better understanding of the persistence of health inequalities.
- Policy action needs to take into account the unequal distribution of economic, social, cultural, and person capital.

HPV self-sampling as an additional option in cervical cancer screening: a pilot study in Estonia

Reeli Hallik

R Hallik[1], K Innos[1], J Jänes[1], P Veerus[1]
[1]Epidemiology and Biostatistics, The National Institute for Health Development, Tallinn, Estonia
Contact: reeli.hallik@tai.ee

Background:

Cervical cancer incidence and mortality rates remain high in Estonia and participation in organized cervical cancer screening program is low. The aim of this pilot study was to estimate the impact of offering an HPV self-sampling option on screening uptake.

Methods:

A randomized intervention study was conducted within Estonian organized cervical cancer screening program in 2021. Among target group women who had not participated in screening by August 2021, 26,000 women were randomly selected and allocated to two equally sized intervention arms offering a choice between attending a clinic or taking a self-sample. The opt-out group received a Qvintip sampler by regular mail to home address, the opt-in group received by e-mail a link to order the sampler from a web-site. A control group of 32,000 women received the usual reminder to attend screening at a clinic. Participation rates were calculated and data on user experience were collected with a questionnaire.

Results:

Significant difference in participation rates was observed between opt-out (41%) (among them 20% chose self-sampling, 21% chose clinic attendance), opt-in (34%) (8% self-sampling, 26% clinic) and control group (28%). Intervention arms showed higher screening uptake in all age-groups and regions, but the largest effect was seen at ages 60 and 65 years and in regions showing the lowest screening participation rates. Among self-sampling users, 99% agreed that self-sampling was easy and only 3% prefer testing at a clinic.

Conclusions:

Offering women a choice between HPV self-sampling or attending a clinic significantly increased cervical cancer screening uptake. Sending an HPV self-sampling kit to home address was the most effective approach. Majority of women who chose HPV self-sampling want to use this option in the future. HPV self-sampling should be integrated in the cervical cancer screening program in Estonia.

Key messages:

- HPV self-sampling increased cervical cancer screening participation in Estonia and was highly accepted.
- It is important to make HPV self-sampling available in cervical cancer screening program.

Assessment of needs-based usefulness of interventions to address system barriers to HPV vaccination

Tamara Schloemer

T Schloemer[1,2], H Hecht[1], K Horstman[1]
[1]Care and Public Health Research Institute, Maastricht University, Maastricht, Netherlands
[2]Department of Applied Health Sciences, Hochschule für Gesundheit, Bochum, Germany
Contact: tamara.schloemer@maastrichtuniversity.nl

Background:

Adolescents of underserved communities face multiple health system barriers to access HPV vaccination. The Horizon 2020 project RIVER-EU will implement interventions to address these barriers in the migrant community in Greece, the Turkish and Moroccan communities in the Netherlands, the Ukrainian community in Poland and the Roma community in Slovakia. The objective of this study was to identify promising evidence-based interventions that potentially meet the specific contextual needs of the target groups, as a basis for assessing their transferability.

Methods:

Based on the PIET-T models of transferability, we developed a methodology to assess the needs-based usefulness of an intervention for a target context. Criteria of intervention usefulness addressed specific aspects of the health issue, population, intervention content, outcomes, up-to-datedness, applicability, quality and usefulness of the evidence-base. Guided by methodological workshops, country members with their local advisory boards performed a rating of 32 interventions identified from a systematic literature search.

Results:

Through independent assessment in each country, 5 of 32 interventions were selected as useful, with overlap: 2 interventions were selected by all countries, and 1 by 2 countries. In all countries, trained community members to support HPV vaccination were seen as promising. In Greece and the Netherlands, an educational programme in schools was included. Further, the Netherlands chose an intervention addressing providers' HPV vaccine communication, and Slovakia a multilevel intervention.

Discussion:

The feedback of the country members on the assessment emphasised the structured way to face complexity of understanding the potential usefulness of an intervention from the perspective of the target country. Critical discussions on the interventions enabled to specify needs for further clarification, for adaptations, and alternatives to consider for transferability analyses.

Key messages:

- Identifying potentially useful health system approaches to vaccination in specific contexts is a complex step that goes beyond analysing quality of primary evidence.
- Our methodology for intervention selection emphasises the consideration of the unique needs of target communities to address health system barriers to vaccination.

Comparison between recommended and mandatory vaccine uptake during adolescence in Italy

Maria Rita Caracciolo

MR Caracciolo[1]*, S Angelillo*[1]*, F Ficara*[1]*, D Venturi*[1]*, F Licata*[1]*, A Bianco*[1]
[1]Department of Health Sciences, University of Catanzaro ''Magna Græcia'', Catanzaro, Italy
Contact: mariarita.caracciolo@gmail.com

Background:

Immunization programs are key preventive interventions and have largely contributed to reducing the burden of infectious diseases and decreasing related morbidity, mortality and healthcare costs. The study aimed to investigate coverage regarding diphtheria, tetanus, and acellular pertussis (dTap) - Inactivated Poliomyelitis Vaccine (IPV) and Human Papilloma Virus (HPV) vaccine and attitudes towards vaccinations among undergraduate university students in Southern Italy.

Methods:

This cross-sectional study was conducted among 327 students through an anonymous online questionnaire and included socio-demographic characteristics, attitudes towards vaccinations overall and specifically on dTap-IPV and HPV, reasons for having received or not vaccinations and willingness to receive vaccinations.

Results:

One third of the students were concerned about serious adverse effects of vaccines and 95% believed that vaccines for uncommon diseases are useless. During adolescence, 89% of the sample received the mandatory dTap-IPV vaccine booster. Among unvaccinated students, 45% were unwilling to get vaccinated against dTap-IPV because they believed not to be at risk of infection (59%) and had lack of recommendation (35.3%). Regarding vaccination against HPV, 67% had received the recommended schedule. Among those who did not receive it, 34% were unwilling to get vaccinated because they did not feel at risk of HPV infection (41%). Interestingly, 16% of the sample disclosed some barriers to access vaccination centers. Moreover, 30% declared that HPV vaccination was discouraged by healthcare professionals (HCPs).

Conclusions:

Vaccination uptake is worryingly low and national objective coverage seems not still achieved. Likewise, risk perception of vaccine-preventable diseases was low and it seems negatively impact on the intention to get vaccinated. Improving vaccine confidence among HCPs is crucial as they have been shown to have the potential to influence patient vaccination uptake.

Key messages:

- Skilled communication with a trusted HCP could increase acceptance of vaccine during adolescence and address vaccine hesitancy.
- Strategies to disseminate information on vaccines should be established to increase mandatory and recommended vaccines coverage.

The positive impact of a care–physical activity initiative for people with low socioeconomic status

Annemarie Wagemakers

LS Mulderij[1]*, KT Verkooijen*[1]*, AS Groenewoud*[2]*, MA Koelen*[1]*, MAE Wagemakers*[1]
[1]Health and Society, Wageningen University & Research, Wageningen, Netherlands
[2]IQhealthcare, Radboudumc, Nijmegen, Netherlands
Contact: annemarie.wagemakers@wur.nl

Background:

Overweight and obesity rates are increasing worldwide, particularly among people with a low socioeconomic status (SES). Care-physical activity (care-PA) initiatives may lower overweight and obesity rates. A two-year care-PA initiative specifically developed for citizens with a low SES, X-Fittt 2.0, included 12 weeks of intensive guidance and sports sessions, and 21 months of aftercare. We answered the research question: what are the short- and long-term outcomes of participation in X-Fittt 2.0 in terms of health, quality of life and societal participation?

Methods:

Questionnaires and body measurements were taken from 208 participants at the start of X-Fittt 2.0 (t0) and after 12 weeks (t1), 1 year (t2) and 2 years (t3). We also held 17 group discussions (t1, n = 71) and 68 semi-structured interviews (t2 and t3). Continuous variables were analysed using linear mixed-model analysis, while we used descriptive statistics for the categorical variables. Qualitative data were analysed using thematic analysis.

Results:

Body weight was significantly lower at all three post-initiative time points compared with t0, with a maximum of 3.8 kg difference at t2 ($p < 0.05$). BMI, waist circumference, blood pressure and self-perceived health only significantly improved during the first 12 weeks ($p < 0.05$). A positive trend regarding paid work was observed, participants reported increased PA levels (including sports) and a few stopped smoking or drinking alcohol. Participants felt healthier and more energetic, reported improved self-esteem and stress levels, and had become more socially active. However, barriers to being physically active included a lack of money or time, or physical or mental health problems.

Conclusions:

X-Fittt 2.0 improved the physical health, QoL and societal participation of the participants. Future initiatives should take into account the aforementioned barriers, and consider a longer intervention period for more sustainable results.

Key messages:

- Care-physical activity initiatives can improve the physical and mental health, quality of life, lifestyle and societal participation of citizens with a low socioeconomic status.
- It is vital to improve the accessibility of care-physical activity initiatives, for example by lowering costs, so that existing and future initiatives better suit people with low socioeconomic status.

Abstract citation ID: ckac130.008
Screening intimate partner violence in the healthcare services during Covid-19 lockdowns in Israel

Beatris Pekar Agronsky

B Pekar Agronsky[1]*, N Daoud*[1]
[1]Public Health, Ben-Gurion University of the Negev, Beer-Sheva, Israel
Contact: Pekarbe@post.bgu.ac.il

Background:

Studies have shown increased rates of intimate partner violence (IPV) during the Covid-19 lockdowns. Healthcare services (HCS) have an important role in detection and screening of women victims of IPV. These women tend to visit the HCS more frequently, which creates an opportunity to detect, screen, and inform them about relevant support services.

Methods:

We conducted an online survey during Israel's 2nd and 3rd lockdowns (October 2020-February 2021). A self-administrated structured questionnaire was distributed in Arabic and Hebrew via social media. Eligibility criteria included women >18 years old. 519 women completed the questionnaire: Palestinian-Arab = 73; non-immigrant Jew = 319; and immigrant Jew = 127. We asked women whether they were ever screened (ES) for IPV or received information (RI) on support services in the HCS.

Results:

37.2% of the women reported any IPV; Palestinian-Arab women reported higher rates of IPV (49.3%) compared to non-immigrant Jew (34.2%) and immigrant Jew (37.8%). Prevalence of ES and RI on support services were low among the total study sample (21.8%, 47% respectively). Only 12.1% reported on both (ES and RI). Among women who reported IPV, only 26.9% reported that they had been ES, 39.4% RI, and 13.5% both. Whilst Palestinian-Arab women victims of IPV reported higher ES and a lower RI (30.6%,25% respectively) non-immigrant and immigrant Jew reported the opposite - higher prevalence of RI and less ES (non-immigrant Jew 45%,25.7%. Immigrant Jew 37.5%,27%, respectively). In the multivariate analysis after adjusts, Palestinian-Arab women were less likely to RI regarding support services (OR = 0.33,90%CI = 0.19-0.57), while immigrant Jew women had a greater chance to be ES in HCS (OR = 4.29, 90% CI = 1.43-12.80).

Conclusions:

To increase IPV detection in the HCS, there is a need for interventions on screening and providing information on support services specifically during emergencies where IPV is likely to increase.

Key messages:

- During emergency situations such as the Covid-19 when IPV is likely to increase, HCS should make more efforts for IPV screening and providing information on support services to women victims of IPV.
- Tailored intervention should consider barriers in the HCS for providing less information on support services to minority women, and less screening for immigrant women.

Implementation of Case Management in emergency departments: the view of the involved staff

Elodie Schmutz

E Schmutz[1], M Graells[1], J Moullin[2], M Kasztura[1], O Chastonay[1], M Canepa Allen[1], O Hugli[3], JB Daeppen[4], V Grazioli[1], P Bodenmann[1]

[3]Emergency Department, Lausanne University Hospital, Lausanne, Switzerland
[4]Addiction Medicine, Department of Psychiatry, University of Lausanne, Lausanne, Switzerland
Contact: elodie.schmutz@chuv.ch

Introduction:

Frequent users of emergency departments (FUED; ≥ 5 ED visits in the previous 12 months) often present with somatic, psychological and substance use problems. Providing a Case Management (CM) intervention may reduce their number ED visits and improve their quality of life. However, there is limited knowledge about the implementation process of CM.

Methods:

This study aimed to introduce CM into the EDs in the French-speaking part of Switzerland and to identify the facilitators, barriers and needs encountered in this process. Semi-structured interviews were conducted with ED involved staff. An inductive content analysis was conducted.

Results:

Among 13 invited hospitals, 8 implemented CM (62%); 23 ED staff were sampled from all participating ED: 17 nurses (74%), 5 physicians (22%) and 1 healthcare manager (4%). The average age was 48,48 years (SD = 8,64) and 74% were female. Four main facilitators emerged from the analysis: 1) Direct hierarchy support and flexibility (e.g. time management, supplemental paid hours); 2) Exchange with colleagues (e.g. debriefing, support); 3) Supervision by the research team (training and toolkit consisting of a binder and USB stick containing the study presentation and implementation procedures); and 4) Motivation (pleasure to work on an innovative project, benefit for patients and caregivers). Lack of resources was an unanimously mentioned barrier (e. g., time to identify and contact FUED medical and social support). Finally, participants identified the following needs to enable CM implementation: official and protected time for the project, a dedicated room for CM, at least two team members involved in the project since its initiation with complementary skills (e.g.: somatic, psychiatric and social).

Conclusions:

Our study suggests that successful CM implementation is a complex process that, in addition to motivated ED staff, requires significant dedicated resources, such as protected time and a devoted support team.

Key messages:

- Future research should establish a case management intervention with resources (time, space, teams with complementary skills) specifically dedicated to this process.
- In order to increase the quality of care, institutions should dedicate more funding for the implementation and sustainability of case management to enable its optimal application by caregivers.

Improving population health in Germany – lessons of a pilot study to assess health system performance

Katharina Achstetter

K Achstetter[1], M Blümel[1], P Hengel[1], V Schwarzbach[1], R Busse[1]
[1]Department of Health Care Management, Technische Universität Berlin, Berlin, Germany
Contact: katharina.achstetter@tu-berlin.de

Background:

Improving the population health, both its level and equity, is a major goal of health systems. Health System Performance Assessment (HSPA) is a tool to evaluate the performance of different health system dimensions, e.g., population health, access, efficiency. For the first time, a systematic HSPA was piloted for Germany including the dimension population health.

Methods:

The conceptual framework for the German HSPA pilot has been developed in a previous feasibility study. The selection of indicators was based on established indicators used in other HSPA initiatives. Another inclusion criterium was data availability. The ten indicators to measure population health cover e.g., maternal and neonatal health, amenable mortality, infectious diseases, and cancer screening. The indicators are evaluated in terms of their trend over time (2000-2020), in international comparison (e.g., Austria, Denmark, France), and by various equity criteria (e.g., age, gender, region).

Results:

Overall, Germany's health system performs moderately regarding population health, especially when compared to selected European countries. While Germany performs very well in terms of incidence rates of infectious diseases, amenable mortality is an area with need for improvements. However, trends over time show improvements of the population health in Germany.

Conclusions:

Measuring population health in Germany using ten predefined indicators reveals areas for improvement. Furthermore, subgroup analyses indicate inequities. These results should be considered in further efforts aiming at the improvement of population health in Germany.

Key messages:

- Population health in Germany has improved over time.
- However, measuring population health within the German health system identified needs for improvement and inequities.

[4]Departmental Faculty of Medicine and Surgery, Campus Bio-Medico University of Rome, Rome, Italy
[5]Istituto Superiore di Studi Sanitari Giuseppe Cannarella, Rome, Italy
Contact: aircerri@gmail.com

Background:

The SARS-CoV-2 pandemic put under pressure all the world's health systems, to the point that it was a severe threat to their stability. At the same time, this scenario confirmed the importance of primary health care to guarantee effective care for patients who suffer from complex and chronic diseases. From these considerations and in the light of the funding provided by the European Union for enhancing the health care system in Italy, our working group has decided to analyse various organisational models of Primary Health Care founded around the world to set up innovative Primary care community Centers in Italy, called Community Houses.

Methods:

A scoping review of the international literature was conducted on Pubmed, searching for primary care models based on integration and co-location of services. Each organisational model was then evaluated using different levels of multi-dimensional integration inspired by the taxonomy work of P. P. Valentijn, such as clinical, professional, organisational, system, functional and normative integration levels.

Results:

The search produced 2053 results, initially screened by title and abstract and, subsequently, by full-text, finally obtaining 116 articles. When a model is characterised by integrating services with external stakeholders, it also presents more integration levels than the others. In particular, these models are, on average, about 20% more likely to have an organisational, functional and normative integration in the model. Moreover, by stratifying for population complexity, we can find an increase in integration levels for populations suffering from chronic diseases with a higher degree of complexity, such as diabetes or cancer.

Conclusions:

From these preliminary results, we can conclude that it is necessary to prefer primary care models with more integration levels to deliver better healthcare for people with complex or chronic diseases, improving the performance of the Health Care System, especially in Italy.

Key messages:

- Our work has allowed us to advise the policymakers on a correct reorganisation of the National Health System in Italy employing the European Union funds.
- The results of this study will be used to organised Primary care community Centers in Italy, called Community Houses, which aim to facilitate the integration and co-location of services.

Communication between cancer patients, caregivers and oncologists about out-of-pocket spending

Aviad Tur-Sinai

A Tur-Sinai[1], N Bentur[2], D Urban[3]
[1]Health Systems Management, The Max Stern Yezreel Valley College, Yezreel Valley, Israel
[2]School of Health Professions, Tel-Aviv University, Tel-Aviv, Israel
[3]Oncology, Sheba Medical Center, Tel Hashomer, Israel
Contact: avts2309@netvision.net.il

Background:

Concern about the cost and affordability of cancer drugs is widespread and well known. Even in countries with universal healthcare systems or health insurance for all, additional patient out-of-pocket (OOP) expenses are prevalent. Studies showed that honest communication between oncologists and patients is an important component in alleviating financial burden of cancer care. The study explores patient-caregiver-oncologist communication regarding the affordability of OOP medication and the extent to which this communication is related to families' financial burden after their loved ones' death.

Methods:

A cross-sectional survey is conducted in Israel among 491 primary caregivers of deceased cancer patients, Jewish and Arab, in three oncology centers.

Results:
