Objectives: Progressive Supranuclear Palsy (PSP) is a neurodegenerative disease clinically characterized by symmetric parkinsonism associated with earlier postural instability and falls compared to Parkinson's disease (PD). Mobile Health Technology (MHT) assessment can objectively evaluate postural instability under supervised conditions. The differences between postural instability characteristics and compensations mechanisms in PD and PSP are still theme of debate.

Materials: 250 subjects entered the study, namely 27 participants with PSP, 44 with PD who have experienced at least 1 fall in the last year, 63 with PD who have not experienced any fall in the last year, and 116 healthy control subjects performed static sway tests.

Methods: Static balance was evaluated with instrumented (lower back accelerometer, Rehagait®, Hasomed, Germany) 30-s trials in side by side, semitandem and tandem positions and functional reach test. The data were analysed to determine what balance parameters discriminated PSP from PD and HC and to detect the correlation of these technological measures with clinical assessment.

Results: PD with falls and PSP exhibited similar increased volume of perturbation compared to both HC and PD falls; only 44.4% of PSP patients were able to complete the functional reach tests and exhibit the worste performance in the cohort. When adjusted for severity, PSP exhibited lower volume of perturbation compared to PD with falls and higher anteroposterior acceleration and speed in PSP compared to PD without falls. The fear of falling was higher in PSP (100%), followed by PD with falls and PD. In parkinsonian patients with and without fear of falling, the volume of perturbation in static balance was higher in PD with falls compared to PSP. In PSP patients, disease severity did not correlate with age, or disease duration but with several digital parameters, including the volume of perturbation and anteroposterior speed/acceleration.

Discussion: PSP patients exhibit a similar postural instability pattern compared to PD with falls but lower perturbation volume when adjusting for severity. Different pathophysiology and compensations mechanism are thus probably related to postural instability and falls in parkinsonian patients.

Conclusions: In this study we compared postural instability characteristics in patients with PD (with and without falls) and PSP, finding significant differences in the volume of perturbation between these groups. Further studies evaluating the progression of postural instability using MHT and the efficacy of rehabilitation in different settings are pivotal to improve the general management of parkinsonian patients with falls.

## BODY-FIRST VS. BRAIN-FIRST SUBTYPES OF PARKINSON'S DISEASE: PATHOPHYSIOLOGICAL INSIGHTS FROM EEG-BASED FUNCTIONAL CONNECTIVITY

M. Conti[1], A. Guerra[2], R. Bovenzi[1], R. Cerroni[1], V. D'Onofrio[2], N. Mercuri[3], M. Pierantozzi[3], T. Schirinzi[3], A. Stefani[1]

[1]Parkinson Centre, Department of Systems Medicine, University of Rome Tor Vergata (Roma); [2]Parkinson and Movement Disorders Unit, Study Centre on Neurodegeneration (CESNE), Department of Neuroscience, University of Padua (Padova); [3]Neurology Unit, Department of Systems Medicine, University of Rome Tor Vergata (Roma)

Objective: REM sleep behavior disorder (RBD) is highly associated with Parkinson's disease (PD) [1] and may precede the onset of motor symptoms by years. According to a recent hypothesis, isolated RBD before parkinsonism (premotor RBD, pRBD) is a marker of the PD body-first subtype, where synucleinopathy originates from the peripheral autonomic nervous system and then spreads to the brain. Conversely, in the brain-first subtype of PD, synucleinopathy would initially arise in limbic brain areas [2]. Functional connectivity (FC) could improve the understanding of clinical and pathophysiological features of these putative PD subtypes. In this study, we aim to analyze the possible differences in FC between early-stage PD patients with and without pRBD, by means of high-density EEG.

Materials and Methods: We enrolled 67 subjects, including 26 early-stage PD patients without pRBD (PDpRDB-), 17 early-stage PD patients with pRBD (PDpRBD+) and 24 healthy controls (HC). Resting-state EEG was recorded using a 64-channels system, and a source reconstruction method, based on individual brain MRI, was used to identify brain regions activity. Cortical FC in theta, alpha and beta

bands was analyzed based on weighted phase-lag index. Possible FC changes in the various frequency bands between HC, PDpRDB- and PDpRBD+ were assessed using network-based statistics.

Results: With respect to HC, PD patients showed hypoconnected networks in theta and alpha band, involving prefronto-limbic-temporal and fronto-parietal areas, respectively. When comparing the PDpRDB- and PDpRBD+ subgroups, we found a lower FC in the alpha frequency band in PDpRBD-, which involved a network composed by temporo-parietal (29.6%), frontal (22.8%) and sensorimotor (21.0%) areas (t=2.5, p=0.025). No differences were found in the other frequency bands.

Discussion: Previous evidence suggested a relationship between alpha-FC and cholinergic system dysfunctions in PD. Hence, the reduced FC in the alpha frequency band we found in PDpRBD+ patients may underlie an early alteration of brainstem cholinergic pathway, which projects widely to the cortex, in patients with the body-first PD subtype. Moreover, since alpha rhythm abnormalities have a role in PD dementia [3], our data of an early alpha FC impairment in temporo-parietal areas in PDpRBD+ support the hypothesis that patients with the body-first subtype are more prone to progress to dementia than brain-first PD [2].

Conclusions: Compared to brain-first PD, the body-first PD subtype demonstrates specific EEG-FC dysfunctions in the alpha frequency band, which may reflect an early involvement of the cholinergic subcortical system.

## SLEEP QUALITY IN FLUCTUATING PARKINSON'S DISEASE PATIENTS: ROLE OF DOPAMINERGIC THERAPY

A. Covolo, C. Ledda, G. Imbalzano, E. Montanaro, M. Rizzone, C. Artusi, L. Lopiano, A. Romagnolo, M. Zibetti

City of Health and Science of Turin Hospital, Molinette Presidium, University of Turin, Department of Neuroscience "Rita Levi Montalcini" (Torino)

Introduction: Parkinson's disease (PD) is characterized by cardinal motor symptoms (bradykinesia, rest tremor, rigidity), and several nonmotor symptoms. [1] Among these, sleep dysfunction is highly prevalent (60%-98% of PD patients). [2,3] Several antiparkinsonian drugs have been demonstrated to influence sleep quality, with conflicting results.

Objectives: To evaluate on a large cohort of advanced PD patients the role of dopaminergic treatment in influencing sleep disturbances (i.e., reduced sleep quality and excessive daytime sleepiness [EDS]).

Methods: Patients consecutively evaluated for device-aided therapies eligibility were enrolled. Sleep dysfunction was measured by means of the PD Sleep Scale-2 (PDSS-2; score ≥18 indicates poor sleep quality), and the Epworth Sleepiness Scale (ESS; score ≥10 indicates EDS). The association between dopaminergic therapy (i.e., dopamine agonists [DA], nocturnal extended-release levodopa, total levodopa equivalent daily dose [LEDD], DA-LEDD, and levodopa-LEDD) and disturbed sleep or EDS was evaluated with binary logistic regression analysis, correcting for age, sex, disease duration, motor impairment (Off-state MDS-UPDRS-III), and sleep treatment. Analysis of covariance was used to evaluate differences in PDSS-2 (total and sub-domains scores) and ESS between patients with and without DA treatment, and between patients treated with low or high doses of DA (cut-off: DA-LEDD=180 mg), correcting for the same potential confounders.

Results: We enrolled 281 patients (males: 66.5%; age: 60.3±7.9 years; disease duration: 11.6±3.7 years). 66.2% of patients reported poor sleep quality; 34.5% reported EDS. After adjusting for confounders, DA treatment showed a 2-fold lower odd of presenting relevant nocturnal sleep disturbances (OR: 0.498; p=0.035), while there was no statistically significant association between sleep quality and DA-LEDD, levodopa-LEDD, total LEDD and nocturnal extended-release levodopa. EDS was not significantly influenced by the dopaminergic regimen. We observed a significant better sleep quality in patients with DA therapy compared to those not treated with DA, with lower PDSS-2 total score (21.7±0.7 vs. 24.9±1.3; p=0.027) and lower "nocturnal motor symptoms" domain score (6.4±0.3 vs. 8.1±0.6; p=0.044). Finally, patients with higher doses of DA showed lower PDSS-2 total score compared to patients without DA treatment (p=0.043).

Conclusions: DA, in particular at higher doses, can improve overall sleep quality in advanced PD patients, especially by improving motor symptoms at night. Interestingly, improvement in sleep quality was not accompanied by a significant increase in EDS, a well-known side effect of DA. The recent increasing attention on PD non-motor symptoms may enforce the need to better understand the role of dopaminergic treatment in sleep quality.

## HYPERTENSION IN THE OFF PHASE RESCUED BY LEVODOPA IN ADVANCED PARKINSON'S DISEASE

F. Cucinotta, I. Cociasu, A. Leake, F. Morgante, L. Ricciardi

Neurosciences Research Centre, Molecular and Clinical Sciences Institute, St George's, University of London (London-UK)

Objective: High blood pressure is rarely reported in Parkinson's disease (PD). However, it is unclear how high blood pressure relates to dopaminergic state in PD. Here, we aimed to investigate the relationship between blood pressure values and dopaminergic medication state (OFF and ON) in people with advanced PD.

Materials and Methods: Consecutive subjects with advanced PD were enrolled at the Advanced Therapies MDS Centre of St George's University Hospital. Clinical characteristics, including age, gender, disease duration, and levodopa equivalent daily dose, were recorded. Motor and non-motor symptoms were evaluated using standardized rating scales. Blood pressure measurements were taken in the practically defined OFF-MED (after 12 hours without medication) and ON-MED (at 1 hour after administering 150% of morning Levodopa dose) in sitting and standing up (at 3 minutes) position. The diagnosis of hypertension was based on the 2018 ESC/ESH Clinical Practice Guidelines for the Management of Arterial Hypertension.

Accordingly, we categorized subjects in hypertensive-PD and normotensive-PD.

Results: Among 61 recruited advanced PD patients, 35 had hypertension in the OFF-MED condition as per ESC/ESH guidelines. Only 6 of these subjects had a history of hypertension and were on antihypertensive medication. After levodopa administration, 8 patients still displayed hypertension and 26 became normotensive. None of the subjects with normal blood pressure values in OFF MED, had high blood pressure in ON MED. None of the subjects had hypotension in OFF in the sitting position. Ten subjects had orthostatic hypotension both in the OFF MED and ON MED conditions. Repeated measures ANOVA with group (normotensive-PD vs hypertensive-PD) showed a significant effect of medication ($p<0.001$) and group ($p<0.001$) for blood pressure measured in the sitting position. For blood pressure measured in the standing up position, Repeated measures ANOVA showed an effect of medication ($p<0.001$), group ($p<0.001$) and an interaction between group and medication ($p<0.03$). These effects were driven by the hypertensive-PD group which had significant decrease of blood pressure by levodopa administration. Factorial ANOVA comparing the two groups of PD subjects showed higher scores of the Wearing off questionnaire (WOQ-19) ($p=0.047$) and the Gait and Falls Questionnaire Total Score ($p=0.006$).

Discussion and Conclusion: Hypertension in OFF MED is highly prevalent in advanced PD and it is associated to more severe wearing off and gait dysfunction. These results suggest that hypertension should be considered among OFF period symptoms and properly treated.

## IRON DEPOSITION WITHIN THE BASAL GANGLIA AND THALAMUS IN EARLY DRUG-NAÏVE PARKINSON'S DISEASE PATIENTS WITH AND WITHOUT REM BEHAVIORAL DISORDERS

M. D'Anna[1], R. De Micco[1], N. Piramide[1], F. Di Nardo[1], M. Siciliano[2], G. Caiazzo[1], G. Tedeschi[1], F. Esposito[1], A. Tessitore[1]

[1]Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli" (Napoli); [2]Neuropsychology Laboratory, Department of Psychology, University of Campania "Luigi Vanvitelli" (Caserta)

Objective: Epidemiological studies suggest that Parkinson's disease (PD) patients with REM sleep behavioral disorder (RBD) present an increased risk of worse motor progression and dementia over the disease course. Iron deposition assessed by means of Quantitative Susceptibility Mapping (QSM) has been reported in several cortical and subcortical areas in patients with PD, and a relationship with the development of cognitive decline has been proposed. In this study, we aimed at exploring whether the presence of RBD is associated with a specific pattern of iron deposition in early cognitively unimpaired drug-naïve PD patients, and to correlate MRI findings with cognitive outcomes.

Materials: 3T MRI images of 58 drug-naïve PD patients (29 PD-RBD+ and 29 PD-RBD-) and 18 healthy controls, were analyzed and compared.

Methods: QSM values were extracted from 22 subcortical gray matter nuclei and 16 thalamic subregions. A partial correlation analyses were run between MRI metrics and clinical data. Finally, a ROC curve was performed to test the ability of QSM values in distinguishing PD-RBD+ from PD-RBD- patients.

Results: Compared to PD-RBD-, PD-RBD+ patients showed higher susceptibility values within the right red nucleus, left subthalamic nucleus, left anteroventral thalamus nucleus, right mediodorsal medial magnocellular thalamus nucleus, bilateral medial, left anterior and right lateral pulvinar. QSM values were found to be associated with the cognitive outcome. The ROC curve analysis showed that QSM values could significantly and accurately identify the presence of RBD in drug-naïve PD.

Discussion: This study provides evidence that higher iron deposition within different subcortical nuclei may differentiates PD patients with RBD even in the early stages. This pattern is associated with progressive impairment in executive and attention functioning.

Conclusions: We hypothesize that these findings may reflect the presence of more diffuse neuropathological changes occurring at the disease onset, potentially leading to altered cognitive processing and increased vulnerability to the future development of dementia.

## CERVICAL DYSTONIA IN A PATIENT WITH CERVICAL HYDROMIELIC CAVITY

R. De Fiores, A. Quattrone, L. Vadala', G. Arabia, M. Morelli, U. Sabatini, A. Gambardella

Department of Medical and Surgical Sciences, Institute of Neurology, Magna Graecia University (Catanzaro)

Background: Cervical dystonia is a focal dystonia affecting the neck, resulting in abnormal head postures [1]. Structural lesions of the central nervous system (CNS) represent a cause of secondary cervical dystonia [2]. In the literature, 18 definite cases of concomitant dystonia and syringomyelia have been described, although a causative association between them has not been established [3]. To the best of our knowledge, we report the first case of concomitant cervical dystonia and cervical hydromyelia.

Case presentation: A 42-year-old man presented with a 12-month history of neck stiffness and involontary right head turning. He reported a minor head trauma at the age of 15 and he was not undergoing any pharmacological treatment. Neurological examination revealed cervical dystonia with right torticollis and clear gestes antagonistes, associated with right shoulder elevation and intermittent dystonic head tremor. He also presented mild gait ataxia, bilateral intention tremor, left hand adiadochokinesia and lower limbs brisk reflexes. A comprehensive clinical and laboratory work-up was performed, including blink reflex recovery cycle, somatosensory evoked potentials (SEPs), motor evoked potentials (MEPs), electromyography (EMG), 3-T brain and cervical spine magnetic resonance imaging (MRI) with gadolinium-based contrast. Neurophysiological studies showed increased blink reflex recovery cycle, prolonged latency of MEPs and SEPs and abnormal tonic activity of right trapezius, right splenius capitis and left sternocleidomastoidei muscles at EMG. Brain MRI was unremarkable, while T2-weighted images obtained from a cervical spine MRI study, showed a focal fluid-filled

cavity centrally located within the spinal cord at C6 level and lined by the normal ependymal lining of the central canal, corresponding to a large hydromyelic cavity. The clinical picture and MRI findings remaines unchanged at 6-month follow-up. The patient's dystonia was successfully treated with botulinum toxin injections.

Conclusion: This patient was diagnosed with cervical dystonia and cervical hydromyelic cavity, and as far as we know, this represents the first case described in the literature. Although a causative association has not been definitively established, a possible underlying mechanism could be the alteration of sensorimotor integration, which may lead to a disruption of the dystonia network. The results of our neurophysiology study align with this hypothesis. Further cases need to be described, and additional research is required to investigate the nature of the association between dystonia and hydromyelia, in order to advance towards improved management and treatment of this condition.

## THE EFFECTS OF DOPAMINERGIC TREATMENT ON INTERHEMISPHERIC DISINHIBITION AND BRADYKINESIA ASYMMETRY IN PARKINSON'S DISEASE

M. De Riggi[1], G. Paparella[2], D. Colella[1], A. Cannavacciuolo[2], A. De Biase[1], L. Angelini[1], D. Birreci[1], D. Costa[1], A. Guerra[1], A. Berardelli[1], M. Bologna[1]

[1]Department of Human Neurosciences, La Sapienza University of Rome (Roma);[2]IRCCS Neuromed (Pozzilli-IS)

Objective: Previous evidence demonstrated a reduced interhemispheric inhibition (IHI) in Parkinson's disease (PD), possibly related to the asymmetry of motor symptoms. However, the effects of dopaminergic treatment on interhemispheric disinhibition and motor correlates in PD, have never been investigated. We aim to investigate whether dopaminergic therapy modulates IHI and bradykinesia asymmetry in PD.

Material and Methods: We enrolled seventeen PD patients (mean age ± standard deviation - SD: 67.5±9.2 years) and 15 healthy controls (HCs) (mean age ± SD: 64±8.1 years). Patients were studied with and without their dopaminergic therapy (ON and OFF sessions, mean LEDD ± SD: 483.8±173.2). Paired-pulse transcranial magnetic stimulation (TMS) served to measure IHI, with an interstimulus interval (ISI) between the conditioning (CS) and the test stimulus (TS) of 10 (short-latency IHI, sIHI) and 40 ms (long-latency IHI, lIHI). Objective finger-tapping measurements were obtained bilaterally with a motion analysis system5. We compared data between patients and HCs, and between patients ON and OFF medication using t-tests. We also calculated asymmetry indices (AI) of neurophysiological data. Correlations analysis was performed to test possible relations between TMS and kinematic data.

Results: As compared to HC, PD OFF medication had a reduced sIHI from the most to the less affected hemisphere ($p=0.02$). Finger tapping was slower, more irregular and characterised by the sequence effect in PD OFF medication as compared to HCs (all $p<0.05$). Interhemispheric imbalance quantified by the sIHI-AI correlated with the sequence effect of the less affected side in patients OFF medication ($R=-0.5$, $p<0.03$). Although improving movement velocity ($p=0.009$), dopaminergic treatment did not modify sIHI or the sequence effect ($R=0.23$, $p>0.05$).

Discussion: Only certain bradykinesia features are asymmetrical: the various features of bradykinesia may be underlain by distinct pathophysiological mechanisms. The differential effects of dopaminergic therapy on bradykinesia features and on their asymmetry also support the present hypothesis. We also found novel evidence of the role of interhemisperic connections imbalance in the pathophysiology of bradykinesia, somehow influenced by dopaminergic therapy.

Conclusions: We here provided further evidence on the pathophysiological role of interhemispheric disinhibition in bradykinesia asymmetry in PD with a focus on the effects of dopaminergic treatment.

## FATIGUE AND PARKINSON'S DISEASE: FOCUS ON THE CAREGIVER'S BURDEN

G. Di Francesco, C. Ledda, G. Imbalzano, M. Tangari, A. Covolo, C. Artusi, C. Campisi, E. Montanaro, M. Zibetti, M. Rizzone, M. Bozzali, L. Lopiano, A. Romagnolo

Neurology 2U, AOU Città della Salute e della Scienza, Department of Neuroscience, University of Turin (Torino)

Introduction: Fatigue, defined as a decreased level of energy, or a sense of exhaustion unexplained by physical or psychological distress, is a frequent yet underestimated non-motor symptom of Parkinson's Disease (PD) [1]. It is a key determinant of patient's disability, with a severe impact on quality of life. However, the impact of fatigue on caregiver's burden has not been evaluated so far.

Objective: To assess the impact of fatigue on caregiver's burden on a cohort of PD patients

Methods: We enrolled 53 patients (males: 66.0%; age: 70.53±8.36 years; disease duration: 11.11±7.44 years) and their primary informal caregivers. Patients' fatigue was evaluated with scales validated for PD [2,3], with consistent cut-offs for defining the presence of significant fatigue, the Fatigue Severity Scale (FSS) and the Modified Fatigue Impact Scale (mFIS). Caregiver's burden was measured by means of the Zarit Burden Interview (ZBI). We evaluated the differences in the ZBI score between caregivers of patients with and without fatigue by means of the analysis of covariance, correcting for the following potential confounders: patients' and caregivers' age, disease duration, motor disability (MDS-UPDRS-III score). Linear regression analysis, corrected for the same confounders, was used to evaluate correlations between ZBI, FSS, and mFIS scores.

Results: Significant fatigue was reported by more than 70% of patients with both scales. After correcting for potential confounders, caregivers of patients with fatigue reported 2-fold higher ZBI scores, both using FSS (34.36 ± 2.76 vs. 16.53 ± 6.08; $p=0.013$) and mFIS (36.12 ± 2.72 vs. 17.03 ± 4.80 vs; $p=0.002$) to define significant fatigue. ZBI score was significantly correlated with fatigue, in particular with total mFIS (Beta=0.712; $p<0.001$) and mFIS subdomains

(Physical: Beta=0.568, Cognitive: Beta=0.645, Psychosocial: Beta=0.408; p<0.001).

Discussion and Conclusion: Fatigue is a frequent yet underestimated symptom of PD, frequently reported even in the early stages of the disease. To the best of our knowledge, this is the first study assessing its impact on the quality of life and burden of caregivers. We showed that fatigue is an independent determinant of high caregiver's distress. A better understanding and a careful evaluation of fatigue could be of utmost importance to ameliorate not only patients' but also caregivers' well-being.

## UNCONVENTIONAL THERAPY FOR ACUTE-ONSET LESIONAL HEMIBALLISM

G. Di Rauso[1], N. Orlandi[1], M. Jacopetti[2], G. Bigliardi[3], F. Antonelli[3], S. Meletti[3], V. Rispoli[3]

[1]Department of Biomedical, Metabolic and Neural Science, University of Modena and Reggio Emilia (Modena); [2]UO Medicina Riabilitativa e Neuroriabilitazione, IRCCS Istituto delle Scienze Neurologiche di Bologna (Bologna); [3]Neurology, Neuroscience Head Neck Department, Azienda Ospedaliero-Universitaria di Modena (Modena)

Introduction: Cerebrovascular diseases are the most common causes of secondary hypokinetic or hyperkinetic movement disorders [1]. Among acute-onset hyperkinetic movement disorders, hemiballism (HB) is the most frequent one [2]. Even though up to 90% of them may wear off within six months, involuntary movements may severely compromise patients' quality of life, so that symptomatic treatments are required. Typical and atypical neuroleptics as well as Tetrabenazine represent therapies of choice. Anecdotal reports of antiseizures medications effectiveness and successful use of botulinum neurotoxin (BoNT) injection have been rarely described [1][2][3].

Case presentation: A 78 years-old man with an history of vascular parkinsonism and undetermined onset tonic-clonic seizures, came to our attention for an acute-onset left hemiballism with homolateral hemiparesis. Brain CT scan showed a right thalamo-mesencefalic hemorrhage, while blood tests revealed acute kidney failure secondary to severe rhabdomyolysis (CPK > 80000 U/L). Due to the persistence of severe hemiballism causing cutaneous injuries and interference even with sitting balance together with the ongoing rhabdomyolysis, symptomatic therapy was required. Nevertheless, QTc interval prolongation and renal function impairment limited the dosage of neuroleptics and benzodiazepines. Despite several combined approaches including Tetrabenazine, low-dose of Quetiapine, Clonazepam and Diazepam, 20 days after the onset, the left-sided hemiballism remained severely disabling. Thus, the patient received BoNT injections in his left upper limb muscles (onabotulinumneurotoxinA 200 UI: biceps brachii, triceps brachii, teres major, deltoid) and low-dose of Topiramate (37.5 mg/die), that were followed by the gradual reduction of hyperkinetic movements. In the following months, Topiramate was gradually discontinued after about five weeks of treatment without any significant motor clinical worsening. At 6 months follow-up visit, due to severe HB rebound the patient was wheelchair-bound, so BoNT injections were repeated.

Discussion: We describe a case of disabling HB, where high-dosage of first-line therapies were contraindicated due to comorbidities. In this scenario, we decided to combine Topiramate and BoNT injections in the left upper limb muscles, where ballism was more prominent with consequent gradual reduction of involuntary movements. The discontinuation of Topiramate did not modify the clinical picture, which was, however, more severe at 6-month follow-up. So, the improvement experienced by our patient was probably ascribable to the early treatment with BoNT.

Conclusion: The present case highlights the effectiveness of unconventional therapeutic options in disabling acute onset lesional hemiballism when first-line therapies are contraindicated. Particularly, this report may encourage reflections on BoNT application in the early stage of movement disorder emergencies.

## THEORY OF MIND AND ATTENTIONAL DEFICITS MAY DISTINGUISH FUNCTIONAL MOVEMENT DISORDERS AND PARKINSON'S DISEASE

S. Di Tella[1], M. Lo Monaco[2], A. Tondinelli[1], G. Pozzi[3], S. Fragapane[4], M. Petracca[4], P. Calabresi[5], A. Bentivoglio[5], M. Silveri[1]

[1]Department of Psychology, Catholic University of Sacred Heart (Milano); [2]Medicine of Ageing, Fondazione Policlinico Universitario 'Agostino Gemelli' IRCSS, Institute of Internal Medicine and Geriatrics, Catholic University of the Sacred Heart (Roma); [3]Department of Neuroscience, Section of Psychiatry, Catholic University of the Sacred Heart, Department of Psychiatry, Fondazione Policlinico Universitario Agostino Gemelli IRCCS (Roma); [4]Neurology Unit, Fondazione Policlinico Universitario A. Gemelli IRCCS (Roma); [5]Neurology Unit, Fondazione Policlinico Universitario A. Gemelli IRCCS, Institute of Neurology, Catholic University of the Sacred Heart (Roma)

Objective: This work explores Theory of Mind (TOM) (the ability to attribute mental states), attentional deficits and dissociative symptoms in Functional Movement Disorders (FMDs) and Parkinson's Disease (PD) in order to identify elements that can facilitate distinction between the two pathologies. FMDs are motor manifestations not attributable to known medical conditions. The overlap of FMDs with symptoms of Parkinson's disease (PD) is frequent and distinguishing the functional component can be challenging. A neurobiologically informed model of hierarchical Bayesian inference explains functional symptoms in terms of perception and action arising from inference based on prior beliefs (priors) and sensory information. Brain damage can modify priors; loss of dopamine in the striatum is responsible for degradation of routines that overloads the attention-demanding control supporting goal-directed movements making the system vulnerable and prone to functional symptom onset that overlaps organic symptoms. The concept of altered prediction of the Baysian model is also adopted by psychosocial models on FMDs. In particular, altered TOM contributes to reduce the ability to predict mental states underlying motor behavior during social interaction leading to predicting errors whose content is the anomalous movement.

Materials and Method: Twenty-three FMDs, 23 PDs and 40 healthy controls (HCs) were recruited. Tasks exploring both affective (Reading the Mind-with-the-Eyes test-RMET) and cognitive components (Faux-pas stories) were given. The Stroop Color-and-Word test (SCWT) was adopted to explore the balance between goal-directed actions (naming) and automatic routines (reading). Classical hypothesis on dissociative symptoms related to conversion disorders was also explored by DES-II questionnaire.

Results: FMDs performed lower than HCs, with difference approaching significance (P=0.066) in RMET, and significantly lower than HCs (p<0.001) in Faux-pas stories with normal score in control questions (all p>0.1). PDs performed lower than HCs in both the RMET (p=0.027) and Faux-pas stories (p<0.001); the difference was also significant in control questions (p=0.042). Only in PDs neuropsychological tests were significantly correlated with the RMET (all <0.034); Faux-pas stories were significantly correlated with Phonological Fluency (p=0.050). In SCWT only PD produced a significant higher number of errors than HCs. Dissociative symptoms were more frequent in FMDs (p=0.018).

Discussion: Only FMDs have genuine TOM disorders, which may account for difficulties in predicting motor behavior during social interaction, whereas in PDs TOM deficits are dependent on cognitive impairment. The two groups differ in the balance between goal-directed attention and routines, and dissociative symptoms.

Conclusions: TOM and attentional disorders and dissociative symptoms may distinguish FMDs and PD.

## EFFECTS OF SELEGILINE ON FATIGUE IN PARKINSON'S DISEASE

I. A. Di Vico, A. Sandri, G. Tomelleri, G. Burati, S. Ottaviani, M. Tinazzi

Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona (Verona)

Background: Fatigue is a frequent and disabling non-motor symptoms (NMS) of Parkinson's disease (PD) and no specific treatment is currently available [1]. Evidence for the role of monoamine oxidase-B receptor inhibitor (i-MAO B) in the treatment of NMS is emerging [2].

Objective: This is a single-center, prospective observational study aimed at assessing the efficacy of the selective i-MAO B Selegiline, in the treatment of fatigue in patients with PD.

Methods: Consecutive PD patients complaining of fatigue for at least three months were enrolled at the Neurology Unit, PD and Movement Disorder Division of Verona. Patients with severe NMS or chronic conditions determining secondary fatigue were excluded. Selegiline was administered with a starting dose of 5 mg/day and increased to 10 mg/day after one week. The primary outcome was the 7-point patient-rated perception of change (p-CGI) after eight weeks of treatment (T1). Secondary outcomes were changes in the mean scores of the Parkinson Fatigue Scale (PFS), Fatigue Severity Scale (FSS), and Multidimensional Fatigue Inventory (MFI) and its sub-scales. Apathy, anxiety, depression, and sleep-wake disorders were measured through validated scales.

Results: Twelve patients (8 men); mean age 64.9±11.6 years and mean disease duration 5.8±3.7 years completed the study. Two patients discontinued the medication because of minor side effects (nausea, malaise, and hypertension). After 8 week-treatment, 91.7% (n=11) of patients reported fatigue to be improved (very much-to minimally, p-CGI 1-3), while only 8.33% (n=1) did not report any change (p-CGI 4). None of the patients reported worsening fatigue. Paired samples T-Test showed a significant improvement of fatigue measured through the PFS and the sub-scale for physical fatigue of the MFI (MFI-PF) at T1 compared to baseline (p = 0.017 and p= 0.018). Other measures of fatigue (FSS and MFI-total score) showed a tendency for significance. At T1, UPDRS-III improved significantly (p = 0.03). Correlation analyses showed that improvement in PFS correlated with changes in depression, as measured by the Hamilton Depression Scales (HDS) (r 0.72, p 0.008).

Discussion: With the limitation of an open-label uncontrolled and small sample study, our results show that fatigue related to PD improved after 8 week-treatment with selegiline. All but one of the patients (91.7%, n=11) experienced a subjective amelioration of fatigue (p-CGI 1-3) and the PFS and the physical domain of fatigue significantly improved, along with a parallel reduction of motor symptoms severity (UPDRS-III). Among NMS, changes in depression influenced the positive outcome.

Conclusions: Our preliminary results suggest that Selegiline 10 mg/day might effectively relieve fatigue in PD and should be considered in the algorithm of its treatment.

## MOCA-AOIFD: PSYCHOMETRIC AND DIAGNOSTICS OF THE MONTREAL COGNITIVE ASSESSMENT (MOCA) IN AN ITALIAN COHORT OF PATIENTS WITH ADULT-ONSET IDIOPATHIC FOCAL DYSTONIA

A. D'Iorio[1], E. Aiello[2], A. Trinchillo[3], V. Silani[4], N. Ticozzi[4], A. Ciammola[2], B. Poletti[5], M. Esposito[6], G. Santangelo[1]

[1]Department of Psychology, University of Campania Luigi Vanvitelli (Caserta); [2]Department of Neurology and Laboratory of Neuroscience, IRCCS Istituto Auxologico Italiano (Milano); [3]Department of Neurosciences, Reproductive Sciences and Odontostomatology, University of Naples Federico II (Napoli); [4]Department of Neurology and Laboratory of Neuroscience & Department of Pathophysiology and Transplantation, IRCCS Istituto Auxologico Italiano & University of Milan (Milano); [5]Department of Neurology and Laboratory of Neuroscience & Department of Oncology and Hemato-Oncology, IRCCS Istituto Auxologico Italiano & University of Milan (Milano); [6]Clinical Neurophysiology Unit, Cardarelli Hospital (Napoli)

Objectives: To assess the clinimetrics of the Montreal Cognitive Assessment (MoCA) in an Italian cohort of patients with adult-onset idiopathic focal dystonia (AOIFD).

Materials: N=86 AOIFD patients (blepharospasm: N=36; cervical dystonia: N=31; other phenotypes: N=19) and N=92 healthy controls (HCs) were administered the MoCA. Patients further underwent the Trail-Making Test (TMT-A/-B/-BA) and Babcock Memory Test (BMT), being also screened via the Beck Depression Inventory-II

(BDI-II) and the Dimensional Apathy Scale (DAS). Information on disease duration, disease severity and motor symptoms was also collected.

Methods: Factorial structure and internal consistency were assessed. Construct validity was tested against TMT, BMT, BDI-II and DAS scores, whilst diagnostics against the co-occurrence of a defective performance on at least one TMT measure and on the BMT. Case-control discrimination was examined. The association between MoCA scores and disease-related features was explored.

Results: The MoCA was underpinned by a mono-component structure (38.41% of variance explained) and acceptably reliable at an internal level (McDonald's ω=.67). It converged towards TMT (-.67≤rs(86)≤-.55; ps<.001) and BMT (rs(86)=.66; p<.001) scores, as well as with the DAS (rs(82)=-.37; p<.001), whilst diverging from the BDI-II. Its adjusted scores [1] accurately identified patients with cognitive impairment (i.e., 8%) at a cut-off of <17.212 (AUC=.86; sensitivity=.71; specificity=.92; positive predictive value=.46; negative predictive value=.97; positive likelihood ratio=9.41; negative likelihood ratio=.31; Number Needed for Screening Utility=.82). No association has been detected between the MoCA and disease duration, disease severity and motor phenotype. The MoCA discriminated patients from HCs (z=-5.99; OR=.50, CI 95% [.39, .62]; p<.001) with a classification accuracy of 80% (AUC=.90; sensitivity=.86; specificity=.74).

Discussion: The present study provides evidence on the clinimetric soundness and feasibility of the MoCA in AOIFD patients – by also delivering Italian practitioners and clinical researchers with disease-specific cutoffs for such a screener in this population. Indeed, the MoCA herewith proved to: 1) be valid at both factorial and construct levels; 2) be acceptably reliable at an internal level; 3) be featured by sound diagnostics; 4) be independent of disease-related features; 5) be able to discriminate patients from HCs. Considering the outcome measures herewith addressed (i.e., the TMT and the BMT), this report suggests that the MoCA is able to capture the dysexecutive-inattentive and amnestic profile that not infrequently features AOIFD patients [2].

Conclusions: The Italian MoCA is a valid, diagnostically sound, and feasible cognitive screener in AOIFD patients.

## MOCA-PD: CLINIMETRIC PROPERTIES OF THE MONTREAL COGNITIVE ASSESSMENT (MOCA) IN AN ITALIAN COHORT OF NON-DEMENTED PARKINSON'S DISEASE PATIENTS

A. D'Iorio[1], E. Aiello[2], M. Amboni[3], C. Vitale[4], F. Verde[5], V. Silani[5], N. Ticozzi[5], A. Ciammola[2], B. Poletti[6], G. Santangelo[1]

[1]Department of Psychology, University of Campania Luigi Vanvitelli (Caserta); [2]Department of Neurology and Laboratory of Neuroscience, IRCCS Istituto Auxologico Italiano (Milano); [3]Department of Medicine, Surgery and Dentistry, University of Salerno (Salerno); [4]Department of Motor Sciences and Wellness, University "Parthenope" (Napoli); [5]Department of Neurology and Laboratory of Neuroscience & Department of Pathophysiology and Transplantation, IRCCS Istituto Auxologico Italiano & University of Milan (Milano); [6]Department of Neurology and Laboratory of Neuroscience & Department of Neurology and Laboratory of Neuroscience, IRCCS Istituto Auxologico Italiano & University of Milan (Milano)

Objectives: This study aimed at 1) assessing, in an Italian cohort of non-demented Parkinson's disease (PD) patients, the concurrent and convergent validity of the Montreal Cognitive Assessment (MoCA) against both first- and second-level cognitive measures; 2) delivering an exhaustive and updated evaluation of its diagnostic properties.

Materials: A retrospective cohort of N=237 non-demented PD patients having been administered the MoCA was addressed, of whom N=169 further underwent the Mini-Mental State Examination (MMSE) and N=68 the Parkinson's Disease Cognitive Rating Scale (PD-CRS). A subsample (N=60) also underwent a second-level cognitive battery encompassing measures of attention/executive functioning, language, memory, praxis and visuo-spatial abilities. Patients were free of 1) dementia due to PD, 2) further neurological/psychiatric diseases, 3) severe and/or unstable general-medical conditions and 4) uncorrected hearing/vision deficits.

Methods: Concurrent validity was assessed against the PD-CRS, whilst convergent validity against each second-level cognitive measure. Diagnostics were tested via receiver-operating characteristics analyses against a below-cut-off MMSE score.

Results: The MoCA was predictive of PD-CRS scores (β=.68; p<.001; R2=.46) and related to several second-level measures – i.e., the Stroop Color-Word Test, Trail-Making Test, Phonemic Fluency test, Verb-naming from the Esame Neuropsicologico per L'Afasia, Rey Auditory Verbal Learning Test, Design Copy test and Benton Judgment of Line Orientation test (ps<.003). Both raw and adjusted MoCA scores proved to be highly accurate to the aim of identifying patients with MMSE-confirmed cognitive dysfunctions. A MoCA score adjusted for age and education according to the most recent normative dataset [1] and <19.015 is herewith suggested as indexing cognitive impairment in this population (AUC=.92; sensitivity=.92; specificity=.80; positive predictive value=.44; negative predictive value=.98; positive likelihood ratio=4.57; negative likelihood ratio=.10; Number Needed for Screening Utility=.80).

Discussion: The present study provides Italian practitioners and clinical researchers with updated evidence on the validity and diagnostic value of the MoCA in non-demented PD patients. Indeed, the MoCA herewith proved to 1) be predictive of a disease-specific measure of global cognition (i.e., the PD-CRS), 2) converge with several second-level measures of both instrumental and non-instrumental cognitive domains/functions and 3) be diagnostically sound in detecting MMSE-confirmed cognitive impairment. Overall, the current findings align with the fact that the Movement Disorders Society recommends the use of the MoCA for cognitive screening aims in this population [2].

Conclusions: The Italian MoCA is a valid and diagnostically sound screener for global cognitive inefficiency in non-demented PD patients.

## DIAGNOSTIC ACCURACY OF SKIN BIOPSY IN DISCLOSING EARLY PD

V. Donadio[1], A. Incensi[1], G. Rizzo[1], A. Furia[1], E. Olivola[2], M. Piatti[3], F. Ventruto[1], S. Bonvegna[3], V. Vacchiano[1], E. Fileccia[1], S. Parisini[1], N. Modugno[2], R. Cilia[4], R. Liguori[1]

[1]UOC Neurology, IRCCS Institute of Neurological Sciences of Bologna (Bologna); [2]IRCCS Istituto Neurologico Mediterraneo Neuromed (Pozzili-IS); [3]Parkinson Institute, ASST Gaetano Pini-CTO (Milano); [4]Parkinson and Movement Disorders Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano)

Aim: To analyse the diagnostic accuracy of phosphorylated α-synuclein (p-syn) in autonomic skin fibers in identifying early Parkinson's disease (PD).

Materials and Methods: One hundred twenty participants with early parkinsonian signs (onset within the last 18 months) were included in the study. Proximal and distal skin sites were taken to analyse p-syn by immunofluorescence. Patients also underwent clinical evaluation including focused scales (UPDRS and HY, MoCA, COMPASS-31, NMSQuest) and smell analysis. Clinical evaluation was repeated over a follow-up of 18 months in all patients whereas skin biopsy was repeated in 45 patients in the follow-up. Clinical diagnosis of PD was defined according to the Movement Disorder Society (2019) criteria.

Results: Seventy patients presented clinical criteria for PD (mean disease duration 10±2 months): 45 patients at the baseline recruitment whereas 25 cases only at the follow-up. P-syn was found at baseline in 61 of these patients (87%) included 19 cases with undefined clinical picture at baseline. Fifty patients did not meet clinical criteria for prodromal PD both at baseline and follow-up. They included 21 patients with a clinical diagnosis of tauopathy, vascular PD or MSA at the follow-up. P-syn was absent in these patients at baseline and follow-up except the patient with MSA showing the typical somatic p-syn. Twenty-nine patients showed an undefined clinical picture both at baseline and follow-up and p-syn was found in 6 patients but 23 were negative. Taken into account only patients fulfilling a defined clinical diagnosis at the follow-up skin biopsy (i.e. p-syn in autonomic nerve fibers) presented 87% of sensitivity and 100% of specificity in disclosing an early PD. Skin biopsy showed the same results over the follow-up in 43 patients (96%) while 2 patients fulfilling a clinical diagnosis of prodromal PD who were negative at baseline showed p-syn over the follow-up. Patients with early PD showed higher smell dysfunctions, RBD incidence, UPDRS, HY and COMPASS-31 scales. However, p-syn was not correlated with clinical scales.

Discussion: The early diagnosis for PD is a difficult problem as not reliable biomarkers are available and the clinical picture is highly not specific during this phase of the disease. Thus, reliable biomarkers are urgently needed to identify in an early disease phase patients presenting PD.

Conclusions: Our results showed that skin biopsy and skin p-syn presented an excellent diagnostic accuracy in identifying early PD. Our study corroborates the use of skin biopsy for the diagnosis of early PD.

## IMPACT OF DEEP BRAIN STIMULATION ON THE COGNITIVE AND BEHAVIOURAL PROFILE OF PATIENTS WITH PARKINSON'S DISEASE: A CASE-CONTROL STUDY

V. D'Onofrio[1], R. Biundo[2], L. Weis[3], E. Fiorenzato[3], M. Garon[3], D. Ciprietti[3], M. Nasi[2], A. Landi[3], A. Antonini[3], A. Guerra[3]

[1]Padova Neuroscience Center, University of Padua (Padova); [2]Department of General Psychology, University of Padua (Padova);[3]Department of Neuroscience, University of Padua (Padova)

Objective: Deep Brain Stimulation (DBS) is an established therapy for patients with advanced Parkinson's Disease (aPD). Despite the positive outcomes in improving motor symptoms, the effects on cognitive and behavioural functions are still debated and remain controversial [1,2]. In this single-centre study, we used a case-control design to address this issue.

Materials: Fifty-nine patients with aPD who satisfied the clinical criteria and had no major contraindication for undergoing DBS surgery were enrolled. All patients were evaluated with extensive neuropsychological testing, including standardized scales for functional impairment and quality of life (ADL, IADL, PDQ-8 and PD-CFRS), behaviour (BDI-II, BIS-11, QUIP-RS, SOGS, Apathy Scale, STAI-Y1 and STAI-Y2) and multiple cognitive domains (i.e., attention, executive functions, memory, language, visuospatial abilities). Motor symptoms were evaluated with the third section of the MDS-UPDRS and the H&Y scale. After initial screening, 30 patients underwent DBS surgery (aPD-DBS+, case group), while 29 patients did not provide informed consent for the procedure, mostly due to safety concerns (aPD-DBS-, control group).

Methods: aPD-DBS+ patients were clinically and neuropsychologically evaluated before and after 1-3 and 4-5 years from DBS surgery. aPD-DBS- patients were assessed at comparable timepoints. Nonparametric tests were used for statistical analyses.

Results: There was no significant difference in age, gender distribution, disease duration, the levodopa-equivalent daily dose (LEDD) and motor symptoms severity (MDS-UPDRS-III and H&Y) between aPD-DBS+ and aPD-DBS- at baseline (all Ps>0.05). After surgery, aPD-DBS+ patients showed a statistically significant reduction in LEDD, MDS-UPDRS-III and PDQ-8 scores, whereas aPD-DBS- showed progressive worsening over time. Notably, there was no difference in changes in behavioural functions and cognitive performances over time between the two groups, except for a mild increase in STAI-Y1 and 2 scores in aPD-DBS+ patients.

Conclusions: Our results confirmed the efficacy of DBS in improving motor symptoms and reducing the amount of dopaminergic therapy in aPD compared to patients not undergoing surgery. Importantly, in line with some previous observations, we demonstrated that DBS does not induce significant changes in the cognitive and behavioural profile of patients compared to those occurring in aPD per se [3]. These observations suggest the lack of detrimental effects of DBS on cognition and behaviour over time.

## POTENTIAL USEFULNESS OF FAST BETA-BAND SURVEY FOR DEEP BRAIN STIMULATION PROGRAMMING IN PARKINSON'S DISEASE: A PILOT STUDY

V. D'Onofrio[1], D. Ciprietti[2], F. Baroni[2], C. Porcaro[1], C. Fogliano[2], A. Landi[2], A. Antonini[2], A. Guerra[2]

[1]Padova Neuroscience Center, University of Padua (Padova);[2]Department of Neuroscience, University of Padua (Padova)

Objectives: Deep Brain Stimulation (DBS) is an established therapeutic option for patients with advanced Parkinson's disease (aPD). New DBS systems improved treatment tailoring and sensing-enabled technologies and allow the recording of local field potentials (LFPs), opening new avenues of scientific inquiry into basal ganglia pathophysiology [1,2].

Materials: A group of patients with aPD were clinically evaluated before and after 3 weeks and 3-6 months from DBS surgery of the subthalamic nucleus (STN) or globus pallidus internus (GPi). All patients were implanted with the Medtronic Percept® PC and quadripolar sensing-enabled directional leads (B33005).

Methods: Programming was conducted according to the standard monopolar review of DBS contacts at 3 weeks after surgery. The Brainsense survey was performed in all patients (OFF dopaminergic condition) at 3 weeks and 3-6 months after DBS surgery. The frequency and peak amplitude in the beta band range (13-30 Hz) were collected from the two middle contacts (ring configuration) of both right and left STN/GPi. Motor symptoms were assessed with the third section of the MDS-UPDRS and with H&Y scale.

Results: In more than 75% of cases, lead contacts showing the highest beta peak corresponded to the contact with the largest therapeutic window and the level chosen for chronic stimulation according to the standard monopolar review. Moreover, the contact showing the highest beta peak demonstrated good test-retest reliability across the two different time points (i.e., at three weeks and 3-6 months after DBS). After surgery, all patients showed a statistically significant improvement in the MDS-UPDRS III total scores and a reduction in LEDD at the 3-6 months follow-up.

Conclusions: We here report data from a single-centre pilot study using the new sensing-enabled DBS system for aPD patients. Performing the fast Brainsense survey to identify contacts with the highest beta peak could potentially facilitate stimulation programming by significantly reducing DBS programming time [3]. This approach may be further tested and directly compared with the standard monopolar review to assess whether the two different programming approaches produce similar clinical outcomes in larger aPD patient cohorts.

## EFFICACY OF MULTIDISCIPLINARY INTENSIVE REHABILITATION TREATMENT IN PARKINSON'S DISEASE

G. Donzuso, A. Russo, F. Zagari, A. Luca, G. Mostile, A. Nicoletti, M. Zappia

Department of Medical, Surgical Sciences and Advanced Technologies "GF Ingrassia", University of Catania (Catania)

Objective: To evaluate the efficacy of an 8-week multidisciplinary intensive rehabilitation treatment (MIRT) and virtual reality training (VRT) in patients with Parkinson's disease (PD) assessed with clinical and magnetic resonance imaging (MRI) markers.

Methods: This is a prospective, parallel-group, randomized study (Ethical committee register 149/2020/PO). PD patients attending the Movement Disorders Center of the University of Catania were enrolled and randomly assigned to MIRT treatment without (group A) or with (group B) a VRT with BTs-Nirvana (BTsN). Each patients underwent a comprehensive clinical assessment at baseline (T0), after the rehabilitation treatment (week 8, T1) and after one month without (T2).

Results: Seventeen PD patients were enrolled according to Brain Bank Criteria (10 male, 7 female, age 64.3 ± 8.7 years, UPDRS-ME 56.4 ± 21.2 score). Ten patients were randomized into group A, and 7 into group B. There were no differences between the two-treatment group in demographics and clinical features at baseline. Considering the whole PD sample, patients showed an improvement in the FOG-Q score between T0 and T2 (4.3 ± 4.1 vs 3.0 ± 3.7 score, p-value 0.02), and T1 and T2 (3.6 ± 3.9 vs 3.0 ± 3.7 score, p-value 0.05). Between group analysis showed significant differences between group A and group B at T1 in TUG (11.3 ± 2.2 vs 6.1 ± 2.7 seconds, p-value <0.001), and 10-meters performances (8.5 ± 1.2 vs 5.3 ± 2.4 score, p-value 0.002).

Conclusions: This study showed that physical rehabilitation improves motor symptoms of PD patients. The use of VRT could further improve motor performance of PD patients.

## EVALUATION OF NON-MOTOR FLUCTUATIONS IN PARKINSON'S DISEASE DURING PHARMACOLOGICAL ON PHASE. IS ALWAYS THE "ON" CONDITION BENEFICIAL?

G. Donzuso, G. Mostile, A. Luca, C. Cicero, A. Nicoletti, M. Zappia

Department of Medical, Surgical Sciences and Advanced Technologies "GF Ingrassia", University of Catania (Catania)

Objectives: Non-motor symptoms (NMS) and fluctuations (NMF) are very common in Parkinson's disease (PD) occurring in ON and OFF state and affecting patients' quality of life. Aim of the study was to evaluate NMS occurring during ON pharmacological state.

Material and Methods: Patients with diagnosis of PD according to MDS criteria were consecutively enrolled at the Movement Disorders Center of the University of Catania. For this purpose, a new questionnaire was developed considering 17 items including the main symptoms experienced by PD patients in the ON state. PD patients were evaluated in ON state, 90' after the first morning dose of dopaminergic therapy and were asked if the symptoms were present during the ON state. PD patients who experienced at least one symptom in ON were defined ON Non-Motor Fluctuators (ONMF). Additionally, clinical features, MDS-UPDRS, Hoehn and Yahr stage and levodopa-equivalent dose were collected.

Results: One-hundred and thirty-seven PD patients with a mild to moderate disease stage were enrolled (79 man and 58 woman, age 69.4 ± 9.5 years (mean ± SD), disease duration 8.0 ± 4.6 years). Seventy-seven patients were ONMF (56.6%). ONMF were associated with female gender (OR 2.81, 95%CI 1.37-5.77, p-value 0.005) and with motor fluctuations (OR 2.41, 95%CI 1.20-4.83, p-value 0.013). PD patients with short disease duration (<7 years) showed the presence of "negative" NMS such as "sonnolenza/sleepiness", "sensazione di testa vuota/light-headedness", nausea/vomito/nausea/vomiting". PD patients with longer disease duration experienced more "positive" NSM including "sentirsi pieno di energie/feel lot of energy" and "sensazione di benessere fisico/feel physical well-being".

Discussion and Conclusion: In this study we demonstrated the presence of a different pattern of NMS occurring during ON response in PD patients. PD patients with short disease duration (<7 years) showed the presence of "negative" NMS whereas PD patients with longer disease duration experienced more "positive" NSM. This could help the physician in the therapy management of PD patients.

## GENDER DIFFERENCES IN NON-MOTOR FLUCTUATIONS IN PARKINSON'S DISEASE

G. Donzuso, C. Cicero, E. Vinciguerra, R. Sergi, A. Luca, G. Mostile, C. Terravecchia, M. Zappia, A. Nicoletti

Department of Medical, Surgical Sciences and Advanced Technologies "GF Ingrassia", University of Catania (Catania)

Introduction and Objectives: Non-motor symptoms (NMS) and Non-motor fluctuations (NMF) in Parkinson's Disease (PD) are common, involving several domains and affecting quality of life [1]. Aim of the study is to estimate the burden of NMF in PD patients and to evaluate the possible gender effect.

Materials and Methods: PD patients fulfilling the MDS-PD diagnostic criteria attending the "Parkinson's Disease and Movement Disorders Centre" of the University of Catania were evaluated using the Non-Motor Fluctuations Assessment (NoMoFA) Questionnaire [2]. NoMoFA items were also grouped into the following domains: cognitive, mood, sleep/fatigue, dysautonomia, hallucination/perception and miscellaneous domains were identified.

Results: One-hundred and twenty-one patients with PD (67 men, 55.4%; mean age 70.2 ± 8.9 years, disease duration 8.3 ± 4.6 years) were evaluated. All PD patients reported at least one NMS, whereas 87 (71.9%) also reported NMF (table 1). "Feel sluggish or had low energy levels" (47.2%) along with "Feel excessively sleepy during the day" (40.0%) were the most common NMF reported in the whole sample. The majority of PD patients reported presence NMF during the OFF state (79, 65.3%). At multivariate analysis, NMF were positively associated with the female gender (adjusted OR 3.13; 95%CI 1.21-8.11 p-value 0.01). Women with PD had higher NMF scores especially in depression/anxiety, sleep/fatigue and dysautonomia domains, while men with PD experienced higher NMS in cognitive, sleep/fatigue and mood domains.

Discussion and Conclusion: Our study reported the presence of a gender-related pattern in the frequency of NMS and NMF in PD patients, with female gender associated with a higher risk of developing NMF, highlighting the need for personalized treatment strategies when addressing NMF.

## PROGRESSIVE HEMIDYSTONIA AND ANOSOGNOSIA: AN UNUSUAL PRESENTATION OF PILOCYTIC ASTROCYTOMA

M. Farè[1], A. Micheli[2], P. Di Paolo[2], M. Moleri[2]

[1]Department of Neurology, San Gerardo Hospital, University of Milano-Bicocca (Monza); [2]Neurology Unit, Casa di Cura "San Francesco" (Bergamo)

Objectives: Pilocytic astrocytoma (PCA) is a low-grade glioma, often affecting young adults, characterized by cystic masses, slow growth, and usually good prognosis. PCAs often are located in the posterior fossa, often presenting with obstructive hydrocephalus, but PCAs can have an hemispheric localization with focal signs and seizures.

Materials: We will describe the case of a 29-year-old woman, presented to our Neurology Unit, complaining of progressive hemidystonia, anosognosia and visual impairment.

Method: A detailed history, complete of previous neurological evaluations for the left-hand dystonia, and a neurological examination were obtained. We also performed a head CT scan and brain MRI. Given the need for intervention, a neuropsychological evaluation was not done.

Results: Upon examination, right eye papilledema and left-side spastic hypertonia with dystonic postures of the left hand and foot were found. Asked about the dystonia, the patient said that she has had hand dystonia for 7 years, treated as trigger finger and then as idiopathic hand dystonia with botulinum injections. The disorder progressed to a complete left hemidystonia in the last year and developed blurry vision in the previous month. About the deficits, she said that "didn't care because she was right-handed", which we interpreted as neurological anosognosia with hemispatial neglect.

Discussion: The patient revealed that she had an MRI in 2019, but never picked up the report; the retrieved images showed a right paramedian necrotic lesion and voluminous cystic lesions, compatible with PCA. A brain CT showed an increase in size of the cystic lesions, associated with transfalcial and transtentorial herniation. The patient was transferred to the Neurosurgery Unit, where a brain MRI confirmed the neoplastic lesion and its compressive effect. The patient then underwent surgical decompression and subsequent mass excision. There is a scarce literature about this topic, but according to Baizabal-Carvallo dystonia is a rare manifestation of intracranial neoplasms, being present in about 1% of cases and specifically associated with low-grade (WHO I-II) gliomas such as PCA. In most cases dystonia precedes the diagnosis by weeks or months and contralateral hemidystonia is the most frequent presentation, probably caused by compression or neoplastic infiltration of the basal ganglia.

Conclusions: After the surgery the dystonia and spasticity resolved, but a moderate left hemiparesis remained, with little improvement after physical therapy. This case prompts us to recommend brain imaging and greater attention in the presence of progressive dystonias, especially when accompanied by neuropsychiatric signs, such as anosognosia and neglect.

## A CASE OF SYMPTOMATIC PROGRESSIVE ATAXIA AND PALATAL TREMOR (PAPT) AND INCREASED CSF TAU

C. Fazio, S. Regalbuto, S. Arceri, A. Pisani

IRCCS Mondino Foundation, University of Pavia (Pavia)

Background: PAPT is a rare neurological syndrome, which combines palatal tremor synchronous with pendular nystagmus and progressive cerebellar ataxia. PAPT can be divided into familial, symptomatic (a subgroup of secondary palatal tremor) and sporadic forms, whose causes are currently unknown. Some recent neuropathological evidence, showing 4R-Tau inclusions in neurons of patients affected, suggest sporadic PAPT could be considered a novel rare tauopathy.

Methods: Neurological examination, routine ematochemical analysis, Electromyography (EMG) of pharyngo/laryngeal muscles, magnetic resonance imaging (MRI), neuropsychological tests and cerebrospinal fluid (CSF) biomarker analysis were performed.

Results: A 70 year old male with history of right pontine-midbrain spontaneous hemorrhage, treated with surgical drainage 4 years before, came to our institution complaining insidious onset of progressive gait ataxia 8 months after discharge from neurosurgery department. Blood tests and ECG did not show any pathological sign, except for a mild increase in serum creatinine (1,65 mg/dl). Neurological examination showed left pyramidal signs and vertical and horizontal gaze palsy as result of hemorrhage besides cerebellar syndrome affecting mostly trunk, gait and speech in combination to a palatal tremor synchronous with a pendular nystagmus. MRI revealed, alongside hemosiderin deposit in midbrain and pons, bilateral T2-hyperintensity of the inferior olivary nuclei, a condition termed hypertrophic olivary degeneration (HOD), which is a typical feature of symptomatic oculo-palatal tremor. EMG of pharingo-laryngeal muscles indicated a 2 Hz pseudorhythmic activation of thyroarytenoid and cricoarytenoid muscles, coherent with a larynx myoclonus. Neuropsychological tests showed mild isolated deficits in frontal-executive functions. CSF analysis biomarker showed a major increase of both Tau (844 pg/ml) and phosphorylated Tau (113.60 pg/mL) proteins, whereas levels of Beta-amyloid were normal. Genetic screening ruled out mutations in genes underlying familial degenerative forms.

Discussion: Our findings were consistent with PAPT syndrome with onset 6-8 months after a pontine-midbrain hemorrhage. Our CSF findings, associated with clinical course and onset of cerebellar syndrome, support a degenerative process. The patient was discharged with indication to start treatment with Gabapentin (300 mg three times per day) and physiotherapy with some benefit.

Conclusions: We present the first case of symptomatic PAPT syndrome and evidence of increased CSF Tau and phosphorylated-Tau, strengthening the hypothesis of a degenerative Tau-driven underlying pathogenesis.

## RARE ASSOCIATION BETWEEN SPINOCEREBELLAR ATAXIA TYPE 2 AND AMYOTROPHIC LATERAL SCLEROSIS: A CASE REPORT

V. Ferrari[1], E. Dolcetti[2], M. Conti[3], A. Borrelli[2], N. Mercuri[1], D. Centonze[2], A. Stefani[3]

[1]Neurology Unit, Department of Systems Medicine, Tor Vergata Hospital (Roma); [2]Neurology Unit, IRCCS Neuromed (Pozzilli-IS); [3]Parkinson Centre, Department of Systems Medicine, Tor Vergata Hospital (Roma)

Objective: To describe the possible association between SCA2 and ASL.

Materials: We describe the case of a 58-year-old man who was diagnosed with spinocerebellar ataxia type 2 at the age of 38, following tests carried out for the progressive appearance of postural instability and gait ataxia. At the age of 56 he presented dysphagia and a significant decline in his ability to stand up and walk, with a reduction in autonomy and the need to use a wheelchair.

Methods: We performed electromyography and electroneurography of the four limbs and of the cranial district together with motor evoked potentials to study upper and lower motor neurons.

Results: Electromyography and electroneurography examinations highlighted the presence of moderate/severe sensorimotor axonal polyneuropathy and abundant denervation activity in progress at the level of all the muscles investigated in the upper and lower limbs. Motor evoked potentials showed reduced amplitude in cortical stimulus responses, chronodispersed morphology, slightly increased latency in the left upper and lower limbs, and non-reproducible cortical stimulus responses in the right upper limb. Referring to the revised El Escorial criteria of 2015, the patient was diagnosed with "Laboratory-supported probable ASL".

Discussion: Considering different cases described in literature over the years, SCA2 could represent an important risk factor of developing ASL. In particular, the presence of alleles of ATXN2 with 27 and 28 CAG repeats seems to slightly decrease the risk of developing the disease, which would instead be progressively increased by the presence of alleles with 29, 30, 31, 32 and 33 repeats. The exact physiopathological mechanism by which the mutation leads to an increased risk of developing the disease is currently unknown. The reduction of ATXN2 gene expression in TDP-43 ALS mouse models has been shown to prolong survival. Transcriptomic studies on mouse models have demonstrated the involvement of several pathways, including the innate immunity regulation by STING and the biosynthesis of fatty acid and cholesterol by SREBP.

Conclusion: CAG repeat expansions in ATXN2 gene have been associated with variable neurological presentations, which include SCA2, ALS, Parkinsonism or a combination of them. Further research is needed to better understand the relationship between SCA2 and ASL and explore the underlying molecular mechanisms.

## TRANSCRANIAL SONOGRAPHY IS USEFUL IN IDENTIFY PARKINSON'S DISEASE PATIENTS WITH NORMAL WITH NORMAL 123I-FP-CIT-SPECT

V. Floris[1], C. Frau[2], S. Othmani[2], S. Nuvoli[3], A. Spanu[3], P. Solla[2], C. Bagella[2]

[1]Department of Medical Science and Public Health, University of Cagliari (Cagliari); [2]Department of Medical, Surgical and Experimental Science, University of Sassari (Sassari); [3]Unit of Nuclear Medicine, Department of Medical, Surgical and Experimental Science, University of Sassari (Sassari)

Objective: To evaluate the TCS in the patients affected by SWEDD-parkinsonism. Scans without evidence of Dopaminergic Deficit (SWEDD) represent 10% of patients clinically diagnosed as Parkinson's Disease (PD). According to new diagnostic criteria normal imaging result is defined as absolute exclusion criteria but the significance of DAT still remain unclear and this concept has to be. Recent findings argue that striatal dopamine transporter imaging does not associate with axonal nor somal loss of the nigrostriatal neurons in PD. It may reflect dopaminergic activity rather than number of surviving neurons or their striatal projection. So new methods are required. Hyperechogenicity of Substantia Nigra (SN), detected by Transcranial sonography (TCS) could represent a useful tool to identify these patients.

Material and Methods: 3 patients were observed in Movement Disorder Center of Neurological Clinic of Sassari. All received a clinical diagnosis of tremor-dominant PD according to the new criteria and normal [123 IFP-CIT SPECT scans. TCS was performed a 2.5 MHz transducer using a transtemporal window. Hyperechogenicity of area of SN was defined as an echogenic area above of 0.20 cm2.

Results: Patient 1: female; 55 years old; age at motor symptoms onset: 47 y; disease duration at SPECT: 8 y; disease duration at TCS: 8 y; midbrain hyperechogenicity ( right: 0,41 cm2, left 0,38 cm2); III width: 6,3 mm. patient 2: female; 76 years old; age at motor symptoms: 74 y; disease duration at SPECT: 1 y; disease duration at TCS: 2; midbrain hyperecgogenicity (right:0,46 cm2, left:0,33 cm2); III width: 4,7 mm. patient 3: male; 70 years old; age at motor symptoms: 53 y; disease duration at SPECT: 14 y; disease duration at TCS: 17 y; midbrain hyperechogenicity (right: 0,28 cm2, left 0,22 cm2); III width: 6,1 mm.

Discussion and Conclusions: Clinical diagnosis of PD with normal dopaminergic functional imaging is challenging and still debated, and maybe alternative diagnosis could be considered. TCS, which detects midbrain hyperechogenicity, found in up to 90% of patients with PD, could be a useful tool in identify these patients, when presynaptic dopaminergic nerve terminals are still preserved.

## PAINFUL LIMB SPASMS AT PRESENTATION OF ACUTE LENTICULO-CAPSULAR STROKE

E. Fratto[1], E. Colosimo[2], L. Mumoli[2], V. Vescio[3], D. Bosco[2]

[1]Institute of Neurology, Department of Medical and Surgical Sciences, "Magna Graecia" University (Catanzaro); [2]Department of Neurosciences, Institute of Neurology, Presidio Ospedaliero "Pugliese", AOU "Renato Dulbecco (Catanzaro); [3]Services Department, Institute of Radiology, Presidio Ospedaliero "Pugliese", AOU "Renato Dulbecco (Catanzaro)

Aims: Movement disorders (MDs) can develop following stroke, usually in relation to basal ganglia (BG) lesions [1,2]. We present a case of painful spasms following lenticulocapsular stroke.

Materials and Methods: A 62-year-old woman with diabetes, hypertension and no known neurological history presented to our attention after the appearance of acute-onset left sided hemiparesis (arm > leg). Emergency brain CT and CT angiography were normal; intravenous fibrinolysis with altepase 0.9 mg/kg was administered for suspected acute stroke, without immediate benefit on the left sided weakness. Few hours after symptom-onset, the patient developed painful spasms of the left foot characterized by ankle flexion and successive forced extension-inversion, lasting several seconds, with frequency of several episodes per hour, associated with ipsilateral quadriceps twitching contractions.

Results: Blood exams, including electrolytes and CPK/LDH were normal. Serial electroencephalograms and electroneurography/electromyography were unremarkable; the spasms eventually spontaneously subsided after two days. Brain MRI showed a T2 - Fluid-attenuated inversion recovery (FLAIR) and diffusion-weighted imaging (DWI) hyperintense lesion involving the posterior portion of the right lentiform nucleus and the ipsilateral posterior arm of the internal capsule, with concomitant apparent diffusion coefficient (ADC) hypointensity, consistent with acute right lenticulocapsular ischemic stroke. The patient was discharged after 2 weeks, with marked improvement of the lower limb weakness and modest improvement in the upper limb. After 50 days, she is free from spasms.

Discussion and Conclusions: Based on the clinical and imaging presentation, we think that the patient's spasms could be of central origin. MDs, both hyper- and hypo-kinetic, can arise following stroke, typically in relation to BG lesions [1,2]. Advocated mechanism for MDs in BG stroke is the disruption of the critical BG contribution to motor processing through the different cortico-subcortical motor loops. Among MDs, dystonia has been reported in association with lentiform nucleus involvement, particularly when the putamen is interested but even in case of pallidal lesions [2,3]; a proposed mechanism is that putaminal lesions could have predominant effect on the BG indirect pathway, with consequent cortical hyperexcitation and appearance of contralateral hypermor symptoms [3]. Moreover, lesions of the globus pallidus could possibly decrease pallidal inhibitory output causing thalamo-cortical hyperactivation, and, accordingly, dystonia [3]. We speculate that some of the aforementioned mechanisms may underlie the observed foot spasms and muscle contractions, and we feel that the patient's symptoms may actually be similar to dystonia on pathophysiological grounds. Painful spasms are an uncommon presentation in the setting of BG stroke [1].

## NEUROLEPTIC MALIGNANT SYNDROME IN HUNTINGTON'S DISEASE: A CASE REPORT AND LITERATURE REVIEW

A. Funcis, B. Ravera, P. Zinzi, M. Solito, M. Petracca, A. Bentivoglio

Institute of Neurology, Catholic University of the Sacred Heart (Roma)

Objective: Huntington's disease (HD) is the most common neurodegenerative chorea in adults and is caused by an autosomal dominant inherited CAG trinucleotide expansion in the huntingtin gene. The purpose of this study is to estimate the incidence of neuroleptic malignant syndromes (NMS) in Huntington patients treated with tetrabenazine (TBZ) and/or dopamine receptor blocking agent (DRBA) drugs and discuss the measures to avoid this potentially life-threatening condition.
Methods: This is a review of the literature and description of a clinical case [1-2]. In addition, we consulted the 5th data set of the Enroll-HD study (PDS5), a longitudinal, observational, multinational study of families with HD, including manifest and premanifest HD gene carriers. We selected cases of NMS in Huntington's disease patients who were treated with TBZ and/or DRBA and presented at least one of the core symptoms of NMS (rigidity or hyperthermia) and determined which and how the drugs induced NMS, the clinical manifestations, and the potential risk factors.

Results: We identified 12 cases of NMS in HD patients (mean age of disease onset: 32.2±14.8 years, three with Westphal variant) treated with DBRA and/or TBZ, 9 were undergoing multiple drug treatments. All patients described had a long clinical history (mean: 13.7±3.7 years) and an advanced stage of disease before the onset of NMS. Eight of them were bedridden with symptoms such as akinetic rigidity, dysphagia, and dehydration, suggesting a correlation between the long clinical history of the disease and the onset of NMS. Eleven patients manifested NMS during drug-therapy changes: 7 during substitution of one drug for another, 3 during dosage modification, and one following introduction of a new drug. Only one patient during unmodified TBZ treatment. Three patients manifested the atypical form of NMS (hyperthermia without rigidity), two under TBZ and one under haloperidol. Finally, five cases of unspecified fever in polytherapy with TBZ and DBRA were reported in the ENROLL dataset. After NMS, ten patients made a full recovery, while two died.

Conclusions: The available data suggests that NMS is potentially underestimated in patients with Huntington's, partly due to the difficulty in identifying the atypical form of NMS [3]. The advanced stage of disease, extra-pyramidal signs, abrupt changes in therapy, polytherapy, and dehydration are the main risk factors for NMS in Huntington's patients. As neurodegeneration progresses, the treatment plans require a periodic review, they must be managed with caution, and clinical manifestations associated with therapeutic changes must be carefully monitored.

## AUTONOMIC DYSFUNCTION IN PARKINSON'S DISEASE PATIENTS TREATED WITH LEVODOPA-CARBIDOPA INTESTINAL GEL: A SYSTEMATIC REVIEW

S. Galli[1], L. De Carolis[1], D. Rinaldi[1], E. Bianchini[1], F. Pontieri[1,2]

[1]Department NESMOS, Sapienza University of Rome (Roma);[2]Fondazione Santa Lucia IRCCS (Roma)

Objective: Autonomic dysfunction in Parkinson's disease (PD), encompassing cardiovascular (CV), genitourinary (GU), and gastrointestinal (GI) symptoms, severely affect patient's quality of life. We systematically review the current literature to assess the safety and efficacy of levodopa/carbidopa intestinal gel (LCIG) infusion on autonomic dysfunction in PD patients.

Methods and Materials: Following the PRISMA guidelines, we systematically searched PubMed for studies (only in English), including non-motor symptoms (NMS) outcomes, regarding autonomic dysfunction in LCIG-treated PD patients. We collected data on study design, clinical and demographic features, Unified Parkinson's Disease Rating Scale (UPDRS), Non-Motor Symptoms Scale (NMSS), and safety outcomes in terms of reported adverse events (AEs) possibly related to LCIG. Device and procedure-related AEs were not considered. We evaluated improvement, stability, or worsening of CV, GU, and GI symptoms at four timepoints: <6 months (T1), 6 months (T2), 12 months (T3), and >12 months (T4), according to clinometric scale change in comparison to baseline evaluation.

Results: Thirteen studies were included for an amount of 1340 PD patients. NMS were evaluated using NMSS, UPDRS I, and SCOPA-AUT (questions 15, 16). Regarding CV symptoms, an improvement has been reported in 2/4 (50%), 5/8 (62.5%), 3/4 (75%), and 1/5 (20%) studies, respectively, at T1, T2, T3, and T4. Stability has been reported in 6/13 studies (46%). Regarding GU symptoms, an improvement has been reported in 4/4 (100%), 6/7 (85.7%), 3/4 (75%), and 5/5 (100%) studies, respectively, at T1, T2, T3, and T4. Stability has been reported in 2/12 studies (16.6%). Regarding GI symptoms, an improvement has been reported in 3/4 (75%), 6/6 (85.7%), 3/4 (75%) and 1/5 (20%) studies respectively at T1, T2, T3 and T4. Stability has been reported in 4/12 studies (33%). No studies reported worsening. Concerning safety, seven studies reported LCIG-related AEs, precisely four reported CV AEs in 16 patients, three GI AEs in 96 patients, and none GU AEs.

Discussion: To our knowledge, this is the first qualitative/quantitative assessment of studies evaluating the efficacy and safety of LCIG therapy on autonomic dysfunction in PD patients. Although data is not sufficient to pose definite indications, our analysis suggests that LCIG infusion can help reduce the burden of autonomic symptoms in advanced PD patients.

Conclusion: LCIG is relatively safe and may help manage autonomic symptoms in patients with advanced PD. Prospective studies addressing autonomic dysfunction in LCIG-treated PD patients should be performed to make this evidence more robust.

## MEDITERRANEAN DIET ADHERENCE IN PATIENTS WITH PARKINSON DISEASE AND GLUCOCEREBROSIDASE MUTATIONS

L. Gallo[1], M. Avenali[2], P. Mitrotti[3], I. Palmieri[4], G. Cuconato[5], R. Calabrese[6], C. Galandra[5], R. Zangaglia[7], F. Valentino[7], C. Pacchetti[7], A. Pisani[3], E. M. Valente[4,5], F. Blandini[3,8], C. Tassorelli[2]

[1]IRCCS National Institute of Neurology Foundation "C. Mondino", University of Pavia (Pavia); [2]Department of Brain and Behavioral Sciences, Neurorehabilitation Unit, University of Pavia, IRCCS Mondino Foundation (Pavia); [3]Department of Brain and Behavioral Sciences, University of Pavia (Pavia); [4]Neurogenetics Research Centre, IRCCS Mondino Foundation (Pavia); [5]Department of Molecular Medicine, University of Pavia (Pavia); [6]Neurorehabilitation Unit, IRCCS Mondino Foundation (Pavia); [7]Parkinson's Disease and Movement Disorders Unit, IRCCS Mondino Foundation (Pavia); [8]Ca' Granda IRCCS Foundation, Ospedale Maggiore Policlinico (Milano)

Background & Objectives: In recent years, the Mediterranean diet has been widely studied for its potential protective effects against several chronic diseases [1], including Parkinson Disease (PD) [2]. However, the relationship between PD, GBA mutations and the adherence to Mediterranean diet has still not been explored. We aim to investigate a possible correlation between PD clinical features and Mediterranean diet adherence in a group of GBA-related PD (GBA-PD) patients compared to idiopathic PD (iPD).

Materials & Methods: We analyzed clinical motor and non-motor data (UPDRS part I-IV; SCOPA-AUT, BDI-II, HADS-D, HADS-A, RBDSQ, UPSIT, MoCA) and dietary habits (MEDAS questionnaire) in 51 GBA-PD and 84 iPD patients. PD groups were also stratified by low/ high adherence to the Mediterranean diet using the MEDAS cut-off score of 8. Within group analyses according to low/high diet adherence and between PD groups comparison were also performed.

Results: GBA-PDs showed an earlier age of disease onset and higher scores at UPDRS part I, BDI-II, HADS-D, HADS-A, compared to iPDs. No significant differences were found in MEDAS scores as well as UPDRS (part II, III and IV), MoCA, SCOPA-AUT, RBDSQ and UPSIT scores between the two groups. GBA-PD patients with low diet adherence showed higher BDI-II, HADS-A and HADS-D scores as compared to GBA-PD patients with high diet adherence, while no difference was detected when comparing low diet adherence vs high diet adherence in the iPD group. We also report a significant correlation between a low Mediterranean diet adherence and higher scores in BDI-II (p=0.0312) in the GBA-PD group.

Discussion & Conclusion: These findings show an interesting association between adherence to the Mediterranean diet and mood disorders in PD-GBAs. Further studies are needed to confirm these results and to investigate the underlying mechanisms of this association. If confirmed, these findings may have important implications for the development of personalized dietary interventions for PD patients with genetic mutations.

## THE INFLUENCE OF FRAILTY ON PARKINSON'S DISEASE PROGRESSION: A LONGITUDINAL STUDY

G. Gallo, M. Canevelli, D. Belvisi, M. Costanzo, C. Cutrona, F. Raffaele, P. Agostini, G. Bruno, A. Berardelli, G. Fabbrini

Department of Human Neurosciences, Sapienza University of Rome (Roma)

Objectives: Previous evidence suggests that frailty is a risk factor for Parkinson's disease (PD) development and can influence PD clinical expression. However, the possible influence of frailty on PD progression has been not investigated. The aim of this longitudinal study was to elucidate the role of frailty, assessed by Frailty Index (FI), on PD motor and non-motor symptoms progression.

Materials: One-hundred and fifty patients participated and one-hundred and nine patients completed follow-up at three years. Patients underwent a clinical evaluation that included the administration of standardized clinical scales aimed at assessing motor and non-motor manifestations. To evaluate frailty levels we administered a FI, specifically designed for patients with PD and previously validated by our group.

Methods: Spearman correlation coefficient was used to investigate possible correlations between FI score and motor/non-motor symptoms severity at the baseline and the follow-up assessment. Linear regression models were used to explore possible associations between baseline FI score and PD progression.

Results: At baseline, FI score correlated with motor symptoms, motor complications and non-motor symptoms severity. Furthermore, an inverse correlation between FI score and cognitive performance was observed. At follow-up assessment, we confirmed the positive correlation between FI score and motor and non motor manifestations. In addition, we observed a correlation between FI score and the stage of disease, not observed at baseline. Linear regression models showed a significative association between baseline FI and motor and non-motor symptoms progression.

Discussion: Our findings confirmed that frailty levels modulate the clinical expression of patients with PD. The novel finding of the present study was that frailty levels may also influence motor and non motor symptoms progression in PD.

Conclusions: FI may represent a useful tool to assess and predict disease progression in PD and to decode the clinical variability that characterized PD.

## NEURAL CORRELATES OF BRADYKINESIA IN PARKINSON'S DISEASE: A KINEMATIC AND FMRI STUDY

A. Gardoni[1], E. Sarasso[1], L. Zenere[1], D. Emedoli[2], S. Basaia[1], D. Corbetta[2], F. Agosta[3], M. Filippi[4]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [2]Department of Rehabilitation and Functional Recovery, IRCCS San Raffaele Scientific Institute (Milano); [3]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [4]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: Bradykinesia is one of the cardinal signs of Parkinson's disease (PD) and is usually assessed during repetitive movements. The aim of the study was to investigate the neural correlates of hand tapping performance in patients with PD relative to healthy controls.

Materials: Fifteen PD patients and 15 age- and sex-matched healthy controls were included.

Methods: All the subjects underwent brain magnetic resonance imaging (MRI) including a hand tapping functional MRI (fMRI) task: subjects were asked to alternatively open and close (hand tapping) their right hand as fast and as ample as possible. Hand tapping speed and amplitude was measured during the fMRI task using an optical fiber data glove.

Results: During the fMRI hand tapping task, patients with PD showed reduced hand tapping amplitude and reduced activity of frontoparietal areas and sensorimotor regions including supplementary motor area (SMA), pre/postcentral gyri, pallidum and cerebellum

compared to healthy controls. Decreased activity of SMA, cerebellum lobule VIII and caudate correlated with reduced hand tapping amplitude.

Discussion: As expected, patients with PD showed a worse hand tapping performance in terms of reduced movement amplitude relative to healthy controls. Interestingly, we found a correlation between bradykinesia and brain activity. In particular, areas strongly involved in motor planning such as SMA and caudate correlated with reduced movement amplitude. This study has the major strength of collecting objective motor parameters and brain activity simultaneously, providing a unique opportunity to investigate the neural correlates of bradykinesia in PD.

Conclusions: A reduced recruitment of cortical, cerebellar and basal ganglia areas implicated in motor programming is a hallmark of bradykinesia in patients with PD.

Funding: Italian Ministry of Health grant GR-2018-12366005.

## SPONTANEOUS AND EVOKED PAIN IN PARKINSON'S DISEASE WITH MOTOR FLUCTUATIONS: AN OBSERVATIONAL, PROSPECTIVE, CLINICAL AND NEUROPHYSIOLOGICAL STUDY IN PATIENTS UNDER L-DOPA AND OPICAPONE ADD ON THERAPY

C. Geroin[1], M. Tinazzi[1], I. Di Vico[1,2], C. Geroin[1]

[1]Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona (Verona); [2]The Marlene and Paolo Fresco Institute for Parkinson's and Movement Disorders, NYU Langone Health (New York-USA

Objective: We aimed to evaluate the effectiveness of opicapone on spontaneous and evoked pain -by electrical stimulation- in Parkinson's Disease (PD) patients suffering from motor fluctuations and chronic pain.

Materials and Methods: This is a prospective, single center study in fluctuating patients with stable therapy. Patients with PD and motor fluctuations were consecutively enrolled. Main inclusion criteria were pain intensity with an NRS≥4, no modification of dopaminergic drugs and analgesic therapy with FANS, Hoehn and Yahr stage I–III during OFF time; motor fluctuations (>1.5 hours' OFF time/day). Clinical and neurophysiological assessments were performed before and after 12 weeks of treatment with opicapone 50 mg/day as add-on therapy to levodopa. Primary outcome: Numeric Rating Scale (NRS). Secondary outcomes: King's Pain Scale for Parkinson's Disease (KPS), Brief Pain Inventory (BPI), Clinical Global Impression of Change (CGI), Parkinson's disease Questionnaire 39 (PDQ-39), non-motor Symptoms Scale (NMS), and pain threshold and tolerance.

Results: 12 out of 28 eligible patients were enrolled (disease duration 9±4). Patients showed a significant reduction of pain in the NRS scale (p=.003). We also found significant changes (reduction) in the secondary outcomes as KPS (p=.008), BPI intensity (p=.011), UPDRS III (p=.002) and IV (p=.011) but not significant changes in the BPI total and interference, PDQ-39, and NMS as well as in the tactile threshold, pain threshold and tolerance. CGI showed an improvement in 8 patients (n=2 very much/much improved; n=6 minimally improved), while no change was observed in 4 patients. We found a significant correlation between changes (reduction) in the UPRDS III and the BPI Intensity (r=.817, p=.001) and NRS scores (r=.611, p=.035), and also a significant correlation between UPDRS IV and KPS (r=.627, p=.029) and BPI Intensity (r=.689, p=.013). None of the patients reported treatment-emergent adverse events.

Discussion: Score changes of the primary outcome NRS and secondary outcomes indicated that patients experienced a relief of pain along with a parallel reduction of motor symptoms and motor complications as suggested by UPDRS III and IV. Opicapone, a once daily, long-acting COMT inhibitor [1] may improve pain through alleviation of motor complications, as suggested by the correlation between a reduction of pain and the reduction of UPDRS IV score, as also confirmed by previous studies [2, 3].

Conclusions: Our preliminary results suggest that opicapone 50 mg/day might be effective for the management of motor complications of PD and related pain, and it is safe.

## DEEP BRAIN STIMULATION FOR MEDICALLY REFRACTORY TREMOR IN WILSON'S DISEASE: A SINGLE CASE AND REVIEW OF THE LITERATURE

A. Giordano[1], R. De Micco[1], M. Sensi[2], A. Gozzi[2], M. Cirillo[1], A. Tessitore[1], G. Tedeschi[1]

[1]I Division of Neurology, University of Campania "Luigi Vanvitelli" (Napoli); [2]Department of Neuroscience and Rehabilitation, Azienda Ospedaliera-Universitaria S. Anna (Ferrara)

A 41-years-old woman was referred to our outpatient clinic for a five year slowly progressive onset of speech impairment and tremor involving the arms and head. She had previously received a genetically confirmed diagnosis of Wilson's disease (WD) at the age of three years. At the admission neurological examination showed: a) action and postural tremor of the upper limbs (left more than right); its amplitude increased with a longer duration of posture (i.e wing-beating tremor); b) horizontal head tremor (i.e. "no-no"); c) voice tremor. Brain T2-MRI showed the typical "face of the giant panda sign"( i.e. normal intensity of red nuclei and lateral portions of substantia nigra pars reticulata with high signal intensity of tegmentum and hypointensity of the superior colliculus) with no other evidence of basal ganglia structural changes. Because of first line (primidone and propranolol) and second line (topiramate, pregabalin, clonazepam) therapy agents for tremor were unsuccessful, a surgical approach was proposed; the patient underwent to Deep Brain Stimulation (DBS) of ventral intermediate (Vim) thalamic nucleus. High stimulation output led to a significant reduction of her tremor amplitude of both arms and head; speech impairment remained stable and no potential DBS-related side effects were reported. Vim has emerged as the most effective and established target for medically refractory tremor in patients with essential tremor (ET) [1]. Even though the pathophysiology of tremor is different between WD and ET our experience and published evidence support the potential role of Vim DBS as an effective and safe approach in carefully selected WD patients, although the presence of structural changes in the basal ganglia may limit the therapeutic success of the surgical procedure [2].

## A JUVENILE CASE OF PARKINSON'S DISEASE ASSOCIATED WITH MAPT MUTATION

D. Greco[1], S. Mombelli[1], S. Valente[1], F. Piattellini[1], G. Grigioni[2], A. Govoni[2], L. Caremani[2], B. Nacmias[1], S. Ramat[2]

[1]Neurosciences, Psychology, Pharmacology and Child Health, University of Florence (Firenze); [2]Parkinson Unit, Department of Neuro-Muscular-Skeletal and Sensorials Organs, Careggi Hospital (Firenze)

Objective: We describe heterogeneous clinical manifestations in a 51 years old man with PD and carrying a mutation in MAPT gene.
Methods: Subject underwent serial neurological visits, Genetic Analysis, brain magnetic resonance imaging (MRI), brain DAT-SPECT, brain PET-FDG and neuropsychological assessments.

Results: We present the case of a man who was diagnosed with PD at the age of 47 years, beginning with right upper limb bradykinesia. The brain SPECT DATscan confirmed low uptake in the left caudate and putamen while the Brain MRI showed mild ventricular dilation. Therapy with dopamine-agonist, rasagiline and levodopa was started. Interestingly the gene analysis identified a pathogenic variant in exon 10 of MAPT gene (c. 1853C>T; p.Pro618Leu). Further diagnostic investigations highlighted left insular and temporo-parietal hypometabolism through Brain PET-FDG and deficit of attentive, executive e visuospatial skills. In the following years motor symptoms worsened, impulse control disorder occurred (with hyperphagia, hypersexuality, gambling and drug abuse) and the patient presented traits of aggression, requiring psychiatric intervention.

Conclusions: Tauopathies refer to a wide range of phenotypically diverse diseases characterised by the aberrant aggregation of tau in neurons and/or glia, tau dysfunction is sufficient for widespread central nervous system neurodegeneration. In this case we increase the knowledge about the possible role of tau dysfunction in non-motor clinical manifestation of Parkinson disease.

## BEYOND CLASSIC PHENOTYPES OF CHOREA: WHAT IS THE ACTUAL SIGNIFICANCE OF INTERMEDIATE ALLELES IN THE HTT GENE?

F. Guajana, N. Rini, P. Alonge, R. Monastero, F. Brighina, V. Di Stefano

Department of Biomedicine, Neurosciences and Advanced Diagnostics, University of Palermo (Palermo)

Introduction: In the context of Huntington's Disease (HD), the pathological significance of intermediate alleles remains controversial. Intermediate alleles are expansions of CAG sequences ranging from 27 to 35 repeats in the HTT gene. Previous studies have shown that intermediate alleles are frequent in the general population, but an increasing number of cases of subjects with "Huntington-like" phenotypes have been recently reported [1]. Furthermore, previous studies suggest that intermediate alleles may also be associated with α-synucleinopathies, such as PD, DLB, MSA [2] [3]

Case Report: A 48-year-old woman presented to our Clinic with a history of involuntary right-hand movements that began at age 39 and progressively worsened in frequency and intensity over time. These symptoms disappeared during the night's rest. The patient reported no neuropsychiatric disturbances and appeared normal on psychiatric examination. The patient did not refer to a family history of neurological diseases or other relevant pathologies. The patient performed a brain MRI about two years after the onset of symptoms, which was unremarkable, while she had not performed a DAT-Scan exam yet. Recent blood tests were normal (CBC, liver and kidney function, serum electrolytes, vitamin B12, folic acid, ceruloplasmin, glycated hemoglobin, ANA, ANCA, HIV test), except for mild hypercholesterolemia and hypereosinophilia. A clinical diagnosis of HD was previously made, but the patient did not show a good response to treatment with Xenazine. At neurological examination, the patient showed resting and intention tremors in the hands bilaterally and in the head. The ambulation was autonomous with a slight reduction of the pendulum movements to the right, and a slight bilateral plastic hypertonicity (right>left). L-DOPA trial was performed with remarkable improvement in tremor and rigidity. Therapy was set up with L-DOPA 200+50 mg TID, and Xenazine 25 mg TID. Genetic testing was requested for Huntington's Disease and Monogenic Parkinsonisms. Genetic testing for CAG amplification of the HTT gene showed the presence of a normal allele of 15 repeat units, and an intermediate allele of 27 repeats.

Conclusions: This case provides clinical evidence to support the hypothesis of a possible association between intermediate CAG repeat and movement disorders other than HD, like early onset parkinsonism or atypical choreas. However, this hypothesis needs to be confirmed by further clinical cases and scientific evidence.

## POST TRAUMATIC DYSTONIA ASSOCIATED TO PRRT2-RELATED PAROXYSMAL KINESIGENIC DYSKINESIA (PKD): CASE REPORT AND REVIEW OF LITERATURE

V. Iacobelli[1], A. Elia[1], G. Devigili[1], F. Invernizzi[2], B. Garavaglia[2], R. Eleopra[1]

[1]Parkinson and Movement Disorders Unit, Neurological Institute C. Besta Foundation IRCCS (Milano); [2]Unit of Molecular Neurogenetics, Neurological Institute C. Besta Foundation IRCCS (Milano)

Objectives: To describe a patient with history of peripheral injury, who developed paroxysmal dyskinesias associated with dystonia and was found to be carrier of a mutation in the PRRT2 gene.

Results: This case report describes a 19-year-old male with a negative family history for neurological diseases, who presented a 3 years history of paroxysmal dyskinesias consisting of brief episodes of involuntary contractions in the right limbs, associated with cervical dystonia, first only during physical activity and later during habitual voluntary movements. The episodes described (about 20 episodes per day) lasted approximately 10-15 seconds and resolved spontaneously. The patient reported a sports-related cranial and mandibular trauma with left orbital, maxillary, and ethmoid fractures 6 months before the onset of the motor symptoms, leading to prolonged immobilization. Our clinical examination revealed a torsional posture of the right upper limb during repetitive movements of the contralateral upper limb. An EEG and a brain and cervical MRI were performed, which resulted normal. Genetic analysis revealed the presence of a heterozygous mutation in exon 2 of the PRRT2 gene, which causes a reading frame shift in the protein and the consequent insertion of a premature stop codon

(p.Arg217Profs*8), compatible with the status of a subject affected by PKD. A therapy with carbamazepine 200 mg daily has lead to the complete resolution of paroxysmal disorders.

Discussion: Peripherally-induced movement disorders (PIMD) should be considered when involuntary or abnormal movements emerge shortly after an injury to a body part. The spectrum of PIMD is broad but dystonia is the most common phenomenology [1]. It has been proposed that in some patients with PIMD there are some pre-existing genetic risk factors [2]. We performed a systematic research of the literature, identifying 87 clinical studies which reported the phenotype of patients with PRRT2-PKD, and post-traumatic onset was never reported.

Conclusions: This case highlights the importance of genetic predisposition in PIMD patients and expands the genotype phenotype correlations in PRRT2-PKD patients.

Background: A few earlier observations and a recent controlled study pointed to the recurrence of thyroid diseases in idiopathic adult-onset dystonia (IAOD).

Objective: The aim of this study was to analyze the frequency of hyperthyroidism and hypothyroidism in a large multicentre cohort from the Italian adult dystonia registry (IADR) and the relationship of thyroid disease with the phenotypic expression of dystonia.

Material and methods: On May 2023, the IADR included 1698 IAOD patients from 42 centers. Patients who were diagnosed with hypothyroidism and hyperthyroidism were selected and compared with patients who had not been diagnosed with any thyroid disease.

Results: Among the 1698 IAOD patients, 202 (11.9%) were diagnosed with thyroid dysfunction: hypothyroidism was diagnosed in 159 patients (9.4%; 95% CI, 8.0% - 10.8%) and hyperthyroidism in 43 (2.5%; 95% CI, 1,8% - 3.2%). No thyroid disease was diagnosed in the remaining 1496 patients. Since the prevalence of both previously diagnosed hypothyroidism and hyperthyroidism in our cohort tend to be greater than in the European population (see below), we thus analysed both thyroid dysfunctions combined. Patients who carried thyroid dysfunction (n. 202) and those who did not (n.1496) were comparable for sex (135/202 vs. 938/1496, $p = 0.3$) but no for age ($66.5 \pm 11.4$ vs. $64.3 \pm 13.9$, $p = 0.01$). Phenotypic analysis yielded a higher age of dystonia onset in the thyroid group ($54.4 \pm 14$ vs. $52.3 \pm 15.1$), that was however no longer detectable after adjustment for age and education. The anatomical distribution of dystonia and spread of dystonia over the follow up did not significantly differ between dysthyroid and euthyroid groups.

Discussions and Conclusion: The frequency of diagnosed thyroid dysfunction in our sample tend to be higher than the prevalence of both previously diagnosed and undiagnosed thyroid dysfunction in the general European population (hypothyroidism, 3.05% [95% CI 3.01%-3.09%]; hyperthyroidism, 0.75% [95% CI, 0.73%-0.77%]). Further strengthening the relevance of our estimates that referred to diagnosed thyroid disease, results of studies in the general population also indicated that 85% of the thyroid dysfunction was subclinical. Since the majority of adult cases with thyroid disease are caused by autoimmune mechanisms, the increased frequency of thyroid disease in IAOD might reflect an autoimmune contribution to dystonia. Our findings would also stimulate investigation on the relationship between thyroid, related hypophyseal hormones, and IAOD.

## GAIT IMPAIRMENT AND NEUROGENIC ORTHOSTATIC HYPOTENSION ARE INDEPENDENTLY ASSOCIATED IN PARKINSON'S DISEASE

G. Imbalzano[1], C. Ledda[1], C. Artusi[1], M. Tangari[1], E. Montanaro[2], C. Campisi[1], M. Zibetti[1], M. Rizzone[1], M. Bozzali[1], L. Lopiano[1], A. Romagnolo[1]

[1]Department of Neuroscience "Rita Levi Montalcini", University of Turin (Torino); [2]SC Neurology 2U, AOU Città della salute e della scienza Torino (Torino)

Objectives: Orthostatic hypotension (OH) and gait impairment are frequent non-motor sources of disability of Parkinson's disease (PD). An association between OH and ambulatory capacity impairment in PD was evaluated also in patients asymptomatic for postural lightheadedness, and wearable sensors demonstrated good sensitivity and specificity to predict risk of falls related to OH. Still, the impact of neurogenic OH (nOH) on gait features need to be clarified. This cross-sectional study aimed to assess the influence of nOH on postural and spatiotemporal gait parameters in a cohort of advanced PD patients by means of wearable inertial sensors.

Materials: Patients with advanced PD were evaluated during their "best-ON" state by means of APDM Mobility Lab™ motion sensors for gait and balance assessment and screened for the presence of nOH using a standardized procedure at bedside.

Methods: Gait/balance parameters were evaluated during a Sway test, a 3-meters Timed-up and go (TUG) test, a 360° Turn Test and a Two-minute walk test (2MWT). The bedside assessment of nOH was performed using the ΔHeart Rate/ΔSystolic Blood Pressure (ΔHR/ΔSBP) ratio, after 5 minutes of supine rest, and then after 3 minutes of active upright tilt. Analysis of covariance was performed to evaluate differences in gait and balance features between the two groups, adjusting for age, disease duration, and Hoehn and Yahr stage (H&Y).

Results: A total 81 patients were enrolled, 18 with nOH (22.2%) and 63 without nOH (77.8%). The two groups showed similar age (62.3±7.3 vs 60.3±8.3, p=0.18), levodopa equivalent daily dose and H&Y stage, while disease duration was longer in patients without nOH (10.2±2.3 12.8±5.4, p=0.03). After correcting for age, disease duration, and H&Y stage, patients with nOH exhibited at the 2MWT lower stride length (p=0.011), lower gait speed (p=0.010), and longer time of double support (p=0.042). No significant differences were found for the other tests.

Discussion: Wearable inertial sensors showed worse gait performances during a prolonged walking test in PD patients with nOH, even after correcting for principal confounders of the advanced disease. Like previously suggested, we hypothesize a detrimental effect of orthostatic hypotension during prolonged walking in PD patients with suspected autonomic failure. Management of nOH could improve gait impairment of these patients, reducing falls, fractures, and other important PD complications.

Conclusion: nOH was independently associated with worse gait features in PD patients, highlighting the possible impact of this non motor feature on mobility.

## ANTI-AMPHIPHYSIN-IGG-SEROPOSITIVE PARANEOPLASTIC SYNDROME: A RARE CAUSE OF STIFF PERSON SYNDROME

D. Intini, V. Velucci, S. Idrissi, S. Scannicchio, M. Gentile, R. Vitobello, D. Galotto, P. Lasorella, T. Francavilla, A. Iaffaldano , M. Guido , M. Troiano, G. Libro , R. Pellicciari

Department of Neurosciences and Sense Organs, Policlinic Hospital (Bari)

Objectives: Amphiphysin is a 128 kDa intracellular protein that promotes cleavage of neuronal synaptic vesicles. Amphiphysin-immunoglobulin G (IgG) autoimmunity was first recognized in stiff-person syndrome, a rare neurological condition characterized by muscle stiffness and painful muscle spasms associated with breast cancer. Herein, we report a case of anti-amphiphysin-mediated paraneoplastic Stiff Person Syndrome in a patient with medium to high-grade invasive ductal breast carcinoma and serum and cerebrospinal fluid (CSF) anti-amphiphysin IgG.

Materials and Methods: A 49-year-old female patient was admitted to our department with a two-year history of right-sided neck and upper limb pain, left foot stiffness, diffuse muscle spasms, and recent onset of hypophonia. Due to the muscle spasms, she was struggling to walk, climb stairs, sleep, and carry out her work activities. One year before the onset of neurological symptoms, the patient received a diagnosis of medium to high-grade invasive ductal left-sided breast carcinoma. Thus, she had a mastectomy, and hormonal therapy is still ongoing. On neurological examination: gait ataxia with intra-rotation of the left foot, dystonic attitude of the right upper limb with hyperflexed forearm on the arm, winged scapula. Passive mobilization of this body segment caused pain, and humeral and antebrachial extension movements were severely limited.

Results: Brain and spinal cord MRI showed mild cerebellar vermis atrophy and discogenic myelopathy extending from C4 to C5. CSF standard analysis revealed mild damage to the blood-brain barrier and systemic oligoclonal IgG. According to the medical history of subacute onset of a stiff person-like syndrome, we also investigated onconeural antibodies. A high titer of anti-amphiphysin IgG was detected both in CSF and serum, with no trace of anti-GAD antibodies.

Discussion: Plasmapheresis was initiated, resulting in a gradual improvement of dystonia and ataxia.

Conclusions: It is mandatory to assess onconeural antibodies in each young patient affected by dystonia or any other movement disorder with a history of malignant tumor. Anecdotal evidence and clinical experience suggest that amphiphysin Ab-associated SPS may not respond to IVIg. Plasmapheresis may be considered as the first-line treatment for Anti-Amphiphysin-IgG-seropositive Stiff Person Syndrome.

## EXPLORING THE IMPACT OF FATIGUE ON CAREGIVER BURDEN IN PARKINSON'S DISEASE

S. Landolfo[1], D. Urso[2], L. Batzu[3], V. Gnoni[2], C. Santoro[1], F. Amati[1], A. Giugno[2], S. Rota[3], K. R. Chaudhuri[3], G. Logroscino[2]

[1]Department of Basic Medical Sciences, Neuroscience and Organ Sense, University of Bari (Bari); [2]Center for Neurodegenerative Diseases and the Aging, Department of Clinical Research in Neurology, Pia Fondazione Cardinale G. Panico, University of Bari (Tricase-LE); [3]Department of Neurosciences, Institute of Psychiatry, Psychology & Neuroscience, Parkinson's Foundation Centre of Excellence, King's College London (London-UK)

Objectives: Fatigue is a common and disabling non-motor symptom (NMS) in Parkinson's disease (PD), affecting up to 60% of patients [1]. It has been suggested that fatigue experienced by people with PD may considerably aggravate caregiver burden [2]. The aim of this study was to evaluate whether PD-related fatigue had a significant impact on caregiver burden.

Materials and methods: Demographic and clinical data were obtained from patients with PD recruited at the Centre for Neurodegenerative Diseases and the Aging Brain, Tricase (Italy), as part of the Non-motor International Longitudinal Study (NILS), a global cohort study. Fatigue was assessed using the Fatigue Severity Scale (FSS), while Caregiver Burden Inventory (CBI) were completed in carers. Univariate and multivariate linear regression models were performed to assess whether patient-related fatigue was a significant predictor of caregiver burden, while controlling for age, sex, disease duration, motor and NMS burden, anxiety, depression and cognitive performance.

Results: A total of 61 patients (mean age 67.84±10.33; 70,5% males; mean disease duration 4.95±4.19) were included in the study. Mean total FSS score was 40.95±16.85, while mean total CBI score was 15.39±18.44. Significant clinical predictors of CBI score in univariate linear regression models were disease duration ($p<0.001$), NMS burden ($p<0.001$), anxiety and depression scores ($p<0.001$), cognitive performance ($p=0.008$) as well as FSS score ($p<0.001$). These were then included as independent variables in a multivariate linear regression model with CBI as dependent variable: only FSS score and disease duration remained significant predictors of caregiver burden ($p<0.001$ and $p=0.003$ respectively).

Discussion: Despite its high prevalence, fatigue remains underrecognized and undertreated in the management of PD, leading to a significant burden on patients and their caregivers. We showed that fatigue, as measured by FSS, emerged as a major determinant of worsening caregiver burden in PD, when compared to other previously recognised factors, such as disease duration, motor performance and specific NMS, in particular anxiety, depression and cognitive impairment.

Conclusion: Our findings highlight the significant impact of patients' fatigue on their caregivers' burden. The existing literature lacks studies exploring this association using validated assessment tools as FSS [3]. Our study fills this gap and emphasises the importance of including the evaluation of fatigue, and therefore its management, in clinical practice to improve the well-being of both patients with PD and caregivers.

## SLEEP QUALITY AND AUTONOMIC DYSFUNCTION IN A-SYNUCLEINOPATHIES

G. Lazzeri[1], A. Carandina[2], G. Dias Rodrigues[2], G. Franco[1], F. Arienti[1], N. Montano[2], E. Tobaldini[2], A. Di Fonzo[1]

[1]Neurology Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico (Milano); [2]Department of Internal Medicine, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico (Milano)

Aims: Clinical observations suggest a close relationship between the severity dysautonomic symptoms and RBD in Parkinson's Disease [1]. We aimed to determine whether PD patients with clinical history of RBD have more severe dysautonomia and whether sleep quality is correlated with autonomic dysfunction. Cardiovascular autonomic control was assessed through heart rate variability (HRV) analysis, a non-invasive method quantifying the activity of the two branches of the ANS.

Materials and Methods: We enrolled 15 PD patients (8 RBD+, 7 RBD-), at the Neurology Unit of Policlinico Hospital, Milan, Italy. ECG and respiratory traces were recorded for 10 minutes in supine position; subsequently, a segment of 250 ± 50 beats was selected for the HRV spectral and symbolic analysis. Sleep quality was evaluated using a wireless monitoring patch for 1 night (RootiRx; 3 channels: ECG, thoracic effort and actigraphy). Questionnaires for subjective evaluation of sleep quality and autonomic symptoms were administrated.

Results: PDSS score negatively correlated with LF/HF, an index of sympathetic modulation, suggesting that sleep impairment is related to a sympathetic predominance. Low sleep efficiency and higher Wake time After Sleep Onset (WASO) scores were associated with higher sympathetic modulation (0V%) and reduced parasympathetic modulation (2UV%). Moreover, RBD+ patients had higher COMPASS-31 scores and worse sleep quality, assessed by PDSS.

Discussion: Our preliminary data showed that altered sleep quality is significantly associated with cardiovascular sympathetic predominance in PD patients and that RBD+ patients have severer global autonomic dysfunction.

Conclusion: Overall, this suggests that the link between altered sleep and autonomic dysfunction in PD should be more deeply investigated.

## LATERAL TRUNK DEVIATION AND PISA SYNDROME: BOTULINUM TOXIN TREATMENT IN THE SHORT- AND IN THE LONG-TERM

C. Ledda[1], E. Panero[2], U. Dimanico[2], M. Parisi[3], M. Zibetti[1], G. Imbalzano[1], A. Romagnolo[1], M. Rizzone[1], M. Bozzali[1], L. Lopiano[1], C. Artusi[1]

[1]Department of Neuroscience "Rita Levi Montalcini", University of Turin (Torino); [2]Department of Orthopedics, Traumatology and Rehabilitation, University of Turin (Torino); [3]Department of Neurology, Ospedale Rivoli (Rivoli-TO)

Objective: Lateral trunk flexion is a frequent, disabling complication of Parkinson's disease (PD) with uncertain management options [1,2]. We aimed to evaluate long-term use of botulinum toxin (BoNT) in PD-lateral trunk flexion.

Materials: 13 PD patients with a lateral trunk flexion >5° were evaluated for posture, quality of life (8-Item Parkinson's Disease Questionnaire -PDQ-8-), and back pain (visual analogue scale -VAS-) before (T0) and one month after (T1) BoNT. Posture was then followed-up at each next BoNT course by validated measurements based on patients' pictures taken while standing in relaxed trunk position and at their best effort to avert the back [3].

Methods: Patients were treated by US- and EMG-guied Onabotulinumtoxin-A injections in the longissimus (50 Units) and iliocostalis lumborum (50 Units) at the same side of flexion at T0. All following treatment courses were personalized for each patient based on muscular hyperactivity on EMG when sitting without support.

Results: Comparing T0 vs. T1, we didn't observe a significant improvement of the lateral trunk flexion angle (from 11.2±4.6 to 12.4±7.5 for relaxed posture -p=0.507-; from 9.7±4.7 to 12±7.7 with effort -p=0.196-). VAS score changed from 6±3 to 5±3.3 (p=0.606) and PDQ-8 score from 23.6±20.3 to 19.8±14 (p=0.878). 30.8% of patients were treated once, 15.4% twice, and 53.8% beyond 12 months (≥ 3 BoNT courses). The duration of lateral trunk flexion was different between long- and short-term groups (2.4±2.2 vs 6.2±6.8; p=0.057); albeit not significant, the T0 lateral trunk flexion angles at rest and with effort were lower in the long-term treatment group (10.4±2.8 vs. 12.2±6.2 and 8.6±2.6 vs. 11.1±6.5). In the long-term group, the mean angle of flexion was 10.4±2.8 at T0 and 9.2±6.4 at last follow-up (p=0.237).

Discussion: This is the first study analyzing the effect of BoNT for treating PD lateral trunk flexion in the long term. Patients who benefit the most and decide to continue BoNT treatment are those with a shorter duration of the trunk flexion, which may suggest that patients should be treated early. Also, our data suggest that the personalized approach based on EMG and US characteristics of paravertebral muscles is more efficacious than a standardized protocol.

Conclusion: BoNT treatment, tailored according to EMG and US-guidance, could be considered a safe and efficacious treatment to prevent worsening of lateral trunk flexion in PD.

## TRANSCRANICAL PULSE STIMULATION IN PARKINSON'S REST TREMOR: A PILOT STUDY

M. Liccari, M. Catalan, T. Lombardo, V. Cenacchi, P. Manganotti

Neurology Unit, Department of Medical, Surgical and Health Sciences, Cattinara University Hospital, ASUGI, University of Trieste (Trieste)

Introduction: Transcranical Pulse stimulation (TPS) is a recent, safe and painless non-invasive brain stimulation technique that has been proved to ameliorate cognitive performance in neurodegenerative diseases [1]. There is not yet a study investigating the effectiveness of this stimulation on PD patients, especially in terms of rest tremor.

Objective: Therefore, the goal of this paper is to explore a possible effect of TPS on the PD rest tremor circuit, stimulating the motor cortex (M1) of the contralateral most affected side.

Materials and Methods: The study included only patients suffering from Parkinson Disease accordingly to MDS criteria, attending the Movement Disorders Outpatient Clinics of the University Hospital of Trieste. All patients displayed a rest tremor, referred as frustrating, and accepted to undergo a single session of TPS. All subjects were tested with UPDRS III and accelerometer recording the upper limbs tremor at T0 (before TPS), T1 (right after TPS) and T2 (24-hours after TPS). At the end of the study, patients were asked to fill a questionnaire about a potential improvement of the PD symptoms (tremor, rigidity, bradykinesia).

Results: 14 PD tremor dominant patients were recruited and underwent all items. In our cohort of patients, the efficacy on the UPDRS was displayed in 13 individuals. The reduction up to 19 points was evaluated after 24h. The mean UPDRS decrease reached 7 points in the next day. On the accelerometer graphic, a cut of the width of the tremor was evaluated in 12 patients at T2. We appreciated a mean width reduction of the tremor reached the 57% compared to baseline. 13 patients were satisfied with the TPS session and reported a subjective improvement of the tremor. No adverse effect were reported.

Discussion and Conclusions: TPS is a harmless, non-invasive brain stimulation method that is well tolerated by the patients. This technique can be safely practiced on M1 to help in reducing the PD rest tremor in the next 24 hours after stimulation. This is supported by a clear improvement of the tremor symptoms highlighted by both the clinician (decrease in UPDRS III and reduction in the width of the tremor) and subjectively by the patient. More studies or a larger group of are needed to better understand an eventual long-lasting function of this technique on PD rest tremor.

## ACUTE RESPIRATORY FAILURE AS COMPLICATION OF MULTIPLE SYSTEM ATROPHY: DOES LARYNGEAL STRIDOR PLAY A ROLE?

F. Ligato, S. Dominici, F. Contrafatto, E. C Cicero, A. Nicoletti, M. Zappia

Department of Medical, Surgical, and Advanced Technology "G.F. Ingrassia", Section of Neurosciences, University of Catania (Catania)

Laryngeal stridor is one of the several breathing disorders that can occur in multiple system atrophy (MSA), described as a strained, high-pitched, harsh respiratory sound, caused by narrowing of rima glottidis, that can be present both during sleep and wakefulness and has been associated with a worse prognosis. Respiratory complications in MSA can determine acute respiratory failure, but it is not known the role that stridor plays. We present the case of a 69-year-old man with akinetic-rigid syndrome not responsive to levodopa, admitted in an Intensive Care Unit for respiratory acidosis requiring intubation. The patient reported a four-year history of progressive slowness of movements associated with constipation, urinary incontinence and episodes, especially during sleep, of noisy and wheezing breaths.

At the neurologic examination the presence of an akinetic-rigid parkinsonism was found. Functional respiratory and polysomnographic studies revealed dysventilatory syndrome with a restrictive pattern and mild sleep apnea syndrome while laryngoscopy excluded any structural lesion and revealed normal vocal cord motility. Neurovegetative testing showed orthostatic hypotension. The patient was discharged with the diagnosis of clinically established MSA-P according to MDS criteria and the prescription of continuous positive airway pressure (CPAP) during sleep (CPAP) in order to treat laryngeal stridor. This case shows as, in patients with MSA, stridor can be associated with acute respiratory insufficiency, and it is crucial to recognize it quickly and provide the patient with ventilatory support treatment.

## HEMICHOREA AS FIRST MANIFESTATION OF POLYCYTHEMIA VERA: A CASE REPORT

C. Lozi, M. Conti, G. Cola, N. Mercuri, A. Stefani

Department of Neurology, Tor Vergata University (Roma)

Background: Acquired lateralized chorea is mainly caused by stroke, metabolic disorders and autoimmune diseases, while Polycythemia Vera represents a rare etiology of this neurological disorder. [1]

Case presentation: In October 2022, an 84-year-old man was admitted to our Neurology Department 5 days after a sudden onset of involuntary movements at the right side of the face and right limbs. His medical history included hypertension, atrial fibrillation and left cerebellar infarction the previous year. His home therapy included Cardioaspirin, Amiodarone, Enalapril, Simvastatin and Pantoprazole. On hospital admission, high blood pressure was recorded, and blood tests were normal except for elevated hemoglobin (19.7 g/dl) and high hematocrit (70%). Neurological examination showed non-stereotyped involuntary movements involving right orofacial muscles and right limbs, interpreted as hemichorea. Brain MRI documented cerebral small vessel disease, while it was negative for acute cerebrovascular event. A brain 18F-FDG PET was also conducted, revealing hypometabolism in the left thalamus. Further investigations revealed JAK2V617F mutation in peripheral blood. Therefore, diagnosis of polycythemia Vera was made according to 2016 WHO criteria. The patient underwent a phlebotomy (about 250 mL). As a result, the hematocrit level decreased to 45%, and complete resolution of hemichorea was observed three weeks after the treatment. Subsequently, treatment with oncocarbide was initiated, aiming to maintain the hematocrit level below 47%. Since the hematocrit levels normalized, there have been no further episodes of involuntary movements.

Discussion: In our case, the detection of polycythemia occurred simultaneously with the onset of involuntary movements. Furthermore, the decrease in hematocrit levels through phlebotomy strongly correlated with the improvement of the symptoms. This association implies that chorea could potentially arise as a consequence of Polycythemia Vera, with hyperviscosity potentially influencing pathophysiological processes. [2] Elevated hematocrit levels increase blood viscosity, impairing cerebral blood flow and consequently metabolism in basal ganglia and thalamus, without ischemic lesions. [3] Indeed, in our case, brain MRI did not reveal any sign of recent brain injury, while PET-FDG demonstrated decreased activity in the left thalamus, providing evidence of localized metabolic alterations consistent with the patient's symptoms.

Conclusions: Our case underlines the importance to consider polycythemia vera as a potential etiology of acute onset of hemichorea, when polyglobulia is present and other diagnoses have been excluded. In such cases, regression of symptoms can be observed following phlebotomy. Furthermore, FDG-PET may represent a supportive diagnostic tool in order to reveal a metabolic dysfunction especially when routine imaging examinations are negative.

## PERSONALITY AND PSYCHOPATHOLOGICAL CHARACTERISTICS IN FUNCTIONAL MOVEMENT DISORDERS

A. Luca, T. Lo Castro, G. Mostile, G. Donzuso, C. Cicero, A. Nicoletti, M. Zappia

Department of Medical, Surgical Sciences and Advanced Technologies "GF Ingrassia", University of Catania (Catania)

Introduction: Aim of the present study was to assess personality and psychopathological characteristics in patients with functional movement disorders (FMDs) compared to patients with organic weakness (OW).

Methods: Personality characteristics were assessed with the Rorschach test coded according to Exner's comprehensive system and the Structured Clinical Interview for DSM-5 (SCID-II). Alexithymia was assessed with the Toronto Alexithymia Scale (TAS-20) total score and sub-scales Difficulties in Describing Feeling (DDF), Difficulties in Identifying Feeling (DIF) and Externally Oriented Thinking (EOT).

Results: Thirty-one patients with FMDs (27 women; age 40.2±15.5 years; education 11.7±3.2 years; disease duration 2.3±2.5 years) and 24 patients affected by OW (18 women; age 35.8±16.3 years; education 11.9±2.9 years; disease duration 3.4±2.8 years) were enrolled. At the Rorschach, FMDs presented a significantly higher frequency of Popular (P) and sum of all Human content codes (SumH>5) responses and avoidant coping than OW. Moreover, FMDs presented significantly higher scores than OW in TAS-20 total score and sub-scales DDF and DIF.

Conclusion: FMDs presented "conformity behaviors" and excessive interest in others than usual, a maladaptive avoidant style of coping and a difficulty in verbalizing emotional distress. These psychopathological characteristics, may "favor", acting together, the occurrence of FMDs.

## GENERALIZED MILD CHOREA IN A YOUNG MALE, AFTER CARDIAC ARREST DUE TO ANAPHYLACTIC SHOCK

F. Macchione

Neurology Department, Hospital of Arzignano, University of Bari (Bari)

Purpose: Post-hypoxic movement disorders (PMD) after cardiac arrest are under-reported phenomena most probably related to basal ganglia dysfunction; ballism and chorea are the most frequently occurring movement disorders associated with basal ganglia infarction. Chorea is one of the major types of involuntary movement disorders originating from dysfunctional neuronal networks interconnecting the basal ganglia and frontal cortical motor areas. The syndrome is characterized by a continuous flow of random, brief, involuntary muscle contractions and can result from a wide variety of causes. We report a case of a young male with a medical history relevant only for asthma, who presented a generalized chorea, prevalent to left side of the body, few days after a cardiac arrest due to anaphylactic shock and concomitant swab positive for COVID19.

Methods: An MRI of brain performed after several days showed hyperintense lesions in T2 weighted and FLAIR sequences involving globus pallidus, bilaterally; blood exams revealed the presence of p-ANCA antibodies with a moderate title. A diagnosis of Churg Strauss wasn't stated for absence of the main diagnostic features, except for asthma.

Results: The irregular movements regressed with introduction of very low dosage therapy with tetrabenazine. At 3-month follow-up neurological examination was negative and so the therapy was suspended, at 6-month follow-up irregular movements where still absent.

Conclusions: In conclusion, our patient showed a generalized chorea due to bilateral globus pallidus infarcts, caused by cardiac arrest after anaphylactic shock; the other possible intervening etiologies (COVID19, presence of p-ANCA) are less likely.

## TIC SUPPRESSION IN GILLES DE LA TOURETTE SYNDROME, A TRANSCRANIAL MAGNETIC STIMULATION-ELECTROENCEPHALOGRAPHY STUDY

M. Mancuso[1], G. Leodori[2], D. Belvisi[2], C. Cutrona[2], G. Gallo[2], L. Cori[2], A. Berardelli[2], A. Conte[2]

[1]Human Neurophysiology Dept., Sapienza University of Rome (Roma); [2]Human Neuroscience Dept., Sapienza University of Rome (Roma)

Introduction: The role of the primary motor cortex (M1) and dorsolateral prefrontal cortex (DLPFC) in Gilles de la Tourette syndrome (GTS), although relevant to the inhibition of tics, is poorly understood [1,2]. The only studies that have characterized these areas in GTS involve functional magnetic resonance, characterized by poor temporal resolution [1,2]. On the other hand, transcranial magnetic stimulation with EEG co-registration (TMS-EEG) can investigate the dynamics of these areas with a perturbational approach and with greater temporal precision. The aim of our study is to search for excitability alterations of M1 and DLPFC in patients with GTS that could explain their role in tic suppression.

Materials and Methods: 10 subjects with GTS and 10 healthy subjects, matched for age and sex, were enrolled. Each subject underwent M1 and DLPFC stimulation in real condition (110% of the resting motor threshold, RMT) and sham (same intensity as real, using a coil sham) in two conditions: release of tics (free blink in healthy subjects) and voluntary inhibition of tics (inhibition of blink in healthy people). TMS-EEG data were preprocessed with standard pipelines, and the epochs thus obtained were averaged to obtain transcranial evoked potentials (TEPs). Each patient underwent administration of a battery of validated scales for the evaluation of the motor symptoms of the syndrome and the severity of psychiatric comorbidities. The local excitability of each area (15-60 ms) and the modulation between conditions were compared by mixed-model ANOVA.

Results: Compared to healthy controls, GTS patients exhibited reduced M1 excitability during the tic release condition and reduced M1 modulation during the tic suppression condition. Furthermore, greater modulation of M1 during tic suppression corresponded to less severity of motor symptoms and psychiatric comorbidities. Modulation of DLPFC during tic suppression correlated inversely with the severity of motor and psychiatric symptoms.

Discussion and Conclusion: The reduced excitability and modulation of M1 during tic suppression in patients with GTS is a possible expression of entrainment of M1 by subcortical circuits, which makes it refractory to TMS stimulus and voluntary modulation. Although not different from healthy volunteers, also the modulation of DLPFC seems to have a role in the inhibitory control on involuntary movements, in line with the generally known inhibitory role of this area [3].

## HIGH-DENSITY ELECTROENCEPHALOGRAPHIC CORRELATES OF GAIT DISORDERS IN POST-STROKE PATIENTS

G. Marangon[1], S. Vasta[2], A. Orejel Bustos[3], R. Montemurro[3], V. Betti[2,3], M. Tramontano[3]

[1]Department of Neurosciences, Imaging and Clinical Sciences, Gabriele d'Annunzio University of Chieti (Chieti); [2]Department of Psychology, Sapienza University of Rome (Roma); [3]IRCCS Fondazione Santa Lucia (Roma)

Aim: Stroke causes sensorimotor impairments that disrupt motor skills performance, including balance and gait. In the clinical scenario of stroke recovery, tracking how individual human brains adapt is critical for therapy outcomes. However, the neurophysiological changes underlying this condition are still debated. This study aims to characterize alterations in electroencephalographic (EEG) signal dynamics as biomarkers of gait disorders.

Materials and Methods: EEG signals were acquired from 20 stroke patients and 21 control participants age-matched using a high-density recording system (128 channels) during 14 meters of straight walking (three phases: acceleration, 10 meters, deceleration) and 5 min of resting-state. Mini-BESTest and Gait dynamic index were used to assess the dynamic balance and functional gait abilities, respectively. Weighted Phase Lag Index (wPLI) analysis was used

to characterize functional connectivity within four regions: Centroparietal (CP) and Frontocentral (FC) in the right/left hemispheres. Statistical analyses were performed using a t-test between groups in alpha and beta bands. The correlations between the straight walking wPLI and clinical scales were obtained through Pearson's correlation analysis.

Results: A pairwise between groups t-test of straight walking task analysis revealed significant reductions of functional connectivity in stroke patients as compared to healthy participants in both alpha and beta bands. These reductions observed in stroke patients correlate with the clinical scales. Furthermore, the t-test showed increments of wPLI during the walking task compared to the resting state in both groups.

Discussion: According to the literature [1], decrements of wPLI in both bands in stroke patients compared to healthy participants suggest alterations in functional connectivity. The increased connectivity observed during the straight walking could be due to the task constraints that imply a reorganization of connectivity in both groups compared to the resting state. The correlations between sensor pairs and clinical assessments suggest that alterations of functional connectivity provide a neurophysiological marker of gait disorders in post-stroke patients.

Conclusions: WPLI is an interesting method for detecting abnormal changes in the dynamics of EEG signals associated with stroke. Furthermore, these changes are associated with clinical outcome measures. These results may open interesting new approaches to stroke rehabilitation.

## DRIVING ABILITIES, PARKINSON'S DISEASE, AND THE WEARING-OFF MANAGEMENT: INSIGHTS BY THE OPICAR-PARK STUDY

M. Marano[1], G. Sergi[2], M. Esposito[1], A. Bonura[1], A. Magliozzi[1], G. Anzini[1], V. Di Lazzaro[1]

[1]Unit of Neurology, Neurobiology, Neurophysiology and Psychiatry, Fondazione Policlinico Universitario Campus Bio-Medico (Roma); [2]Unit of Geriatrics, Fondazione Policlinico Universitario Campus Bio-Medico (Roma)

Objectives: To assess driving abilities, and to compare the use of OPICapone versus other add-on strategies on virtual CAR driving performances of PARKinson's disease with motor fluctuations.

Materials: Driving Questionnaire by the Oregon University was adopted to assess real driving performances. All subjects received a virtual driving evaluation with a driving simulator on a standardized path with traffic lights, jam, pedestrians, and a parking challenge after a training with calculation of learning curve (calculated in seconds) of various driving items. A customized virtual driving rating scale (VDRS) with reaction times (RT) and learning curves (LC) was adopted to assess simulated driving performances. All patients were assessed with the WOQ9 at screening, and with UPDRS and MoCA at the various time points.

Methods: The study had a prospective observational design. Parkinson's disease patients (PD) reporting motor fluctuations were consecutively enrolled according to the following criteria: non-demented PD without sensory disturbances who received an add-on therapy to levodopa in the previous 6 months (PD1, iMAO and other; PD2, opicapone); WOQ9≥2; still on driving. Enrolled subjects received a V1 during their pharmacological "best on" and a V2 during their "wearing-off". A matched healthy population was also recruited (HC).

Results: 36 PD patients and 12 HC were recruited. Mean age and sex did not differ across groups. PD patients described worse real driving performances ("maintaining the lane" item; $p<0.05$). VDRS, RT and LC were significantly altered in PD vs HC ($p<0.01$). The motor impairment (UPDRS-III) and the WOQ9 were associated to the VDRS at V2. At a sub analysis, PD2 were younger than PD1 and had higher WOQ-9 and LEDD values. Moreover, after correcting for the age, PD2 subjects showed better VDRS ($p<0.05$) and reaction time ($p<0.05$) at V1 and better learning curves at V2 than PD1 ($p<0.05$).

Discussions: PD is associated with history of driving impairment and lower performances at driving simulation. This is influenced by the the detrimental motor performance that is observed during the wearing-off. Patients on opicapone performed better than others during the best-on and showed a better learning profile at V2 despite the wearing-off condition.

Conclusions: This is the first study investigating the role of motor fluctuations and the effect of therapies on PD driving abilities [1,2]. A possible positive effect of opicapone on driving abilities has been detected. Further studies are needed to elucidate how to shape the PD pharmacological therapy on the patient needs, focusing on driving.

## NEUTROPHIL-TO-LYMPHOCYTE RATIO AND LYMPHOCYTE COUNT REFLECT ALTERATIONS IN CENTRAL NEURODEGENERATION-ASSOCIATED PROTEINS AND CLINICAL SEVERITY IN PARKINSON DISEASE PATIENTS

D. Mascioli[1], P. Grillo[1], G. Sancesario[2], R. Bovenzi[1], J. Bissacco[1], C. Simonetta[1], P. Forti[1], M. Pieri[3], V. Chiurchiù[4], T. Schirinzi[1], A. Stefani[1], N. Mercuri[1]

[1]Policlinico Tor Vergata Hospital, University of Roma Tor Vergata (Roma); [2]Clinical Neurochemistry Laboratory, IRCCS Fondazione Santa Lucia (Roma); [3]Department of Experimental Medicine, University of Rome Tor Vergata (Roma); [4]Laboratory of Resolution of Neuroinflammation, IRCCS Fondazione Santa Lucia (Roma)

Introduction: Peripheral inflammation has recently been associated with Parkinson's disease (PD) [1], although correlations between peripheral immune activation and clinicopathological stage of PD remain unclear. Neutrophils and lymphocytes are the two major leukocyte populations of the innate and adaptive immune responses, respectively. The neutrophil-to-lymphocyte ratio (NLR), is now considered a meaningful biomarker for conditions accompanied by systemic inflammation due to various underlying causes such as infections, trauma or stroke.

Objectives: In this study we evaluated the peripheral immune profile of a well-characterized cohort of PD patients, examining correlations with both CSF biomarkers of neurodegeneration and key clinical parameters, in order to better understand the complex dynamics of brain-periphery interactions in PD.

Materials and Methods: Leukocyte population counts (neutrophils, lymphocytes, monocytes, eosinophils, and basophils) and the NRL were collected and compared in 61 PD patients and 60 sex/age matched controls (CTRL). Immune parameters were correlated with CSF levels of total α-synuclein, amyloid-β-42, total and phosphorylated tau, and with scores on major motor and non-motor scales.

Results: PD patients had lower lymphocyte counts and higher NLR than CTRL patients. In PD patients, lymphocyte count was directly correlated with CSF α-synuclein levels, while NLR showed an inverse correlation with CSF amyloid-β42 levels. Lymphocyte count also correlated negatively with HY stage, while NLR positively with disease duration.

Discussion: The purpose of the study was to evaluate leukocyte populations and NLR in a cohort of PD patients, assessing the possible association with CSF biomarkers and disease burden. The study found that PD patients, compared with controls, had lower lymphocyte counts and higher NLR. The lower lymphocyte count was found to correlate with greater severity of motor disturbances and lower CSF total α-syn levels. Increased NLR was found to correlate with lower CSF levels of Aβ42 and longer disease duration. Increased NRL may underlie a systemic inflammatory state secondary to increased release of cytokines and pro-inflammatory molecules. Lymphocyte counts and NLR correlated positively with total α-syn levels and inversely with CSF Aβ42 levels, thus revealing a link between peripheral inflammation and central neuropathology.

Conclusions: In this study, it was shown that, in PDs, peripheral immune system alterations, such as relative lymphopenia and increased NLR, are associated with increased clinical severity and changes in neurodegeneration-associated proteins centrally, particularly in the α-synuclein and amyloid-β pathways.

## NEGATIVE MYOCLONUS IN SEVERE CHRONIC RESPIRATORY FAILURE: A CASE REPORT

G. Mazza, V. Badioni, E. Domina, S. Fermi, M. Fruguglietti, L. Guri, B. Incorvaia, S. Iurlaro, M. Pascarella, S. Sperber, A. Zilioli, V. Belcastro

Neurology Unit, Maggiore Hospital (Lodi)

Background: Negative myoclonus (NM) is an unspecific motor disorder that can characterize a variety of neurological conditions. NM is a shock-like involuntary jerky movement caused by a sudden, brief interruption of muscle activity [1]. Patients with transient myoclonus represent about 30% of all patients with myoclonus who visit an emergency room (ER) for a movement disorder. We describe a patient who de novo developed almost continuous NM triggered by respiratory hypercapnic acidosis.

Clinical Case: A 64-year-old woman was referred to our attention because she experienced continuos brief loss of the muscular tone of the arms, clearly predominating in the upper limbs. She complained of episodes characterized by drops of her upper limbs, which caused the patient to let objects fall. She was taking at home pregabalin 25 mg TID for neuropathic pain and O2 medication for a clinical picture of OSAS.

Methods: At ER a brain CT scan was unremarkable while an arterial blood gases analysis (ABGA) showed severe respiratory hypercapnic acidosis (pH 7.29, pCO2 125.98 mmHg, pO2 64.2). Polygraphic EEG recordings, including the EMG tracing of the deltoid and wrist extensor muscles showed an abrupt and brief period of electrical silence when the patient was asked to extend the arms and dorsiflex the hands in a sustained posture. EEG recordings showed intermittent frontal and bilateral sharp waves without any temporal correlation with NM. The interruption of tonic muscle activity occurred without conjunction with epileptiform EEG abnormalities. An MRI brain study was unremarkable.

Results: To exclude the possibility that pregabalin might have caused the symptom the medication was abruptly stopped. Further, after BIPAP placement we observed a progressive improvment of ABGA values risulting in remission of NM. At this time, polygraphic video EEG recording was normal. Noteworthy, pregabalin medication 25 mg TID was restarted at home but at the present follow-up the patient was asymptomatic for NM.

Discussion: In our case a direct relationship between NM and respiratory hypercapnic acidosis was found. NM is commonly seen in patients with hepatic failure whereas respiratory failure is not commonly associated with NM [2-3]. After resolution of hypercapnia, pregabalin was restarted but no clinical events where observed.

Conclusions: A complete respiratory function screening should be taken into account in the diagnostic workup of NM.

## MOTOR AND NON-MOTOR CORRELATES OF HYPOSMIA DETECTED BY THE ITALIAN OLFACTORY IDENTIFICATION TEST (IOIT) IN AN ITALIAN COHORT OF PARKINSON'S DISEASE PATIENTS

A. Mechelli[1], S. Simoni[2], P. Nigro[3], E. Cresta[2], M. Pierini[2], G. Susca[2], A. Tufo[2], C. Maremmani[4], N. Tambasco[2]

[1]Movement Disorders Center, Neurology Department, University of Perugia (Perugia); [2]Neurology Department, Perugia General Hospital and University of Perugia (Perugia); [3]Movement Disorders Center, Neurology Department, Perugia General Hospital and University of Perugia (Perugia); [4]Neurology Department, Apuane Hospital (Massa)

Objectives: To characterize olfaction in a cohort of Parkinson's disease (PD) patients and to investigate the relationship between olfactory impairment and both motor and non-motor features and other clinical characteristics (duration, stage and severity).

Materials: One hundred fifty-four patients with idiopathic PD without dementia (Mini-Mental State Examination score >25) were included in the study.

Methods: Odor identification ability was tested using the validated Italian Olfactory Identification Test (IOIT) (33-testers), specifically designed for the Italian population [1]. A comprehensive spectrum of motor (tremor, bradykinesia, rigidity, postural stability, gait, masked face, speech, voice, posture) and non-motor features (urinary symptoms, depression, sleep disorders, constipation) was assessed, using Unified Parkinson's Disease Rating Scale (UPDRS-III), modified Hoehn and Yahr (mH&Y) staging and a semi-structured interview. Patients were divided into 3 clinical phenotypes: tremor-dominant type (TDT), akinetic-rigid type (ART) and mixed type (MXT) [2].

Results: Hyposmia was found in 141/154 (93%) patients (mean mH&Y:1.99±0.6, mean UPDRS-III:23.4±11.56, mean age 66.96±9.2 years, mean disease duration 5.57±4.9 years). Hyposmic patients were older than those with normal olfaction (p=0.012). mH&Y score≥2 was associated with a higher probability of being hyposmic (OR=1.18, p=0.01). IOIT score did not significantly differ between TDT, ART and MXT PD patients. IOIT score directly correlated with patients' age

(p<0.001), disease duration (p=0.01) and mH&Y score≥2(p<0.05). Clinical features associated with higher IOIT score were freezing of gait (FOG) (+2.38, p=0.027) and camptocormia (+2.31, p=0.022).

Discussion: In line with previous studies [3], our investigation highlighted that worse IOIT scores were more likely to associate with camptocormia and FOG among motor symptoms, but not with non-motor symptoms. These results suggest that more severe olfactory impairment is associated with more severe disease manifestations, such as camptocormia and FOG, and it is comparable across clinical phenotypes (TDT, ART, MXT).

Conclusion: Assessing olfactory dysfunction through IOIT may help identify PD patients at higher risk of developing severe motor features (camptocormia and FOG). Overall, IOIT may be a useful tool not only for supporting PD diagnosis but also for providing prognostic information about motor function. Follow-up studies are warranted to confirm IOIT's ability to predict more severe motor symptoms in PD patients.

## THE ACUTE EFFECTS OF SUBTHALAMIC DEEP BRAIN STIMULATION ON CARDIOVASCULAR AND SUDOMOTOR FUNCTION ASSESSED BY HEAD-UP TILT TEST AND SUDOSCAN

K. Meksi, R. Cerroni, E. Garasto, N.B. Mercuri, A. Stefani, C. Rocchi

Parkinson's Disease Center, Policlinico Tor Vergata, University of Rome "Tor Vergata" (Roma)

Objective: Deep brain stimulation (DBS) of the subthalamic nucleus (STN) is an effective treatment for advanced Parkinson's disease (PD), but its effects on the autonomic nervous system are not well understood. Aim of this study is to investigate the acute effects of STN-DBS on cardiovascular and sudomotor regulation using objective neurophysiological tests.

Materials and Methods: Ten patients with advanced PD who had undergone STN-DBS implantation were enrolled in the study. Patients with certain medical conditions or medications affecting the autonomic nervous system were excluded. Heart rate (HR), blood pressure (BP), and respiratory rate were recorded at rest and during a head-up tilt test (HUTT). Sudomotor function was assessed by measuring electrochemical skin conductance (ESC) using Sudoscan. The patients were evaluated under three conditions: under DBS ON and therapy OFF (DBS ON/Th OFF), 30 minutes after switching off the DBS (DBS OFF/Th OFF) and 30 minutes after switching on the DBS and administering melevodopa/carbidopa 100/25 mg (DBS ON/Th ON). Statistical analysis was performed using t-tests.

Results: A significant reduction in systolic BP was observed at the 10th minute of HUTT in the DBS ON/Th ON condition (p 0.036). No other significant differences were found in HR, BP, or ESC conductance among the three conditions.

Discussion: Most of the previous studies regarding the effects of STN-DBS on autonomic symptoms are based on subjective questionnaires. This study applied objective neurophysiological tests to evaluate autonomic control. Our findings did not show significant differences in HR, BP, or sudomotor function between conditions, except for the decrease in systolic BP at the 10th minute of HUTT during DBS ON/Th ON. This reduction in BP is likely attributed to the acute effect of levodopa therapy rather than direct STN stimulation. The results align with previous studies that found no changes in BP or its responses to tilting in PD patients receiving STN-DBS. Regarding sudomotor function, this study did not find a significant effect of DBS on sweating, consistent with previous literature data.

Conclusion: STN-DBS does not appear to have a direct impact on cardiovascular and sudomotor autonomic regulation. However, it may indirectly improve cardiovascular reactivity by reducing levodopa load.

## POLYNEUROPATHY, TREMOR AND MR ABNORMALITIES IN KLINEFELTER SYNDROME

D. Melchionda, E. D'Amico, A. Zanghi, C. Avolio

Department of Neurosciences, Policlinico Riuniti (Foggia)

Introduction: Klinefelter syndrome (KS) represent a genetic disorder interesting the sexual chromosomes, with an extra-X chromosome added to the normal karyotype (XXY) Neurological deficits are often present in Klinefelter Syndrome (KS). Tremor, expecially essential tremor, is quite a characteristic tract of the disease. Leukoencephalopathy in MRI hyperlucency spots in white matter is sometimes described. Polyneuropathy is another neurological problem described in KS, although rarely described. Leucoencephalopathy has also rarely been described in KS. We report three cases of KS patients carrying all these three alterations: tremor, sensory-motor polyneuropathy and leukoencephalopathy.

Study subjects: We report three patients affected by KS (XXY) occurred in the last 10 years in our Universitary Department of Neurology. They were 42, 45 and 51-year-old male with numbness, tingles and pain in both the feet, difficult in walking too, with frequent falls. They complained a postural tremor of the upper extremities, with frequency of 12 Hz, exacerbated by anxiety and stress. Neurological examination highlighted an high frequency hand tremor, slightly prevalent in the right side, and reduced sensibility in lower extremities; deep tendon reflexes were symmetrically diminished in lower extremities. Brain MRI showed a pattern of hyperlucency spots in white matter, referred as vascular leucoencephalopathy. Nerve conduction studies showed decreased amplitude and conduction velocities in both motor and sensory fibers.

Discussion: Klinefelter syndrome, 47 XXY, is the most common chromosomal aberration among men. Tremor is one of the most frequent neurological problem described in KS. Although tremor is reported at a younger age, our patients are older than forty. In the report by Harlow et al. the average age of tremor onset in KS was twenty years. The presence of white matter alterations is also reported in different reports, with a distribution of lesions typical of the vascular encephalopathy. The presence of Polyneuropathy is another

neurological pathology less often described in patients with Klinefelter syndrome. There are few reports of these in literature. The Authors considered the polyneuropathy a potentially hypogonadic complication of KS or a complication of pathologies strictly related to the KS, such as Diabetes mellitus or Thyroid disfunction.

Conclusion: In conclusion, the presence of cromosomal alteration typical of KS, would address the presence of tremor, PNP and leukoencephalopathy and do brain MRI, EMG and cognitive tests in these patients in order to find these pathologies and treat them.

## A NEWLY IMPLEMENTED NGS-BASED METHOD TO DETECT GBA1 VARIANTS IN PATIENTS WITH PARKINSON'S DISEASE

E. Monfrini[1], I. Palmieri[2], G. Cuconato[3], M. Percetti[1], M. Morelli[4], E. Zapparoli[4], A. Di Fonzo[1], E. Valente[2]

[1]Neurology Unit, IRCCS Ca' Granda Ospedale Maggiore Policlinico (Milano); [2]Neurogenetics Research Center, IRCCS Mondino Foundation (Pavia); [3]Dept. of Molecular Medicine, University of Pavia (Pavia); [4]Bioinformatics, IRCCS San Raffaele (Milano)

Objectives: Heterozygous variants in GBA1, encoding for the lysosomal enzyme β-glucocerebrosidase, are the most common genetic risk factor for PD, accounting for 5-15% of all PD cases. Sequencing of the whole GBA1 coding region (11 exons) is a burdensome task, both employing conventional techniques such as Sanger sequencing as well as more innovative strategies such as standard NGS. In particular, the high degree of homology (96-98%) between GBA1 and its pseudogene GBAP1 often leads to recombination events that eventually produce complex alleles which are misaligned and missed by the standard NGS pipelines. We aim to implement a new rapid and cost-effective next-generation-sequencing (NGS)-based technology to sequence GBA1 gene in Parkinson's disease (PD) patients.

Materials and Methods: The experiment was designed to start from a specific long-range PCR which amplifies a unique 7kb amplicon encompassing the GBA1 gene and excluding the neighboring pseudogene GBAP1. This was used as a template to create NGS libraries, which were amplified using Nextera technology and then run on an Illumina MiSeq instrument. In parallel to standard bioinformatic analyses, a tailored pipeline was used, masking GBAP1 pseudogene on the reference sequence and forcing the alignment of sequencing reads against the genomic coordinated of GBA1 gene only. To assess the validity of this approach we studied selected PD patients who were already tested with conventional techniques (Sanger sequencing or standard NGS).

Results: The tailored pipeline displayed a significant increase in read depth and mapping quality compared to the standard bioinformatic analysis. All known GBA1 variants were correctly called and identified using this approach. In several PD patients resulting GBA1-negative with conventional strategies this novel method identified previously missed GBA1 pathogenic variants, particularly those originating from the pseudogene (gene conversions and fusions).

Conclusions: The proposed NGS-based approach appears a cost-effective and reliable alternative for GBA1 sequencing, holding promise to increase speed analysis and variant detection rate compared to conventional strategies.

## AGE AT ONSET AND FUNCTIONAL STRIATAL CONNECTIVITY IN DRUG-NAÏVE PATIENTS WITH PARKINSON'S DISEASE

E. N. Mosca, R. De Micco, N. Piramide, F. Di Nardo, G. Caiazzo, M. Siciliano, G. Tedeschi, F. Esposito, A. Tessitore

Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli" (Napoli)

Objective: Compelling evidence suggests that age at onset may significantly affect the clinical picture of Parkinson's disease (PD), in terms of motor and nonmotor symptoms as well as rate of disease progression and development of complications. We investigated the potential effect of age on the whole-brain functional connectivity (FC) from different striatal subregions in a cohort of early PD patients using resting-state functional MRI (rs-fMRI).

Materials: 147 drug-naive PD patients and 38 healthy controls were enrolled. Non-hierarchical cluster were applied to stratify PD patients according to age at onset in 3 subgroups: 32 "early/young", 69 "early/intermediate" and 46 "early/old".

Methods: Clinical assessments as well as rs-fMRI were performed at baseline. Longitudinal clinical data were also collected at 4-year follow-up. Using connectivity-based parcellation, we obtained three regions-of-interest (ROIs) for different striatal functional subregions: sensorimotor, limbic and associative.

Results: "Early/old" PD were presenting with more severe motor and cognitive impairment relative to "early/young" patients. No differences were detected in terms of disease duration between the PD subgroups. The sensorimotor ROI showed increased FC with the left superior frontal gyrus, precuneus and cerebellum, and decreased FC with right lingual gyrus, paracentral lobule and left inferior frontal gyrus in "early/young" compared to "early/old" PD. The limbic ROI showed increased FC with the right temporal gyrus and decreased FC with the posterior cingulate cortex (PCC) in "early/young" compared to "early/old" PD. The cognitive ROI showed increased FC with the cerebellum and decreased FC with PCC in "early/young" compared to "early/old" PD. "Early-young" PD presented a higher risk to develop treatment-related motor complications after 4 years.

Discussion: Specific changes in the striatal FC are associated with age at onset in PD patients. This pattern is related with better motor outcome at baseline and increased vulnerability to develop treatment-related motor complications overtime.

Conclusions: These results may suggest the presence of early compensatory mechanisms occurring in the early stages, that may potentially become dysfunctional under chronic dopaminergic stimulation, likely shifting towards those maladaptive changes of the striatal dopaminergic firing which have been hypothesized to underlie the development of motor complications over time.

## DATA-DRIVEN CLUSTERING OF NEURODEGENERATIVE DISEASES BASED ON EEG SPECTRUM POWER-LAW DECAY: THE DACNES STUDY

G. Mostile, R. Terranova, G. Carlentini, F. Contrafatto, C. Terravecchia, G. Donzuso, G. Sciacca, C. Cicero, A. Luca, A. Nicoletti, M. Zappia

Department of Medical, Surgical Sciences and Advanced Technologies "G.F. Ingrassia", University of Catania (Catania)

Background: Neurodegenerative diseases are common causes of impaired mobility and cognition in the elderly. Among them, tauopathies (including Alzheimer's Disease, Progressive Supranuclear Palsy and Corticobasal Degeneration) and α-synucleinopathies (including Parkinson's Disease and Multiple System Atrophy) were considered. The neurodegenerative processes and relative differential diagnosis were addressed through a qEEG non-linear analytic method.

Objectives: To test accuracy of the power law exponent β applied to EEG in differentiating neurodegenerative diseases and to explore differences in neuronal connectivity among different neurodegenerative processes based on β.

Methods: N = 230 patients with a diagnosis of tauopathy or α-synucleinopathy and at least one artifact-free EEG recording were selected. Welch's periodogram was applied to signal epochs randomly chosen from continuous EEG recordings. Power law exponent β was computed as minus the slope of the power spectrum versus frequency in a Log-Log scale. A data-driven clustering based on β values was performed to identify independent subgroups.

Results: In bilateral frontal-temporal regions, β values were significantly higher for Parkinson's Disease with respect to the atypical parkinsonism; in parietal areas, differences remained significant only for Progressive Supranuclear Palsy and Corticobasal Degeneration. Data-driven clustering based on β differentiated tauopathies (overall lower β values) from α-synucleinopathies (higher β values) with high sensitivity and specificity. Tauopathies also presented lower values in the correlation coefficients matrix among frontal sites of recording.

Conclusions: Statistically significant differences in β values were found between tauopathies and α-synucleinopathies. Hence, β is proposed as a possible biomarker of differential diagnosis and neuronal connectivity.

## FRONTOTEMPORAL DEMENTIA PHENOTYPE IN LATE-ONSET HUNTINGTON DISEASE WITHOUT CHOREA

S. Mozzetta[1], G. Bonato[1], C. Busse'[1], D. Cecchin[2], A. Cagnin[1]

[1]Department of Neuroscience, University of Padua (Padova); [2]Nuclear Medicine Unit, University of Padua (Padova)

Introduction: Huntington disease is a neurodegenerative disorder with autosomal dominant transmission, caused by CAG-repeat expansion in the IT15 gene in chromosome 4, typically characterized by movement disorders such as involuntary choreic movements, gait disturbance, extrapyramidal rigidity and dystonia, associated with neuropsychiatric and cognitive disturbances. Disease onset and severity of manifestations varies depending on repeats number. Age of onset is usually between 40 and 50 years of age, but older presentations are possible and usually associated with more prominent motor onset rather than psychiatric or behavioural, and with a lower number of CAG repeats. We here report a case of HD presenting as behavioural frontotemporal dementia (bvFTD), without movement disorder, in which diagnosis was prompted by [18F]FDG PET/MRI findings.

Case report: A 77-year-old Caucasian man came to our attention for behavioural alterations (irritability, lack of inhibition and hypersexuality) and memory deficits starting at age 75. He had a past history of post-traumatic stress disorder (PTSD) after a car accident treated with SSRI, and treated skin melanoma. In his family, an 80-year-old sister was affected by dementia. In the following months, he developed memory and attention deficits, occasional outdoor space disorientation. brain CT scan revealed mild global brain atrophy, redominantly in temporo-mesial areas. Neuropsychological examination showed mild impairment of attention, executive functions, working memory, visuospatial and visuoconstructive functions (MMSE score: 25/30). Behavioural evaluation showed presence of apathy, lack of inhibition and sleep disturbances. Neurological examination revealed no pyramidal and extrapyramidal signs; however, it documented disrupted pursuit and slow saccades, failure in performing Luria sequence. A diagnosis of possible bvFTD was made. CSF examination documented a normal cell and protein count, normal total tau and phosphorylated tau (whereas amyloid deposition was confirmed with decreased beta1-42/1-40 ratio [0.041]). Brain [18F]FDG PET/MRI highlighted a subtle hypometabolism in bilateral fronto-mesial cortex and discrete hypometabolism in both caudate nuclei. Genetic testing for the most frequent causes of FTD including GRN, MAPT, TARDBP, FUS and c9orf72 resulted negative. A search for CAG expansion in HD gene prompted by the presence of mild caudate hypometabolism, and 41 CAG repeats were found (NM_002111.8:c.53AGC[18]; c.53AGC[41]). A diagnosis of HD with bvFTD phenotype was made.

Conclusion: In our case low number of CAG repeats may explain the late onset and bvFTD clinical presentation. HD is a rare cause of FTD. Decreased metabolism in caudate should rise the suspicion of HD also in atypical and very-late onset patients, even in the absence of motor symptoms.

## A CASE OF AUTOSOMAL RECESSIVE SPINO-CEREBELLAR ATAXIA TYPE 10 (SCAR10) CAUSED BY HOMOZYGOUS MUTATION IN THE ANO10 GENE: CLINICAL PRESENTATION AND FUNCTIONAL SIGNIFICANCE

D. Norata[1], P. Alonge[2], L. Grillo[3], F. Calì[3], F. Brighina[2], V. Di Stefano[2]

[1]Department of Medicine and Surgery, Unit of Neurology, Neurophysiology, Neurobiology and Psychiatry, Campus Bio-Medico University of Rome (Roma); [2]Unit of Neurophysiopathology, Department of Biomedicine, Neuroscience and Advanced Diagnostic (BIND), University of Palermo (Palermo); [3]Research Unit of Rare Diseases and Neurodevelopmental Disorders, Oasi Research Institute-IRCCS (Troina-EN)

This report describes a case of Autosomal Recessive Spino-Cerebellar Ataxia Type 10 (SCAR10) resulting from a pathogenic variant in the ANO10 gene. SCARs are a group of inherited neurodegenerative disorders characterized by progressive ataxia with cerebellar atrophy. Unlike autosomal dominant SCAs, most ARSCAs are caused by single-nucleotide exon mutations, making the disease challenging to diagnose using traditional sequencing methods. SCAR10 is a rare variant of SCAR caused by mutations in the ANO10 gene. The pathogenesis of SCAR10 is not well understood, but it is thought to involve impairment of endosomal retrograde trafficking and the endolysosomal pathway. The case report describes a 44-year-old male patient with a 13-year education level and a history of gait unsteadiness since childhood. The patient presented with progressive cerebellar ataxia, gait and balance impairment, upper limb coordination problems, and speech and swallowing difficulties. Neurological examination revealed dysarthria, dysphagia, hearing loss, strabismus, and limitation of eye movements. The patient also exhibited pyramidal manifestations, but no peripheral neuropathy's signs. A brain MRI showed a severe diffuse cerebellar atrophy. Genetic testing identified the homozygous variant c.289delA(p.Met97Ter) in the ANO10 gene. The ANO10 gene encodes the endoplasmic reticulum transmembrane protein 16K (TMEM16K), which is involved in various cellular processes, including phospholipid distribution, calcium regulation, apoptosis, and endosomal transport and sorting. Changes in TMEM16K function can impact these processes and contribute to the development of SCAR10. The identified variant in the ANO10 gene is a pathogenic variant and has been reported in a few other individuals with SCAR10. This case report expands our limited knowledge about SCAR10 and provides further evidence of the association between ANO10 gene mutations and the clinical presentation of the disease. Understanding the functional significance of TMEM16K and its role in cellular processes may help in the development of targeted therapies for SCAR10 and related disorders. Further research is needed to elucidate the genotype-phenotype correlation and explore potential treatment options for SCAR10.

## BRAIN PARENCHYMA SONOGRAPHY FINDINGS IN PATIENTS AFFECTED BY PARKINSON'S DISEASE ASSOCIATED WITH GBA GENE MUTATIONS

S. Othmani[1], C. Frau[1], M. Murru[2], M. Azzena[3], P. Solla[1], C. Bagella[3], C. Bagella[1]

[1]Unit of Neurology, Department of Medical, Surgical and Experimental Sciences, University of Sassari (Sassari); [2]Multiple Sclerosis Laboratory, University of Cagliari (Cagliari); [3]Unit of Nuclear Medicine, Department of Medical, Surgical and Experimental Sciences, University of Sassari (Sassari)

Objective: The aim of this study is to describe the Brain Parenchyma Sonography (BPS) finding in a series of Parkinson's disease associated with GBA mutations (PD-GBA) patients which could be consider as a biomarker both in early and advanced stages of PD-GBA.

Methods: Case series of patients with diagnosis of Parkinson's disease admitted to the Neurological Department of the University Hospital of Sassari.

Discussion: PD-GBA is a common cause of early onset PD, with a peculiar phenotype characterized by prominent non-motor features and even in the early stages of the disease. Single-photon emission computed tomography (SPECT) with DaT has high specificity and sensitivity, but in early stage of disease can be negative [1]. BPS have been shown to be a useful tool in identifying early and already premotor stage of PD [2] through the detecting of bilateral substantia nigra (SN) hyperechogenicity. Previous studies have found that BPS findings in PD-GBA is similar to those of patients with sporadic PD [3].

Results: 6 patients affected by PD-GBA were investigated by BPS. Four patients carried the N370S mutation, one patient carried the E365K mutation and one patient was found to be carrier of a new mutation c.1312C>T. The age at onset of the motor symptom was 52,2 years (range 40-59). Upon execution of BPS, the average duration of the disease was of 8,5 years (range 1-25). A DaT SPECT showed bilateral dopaminergic denervation in 4 patients and unilateral in 2; a BPS revealed bilateral and symmetric hyperechogenicity of SN in 3 patients, asymmetrical hyperechogenicity, contralateral to the site of motor onset, in the others 3.

Conclusions: GBA mutation carriers with PD have greater hyperechogenicity similar to sporadic PD. The mechanism underlying parkinsonism in these patients is still debated. The presence of this sonographic finding is consistent with iron deposition. Larger simple size is needed to explore possible differences in nigral echogenicity in PD patients with different genotypes.

Objective: To test whether degeneration of the Locus Coeruleus (LC) is associated with Orthostatic Hypotension (OH) in Parkinson's disease (PD).

Materials and Methods: OH is a common and debilitating non-motor symptom in PD but the mechanisms underlying its development remain largely elusive. Peripheral and central noradrenergic denervation are both likely to play a key role. LC is the main noradrenergic nucleus of the brain and its early degeneration in PD has been put in relation with a variety of non-motor symptoms, including OH, but with inconsistent results. A total of 22 cognitively intact PD patients and 52 age-matched healthy volunteers underwent 3T magnetic resonance (MRI) with neuromelanin-sensitive T1-weighted sequences. For each subject, a template space-based LC-MRI was used to calculate LC signal intensity (LC-contrast ratio) and the estimated number of voxels (LC-Vox) belonging to LC. In a case-control study we compared the LC-MRI parameters in 11 PD patients with OH (PDOH+) versus 11 without OH (PDOH-) (matched for sex, age and disease duration) using one-way analysis of variance followed by multiple comparison tests. We also tested for correlations between subject's LC-MRI features and orthostatic drop in systolic blood pressure (SBP).

Results: PDOH- and PDOH+ did not differ significantly ($p>0.05$) based on demographics and clinical characteristics, except for blood pressure measurements and SCOPA-AUT cardiovascular domain ($p<0.05$). LC-contrast ratio and LC-Vox measures were significantly lower in PD compared to HC, while no differences were observed between PDOH- and PDOH+. Additionally, no correlation was found between the LC-MRI parameters and the orthostatic drop in SBP or the clinical severity of autonomic symptoms ($p>0.05$). Conversely, RBD symptom severity negatively correlated with MRI-LC parameters.

Conclusions: Our results failed to indicate a link between the LC -MRI features and the presence of OH in PD but confirmed a marked alteration of LC signal in PD patients.

## PARA-INFECTIOUS ACUTE CEREBELLITIS IN A YOUNG WOMAN CAUSED BY MYCOPLASMA PNEUMONIAE: A CASE REPORT

M. Passamonti[1], V. Zangaro[1], M. Gaiola[1], M. Gaggiola[1], A. Fattorello Salimbeni[1], G. Sorarù[1], D. Cecchin[2], P. Gallo[1], M. Corbetta[1], A. Salvalaggio[1]

[1]Department Neurosciences, University of Padua (Padova); [2]Department of Medicine DIMED, University of Padua (Padova)

Introduction: Acute cerebellitis occurs more frequently in childhood, however some cases are described in adulthood. The aetiology of acute cerebellitis in adults is often undetermined. It may be associated with medications, infections, para-infectious processes, auto-immune disorders and para-neoplastic syndromes.

Case Report: A 26-year-old North-African woman presented to our Emergency Department complaining for subjective vertigo associated with headache, blurred vision, nausea, diarrhoea and night sweats since three days. Medical history revealed nasal polyposis, allergic asthma, episodic vertigo and an anxiety disorder, not requiring chronic treatments. Neurological examination showed opsoclonus, postural and action tremor. Hence, she was admitted to the Neurology Clinic. During the first hours of hospitalisation she worsened with new onset of dysmetria, gait instability, till inability to keep an upright position. MRI showed bilateral peri-cerebellum leptomeningeal enhancement. Cerebrospinal fluid (CSF) examination revealed an elevated leukocyte count (13.7/microL, 100% lymphocytes) and protein (43 mg/%). Due to the occurrence of fever, acyclovir, ceftriaxone and levofloxacin were started, without a clinical meaningful benefit. Extensive microbiological analysis on blood, cerebrospinal fluids, throat swab, urine and stool did not reveal any pathogen. Blood serology at the admission showed dubious results for Mycoplasma pneumoniae immunoglobulin M (IgM), while immunoglobulin G (IgG) title was negative. Tests for auto-immune antibodies were negative both in plasma and CSF. Total-Body CT and FDG-PET-RM ruled out malignancies or infectious foci. Opsoclonus was investigated with nystagmography. The clinical situation dramatically improved after high-dose steroid treatment (methylprednisolone 1 g/day for 3 days and then de-escalating): firstly, nausea disappeared, and then, opsoclonus and tremor improved. Meanwhile, a follow up MRI showed a partial resolution of the leptomeningeal enhancement. Ten days from the admission, serology tests demonstrate plasmatic IgM for Mycoplasma turned positive (with negative IgG). After a rehabilitation treatment, the patient was discharged. After a 15 days hospitalisation, the neurological examination showed reduced opsoclonus and a low intensity postural and action tremor, with restoration of gait ability.

Discussion: This is a rare case of acute cerebellitis with opsoclonus in an adult woman associated to Mycoplasma Pneumonia acute infection. Patient was responsive to high dose of intravenous steroids. In case of acute onset cerebellitis and/or opsoclonus, mycoplasma pneumonie infection should be ruled out and early treatment started.

Objectives: Motor reserve is defined as the resilience mechanisms of the brain coping with neurodegeneration in idiopathic Parkinson's

Disease (PD). [1] Several different mechanisms have been proposed for motor reserve. However, motor reserve has never been investigated on PD patients with clinical unilateral signs and bilateral binding reduction at dopamine transporter (DAT) imaging using a rigorous neurophysiological method.

Materials: In this cross-sectional case-control study, we included 16 PD patients and 28 healthy control subjects. Patients were included if their motor symptoms and signs were unilateral (Hoehn and Yahr stage =1/5, confirmed by two independent raters) but DAT density (assessed using [123I] Ioflupane SPECT imaging) was significantly reduced in the bilateral putamina (Putamen z-score > 0.5).

Methods: Patients and healthy control subjects were extensively investigated using the Movement Disorder Society-sponsored revision of the Unified Parkinson's Disease Rating Scale (MDS-UPDRS; part III was videorecorded), Hoehn & Yahr (H&Y) stage. Transcranial magnetic stimulation (TMS) was performed on primary motor cortices (M1) in both presymptomatic and symptomatic hemispheres in patients and on dominant hemisphere for HC. TMS testing included cortical excitability and plasticity assessment and the analysis of interhemispheric inhibition (IHI). Data analyzed with paired and unpaired t-test, one-way and two-way repeated measures analyses of variance, multiple regression models, logistic regression. We also used ROC curve to identify a Motor Reserve Coefficient (MRC).

Results: TMS testing revealed asymmetries in corticospinal excitability measures with higher values in the symptomatic hemisphere. Here we also found lower M1 plasticity (compared to the asymptomatic hemisphere). Finally, we found reduced IHI from presymptomatic to symptomatic hemisphere. Interestingly, reduced putamen binding was predicted by reduced ICF in symptomatic hemisphere and by higher plasticity and reduced IHI in presymptomatic hemisphere. Putamen/caudate ratio was directly associated with corticospinal excitability in presymptomatic hemisphere and inversely associated with cortical plasticity in symptomatic hemisphere. MRC distinguished presymptomatic from symptomatic hemisphere (AUC 0.9844). MRC was associated in presymptomatic hemisphere with PAS increment, IHI and corticospinal excitability reduction.

Discussion: Cortical response to nigrostriatal degeneration induced by PD involves a M1-putamen network, sustaining an increased corticospinal excitability, and cortico-M1 connections, responsible for excitability and plasticity changes, depending on caudate activity and becoming more effective with binding reduction in putamen. The balance between these networks results in motor reserve, where cortical plasticity seems to be the main actor.

Conclusion: These new insights on motor reserve networks in PD are essential to develop novel neuromodulation approaches, aimed at reducing motor burden in daily life.

## CLINICAL PRESENTATION OF FACIO-SCAPULO-HUMERAL DYSTROPHY AND PROGRESSIVE SUPRANUCLEAR PALSY OVERLAP

G. F. Patanè, D. Calisi, M. De Rosa, F. Dono, M. Onofrj, M. Russo, S. Sensi

Department of Neuroscience, Imaging and Clinical Sciences, University "G. d'Annunzio" of Chieti-Pescara (Chieti)

Facio-scapulo-humeral dystrophy (FSHD) is a common type of muscular dystrophy characterized by gradual weakness, particularly in the facial and scapular muscles. While individuals with FSHD generally have a relatively long life expectancy, approximately 20% of FSHD patients become reliant on wheelchairs by their fifties. A 60-year-old man, who had been diagnosed with FSHD during his childhood, visited our Movement Disorder outpatient service due to progressive slowness and fatigue. Over the past five years, the patient had experienced a continuous decline in motor function. Initially, his difficulties were attributed solely to his genetic condition. However, concerns arose when his clinical condition worsened significantly, accompanied by the emergence of cognitive and behavioral abnormalities. Neurological examination revealed signs of atypical parkinsonism that had been concealed by FSHD for many years. Specifically, the weakness in his face masked the lack of facial expression (hypomimia), the weakness in his spinal muscles disguised the stooped posture (camptocormia), and the low muscle tone concealed the presence of rigid movements associated with extrapyramidal symptoms. An MRI scan of the brain confirmed a diagnosis of progressive supranuclear palsy (PSP). The symptoms of FSHD can obscure the initial signs of a subsequent neurodegenerative disorder. In cases of FSHD, a late deterioration in motor symptoms should be seen as a warning sign indicating the possible onset of an accompanying neurological condition. The convergence of a neurodegenerative disorder with FSHD significantly impacts the prognosis of the patient and therefore necessitates an early diagnosis to establish appropriate management.

## EARLY-ONSET PARKINSON'S DISEASE IN WOMEN: ROLE OF HORMONAL EXPOSURES

G. Patane'[1], A. Mullan[2], K. Ghoniem[1], C. Piat[1], J. Jacobson[1], R. Savica[1]

[1]Mayo Clinic Department of Neurology, Mayo Clinic College of Medicine & Sciences (Rochester-USA); [2]Mayo Clinic Department of Health Sciences Research, Mayo Clinic College of Medicine & Sciences (Rochester-USA)

Objective: To assess the demographic characteristics and the exogenous/endogenous exposure to estrogen and progesterone related hormones in an incident cohort study from 1991 to 2020 in Olmsted County, Minnesota (USA).

Materials: We used the Mayo Clinic Data Management tool to identify patients with a diagnosis of Early Onset Parkinson's disease. A movement disorder specialist reviewed all medical records to confirm the clinical diagnosis of EOPD, defined as patients with motor symptoms onset between the ages of 21 and 50.

Methods: Medical records of EOPD patients were reviewed to identify their BMI, hormonal exposure, history and features of EOPD.

Results: 87 incident EOPD female patients were identified (90% white, 7% Asian and 3% other/unknown). Median age at motor onset was 43.1 years; the cardinal motor symptoms were tremor (85%), bradykinesia (83%), rigidity (77%) and impaired postural reflex (11%). 28

patients (32%) had a normal BMI (<25), 21 patients (24%) were overweight (BMI 25-30) and 51 patients (44%) were obese (BMI>30). 49 (56%) used hormonal contraception: 32 (54%) ethinyl estradiol and progesterone, 15 (25%) progesterone only and 8 (14%) medicated IUD. The majority of patients had at least one pregnancy (84%): with a median number of 3 pregnancies and 2 deliveries after full term pregnancy, whereas 29% had at least one miscarriage. Menopause had occurred in 63% of the patients (75% patients non-provoked menopause and 24% surgical menopause), with a median age of menopause of 47.6 years; only 10% were menopausal before the onset of EOPD.

Conclusions: Our study reports a high frequency of obesity and exogenous hormonal exposure in female patients with EOPD. The role of exogenous hormones and obesity-correlated hyperestrogenism on the pathogenesis of PD is still controversial, while is unexplored in EOPD. Further studies are needed to address the causality of such observations.

## ARM SWING REDUCTION IN PARKINSON DISEASE: A STUDY WITH A NETWORK OF WEARABLE SENSORS

M. Patera[1], A. Zampogna[1], L. Pietrosanti[2], A. Calado[2], A. Pisani[3], F. Fattapposta[1], C. Verrelli[2], V. Rosati[4], F. Giannini[2], G. Saggio[2], A. Suppa[1]

[1]Department of Human Neurosciences, Sapienza University of Rome (Roma); [2]Department of Electronic Engineering, University of Rome Tor Vergata (Roma); [3]Department of Brain and Behavioral Sciences, University of Pavia (Pavia); [4]A.O.U. Policlinico Umberto I (Roma)

Objective: Patients with Parkinson 's disease (PD) commonly manifest arm swing reduction during gait [1]. Previous kinematic studies performed in a laboratory setting using traditional gait analysis have shown decreased arm swing range, amplitude, and velocity in PD compared with controls. The pathophysiology of arm swing abnormalities in PD is still under debate since it is thought to reflect bradykinesia as well as limitation of articular range of motion secondary to upper limb rigidity [2][3]. The present study aims to examine arm swings in PD patients while performing the timed-up and go (TUG) test, in an ecological experimental setting, using a network of wearable sensors. A second aim of the study is to correlate the collected instrumental measures with specific UPDRS subitems for bradykinesia, rigidity, and tremor.

Materials & Methods: We recruited a total of 44 PD patients in the early stage of the disease (H&Y<2) and never exposed to L-Dopa (drug-naïve) and 31 age-matched healthy controls. We performed a novel frequency-based analysis of arm swings during gait extracting data by a network of wearable sensors. The collected data were FFT transformed, and the frequency content was further analyzed. The Spearman's test was used to assess possible correlation among specific harmonic features and clinical scores for bradykinesia, rigidity, and tremor.

Results: The kinematic analysis demonstrated that arm-swing reduction in PD patients can be objectively described in terms of decreased amplitude of all harmonics extracted from upper limb movements. Specific kinematic features highly correlated with rigidity and, in a lesser extent, with bradykinesia; there was no significant correlation with upper limb tremor.

Discussion & Conclusions: The kinematic analysis based on our wearable sensors network allowed us to demonstrate arm-swing reduction objectively during gait in patients with PD while performing a TUG test in an ecological experimental setting. Our findings also suggest that reduced arm swings in PD more likely reflect the severity of rigidity rather than bradykinesia in the upper limb. The findings overall gain new insights into the pathophysiology of abnormal arm swings in PD.

## EARLY ONSET PARKINSONISM, PHYSIOPATHOLOGY THEORY AND THERAPY

A. Pavone[1], F. Fichera[2], A. Antonini[3]

[1]Department of Neurology, Garibaldi Nesima Hospital (Catania); [2]Department of Neurology, University Vita e Salute, San Raffaele (Milano); [3]Department of Neuroscience, University of Padova (Padova)

Introduction: Parkinson disease (PD) is a progressive neurodegenerative disorder characterized by loss of nigrostriatal dopaminergic neurons and it manifests at variable age. Early onset (< 50 yrs) PD is frequently associated with genetic mutations.

Description: Genetic mutations are common in PD especially in the Mediterranean including Sicily and some have a documented pathogenetic role. Those most relevant in early onset PD are Parkin (PARK-2) and PINK1 (PARK-6) both causing autosomal recessive forms characterized by greater prevalence of dystonia, sleep disorders, common motor and psychiatric complications. Heterozygous carriers (only one altered allele) may present a greater risk of disease stressing the importance of genetic counselling. Parkin is a protein of 465 amino acids, expressed in different tissues and at neuronal level in cell body and presynaptic nerve terminals. Parkin is involved in the transcription and replication of mitochondrial DNA, its over expression prevents mitochondrial swelling and stress-induced apoptosis. Where the action of Parkin fails, there is an increase in intracellular levels of $Ca^{2+}$, which is responsible for cell death. In addition, it activates the process of mitophagy. PINK1 is a protein of 581 highly conserved amino acids. Under physiological conditions the high membrane potential of healthy mitochondria is exploited to import PINK1 into the inner membrane, where it will be cut by PARL (presenilin-associated rhomboid like), the protein is then exported to the cytoplasm and will undergo degradation. As a result of a toxic insult and membrane potential variation, internalization does not occur and the protein accumulates on the outer membrane of damaged mitochondria, where it serves as a signal for the recruitment of Parkin and the initiation of the mitophagy process.

Therapy: Therapy in early onset genetic PD considers the use of levodopa possibly in combination with MAO-B (rasagiline, safinamide) and COMT (opicapone and entacapone) inhibitors and should include deep brain stimulation therapy and infusion treatments both providing excellent benefit.

Conclusion:

- Early and late onset PD differ in symptomatology and progression of the disease between.
- Early onset PD has often a genetic cause, mutations alter mitochondrial function and do not cause aggregates of oligomers of phosphorylated synuclein
- Therapy should be optimized early given the risk of motor and psychiatric complications

## ARE DIETARY COMPONENTS POTENTIAL RISK/PROTECTIVE FACTORS OF PARKINSON'S DISEASE?

R. Pellicciari[1], S. Altomare[2], M. Costanzo[3], C. Cutrona[3], A. Fabbrini[4], S. Pietracupa[3], M. De Bartolo[3], T. Giloni[3], N. Modugno[3], F. Magrinelli[5], C. Dallocchio[6], T. Ercoli[7], A. Nicoletti[8], M. Zappia[8], P. Solla[7], G. Iliceto[1], G. Fabbrini[3,4], M. Tinazzi[5], A. Conte[3,4], A. Berardelli[3,4], G. Defazio[1], D. Belvisi[3,4]

[1]Department of Basic Medical Sciences, Neuroscience and Sense Organs "Aldo Moro", University of Bari (Bari); [2]Neurology Unit, Ospedale Dimiccoli, ASL BT (Barletta); [3]Department of Neurology, IRCCS Neuromed (Pozzilli-IS); [4]Department of Human Neurosciences, Sapienza University of Rome (Roma); [5]Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona (Verona); [6]Neurolgy Unit, ASST Pavia, Ospedale Civile (Voghera-PV); [7]Department of Medical Sciences and Public Health, University of Cagliari (Monserrato-CA); [8]Department G.F. Ingrassia, Neuroscience Section University of Catania (Catania)

Aim of the study: Parkinson's disease (PD) is a multifactorial disease. Previous studies identified several modifiable risk and protective factors for developing PD. Among possible modifiable factors, dietary components may play a relevant role but the relationship between PD risk and diet factors/patters is still poorly understood. The aim of this multicentric case-control study was to investigate the potential influence of dietary components and patterns on PD development in a large sample of patients.

Materials: Six hundred and ninety-four case patients were recruited from among consecutive outpatients with PD who attended six Italian Movement Disorders Centers. PD was diagnosed by neurologists who were experts in movement disorders according to published standard criteria. Six hundred twelve healthy controls were enrolled among the relatives of neurologic outpatients without PD who visited participating outpatient neurology departments during the study period. Healthy controls were frequency-matched to cases by 5-year age stratum, sex, and referral center.

Methods: Dietary factors were explored using a validated 77-item food-frequency questionnaire. The questionnaire was administered in person by a medical interviewer in each centre. Cases and controls were asked to specify the side of the portion of each food and the frequency of consumption. Age-, sex- and referral center-adjusted multivariate logistic regression models were used to investigate possible associations between the risk of PD and the 77 dietary components examined. Factor analysis was used to examine possible relationship between PD risk and diet patterns.

Results: The multivariate logistic regression models showed that eight dietary factors had an independent positive association with PD. These included pizza, prosciutto, artichoke, cruciferae, biscuits, chocolate snacks, sugar and soft drinks. Five factors were inversely associated with PD development and included whole wheat bread, raw carrots, citrus fruits, coffee and beer. The factor analysis identified two diet patterns. The first one ("Western pattern") included meat, sweets, pasta, pizza and potatoes and was positively associated with PD risk. The second one ("Prudent pattern") included vegetables and fruits and there was a trend for an inverse association with PD risk.

Discussion: Our findings demonstrated a relationship between PD risk and dietary components and patterns. This relationship may depend on the ability of different foods to influence the "gut-brain axis" that is thought to play a pivotal role in PD development.

Conclusions: Dietary factors may influence PD risk. Future strategies aimed at preventing PD development should take into account diet components among the modifiable risk/protective factors.

## COGNITIVE AND AFFETTIVE THEORY OF MIND IN PATIENTS WITH FUNCTIONAL MOVEMENT DISORDERS

M. Petracca[1], S. Di Tella[2], P. Zinzi[3], I. Anzuino[2], M. Lo Monaco[4], P. Calabresi[5], A. Bentivoglio[1], M. Silveri[2]

[1]Movement Disorders Unit, Fondazione Policlinico Universitario 'Agostino Gemelli' IRCCS (Roma); [2]Department of Psychology, Università Cattolica del Sacro Cuore (Milano); [3]Movement Disorders Unit &Clinical Psychology Unit, Fondazione Policlinico Universitario 'Agostino Gemelli' IRCCS (Roma); [4]Center for the Medicine of Aging, Fondazione Policlinico Universitario 'Agostino Gemelli' IRCCS (Roma); [5]Institute of Neurology, Università Cattolica del Sacro Cuore (Roma)

Background and Aims: Functional movement disorders (FMD) are a heterogeneous group of abnormal motor manifestations, alterable by attention or distracting maneuvers, not attributable to a known neurologic disease. It has been recognized that psychosocial and affective-emotional factors play a role in FMD, at least as risk factors. Silveri et al. reported disorders of Theory of Mind (ToM) in FMD [1]. ToM is the ability to predict others behavior by inference of their mental states. The affective component is responsible for understanding others' emotions, while the cognitive component is related to the knowledge of others' mental states, beliefs, thoughts, and intentions [2]. The aim of this study was two-fold: 1) to confirm whether FMD might be related to ToM disorders and 2) to explore the relationship between ToM abilities and neuropsychiatric and behavioral dimensions.

Materials and Method: Eighteen Italian-speaking FMD subjects underwent the Yoni task to assess ToM affective and cognitive dimensions, balanced for level of difficulty (first and second order). This computerized task also contains control items (Physical) [3]. Patients were also administered several questionnaires for measuring depression (BDI-II), anxiety (BAI), dissociative experiences (DES-II), alexithymia (TAS-20), pain (BPI), health-related quality of life (SF-12), and fatigue (MFI-20). The severity of symptoms was rated by the Simplified-FMD Rating Scale (S-FMDRS).

Results: No differences emerged in the Yoni task accuracy between cognitive, affective, and physical condition on the first-order items ($p>0.1$). However, a significant between-condition difference emerged on the second-order items ($p<0.001$); in particular, pairwise comparisons revealed that FMD subjects scored worse on the cognitive and affective items than the control items ($ps\leq0.001$). Accuracy on the second-order ToM items was negatively correlated with anxiety (Spearman's rho=-0.587, p=0.005), the TAS-20 subscore "difficulty describing feelings" (Spearman's rho=-0.465, p=0.026) and MFI-20 fatigue global score (Spearman's rho=-0.436, p=0.035) and mental score (Spearman's rho=-0.446, p=0.032).

Discussion: The results are consistent with the hypothesis that a ToM disorder might underlie FMD. The Yoni task showed the decay of the more complex ToM inferences both cognitive and affective second-order levels of reasoning. The first level of cognitive and affective ToM

seemed to be preserved. Moreover, these data contribute to highlight the relationship between disorders of social cognition and emotion regulation.

Conclusions: FMD could represent an experimental model to explore the overlap between organic and non-organic illness and help clinicians to reconsider some of the symptoms that are present in patients with neurological disorder.

Objectives: Nigrostriatal dopaminergic alterations in iRBD have been associated with a higher risk of phenoconversion to α-synucleinopathies [1]. However, in a very early phase iRBD patients often result negative at DAT-SPECT imaging. Thus, we aimed to i) evaluate striatal and extra-striatal dopamine binding characterizing iRBD and ii) test the ability of extra-striatal dopamine alterations in predicting phenoconversion.

Materials: In this multicenter study, consecutive polysomnography-confirmed iRBD (n=50), drug-naïve PD (n=50) and age-matched control (n=50) underwent a standardized neurological examination and dopaminergic imaging with 123I-FP-CIT Brain SPECT. iRBD subjects were further classified in RBD-DAT- (n=36), and RBD-DAT+ (n=14) according to visual rating assessment. For all iRBD patients, we collected conversion to clinical diagnosis at follow-up (mean time= 3.16 years).

Methods: Between-groups differences in 123I-FP-CIT striatal and extra-striatal binding were evaluated both with ROI-based and voxel-wise analyses - in age, sex, and center adjusted models. An ANCOVA model- adjusted for age, sex, center, and DAT-SPECT positivity at baseline- was applied to test demographic and dopaminergic differences between iRBD converters and stable over time. Cox regression analysis was used to assess the ability of extra-striatal alterations characterizing iRBD to predict longitudinal clinical progression over follow-up time – adjusting for DAT-SPECT positivity at baseline.

Results: Both ROI-based and voxel-wise analyses showed an early involvement of the left insula in RBD-DAT- with an additional impairment in nigrostriatal regions extending from RBD-DAT+ to PD conditions. In the whole iRBD sample, insular binding was lower in those who converted to α-synucleinopathies over time. A lower insular binding was significantly associated with a greater conversion to α-synucleinopathies with a hazard risk ratio of 3.64 [C.I. 95% 1.22-10.89].

Discussion: Insular dopaminergic deficits are an early signature of iRBD, even before DAT-SPECT positivity according to cut-off used in clinical practice. Moreover, insular alterations are associated with a greater risk of conversion to α-synucleinopathies over time - therefore being a promising biomarker of progression.

Conclusions: Together, these results suggest insular dopaminergic deficits as core features of iRBD, even before the nigrostriatal deficits and motor impairment.

## DETECTION OF FATIGUE IN PARKINSON'S DISEASE PATIENTS AND CORRELATION WITH OLFACTORY AND COGNITIVE IMPAIRMENT, APATHY AND NON-MOTOR SYMPTOMS

F. Pinna[1], C. Cara[2], V. Floris[1], S. Othmani[1], P. Chessa[1], P. Zara[1], A. Masia[1], M. Usai[1], R. Meloni[1], C. Bagella[3], C. Frau[3], C. Masala[4], P. Solla[5]

Objective: Although fatigue represents a frequent non-motor symptom in patients affected by Parkinson's disease (PD), correlations with motor and other non-motor symptoms are often underevaluated. Our aim was to identify the presence of fatigue in PD patients, and subsequently to analyze the correlations between fatigue and apathy, olfactory and cognitive impairment, and motor symptoms.

Materials and Methods: One hundred and seventy-three PD patients (105 males/68 females) were enrolled. Mean age ± standard deviation at enrollment was 70.1± 9.1 years. Participants with PD were recruited during regular out-patient follow-up visits. PD was diagnosed according to the Postuma criteria [1]. Fatigue was evaluated by the PD Fatigue Scale (PFS) with the score of 3.3 considered the cut-off [2]. Motor impairment in PD patients was assessed using the Modified Hoehn and Yahr Scale and the Unified PD Rating Scale (UPDRS) part III. Montreal Cognitive Assessment (MoCA) was used for cognitive evaluation. Olfactory impairment was examined using the "Sniffin' Sticks" test. Apathy was evaluated by the self-report version of the Starkstein Apathy Scale.

Results: Using the PFS cut-off score of 3.30, 68 PD patients with PD (39.3%) were considered affected by fatigue. Multivariate linear regression analyses analyzing motor and non-motor features showed that both apathy ($p<0.001$) and UPDRS part III ($p<0.002$) were the strongest predictors related to the severity of fatigue.

Discussion and Conclusions: In our study, we confirm as fatigue represents a frequent condition among parkinsonian patients. Our findings highlighted the fact that fatigue in PD patients may arise from the convergence of both motor and non-motor disturbances.

## DISTINCT STRIATAL CONNECTIVITY PATTERNS IN PATIENTS WITH PARKINSON'S DISEASE WITH AND WITHOUT URINARY SYMPTOMS

N. Piramide, R. De Micco, F. Di Nardo, M. Siciliano, G. Caiazzo, G. Tedeschi, F. Esposito, A. Tessitore

Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli" (Napoli)

Objectives: To investigate the possible association of urinary symptoms with whole-brain functional connectivity (FC) alterations from distinct regions-of-interest (ROI) of the striatum in a large cohort of drug-naïve Parkinson's disease (PD) patients applying a seed-based analysis approach to resting-state functional MRI data.

Materials: Seventy-nine drug-naive PD patients (45 PD-urinary+/34 PD-urinary-) and 38 healthy controls (HC) were consecutively enrolled.

Methods: Motor, nonmotor and cognitive assessments were performed. Using an a priori connectivity-based domain-specific parcellation, we obtained three ROIs for different striatal functional subregions, sensorimotor, limbic, and cognitive, from which seed-based FC voxelwise analyses were conducted over the whole brain. Clinical data were also correlated with imaging findings.

Results: No demographical/clinical differences were found between patients' subgroups. In PD-urinary+ compared to PD-urinary- patients the sensorimotor ROIs showed increased FC with the right premotor area, supplementary motory area and primary motor area, and decreased FC with the right angular gyrus; the limbic ROI showed increased FC with the left anterior prefrontal cortex (aPFC). In PD-urinary+ patients compared to HC, the sensorimotor ROI showed increased FC with the bilateral fusiform gyri; the limbic ROI showed increased FC with the right superior temporal gyrus, and decreased FC with left insula, left anterior cingulate cortex and right aPFC; the right cognitive ROI showed increased FC with the left insula. In PD-urinary- compared with HC, the sensorimotor ROI showed decreased FC with the bilateral substantia nigra; the limbic ROI showed decreased FC with the bilateral aPFC. Correlation analysis showed that FC alterations between striatal subregions and fronto-parietal areas correlated with motor/cognitive outcomes in PD-urinary+.

Discussion: We found specific FC changes potentially associated with urinary dysfunction in PD: ) increased FC between striatal regions and insula/anterior dorsolateral PFC, aiming at inhibiting the urinary urge while in social context; ii) increased FC between striatal regions and motor and premotor/supplementary motor areas as an attempt to recruit the pelvic floor muscles and overcome urinary frequency and urgency to delay micturition; iii) decreased FC between striatal regions and parietal, insular and cingulate cortices as an early biomarker for altered autonomic and behavioral sensorimotor integration of the timing of voiding; iv) increased FC between striatal regions and temporo-occipital areas as a compensatory mechanism for altered sensorimotor control.

Conclusions: Our findings revealed that a specific pattern of striatal FC may be associated to altered stimuli perception and sensorimotor integration in PD patients. These results may potentially help clinicians to design tailored rehabilitation programs.

## PROGRESSIVE IMMUNE-MEDIATED CEREBELLAR ATAXIA IN A PATIENT WITH PRIMARY SJÖGREN'S SYNDROME AND CONCOMITANT HASHIMOTO ENCEPHALOPATHY: A CASE REPORT

F. Pirone[1], G. Franco[2], F. Arienti[2], A. Di Maio[1], G. Lazzeri[2], E. Monfrini[2], I. Trezzi[2], A. B. Di Fonzo[1]

[1]Neurology Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan (Milano); [2]Neurology Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico (Milano)

Objective: To describe a patient with progressive cerebellar ataxia with Primary Sjögren's Syndrome (PSS) and concomitant Hashimoto encephalopathy.

Case report: A 68-year-old Iranian woman with a history of breast cancer without relapses after surgery. In the last year, she developed a progressive cerebellar syndrome. She also reported outbursts of uncontrolled crying, impulsivity, and dry mouth. The neurological examination was remarkable for the presence of mild dysarthria, gait ataxia, and behavioral abnormalities. A neuropsychological assessment was performed, which revealed a dysexecutive syndrome. Brain MRI documented cerebellar atrophy which was more severe in the vermis. Cancer screening (paraneoplastic autoantibodies and whole-body PET/CT) was negative. Anti-nuclear antibodies (ANA 1/1280 with speckled granular pattern), antibodies against Extractable Nuclear Antigen (ENA anti-Ro 60 and 52), anti-thyroid peroxidase (TPO) and anti-thyroglobulin (TG) antibodies were detected in the blood. The Schirmer test was positive. The Cerebrospinal Fluid (CSF) showed mild protein elevation and the presence of oligoclonal bands with pattern IV. A diagnosis of Sjogren's Syndrome was made according to the 2016 ACR-EULAR classification criteria. The neurocognitive impairment and the presence of anti-thyroid antibodies make also possible the diagnosis of Hashimoto encephalopathy. The patient was treated with methylprednisolone 1 g daily for 5 days with a slight improvement of cerebellar ataxia and impulsivity.

Discussion: This is a case of progressive cerebellar ataxia in a patient with PSS and concomitant Hashimoto encephalopathy. Neurological involvement in PSS is a common extra glandular manifestation but cerebellar involvement is rare and the pathophysiology is still unclear. The prevalence is 1.5%, with a high female-to-male ratio, a mean age at onset from fifth to sixth decade, a detection of anti-Ro positivity and evidence of mild cerebellar atrophy. [1] Most of the cases reported so far show mild protein elevation and the presence of oligoclonal bands in the CSF, suggesting an active role of autoantibodies in CNS damage. [2] Because of the concomitant presence of HE, the cerebellar involvement in this case cannot be attributed with certainty to either autoimmune disease. Despite this, high-dose glucocorticoid therapy, prescribed as the initial treatment or during neurological exacerbations, remains the first-line therapy. Corticosteroid-sparing immunosuppressive therapy might be indicated in those cases with a progressive course. [3]

Conclusion: Primary Sjögren's Syndrome and Hashimoto encephalopathy are rare but potentially treatable causes of progressive cerebellar syndrome. Early diagnosis is of paramount importance to start timely a specific therapy and stop the CNS damage.

## GENDER DISPARITY IN ACCESS TO ADVANCED THERAPIES FOR PATIENTS WITH PARKINSON'S DISEASE

F. Pistoia[1], G. Saporito[1], C. Rizi[1], F. Bruno[2], A. Catalucci[2], A. Splendiani[1], A. Ricci[3], C. Marini[4], P. Sucapane[4]

[1]Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila (L'Aquila); [2]Neuroradiology and Interventional Radiology, San Salvatore Hospital (L'Aquila); [3]Neurosurgery, San Salvatore Hospital (L'Aquila); [4]Neurological Unit, San Salvatore Hospital (L'Aquila)

Objective: The objective of this study was to investigate the presence of any gender disparity in the access to advanced therapies for patients with Parkinson's disease (PD).

Materials and Methods: All patients consecutively referring to the Parkinson's and Movement Disorder Center of L'Aquila from April 2011 to May 2023, and screened for the possible access to advanced therapies for PD, were investigated. All clinical data were retrospectively reviewed, with attention being paid to anagraphical and clinical data of patients finally undergoing advanced therapies.

Results: 626 medical records were reviewed (mean age±SD 73.3±9.9; 67% males). Out of them, 172 patients (mean age±SD 70.0±10.0; 73% males; median Hoen Yahr level: 3, minimum 1 maximum 5) were considered clinically eligible for advanced therapies. Specifically, 133 were considered eligible for MRI Guided Focused Ultrasound Thalamotomy (mean age±SD 70.0±8.9; 77% males), 25 patients for Levodopa/carbidopa intestinal gel (LCIG) infusion (mean age±SD 71.2±6.3; 56% males), 12 for Deep Brain Stimulation (DBS) (mean age±SD 71.2±6.3; 75% males), and 2 for subcutaneous apomorphine (mean age±SD 63.5±0.7; 50% males). With respect to MRgFUS, 95 patients already underwent the procedure (mean age±SD 70.4±9.6; 73% males), while 38 patients are still waiting for the treatment (mean age±SD 68.9±9.2). No sex differences were found in all groups in relation to age (MRgFUS group: males vs females 70.2±8.9 vs 70.8±8.9, p 0.809; LCIG group: males vs females 71.8±4.6 vs 70.5±8.21, p 0.234; DBS group: males vs females 77.2±8.1 Vs 67.3±8.6, p 0.843) and disease duration (MRgFUS group: males vs females 8.3±4.4 vs 9.6±6.7, p 0.419; LCIG group males vs females 11.5±3.8 vs 15.4±5.4; p 0.154; DBS group: males vs females 15.0±9.62 Vs 15.50±7.78, p 0.796). In the whole group, a higher mean Levodopa equivalent daily dose (LEDD) was reported in men (mean LEDD±SD 551± 356 mg) then in women (mean LEDD±SD 456± 278 mg), although the difference was not statistically significant (p 0.215).

Discussion: To date, no data are available about the different access among sexes to advanced therapies for PD. The higher prevalence of PD in men than in women explains only in part the reported management gender disparity that is higher than that expected.

Conclusions: Motor fluctuations and dyskinesias, that are the main indications for advanced therapies, are more frequent in women that in men. Therefore, the above gender disparity deserves further investigation to identify the factors accounting for the discrepancy in the access to advanced therapies.

## POST-COVID PARKINSONISM: A SYSTEMATIC REVIEW OF CLINICAL PRESENTATIONS

P. Polverino, T. Desantis, A. Cocco, S. Lalli, A. Albanese

Department of Neurology, IRCCS Humanitas Research Hospital (Rozzano-MI)

Objectives: Among neurological manifestations associated to Covid-19, few cases of parkinsonism with a close temporal relationship with SARS-CoV-2 infection have been reported. The objective of this review is to provide a critical appraisal of all the reported COVID-19-related cases of parkinsonism. We assessed the quality of reporting and propose a phenomenological and diagnostic classification based on clinical features and current diagnostic criteria.

Materials and Methods: A comprehensive PubMed search was conducted for cases of parkinsonism occurring in temporal connection with Covid-19 published until May 2023. The methodological quality of reports was assessed by two independent reviewers, applying a tool assessing different domains. Parkinson's disease was diagnosed based on MDS criteria for clinically established early PD and multiple system atrophy according to consensus MDS criteria. Reports were grouped into consistent phenomenological sets.

Results: The search strategy identified 25 cases of parkinsonism following a confirmed SARS-CoV-2 infection. Quality was rated low in 12 cases (48%), moderate in 11 (44%), high in the remaining two cases (8%). Cases were grouped into four consistent categories according to phenomenology. Eleven patients matched criteria for clinically established early PD or clinically probable PD, 1 for clinically probable MSA. Five cases were assessed as acquired parkinsonism, while eight remained unclassified.

Discussion: We found a moderate or low overall quality in most of the reviewed reports. Adherence to CARE checklist was insufficient in most cases highlighting the need for a systematic approach of data collection and reporting. We identified four main clinical categories notwithstanding a certain degree of heterogeneity. The putative role of Covid-19 in causing or accelerating a preexisting neurodegenerative condition have been previously discussed, but these hypotheses are not supported by robust evidence. These include: direct CNS invasion; hypoxic damage, neuroinflammation or immune-mediated events. Evidence of a direct pathogenic connection between SARS-CoV-2 infection and parkinsonism was lacking in all cases, raising

the question whether Covid-19 was indeed the cause or was instead a coincidental occurrence. SARS-CoV-2 infection may otherwise have acted as an environmental trigger to facilitate onset or progression of parkinsonism.

Conclusions: Whether parkinsonian syndromes may occur following Covid-19 infection remains a yet unexplored possibility. High quality reports fulfilling CARE guidelines are therefore crucial in order to extend evidence derived from single observation to clinical care. Prospective cohort studies collecting patients affected by Covid-19 are needed to observe the real impact of Covid-19 on a potential rise in parkinsonism cases.

## RESTLESS LEG SYNDROME AND PRIMARY HYPERPARATHYROIDISM: AN INTRIGUING RELATIONSHIP

V. Pozzilli[1], S. Toro[1], A. Magliozzi[1], A. Palermo[2], A. Naciu[2], G. Tabacco[2], V. Di Lazzaro[1], M. Marano[1]

[1]Unit of Neurology, Neurophysiology and Neurobiology, Campus Biomedico University (Roma); [2]Unit of Metabolic Bone and Thyroid Disorders, Campus Biomedico University (Roma)

Objectives: Restless leg syndrome (RLS) is an invalidating neurological disorder with a complex and still largely unknown pathophysiology. RLS may be observed in Parkinson's disease (PD) and in renal failure, but idiopathic cases are also common. Few reports and small studies associated RLS with parathyroid metabolism. Herein, we aim to analyze a cohort of patients affected by primary hyper and hypoparathyroidism, investigate the prevalence of RLS, and the associated risk factors.

Materials: A total of 94 patients, 57 affected by primary hyperparathyroidism and 37 by iatrogenic hypoparathyroidism were consecutively recruited. Patients affected by peripheral neuropathy, iron deficiency, PD, and rheumatological disorders were excluded.
Methods: All patients underwent neurological examination, the Revised IRLSSG diagnostic criteria for RLS were administered, and if the diagnosis was met, the RLS severity scale was dispensed. Retrospective records including baseline serum levels of parathyroid hormone (PTH), calcium, phosphorus, 25-OH-vitamin D, and creatinine, but also data on parathyroidectomy, renal lithiasis, bone fractures, T-scores, and the presence of osteoporosis were collected.

Results: RLS was diagnosed in 14 patients with hyper PTH (32%) compared to 3 patients with hypoPTH (8%) (p=0.04). The mean score severity of RLS was 16 (0-27) which is defined as moderate. Out of 11 patients with hyper PTH and RLS that had undergone parathyroidectomy, 8 of them reported improvement of RLS symptoms after the procedure. Patients with hyper PTH who had undergone surgery had a higher prevalence of RLS compared to those who did not undergo the procedure (p=0.036). PTH and calcium levels were higher in patients with RLS than those without, the latter showing the strongest correlation.

Conclusion: Our study shows that primary hyperparathyroidism is associated with the presence of RLS. Their relationship may be in part related to electrolyte imbalance. Patients with hyper PTH and who have undergone therapeutical parathyroidectomy have a higher prevalence of RLS, implicating a more severe disease at baseline. Surgery however alleviated but did not completely resolve RLS symptoms. Possibly hyper PTH, via renal, intestine, and bone reabsorption with the release of calcium levels in the blood, may act on the central nervous system (together with the hormone itself) by facilitating the nociceptive processing through the neuroendocrine system, a result which should be further investigated.

## NEUROIMAGING CORRELATES OF POSTURAL INSTABILITY IN PARKINSON'S DISEASE

A. Quattrone[1], C. Calomino[2], A. Sarica[2], M. Caligiuri[2], M. Bianco[2], B. Vescio[3], J. Buonocore[1], M. De Maria[2], M. Vaccaro[2], A. Quattrone[2]

[1]Institute of Neurology, Department of Medical and Surgical Sciences, University Magna Graecia of Catanzaro (Catanzaro); [2]Neuroscience Research Center, Department of Medical and Surgical Sciences, University "Magna Graecia" (Catanzaro); [3]Biotecnomed S.C.aR.L. (Catanzaro)

Objective: Neuroimaging correlates of postural instability (PI) in Parkinson's disease (PD) are largely unknown [1-2]. In this study, we aimed to identify the brain structures associated with PI in PD patients, using different MRI approaches.

Methods: One-hundred and forty-two patients with PD and 45 control subjects were enrolled in the study. PI was assessed using the MDS-UPDRS-III pull-test item (PT) [3]. A whole-brain regression analysis identified brain areas where grey matter (GM) volume correlated with the PT score in PD patients. Voxel-based morphometry (VBM) and Tract-Based Spatial Statistics (TBSS) were also used to compare unsteady (PT=1) and steady (PT=0) PD patients. Associations between GM volume in regions of interest (ROI) and several clinical features were then investigated using a multivariate regression analysis.

Results: PI was present in 44.4% of PD patients. The whole-brain approach identified the bilateral inferior frontal gyrus (IFG) and superior temporal gyrus (STG) as the only regions associated with the presence of postural instability. VBM showed reduced GM volume in fronto-temporal areas (superior, middle, medial and inferior frontal gyrus, and STG) in unsteady compared with steady PD patients, and GM volume in these regions was significantly associated with the PT score after correcting for confounding factors.

Conclusions: This study demonstrates a significant atrophy of the IFG and STG in unsteady PD patients, suggesting that these brain areas may play a role in the pathophysiological mechanisms underlying postural instability in PD. This result paves the way for further studies on postural instability in parkinsonism.

## MOTOR OUTCOMES AND POSSIBLE PREDICTIVE FACTORS FOR DIRECTIONAL DEEP BRAIN STIMULATION

L. Rigon[1], F. Bove[2], D. Genovese[2], A. De Biase[2], A. Bentivoglio[1], P. Calabresi[1], C. Piano[2]

[1]Neurology, Università Cattolica del Sacro Cuore (Roma);[2]Neurology, Fondazione Policlinico Agostino Gemelli IRCCS (Roma)

Background and Aim of the Study: Deep Brain Stimulation (DBS) is a well-established therapeutic approach for patients with advanced Parkinson's disease. Directional stimulation (DS) extended the therapeutic window by increasing the side effects threshold and minimizing the impact of suboptimal lead placement as compared to conventional stimulation (CS)3, although its superiority in motor outcomes is still debated. We aimed to assess possible predictive factors for DS use and its motor outcomes as compared to CS.

Methods: Patients with DBS implant compatible with DS with at least six-months follow-up were included. Subjects were divided into two subgroups (DS vs CS), according to the stimulation settings at the latest follow-up. Motor outcomes were compared between the two groups. Predictive factors for the use of DS were evaluated.

Results: A total of 42 patients were included. At the latest follow-up, DS and CS subgroups showed the same population (21 subjects each). DS seemed to achieve better, although not significantly superior, motor outcomes, in particular in the stimulation-induced improvement of the Unified Parkinson's Disease Rating Scale (UPDRS) III in off-medication state (DS 31% vs CS 24%, p=0,9) and in the reduction of the Levodopa Equivalent Daily Dose (LEDD) (DS 47% vs CS 40%, p=0,6). Moreover, UPDRS scores in items evaluating axial symptoms decreased significantly after DS (6,9 vs 4,3, p=0,01). Such improvement seemed to be more prominent in the DS group as compared to CS, although statistical significance was not achieved (DS 37,1% vs CS 12,8%, p=0,8). Among those considered at baseline (demographic variables, disease duration, motor phenotype, Hoehn & Yahr stage, LEDD, motor impairment, axial symptoms, improvement after levodopa challenge), no clear predictive factor for DS use was highlighted.

Conclusions: In our study DS seemed to achieve better motor outcomes as compared to CS, although such trend resulted not statistically significant, possibly due to the limited sample size and short follow-up period. In particular, a significant improvement in axial symptoms was obtained with DS, whereas it was not reached with CS. No clinical feature at baseline correlated with future DS use, again possibly due to limited numerosity. Larger study samples and longer follow-up periods are needed to elucidate whether DS, along with the renown milder side effects, achieves better motor outcomes as compared to CS.

## EFFICACY AND STABILITY OF TREATMENT WITH MAO-B AND COMT-INHIBITORS IN PATIENTS WITH PARKINSON'S DISEASE AND MOTOR FLUCTUATIONS: A RETROSPECTIVE STUDY

D. Rinaldi, E. Bianchini, S. Galli, L. De Carolis, M. Alborghetti, F. Pontieri

NESMOS, Sapienza University of Rome (Roma)

Objective: To compare the efficacy and stability of three add-on options (safinamide (SF), rasagiline (RS), and opicapone (OP)) for treating Parkinson's disease (PD) patients with motor fluctuations.

Methods: Data were retrospectively collected from PD patients at Sant'Andrea Hospital from January 2012 to January 2022. Patients had at least 12 months of observation. The primary objective was to determine differences in treatment stability, in terms of months without pharmacological changing, among the add-on options.

Results: Data from 61 subjects (78 observations in total) were analyzed. Baseline characteristics did not significantly differ among the groups. Therapy stability duration (months) did not differ significantly (p=0.595). However, patients on OP therapy had higher LEDD values (p=0.009) and were younger (p=0.042) than those on RS therapy. RS therapy had a higher discontinuation rate (45%) compared to SF therapy (p=0.015). RS patients more frequently switched MAO inhibitors (p=0.003), while SF patients often replaced a previous MAO inhibitor (p=0.001).

Discussion: Therapy stability did not significantly differ among the add-on options. Differences in LEDD and age at add-on starting suggest variations in patient characteristics and treatment strategies.

Conclusion: RS, SF, and OP are valid, effective, and well-tolerated add-ons with similar therapy stability. OP is commonly used in patients with MAO inhibitors, while SF is preferred as a first-line add-on for initial motor fluctuations. Add-on therapy choice currently relies on individual patient evaluation for personalized medicine. Further studies are needed to validate these findings.

## CEREBELLAR CHANGES ON MR SPECTROSCOPY IN HEREDITARY SPASTIC PARAPARESIS

G. Rizzo[1], S. Evangelisti[2], C. Bianchini[2], G. Vornetti[2], V. Donadio[3], L. Morandi[2], F. Palombo[3], L. Guidi[3], C. Testa[4], V. Carelli[2], R. Lodi[2], R. Liguori[2], C. Tonon[2]

[1]IRCCS Istituto delle Scienze Neurologiche di Bologna (Bologna); [2]Department of Biomedical and Neuromotor Sciences, University of Bologna (Bologna); [3]IRCCS Istituto delle Scienze Neurologiche di Bologna, AUSL Bologna (Bologna); [4]Department of Physics and Astronomy, University of Bologna (Bologna)

Background and Aim: Hereditary spastic paraplegia (HSP) is a group of neurodegenerative disorders characterized by underlying wide genetic and clinical heterogeneity. The core clinical presentation is a pyramidal syndrome which starts in the lower limbs. They can present as pure or complex forms. In the latter, a wide range of clinical symptoms and signs are reported, including cerebellar ataxia. The aim of this study was to explore in-vivo cerebellar metabolic alterations with proton MR spectroscopy (1H-MRS) technique in patients with pure and complicated HSP.

Methods: We enrolled 20 patients with HSP (51.3±11.2years, 8F). To date the genetic diagnosis was available for 13 patients (subtypes: 1 SPG3A, 6 SPG4, 1 SPG7, 1 SPG10, 1 SPG15, 1 SPG26, 1 with ABCD1 mutation and 1 with MFN2 mutation). The neurological evaluation included the Spastic Paraplegia Rating Scale (SPRS). Three patients had mild cerebellar signs. A cohort of 20 matched healthy control subjects (HC) was also recruited (48.5±12.4years, 8F). The participants underwent a standardized high-field (3T scanner) MR protocol including single voxel (6 ml volume) 1H-MRS within the left cerebellar hemisphere. Metabolites content was quantified with the automatic software LCModel and evaluated relative to creatine (Cr), marker of energy metabolism. In particular, N-Acetylaspartate (NAA), marker of neuronal integrity, choline (Cho), marker of membrane turnover, and myo-Inositol (mI), marker of glial cells, were evaluated. Tissue fractions within the 1H-MRS VOI were estimated and included as nuisance covariates. Voxel-based morphometry of cerebellar volumes was also performed.

Results: NAA/Cr was lower in HPS patients compared to HC (1.19±0.18 vs 1.55±0.23, p=0.0003) also when three patients with clinical cerebellar involvement were excluded (p =0.0002). NAA/Cr correlated with SPRS (r=-0.451, p=0.046) and with the cerebellar grey and white matter volume loss (GM: r=0.427, p=0.006; WM: r=0.482, p=0.002)

Discussion and Conclusion: 1H-MRS disclosed biochemical alterations in the cerebellar hemisphere of HSP patients, even in the absence of cerebellar signs. Such alterations correlated with both volume changes and disease severity. These results support the hypothesis of a shared vulnerability of cerebellar and corticospinal neurons for common pathophysiological processes.

## ASSESSING SMELL PERFORMANCE IN ESSENTIAL TREMOR PLUS PATIENTS

M. Russo, C. Sorrentino, M. Picillo, A. Landolfi, M. Pellecchia, P. Barone, R. Erro

Department Of Medicine, Surgery and Dentistry, Scuola Medica Salernitana, University of Salerno (Salerno)

Objectives: Essential tremor (ET) plus is a heterogeneous syndrome of bilateral upper limb action tremor with either rest tremor or soft signs, which has been suggested to represent a prodromal stage of Parkinson disease (PD) in some cases. Hyposmia is a prodromal symptom of PD, which can be detected with the University of Pennsylvania Smell Identification Test (UPSIT). To get a deep phenotyping of ET plus with rest tremor we evaluated smell performance in these patients and compared it with that of patients with Parkinson's disease and with that of healthy subjects (HS).

Materials: We used a shorter version of the Italian adapted UPSIT test with 8 items, able to discriminate between PD patients and HS using a cut-off point of $\leq 6$.

Methods: Kruskal-Wallis nonparametric test was performed to compare the 8-item UPSIT scores between the three groups using SPSS software, version 26.0.

Results: The study sample consisted of 35 ET plus patients, 42 PD patients and 38 HS. The three groups were homogeneous in terms of age (70.89 ± 8.96 vs. 65.38 ± 6.88 vs. 63.71 ± 6.93, ET plus, PD and HS, respectively, $p = 0.20$) and sex distribution (men/women: 62.9%/37.1% vs. 57.1%/42.9% vs. 57.9%/42.1%, ET plus, PD and HS, respectively, $p = 0.863$). The mean UPSIT score was significantly different between the groups [Kruskal-Wallis chi-squared = 42.649; df = 2; $p < 0.05$]. Post-hoc analyses demonstrated the mean UPSIT score in ET plus patients was significantly different from both PD (5 ± 3 vs 3 ± 3, $p<0.05$) and HS (5 ± 3 vs 7 ± 3, $p<0.05$). Twenty-eight (80%) ET plus patients exceeded the proposed cut-off (i.e., $\leq 6$) for pathological smell performance, so nearly 50% of ET plus patients were evaluated with 40-item UPSIT Italian version. Only two patients exceeded the pathological cut-off (i.e., $\leq 21$).

Discussion: A small fraction of ET plus with rest tremor has a smell performance in the pathological range therefore they should be closely monitored. The remaining fraction of ET plus with rest tremor has a normal smell, in these patients rest tremor is not a prodromal of Parkinson's disease.

Conclusions: The assessing of smell performance in Essential tremor plus with rest tremor contributed to a deep phenotyping. However, the 8-item UPSIT had poor diagnostic performance because it was unable to discriminate between ET plus with resting tremor and HS.

## "MY EAR IS CLICKING": A CASE OF SECONDARY PALATAL TREMOR

G. Saccardin[1], S. Coniglio[1], G. Argenziano[1], G. Di Rauso[1], F. Antonelli[2], G. Federici[3], V. Rispoli[2]

[1]Neurology Unit, Department of Biomedical, Metabolic and Neural Science, University of Modena and Reggio Emilia (Modena); [2]Neurology Unit, Department of Neuroscience, Head and Neck, University Hospital of Modena, University of Modena and Reggio Emilia (Modena); [3]Department of Otolaryngology-Head and Neck Surgery, University Hospital of Modena, University of Modena and Reggio Emilia (Modena)

Background: Palatal tremor (PT) is a rare disorder involving soft palate. The underlying etiology and differential diagnosis could be wide and challenging. In this regard, the choice of the best work-up is essential.

Case presentation: A 54-year-old male patient complained a two-year history of rhythmic, low-frequency palate movement with audible click. Other symptoms were slight dysphagia for liquids and non-progressive balance disorder described as retropulsion with some near falls. Clinical assessment disclosed bilateral palatal tremor at approximately 1,5Hz with preserved palatal motility. No dysarthria,

no rhinolalia, no phonatory click were found. In addition, rotatory gaze-evoked bilateral nystagmus with delayed vertical saccades and unsteady walk with positive Romberg sign were observed. Brain MRI showed SWAN hypointensities involving ponto-mesencephalic junction, pons and the bulbo-pontine junction, left cerebral peduncles, cerebellar folia, postero-inferior portion of the left cerebellar hemisphere, extended to bilateral dentate nuclei. Within these lesions, there were two cavernous angiomas and a developmental venous anomaly (DVA) located in the cerebellar hemispheres. Furthermore, MRI revealed degenerative hypertrophy of both bulbar olivary nuclei.

Discussion: PT can be essential/idiopathic (EPT) when not attributable to a structural cause and symptomatic (SPT) when secondary to lesions involving the dentato-rubro-olivary pathway. A common feature is the hypertrophic olivary degeneration (HOD) that represents the vacuolation of the nucleus and the enlargement of cell bodies due to olivary deafferentation. Patients with SPT usually present other symptoms, while patients with EPT usually report ear clicks rather than the sensation of throat involuntary movements. EPT can be also voluntary (intentional contraction of tensor veli palatini) or psychogenic. Distractibility and entertainability are present in both psychogenic and non-psychogenic EPT, making distinction harder. Conversely, common features in EPT, not typical in SPT, are audible click, disappearance of tremors during sleep, no other clinical signs/symptoms or structural lesions. In our case, despite the presence of a click, PT presentation associated with cerebellar syndrome led us to perform MRI that showed diffused and confluent not recent microhemorrhagic lesions involving both brainstem and cerebellar vermis and hemispheres caused by multiple cavernous angiomas and a DVA. The pivotal role of MRI consists also in providing us with the finding of bilateral HOD, a very specific sign of SPT, which further supports the hypothesis of an EPT.

Conclusions: PT can be secondary to several different etiologies involving the dentato-rubro-olivary pathway: it is mandatory for patients with this disorder to undergo MRI in order to exclude consistent lesions.

## A MACHINE LEARNING APPROACH FOR DETECTING IDIOPATHIC REM SLEEP BEHAVIOUR DISORDER

M. Salsone[1], A. Quattrone[2], B. Vescio[3], L. Ferini-Strambi[4], A. Quattrone[5]

[1]IBFM-CNR, Vita-Salute San Raffaele (Milano); [2]Department of Neurology, Magna Graecia University (Catanzaro);[3]IBFM-CNR (Catanzaro); [4]Sleep Disorders Center, Division of Neuroscience, Vita Salute University (Milano); [5]Neuroscience Research Center, Magna Graecia University (Catanzaro)

Background and Purpose: Growing evidence suggests that Machine Learning (ML) models can assist the diagnosis of neurological disorders. However, little is known about the potential application of ML in diagnosing idiopathic REM sleep behavior disorder (iRBD), a parasomnia characterized by a high risk of phenoconversion to synucleinopathies [1]. This study aimed to develop a novel model using ML algorithms to identify iRBD patients and test its accuracy.

Methods: Data were acquired from 32 participants (20 iRBD patients and 12 controls). All subjects underwent a videopolysomnography. In all subjects, we measured the components of heart rate variability (HRV) during 24 h recordings and calculated night-to-day ratios (cardiac autonomic indices). Discriminating performances of single HRV features were assessed. ML models based on Logistic Regression (LR), Random Forest (RF) and eXtreme Gradient Boosting (XGBoost) were trained on HRV data. The utility of HRV features and ML models for detecting iRBD was evaluated by area under the ROC curve (AUC), sensitivity, specificity and accuracy corresponding to optimal models.

Results: Cardiac autonomic indices had low performances (accuracy 63–69%) in distinguishing iRBD from control subjects. By contrast, the RF model performed the best, with excellent accuracy (94%), sensitivity (95%) and specificity (92%), while XGBoost showed accuracy (91%), specificity (83%) and sensitivity (95%). The mean triangular index during wake (TIw) was the best discriminating feature between iRBD and HC, with 81% accuracy, reaching 84% accuracy when combined with VLF power during sleep using an LR model.

Conclusions: Our findings demonstrate, for the first time, that ML algorithms can accurately identify iRBD patients. Our model could be used in clinical practice to facilitate the early detection of this form of RBD.

## ENLARGED PERIVASCULAR SPACES AND CEREBRAL SMALL VESSELS DISEASE BURDEN IN PARKINSON'S DISEASE: ASSOCIATIONS WITH NON-MOTOR SYMPTOMS FOCUSING ON SLEEP DISORDERS

C. Santoro[1], D. Urso[2], L. Batzu[3], V. Gnoni[2], S. Landolfo[1], A. Giugno[2], S. Rota[3], K. Ray Chaudhuri[3], G. Logroscino[2]

[1]Department of Basic Medical Sciences, Neuroscience and Organ Sense, University of Bari "Aldo Moro" (Bari); [2]Center for Neurodegenerative Diseases and the Aging, Department of Clinical Research in Neurology, University of Bari "Aldo Moro", "Pia Fondazione Cardinale G. Panico" (Tricase-LE); [3]Parkinson's Foundation Centre of Excellence, King's College Hospital and Institute of Psychiatry, Psychology and Neuroscience, King's College London (London-UK)

Objectives: This preliminary study aims to investigate associations between enlarged perivascular spaces (EPVS) as part of the cerebral small vessels disease (SVD), and non-motor symptoms (NMS) burden in Parkinson's disease (PD) patients. We hypothesized that EPVS and SVD burden via the glymphatic system can contribute to the NMS burden and we focused our attention on sleep disorders.

Methods and Materials: We retrospectively evaluated 64 PD patients from an Italian cohort of the Non-motor Longitudinal International Study (NILS) database: 17 female and 47 male patients, average age of 67.2 years (29-84 y), mean disease duration 4.75 years (0-23 y), mean Hoehn and Yahr stage 2.05. Patients underwent baseline brain 3.0 Tesla MRI-scan: a visual assessment of baseline basal ganglia (BG), centrum-semiovale (CSO), hippocampus (H), midbrain (M)-EPVS and SVD burden including white matter hyperintensities, cerebral microbleeds and lacunar lesions was rated by an experienced neurologist (C.S.) on axial T2-weighted images. Baseline NMS burden was established using validated NMS total score with Non-Motor Symptoms Scale (NMSS), Parkinson's Disease Sleep Scale (PDSS)

and Hospital Anxiety and Depression Scale (HADS), together with a first-level cognitive battery (Mini Mental State Examination) and Unified Parkinson's Disease Rating Scale part III (MDS-UPDRS III). Data analyses were performed using Spearman's rank coefficient and non-parametric partial correlations.

Results: Baseline BG/CSO/H-EPVS were significantly positively associated with older patients age ($p<0.01$). BG-EPVS burden negatively correlated with the sleep/fatigue NMSS domain (rho=-0.321; p=0.011) whilst controlling for age (r=-0. 412, $p<0.001$); BG-EPVS burden was positively associated with PDSS scale (rho=0.263; p = 0.04) also when age was included as covariate (r=0.329, p=0.01). EPVS burden was not associated with baseline cognitive or motor impairment.

Discussion: It has been observed that EPVS number, a part of SVD burden, increases with age [1] and has been linked to glymphatic system impairment [2]. Glymphatic pathway dysfunction may lead to PVS enlargement suggesting a possible link with protein misfolding diseases. However, it has also been suggested that increased EPVS burden might represent a compensatory mechanism against accumulation of waste products in brain but, as PD progresses, adaptation may become decompensatory: α-synuclein aggregation might obstruct the PVS drainage system, leading to lower MRI-visible EPVS burden [3]. Similarly, our findings showed that increased sleep disfunction appears to be negatively correlated to BG-EPVS burden.

Conclusion: Despite being related with ageing, lower EPVS burden associated with PD-related sleep dysfunction may reflect a decompensated drainage mechanism, potentially due to underlying α-synuclein misfolding and aggregation.

## AN INFECTIOUS TRIGGER IN A CASE OF PRIMARY FAMILIAL BRAIN CALCIFICATION

P. Santurelli, D. Ciprietti, T. Carrer, M. Carecchio

Movement Disorders Unit, Neurology Clinic, University of Padua (Padova)

Objective: To describe a case of PFBC with atypical clinical onset.

Materials and Method: The patient underwent neurological clinical examination, CSF analysis, brain CT scan, brain MRI and genetic tests.

Results: A 33-year-old man with no relevant medical history presented at the emergency department with fever, altered mental status and agitation. Neurological examination revealed generalized choreoathetoid movements. A brain CT scan showed bilateral calcification in cerebellum, thalami and basal ganglia. Blood tests showed elevated WBC and CRP. A brain MRI showed a DWI and Gad+ hyper-intense area in the left parieto-occipital cortical region. Glucose levels, proteins and WBC were normal on CSF and microbiological analyses turned out to be negative; no oligoclonal bands were detected. Extensive blood screening for neuronal auto-antibodies was also negative. To rule out an infectious etiology an echocardiography was performed, revealing an aortic valve vegetation which required cardiac surgery. Despite negative cultural exams, a diagnosis of possible endocarditis was made. After the surgical procedure and antibiotic therapy the choreiform movements disappeared. At a nine month follow-up visit, he presented with mild chorea in the lower limbs and mild postural tremor in the upper limbs. Genetic tests for PFBC resulted negative.

Discussion: Primary Familial Brain Calcification (PFBC), also known as Fahr's Disease, is a rare neurological disorder characterized by abnormal calcified brain deposits, particularly in the basal ganglia and cerebellum, which are best detected by a brain CT-scan. It is a genetic condition most commonly inherited as an autosomal dominant trait. A negative genetic test does not rule out PFBC diagnosis as 50% of patients do not present with mutation in any of the six known causative genes. PFBC must be differentiated by secondary forms of brain calcification (i.e. metabolic, infectious, toxic) and from other inherited diseases. The acute onset of chorea with altered mental status in the context of an infectious state pointed to an autoimmune or parainfectious etiology; however, CSF analysis did not reveal alterations. After heart surgery and antibiotics, the movement disorder subsided.

Conclusion: We speculate that clinical onset of the disease was facilitated by the infection acting as a trigger, representing an atypical presentation of PFBC.

## NEURAL CORRELATES OF MOTOR IMAGERY VERSUS ACTION OBSERVATION OF GAIT TASKS IN PATIENTS WITH PARKINSON'S DISEASE AND FREEZING OF GAIT: A FMRI STUDY

E. Sarasso[1], A. Gardoni[1], L. Zenere[1], E. Canu[1], S. Basaia[1], E. Pelosin[2], F. Agosta[3], M. Filippi[4]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [2]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics and Maternal Child Health, University of Genoa (Genova); [3]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [4]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: We previously demonstrated that patients with Parkinson's disease (PD) and freezing of gait (PD-FoG) showed an altered recruitment of the mirror neuron system (MNS) during action observation and motor imagery relative to healthy controls. The aim of this study was to compare the neural correlates of motor imagery and action observation of gait tasks in PD-FoG patients relative to healthy controls.

Materials: Twenty-four PD-FoG patients and 19 age- and sex-matched healthy controls were included.

Methods: All the subjects underwent brain magnetic resonance imaging (MRI) including a motor imagery/action observation task: during motor imagery, subjects were asked to imagine themselves performing three gait tasks exacerbating FoG (starting/stopping walking in a narrow hallway; turning around 360° in a small radius; going through a doorway) while navigating first-person videos of realistic environments. Participants were instructed to focus their attention on their body and to imagine moving the body parts involved in the task. During the action observation, subjects were asked to observe third-person

videos representing a person performing the same three actions, in the same environments, presented during the motor imagery period.

Results: During motor imagery relative to action observation, both PD-FoG patients and healthy controls showed higher activity of lingual gyrus and cerebellum lobule VI. Healthy controls also showed increased recruitment of fusiform and middle occipital gyri, while PD-FoG patients showed a higher activity in the calcarine sulcus. Healthy controls also had an increased activity of middle/superior frontal and middle occipital gyri, precuneus and caudate during action observation relative to motor imagery. PD-FoG patients relative to healthy controls showed a reduced activity of lingual gyrus and a higher recruitment of insula during motor imagery relative to action observation.

Discussion: Both healthy controls and PD-FoG subjects showed an activation of areas belonging to the MNS during both motor imagery and action observation. Motor imagery relative to action observation required higher recruitment of lingual gyrus that is involved in visual memory and motion perception, and of cerebellum VI that is implicated in body representation, motor processing and attentive-executive functions. Only in healthy subjects, action observation compared to motor imagery activated more the fronto-parietal MNS that plays a role in action understanding and imitation learning of complex actions.

Conclusions: Motor imagery and action observation might represent complementary approaches in PD-FoG patients to stimulate the activity of sensorimotor and MNS brain areas in a specific way.

## GAA-FGF14 ATAXIA (SCA27B): CLINICAL PHENOTYPE OF AN ITALIAN MULTICENTER COHORT

Objective: Autosomal dominant spinocerebellar ataxia due to intronic GAA repeat expansion (RE) in the FGF14 gene (GAA-FGF14 ataxia; SCA27B) is a recently identified, relatively common, potentially treatable form of late onset ataxia. Here, we aimed to characterize the clinical phenotype in Italian GAA-FGF14 patients collected in a multicenter study.

Materials: We analyzed the clinical, genetic and neuroradiological features of 25 index cases carrying a heterozygous GAA-FGF14 RE. We also focused on 4-aminopyridine (4-AP) treatment response. Methods: Longitudinal clinical records were systematically assessed according to a comprehensive eCRF data form. We assessed disease severity and progression by using the Scale for the Assessment and Rating of Ataxia (SARA), the Friedreich Ataxia Rating Scale functional disability stage (FARS-DS) and functional impairment in terms of mobility aids. Finally, we analyzed longitudinal SARA scores by linear regression over disease duration.

Results: Twenty-four out of 25 GAA-FGF14 patients consistently presented as late-onset (57.5 years ± 14.4) cerebellar syndrome, partly combined with afferent sensory deficits (30%). A single case, age 17 years, was asymptomatic at the time of our study, though his examination was significant for mild intellectual disability and slight pyramidal signs in lower limbs. All symptomatic individuals showed evidence of impaired balance and gait; cerebellar oculomotor signs (saccadic intrusion, nystagmus, slowing saccades) were also frequent (78%). Episodic manifestations at onset occurred in 39% of patients; episodes were characterized mostly by dysarthria (44%) and vertigo (55%). Dysautonomia and cognitive impairment were infrequent. Peripheral neuropathy was reported in 26% of patients. Brain magnetic resonance imaging showed cerebellar atrophy in most cases (18/21). Longitudinal assessments indicated slow progression of ataxia (0.33 SARA points/year) and minimal functional impairment (11 patients are still fully ambulant after 8 years of disease duration). We found no correlation between RE, age at onset, longitudinal SARA scores or disease duration. Series of N-of-1 trials with 4-AP are ongoing.

Discussion: Consistent with previous reports, Italian GAA-FGF14 patients present an adult-onset, slowly progressive cerebellar ataxia with predominant impairment of balance and gait and frequent cerebellar oculomotor signs.

Conclusion: Combined with multisite international efforts, our study paves the way towards large-scale natural history studies in this newly discovered late-onset ataxia.

## SUBSTANCE P IS OVEREXPRESSED IN OLFACTORY NEURONS FROM PARKINSON DISEASE PATIENTS REFLECTING GASTROINTESTINAL DYSFUNCTION

T. Schirinzi[1], D. Maftei[2], P. Grillo[1], R. Bovenzi[1], C. Simonetta[1], H. Zenuni[1], J. Bissacco[1], D. Mascioli[1], A. Stefani[1], R. Lattanzi[2], C. Severini[3], N. Mercuri[1]

[1]Dpt Systems Medicine, Tor Vergata University (Roma); [2]Dpt of Pharmacology, Sapienza University (Roma); [3]Dpt of Biochemistry, National Research Council (Roma)

Objective: To clarify the role of Substance P (SP) in Parkinson disease (PD) using a molecular characterization of patients' olfactory neurons (ONs).

Materials: ONs were withdrawn from 30 PD patients and 20 sex/age-matched healthy controls through mucosa brushing.

Methods: Gene expression levels of SP and the NK1 receptor were comparatively assessed by the Real Time-PCR. The immunofluorescence staining was also performed to measure SP. In patients, the biochemical data were correlated with main clinical scores (MDS-UPDRS III, MoCA, NMSS, LEDD calculation), the Gastrointestinal Dysfunction Scale for PD (GIDS-PD), and the presence of constipation.

Results: SP mRNA expression was significantly higher in PD patients' ONs (PD: 5.1±7.4 fold increase vs controls:1.6±1.6; U=139, p=0.04). In PD, the SP mRNA levels directly correlated with GIDS-PD total score (R Spearman = 0.47, p=0.02) and was significantly higher in patients with constipation than those without (7.9±9.3 vs 1.9±1.6; U=44, p<0.05). NK1 receptor mRNA levels, instead, were similar between patients and controls. Also the SP protein levels were increased in the ONs of PD patients compared to controls, as demonstrated by immunofluorescence staining.

Discussion: SP and its cognate receptor NK1R are expressed in the CNS, the PNS, the enteric nervous system, and the immune cells, operating as neuroinflammatory mediators. In particular, SP expression is abundant in the gastrointestinal-nervous ascending pathway in response to various triggers. Preclinical evidence indicates that SP might be involved in PD pathogenesis through inflammatory mechanisms. However, no direct proof exists yet. ONs are now emerging as a reliable model to analyse molecular events underlying PD in vivo. Here, we thus used the ONs to explore the role and relevance of the SP/NK1R pathway in PD.

Conclusions: ONs SP overexpression in association with gastrointestinal dysfunction suggests a main role of the tachykinergic system within the clinical-pathological dynamics of PD. SP might represent a mediator of the "body-first" trajectory, serving either as a specific biomarker or a novel therapeutic target.

## REMOTE PHYSICAL ACTIVITY IN PATIENTS WITH PARKINSON DISEASE DURING SARS-COV-2 PANDEMIC: EXPERIENCE OF AN ITALIAN CENTER

G. Schirò[1], C. Davì[1], A. Amato[2], P. Proia[2], M. D'Amelio[1]

[1]Department of Biomedicine, Neuroscience and Advanced Diagnostics, University of Palermo (Palermo); [2]Department of Psychological, Pedagogical and Educational Sciences, Sport and Exercise Sciences Research Unit, University of Palermo (Palermo)

Background: The Sars-Cov-2 pandemic decreased people's participation in many social activities. This consequence has been deleterious for patients with chronic disease, such as Parkinson's disease (PD), who often discontinued follow-up visits and neuromotor treatments. Therefore, during the Sars-Cov-2 pandemic, the interest in telemedicine and remote patient monitoring increased. Different experiences of physical exercise via digital platforms on small numbers of patients with neurological disorders has been reported (1).

Aims: To asses efficacy of remote physical activity on some motor and not motor parameters of patients with PD.

Methods: Remote physical activity was proposed to patients during visits at our hospital. At baseline (T0), and at the end of the intervention (T1), after 11 weeks in a period between December 2021 and February 2022, patients were evaluated via UPDRS I, UPDRS II, UPDRS III for motor and non motor evaluation of PD; Beck depression inventory (BDI) to investigate depression; Epworth sleepiness scale (ESS) to assess the probability of falling asleep; King's Parkinson's disease Pain Scale (KPPS) to assess pain; abnormal involuntary movement scale (AIMS) to detect dyskinesia, Parkinson's Disease Fatigue Scale (PFS-16) to explore fatigue perception; and Non-Motor Symptoms Scale for Parkinson's Disease (NMSS) for non-motor symptoms.

Results: 13 participants underwent physical exercise three times a week. Each meeting lasted 90 minutes. Only one patient has dropped-out. The evaluations before and after physical exercise showed an improvement in fatigue perceptions as evaluated by PFS-16 (mean and SD, 6.7 ± 5.2 vs 5.4 ± 4.4, p= 0.004), and a reduction in depression score as evaluated by BDI (mean and SD, 10.7 ± 9.01 vs 8.2 ± 6.7, p= 0.065), although statistical significance was not reached in the latter case. Other evaluations showed no significant results. No adverse effects occurred during physical activity.

Discussion and Conclusions: Our experience demonstrated that remote exercise can be safe and effective in improve fatigue of patients with PD and could be used in case of physical impediment to the attendance of rehabilitation programs in site.

## ANODAL TRANSCRANIAL DIRECT CURRENT STIMULATION (TDCS) ON SENSORIMOTOR CORTEX IN PATIENTS WITH EARLY-ONSET PARKINSON'S DISEASE: A PILOT STUDY

C. Simonetta, J. Bissacco, M. Conti, C. Salimei, V. Ferrari, M. Pierantozzi, A. Stefani, N. Mercuri, T. Schirinzi

Department of Systems Medicine, University of Rome Tor Vergata (Roma)

Objective: To evaluate the clinical effects of anodal Transcranial Direct Current Stimulation (tDCS) application on sensorimotor cortex in a group of early-onset Parkinson's Disease (EOPD) patients.

Materials and Methods: We recruited 11 idiopathic EOPD patients. tDCS was administered by a transcranial direct current stimulator (Model BrainSTIM, EMS) with the anode placed over the left sensorimotor cortical area (C3) and the cathode over the contralateral supraorbital ridge (Fp2). The protocol consisted of 10 sessions of stimulation of 20 minutes each, administered in two weeks, with a current intensity of 2mA. Participants were assessed at baseline and at the end of the stimulation cycle with MDS-Unified Parkinson's Disease Ranking Scale (MDS-UPDRS) part III, Non-motor symptoms scale (NMSS), PD-cognitive rating scale (PD-CRS), and PD Quality of Life Questionnaire-39 (PDQ-39). Paired T-test was used to compare changes in clinical scores.

Results: At the end of the protocol significant score reduction resulted in NMSS (M 32,36± DS 29,07 vs 17,45±20,92, p=0.001); score improvement was also found in PD-CRS (M 100,82±13,95 vs 106,55±13,97, p=0. 040). Total UPDRSIII score did not change pre and post treatment. However, by grouping the items of the scale into rigidity, bradykinesia and tremor subscores, a significant amelioration of the rigidity subscore emerged (M 0,67±0,78 vs 0,42±0,70, p=0.05). PDQ-39 score was unmodified. No relevant side effects were recorded.

Discussion: Early-onset PD (EOPD) labels PD patients with an age at onset < 50 years. EOPD seems to have a slower progression and lesser number of comorbidities when compared to the late-onset PD (LOPD). However, EOPD affects people in the full of the employment and fertility, with a severe impact on the quality of life. Transcranial direct current stimulation (tDCS) is a non-invasive brain stimulation

technique used for therapeutic modulation of cortical excitability in various neurological diseases [1], including Parkinson's Disease (PD) [2]. To date, tDCS has never been specifically applied to EOPD patients. This pilot study showed that a 10 session-long protocol of anodal sensorimotor tDCS might exert beneficial clinical effects in EOPD patients in non-motor symptoms and cognitive performances, consistently with a direct effect of the stimulation on cortical cognitive network. Motor symptoms did not significantly improve, albeit some amelioration was noticed in rigidity. Further confirmation in larger samples and with sham-controlled subjects is now needed.

Conclusions: Anodal tDCS on sensorimotor cortex emerges as a promising therapeutic option for non-motor symptoms in EOPD patients.

## CREATION AND PRELIMINARY VALIDATION OF THE ITALIAN VERSION OF THE DBS IMPAIRMENT SCALE

S. Simoni, P. Nigro, E. Cresta, A. Mechelli, M. Pierini, N. Tambasco, L. Parnetti

Movement Disorders Center, Neurology Department, Perugia General Hospital and University of Perugia (Perugia)

Objectives: The present study aim was to create and provide a preliminary validation of the Italian version of the Deep Brain Stimulation-Impairment Scale (DBS-IS) [1] and to investigate its relationships with functional status and quality of life (QoL) in Parkinson's disease (PD) patients who underwent subthalamic nucleus deep brain stimulation (STN-DBS) [2].

Materials: Thirteen patients (6 males, 7 females) with PD were included in the study. The participants had a mean age of 69 ± 5.4 years and an average disease duration of 20 ± 5.1 years. Various assessment tools were utilized, including the Hoehn and Yahr (H&Y) scale, Unified Parkinson's Disease Rating Scale (UPDRS), Apathy Evaluation Scale (AES), Beck Depression Inventory-II (BDI-II), Self-Report Manic Inventory (SRMI), Parkinson's Disease Questionnaire (PDQ-39), and the Italian version of the DBS-IS (DBS-IS-IV). Statistical analyses were conducted using R Studio.

Methods: The Italian version of the DBS-IS scale was translated [3] and preliminarily validated. The participants completed the assessment scales, which were administered either directly or to their caregivers, ensuring confidentiality. The Mann-Whitney U Test was employed to compare scores between subgroups, and Pearson correlation coefficients were calculated to examine relationships between variables.

Results: The participants had moderate PD severity (mean H&Y score of 2.9) and a mean UPDRS score of 33.3. Apathy was observed in 62% of the patients, while 31% exhibited symptoms of depression. No clinically significant scores for mania or psychotic symptoms were detected. The PDQ-39 and DBS-IS-IV scales demonstrated a significant correlation, indicating the validity of the DBS-IS-IV scale. Correlations were also observed between different variables, such as DBS-IS x PDQ-39, Age x UPDRS, H&Y x UPDRS, H&Y x SRMI, and AES x PDQ-39.

Discussion: Although the study was conducted on a limited number of patients, the results support a preliminary validation of the DBS-IS-IV scale as a measurement tool for assessing various aspects related to DBS treatment. Apathy, postural instability and gait difficulties (PIGD), and language disorders were commonly reported symptoms. The absence of statistically significant differences in subgroups suggests that age, sex, and disease duration may not strongly influence functional impairment in this context.

Conclusion: The Italian version of the DBS-IS scale was successfully translated and a preliminary validation was provided. Further studies with larger sample sizes are warranted to complete the validation process and enhance the robustness of the scale.

## THE USE OF AN INSTAGRAM FILTER FOR POSTURAL TREMOR ASSESSMENT

C. Sorrentino, M. Russo, M. Pellecchia, M. Picillo, P. Barone, R. Erro

Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Neuroscience Section, University of Salerno (Salerno)

Objective: The aim of this study is to evaluate an Instagram filter as a complementary tool for postural tremor assessment.

Materials: We recruited 34 patients with the most common tremor syndromes: Essential Tremor, Essential Tremor plus and Dystonic Tremor according to the new classification of tremor1.

Methods: We asked patients to take a video of a printed Archimedes' spiral using an Instagram filter (i.e., Slit-scan), which overlaps the single video frames into one picture. The photographed spirals (p-spirals) were then scored by a blinded rater using the identical system used to score the classic Archimedes' spirals drawn by the patients themselves (d-spirals) according to the TETRAS. The Spearman test was used to correlate p-spiral scores with d-spiral scores, with a measure of postural severity for single arm calculated as the mean of the items assessing arm tremor in the outstretched, wing-beating positions and dot approximation, with a measure of kinetic severity for single arm calculated as the mean of the items assessing arm tremor with Archimedes' spiral, index-index proof and glasses proof and finally with the mean score of p-spirals and total TETRAS score.

Results: The Spearman test disclosed a significant correlation between p-spirals and d-spirals scores ($\rho$=0.316, $p<0.009$), between p-spirals scores and the mean of the items assessing postural tremor ($\rho$=0.306, $p<0.011$) and between the mean score of p-spirals and total TETRAS severity ($\rho$=0.441, $p<0.009$). While severity of kinetic tremor did not correlate with p-spirals scores.

Discussion: The assessment of tremor is currently performed by means of validated scales which require patients to be evaluated in person, but there is the need for remote tremor telemonitoring, so the use of slit-scan could represent a useful tool for measuring postural tremor in addition the classic Archimedes' spirals drawing.

Conclusions: The use of this filter might be useful in distinguishing the various components of action tremor and their response to therapeutic treatment. Larger studies are needed to validate this Instagram filter as a tool to be used in clinical practice.

Objectives: MRI connectomics is an ideal tool to test the model of network-based spread of pathological protein aggregates in neurodegenerative disorders. Stepwise functional connectivity (SFC) is a graph-theory-based neuroimaging method, which detects whole-brain functional couplings of a selected region of interest, at increasing link-step topological distances. This study applied SFC to test the hypothesis that topological stepwise architecture propagating from the disease epicenter would shape patterns of grey matter (GM) atrophy in a cohort of patients with progressive supranuclear palsy (PSP).

Materials: Thirty-nine patients with PSP and 44 healthy controls underwent brain magnetic resonance imaging (MRI) on a 3T scanner, including 3D-T1 weighted and resting-state functional MRI sequences. Methods: The disease epicenter was defined as the peak of atrophy observed in an independent cohort of 13 cases with post mortem confirmation of PSP pathology, and used as seed region for an SFC analysis. GM was parcellated into 90 regions using the Automated Anatomical Labeling (AAL) atlas. First, SFC modifications in PSP patients were assessed. Then, correlations between SFC architecture in controls and atrophy patterns in PSP patients were tested.

Results: The disease epicenter was identified in the left midbrain tegmental region. In PSP patients, a pattern of mostly increased functional connectivity of the midbrain within direct connections was mirrored by a progressively widespread decreased connectivity through indirect connections with sensorimotor cortical regions. Compared with controls, PSP patients showed prevalent atrophy in the subcortical GM (mostly, in the thalami and caudate nuclei), but also in frontal, parietal and cerebellar cortical regions. For each region of the AAL atlas, a correlation was found between average link-step distance from the left midbrain in controls and mean normalized GM volume in PSP patients ($r=0.38$, $p<0.001$).

Discussion: We demonstrate that the brain architectural topology, as described by SFC propagating from the disease epicenter, shapes the pattern of atrophic changes in PSP. The present findings support the view of a network-based pathology propagation in this primary tauopathy.

Conclusions: The results of this study open fundamental insights supporting the notion of PSP and other neurodegenerative diseases as "disconnection syndromes", providing promising perspectives to understand the physiopathological underpinnings and to model disease evolution in future longitudinal studies.

## HYPOTENSIVE EPISODES AT AMBULATORY BLOOD PRESSURE MONITORING PREDICT DISABILITY MILESTONES IN PARKINSON'S DISEASE: A LONG-TERM RETROSPECTIVE STUDY

M. M. Tangari[1], A. Covolo[1], G. Imbalzano[1], C. Ledda[1], E. Montanaro[1], C. Campisi[1], M. Laudadio[1], C. Artusi[1], M. Bozzali[1], M. Rizzone[1], M. Zibetti[1], M. Valente[2], S. Maule[2], F. Vallelonga[2], L. Lopiano[1], A. Romagnolo[1]

[1]Department of Neuroscience "Rita Levi Montalcini", University of Turin (Torino); [2]Autonomic Unit and Hypertension Unit, Department of Medical Sciences, University of Turin (Torino)

Objectives: Neurogenic orthostatic hypotension (nOH) is a frequent non-motor feature of Parkinson's disease (PD), associated with severe complications and shorter survival. [1,2] Due to the important circadian variability of blood pressure (BP) in PD, bedside evaluation could misestimate the actual prevalence of nOH. Recently, 24-hour ambulatory BP monitoring (ABPM) has been proposed as a useful tool to detect nOH [3]; in particular, the presence of at least 2 episodes of systolic BP drop $\geq$15 mmHg demonstrated a high level of accuracy. This study aims at evaluating the prognostic role of ABPM-hypotensive episodes in predicting PD disability milestones and mortality and comparing it to the prognostic role of bedside nOH on the same outcomes.

Materials and Methods: PD patients who underwent ABPM from January 2012 to December 2014 were retrospectively enrolled and assessed for age, disease duration, motor disability (H&Y stage), and Charlson Comorbidity Index (CCI) at baseline, and for the development of the following complications, during an up-to-10-year follow-up: falls, fractures, dementia, bed/wheelchair confinement, hospitalization, mortality. Unadjusted Kaplan-Meyer analysis and Cox regression analysis (corrected for age, disease duration, CCI, and H&Y stage at baseline) evaluated the association between ABPM-hypotensive episodes or bedside nOH and disability milestones/mortality.

Results: Ninety-nine patients (men: 73.7%; age: 64.2±10.1 years; PD duration: 6.4±4.2 years) satisfied inclusion criteria. The mean follow-up was 5.9±2.7 years (range 1-10). At baseline, 38.4% of patients had at least two ABPM-hypotensive episodes, while 46.4% had nOH at bedside evaluation. The Kaplan-Meier analysis showed that patients with ABPM-hypotensive episodes had an earlier onset of falls (4.9 vs. 7.9 years; $p<0.001$), fractures (6.4 vs. 9.0 years; $p=0.004$), hospitalizations (5.3 vs. 8.2 years; $p=0.009$), bed/wheelchair confinement (7.1 vs. 9.4 years; $p=0.032$), and dementia (5.0 vs. 8.1 years; $p<0.001$). The mortality rate was 13.1%, and patients with hypotensive episodes showed a shorter survival (8.0 vs. 9.5 years; $p=0.009$); however, adjusted Cox regression analysis did not confirm a significant association ($p=0.655$). Cox-Regression analysis showed significant association between ABPM-hypotensive episodes and falls (OR:3.626; $p<0.001$), hospitalizations (OR:2.016; $p=0.038$), and dementia (OR:2.926; $p=0.008$), while bedside nOH was only associated with dementia (OR:2.100; $p=0.025$).

Discussion and Conclusion: ABPM represent a widely available and reliable assessment. The presence of at least two ABPM-hypotensive episodes independently predicted the development of falls, dementia

and hospitalization, showing a stronger prognostic value than the simple bedside assessment. Although larger and prospective confirmatory studies are needed, our observations support the usefulness of ABPM in PD clinical practice.

## SALIVARY EXTRACELLULAR VESICLE A-SYNUCLEIN AS A NOVEL POTENTIAL BIOMARKER OF PARKINSON'S DISEASE ONSET AND PROGRESSION

M. M. Tangari, A. Gurgone, V. Cardinale, C. Ledda, G. Imbalzano, L. Lopiano, M. Giustetto, M. Zibetti

Department of Neuroscience "Rita Levi Montalcini", University of Turin (Torino)

Objective: Extracellular vesicles (EVs) are small vesicles released by many cells, including neurons and can be isolated from body fluids, like saliva[1]. α-Synuclein (α-syn) has recently been detected in EVs and may contribute to the spreading of disease pathology in α-synuclein-related neurodegeneration[2]. The detection of α-syn in salivary EVs may contribute to find potential biomarker for Parkinson disease (PD) onset and progression. So, the main objectives of this work are: 1) to establish the methodology to isolate EVs from saliva; 2) to examine both oligomeric (α-synOlig) and total α-Syn (α-synTotal) contained in the EVs to validate their potential diagnostic and 3) to evaluate their possible role as progression biomarkers in PD.

Materials and Methods: Saliva samples were obtained from 48 PD patients (PDs) and 31 healthy controls (HCs). The EVs were isolated by differential ultracentrifugation[3]; western blot (WB) and Nanosight (NTA) were used to validate the protocol and to analyze EVs size and concentration. The transmission electron microscopy (TEM) was used to assess EVs morphology4. The concentration of α-synTotal, α-synOlig was determined by ELISA technique. Diagnostic value and clinical relevance of salivary EVs α-syn were assessed by Receiver Operator Characteristic (ROC) curve and Pearson correlation6. We are now recalling patients, after one year from the first collection, to evaluate if the two forms of α-Syn should be considered as progression biomarkers for PD.

Results: We first characterized the EVs by WB and TEM, the NTA showed that the concentration of EVs is higher in HCs than PDs, while the dimensions do not change. The ELISA test revealed that the level of both α-synTotal and α-synOlig are higher in PDs compared to the HCs (α-synTotal: sensitivity = 66%, specificity = 76%; α-synOlig sensitivity = 83%, specificity = 60%). We found correlations of α-synOlig with the duration of the disease and the mini mental state examination (MMSE).

Conclusions: These findings support the role of salivary EVs cargoes as a promising biomarker for PD and purpose to further investigate the possible correlation of α-Syn with disease severity, which could reveal α-Syn as a predictor of PD progression.

## CLINICAL AND AUTONOMIC PROFILE OF MULTIPLE SYSTEM ATROPHY WITH POSTGANGLIONIC CARDIOVASCULAR DYSFUNCTION

R. Telese, A. Elia, F. Cencini, N. Golfré Andreasi, R. Cilia, L. Romito, F. Colucci, A. Braccia, S. Rinaldo, M. Corradi, R. Eleopra, G. Devigili

Department of Clinical Neurosciences, Parkinson and Movement Disorders Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano)

Introduction: Cardiovascular autonomic dysfunction in Multiple System Atrophy (MSA) clinically manifests with orthostatic hypotension and in most of patients is related to preganglionic abnormalities. In fact, cardiac imaging using iodine-123-metaiodobenzylguanidine(123I-MIBG), which examines the sympathetic innervation of the heart and thereby enables the quantification of the postganglionic cardiac sympathetic innervation, is typically normal in MSA [1][2]. However, reduced cardiac tracer uptake has been reported in one third of patients with MSA. Whether cardiac postganglionic denervation in MSA is associated to a different and/or more severe clinical phenotype is still unclear.
Objectives: To compare clinical and cardiovascular autonomic tests findings of patients affected by MSA with normal (N) and reduced (R) cardiac postganglionic sympathetic innervation.

Materials and Methods: Clinical records, plasma cathecolamine dosages and cardiovascular autonomic tests findings of patients affected by MSA, who underwent cardiac 123I-MIBG scintigraphy, referring to our clinic from 2018 to 2023, were retrospectively revised.

Results: Data from 60 patients diagnosed with clinically established or probable MSA according to the Movement Disorders Society 2022 diagnostic criteria [3], 46 with normal and 14 with reduced sympathetic innervation on cardiac 123I-MIBG scintigraphy were collected. Mean age of disease onset (57.4-N vs 59.1-R), disease duration (3.6vs4 yrs), Levodopa Equivalent Daily Dose (527.1vs513.5), Unified MSA Rating Scale scores in part I (18.5vs19.4) and part II (20.7vs22.6) showed no significative difference. Parkinsonian and cerebellar phenotypes were equally represented in both groups. Self-rated composite autonomic system scale total score (35.3vs33) and subscores, were similar. Patients with reduced cardiac innervation had lower supine noradrenaline plasmatic concentration, while no difference was found in the orthostatic condition. Moreover, such patients had significantly lower blood systolic (-23vs-7 mmHg) and diastolic (-11vs-2) pressure values reduction around the 7th minute of tilt test. No difference was found in the incidence of orthostatic hypotension within 3 minutes of standing, as well as in other indexes of sympathetic dysfunction on autonomic testing, such as mean blood pressure (BP) fall in early phase II, mean BP rise in late phase II, pressure recovery time and presence of BP overshoot during Valsalva maneuver. We also analysed cardiac vagal indexes, which were similar in both groups.

Discussions and Conclusions: Patients with MSA and postganglionic cardiovascular dysfunction show similar clinical features and

disease severity scales scores compared to those with preganglionic, while they had lower supine plasma noradrenaline levels. Cardiovascular autonomic testing showed similar results in both groups, except for a more marked tardive BP decrease on tilt test in postganglonic patients.

## QUANTITATIVE EEG IN PD-RBD: WHEN RBD ONSET REALLY MATTERS

R. Terranova[1], C. Cicero[1], R. Garofalo[1], S. Tabbì[1], A. Luca[1], G. Mostile[2], L. Giuliano[1], G. Donzuso[1], M. Zappia[1], A. Nicoletti[1]

Ingrassia, Section of Neurosciences, University of Catania and Oasi Research Institute-IRCCS (Catania)

Introduction and Aim: Intraneuronal a-synuclein aggregates are the pathologic hallmark of Parkinson's disease (PD). According to a recently proposed hypothesis, alpha-synuclein pathology may originate and spread in two different directions: either downward from the brain to the enteric or peripheral autonomic nervous system or upward in the opposite direction. The temporal relationship between RBD and motor symptoms onset has been considered as the key factor in differentiating these two subtypes. The aim of this study was to investigate electrocortical differences between patients with PD and different RBD onset timing.

Methods: PD patients were retrospectively selected and according to the presence of probable RBD, were divided into: N = 38 patients without RBD (NRBD), N = 14 patients with RBD onset before motor symptoms onset (PRERBD) and N = 31 patients with RBD onset after motor symptoms onset (POSTRBD). Spectral analysis was performed in resting state EEG and the absolute power spectral density was calculated for the common frequency bands. Kruskal-Wallis H test was used to assess between-group differences.

Results: Comparing global PSD absolute values, significantly lower beta band values were obtained in patients with RBD onset before motor symptoms (60,25 ± 30,52) as compared to both NRBD (116,13 ± 90,39; p = 0.02) and POSTRBD (112,79 ± 101,57; p = 0,06). Site specific lower beta values were also found PRERBD in frontal, temporal, and parietal regions. The post-hoc comparison showed highest differences between NRBD and PRERBD patients. On the contrary, no differences were found between NRBD and POSTRBD patients. In addition, no significant differences were obtained comparing delta, theta and alpha absolute powers across all the investigated sites.

Discussion: PRERBD patients have lower fast-frequencies representation in resting-state EEG and they show different electrocortical features as compared to both patients with later RBD onset and without RBD.

Conclusion: RBD onset as compared to motor symptoms is a crucial determinant in PD: PRERBD represent a different subgroup of patients with unique quantitative EEG features.

## UNSUPERVISED MACHINE LEARNING STRATEGY AND SHAPLEY ADDITIVE EXPLANATION TO DISTINGUISH GAIT ABNORMALITIES THROUGH IMU-BASED GAIT ANALYSIS IN SUBJECTS WITH MOVEMENT DISORDERS

D. Trabassi[1], S. Castiglia[1], C. Carlone[1], C. Conte[2], A. Ranavolo[3], T. Varrecchia[3], G. Sebastianelli[1], C. Abagnale[1], G. Coppola[1], C. Casali[1], C. Tassorelli[4], M. Serrao[1]

[1]Department of Medical and Surgical Sciences and Biotechnologies, Sapienza University (Latina); [2]Movement Analysis LAB, Policlinico Italia (Roma); [3]Department of Occupational and Environmental Medicine, Epidemiology and Hygiene, INAIL (Monte Porzio Catone-RM); [4]Department of Brain and Behavioral Sciences, University of Pavia (Pavia)

Objectives: When paired with gait analysis using magneto-inertial measurement units (mIMUs), automated classification of gait disorders using Machine Learning algorithms can enable fast and clinically significant assessment of gait abnormalities in persons with gait disorders [1]. Unsupervised methods can be used to classify gait patterns of people suffering from various neurological illnesses [2-3]. In this study, the ability of clustering algorithms to detect differences in gait patterns between subjects with movement disorders and healthy subjects (HS) using mIMUs-derived gait data was investigated.

Materials: In this study, 59 subjects with Parkinson's disease (swPD) at moderate disease stage, 39 subjects with hereditary cerebellar ataxia (swCA), and 35 age and gait speed-matched HS were included. Spatiotemporal and kinematic gait parameters, and trunk acceleration-derived gait indexes were calculated using a mIMU.

Methods: Unsupervised machine learning methods such as partitioned clustering (K-Means), hierarchical clustering, and density clustering (DBSCAN) were implemented to observe their ability to distinguish subjects based on diagnosis on the initial dataset and on a second dimensionality-reduced dataset obtained through feature extraction. Finally, supervised statistical analysis and Shapley Additive Explanations (SHAP) analysis were performed to identify the most impactful set of features for differentiating between movement disorders and healthy subjects.

Results: Partitioned clustering performed better than the other algorithms in differentiating movement disorders in both internal cluster metrics and external metrics. Feature extraction by Principal Component Analysis (PCA) improved internal cluster metrics making them more recognizable and homogeneous while slightly worsening external metrics. On the K-Means cluster with the best external metric results (Accuracy = 0.91, F1-Score = 0.91), SHAP analysis revealed how several gait features mostly weighted for differentiating subjects with movement disorders from each other and from healthy subjects.

Discussions: ML algorithms may generate excellent classification metrics when considering gait data from single lumbar-mounted IMUs in CA and PD populations at moderate disease stage. To improve classification performances and obtain reliable results, initial data exploration and pre-processing is mandatory, particularly to avoid multicollinearity and overfitting.

Conclusions: The results of this study demonstrated that, when considering gait data from single IMUs mounted at the lumbar level in moderate disease-stage pwCA and pwPD populations, the unsupervised K-Means and hierarchical clustering algorithms can generate excellent insights and classification metrics, and that pelvic rotation plays a key role in differentiating extrapyramidal and cerebellar gait disorders.

Background: Diabetic Striatopathy (DS) is a rare complication of a poor-controlled Diabetes Mellitus consisting of sudden onset of movement disorders. To date, there is still poor knowledge about the pathogenesis.

Case: We describe a 79 y.o men affected by sudden onset hemichoreic movements whose cause was a nonketotic hyperglycaemia diagnosed despite the normal blood glucose levels thanks to brain CT and MRI. Then, we introduce a new MR-spectroscopy (MRS) finding never described until today which allowed us to produce a new pathogenetic theory of a phenomenon still without definitive explanations.

Conclusions: Thanks to our MRS we show new imaging findings never described until today, with a new pathogenetic explanation, since all the causative hypotheses produced during the past years have never found evidence.

## OROMANDIBULAR DYSTONIA: CLINICAL PHENOMENOLOGY AND NATURAL HISTORY

A. Trinchillo[1], M. Esposito[2], G. De Fazio[3]

[1]Department of Neurosciences, Reproductive Sciences and Odontostomatology, "Federico II" University (Napoli); [2]Clinical Neurophysiology Unit, Cardarelli Hospital (Napoli); [3]Department of Basic Medical Sciences, Neuroscience and Sense Organs "Aldo Moro", University of Bari (Bari)

Introduction: Oromandibular dystonia (OMD) is a cranial dystonia affecting the lower face. It can be isolated, or combined if other sites are affected. To date, association between OMD and other kinds of dystonia has been poorly investigated.

Objectives: To define the clinical and demographic features of the Italian population affected by OMD and to search for possible variables which could predict its spread to other body regions.

Methods: Data were obtained from the Italian Dystonia Registry (IDR), a multicenter Italian dataset of patients with adult-onset dystonia. We extracted and analysed the main features of those patients who presented an OM dystonia.

Results: Study population included 313 patients with OMD. Most of them presented a primary dystonia – mainly idiopathic - while among the secondary forms, the majority had a drug-induced one. 53 patients (17%) presented an OMD onset; 109 (34.8%) a combined onset (OM plus another site); 151 (48.2%) manifested the onset of dystonia in a non-OM site. Spread occurred with a significant lower prevalence in the following groups: patients with combined onset when taken from the entire sample (P=0.001) and when analysing just the idiopathic forms (P=0.001), and in patients with acquired dystonia (P=0.04). Those populations presented also a significantly llow prevalence of sensory trick. Patients presenting sensory trick, regardless of the site of onset, presented a significantly higher rate of spread. Finally, spread of dystonia in those patients with idiopathic syndrome and OM onset resulted to occur within 10 years from the onset (mainly in 4 years).

Discussion and Conclusion: Data from IRD show that OMD is prevalently idiopathic and associated with dystonia in other sites. When the onset is combined and in acquired dystonia, the spread of dystonia in other body regions has a very low prevalence whereas sensory trick seems to increase the rate of spread in overall OMD patients. Results of the study confirm evidence of previous research and point out the possibility of pathogenetic mechanisms of dystonia depending on the increase of neurons' activation threshold and the cortical neural plasticity.

## NETWORK-BASED ANALYSIS OF MOVEMENT PATTERNS: ENHANCING MOTOR EVALUATION IN PARKINSON'S DISEASE

E. Troisi Lopez[1], P. Sorrentino[2], M. Liparoti[3], R. Minino[4], A. Polverino[5], A. Romano[4], E. Amico[6], G. Sorrentino[4]

[1]Department of Motor Sciences and Wellness, University of Naples "Parthenope", Institute for Diagnosis and Care Hermitage Capodimonte, Hermitage Capodimonte (Napoli); [2]Department of Biomedical Sciences, University of Sassari (Sassari); [3]Department of Developmental and Social Psychology, University "La Sapienza" of Rome (Roma); [4]Department of Motor Sciences and Wellness, University of Naples "Parthenope" (Napoli); [5]Institute for Diagnosis and Care Hermitage Capodimonte, Hermitage Capodimonte (Napoli); [6]Institute of Bioengineering, Center for Neuroprosthetics, EPFL (Geneva-CH)

Aims: Motor assessment of Parkinson's disease is highly valuable in evaluating the severity of the disease and its progression over time [1]. Typically, quantitative outcomes such as step length, stance time, etc., are considered. However, these measures do not capture higher-level functions such as coordination and fail to account for the fact that movement arises from the finely regulated synergy of different body parts. Therefore, we applied network theory [2] to human movement to capture these aspects and assess the coordination characteristics of patients with Parkinson's disease (PD).

Materials: We recruited twenty-three PD patients (in OFF condition) and twenty-three healthy age, education and gender matched subjects (HS). Using a stereophotogrammetric system, we conducted 3D gait analysis to capture the three-dimensional position of 21 anatomical markers.

Methods: From this data, we calculated acceleration time series and, by applying Pearson's correlation, we obtained a movement connectivity matrix, referred to as the kinectome. Each kinectome presented body landmarks on the rows and the columns, while the elements in the matrix represented the level of coordination between each couple of body landmarks. Then, through a permutation test, we analyzed the characteristics of each kinectome to perform topological analysis.

Results: Topological analysis revealed that individuals with PD displayed higher values of nodal strength at the level of the 10th thoracic vertebra. Furthermore, the nodal strength was significantly correlated with the UPDRS motor score of the patients and was able to predict the test through a cross-validated multilinear regression model.

Discussion: Our results might be capturing the trunk rigidity typical of PD, causing hyper-synchronization of the movement between the trunk and the limbs [3]. Moreover, the prediction based on the multilinear model highlighted that such a hyper-synchronization shown that the topological characteristics of movement network were related to the subject-specific clinical condition.

Conclusions: The application of network theory to human movement presents a novel technique for studying motor function both in health and disease such as in PD. This approach has the potential to provide valuable insights for rehabilitation protocols and therapeutic follow-up.

## ATYPICAL SONOGRAPHIC FINDINGS IN A YOUNG MAN WITH PARKINSONISM IN MACHADO-JOSEPH DISEASE

M. L. Usai[1], R. Meloni[1], C. Frau[2], P. Chessa[1], V. Floris[1], C. Bagella[3], A. Mura[3], P. Solla[2], C. Bagella[2]

[1]Department of Medical Sciences and Public Health, University of Cagliari (Cagliari); [2]Unit of Neurology, Department of Medical, Surgical and Experimental Sciences, University of Sassari (Sassari); [3]Unit of Nuclear Medicine, Department of Medical, Surgical and Experimental Sciences, University of Sassari (Sassari)

Introduction: Machado-Joseph disease (MJD), also known as spinocerebellar ataxia type 3 (SCA3), is an autosomal dominantly inherited cerebellar ataxia caused by CAG trinucleotide repeat expansions in the coding regions of ATXN3 gene [1]. Few studies have performed transcranial sonography (TSC) in SCA 3 patients and found hyperechogenicity of Substantia Nigra (SN) associated with a larger width of third ventricle and lenticular nucleus hyperechogenicity compared to healthy controls [2]. The disease is characterized by phenotype variability and several subtypes have been defined that could be related to the atypical echofeatures found in our young patient.

Objective: Case report.

Methods: We studied the case of a 27 years old African man with a 3-years history of gradually progressive slowness of movements and balance difficulty, with referred negative family history for neurological diseases. He underwent full neurological examination and genetic analysis on peripheral blood sample using PCR and capillary electrophoresis.

Results: Neurological examination revealed marked bradykinesia (mainly on the left) and gait ataxia, moderate gaze-evoked horizontal nystagmus and generalized hyperreflexia, without tremor, hypertonia or rigidity. Poor response to L-dopa therapy. Brain MRI showed cerebellar vermian atrophy with ventricular enlargement. 123I-FP-CIT SPECT (DaTscan) revealed a moderate bilateral reduction of dopamine presynaptic transporter levels. TCS showed third ventricular enlargement and right lenticular nucleus hyperechogenicity. There was no evidence of SN hyperechogenicity. Genetic analysis demonstrated pathogenetic CAG repeat expansion (67 repeats) in the coding region of ATXN3 gene.

Conclusion: In agreement with previous studies, MJD should be considered in the differential diagnosis of PD-like symptoms. The enlargement of third ventricle but the absence of SN hyperechogenicity found in our patient may suggest the presence of different pathophysiologic substrates correlated to a possible distinctive phenotype, that deserves to be investigated. Furthermore, given the fact that lenticular nucleus hyperechogenicity is associated with dystonia [3], follow-up is indicated regarding a possible development of this symptom.

## THERMAL QUANTITATIVE SENSORY TESTING AND ENDOGENOUS MECHANISMS OF PAIN CONTROL ASSESSED BY THE OFFSET ANALGESIA PARADIGM IN PATIENTS WITH PARKINSON'S DISEASE

F. Valentino[1], M. Todisco[2], G. Belluscio[1], S. Malaspina[1], L. Cabrino[3], E. Antoniazzi[2], C. Cavigioli[2], C. Tassorelli[4], R. Zangaglia[5], C. Pacchetti[5], G. Cosentino[4]

Objective: Pain represents a major, though poorly understood aspect of non-motor symptoms of Parkinson's disease (PD). The etiology of pain in PD has not been completely clarified and can be multifactorial. Alterations in emotional-motivational and sensory-discriminative pain processing have been supposed. Our aim was to assess in a group of PD patients both in on- and off-medication state the thermal sensory thresholds (TST), the heat pain threshold (HPT) and the response to a offset analgesia (OA) paradigm, that evaluates the function of the endogenous pain modulation system.

Material and Methods: Nine PD patients (mean age 62 yrs, 3 F) and 8 age- and sex-matched healthy subjects underwent an experimental paradigm including assessment of warm and cold detection thresholds (using the levels method), HPT, 3 stimulus offset trials and 3 constant temperature trials based on the individual HPT. Both the forearm and the dorsal foot were assessed on the most affected side of PD patients (the right side in the healthy subjects) when on- and off-medication state (two different sessions) when assessing the TST. The constant and offset trials were applied only at the forearm.

Results: Compared to healthy subjects, patients with Parkinson's disease in off-state had a reduced threshold for perception of the cold (less discriminative ability) stimulus at the forearm. The offset analgesia phenomenon was similarly observed in both off and on-therapy patients, with no difference vs. healthy subjects, albeit in off-therapy patients the visual analogue scale (VAS) score reduction was observed with a delayed latency.

Discussion: The altered perception threshold of the cold stimulus seems due to disease-related brain network abnormalities rather than to the loss of small fibers, in consideration of both the non-length-dependent pattern of the alteration and the normalization in the on-state. Findings form the OA paradigm are not compatible with alterations in the endogenous mechanisms of pain modulation in off-state patients. Noteworthy, only a delay of a few seconds in the VAS reduction recording during the OA paradigm was observed in the off-state patients, that was probably linked to bradykinesia.

Background: Sex is thought to be a significant factor in the phenotypic expression of idiopathic adult-onset dystonia (IAOD). Earlier observations suggested a women preponderance in most forms but task-specific upper limb dystonia, and an earlier age at dystonia onset in men. Since most information was from relatively small clinical series recruited in one or a few centers, a referral bias could not be excluded.

Objective: To analyse sex differences in the phenotype of IAOD in a large multicentre cohort from the Italian Adult-onset Dystonia Registry (IADR).

Materials and Methods: On May 2023, the IADR included 1698 IAOD patients from 42 centers. Age at dystonia onset, anatomical localization of dystonia, spread of focal dystonia, family history of

dystonia and dystonia associated sensorimotor features were compared between men and women.

Results: We observed that: (i) age at dystonia onset was similar in men and women (mean age 52.2 ± 14.7 vs 52.7 ± 14.4 years, p = 0.5); (ii) women predominate over men in cranial dystonia; (iii) the sex ratio was reversed in upper limb and lower limb dystonia; (iv) no clear sex difference emerged in cervical and trunk dystonia; (v) neck tremor predominates in women, while no sex difference emerged in terms of spread and family history of dystonia, sensory trick and sensory symptoms.

Discussion and Conclusions: Information from this large multicentre cohort indicated that the influence of sex on the phenotypic expression of IAOD is limited to some forms and features. It is possible that certain sex differences result from sociocultural rather than biological factors.

## GAIT PARAMETERS DIFFERENTIATE PHENOTYPES IN AN APPARENTLY HOMOGENEOUS COHORT PATIENTS AFFECTED BY PARKINSON'S DISEASE

A. Volzone[1], C. Ricciardi[2], M. Russo[2], F. Amato[2], M. Romano[2], P. Barone[1], M. Amboni[1]

[1]Department of Medicine, Surgery and Dentistry, University of Salerno (Baronissi-SA); [2]Department of Electrical Engineering and Information Technology, University of Naples "Federico II" (Napoli)

Background: Parkinson Disease (PD) subtypes have been generally based on motor symptoms such as the tremor-dominant versus postural instability and gait disorder or akinetic/rigid form. Non-motor symptoms in PD represent a significant burden of disease with high impact on quality of life. Non-motor symptoms phenotyping in PD is relevant to identify subtype-directed treatment strategy [1]. Cluster analysis is a method of unsupervised Machine Learning (ML) algorithms, which do not require labelled dataset [2].

Objectives: The aim is to identify different phenotypes of PD through a clustering method implemented with subclinical gait changes detected by gait analysis.

Materials and Methods: Ninety-four PD Patients were consecutively enrolled according to inclusion and exclusion criteria reported elsewhere [3]. All subjects were clinically assessed by total MDS-UPDRS scale and were evaluated by Gait Analysis, using an optoelectronic system supplied by BTS Bioengineering. An unsupervised approach to ML was performed through MATLAB (v.2020b). A k-means clustering algorithm was implemented to evaluate if different phenotypes could be distinguished in PD patients based on spatial-temporal parameters. After obtaining the clustered data, a univariate statistical analysis with IBM SPSS (v.28) was performed to find any other demographic and clinical difference between the clusters.

Results: K-means algorithm clustered the data into two groups: Cluster 1 and Cluster 2 with a sample size of 67 and 27, respectively. When comparing the two clusters on gait parameters, Cluster 2 in comparison with Cluster 1 patients showed reduction in single support phase, mean velocity, step, cadence and mean cycle length (p-value=0,001). In addition, Cluster 2 versus Cluster 1 exhibited increase in double support phase, stance phase and stance duration (p-value=0,001). Regarding demographical and clinical variables, Cluster 2 versus Cluster 1 showed worse scores on the Part I, Part II and Part III of the MDS-UPDRS scale and on H&Y scale (p-value=0.012, 0.004, 0.026, 0.016 respectively). Thus, Cluster 2 as compares to Cluster 1 patients showed more severe non motor symptoms, despite comparable disease duration and age.

Discussions and Conclusions: The present study shows that a cluster analysis was able to identify two discrete PD phenotypes based on a data-driven approach implemented with gait parameters. Therefore subclinical gait impairment could identify a worse PD phenotype characterized by more severe non-motor symptoms and more disability, as displayed by worse scores on MDS-UPDRS Part I and II.

## MUSCLE SYNERGIES DURING GAIT IN PARKINSON'S DISEASE

A. Zampogna[1], F. Castelli Gattinara Di Zubiena[2], M. Patera[1], G. Cusolito[3], M. Paoloni[3], E. Palermo[2], A. Suppa[1,4]

[1]Department of Human Neurosciences, Sapienza University of Rome (Roma); [2]Department of Mechanical and Aerospace Engineering, Sapienza University of Rome (Roma); [3]Department of Physical Medicine and Rehabilitation, Sapienza University of Rome (Roma); [4]IRCCS Neuromed (Pozzilli-IS)

Rationale/Objectives: Gait disorders are a major cause of morbidity and mortality in Parkinson's disease (PD), involving continuous and episodic disturbances associated with abnormal activation of individual muscles [1]. Still, it is unclear whether muscle synergies (i.e., groups of synchronously-activated muscles, variably combined to produce complex movements) are impaired during gait and affected by dopaminergic therapy [2,3]. This study aims to investigate muscle synergies during gait and their relationship with L-Dopa in PD.

Material/Methods: Fifteen PD patients (OFF and ON state of therapy) and 10 healthy subjects (HS) were monitored through inertial and electromyography (EMG) wearable systems while walking on a 20-m straight path. Eight IMUs, placed on the trunk, pelvis and lower limbs, were used to reconstruct joint angles and the gait cycle of at least ten consecutive strides. Muscle synergies were extracted from the surface EMG of 11 muscles of the dominant lower limb by a non-negative matrix factorization method. The "Variance Accounted For" (VAF) (i.e., the correlation coefficient between measured and reconstructed EMG signals) was analysed to examine the variability amount of recorded data explained by extracted synergies.

Results: PD patients showed a comparable number and composition of muscle synergies to HS, regardless of their therapeutic status. Moreover, the temporal activation profile of muscle synergies was similar between patients and HS. In both subgroups, four muscle synergies were associated with a VAF greater than 90% in reconstructing muscle activity during gait. Despite the similar composition and activation

profiles of synergies, PD patients exhibited higher amplitude peaks of involved muscles compared to HS. L-Dopa did not significantly impact the number, composition and amplitude peaks of muscle synergies in PD but partially enhanced the VAF, in line with improved gait kinematics in patients ON compared to OFF therapy.

Discussion/Conclusions: The number, internal structure and temporal activation profiles of muscle synergies during gait are normal in PD, suggesting preserved lower-level central generators. Dysfunctional higher-level centres, including basal ganglia and cortical motor areas, may be responsible for abnormal modulation of muscle synergies leading to co-contraction and increased amplitude peaks of involved muscles. The limited effects of L-Dopa on muscle synergies support the contribution of non-dopaminergic pathways in the pathophysiology of gait disorders in PD. However, the low sensitivity of sEMG to changes associated with dopaminergic therapy can not be excluded.

Objectives: Gait alterations are a prominent feature of Parkinson's disease (PD), whereas their progression and differences between stages is still theme of debate. Idiopathic REM sleep behavioral Disorder (iRBD) is the condition with the highest conversion to PD and other alpha-synucleinopathies, thus it is studied as a prodromal phase of PD. Aim of the study was to analyze gait temporal and spatial parameters in PD spectrum from the prodromal phase to the overt phase and to compare these parameters to Healthy controls and treated PD.

Methods: The prospective study included consecutively individuals with PSG- confirmed iRBD, drug-naïve PD patients, middle-stage treated PD patients and healthy controls. Each individual underwent a multidimensional assessment including evaluation of motor and non-motor symptoms, cognitive status and comorbidity. All individuals underwent a gait assessment using mobile health technology (MHT) in supervised condition at normal and fast pace and during dual-task performance.

Results: The study included 23 individuals with iRBDs, 60 drug-naïve PD patients (nPD), 60 middle-stage treated PD patients (tPD) and 65 controls (HC). MHT showed an increased step time in normal gait in nPD and in iRBD in comparison to controls, whereas tPD showed values similar to HC. Conversely, in fast gait MHT showed increased step time in untreated and treated PD in comparison to HC and iRBD. In dual task gait, iRBD, nPD and tPD showed increased step time in comparison to HC. Persons with PD, Naïve or not, exhibited shorter step length compared to HC in all tests ($p<0.001$), while iRBD showed values similar to HC and significantly greater than PD.

Conclusion: This multicenter study using MHT showed that step temporal parameters are more sensitive to change in prodromal phases of the disease, while step length seemed to be preserved in this phase. The dopaminergic treatment in PD appear to reduce the temporal gait differences to control in normal gait but exhibited no impact on dual-task and fast gait. Further ongoing longitudinal studies are warranted to evaluate the value of MHT in defining the risk of conversion and track the subtle motor progression in prodromal phases and early response to treatment in PD.

## SEED-BASED FUNCTIONAL CONNECTIVITY CHANGES AND CERVICAL MOTION ANALYSIS ALTERATIONS IN PATIENTS WITH CERVICAL DYSTONIA

L. Zenere[1], E. Sarasso[1], D. Emedoli[2], A. Gardoni[1], S. Basaia[1], S. Iannaccone[2], S. Amadio[3], U. Del Carro[3], F. Agosta[4], M. Filippi[5]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [2]Department of Rehabilitation and Functional Recovery, IRCCS San Raffaele Scientific Institute (Milano); [3]Neurophysiology Service, IRCCS San Raffaele Scientific Institute (Milano); [4]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [5]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: Evaluating neck movement quality and studying the brain mechanisms underlying cervical dystonia (CD) are fundamental to plan the best treatment strategy. This study aimed at assessing kinematic and resting-state functional connectivity (FC) characteristics in patients with CD relative to healthy controls.

Materials: Seventeen CD patients and 14 age- and sex-matched healthy controls were recruited.

Methods: Electromagnetic sensors were used to obtain spatio-temporal parameters of neck movements in CD patients and healthy controls during three tasks: repeated cervical movements, target reaching and joint position error. Mean and maximal cervical movements amplitude was measured, both with eyes open and closed. Movement quality parameters during target reaching were obtained. Joint position error parameters were registered with both eyes open and closed. The precise dystonic position was also calculated. All participants underwent resting-state functional MRI (RS-fMRI). A seed-based FC analysis with supplementary motor area (SMA) as region of interest was performed. Correlations between motion analysis parameters and FC data were assessed.

Results: CD patients relative to controls showed reduced mean and maximal range of motion (ROM) in rotation both towards and against

dystonia pattern and reduced total ROM in rotation both with eyes open and closed. Moreover, CD patients had less severe dystonia pattern with eyes open relative to eyes closed. The RS-fMRI analysis showed reduced FC in CD patients between SMA and bilateral occipital and cerebellar areas compared to controls. A reduced FC within the visuo-motor network correlated with a lower cervical ROM in rotation both with eyes open and closed and with a worse cervical movement quality during target reaching.

Discussion: Our results highlighted specific motor deficits of CD patients: movement amplitude resulted compromised not only against dystonia, but also towards. Moreover, visual input could play an important role in movement control in CD patients as shown by the results of the comparison between movement with eyes closed and open. Functional changes of the visuo-motor network correlated with a worse cervical motor control.

Conclusions: FC alterations in the visuo-motor network may represent the neural basis of cervical motor control deficits in CD patients. Electromagnetic sensors and RS-fMRI might be promising tools to monitor CD and to assess the efficacy of rehabilitative interventions.

## CLINICAL UTILITY AND REPRODUCIBILITY OF VISUAL RATING SCALE FOR CINGULATE ISLAND SIGN IN A REAL-WORLD MEMORY CLINIC: A FDG-PET/MRI STUDY

G. Zorzi[1], G. Gazzola[2], F. Rossato[2], G. Camporese[3], C. Busse'[2], E. Gasparoli[1], F. Magnani[4], C. Gabelli[1], D. Cecchin[4], A. Cagnin[5]

[1]Research Center for the Aging Brain (CRIC), Department of Systems Medicine, University of Padua (Padova); [2]Neurology, Department of Neurosciences (DNS), University of Padua (Padova); [3]CDC AULS6 (Padova); [4]Nuclear Medicine Unit, Department of Medicine (DIMED), University of Padua (Padova); [5]Neurology Unit, Department of Neurosciences (DNS) and Padova Neuroscience Centre, University of Padua (Padova)

Purpose: Brain [18F]FDG-PET is a supportive biomarker for dementia with Lewy bodies (DLB) showing occipital hypometabolism and presence of the cingulate island sign (CIS), a relative preservation of the posterior cingulate cortex (PCC) metabolism compared with that of precuneus and cuneus. We assess the clinical utility and reproducibility of a visual qualitative CIS scale in differentiating DLB from Alzheimer's disease (AD) in the memory clinic setting.

Methods: Patients with a diagnosis of Lewy bodies disease (DLB and MCI-LB) and with AD with available FDG-PET/MRI were recruited and followed for at least 24 months. data were retrospectively collected. Visual rating scale was applied independently by a nuclear medicine and neurologist physician. Validation of qualitative CIS scores was made with ROI-based semiquantitative analysis of FDG uptake ratio of PCC, cuneus and precuneus.

Results: 77 patients were recruited: 36 with LBD (30 DLB and 6 MCI-LBD) and 31 patients with AD (20 typical and 11 atypical presentations). Mean CIS score was 1.84±1.69 for DLB and 0.9±1.24 for AD patients (p=0.001). With a cut-off CIS score ≥ 2, sensitivity and specificity were 0.56 and 0.81, respectively (accuracy 0,67). Positive CIS in patients with a biological diagnosis of AD was mainly due to atypical presentations. Negative CIS in LBD were due to (a) normal FDG-PET or (b) marked hypometabolism of both PCC and cuneus. Scores of CIS rating scale correlated with uptake of FDG tracer ($r = 0.45$; $p < 0.001$) and showed high concordance among different specialists (K 0.62, p<0.001).

Conclusion: A visual CIS scale can be a surrogate for a quantitative CIS ratio and can be successfully applied by different specialists. Lower sensitivity is expected for cases of MCI-LB or dementia due to mixed DLB/AD changes. Specificity may be influenced by inclusion of atypical AD cases, mostly young-onset cases posterior variant of AD.

## MULTIPLE SCLEROSIS

## OPTIMAL RESPONDERS TO PLATFORM DISEASE MODIFYING THERAPIES FOR RELAPSING MULTIPLE SCLEROSIS: A REAL-WORD STUDY

I. Addazio[1], E. Portaccio[1], E. De Meo[1], L. Pastò[1], L. Razzolini[1], G. De Luca[2], F. Patti[3], V. Brescia Morra[4], M. Simone[5], I. Iaffaldano[6], M. Filippi[7], M. Trojano[6], M. Amato[1]

Objective: The objective of the present study is to identify the proportion and characteristics of relapsing MS patients who can obtain greater benefits from a less effective but safer, platform DMT.

Methods and Materials: relapsing MS patients starting a platform DMT (interferons, glatiramer acetate, teriflunomide, dymethilfumarate, azathioprine), with follow-up ≥ 10 years (n=7852) were extracted from the Italian MS Registry. Confirmed disability accrual (CDA) was defined as an increase in Expanded Disability Status Scale (EDSS) score confirmed at 6 months. Optimal responders to platform DMT (patients remaining on platform DMT and without any CDA during the follow-up) were compared with patients remaining on platform DMT experiencing a CDA and patients switching to high efficacy DMT using multinomial regression models.

Results: Over a follow-up of 14.7+3.8 years, 2112 (26.9%) patients were considered optimal responders to platform DMT, while 2238 (28.5%) experienced a CDA and 3502 (44.6%) switched to a high efficacy DMT. As compared with patients still on platform DMT and those experiencing a CDA, optimal responders had younger age (OR=0.96,95%CI 0.95-0.97, p<0.001) and shorter disease duration at baseline (OR=0.97,95%CI 0.96-0.98, p<0.001). As compared with switchers, optimal responders had older age (OR=1.03,95%CI 1.02-1.04, p<0.001), shorter disease duration (OR=0.98,95%CI 0.97-0.99, p<0.001), lower EDSS at baseline (OR=0.76,95%CI 0.72-0.80, p<0.001) and monofocal onset (OR=1.26,95%CI 1.05-1.51, p=0.011). These findings were confirmed in the subgroup of 4500 patients with baseline magnetic resonance imaging (MRI) data available. In addition, as compared with patients still on platform DMT and CDA, a greater proportion of optimal responders had an active baseline MRI (OR=1.28,95%CI 1.09-1.51, p=0.003).

Discussion: The superiority of early introduction of high efficacy disease modifying therapies (DMT) in relapsing Multiple Sclerosis (MS) is being increasingly recognized, although long-term safety

data are largely missing and some patients may still obtain benefits from a safer DMT.

Conclusion: In this real-world population, the majority (two thirds) of patients initially treated with platform DMT had poor outcomes or switched to high efficacy DMT in the long term. Platform DMT might be considered in young adults with monofocal onset, active MRI, short disease duration and low disability levels.

## THE POSITIVE EFFECTS OF AEROBIC CAPACITY ON FATIGUE ARE MEDIATED BY THALAMIC NUCLEI IN PEOPLE WITH MULTIPLE SCLEROSIS

M. Albergoni[1], E. Pagani[1], P. Preziosa[2], M. Margoni[3], M. Rocca[2], M. Filippi[4]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [2]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [3]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute (Milano); [4]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Aims: Fatigue is a common symptom in people with multiple sclerosis (pwMS) affecting mental and physical domains. Aerobic capacity (AC), disability and cognitive impairments contribute to fatigue perception. The thalamus has been consistently involved in fatigue pathogenesis. Aims of this study were to identify associations between thalamic nuclei volumes and fatigue and explore whether the effect of AC on this symptom is mediated by the volume of thalamic nuclei in pwMS.

Materials and Methods: In this cross-sectional study, Modified Fatigue Impact Scale (MFIS), Expanded Disability Status Scale (EDSS), Symbol Digit Modalities Test (SDMT), maximal oxygen uptake (VO2max) and brain MRI data of thalamic volumes were collected from 74 pwMS. 47 sex- and age-matched healthy controls (HC) were included for MRI comparison. Thalamic nuclei volumes were obtained using Freesurfer 7.1.1 on 3D T1-weighted lesion-filled images. PwMS and HC were compared using the $\chi 2$ Pearson, Mann-Whitney or t-test. Correlations between thalamic nuclei and MFIS scores were performed using Pearson's or Spearman's partial correlations. A mediation model was applied in pwMS to assess the existence of an indirect pathway of AC acting through thalamic nuclei on fatigue.

Results: Patients and HC did not differ for age and sex ($p>0.557$). Compared to HC, pwMS were characterized by global atrophy and lower thalamic nuclei volumes ($p\leq0.001$). In pwMS, fatigue was associated with atrophy of left latero-dorsal nucleus (left-Dor) (r-value=-0.278; $p\leq0.018$), with a stronger association with cognitive rather than physical fatigue. More severe disability (r-value=0.355; p=0.004) and worse processing speed (r-value=-0.353; p=0.003) were associated with more severe fatigue and diffuse thalamic atrophy. In contrast, higher AC was associated with less severe fatigue (r-value=-0.263; p=0.027) and atrophy of the left-Dor (r-value=-0.288; p=0.015). The mediation model showed that in pwMS there was a significant indirect effect of VO2max on fatigue through the volume of the left-Dor nuclei (b =-0.305, CI [-0.678;-0.005]).

Discussion: The aim of this study was to better understand fatigue in pwMS, taking in consideration the multifactorial nature of this symptom and with a special focus on the role of AC and thalamic nuclei. Our results confirmed the positive effects of AC on fatigue, which seems to be partially mediated by the integrity of a specific thalamic nucleus.

Conclusions: Aerobic capacity exerts a positive effect on fatigue in pwMS, which is indirectly mediated by a preserved volume of the left-Dor thalamic nucleus.

Funding. Partially supported by Italian Ministry of Health (GR-2019-12369599).

## INEBILIZUMAB FOR NEUROMYELITIS OPTICA SPECTRUM DISORDER: THE FIRST ITALIAN PATIENT

P. E. Alboini[1], L. Florio[1], P. Crociani[1], A. Biancofiore[2], M. Di Viesti[2], G. Cristiano[2], G. d'Orsi[1]

[1]Neurology Department, IRCCS Casa Sollievo della Sofferenza (San Giovanni Rotondo-FG); [2]Hospital Pharmacy Unit, IRCCS Casa Sollievo della Sofferenza (San Giovanni Rotondo-FG)

Introduction: Neuromyelitis optica spectrum disorder (NMOSD) is an antibody-mediated disease of CNS where autoantibodies directed against aquaporin-4, a water channel, destroy astrocytes. Transverse myelitis, optic neuritis and area postrema syndrome are typical presentations of this disease. If untreated, patients will experience a severe illness which may bring to wheelchair or even to death. Relapses must be treated aggressively to prevent disability. A relapse prevention is crucial and needs long-term immunosuppression. In 2022 the Italian regulatory agency for drug prescription approved two new drugs for NMOSD: eculizumab and satralizumab; both of them must be prescribed to those patients with an EDSS $\leq$ 6.5. With an higher EDSS score there have been no chance until march 2023 when inebilizumab have been approved. Actually this drug may be administered to those NMODS patients with an EDSS score $\leq$ 8. We present our experience with the first Italian patient treated with inebilizumab.

Case report: A 40 years old male patient was referred to our institution with a diagnosis of CIDP to continue IVIg treatment. The patient was on wheelchair and he was able to walk just for few steps. Deep tendon reflexes were brisk with clonus; Babinski sign and ankle clonus were recorded. Diagnosis of CIDP was reconsidered. Patient underwent to brain and spine MRI revealing a transverse myelitis. Cerebrospinal fluid tests showed and albumin-cytological dissociation. Nerve conduction studies were consistent with CIDP. Anti-AQP4 antibodies were present: patient was diagnosed with CIDP and NMOSD and began rituximab, with no benefits: he experienced one relapse per year requiring plasma-exchange. So rituximab was discontinued and mycophenolate was began. In 2022 his clinical status worsened with a marked spasticity and he reached an EDSS score of 7.5. As eculizumab and satralizumab could not be prescribed, when inebilizumab was available it was suggested. The patient accepted; a wide viral screening did not show any contraindications. The day of the administration, patient was pre-treated with a steroid pulse and an antihistamine; then inebilizumab was reconstituted in 250 cc of saline solution in the fume hood of our hospital pharmacy. Inebilizumab was administrated in one hour and a half and no side effects were recorded. The day after first administration patient referred an improvement of spasticity, noticeable during the clinical evaluation before the second administration.

Conclusions: In our experience inebilizumab seems a promising drugs and may be indicate for those patients who suffer from a severe form a NMOSD.

## BALANCE DISORDERS IN MULTIPLE SCLEROSIS: ASSESSMENT AND ROBOTIC REHABILITATION TREATMENT

A. Aleo[1], A. Quaglia[1], S. Pozzi[2], L. Venturi[2], A. Lugaresi[3], L. Sabattini[3]

[1]IRCCS Institute of Neurological Sciences Bologna, University of Bologna (Bologna); [2]DATeR Hospital Rehabilitation, Ospedale Bellaria, UOSI Multiple Sclerosis Rehabilitation (Bologna); [3]IRCCS Institute of Neurological Sciences Bologna, UOSI Multiple Sclerosis Rehabilitation, Ospedale Bellaria (Bologna)

Balance impairment is present in 50-80% of people with multiple sclerosis (PwMS), significantly impairing patients' quality of life and autonomy. Robotic rehabilitation has been shown to be a promising modality of intervention to improve balance in orthopedic, geriatric, and neurological settings, with applications in post-stroke rehabilitation, Parkinson's disease, and MS. This study evaluated the use of Hunova robotic footplate rehabilitation treatment in PwMS. The study involved 35 PwMS, who each performed ten sessions of 30 minutes on a biweekly schedule with Hunova. In order to identify the patients' achieved progress, clinical and robotic assessments were performed at the beginning and end of the rehabilitation course. Results revealed a significant improvement in balance assessed with the Berg balance scale (BBS, p value=0.0081). In the robotic assessment, positive changes in parameters related to elastic, passive, reactive balance and Five Times Sit to Stand tests were significant. The improvement in these specific parameters is mainly related to an optimization of the vestibular component of balance and trunk control. The effects on BBS are similar to those found in other pathologies, like in the Parkinson's disease. Results in the PwMS subgroups differed from the trend in the total population, identifying a different response depending on the age (under and over 50 years old) and the degree of disability (EDSS 0-3.5 and 4-6.5). In conclusion, we were able to show that robotic rehabilitation with Hunova effectively improved balance in patients with mild to moderate MS. Improvements mainly regarded trunk control and the vestibular component of balance. We therefore assume that PwMS suffering from balance impairment can benefit from Hunova treatment. However, additional studies are needed to further assess efficacy and to define the optimal therapeutic dose of robotic rehabilitation in the setting of PwMS and in specific subgroups, differentiating, for example, between patients with main spinal or cerebellar involvement.

## DIMETHYL FUMARATE-ASSOCIATED LYMPHOPENIA FOLLOWING BARIATRIC SURGERY: TWO CASE REPORTS

V. Andreozzi[1], R. C[1]apuano[2], S. Scannapieco[2], F. Barra[2], B. D'Arco[1], M. Caterino[1], F. Di Filippo[1], U. De Marca[1], C. Giordano[1], P. Barone[1], M. Di Gregorio[2]

[1]Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", University of Salerno (Salerno); [2]Neurology Clinic Department of Medical Sciences, AOU San Giovanni di Dio e Ruggi d'Aragona (Salerno)

Introduction: Lymphopenia is a common side effect of treatment with dimethyl fumarate (DMF) in patients with multiple sclerosis (PwMS) [1]. Higher baseline absolute lymphocyte count (ALC) and a body mass index (BMI) $\geq$ 30 kg/m2 has been identified as protective factors for lymphopenia [2]. Although there are data about higher BMI, no data are available on ALC changes in pwMS undergoing to weight loss due to diet modification or to bariatric surgery.

Objective: We herein report two cases of lymphopenia in female pwMS treated with DMF and history of bariatric surgery.

Methods: Patients underwent a multidimensional assessment including neurological and hematological evaluation, with a longitudinal follow up.

Results: Patient 1 is a 25-year-old woman with history of obesity treated with gastric bypass in 2016. She started DMF due to intolerance to DMTs injection in 2021. Since DMF beginning, ALC showed a downward trend until a grade 3 lymphopenia persisting for more than 6 months. Patient 2 is a 50-year-old woman with history of obesity treated with bariatric surgery in 2006. Due to injection site reaction she underwent to DMF in December 2020. Four months after blood examination showed lymphopenia that worsened and persisted for more than 6 months. Both patients discontinued DMF treatment due to persistent lymphopenia with rapid normalization of ALC and switched to another oral platform therapy that was well tolerated.

Discussion: After bariatric surgery, several mechanisms can affect drug bioavailability. After oral intake, DMF is hydrolyzed to monomethyl-fumarate (MMF), its main bioactive metabolite, mostly in the small intestine, where there is an alkaline environment that promote the transformation [3]. The exposure to stomach higher pH levels and the faster transfer of this drug to the bowel due to increased gastric emptying rate, but also changes in body compositions, alterations of molecular pathways and changes in gut microbiota could lead to an increased absorption rate, hypothetically enhancing some side effects.

Conclusions: To improve the care provided to bariatric surgery pwMS, additional clinical studies are necessary to explore the impact of this surgery on DMT.

## DORSOLATERAL PONTO-MEDULLARY SYNDROME WITH IPSILATERAL HEMIPARESIS AFTER HERPES ZOSTER OPHTALMICUS

M. G. Aprea[1], L. Pasto'[2], E. Portaccio[3], A. Ginestroni[4], E. Fainardi[5], M. Amato[3]

[1]Careggi University Hospital, Department of Neurosciences, Psychology, Drug Research and Child Health (NEUROFARBA), University of Florence (Firenze); [2]Division of Neurological Rehabilitation, Careggi University Hospital (Firenze); [3]Department of NEUROFARBA, University of Florence (Firenze); [4]Neuroradiology Unit, Department of Radiology, Careggi University Hospital (Firenze); [5]Neuroradiology Unit, Department of Experimental and Clinical Biomedical Sciences Mario Serio, University of Florence (Firenze)

Objectives: To underline the value of MRI in diagnosis and early detection of Central nervous system (CNS) involvement after Herpes Zoster infection.

Methods - Case presentation: A 71-year-old woman affected with Relapsing Remitting Multiple Sclerosis (RRMS) treated with dimethyl fumarate (DMF) complained itch/tingling and pain followed by a skin maculopapular and vesicular rash in the V1 distribution of the left trigeminal nerve, six days after the administration of the first dose of COVID-19 vaccine. A diagnosis of herpes zoster opthalmicus was done and oral antiviral treatment was started. Despite treatment, vesicular rash worsened and the patient complained dizziness and paraesthesia/hypoesthesia involving right arm and leg. Neurological examination revealed cranial multineuropathy involving left facial and trigeminal nerves, a mild ipsilateral limb ataxia, decreased pain and temperature sensation in controlateral limbs, and a mild ipsilateral hemiparesis with Babinski sign. Intravenous therapy with acyclovir was started.

Results: A brain and cervical spinal cord MRI showed a T2 hyperintensity of the left trigeminal nerve, in the dorsolateral regions of the pons and medulla, extending to the upper cervical cord (C2), with T1 hypointensity and diffuse contrast enhancement after gadolinium administration in the same regions, findings that confirmed the suspicion of herpetic encephalomyelitis. Cerebrospinal fluid (CSF) examination showed a slightly elevated total protein level of 0.48 g/L, CSF/serum glucose ratio of 55% and 7 leukocytes/microL. Polymerase chain reaction (PCR) analysis was negative for Varicella-Zoster DNA. Intravenous acyclovir was continued for 21 days with symptomatic improvement. A brain MRI performed 4 months after showed a reduction of lesion extension and contrast enhancement was no longer seen.

Discussion: CNS involvement after Herpes Zoster infection is a rare complication that can lead to permanent neurological damage or even death [1]. In our case report, Varicella-Zoster DNA was not detected in the CSF. However, the analysis was performed 14 days after the onset of antiviral treatment and in the majority of treated cases there is a substantial decline of PCR-positivity [2]. Brain MRI provided a sort of "in-vivo tracing" of trigeminal nerve and nuclei, following the diffusion of herpes zoster reactivation from Gasser ganglion to the pontine, and medullary-spinal nuclei and neighboring areas. In our patient, the involvement of CNS led to the complex and unusual clinical picture of a dorsolateral ponto-medullary syndrome with ipsilateral hemiparesis.

Conclusion: Although rare, potential CSN involvement should be considered, since prompt diagnosis and consequent early treatment are essential to favorable outcome [3].

Objectives: To assess maternal and fetal outcomes and their predictors in pregnant women with Multiple Sclerosis (MS) and COVID-19 infection selected from two large national registries and compared with matched control pregnancies extracted from a historical Italian cohort.
Methods: We recruited pregnant patients with MS who contracted COVID-19 after conception and were followed-up in Italian and Turkish Centers, in the period 2020-2022. A control group was extracted from a previous Italian multicenter cohort. The primary outcome measures were maternal complications, fetal malformations and spontaneous abortion. Associations between group (COVID-19 or healthy patients) and clinical outcomes were investigated with a weighted logistic regression where propensity score-based inverse probability of treatment weighting (IPTW) approach was applied for adjusting for difference in baseline confounders. Variables considered possibly associated with the outcome in univariate analysis ($p<0.10$) were tested for multivariable analysis.

Results: Data on pregnancy outcome are available for 61 out of 67 pregnant MS women with COVID-19 after conception. In the

multivariable analysis, COVID-19 during pregnancy was associated with a higher risk of maternal complications (OR 2.00, CI 1.25 – 3.24; p = 0.005). The infection was not associated with higher risk of spontaneous abortion and fetal malformations (respectively 0.53, CI 0.23 – 1.17; p = 0.13 and 1.40, CI 0.53 – 3.87, p = 0.50). The sole independent predictor of spontaneous abortion and fetal malformations was a previous spontaneous abortion (respectively 5.06, CI 1.93 – 12.17, p < 0.001 and 12.26, CI 4.23 – 34.47, p <0.001).

Discussion: Data in the general population have shown an increased risk for adverse maternal and fetal outcomes in infected women [1]. So far, only one small study [2] and a larger international study [3] have assessed COVID-19 clinical outcomes in pregnant women with MS, showing no significant increase of severe COVID-19 outcomes, but there is total lack of information about maternal and fetal outcomes. This is the first study assessing the impact of COVID-19 on pregnancy and fetal outcomes in women with Multiple Sclerosis, showing that COVID-19 during pregnancy was associated with higher risk of maternal complication, in line with data from the general population. As concerning spontaneous abortion and fetal malformations, our findings seem to be in contrast with data from the obstetric literature, as we found no significant correlation between COVID-19 and adverse fetal outcomes.

Conclusion: Our data indicate that SARS-CoV-2 infection during pregnancy increases the risk of maternal complications, while it seems to have no significant impact on fetal outcomes.

## OCRELIZUMAB-INDUCED NUMMULAR ECZEMA IN A PATIENT WITH RELAPSING MULTIPLE SCLEROSIS

F. Aprile[1], S. Casali[2], M. Stromillo[1], L. Lazzeri[3], G. Maccanti[1], M. Ulivelli[2]

[1]Department of Medicine, Surgery and Neuroscience, University of Siena (Siena);[2]UOC Neurology and Neurophysiopathology, University of Siena (Siena);[3]UOC Dermatology, University of Siena (Siena)

Aims: Anti-CD20 monoclonal antibodies are among the drugs that showed the greatest efficacy in controlling disease activity and in preventing long-term disability in patients with multiple sclerosis (MS). Main adverse reactions of these therapies are hypogammaglobulinaemia, infections, infusion-related skin reactions. We describe a case of an ocrelizumab-induced nummular eczema in a female patient with relapsing MS.

Material: In 2008, at the age of 25, diagnosis of relapsing-remitting MS. In the medical history: contact/atopic dermatitis. She was first treated with interferon and then with natalizumab, both suspended due to ineffectiveness, without any dermatological adverse effects. Ocrelizumab was started in May 2020, without any infusion-related hypersensitivity reaction.

Method: About 3 months after the third infusion, onset of hands dermatitis with subsequent appearance of exuding and itchy vesicles; initially, these symptoms were associated with the known atopic/contact dermatitis, so corticosteroids, antihistamics and antibiotics were performed with partial benefit. Then, Ocrelizumab was repeated. At the same time, the patient was vaccinated for Sars-CoV-2. In the next moths, skin lesions got worse again and diagnosis of nummular eczema was done but, since vaccinations or infections may worsen pre-existing dermatological lesions, it was uncertain if the responsible was the vaccine or the drug. So, Ocrelizumab was re-infused, with further worsening of the skin lesions and a biopsy was performed.

Results: Histological examination revealed chronic inflammatory skin lesions with superficial spongiotic dermathosis: these features confirmed nummular eczema. Due to the severity of the clinical picture, Ocrelizumab was definitely stopped.

Discussion: The correlation between anti CD-20 therapies and the onset of skin manifestations is well known. Reports of induced or worsened psoriasis by Rituximab[1] and palmoplantar or oral pustulosis and lichen planus following Ocrelizumab infusion are described[2]. The mechanism below could be the disruption of the balance between T and B cells, with hyperfunctioning of T cells and consequent increase in susceptibility to viral and bacterial infections, or the alteration of the skin barrier, with hypersensitivity to common environmental factors. As a result, these features can lead to various types of skin lesions. In medical literature, only another case of nummular eczema following Ocrelizumab infusion is reported[3].

Conclusions: In this case, the temporal connection between Ocrelizumab and the skin lesions and the lack of any other causative factor support their causal connection. It's important for the clinicians to consider this relationship, in order to early recognize these manifestations, and to promptly reevaluate the therapy.

## PEDIATRIC ONSET OF MULTIPLE SCLEROSIS FOLLOWING EBV INFECTION AND COVID-19 VACCINATION

F. Aprile[1], M. Mortilla[2], N. De Stefano[1], M. L. Stromillo[1]

[1]Department of Medicine, Surgery and Neuroscience, University of Siena (Siena); [2]Department of Radiology, Meyer Children's Hospital, University of Florence (Firenze)

Background: Epstein Barr Virus (EBV) infection has recently received attention as a potential environmental trigger that may contribute to the development and progression of multiple sclerosis (MS). Several lines of evidence suggest a link between EBV and MS, including the observation that individuals who were infected with EBV at a younger age have more risk of developing MS. During the vaccination campaign against SARS-CoV-2, there have been reports of autoimmune CNS demyelinating diseases, including cases where MS was the first manifestation. We present a case involving a young patient who experienced the clinical onset of pediatric MS (POMS) following EBV infection and COVID-19 vaccination.

Case description: A 16-year-old girl referred to our center for onset of symptoms including numbness and weakness on the right side of her face, as well as tingling sensations in her right hand. Approximately three weeks prior to the neurological symptoms, she received

the third dose of the Pfizer-Cominarty COVID-19 vaccine, which was well-tolerated. About a year and a half before the onset of her current symptoms, the patient was hospitalized with fever and severe occipital headache due to EBV infection. In that occasion, a brain CT scan was normal. At presentation (one week after symptom onset), the patient showed tingling in right side of face and in the right hand (EDSS 2.0). Brain magnetic resonance imaging (MRI) revealed multiple voluminous white matter (WM) lesions that resembled Acute Disseminated Encephalomyelitis (ADEM), with most of the lesions located in the periventricular region and showed enhancement after the administration of gadolinium. The patient underwent a diagnostic workup, including basic metabolic panel and autoimmune tests, which all came back within the normal range. Oligoclonal bands were detected in the cerebrospinal fluid analysis. Screening for antibodies associated with CNS demyelinating disorders, including MOG and AQP4, yielded negative results. A follow-up brain MRI performed four months later showed an increase in the size of previously enhancing lesions and presence of new WM lesions. Based on the evidence of spatial-temporal dissemination on MRI, in accordance with the 2017 McDonald criteria, a diagnosis of pediatric multiple sclerosis (POMS) was made.

Discussion and Conclusion: This case highlights a potential association between EBV infection, possibly complicated by COVID-19 vaccination, and the development of pediatric MS. It supports the existing evidence suggesting a link between EBV and MS and emphasizes the importance of monitoring potential neurological complications in individuals with EBV infection.

## SPONTANEOUSLY RESOLVING BRAIN RING-ENHANCING LESIONS DUE TO IMMUNODEFICIENCY-ASSOCIATED CENTRAL NERVOUS SYSTEM LYMPHOMA: A CASE OF "VANISHING LYMPHOMA"

M. Azzimonti[1], F. Esposito[1], P. Poliani[2], F. Gagliardi[3], N. Anzalone[4], P. Panni[5], A. Giordano[1], V. Martinelli[1], M. Rocca[6], M. Filippi[7]

[1]Neurology Unit, IRCCS San Raffaele Scientific Institute (Milano); [2]Pathology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [3]Neurosurgery and Gamma Knife Radiosurgery Unit, IRCCS San Raffaele Scientific Institute (Milano); [4]Neuroradiology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [5]Neuroradiology Unit, IRCCS San Raffaele Scientific Institute (Milano); [6]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [7]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Background: The differential diagnosis of brain ring-enhancing lesions is broad, especially in patients with systemic autoimmune diseases undergoing immunosuppression, and includes infections, inflammatory lesions and treatment-related malignancies. We present the case of a patient with several ring-enhancing lesions, some of which resolved without treatment at a follow-up MRI, due to immunodeficiency-associated central nervous system (CNS) lymphoma secondary to immunosuppression for systemic lupus erythematosus (SLE).

Description: A 57-years old woman was evaluated at emergency department after tonic-clonic seizure. Her past medical history included SLE, diagnosed 34 years before, with renal and hematologic involvement. She was treated with mycophenolate mofetil (MMF) for 20 years (initially 2000 mg daily, then 1000 mg daily for 6 years), hydroxychloroquine for 6 years and prednisone from disease onset. She underwent brain MRI, which showed 7 ring-enhancing lesions located both at the grey/white matter junction and in the basal ganglia. The largest lesion measured 13x13x13 mm, was located in the parieto-occipital lobe and showed MRI signs of central necrosis. Cerebrospinal fluid (CSF) proteins, glucose level and cell count was within normal limits; microbiological analyses, comprehensive of Cryptococcus, Toxoplasma, Aspergillus, Mycobacterium tuberculosis and EBV, were negative. Isoelectric focusing showed the presence of CSF-restricted oligoclonal bands. Full-body computed tomography and [18F]-fluorodeoxyglucose positron emission tomography showed no evidence of systemic disease and hypermetabolism of the known brain lesions. A follow-up MRI scan, performed one month after presentation, showed increase of the size of the largest brain lesion and substantial resolution of contrast-enhancement in the other lesions. She underwent brain biopsy: histological analysis showed large lymphoid elements with irregular nuclei, positive for CD20, BCL2 and EBV-related markers. A diagnosis of immunodeficiency-associated CNS lymphoma was made.

Discussion: Immunodeficiency-associated CNS lymphoma is a known adverse effect of MMF treatment for SLE [1]; its pathogenesis is related to EBV-sustained replication, transformation and immortalization of B-lymphocytes [2]. Immunodeficiency-associated CNS lymphoma is more often multifocal than primary CNS lymphomas occurring in immunocompetent patients; however, presentation with seven different contrast-enhancing foci is unusual. Moreover, in our patients some of the lesions resolved without treatment while other progressed, a rare pattern known as "vanishing lymphoma" [3].

Conclusions: Our case highlights the importance of brain biopsy, even in the context of spontaneously resolving lesions, in the diagnostic workup of brain ring-enhancing lesions.

## ALL IS WELL THAT ENDS WELL: A CASE OF PREGNANCY DURING SC NATALIZUMAB

S. Bartolomeo, D. Landi, C. Nicoletti, G. Mataluni, G. Marfia

Multiple Sclerosis Clinical and Research Unit, Department of Systems Medicine, Tor Vergata University (Roma)

Objectives: Natalizumab (NTZ) is a humanized monoclonal IgG4 antibody directed against the a4-ß1 integrin (VLA-4). In 2021 the subcutaneous (SC) injection of natalizumab, dosed 300 mg every 4 weeks (Q4W), received marketing authorization in Europe to treat Relapsing-Remitting Multiple Sclerosis (RMS), building on the similar efficacy, pharmacokinetic and pharmacodynamic profiles of the intravenous formulation. In recent years, several studies have shown that continuation of intravenous infusion of NTZ during gestation protects from relapses during pregnancy and post-partum, without major risks for newborns. No data is yet available for the new SC route. To describe efficacy and safety of the use of sc NTZ during pregnancy we report the case of a patient followed up at the Pregnancy Clinic of MS center of Tor Vergata University Hospital who found out being pregnant during SC Natalizumab treatment.

Materials and Methods: We report on a 33-years-old, nulliparous Italian woman, 40 kg body-weight at conception, treated with i.v. Natalizumab for 10 years, Q4W, which was switched to the SC formulation due to difficult venous access. She was found out being pregnant after the first injection and she accepted to continue therapy throughout pregnancy with extended interval dose (EID) Q6W.

Results: No relapses or other relevant side effects during pregnancy and postpartum were recorded. She delivered a healthy baby through cesarean section (weight 2500 g and length 46cm). No major congenital nor hematological anomalies were reported after birth and at 6 months follow-up.

Conclusion and Discussion: This case confirms the good maternal-fetal safety profile of NTZ administered during pregnancy. Indeed, it shows that extending the interval doses during pregnancy does not affect the risk of MS relapses also in the case of subcutaneous formulation. Further research on larger case series is needed to confirm present results.

## ANTI-JCV ANTIBODY INDEX KINETICS DURING PREGNANCY AND POST-PARTUM IN WOMEN WITH MULTIPLE SCLEROSIS TREATED WITH NATALIZUMAB

S. Bartolomeo, D. Landi, F. Napoli, L. Pizzuti, G. Mataluni, C. Dionisi, C. Nicoletti, G. Marfia

Multiple Sclerosis Clinical and Research Unit, Department of Systems Medicine, Tor Vergata University (Roma)

Background and Objectives: During pregnancy maternal immune system undergoes major reorganizations in order to establish fetal immunotolerance. Such immunological changes may impair immunosurveillance against pathogens. The John Cunningham virus (JCV) is a latent pathogen occasionally causing progressive multifocal leukoencephalitis (PML) in patients with Multiple Sclerosis (MS) treated with natalizumab (NTZ). Although there is a general consensus upon continuation of NTZ during pregnancy, it is not yet known whether the interaction between pregnancy immunology and NTZ pharmacodynamic may alter the immunosurveillance for JCV. This retrospective study aims to describe the kinetic of humoral response to JCV before, during and after pregnancy in women with MS exposed to NTZ during pregnancy and post-partum.

Materials and Methods: Serum levels of anti JCV antibodies index (JCV-Index) assessed before conception (baseline), at each pregnancy trimester, and 3 months after delivery were collected in women with MS treated with NTZ during pregnancy and post-partum. JCV-index was analysed by a two-step second-generation enzyme-linked immunosorbent assay provided by STRATIFY Unilabs. For risk stratification three risk categories were considered: low (≤0.9), intermediate (0.9 < JCV index > 1.5), and high (>1.5). Results: Data from 26 pregnant MS women were analyzed (mean age 32 ±4.3 years, median infusions number during pregnancy 4 (1-6). 15/26 (58%) women had a negative JCV-index at baseline. Among these, 13/15 (87%) remained negative throughout pregnancy and at 3-months post-partum (PP); 2 women seroconverted to the low risk category, respectively during 2 trimester and at 3 months-PP. Among positive (n=11), 6/11 (54%, high risk category) showed no changes in JCV Index during pregnancy and at 3-months PP; in 4/11 (36%) JCV-index shifted from a higher to a lower risk category during pregnancy returning to the higher category after delivery (2/4 cases), and in 1/11 from a lower to intermediate. Looking at mean values, positive women overall showed a trend toward a reduction of JCVindex title from the first to the third pregnancy trimester.

Discussion and Conclusions: Our results show that continuing NTZ during pregnancy does not impact JCV serostatus; therefore, this approach does not expose pregnant women with MS to increased risk of PML. Conversely, the decrease of JCV index in the third trimester, although it has to be confirmed by larger samples, is possibly explained by increasing plasma volumes along with pregnancy advancement or to physiological rearrangement of B cells compartments.

## THE EFFECT OF NATALIZUMAB ON THE RETINA OF PATIENTS WITH MULTIPLE SCLEROSIS: A LONGITUDINAL OCT STUDY

E. Basili[1], V. Mauceri[1], A. Miscioscia[1], M. Ponzano[2], F. Bovis[2], G. Zanotelli[1], F. De Napoli[1], M. Gaggiola[1], F. Rinaldi[3], P. Perini[3], P. Gallo[1], M. Puthenparampil[1]

[1]Department of Neuroscience, University of Padua (Padova); [2]Department of Health Science (DiSSAL), University of Genoa (Genova); [3]Department of Neuroscience, University hospital of Padua (Padova)

Objectives: This study enrolled patients with the indication to undergo Natalizumab treatment, aiming to: 1) characterize variations in retinal volumes and thickness in patients affected by Relapsing-Remitting MS (RRMS), 2) examine the origin and significance of retinal hyper-reflective foci (HRF).

Materials and Methods: Retina of RRMS patients was studied by performing several OCT: the first one within one month from the initial Natalizumab infusion (baseline, T1), the second one 2-3 months later (T2), and the last one 5-6 months after the first infusion (T3). OCT parameters were investigated together with HRF behaviour during the recruitment

period. The HRF number in each layer and timepoint was analyzed with Wilcoxon test. The mixed effects model (adjusted for age, sex and previous treatments) with random intercept for subject and eye within subject was performed to see how the HRF modified during the study.

Results: 29 patients with a diagnosis of RRMS were recruited and a total of 58 eyes were analyzed. The results did not show significant changes in peripapillary RNFL and macular volumes and thickness, while an early increase of INL HRF between T1 and T2 was detected (p=0.041), further confirmed by the mixed effect model (β=2.72, p=0.019, between T1 and T2, p = 0.053 for the whole timespan).

Discussion: Retina and the optic pathway may represent an ideal model to assess both neurodegeneration and inflammation in multiple sclerosis (MS) by using Optical Coherence Tomography (OCT) to investigate changes in volumes and thickness of macular and peripapillary retina. In addition, through OCT, it is possible to evaluate the presence and number of HRF, presumably consisting of aggregates of activated and proliferating microglia. All the variations of these OCT parameters can be considered as a further means to describe the Natalizumab effect.

Conclusions: This study evidences substantial stability in terms of thickness and volumes of the peripapillary and macular retina in RRMS patients undergoing Natalizumab treatment, while a significant increase in INL HRF number has been found. The latter result needs to be clarified in order to establish whether the activation/proliferation of retinal microglia is due to a pro- or anti-inflammatory process.

Case report: A 62-years-old overweight woman, with a history of well-controlled type 2 diabetes and hypertension, was admitted to our department for subacute bilateral vision loss accompanied by severe, dull, non-throbbing headache. An ophthalmological examination performed three days after the onset of symptoms revealed bilateral papilledema, visual acuity of 5/10 in the right eye and 9/10 in the left eye, and normal eye pressure. Head CT scan showed no intracranial masses nor hydrocephalus. A contrast-enhanced brain MRI showed two non-specific deep white matter hyperintensities. Brain MRI, with angiography and venography were normal. Neurological and general examination, aside visual loss and bilateral pupillary light reflex impairment were unremarkable. A lumbar puncture was performed: intracranial pressure was only slightly increased (37 cm H2O, sitting position); CSF testing including biochemical analysis, cytology, microbiological evaluation and immunoelectrophoresis were negative. For suspected idiopathic intracranial hypertension (IIH), acetazolamide therapy was initiated. The patient's condition worsened: two weeks after symptoms onset, visual acuity was "count fingers" at 30 cm bilaterally, with severe papilledema, flame-shaped haemorrhages and persistent headache. Optical coherence tomography (OCT) confirmed marked optic discs swelling. Visual evoked potentials (VEPs) were undetectable bilaterally. Blood count, erythrocyte sedimentation rate, and C-reactive protein were normal. Bilateral optic neuritis was suspected. Infectious serum screening was negative for herpes viruses, HIV, Mycoplasma pneumoniae, Borrelia burgdorferi and Treponema pallidum. Serum and CSF anti-aquaporin-4 (AQP4) and anti-myelin oligodendrocyte glycoprotein (MOG) were undetectable. Blood autoimmune autoantibody screening was negative. Orbit MRI scan revealed bilateral optic nerve T2 hyperintensity and peripheral enhancement compatible with bilateral optic perineuritis; spinal cord MRI was normal. A 5-days course of high-dose intravenous methylprednisolone (ivMP) was initiated and visual acuity slightly improved. A second course of 3 days ivMP was administered, followed by every-other-day 7 plasma exchange sessions and oral prednisone tapering. Following this therapy, we observed a significant clinical response with headache improvement and substantial recovery of visual acuity (7/10 bilaterally). Funduscopic examination showed resolution of papilledema and hemorrhages, with residual optic discs pallor. VEPs were evocable, with prolongation of P100 latency and amplitude reduction, suggestive of residual optic nerve damage.

Discussion: Optic perineuritis is an uncommon inflammatory disorder of the optic nerve sheath. Simultaneous bilateral involvement is extremely rare and can mimic IIH. Although some cases are associated with MOGAD, systemic autoimmunity, vasculitis or infections, most are idiopathic. Clinical suspicion in the setting of atypical features for IIH should be raised to ensure prompt antinflammatory treatment.

Objectives: Growing evidence supports Epstein Barr virus (EBV) as a causal factor in Multiple Sclerosis (MS). However, we still do not completely understand how the complex interaction between the virus and human predisposing genetic variability leads to MS, whether this is a disease-specific process, how it mechanistically translates to pathological processes and whether it is therapeutically actionable. Here, we aimed to address these issues exploiting human genetic information to assess non-genetic influences in MS and other complex diseases, analyzing gene modules whose products physically interact with environmental exposures ("interactomes").

Materials: Genome-wide association studies (GWAS) data of autoimmune diseases (MS, Crohn disease, celiac disease, rheumathoid arthritis, type 1 diabetes mellitus) and other complex diseases (Type 2 diabetes; Hypertension; bipolar disorder; coronary artery diseases). Interactomes of viral exposures and biological processes derived from public databases or were manually curated. Spontaneously-outgrowing lymphoblastoid cell lines (spLCLs), carrying the endogenous EBV strain, were generated from 13 subjects with relapsing remitting MS and 8 healthy donors (HD); PBMC infected with laboratory EBV B95.8 strain (B95.8-LCLs) were generated from 5 MS subjects and 4 HD.

Methods: Enrichment analysis of nominally significant SNPs from GWAS, and SNP-to-gene mapping, was performed through ALIGATOR. Definition of proteins binding MS-associated-interactome SNPs was assessed in RegulomeDB and through colocalization analysis. Frequency of MS-associated interactome genes (MSAIG) was evaluated in blood and brain gene expression data from MS patients. In vitro validation of bioinformatic results was performed by flow cytometry of lymphoblastoid cell lines from MS subjects and healthy controls. Network-based drug repurposing was implemented through NEDrex algorithm and leveraging the Priority Index resource.

Results: Modules of Herpesviruses- and, prominently, EBV-interacting genes are specifically associated with MS. Viral (EBNA2) and human (POLR2A, CTCF) factors cooperate in regulating MSAIGs. Analyses of MS blood and brain transcriptomes confirmed a dysregulation of MS-associated EBV interactors. The CD40 pathway emerged as the convergence of pathogenic interactions. EBV-interacting MS-associated genes are endowed with a high therapeutic potential and could be readily targeted by repurposable drugs.

Discussion: Our results strengthen a causal interpretation of sero-epidemiological associations between viruses and MS, highlighting widespread, MS-specific pathogenic interactions between the host's genetic background and EBV. Multi-omics analysis revealed functional implications of such interactions, pinpointing candidate therapeutic targets and drugs.

Conclusions: EBV-host interactions contain the causal structures of MS and hold promise for etiology-based therapeutic strategies.

## NEED FOR AQP4 AND MOG ANTIBODY TESTING IN THE WORKUP OF INFLAMMATORY CNS DISEASES: TO TEST OR NOT TO TEST?

E. Bernardi[1], S. Crisafulli[1], F. Andreetta[1], P. Confalonieri[1], V. Torri Clerici[1], C. Antozzi[1], E. Giacopuzzi[2], R. Mantegazza[1], L. Brambilla[1]

[1]Neuroimmunology and Neuromuscular Diseases Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [2]Neuroimmunology and Neuromuscular Diseases Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta, University of Milan (Milano)

Aim: The 2015 criteria for Neuromyelitis Optica Spectrum Disorders (NMOSDs) improved diagnostic accuracy for anti-aquaporin4 (AQP4) antibodies (Ab) associated NMOSDs. Recently, Myelin oligodendrocyte glycoprotein (MOG) Ab Associated Diseases (MOGAD) criteria have been proposed [1]. In most Multiple Sclerosis (MS) Centers, the workup for inflammatory diseases of the Central Nervous System (CNS) includes AQP4 and MOG Ab. Given the accuracy of criteria for MS, NMOSD, and those proposed for MOGAD, Ab testing could be considered only in cases with clinical and magnetic resonance imaging (MRI) features typical for NMOSD/MOGAD or atypical for MS. The study aim is to investigate the need for routine AQP4/MOG Ab testing in the workup of inflammatory CNS disease.

Materials: We selected subjects evaluated for an inflammatory CNS disease and tested for serum AQP4/MOG Ab (fixed cell-based assay) at Foundation IRCCS Neurological Institute Carlo Besta, Milan, from 2019 to 2023. Clinical and MRI data at first evaluation were collected.

Methods: We selected clinical, MRI and laboratory data suggesting MS [monolateral anterior optic neuritis (ON); spinal cord syndrome with multifocal posterior lesions; brain focal/polyfocal deficits with periventricular/corpus callosum/infratentorial/cortical ovoidal brain lesions; presence of oligoclonal bands (OCB) in cerebrospinal fluid (CSF)] or NMOSD/MOGAD (bilateral or longitudinal ON or with chiasm or optic nerve stealth involvement; transverse or longitudinally extensive myelitis or conus lesions or nerve roots involvement; encephalic/diencephalic/area postrema symptoms with deep grey matter or area postrema or periependimal involvement) [1]. All subjects were grouped as MS (at least one clinical and one MRI MS feature, none of NMOSD/MOGAD, presence of CSF OCB); NMO (at least one clinical or MRI feature of NMOSD/MOGAD) and OTHER (no MS or NMOSD/MOGAD features).

Results: We included 216 subjects, 66,7% female, mean age 41.6±12.7 years. 3,2% (7/216) were AQP4 Ab positive, 1.9% (4/216) were MOG Ab positive. We found a significant association between group assignment and positivity for AQP4/MOG Ab (Fisher's exact test, $p<.001$). There was no Ab positivity in the MS group, 11,7% in the NMO group, 2% in the group OTHER.

Discussion: Initial stratification based on typical disease characteristics could guide the need to test for AQP4/MOG Ab. Identification of key clinical and MRI features may properly differentiate MS from NMOSD/MOGAD or atypical cases, without the support of serological tests.

Conclusions: We suggest that AQP4/MOG Ab testing should be performed according to clinical/MRI presentation, in the presence of features typical for NMOSD/MOGAD or atypical for MS.

## TOPOGRAPHICAL DISTRIBUTION OF BRAIN WHITE MATTER LESIONS VISUALIZED BY MRI IN PATIENTS WITH MULTIPLE SCLEROSIS AND MARKERS OF BETTER EXPLANATION OF THE DIAGNOSIS

A. Bertozzi[1], A. Repice[2], A. Barilaro[2], F. Azzolini[3], L. Massacesi[1]

[1]Department of Neurosciences, Drug and Child Health, University of Florence (Firenze); [2]Department of Neurology 2 and Tuscan Region Multiple Sclerosis Referral Centre, Careggi University Hospital (Firenze); [3]IRCCS Neuromed (Pozzilli-IS)

Objective: The specificity of the diagnostic criteria for Multiple Sclerosis (MS) is suboptimal [1], especially in patients carrying a least one red flag for better explanation without fulfilling criteria of other diseases (MS plus). Frequency of brain white matter lesion lesion (WML) in typical location (juxtacortical, juxtaventricular, infratentorial), a MRi marker easily detectable by routine conventional MRi, is not included in the diagnostic criteria and its association with MS is unknown. In this study this marker will be evaluated in MS and MS plus patients versus a reference standard of MS as the "central vein sign" (CVS) a MRi marker currently detectable mainly in research setting.

Materials: Monocentric retrospective study in MS and in MS-plus patients stratified according to the CVS perivenular lesions frequency(>50%threshold), evaluating the frequency of WMLs in location typical for MS.

Methods: Each patient underwent a standardized MRi examination, including FLAIR* sequences. In each patient stratified according to presence of the CVS, frequency of WML lesions in typical MS sites was classified.

Results: Definite MS patients (n=28; 100% CVS+) and MS plus (n = 59), were included. Out these 32 (53%) had >50% PVL (CVS+). The proportion of WMLs in the typical MS sites was similar in MS and in MS-plus patients fulfilling the CVS (59% and 57%, respectively). In the CVS negative MS plus patients, the proportion of WMLs in the typical MS sites was significantly lower (22%) compared to the other two groups ($p < 0.0001$). This marker predicted CVS positivity with 89% specificity and 85.7% positive predictive value (PPV). On the contrary sensitivity and negative predictive value of this marker for detecting MS seems low (64% and 71.4% respectively).

Discussion: Frequency of WMLs in typical MS lesion sites segregates with the CVS ad therefore with MS with remarkably good specificity and PPV.

Conclusions: These data shows that WML lesion frequency in typical MS site is helpful for increasing MS diagnostic criteria specificity and confirm also that in the MS-plus cases with low WML frequency in MS typical sites, MS diagnosis should postponed and confirmed by CVS analysis. In CVS negative cases a "better explanation" of the diagnosis should be further searched.

Objectives: A meta-analysis of 38 clinical trials published in 2017 showed that disease-modifying therapies (DMTs) efficacy decreased with age and that after age of 53 there was no predicted benefit. On the other side, peak-age prevalence of people with Multiple Sclerosis (pwMS) is shifting towards 55-59 years and nation-wide registry data show that DMTs continue to be commonly prescribed in pwMS >60 years. In our study we evaluated age-dependent efficacy of DMTs in a real-world population of Relapsing Remitting Multiple Sclerosis (RRMS) patients.

Materials: We studied a real-world population of RRMS patients extracted from the Italian Multiple Sclerosis Register.

Methods: In this multicentric, retrospective, cohort study based on prospectively acquired data from the Italian Multiple Sclerosis Register, 22196 pwMS were extracted with the following inclusion criteria: diagnosis of Clinically Isolated Syndrome (CIS) or RRMS, at least four Expanded Dysability Status Scale (EDSS) evaluations, at least 2 years follow up. We evaluated confirmed disability accumulation (CDA), defined as 24 weeks confirmed EDSS increase from study baseline (1.5 points if baseline EDSS=0; 1.0 point if EDSS>1.0 and <5.5; 0.5 point if EDSS>6.0), and determinants of CDA performing a logistic regression analysis with the following covariates: age, sex, disease course, disease duration, EDSS, number of relapses at baseline and class of efficacy of DMT (platform vs high efficacy).

Results: After 2 years follow up 3178 pwMS had CDA; these patients, at baseline, were older (39,8+11,3 vs 36,5+10,9; p<0,001), had greater EDSS (2,2+1,5 vs 2+1,3; p<0,001), had longer disease

duration (7,2+7,7 vs 6+7; p<0,001) and were less frequently treated with a high-efficacy DMT as first DMT (4,5% vs 5,9%;p=0,002). In the logistic regression analysis older age at baseline (OR 1,29, CI 1,25-1,35, p<0,001), a multifocal onset (OR1,24, CI1,1-1,39, p<0,001), a greater number of relapses before baseline (OR1,07, CI1,06-1,09, p<0,001), and platform therapies (OR1,26, CI1,04-1,51, p=0,016), resulted as predictors of CDA in the first 2 years of follow up.

Discussion: In this real-world population of CIS and RRMS patients older age at DMT start was associated with decreased efficacy in terms of disability worsening prevention. However, independently of age, early treatment with high efficacy DMTs reduced the risk of disability accrual.

Conclusion: This study adds evidence that DMT efficacy could be age-related; early high efficacy treatment confirms to be the best treatment strategy.

## CGRP BEYOND MIGRAINE: EXPLORING ITS SERUM AND CSF LEVELS IN MULTIPLE SCLEROSIS

A. Bianchi[1], D. D'Onghia[2], E. Virgilio[1], S. Tonello[2], P. Sainaghi[3], C. Comi[1], R. Cantello[1], M. Bellan[3], D. Vecchio[1], D. Colangelo[4]

[1]Department of Translational Medicine, Neurology Unit, Multiple Sclerosis Center Maggiore Della Carità Hospital, University of Piemonte Orientale (Novara); [2]Department of Health Sciences, Interdisciplinary Research Center of Autoimmune Diseases, University of Piemonte Orientale (Novara); [3]Department of Translational Medicine, Department of Rheumatology, University of Piemonte Orientale (Novara); [4]Department of Health Sciences, Pharmacology, University of Piemonte Orientale (Novara)

Background: Multiple Sclerosis (MS) is a disease of the central nervous system (CNS) characterized by progressive demyelination and inflammatory process. While the exact etiology of MS remains unknown, it relies on an autoimmune process that includes the activation of microglia and localizes at the perivenular site. Calcitonin Gene Related Peptide (CGRP) is a neuropeptide ubiquitous in the peripheral and CNS, mostly known for the role in vasodilation and pain signal transmission during migraine attacks. Recent studies have been unraveling its immunomodulatory properties, showing both anti and pro-inflammatory effects.

Objective: In this study we evaluated soluble CGRP, determined at MS diagnosis in cerebrospinal fluid (CSF) and serum, and correlated its levels with progression and short-term disease severity.

Patients and Methods: We enrolled for a retrospective cohort study 59 patients (39 females, mean age at diagnosis 38.79 years ± standard deviation or SD 9.89) with Radiological Isolated Syndrome (RIS), Clinical Isolated Syndrome (CIS) and Relapsing-Remitting (RR) MS. During the diagnostic work-up were collected clinic-demographic data, serum and CSF. Patients were followed with clinical visits in which clinical data were collected. CGRP levels were determined through an ELISA commercial kit (MyBioSource Inc, MBS267126, San Diego, CA, USA). None had a history of migraine attack at diagnosis. Statistical analyses were conducted with STATA software to determine Mann–Whitney, Kruskal-Wallis test and Spearman's rank correlation coefficient significance.

Results: CGRP levels were significantly higher in MS patients if compared to healthy controls published by Papiri et Al. [1] and Han et Al. [2]. Mean values resulted 73.10 pg/ml in serum (±9.42 vs 29.50 ± 8.91, p<0.05 t-test) and 64.01 in CSF (± 10.39 vs 52.05 ± 5.70, p<0.05 t-test). CGRP levels did not relate to clinical variables at diagnosis: age, gender, Expanded Disability Status Scale (EDSS), number of T2, gadolinium enhancing and spinal cord lesions. However, there was a positive correlation between serum CGRP and the Multiple Sclerosis Severity Score (MSSS) at the last follow up (r^2 = 0.27, p<0.05 Spearman's rank correlation).

Discussion: We observed an increased CGRP level in the CSF and serum of MS patients at diagnosis. Our study firstly evaluated this biomarker both in CSF and serum and subsequently confirmed and expanded on its possible role in identifying cases with poor prognosis, as suggested by the work of Al-Keilani et Al. [3]. However further research is needed to better understand the potentials of this neuropeptide in MS.

## MICROCHIMERISM AND MULTIPLE SCLEROSIS: THE IMPACT OF FETAL MICROCHIMERIC CELLS ON MATERNAL CLINICAL AND OPHTHALMOLOGICAL FEATURES

A. Bianchi[1,2], M. Aprile[2], S. Viscomi[2], G. Schirò[2], R. Di Blasio[2], G. Sabatino[2], L. Buggea[2], M. Marrale[3], G. La Tona[2], M. Midiri[2], C. Gagliardo[2], F. Caradonna[4], M. Vadalà[2], V. Bonfiglio[2], G. Salemi[2], P. Ragonese[2]

[1]Queen Square Multiple Sclerosis Centre, University College London (London-UK); [2]Department of Biomedicine, Neuroscience & Advanced Diagnostics, University of Palermo (Palermo); [3]Department of Physics and Chemistry, University of Palermo (Palermo); [4]Department of Biological, Chemical and Pharmaceutical Sciences and Technologies, University of Palermo (Palermo)

Introduction and Aims: Multiple sclerosis (MS) is a chronic disorder characterised by inflammation and neurodegeneration. Pregnancy is considered a protective factor in MS in the short-term, while evidence on its long-term effects remain inconclusive. During pregnancy, fetal microchimeric cells (fMCs) migrate to maternal blood and tissues, where they can survive for decades. A role for fMCs as a possible long-term factor influencing MS course could be hypothesised, although the available data are still limited. The aim of this study was to investigate the effect of fMCs on MS features.

Methods and Materials: We enrolled 14 female MS patients, including 7 nulliparous patients and 7 parous patients. Each patients underwent (1) blood test analysis using real-time qPCR to amplify Y chromosome-specific sequences and identify XY fMCs, (2) a clinical assessment, including Neurostatus, Multiple Sclerosis Functional Composite (MSFC), and Brief International Cognitive Assessment for MS (BICAMS), and an optical coherence tomography (OCT) scan using Toccon DRI OCT Triton machine to obtain data on retinal nerve fibre layer (RNFL) and ganglion cell-inner plexiform layer (GCIPL) of the optic nerve. Multiple regression models and mixed regression models with adjustments were performed to evaluate the relationship between

fMCs and disease features testing the possible effects of confounding factors.

Results: We found that 3 nulliparous patients and 5 parous patients were positive for fMCs (fMCs+), while no fMCs were detected in the remaining 6 patients (fMCs-). The prevalence of fMCs was non-significantly higher in parous patients (71.4% vs 42.9%, p=0.280) and fMCs- had a longer interval from last pregnancy (174.8±131.1 vs 478.5±72.8, p=0.031). At onset, the involvement of brainstem was more frequent in fMCs+ (62.5% vs 0.0%, p=0.004). At diagnosis, the same group reported more gadolinium-enhancing lesions (0.7±0.8 vs 0.4±0.5, p=0.018), although a trend towards a difference for higher number of T1-weighted lesions in fMCs- was detected (0.7±0.8 vs 2.0±0.0, p=0.059). fMCs- also reported higher frequencies of previous optic neuritis (0.1±0.3 vs 0.8±0.8, p=0.046), although no differences were detected in RNFL and GCIPL thickness (p>0.050). Finally, although an unbalance was detected comparing z-scores from cognitive tests, the differences were not significant (p>0.050).

Discussion: Our findings showed different trends in the involvement of brainstem and optic pathway and in lesion load between patients with and without fMCs, letting hypothesise that the disease features could be influenced by fMCs.

Conclusion: These preliminary results support the hypothesis of a possible role for fMCs in the biological processes underlying MS.

## A CASE OF VERY LATE-ONSET NEUROMYELITIS OPTICA SPECTRUM DISORDER MIMICKING ANTERIOR ISCHEMIC OPTIC NEUROPATHY

A. Bianco, F. Caputo, G. Milella, A. Introna, A. Fallacara, P. Iaffaldano, D. Paolicelli

Department of Basic Medical Sciences, Neuroscience and Sense Organs, University of Bari "Aldo Moro" (Bari)

Introduction: The most common cause of isolate acute optic nerve damage in the elderly is acute ischemic optic neuropathy (AION); while the typical age of onset of optic neuropathy (ON), in particular neuromyelitis optica spectrum disorder (NMOSD), is between 30-40 years. Nevertheless, there is growing evidence about the possibility of a late or of a very late onset (VLO) NMOSD, i.e. respectively over 50 and over 70 years old at onset.

Case description: An 82-year-old male presented to hospital with a sudden-onset painless loss of vision in both eyes. Neurological examination revealed loss of the inferior region of the right visual field and of the superior region of the left visual field. A CT scan of the brain and an angiography of the cranial vessels excluded an ischemic attack. Hence, he was initially suspected of AION, however coherence tomography (OCT) and fluroangiography were negative. In the following days, the patient's condition worsened: he was almost blind from both eyes. Unexpectedly, a brain magnetic resonance imaging (MRI) showed a T2-hyperintensity and a gadolinium-enhancing lesion in T1 in the left optic nerve. In consideration of a serum positivity for anti-AQP4 antibody (titer 0.68), a diagnosis of VLO-NMOSD was made. The patients received high-dose glucocorticoid treatment and successive rescue therapy with plasmapheresis with slowly and partial recovery. He was discharged whit a chronic immunosuppressive treatment with azathioprine. At the last follow-up, he showed clinical stability; azathioprine was well tolerated in absence of adverse events (AEs).

Discussion: The acute-onset, the altitudinal vision loss, the patient's vascular risk factor (hypertension) and in particular the age of the patient were all strongly suggestive of AION. NMOSD has been rarely described in elderly patients (onset over 70 years); however, VLO-NMOSD in patients over the age of 80 is even rarer. According to the current data, it is characterised with a poor prognosis because of high disability and mortality rate. Therefore, an early diagnosis and prompt treatment is crucial, even if in these patients the use of high steroids treatment and, in particular, of strong immunosuppressive agents is not always possible for the higher risk of AEs.

Conclusions: Even in the elderly, a diagnosis of NMOSD should be considered for patients with the with acute painless vision loss. Despite the importance of early treatment, close monitoring for drug-related side effects throughout the disease course is vital in elderly individuals.

## SIPONIMOD FROM FINGOLIMOD DIRECT SWITCH IN PATIENTS TRANSITIONING IN SECONDARY PROGRESSIVE MULTIPLE SCLEROSIS: A CASE SERIES

A. Bianco, T. Guerra, R. Vitobello, F. Oggiano, D. Paolicelli, P. Iaffaldano

Department of Basic Medical Sciences, Neuroscience and Sense Organs, University of Bari "Aldo Moro" (Bari)

Introduction: Fingolimod (Gilenya® - FIN) and siponimod (Mayzent® - SIP) are both sphingosine-1-phosphate (S1P) receptor modulators approved for relapsing form of multiple sclerosis (RMS). The concept of RMS applied by the European Medicines Agency (EMA) for regulatory purposes includes both relapsing remitting MS and secondary progressive MS with relapses. Nevertheless, solely SIP showed a documented reduction in disability progression in an active secondary progressive multiple sclerosis (SPMS) cohort of patients. Therefore, in patients transitioning to SP course, an early switch from FIN to SIP could determine a better prognosis in the long term.

Objectives: The main objectives of this charts review were to evaluate the efficacy, in terms of annualized relapse rate (ARR) and radiological activity, and safety in the patients who switched to SIP.

Methods: The study population included all the patients who switched directly from FIN to SIP due to transitioning to SP course at the Multiple Sclerosis (MS) Center of the University Hospital Policlinico of Bari. The patients were extracted from Italian MS Registry

Results: In April 2023, we extracted data of nine MS patients who had switched directly from FIN to SIP. The mean time of FIN washout was of 10 ±6.17 weeks, during which four patients assumed steroid

therapy to reduce rebound risk4 after FIN withdrawal. The mean age at first administration of SIP was 50.22±9.76 years. During SIP exposure the patients presented clinical stability, in particular, we found a significative reduction of the ARR during FIN (0.56%) and SIP (0%). Only one patients presented radiological activity during SIP. In regard to safety, we registered only one adverse event during SIP, a grade 4 lymphopenia for which the treatment was interrupted. The incidence of grade 3 and 4 lymphopenia resulted higher during SIP than during FIN exposure.

Conclusions: Our data showed that the direct switch from FIN to SIP in patients transitioning in SP course is associated with clinical and disability progression stability. There were no safety concerns to declare.

Further research with larger populations is needed to confirm these results.

## LESION PHENOTYPING USING QSM IN PEDIATRIC AND ADULT MULTIPLE SCLEROSIS

V. D. Boccia[1], G. Boffa[1], C. Lapucci[2], M. Cellerino[1], M. Costagli[1], M. Mancardi[3], M. Inglese[1]

[1]Department of Neurology, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa (Genova); [2]Department of Neurology, IRCCS Ospedale Policlinico San Martino (Genova); [3]Department of Child Neuropsychiatry, Giannina Gaslini Institute (Genova)

Objectives: To compare different multiple sclerosis (MS) lesion phenotypes distribution in pediatric and adult MS.

Materials: A sample of pediatric and disease duration matched-adult MS patients underwent a 3T-MRI brain exam including T2-FLAIR, T1-MPRAGE and 3D echo-planar imaging (EPI) sequences. EPI was used to obtain Susceptibility Weighted Imaging (SWI) and Quantitative Susceptibility Mapping (QSM) with an isotropic resolution of 0.65 mm.

Methods: White Matter Lesions (WMLs) were classified as Paramagnetic Rim Lesions (PRLs), Hyper-intense lesions (HILs) or iso-hypo intense lesions on the basis of QSM appearance by two independent raters. SWI was used to support WMLs classification by identifying QSM hyperintensities ascribable to veins.

Results: Fourteen pediatric- and fifteen adult-RRMS patients were included in the analysis with a mean (SD) age of 16.1 (2.1) and 22.8 (10.6) respectively. Mean (SD) disease duration was 2.2 (1.9) years [Pediatric MS: 2.5 (2.1); Adult MS 2.0 (1.8)]. No differences in EDSS score ($p = 0.49$), total lesion burden ($p = 0.66$) and total brain volumes ($p = 0.70$) were found. 577 lesions were analyzed; 123/577 lesions were excluded due to infratentorial position, confluent shape or movement artifacts. PRLs were found in 6/14 (43%) of pediatric and 8/15 (53%) of adult MS patients. PRLs represented 6% of WMLs in pediatric (0.86 per subject) and 10% (1.73 per subject) in adult MS ($p =0.27$), with 1/14 pediatric and 2/15 adult patients exhibiting ≥4 PRLs. A trend toward a higher number of HILs both expressed as number per subject [mean (SD): 3.6 (3.1) in pediatric MS and 1.6 (2.1) in adult MS; $p = 0.05$] and as a percentage with respect to total lesion (20% in pediatric MS and 9.9% in adult MS; $p = 0.03$) was noted in pediatric MS patients. No differences were found in iso-hypointense lesion number ($p= 0.45$) and percentage ($p= 0.41$).

Discussion: PRLs are considered a biomarker of chronic inflammation in MS. Although PRLs seem to be associated with an older age and a longer disease duration they have been detected since the early phases of the disease. PRLs distribution largely overlapped between pediatric and adult MS in our sample. Pediatric patients showed a slightly higher prevalence of HILs which have been associated with chronic inactive lesions with potential for remyelination.

Conclusions: Although older age may favour PRLs formation, chronic inflammation seems to arise in a similar fashion in pediatric MS as compared to adult patients with a similar disease duration.

## OPTIC NERVE IMAGING WITH OPTICAL COHERENCE TOMOGRAPHY IS ABLE TO PREDICT DISEASE PROGRESSION AND TO MONITOR CEREBRAL AND SPINAL CORD ATROPHY IN PRIMARY PROGRESSIVE MULTIPLE SCLEROSIS (PPMS)

L. Bollo[1], D. Pareto[2], P. Tagliani[1], S. Sceppacuercia[2], M. Alberich[2], S. Cabello[1], P. Carbonell[1], C. Tur[1], G. Arrambide[1], J. Castilló[1], J. Rio[1], I. Galan[1], N. Mongay-Ochoa[1], J. Villacieros-Álvarez[1], A. Cobo-Calvo[1], A. Pappolla[1], L. Midaglia[1], B. Rodriguez[1], A. Villaseca[1], A. Zabalza[1], M. Comabella[1], C. Auger[2], M. Tintoré[1], J. Sastre-Garriga[1], À. Rovira[2], X. Montalban[1], A. Vidal-Jordana[1]

Background: A previous international study using optical coherence tomography (OCT) in MS patients (mostly with a relapsing phenotype), found that a lower retinal nerve fiber layer (pRNFL) (≤87µm) was linked to a higher risk of confirmed disability progression (CDP). Our study aimed to [1] compare disease characteristics based on this pRNFL threshold, and [2] assess the predictive value of this threshold in primary progressive MS (PPMS) patients.

Materials and Methods: Retrospective study including PPMS patients with OCT; demographic, clinical, and MRI data were collected. Brain volumetric measures and spinal cord cross-sectional area (SCA) were obtained from a filled brain 3D MPRAGE sequence using Statistical Parametric Mapping and Spinal Cord Toolbox. Group comparison (pRNFL ≤87µm and >87µm) was done as appropriate. Partial Pearson (rp) correlation analysis (adjusted for age and MRI machine) was used to evaluate OCT and MRI association. A univariate survival analysis and a multivariate Cox regression analysis were done to evaluate the ability of pRNFL≤87µm to predict CDP (defined as a confirmed ≥1 point increase in the EDSS score or ≥0.5-point increase for patients with a baseline score of ≥5.5), adjusting for age, disease duration, sex, and baseline disability.

Results: 69 PPMS patients were analysed, 21(31%) with pRNFL≤87µm, mean follow-up: 2.3 years (SD 1.3). Compared to pRNFL>87um, in the pRNFL≤87um group a higher proportion of patients presented a higher number of spinal cord lesions (≥3 lesions:

89% vs 68%, p=0.001) and lesions at the bulbomedullary junction (75% vs 43%, p=0.001). pRNFL showed a positive correlation with grey matter (rp=0.332, p=0.048), white matter (rp=0.457, p=0.005), brain parenchymal (rp=0.463, p=0.005) fractions, and SCA (rp=0.441, p=0.007). 17/58 patients (29%) presented CDP after a mean time of 1.4 years (SD 0.92). Patients with pRNFL≤87µm had a significantly higher probability of experiencing CDP (47% vs 21%, p=0.001), and the progression occurred at a faster rate: at 2 and 4 years, 83% of patients with pRNFL≤87µm experienced CDP, while 25% and 45% with pRNFL>87µm did so (p=0.027). In multivariate Cox regression analysis, pRNFL≤87µm was the only measure that predicted CDP (aHR 3.44, 95%CI 1.21-11.30).

Conclusions: PPMS patients with pRNFL thickness ≤87µm had a higher risk for disability worsening adjusting for disease duration, sex, and baseline disability. This supports pRNFL thickness as a biomarker for predicting disability worsening in PPMS, aiding treatment decision-making.

Aims: To conduct a multi-centric unbiased genome-wide screen to identify genetic predictors of response to first-line treatments (dimethyl fumarate, interferon and glatiramer acetate) in multiple sclerosis (MS) patients.

Material and Methods: We included MS patients from different centers using a harmonized protocol to standardize clinico-demographic variables. Inclusion criteria comprised relapsing-remitting MS at drug start and follow-up for 4 years. Imputation yielded ~4.7M autosomal common variants after quality control for downstream analyses. Association analyses with the number of relapses occurring in 2 years of follow-up were carried out by fitting negative binomial regression models, adjusting for gender, age, disease duration, number of relapses 1 and 2 years before drug start and principal components to control population sub-structure, using duration of treatment exposure as an offset in the models. Rate ratios were meta-analyzed across centers with an inverse-variance weighted meta-analysis, under a fixed effect model.

Results:1802 patients were included for Interferons, 962 for dimethyl fumarate and 705 for glatiramer acetate from different European countries including Italy, Belgium, Denmark, Germany, Norway and Sweden. Strongest signals of associations were rs10835054, located at the 3'UTR of a gene named SLC5A12 (p=2.68*10-8) for Interferons, rs34140003 in the intronic region of an uncharacterized non coding RNA named LOC107984282 (p=4.91*10-8) for dimethyl fumarate and rs150307803 (p=2.68*10-8) in an intergenic region between LINC00659 and MRGBP and rs78852235 (p=4.08*10-8) in an intronic region of MAP3K1 gene for Glatiramer Acetate.

Discussion: Inter-individual differences in treatment response are marked in Multiple Sclerosis (MS), with only a paucity of body-fluid biomarkers aiding clinicians to individualize optimal drug choice. This includes first-line treatments, where a subset of patients displays suboptimal treatment response.

Conclusion: This large, unbiased genome screen of response to first-line treatments suggests potential variant candidates which are deemed for further investigations.

## THE RELATIONSHIP BETWEEN COGNITIVE IMPAIRMENT, RETINAL DAMAGE AND BRAIN ATROPHY IN MULTIPLE SCLEROSIS: AN OCT-MRI STUDY

R. M. Borgo, M. Altieri, A. De Rosa, R. Capuano, A. d'Ambrosio, A. Bisecco, F. Esposito, G. Tedeschi, A. Gallo

Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli" (Napoli)

Introduction: Multiple sclerosis (MS) is one of the most common chronic, inflammatory, demyelinating and neurodegenerative diseases involving the central nervous system. Cognitive impairment (CI) is a common and debilitating feature of MS, occurring in 40-65% of patients. MRI showed how brain atrophy in many cortical and subcortical structures is highly correlated to such cognitive impairment in MS patients. Optical Coherence Tomography (OCT), with the measure of retinal layers thickness, represents a rapid, low-cost, noninvasive and well-tolerated alternative to MRI in the evaluation of neurodegeneration in MS.

Objective: In order to understand whether retinal damage could be a good marker, as well as brain atrophy, of cognitive impairment in people with MS (pwMS), our objective was to identify the relationship between cognitive performance, retinal damage, and brain atrophy in pwMS.

Materials and Methods: One hundred pwMS were consecutively enrolled at our MS Center. For each patient we performed: (i) Neurological examination; (ii) Cognitive assessment by means of the Brief Repeatable Battery of Neuropsychological Tests and STROOP Test;

(iii) 3T-MRI scan for the evaluation of the brain lesion load and brain volumetric measures using SIENAx software on 3DT1 refilled images; (iv) OCT for the evaluation of the peripheral retinal nerve fiber layer (pRNFL) thickness. Analyses were performed by means of SPSS, version 25. Pearson's r coefficients were calculated to assess the possible association between cognitive performance, pRNFL mean thickness and brain volumes. A p-value ≤0.05 was considered the threshold of statistical significance.

Results: We found a significant correlation between pRNFL thinning and worse cognitive performance measured by SDMT, and STROOP tests, showing a relationship between retinal thickness and information processing speed (IPS) and executive functions in pwMS. Moreover, white matter (WM) involvement, measured by T2 lesion volume (T2LV) and normalized white matter volume (nWMV), also showed a relationship with cognitive performance in the same cognitive domains (IPS and executive functions). As expected, normalized gray matter volume (nGMV) and normalized brain volume (nBV) showed a significant correlation with cognitive performance in many cognitive domains: IPS, memory, executive functions.

Conclusions: Our results showed a relationship between retinal damage and cognitive performance in the same cognitive domains (IPS and executive functions) related with WM damage. Our study showed that retinal damage (measured by OCT) is a good marker for cognitive decline in pwMS, further highlighting the role of OCT as a rapid, low-cost, well-tolerated and noninvasive tool for pwMS evaluation.

## BREAKTHROUGH PRIMARY VARICELLA PNEUMONIA IN A PATIENT WITH SECONDARY PROGRESSIVE MULTIPLE SCLEROSIS TREATED WITH SIPONIMOD: A CASE REPORT

C. Bosa[1], P. Garelli[1], A. Rolando[1], S. Marasciulo[1], P. Cavalla[2], M. Vercellino[2]

[1]Department of Neurosciences, University of Turin (Torino); [2]Department of Neurosciences, City of Health and Science University Hospital, University of Turin (Torino)

Introduction: Varicella (chickenpox) is a common contagious infection caused by Varicella Zoster Virus (VZV), affecting mostly childhood, but with increasing incidence in adults. Varicella pneumonia, although rare, is a serious complication of VZV infection in adults. S1PR modulators, such as recently approved siponimod, are associated with increased rates of herpesvirus infections, both primary and secondary.

Objectives: To describe a case of breakthrough primary varicella pneumonia despite varicella vaccination and seroconversion, in a patient with active secondary progressive multiple sclerosis (SPMS) under treatment with siponimod.

Methods: Case report.

Results: We report the case of a 48-year-old woman who came to our attention in 2021 complaining of recent balance disorder, bladder dysfunction and progressive bilateral lower limb motor deficit; the clinical onset had probably been in 1999 with right leg motor deficit. On the basis of clinical history, MRI (multiple demielinating lesions of brain and spine), and CSF analysis (oligoclonal bands with a type II pattern), a diagnosis of active SPMS was made and treatment with siponimod was proposed; however, since the basement serological assessment showed the absence of neutralizing antibodies against VZV, the patient started beta-IFN1b and received two doses of vaccination against VZV in the meanwhile. Once immunized (VZV IgG 427 mUI/mL), she started siponimod in December 2021. At the end of March 2023, 15 days after coming into contact with a person with herpes zoster, the patient started having fever, cough, headache and diffuse skin rash. She was hospitalized in isolation and started on intravenous acyclovir, while treatment with siponimod was interrupted. The CT scan showed signs of bilateral interstitial pneumonia. VZV DNA was detected in skin lesions. Five days after siponimod discontinuation, the patient started having diplopia. In order to exclude neurological complications of VZV, a contrast enhanced brain MRI + MRA and a lumbar puncture to detect VZV DNA and meningitis/encephalitis pathogens, were performed: all negative. After two weeks of acyclovir treatment, the neurological symptoms were improving, the skin rash had resolved and the patient was asymptomatic for pneumonia.

Conclusion: To our knowledge, this is the first described case of breakthrough primary varicella in a MS patient treated with siponimod. Is is important to suspect VZV infection even in immunized patients, as early identification and treatment can improve the outcome.

## UNUSUAL REBOUND AFTER FINGOLIMOD DISCONTINUATION MIMICKING STROKE IN A MULTIPLE SCLEROSIS PATIENT

R. Bottero[1], M. Lo Re[1], M. Malentacchi[1], S. Malucchi[1], D. Gned[2], A. Di Sapio[1]

[1]SCDO Neurology CReSM, Department of Specialistic Medicine, San Luigi Gonzaga Hospital (Orbassano-TO); [2]SCDU Radiodiagnostic, Department of Medical and Oncologic Area, San Luigi Gonzaga Hospital (Orbassano-TO)

Objectives: We report the case of a multiple sclerosis female patient, 42 years old, who presented an acute neurological deterioration with a challenging radiological finding, following a therapeutical shift.

Methods and Results: The patient was diagnosed with Multiple Sclerosis in 2004, with a highly active disease during the first years. In 2012 treatment with fingolimod was started, with clinical and radiological stability until August 2022, when MRI showed two new demyelinating lesions, in the frontal lobe and in the cervical medulla. A therapeutic shift was planned. Fingolimod was interrupted; fifteen days after stopping fingolimod the patient reported a mild facial-brachial sensitive impairment, resolved with oral prednisone for few days. MRI didn't show any new lesion. Therapy with ofatumumab was started

after a wash out period of 40 days. After three months of ofatumumab treatment, the patient complained about sensitive impairment on the right side and gait imbalance; she underwent MRI scan that revealed a new small left thalamus-capsular lesion, hyperintense inT2-weighted and DWI images, without contrast enhancement. Radiological report was of an acute vascular ischemic lesion and diagnosis was confirmed by a different neuroradiologist on a new MRI scan. Antiplatelet therapy was started and vascular screening exams were performed. After initial fluctuation in the severity of neurological deficit, without substantial changes of radiological finding, between day 21 and 28 from the onset, neurological deficits got worse progressing to right hemiplegia, severe visual impairment, dysarthria and dysphagia. A fourth MRI scan showed an evolution of the left thalamus-capsular lesion to a pseudotumoral lesion with mass effect involving left optic nerve and brainstem, without contrast enhancement. Lumbar puncture was performed: CSF analysis was negative for JCV DNA and cytochemical parameters were in the normal range. High dose i.v. methylprednisolone treatment was started and antiplatelet therapy stopped, with a subsequent gradual clinical and radiological improvement.

Discussion: The presented case was challenging because of the atypical radiological finding, initially mimicking a stroke, then evolving into a pseudotumoral inflammatory lesion without contrast enhancement. This particular disease activity should be considered a rebound after fingolimod discontinuation (even if atypical for its timing of onset), that anti CD20 treatment didn't prevent, possibly because of its latency in being effective.

Conclusions: Because of the various therapeutic options now available, sequencing therapies in MS is frequent and still more experience is needed to manage the delicate phase of shifting.

## AN ATYPICAL WERNICKE'S ENCEPHALOPATHY PRESENTATION WITH PAPILLEDEMA AFTER SLEEVE GASTRECTOMY

J. Bottini, A. Braccia, V. Pilato, M. Corato

"Città Studi" Clinical Institute (Milano)

To raise awareness of Wernicke's encephalopathy diagnostic challenge outside the alcohol-related, classic triad of symptoms. We present the case of a 19 years old woman who started to vomit a month after she underwent a sleeve gastrectomy for obesity with no obvious complications. On admission she had a negative abdominal exam, increased bilirubin and transaminases. A biliary tree stenosis was ruled out. A gastroscopy showed gastritis. She was treated with antiemetics and parenteral nutrition and stopped vomiting. A few days after she complained of reduced sensation in the lower limbs from the knees up to the umbilical line. She had a painful sensation in the perineal region without saddle anaesthesia or sphynteric disfunction and referred of pain in the right shoulder. Her neurological examination was unremarkable. A thoracic and lumbo-sacral mri of the spine was normal. A functional disorder was suspected and she was referred to the bariatric surgery psychologist. The day after she complained of blurred vision and she couldn't walk or stand. The ophthalmologist found her to have a severe vision loss with bilateral papilledema and retinal haemorrhages, bilateral VIth cranial nerve palsy with nystagmus both horizontal and vertical in primary position and all gaze directions. A further neurological examination showed also reduced tendon reflexes in the lower limbs with ataxia. She underwent brain and cervical MRI which demonstrated increased signal both on DWI and FLAIR sequences in the paramedian thalamic nuclei, mammillary bodies and periaqueductal area. A diagnosis of Wernicke encefalopathy was made and she was treated with thyamine 200 mg im three times a day for a week, then switched to oral. B1 vitamin level after the first dose were normal. 24 hours later she started to gradually improve. Visual acuity and eye movements were restored, sensation in the lower limbs subjectively improved. She had gait ataxia but could walk. Somatosensory and visual evoked potentials were normal as well as nerve conductions study. Eventually she was transferred to a rehabilitation facility. Wernicke's Encephalopathy (WE) presents with the classic triad in less than a third of cases [1]. The association with papilledema has been rarely described in previous case series [2]. Bariatric surgery, including sleeve gastrectomy, can lead to thyamin deficit especially in young women with vomiting; atypical neurological features are common [3]. Neurologists should be aware of the risk of WE in this clinical setting.

## IL-1 RS1143634 SNP INFLUENCES CSF INFLAMMATION AND CLINICAL PRESENTATION IN MULTIPLE SCLEROSIS

A. Bruno[1], E. Dolcetti[1], F. Azzolini[1], F. Buttari[1], S. Gambardella[2], L. Gilio[1], G. Galifi[1], R. Furlan[3], A. Finardi[3], M. Stampanoni Bassi[1], D. Centonze[1]

[1]Neurology, IRCCS Neuromed (Pozzilli-IS); [2]Biomolecular Sciences, University of Urbino "Carlo Bo" (Urbino); [3]Clinical Neuroimmunology Unit, San Raffaele Scientific Institute (Milano)

Objectives: The clinical course of multiple sclerosis (MS) is critically influenced by interplay between proinflammatory and anti-inflammatory cytokines [1]. Interleukin 1 (IL-1) has been reported as a factor capable of influencing clinical presentation of relapsing remitting MS (RR-MS) [2]. However, only few studies focused on its single-nucleotide polymorphisms (SNPs) in MS.

Materials: We explored in a cohort of 188 RR-MS patients at the time of diagnosis the associations between four IL-1 SNPs (rs315952, rs1143623, rs1143634 and rs1143627). Clinical and biochemical parameters at the diagnosis including age, sex, disease duration, oligoclonal band presence Bayesian Risk Estimate for Multiple Sclerosis (BREMS) score. Clinical disability was also evaluated after three years of follow up in a sub-group of 66 patients treated with low efficacy disease modifying therapy. We also performed a comprehensive neuropsychological assessment including Beck's Depression Inventory (BDI), State-Trait Anxiety Inventory, and Brief Visuospatial Memory Test - Revised (BVMT-R), Symbol digit modality test (SDMT). Finally, we

dosed the concentrations of lactate and group of 14 pro-inflammatory and anti-inflammatory cytokines in the cerebrospinal fluid (CSF).

Methods: Shapiro–Wilk test was used to evaluate normality distribution of continuous variables. Data were shown as mean (standard deviation, SD) or median (interquartile range, IQR). Categorical variables were presented as absolute (n) and relative frequency (%). Chi-square or, when necessary, Fisher exact test, were applied to explore the association between categorical variables. Difference in continuous variables between RR-MS patients and controls was evaluated using nonparametric Mann–Whitney test, considering the high number of variables, we corrected for multiple comparisons using Benjamini-Hochberg (B-H) procedure.

Results: Using Mann-Whitney test we identified an association between rs1143634 A minor allele carriers, TNF-α (p= 0.04) and IL-17 (p=0.09). Investigating clinical characteristic at the diagnosis we found that A minor allele carriers presented also a higher EDSS score at the diagnosis (p= 0.04) and after three years (p=0.05). We also found an association between A minor allele carriers and worse BVMT-R score at the diagnosis (p= 0. 04). No association were found between other SNPs and clinical or inflammatory parameters.

Conclusions: Our results suggest that rs1143634 polymorphism minor allele carriers present a distinct neuroinflammatory phenotype associated with worse disability and visuospatial memory at diagnosis. We also associated the presence of the A allele with worse disability after three years of follow-up.

## FACTORS INFLUENCING LONGITUDINAL MRI STRUCTU RAL AND COGNITIVE MEASURES IN MOGAD AND MS

V. Camera[1], S. Messina[2], A. Tamanti[1], L. Petralia[3], L. Griffanti[4], P. Bontempi[5], M. Guandalini[1], A. Daducci[6], M. Leite[2], R. Geraldes[2], M. Calabrese[1] and J. Palace[2]

[1]Department of Neuroscience, Biomedicine and Movement Sciences, University of Verona (Verona); [2]Nuffield Department of Clinical Neurosciences, University of Oxford (Oxford-UK); [3]Department of Chemistry, Physical and Theoretical Chemistry Laboratory, University of Oxford (Oxford-UK); [4]Wellcome Centre for Integrative Neuroimaging, Nuffield Department of Clinical Neurosciences, University of Oxford (Oxford-UK); [5]Department of Engineering for Innovation Medicine, University of Verona (Verona); [6]Department of Computer Science, University of Verona (Verona)

Objectives: In contrast to multiple sclerosis (MS), progression independent from relapses does not occur in Myelin-Oligodendrocyte-Glycoprotein antibody disease (MOGAD) with only rare exceptions. Longitudinal volumetric MRI measures can detect subtle neurological decline before it becomes clinically relevant. In this prospective study, we aimed to compare longitudinal brain MRI measures across MS, MOGAD and healthy controls (HC) and to identify factors influencing these markers of neurodegeneration in MS versus MOGAD.

Materials and Methods: At the Oxford National NMO Service and the Verona MS Centre, 32 MS, 21 MOGAD and 22 HC clinically stable patients were prospectively studied with 3T brain MRIs and cognitive tests (Rao-Battery using modified z-scores) at least 12 months apart. FSL and Freesurfer tools were used to derive annual: % brain volume change (PBVC/y), % cortical thickness change (CThc/y), % deep grey matter structures volume change (DGMVc/y), white matter lesions volumes (WMLV) variation, baseline cross-sectional brain volumetrics, cortical lesions number (CLs), normal-appearing white matter fractional anisotropy (NAWM-FA). ANCOVA and mixed effects models were used.

Results: Baseline demographics were matched as were the EDSS and SDMT scores in the disease groups. Change over time was only significantly different for the mean percentage change of thalamus volume per year (ThalVc/y) in MS group compared to the other two groups (p=0.013). In both MS and MOGAD, PBVC/y was associated with WMLV variation and ThalVc/y while in only the MS group it was associated with CLs and hippocampus volume change per year (HypVc/y). In MOGAD, CThc/y was associated to DGMVc/y (p=0.040) and WMLV variation (p<0.001). In both MS and MOGAD, DGMVc/y was related to corpus callosum volume change per year (p=0.01 and p=0.002 respectively). In MOGAD, delta SDMT z-score was associated to PBVC/y (p=0.034) and DGMVc/y (p=0.021) while in MS delta SDMT z-score was found associated with CLs (p=0.006).

Conclusions: Our prospective study shows that 1) thalamus volume change could distinguish MS from MOGAD, 2) white matter lesions and subcortical structures volume variation influence the longitudinal brain volumetrics and cognitive measures in both MOGAD and MS and, 3) CLs influence the longitudinal brain volumetrics and cognitive measures in MS.

Objectives: Ofatumumab is the first fully human anti-CD20 monoclonal antibodies (mAb) for the treatment of MS. Ofatumumab has similar clinical efficacy to, and more favorable safety and tolerability profiles than other highly efficacious mAb disease modifying drugs (DMDs)

due to its subcutaneous administration. However, real-world data on efficacy, safety, tolerability, patient's reported outcomes (PROs), and relationships with previous therapies and serum immune profiles have been not described yet. In this preliminary multicentre prospective study we aimed to verify the real-world efficacy of ofatumumab on clinical, MRI activity, PROs scores measures and to explore its effect on lymphocytes subpopulations, serum cytokines, and chemokines levels measured before and after the ofatumumab treatment initiation.

Materials and Methods: 47 MS patients (72.3% female, mean age 37.3 ± 9.7, median EDSS 2 (range:0-7)) were enrolled at the time of Ofatumumab initiation (T0) due to inefficacy, intolerance, and safety using another disease-modifying treatment or due to highly active disease at the time of diagnosis. Expanded disability status scale (EDSS), reports of adverse reactions, Symbol-Digit-Modalities tests (SDMT), Modified Fatigue Impact Scale (MFIS), Depression, Anxiety and Stress Scale-21 (DASS-21), Multiple Sclerosis Impact Scale-29 (MSIS-29), Multiple Sclerosis Neuropsychological Questionnaire (MSNQ), Treatment Satisfaction Questionnaire Medication (TSQM) were recorded at T0, after 1 month (T1), 3 months (T3), 6 months (T6). Serum samples were collected at T0 and T6 and bioplex-multiplex analysis was performed. 3T MRI with contrast data was collected before starting the therapy and at the T3 timepoint.

Results: Of the 47 RRMS patients, naïve patients were 25.5%, patients switching from a first-line therapy (teriflunomide, glatiramer acetate, IFN-beta, dimethyl fumarate) were 25.5% while those switching from a second-line therapy (S1PR-inhibitors and natalizumab) were 49%. At 6-months of follow-up, no patients relapsed. Two patients (6.6%), presenting gad-enhancing lesions during natalizumab treatment, showed persistent gadolinium-enhancing lesions at MRI performed at 3 months from ofatumumab initiation. Injection-related adverse reactions were more frequent during the first months of therapy ($p<0.001$), while infections were mild and occurred randomly during the follow-up. CD 19+ B cells were completely suppressed within one month from the ofatumumab initiation independently of the proceeding therapy ($p<0.001$). Interestingly, the treatment appeared to improve MS related quality of life measured by MSIS-29 when comparing T0 and T3 timepoints ($p=0.039$).

Conclusions: Ofatumumab treatment appears to be effective and safe either in naïve patients or in switching from other highly effective treatments and seems to improve the impact of MS-related quality of life.

## SUBACUTE ONSET HEMIPARESIS IN A PATIENT AFFECTED BY MULTIPLE SCLEROSIS UNDER NATALIZUMAB THERAPY: LOOKING FOR AN ANSWER IN OCCAM'S RAZOR

G. Campana, M. Calabrese, D. Marastoni

Neurology, University of Verona (Verona)

The subacute onset of a focal neurological deficit in a Patient affected by Multiple Sclerosis under Natalizumab therapy for more than two years and with a high JCV index, always leads the clinicians' suspect they are facing a Progressive Multifocal Leukoencephalopathy (PML). However, when the clinical, laboratory and radiological findings are not completely suggestive of such diagnosis, other possible conditions as Multiple Sclerosis relapse, other infectious diseases of the Central Nervous System (CNS) and haematological disorders, should be taken into consideration [1]. We present a case of subacute onset of right facial-brachial-crural paresis and dysarthria in a patient with the aforementioned characteristics whose diagnostic workup was complicated and still full of unsolved questions. Three lumbar punctures were performed and high sensitivity PCR for JCV was always negative. On the other hand, both the clinical evolution and brain MRI features were strongly consistent with a possible PML [2,3]. Sometimes the final diagnosis cannot be made on the basis of the commonly accepted diagnostic criteria, but it is a result of the clinician's interpretation of the clinical and paraclinical elements and the evolution of the course of the disease. Occam's razor, the principle according to which the simplest explanation is the best one, fits perfectly with our case.

## LONGITUDINAL CHANGES IN HIPPOCAMPAL SUBFIELD VOLUMES OF RELAPSING REMITTING MULTIPLE SCLEROSIS PATIENTS

A. Caporali[1], E. Portaccio[1], C. Niccolai[1], V. Penati[1], M. Betti[1], C. Ballerini[1], C. Fabbiani[1], R. Bonacchi[2], R. Tartarone[1], A. Biscarini[1], E. Fainardi[1], E. De Meo[1], M. Amato[1]

Background: Neuronal loss has been considered irreversible in the adult human brain for a long time. However, recent evidence demonstrated that neurogenesis occurs in adult human brain in the dentate gyrus of hippocampus and in the subventricular zone. A few studies suggested neurogenesis can follow a damaging stimulus, such as lesion formation in multiple sclerosis (MS). Due to the coexistence of neurogenesis and neurodegeneration, the hippocampus represents an interesting structure to analyze the interplay between these two processes in MS patients.
Objectives: To identify longitudinal trajectories of hippocampal subfield volume loss and the contribution of its progression in determining clinical disability and cognitive impairment.

Methods: Using a 3T scanner, 3DT1- and T2-weighted images were obtained from 62 early relapsing remitting MS patients at baseline and yearly for a maximum of 5 years, together with clinical and cognitive evaluation. Hippocampal subfields were segmented by using Freesurfer version 7.2.0. Algorithms of growth models by alternating conditional expectation were used to assess long term trajectories of hippocampal subfield volume changes, and linear regression models were used to assess the relationship of a progression index of thalamic damage with clinical disability and cognitive decline.

Results: Most hippocampal subfields showed progressive volume loss over disease course. Instead, dentate gyrus and cornus ammonis 1 (CA1) – related to neurogenesis – showed a bimodal pattern: early volume stability, then rapid volume decrease, and finally again stability. By using algorithms of growth models by alternating conditional expectation, we were able to identify an index of relative progression $\gamma$, considering the shared variance among hippocampal subfields.

Significant associations were observed between γ and performance at visuo-spatial memory (β=-1.94, p<0.001) and verbal fluency tests (β =-0.94, p<0.001). No significant associations were observed with clinical disability or cognitive decline in other domains.

Conclusions: The different pattern of progression of hippocampal subfield volume loss suggests an initial resilience of hippocampal regions related to neurogenesis, which then experience volume exhaustion after few years of disease. The association observed between γ and cognitive functions makes this index relevant for monitoring specific cognitive abilities.

## COMPARISON BETWEEN OPTIC NERVE MRI AND OPTICAL COHERENCE TOMOGRAPHY (OCT) IN DETECTING PREVIOUS OPTIC NEURITIS IN PWMS

R. Capuano[1], M. Cirillo[2], A. d'Ambrosio[2], R. Borgo[2], M. Altieri[2], A. De Rosa[2], M. Di Gregorio[1], M. Risi[2], G. Tedeschi[2], A. Bisecco[2], A. Gallo[2]

[1]Neurology Clinic, Medical Sciences Department, San Giovanni di Dio and Ruggi d'Aragona (Salerno); [2]Advanced Medical and Surgical Sciences, DAMSS, University of Campania (Napoli)

Objectives: Few data are available on comparison between optic nerve MRI (ON-MRI) and optical coherence tomography (OCT) efficacy in identifying previous ON neuritis (ONIS) in pwMS. Paraclinical diagnostic criteria for ONIS include: i) abnormal (increased) ON signal on ON-MRI, or ii) inter-eye asimmetry in OCT-derived measures. On this background we aimed to assess diagnostic efficacy of MRI vs OCT criteria in a group of pwMS with and without previous ONIS.

Material and Methods: 101 pwMS were included in the study. MRI signal abnormality of the ON (ON-MRI-A) was detected through review of axial and coronal STIR sequences of the ON. OCT was defined as abnormal if was detected an inter eye difference >4μm for macular ganglion cell+inner plexiform layers (mGCIPL-A) or >5 μm in the peripapillary retinal nerve fiber layer (pRNFL-A).

Results: Eighty pwMS did not have clinical history of ONIS (ON-wo-ONIS), 21 had suffered of monolateral previous (more than 3 months) ONIS (ON-w-ONIS) (11 in the right ON and 10 in the left). No clinical-demographic differences were observed in pwMS with and without ONIS. We observed: pRNFL-A in 90.5% of ON-w-ONIS and in 15.4% of ON-wo-ONIS; mGCIPL-A in 90.5% of ON-w-ONIS and in 20.5% of ON-wo-ONIS; ON-MRI-A in 33.3% of ON-w-ONIS and in 25.6% of ON-wo-ONIS. OCT-A and ON-MRI-A was observed in 33.3% of ON-w-ONIS and 12.5% of ON-wo-ONIS. ROC analysis showed 100% sensitivity and 73.7% specificity in identifying previous ONIS when using OCT-A (area under ROC curve (AUC) = 0.93) criteria; 33.3% sensitivity and 74.4% specificity when using ON-MRI-A (AUC=0.54) criteria; 33% sensitivity and 87.5% specificity when combining OCT-A and ON-MRI-A (AUC=0.6).

Discussion and Conclusions: OCT-A criteria performed better than both ON-MRI-A criteria and the combination of OCT-A and ON-MRI-A criteria in ONIS diagnosis.

## THE NEW PADOVA EMOTIONAL DATASET OF FACIAL EXPRESSIONS (PEDFE) DETECTS EARLY IMPAIRMENT OF SOCIAL COGNITION IN ACTIVE RELAPSING-MULTIPLE SCLEROSIS: A COMBINED NEUROPSYCHOLOGICAL AND MRI STUDY

T. Carandini[1], T. Di Fonzo[1], M. Mancini[2], C. Scarpazza[3], G. Verrini[4], L. Sacchi[4], A. Pietroboni[1], L. Ghezzi[4], M. De Riz[1], A. Arighi[1], F. Triulzi[1], S. Zago[1], D. Galiberti[4], M. Saetti[4]

[1]Fondazione IRCCS Cà Granda, Ospedale Maggiore Policlinico (Milano); [2]Brain Research Imaging Center (CUBRIC), Cardiff University (Cardiff-UK); [3]University of Padua (Padova); [4]Fondazione IRCCS Cà Granda, Ospedale Maggiore Policlinico, University of Milan (Milano)

Background: Social cognition is frequently impaired in patients with multiple sclerosis (MS), even from the early stages of the disease [1]. The Padova Emotional Dataset of Facial Expressions (PEDFE) is a new social cognition test for facial emotion recognition (FER) in which subjects are asked to recognize the type and genuineness of different genuine or posed emotions [2].

Aims: Our aim was to test the PEDFE in a group of recently-diagnosed (<2 years from diagnosis) relapsing-MS and controls and to evaluate association with neuropsychological scores and MRI measures of grey matter (GM) atrophy and white matter (WM) macro- and micro-structural damage.

Methods: PEDFE was acquired in 36 relapsing-MS (15 highly-active [HA]-MS and 21 not-HA-MS) and 32 controls, by calculating emotion-type (ET) and emotion-genuineness (EG) scores. Patients also underwent neuropsychological and brain-MRI. Segmentation with FreeSurfer of regional GM-atrophy and WM-lesion probability map were obtained. WM fibre density and cross-section measures were extracted from 72 WM-tracts, using fixel-based analysis (MRtrix and TractSeg software). Spearman correlations with FER-scores and regression analyses were conducted, setting p<0.05.

Results: HA-MS showed reduced EG-scores, but not ET-scores, compared to both not-HA-MS and controls (one-way-ANOVA p=0.008). ET correlated with executive performance at SDMT (p=0.02) and SRT (p=0.006) and with GM thickness in many cortical frontal, parietal and temporal areas. Conversely, EG correlated with GM thickness in cingulum-isthmus and different subcortical GM-volumes. Despite significant correlations between axonal damage within different WM-tracts and PASAT scores (p<0.001) were found, no associations with PDFE were observed. Similarly, WM-lesion load did not affect our PEDFE results.

Discussion and Conclusions: This study tested for the first time the new PEDFE in MS. Our results suggest that PEDFE may represent a valid tool to assess FER in MS, possibly distinguishing different anatomical structures involved in FER, with ET scores that are mostly linked to executive and memory functions, while EG scores that are more related to the limbic system functioning. EG-scores are impaired earlier in active relapsing-MS, possibly detecting early alteration in social cognition. Notably, impairment of social cognition as measured by PEDFE is not linked to WM-damage.

## VALIDATION OF THE ROAD SCORE IN AN ITALIAN COHORT OF PEOPLE WITH RELAPSING MULTIPLE SCLEROSIS

V. Carlomagno, A. Cicia, V. Nociti, A. Bianco, M. Mirabella, M. Lucchini

Neurology Department, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Catholic University of the Sacred Heart Rome (Roma)

Objectives: Scoring the risk of future disability in Multiple Sclerosis (MS) is a big challenge of today's clinical practice. Recently, the Risk of Ambulatory Disability (RoAD) Score was proposed as an useful tool to predict individual prognosis and optimize treatment strategy for MS patients. The score includes both baseline factors and one-year outcomes on platform treatment with a score of >= 4 as the best cut-off score for the risk of reaching EDSS score >= 6. In this study, we evaluated the performance of RoAD score in our cohort of long-term RMS patients.

Materials: We analysed a dataset of RMS patient from our MS centre.

Methods: the cohort included in the study had to be made up of patients who had started platform injectable disease modifying therapies (DMTs) with at least 10 years of follow-up. EDSS at the time of initiation of therapy had to be less than 4.

Results: 255 patients met all inclusion criteria and were included in the analysis. Median RoAD score was 2 with 61(24%) patients having a RoAD score >= 4. At 10-year follow-up, 42(16.5%) patients reached a confirmed EDSS score >= 6. The best RoAD score cut-off for estimating the risk of EDSS score >= 6 was 4 with an AUC of 0.77 (IC 0.70-0.85, p<0.01).

Discussion: In our study we confirmed a RoAD score >= 4 as the best cut-off score for discriminating patients at higher risk of reaching the disability milestone of EDSS score >= 6.

Conclusion: This study confirmed that RoAD score could represent a valuable tool to help the clinician in the assessment of long-term prognosis in patients treated with platform injectable DMTs as first-line treatment.

## ATYPICAL PRESENTATION OF ALZHEIMER'S DISEASE AND MULTIPLE SCLEROSIS IN A 54-YEAR-OLD PATIENT

E. Carta, M. Mascia, J. Frau, G. Cadeddu, E. Cocco

Multiple Sclerosis Centre, ASL Cagliari, University of Cagliari (Cagliari)

Introduction: Multiple Sclerosis (MS) and Alzheimer's disease (AD) are two neurological conditions that have a significant impact on patients, families, and society. It could be challenging to diagnose AD in a patient with MS, because MS itself can cause cognitive decline, dementia, and brain atrophy. However, little research has been conducted into the coexistence of MS and AD.

Objectives: To describe a 54-year-old female patient that was admitted to our MS centre in June 2022 due to demyelinating lesions on a brain magnetic resonance imaging (MRI) which was indicated due to visual difficulties. The husband reports progressive cognitive difficulties beginning in September 2021 and affecting daily activities such as manipulating or finding objects, driving, navigating her environment, getting dressed, and behavioural disturbances such as delusions. No other clinical events were referred.

Materials and Methods: The patient underwent screening tests such as neurological examination, evoked potentials, brain and spinal MRI, lumbar puncture and cognitive evaluation.

Results: The neurological examination revealed abnormal tendon hyperreflexia; evoked potentials were normal. The MRI showed posterior cortical regions atrophy, altered signal in supratentoral and infratentorial white matter bilaterally, spinal lesions in C2-C3 and D7-D8. The cerebrospinal fluid (CSF) analysis showed the presence of oligoclonal bands, reduced amyloid-β-42 concentration, and increased phosphorylated-tau-levels, while total-tau-levels were normal. No mutations were detected in APP, PSEN1 and PSEN2, C9orf72, TDP-43 and NOTCH3. The neuropsychological evaluation revealed visuo-spatial and visuo-perceptual deficits, simultanagnosia, environmental agnosia, left-right disorientation, neglect, constructional and limb apraxia, although verbal anterograde memory and executive abilities were mostly unaffected.

Discussion: The patient was diagnosed with Radiologically Isolated Syndrome (RIS) and probable presenile onset AD (non amnestic presentation, according to NINCDS-ADRDA criteria) based on his history, CSF levels, MRI findings, and cognitive profile. She began treatment with memantine and was later administered quetiapine due to the presence of behavioural and psychological symptoms of dementia.

Conclusion: This case report adds to the body of data that AD and MS can coexist in the same patient. The potential that AD and MS may both contribute to cognitive decline, possibly with cumulative consequences, warrants further investigation.

## BRAINSTEM LESIONS IN ADULTHOOD: THINKING OUTSIDE THE BOX

M. Caterino[1], S. Scannapieco[1], V. Andreozzi[2], B. D'arco[2], F. Di Filippo[2], U. De Marca[2], C. Giordano[2], F. Barra[1], R. Capuano[1], P. Barone[2], M. Di Gregorio[1]

[1]Neurology Unit, University Hospital "San Giovanni Di Dio E Ruggi D'Aragona" (Salerno); [2]Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Neuroscience Section, University of Salerno (Salerno)

Introduction: Differential diagnosis of adult-onset subacute brainstem syndromes is very challenging. We report a rare case of late onset isolated brainstem involvement of Myelin oligodendrocyte glycoprotein (MOG)-immunoglobulin G (IgG)-associated disease (MOGAD).

Clinical case: A 61-year-old female patient was admitted in March 2023 to the Emergency Room of our Hospital for subacute onset of diplopia, followed by dysarthria, dysphagia and gait instability. Her

past medical history was unremarkable except for colorectal polypectomy in 2009. Neurological examination showed: up-beating nystagmus, dysarthria, dysphagia, ataxic gait, dysmetria and adiadochokinesia (L>R). Brain MRI scan showed 3 poorly demarcated hyperintense lesions on T2 sequences: one in the midbrain (10x9 mm in axial diameter and 8 mm in craniocaudal diameter) with margin enhancement (gd+) and perilesional edema, one in the right occipital cortex and one in the left middle cerebellar peduncle, both millimeter and gd-. In the suspicion of secondary brain lesions, blood and instrumental exams were performed: routine, autoimmunity, thyroid screening, antibodies against neuronal intracellular antigens and antibodies against synaptic neuronal antigens, whole-body contrast-enhanced CT were unremarkable. Cerebrospinal fluids (CSF) analysis showed normal biochemical values, without cells or oligoclonal bands. Therefore, in the suspicion of an autoimmune inflammatory disease, 1 gr iv Methilprednisolone for five days was started with improvement of neurological symptoms. Fifteen days after steroid administration MRI showed reduction of brain lesions. Anti-MOG-IgG were analyzed and resulted positive in serum (1:160). A Diagnosis of MOGAD was made and oral prednisolone with long term (across 3 months) tapering was started. Two months follow-up visit showed complete resolution of neurological symptoms and resolution of MRI lesions.

Conclusion and Discussion: This case report highlights two important aspects. Firstly, although brainstem involvement in MOGAD is usually associated with optic neuritis or myelitis, in 1.8% is observed an isolated brainstem involvement specially in adult onset of MOGAD. Secondly, even if MOGAD is typically described in children or young adults (median onset between 20 and 30 years) an onset in older patients is possible.

## IMPACT OF AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION ON RETINAL ATROPHY IN MULTIPLE SCLEROSIS

M. Cellerino[1], G. Boffa[1], T. Sirito[1], E. Sbragia[1], A. Uccelli[2], C. Lapucci[3], M. Inglese[1,3]

[1]DINOGMI, University of Genoa (Genova); [2]DINOGMI, Direzione Scientifica, University of Genoa, IRCCS Ospedale Policlinico San Martino (Genova); [3]Clinic Neurology, IRCCS Ospedale Policlinico San Martino (Genova)

Background: Together with sustained suppression of clinical and MRI inflammatory activity, early accelerated brain volume loss - declining after the first year - is commonly observed following autologous hematopoietic stem cell transplantation (AHSCT) in multiple sclerosis (MS). Possible explanations for this phenomenon include treatment-related "neurotoxicity" as well as reduced inflammation-related "pseudoatrophy". The progressive thinning of peripapillary retinal nerve fiber layer (pRNFL) and of ganglion cell+inner plexifom layer (GCIPL) as assessed with optical coherence tomography (OCT) are considered biomarkers of neurodegeneration, while increased inner nuclear layer (INL) thickness might reflect inflammatory activity in MS, but data regarding the effect of AHSCT on retinal layers' thickness are still lacking.

Aims: To assess how AHSCT affects medium-term evolution of retinal layers' thickness dynamics in MS.

Methods: Spectral-domain OCT scans of 5 MS patients were obtained 3 months before, 12-months after, and at least 18-months following AHSCT. Eyes with previous optic neuritis were excluded. Atrophy rates of pRNFL, GCIPL and INL were assessed at different timepoints.

Results: At the time of inclusion, all patients had a relapsing-remitting disease course and showed MRI activity; mean age and disease duration were 30.8+9.9 and 11.8+8.4 years, respectively; median (range) EDSS: was 4.5 (2-6). Mean follow-up (FU) duration (time between baseline and last OCT performed) was 35 months (range 18-58). None of the patients showed MRI activity, relapses or disease progression following the transplant procedure. We found no pRNFL/GCIPL atrophy throughout FU (BL vs 12-months vs last pRNFL/GCIPL thickness: 95.8±8.8 vs 95.4±9.8 vs 96.4±9.3 μm/85.7±6.3 vs 85.9±7.1 vs 86.2±7.4 μm, respectively). A transient INL thinning during the first 12-moths with return to baseline thickness during the subsequent FU was observed (BL vs 12-months vs last INL thickness: 39.5±4.2 vs 38.9±4.6 vs 39.5±4.1 μm).

Conclusions: We observed an overall stability of neuro-axonal measures (pRNFL and GCIPL thickness) during the 1st and up to 3-years following AHSCT, together with an early transient INL thinning. Although still very limited, our data might be consistent with the notion that AHSCT-induced immunosuppression could reduce retinal inflammation resulting in declining INL volumes.

## THE EFFECT OF CLADRIBINE AND FINGOLIMOD TREATMENTS ON RETINAL ATROPHY

M. Cellerino[1], T. Sirito[1], V. Maneschi[1], D. Boccia[1], A. Laroni[2], A. Uccelli[3], C. Lapucci[4], G. Boffa[11], M. Inglese[2]

[1]DINOGMI, University of Genoa (Genova); [2]DINOGMI, University of Genoa, Neurology, IRCCS Ospedale Policlinico San Martino (Genova); [3]DINOGMI, Direzione Scientifica, University of Genoa, IRCCS Ospedale Policlinico San Martino (Genova); [4]Neurology, IRCCS Ospedale Policlinico San Martino (Genova)

Introduction: Data regarding the effect of cladribine and fingolimod treatment on retinal atrophy are still lacking.

Aims: To explore and compare the impact of cladribine (I course) and fingolimod treatments on retinal atrophy in a cohort of relapsing remitting multiple sclerosis (RRMS) patients.

Methods: In this ongoing study, patients starting cladribine or fingolimod at the MS Center of the University of Genoa underwent spectral-domain optical coherence tomography (SD-OCT) scans at baseline and at 12-months FU. Eyes with previous optic neuritis were excluded. Atrophy rates of peripapillary retinal nerve fiber layer (pRNFL) and ganglion cell+inner plexiform layer (GCIPL) at different timepoints and their differences between groups were assessed with repeated measures ANCOVA accounting for age, sex, disease duration.

Results: A total of 35 patients were included in the analysis, [17 cladribine and 18 fingolimod; females: 54%; mean (SD) age, disease duration, and relapses in the previous 2-years: 37.3 (14.6) years, 8.6 (10.1) years, and 0.34 (0.53); median (range) EDSS: 1.5 (0-5)]. No differences in terms of age, gender, disease duration, ARR, EDSS, and baseline pRNFL or GCIPL thickness were found between the two groups. At 1-year FU, no significant differences were observed between baseline and FU pRNFL (99.35±10.39 vs 98.10±10.75 μm respectively: p=0.49) and GCIPL (84.63±8.04 vs 83.53±7.27 μm respectively: p=0.31) thickness. Retinal thinning over FU was similar between patients treated with cladribine (pRNFL: -1.23±2.97 μm; GCIPL: -1.56±3.47 μm) or fingolimod (pRNFL: -1.27±1.26 μm; GCIPL: -0.65±2.61 μm) (p=0.86 and p=0.56, respectively).

Conclusions: We observed an overall stability of pRNFL and GCIPL thickness over 1-year in patients treated with cladribine (I course) and fingolimod, without a clear superiority of either one of the two drugs over the other in terms of retinal thinning prevention. Our findings need to be confirmed by larger analyses, which should also take into account the impact of the second course of cladribine treatment.

## ANTI-MOG, A PEDIATRIC CASE REPORT

F. Certo[1], S. Paci[2], G. Banderali[2], F. Martinelli Boneschi[1]

[1]Neurology Unit, ASST Santi Paolo e Carlo Hospital, University of Milan (Milano); [2]Department of Pediatrics, ASST Santi Paolo e Carlo Hospital, University of Milan (Milano)

Acquired demyelinating syndrome is a rare condition in pediatric population. It is important to differentiate from early onset MS and acute disseminated encephalomyelitis (ADEM) associated to anti-AQP4 or anti-MOG because they require a different treatment. A 10-year-old boy previously healthy presented to the hospital with persistent fever responsive to paracetamol, urinary retention and abdominal pain. Symptoms developed in 3 days. His exam revealed a bladder overdistension, pain of the inferior left limb associated with paresthesias, and flaccid paralysis of inferior limbs associated with decreased reflexes. Symptoms were preceded by an upper respiratory tract infection 2 weeks before. WBC count and RCP were normal. Urgent CT scan was not significant. CSF was normal apart from mildly elevated protein levels (87 mg/dl, upper limit 45). Since the examination for the detection of viruses and bacteria was negative, additional studies including anti-MOG, anti-AQP4 and oligoclonal bands were run out. Brain MRI showed T2-weighted hyperintense lesions of thalami, bilaterally in the fronto-parietal and periventricular white matter, corpus callosum and cerebellar peduncles. Spinal cord MRI revealed an extensive longitudinal transverse myelitis from C1 to T1 and from D4 to the conus. Anti-MOG turned out positive only in serum (1: 1280), anti-AQP4 was negative. Nasopharyngeal swab was positive for Adenovirus. The patient's demographic features, exam and laboratory were conclusive for a parainfectious ADEM and myelitis anti-MOG associated. He was treated for five days with high-dose corticosteroids (30 mg/Kg) with partial improvements on the paresis and minimal reduction of T2 alteration on a following MRI, then he underwent IVIg for five days (2g/Kg). Twenty days later from the hospitalization he was discharged, his exam revealed exclusively oscillations of inferior limbs in Mingazzini II and fatigability to walking at the moment of discharge. He continued steroids by oral administration for three months, progressively tapering prednisone up to 15 mg per day. Three months later he underwent a brain and spinal cord MRI, all lesions were healed leaving no apparent gliosis. His neurological exam was completely normal and he did not complain about any other symptoms. Anti-MOG in children has a more benign course compared to adults. 32%-53% of patients suffer of relapses but no MRI features were discriminative to predict relapses. Maintenance therapy with immunosuppressive DMT is indicated only in case of poor recovery with steroids after three months or recurrence of relapses.

## CHRONIC RELAPSING INFLAMMATORY OPTIC NEUROPATHY REQUIRING PLASMAPHERESIS AND RITUXIMAB TREATMENT

C. Chiavazza[1], M. Narracci[1], S. Gasverde[2], C. Baima[2], E. Gentile[2], G. Pattarino[1], C. Pulzella[1], M. Ferrari[2], D. Papurello[2]

[1]Multiple Sclerosis Center, Neurology Unit, Ciriè Hospital (Ciriè-TO); [2]Neurology Unit, Ciriè Hospital (Ciriè-TO)

Introduction: Chronic relapsing inflammatory optic neuropathy (CRION) is a type of recurrent optic neuropathy of idiopathic origin that usually responds to treatment with systemic steroids or immunosuppressant and presents relapses upon withdrawal or tapering dose. This disease affects more women than men and is characterized by unilateral or bilateral optic neuropathy, severe and persistent pain followed by subacute visual loss, with both optic nerves affected and a latency period between attacks of days to years [1,2].

Case report: A 49-year-old woman experienced left optic neuritis in March 2022; she was treated with intravenous methylprendisolone (1 g) for 7 days with transitory improvement; due to new worsening of visual

acuity despite steroid oral tapering, the patient was treated with a new course of steroid in another hospital three weeks later, without recovery. Brain MRI failed to show any demyelinating lesion involving brain or left optical nerve. Reumathological assessment demonstrated ANA positivity and oligoclonal bands were found on CSF isoelectrofocusing. One month later she was admitted to our Neurology Unit for reduction of visual acuity in right eye (7/10); at that time, she was already blind in left eye. She was treated again with intravenous steroid for 5 days with benefit. Brain MRI was unchanged, spinal MRI was negative; visual evoked potentials were consistent with left blindness and right optical neuritis; AQ4 and MOG antibodies tested negative. In the following weeks the patients experienced episodes of transitory scothoma and dyschromatopsia in right eye; control brain MRI showed an extended hyperintensive lesion in left optical nerve and a segmental alteration in right optical nerve. No contrast enhancement was seen. Genetic testing for LHON was negative. A diagnosis of CRION was supposed, and azatioprine was started with maintenance of low dose steroid oral therapy (August 2022). In November, few weeks after steroid withdrawal, she experienced a new optic neuritis (visual acuity 4/10) treated with plasmapheresis due to the partial and unpersistent steroid response in previous attacks. Visual recovery was optimal (8/10 on discharge). She is now treated with intravenous rituximab; brain and spinal MRI is unchanged. AQ4 and MOG antibodies are persistent negative.

Discussion: CRION is a challenging diagnosis; other more common diseases such as Multiple Sclerosis, NMOSD, infectious optic neuropathies, hereditary optic atrophies, metabolic neuropathies must be ruled out. Early treatment with iv steroids or plasmapheresis, followed by chronic immunosuppressant therapy, is required considering the risk of blindness if treated inappropriately. [3]

## NEUROPSYCHOLOGICAL ASSESSMENT IN MULTIPLE SCLEROSIS PATIENTS: THE POLARIS PROJECT

C. Chiavazza[1], A. Bonacci[2], A. Politi[2], M. Narracci[1], G. Pattarino[1], C. Pulzella[1], M. Ferrari[1], M. Giove[2], D. Papurello[1]

[1]Multiple Sclerosis Center, Neurology Unit, Ciriè Hospital (Ciriè-TO); [2]Neuropsychology Center, Adult Health Psychology Service, Ciriè Hospital (Ciriè-TO)

Objectives: Cognitive change is common in adults with Multiple Sclerosis (MS), ranging from 34% to 65% [1]; fatigue is one of the most common symptoms of MS [2], and exerts the greatest impact on patients' quality of life. Risk of anxiety and depression varies from 14% to 54% [3]. The aim of this study is to assess the prevalence of cognitive impairment, anxiety, depression and fatigue in a population of MS patients, in order to improve medical treatment and psychological support.

Material and Methods: We selected 23 patients of our MS Center; this population included newly diagnosed patients, patients switching to high efficacy therapies (HET) due to incomplete clinical response or with apparent radiological stability but complaining of cognitive change. We choose RBANS (Repeatable Battery for the Assessment of Neuropsychological Status) for cognitive evaluation, Hospital Anxiety and Depression Scale (HADS) for anxiety and depression, MSQoL-54 for quality of life, Fatigue Scale for Motor and Cognitive Functions (FSMC) for fatigue evaluation.

Results: 23 MS patients were tested (18 females, 5 males), mean age 45 ± 8,5 years, mean age at onset 37,5± 9,4 years. 6 patients (26,6%) were newly diagnosed (disease duration < 24 months), 7 (30%) had a disease duration > 10 years and 10 (43%) a disease duration ranging from 2 to 10 years. Median EDSS was 2,5 (range 1-6); 60% of patients were on treatment with HET; 26% of patients were on antidepressive drugs; antifatigue therapies were proposed in 21% of cases. 13% of patients reported pathological score on RBANS and 48% had scores at the lower limits. On HADS, 17% of patients reported marked anxiety, 13% pathological depression. Regarding MSQoL, 48% of patients reported lack of physical wellness and 44% a lack of mental wellness. Global fatigue was found in 78% of patients; cognitive fatigue was present in 74% of patients, physical fatigue in 83% of cases.

Discussion: Cognitive difficulties were found in more than 50% of patients, despite early HET in most cases. Fatigue has a deep impact on quality of life and is often under-reported. Neuropsychological testing helps us to identify cases at higher risk of cognitive deterioration or with unmet needs (anxiety, fatigue, job troubles) [1]. Patients' awareness of their difficulties improved and acceptance of antifatigue/antidepressive drugs or psychological support improved, too.

Conclusions: Systematic neuropsychological assessment can help in identification of patients with early cognitive impairment, patients needing additional symptomatic therapies or a longitudinal psychological support.

Objectives: Ocrelizumab is a recombinant humanized monoclonal antibody selectively targeting CD20-expressing B cells. The effect of ocrelizumab on primary progressive multiple sclerosis (PPMS) has been evaluated during phase 3 trials that enrolled patients under 55 years with a maximum Expanded Disability Status Scale (EDSS) of 6.5. However, little is known on older disabled patients with longer of disease duration. We aimed to assess clinical effectiveness of ocrelizumab in PPMS patients out of the ORATORIO eligibility criteria.

Materials: This multicenter retrospective study collected data about the effectiveness of ocrelizumab in PPMS patients who received treatment between May 2017 and June 2022 in the Italian MS centers contributing to the Italian MS Registry who adhered to compassionate use program.

Methods: The confirmed EDSS worsening (CEW) (defined as either a ≤1-point or ≥2-points increase in EDSS score from baseline that was confirmed at T12 and T24) was calculated. Results. At the date of data extraction, out of 887 PPMS patients who had received ocrelizumab, 589 (mean age 49.7 +/-10.7 years, 242 [41.1%) females) were enrolled. The mean follow-up period was 41.3 +/-12.3 months. A total of 149 (25.3%) received ocrelizumab according ORATORIO criteria (ORATORIO group) and 440 (74.7%) outside the ORATORIO criteria (non-ORATORIO group). No differences in terms of cumulative probabilities of 12- and 24-months of CEW of 1 point were found between ORATORIO and non-ORATORIO groups. Cox-regression analyses showed that age older than 65 years (HR 2.51, 25%CI 1.07-3.65; p=0.01) was associated with higher risk of CEW at 24 months.

Discussion: Patients not responding to ORATORIO criteria for reimbursability may benefit from ocrelizumab treatment, as disease activity, disease duration and EDSS seem to not impact the disability outcome.

Conclusions: Our results may suggest to extend the possible use of this powerful agent in selected patients under the age of 65 years.

## REAL-WORLD EVIDENCE FOR OFATUMUMAB IN MULTIPLE SCLEROSIS PATIENTS: A SICILIAN MULTICENTER EXPERIENCE

C. G. Chisari[1], F. Ruscica[2], P. Ragonese[3], S. Toscano[4], C. Finocchiaro[4], G. Vitello[2], B. Palmieri[2], G. Schirò[3], G. Salemi[3], L. Grimaldi[2], F. Patti[1]

[1]Department "GF Ingrassia" Section of Neurosciences, University of Catania (Catania); [2]Neurology and Multiple Sclerosis Center, Foundation Institute (Cefalù-PA); [3]Department of Biomedicine, Neurosciences and Advanced Diagnostics, University of Palermo (Palermo); [4]Department of Medical and Surgical Sciences and Advanced Technologies, University of Catania (Catania)

Objective: Ofatumumab (OFA) is a human recombinant IgG1 CD20 next-generation monoclonal antibody. Two phase III trials investigated the efficacy and safety of OFA in relapsing-remitting Multiple Sclerosis (RRMS) showing a relative reduction of the relapse rate after 3 and 6 months in the OFA arm (50.5% and 58.5%, respectively) compared to teriflunomide. In addition, the risk for confirmed disability was significantly reduced (34.4% and 32.5%, respectively). Subsequent studies confirmed that OFA is a highly effective treatment option for patients with relapsing forms of MS with a manageable tolerability profile. However, to date, real world data about the effectiveness of OFA are still scarce. We aimed to evaluate efficacy and safety of OFA in a real-world setting.

Materials: This prospective real-world study consecutively screened all RRMS patients from three MS centers in Sicily (Italy), who were treated with OFA for at least 6 months.

Methods: Data about Expanded Disability Status Scale (EDSS), relapses, previous treatments, adverse events (AEs) and magnetic resonance imaging (MRI) were collected. We also compared demographical and clinical data between patients naive to treatment before starting OFA (naïve group) and patients switching from other treatments (switch group).

Results: Out of 78 RRMS patients who started OFA treatment in the period between August 2022 and May 2023, a total of 54 patients (32 [59.3%] women, with mean age of 34.8 ± 5 years and mean disease duration of 110.1 ± 21.9 months), were finally enrolled. Of these, 18 (33.3%) were naïve to treatment and 36 (66.7%) switched from another DMTs. At baseline, naive group showed longer disease duration, higher number of relapses before starting OFA, and higher number of brain/spine contrast-enhanced lesions (CELs) before starting OFA compared to the switch group. After 6 months from OFA initiation, 53 (98.2%) of patients remained relapse-free, 50 (92.6%) were EDSS progression-free, and 47 (87%) were MRI activity-free. No significant differences in terms of efficacy outcomes were found between naive and switch groups. During the observation period, all the AEs were mild to moderate and no serious AEs were reported. In particular, fever was the most frequent AE reported in 70.4% of treated patients.

Discussion: Findings from our study confirmed that OFA is effective in reducing risk of relapse and disease progression in a real –world cohort of RRMS patients, also demonstrating a favorable safety profile.

Conclusions: Longitudinal studies are needed to evaluate the long-term effectiveness of OFA for the treatment of RRMS in patients naïve to treatment and in those who have switched from other DMTs.

## PREVALENCE OF PSYCHIATRIC DISORDERS AT MULTIPLE SCLEROSIS ONSET

A. Cicia, M. Lucchini, A. Bianco, V. Nociti, V. Carlomagno, M. Mirabella

Fondazione Policlinico Universitario A. Gemelli IRCCS, Catholic University of the Sacred Heart, Research Center for Multiple Sclerosis (CERSM) (Roma)

Psychiatric syndromes (PS) in multiple sclerosis (MS) are common, with a variable prevalence up to 60%. [1]. PS are often underdiagnosed during routine neurological follow up and therefore receive suboptimal treatment. On the other hand, the prevalence of psychiatric manifestations before disease onset and their impact on patient's care has been poorly explored so far [2][3].

Objectives: To assess the prevalence of PS at MS onset and to explore whether patients with a psychiatric comorbidity presented any significant difference in terms of age, sex, EDSS and time to diagnosis compared to those without psychiatric history.

Materials: We collected the records of patients diagnosed with MS according to the 2017 revision of McDonald's criteria from January 2018 to December 2022 and evaluated the presence of psychiatric manifestations at disease onset.

Methods: We classified PS into five categories according to DSM-5 and evaluated their relative frequencies and the specific treatment adopted. We compared demographic and clinical differences between patients presenting psychiatric comorbidity and those who did not, and assessed whether there was a delay in MS diagnosis in the first group.

Results: We enrolled 254 patients and we found that 28 patients (11%) had a PS before MS onset. The most frequent disorder was depression (50%), followed by anxiety disorder (25%), schizophrenia spectrum disorders (10.7%), bipolar disorder (7.1%) and eating disorders (7.1%). 92.9% of patients took a specific therapy, mainly antidepressants (46.2%), and anxiolytics (34,6%). The mean time from the first psychiatric symptom to the first neurological event was 8.1 years (standard deviation 5.8 years). Patients with PS at onset showed a higher median EDSS at diagnosis compared to those without psychiatric history (p=0.054). We found no statistical differences in age, sex and time from MS onset MS diagnosis between the two groups.

Discussion: We found a significant percentage of patients presenting a psychiatric manifestation before MS onset. It is not possible to establish whether psychiatric symptoms might be considered an inaugural manifestation of MS. The group of patients with psychiatric history did not differ significantly from the group without it, with the exception of median EDSS at diagnosis. In our cohort the presence of a psychiatric comorbidity did not lead to diagnostic delay.

Conclusions: Psychiatric symptoms occur frequently in individuals with MS, either prior to a definitive neurological diagnosis or with disease progression. A thorough psychiatric assessment should be performed at diagnosis, so as to identify underrated disorders and offer proper treatment.

## CENTRAL NERVOUS SYSTEM GLIOMA MASQUERADE AS TUMEFACTIVE DEMYELINATING LESION: A CASE REPORT

G. Cola, C. Dionisi, C. Simonetta, C. Lozi, G. Nardino, N. Salvati, R. Massa, N. Mercuri

Department of Systems Medicine, Tor Vergata University and Hospital (Roma)

Background and Objectives: Central nervous system (CNS) neoplasm and tumefactive demyelinating lesion (TDL) represent a diagnostic challenge for neurologists because they may look radiologically identical, leading to a diagnostic delay.

Materials and Methods: A 27 year-old man, with no known prior medical illness, was admitted in October 2022 to our Neurology Department for a transient vertigo, lasting two hours. His family history was negative for any neurological disease. Neurological examination on admission was unremarkable.

Results: Brain magnetic resonance imaging (MRI) showed a large lesion in the right cingulate gyrus with subcortical cortical involvement,measuring 2x3cm,suspected for TDL or CNS glioma, with normal N-acetylaspartate/choline ratio at spectroscopy and normal perfusion parameters. There were also other small T2-weighted hyperintensity lesions in the deep white matter of bilateral hemispheres, suspected for demyelinating lesions. All lesions showed neither contrast enhancement nor diffusion restriction. Spinal cord MRI was normal. CSF examinations revealed mild lymphocytic pleocytosis (9/mmc), elevated protein level and oligoclonal bands (OCBs) were detected intrathecally. Visual and sensory-evoked potential were normal. Autoimmune profile and MOG antibodies were negative. A diagnosis of TDL in radiologically isolated syndrome (RIS) was made. Patient received pulse steroid therapy for three days. At 4 months follow-up the patient was negative for new symptoms, however MRI showed a mass effect with surrounding edema in the right cingulate lesion without other new lesions. So, biopsy of this lesion was performed and demonstrated histopathological features of low grade oligodendroglioma. The patient finally underwent neurosurgical excision of this lesion.

Discussions and Conclusions: The tumefactive form of demyelinating disorder is rare, however it can be a diagnostic dilemma especially in young adults. Brain tumors are the most frequent misdiagnosis. In our case, a TDL in RIS was initially suspected for the patient's young age and symptom, CSF profile with OCBs and brain MRI showing white matter lesions and a largest lesion without abnormality in spectroscopy and perfusion techniques. TDL could be easily misdiagnosed both for nonspecific clinical presentation and for imaging findings that may mimic intracranial space-occupying lesions. In this case neuroimaging follow-up was crucial to reconsider the diagnosis of CNS glioma. Sometimes, like our case, brain biopsy is needed to confirm diagnosis although it is an invasive procedure and it can imply significant morbidity. Thus, reporting similar cases will help to increase clinicians awareness about this circumstance and highlight the need for additional markers to differentiate these conditions.

## OUTCOMES, ADVERSE EFFECTS AND EXIT STRATEGIES IN MULTIPLE SCLEROSIS PATIENTS TREATED WITH ALEMTUZUMAB: A MONOCENTRIC RETROSPECTIVE STUDY

M. Comar[1], G. Cellante[1], G. Sportelli[1], S. Lorenzut[2], A. Marziali[1], I. Del Negro[1], D. Cutuli[2], D. Cargnelutti[2], M. Valente[1]

[1]Clinical Neurology Unit, University of Udine Medical School (Udine); [2]Neurology Unit, S. Maria della Misericordia University Hospital (Udine)

Objectives: Currently few studies exist concerning a long-term follow-up in multiple sclerosis patients treated with Alemtuzumab. Our study aimed to analize the outcomes, the adverse effects and the exit strategy in multiple sclerosis (MS) patients treated with Alemtuzumab in our center.

Materials: We conducted a single-center retrospective observational study of 51 patients with diagnosis of MS, who underwent a disease-modifying therapy (DMT) with Alemtuzumab at Udine University Hospital from September 2015 to March 2023.

Methods: Patients were followed-up since the first subministration of Alemtuzumab, in order to identify adverse effects, outcomes and exit strategy. The outcomes of interest were relapses, EDSS at 24 months and reactivation or evidence of new lesions reported in MR imaging during the follow-up.

Results: At baseline, 46/51 patients (90.2%) were diagnosed as relapsing-remitting multiple sclerosis (RRMS) and 5/51 (9.8%) as secondary progressive MS with residual inflammatory activity. 46/51 (90.2%) patients had completed the second treatment cycle with Alemtuzumab and their mean follow-up was 57 months. 6/51 (11.8%) patients had disease relapse between the first and the second cycle, while 11/51 (21.6%) patients had disease relapse after the second cycle. 10/51 (19.6%) patients showed reactivation signs on MR during the first and the second cycle, while 15/51 (29.4%) patients had MR reactivation signs after the second cycle. For 37/51 patients (72.5%) the follow-up was at least 24 months: their 24month mean EDSS was 2.76 ± 1.8 and 12 patients were classified as NEDA3. 30/51 patients (58.8%) had adverse events. After Alemtuzumab second cycle, 5/51 patients (9.8%) underwent a third cycle with Alemtuzumab, 2/51 (3.9%) patients were treated with another DMT and 2/51 (3.9%) patients underwent a bone marrow transplant.

Discussion: In our study only 17/51 patients (33.3%) had a clinical disease relapse during the follow-up. Adverse events were mild or resolved spontaneously or with medical therapy in most of the patients analized in our study and they didn't affect the course of Alemtuzumab therapy.

Conclusions: We confirmed a high efficacy of Alemtuzumab, compared to contained adverse effects and we reported the exit strategy used in patients treated in our center. We hope that our study and other evidences in future can help to outline a common therapeutic approach following completion of Alemtuzumab treatment.

## THE IMPACT OF APATHY ON CAREGIVERS BURDEN AND COPING STRATEGIES IN MULTIPLE SCLEROSIS

M. Cropano[1], G. Lus[1], M. Gaita[2], L. Ammendola[2], D. Malangone[2], E. Signoriello[1], S. Raimo[3]

[1]Department of Medical and Surgical Sciences, University of Campania Luigi Vanvitelli (Napoli); [2]Department of Psychology, University of Campania Luigi Vanvitelli (Caserta); [3]Department of Medical and Surgical Sciences, Magna Graecia University of Catanzaro (Catanzaro)

Objective: Our aim was to enhance the current state of knowledge about caregivers of people with MS (pwMS) identifying the impact of apathy on caregivers burden and coping strategies.

Materials: Thirty-four dyads of people with MS and caregivers completed the Apathy-Motivation Index (AMI) [1], tapping apathy in terms of behavioural activation (BA), social motivation (SM), and emotional sensitivity (ES), in self-evaluation (SE) and caregiver (CG) version, respectively. In addition, the caregivers completed the Zarit Burden Interview (ZBI) and the Caregiver Burden Inventory (CBI) tapping the caregiver burden, and the Coping Orientation to Problems Experienced (COPE) tapping coping strategies related to positive reframing, social support, acceptance, denial, and turning to religion.

Methods: To evaluate the differences in the AMI-CG and AMI-SE total and subscales scores the Mann-Whitney test was performed. Moreover, Spearman correlations were performed between AMI-SE and AMI-CG total and subscales scores. Finally, to evaluate the association between apathy, caregiver burden, and coping strategies, Spearman correlations were performed between AMI-CG total and subscale scores with CBI, ZBI, and COPE subscales scores.

Results: No statistically significant differences were found between AMI-CG and AMI-SE total ($U = 519$, $p = 0.469$), SM ($U = 523$, $p = 0.502$), and ES ($U = 504$, $p = 0.362$) subscales scores; however, the BA-CG subscale score was significantly higher than BA-SE subscale score ($U = 396$, $p = 0.025$). Correlation analysis showed a considerable agreement between the AMI-SE and AMI-CG total and subscales scores (rrho >= 0.350 p <= 0.042). Moreover, a significant and negative correlation was found between ES-CG subscale score with COPE total score (rrho = -0.355; $p = 0.039$), and with positive reframing subscale score (rrho = -0.503; $p = 0.002$). No significant correlation was found between AMI-CG total and subscales scores with CBI and ZBI scores.

Discussion: Overall, caregivers rated apathy similarly to pwMS, except for behavioural dimension of apathy, suggesting that reduced individual's self-initiated purposeful behaviour would be a possible anosognosic component in pwMS. Moreover, the negative relation between the emotional dimension of apathy and caregivers' coping strategies, particularly their ability to think about a negative or challenging situation in a more positive way, would underlie the impact of affective blunting of pwMS on caregivers' ability to effectively provide care and lead to positive changes in MS management [2].

Conclusions: These findings suggest that apathy in pwMS involves factors other than the patients' symptoms. Comprehensive care of pwMS should include training on coping strategies of caregivers to provide better support services [3].

## UNUSUAL CLIPPERS PRESENTATION WITH A PREDOMINANT SPINAL CORD INVOLVEMENT

A. Cruciani[1], F. Motolese[1], C. Tortorella[2], V. Pozzilli[1], S. Haggiag[2], M. Rossi[1], F. Pilato[1], C. Gasperini[2], V. Di Lazzaro[1], F. Capone[1]

[1]Neurology, Neurophysiology and Neurobiology Unit, Department of Medicine, Campus Bio-Medico Foundation (Roma); [2]Neurosciences Department, San Camillo-Forlanini Hospital (Roma)

Objective: Chronic lymphocytic inflammation with pontine perivascular enhancement responsive to steroids (CLIPPERS) is a discrete nosological entity characterized by punctate and curvilinear gadolinium enhancement 'peppering' the pons and a strong response to steroids [1]. Despite the extremely rare incident of CLIPPERS hindering the exact characterization of the disease, some authors have tried to assess the most common clinical and radiological features and proposed diagnostic criteria [2]. Among all the proposed features the presence of predominant pontine gadolinium-enhancing nodules has been observed in the total of the described cases, making it the most representative feature of the disease [2]. Herein we present an extremely rare case of CLIPPERS presented with a predominant spinal cord involvement.

Materials and Methods: A 23-years old woman with no past medical history presented to our emergency department with a 1-month history of subacute onset gait disturbance. Neurological examination showed moderate gait ataxia, slight right motor hemiparesis, and bilateral Babinski and Hoffmann signs. Brain and spinal cord MRI showed multiple lesions with punctate and curvilinear gadolinium enhancement with a salt-and-pepper-like appearance involving the midbrain and, predominantly, the spinal cord. CSF and blood examination resulted normal for the exclusion of a "better explanation" [2]. The administration of 5 days of high-dose intravenous methylprednisolone leads to substantial clinical and MRI improvement.

Discussion: Our case describes a rare case of CLIPPERS with prevalent spinal cord involvement. To our knowledge, this MRI pattern has been rarely reported in the literature [3]. It is critical to describe this presentation since must be carefully considered in the diagnostic workup of diffuse spinal cord lesions.

Conclusion: Our case focuses attention on a rare MRI CLIPPERS presentation. Since CLIPPERS has a dramatic response to corticosteroid treatment it is fundamental to promptly recognize its MRI pattern to start treatment as soon as possible.

## MULTIPLE SCLEROSIS AND HEPATIC COMORBIDITIES: CASE REPORTS AND THERAPEUTIC STRATEGIES

C. Cutellè[1], G. Liberatore[2], F. Gallia[2], P. Doneddu[2], E. Nobile-Orazio[1]

[1]Neuromuscular and Neuroimmunology Unit, IRCCS Humanitas Clinical and Research Hospital University of Milano-Bicocca (Rozzano-MI); [2]Neuromuscular and Neuroimmunology Unit, IRCCS Humanitas Research Hospital (Rozzano-MI)

Objectives: The aim of the study is to investigate hepatic comorbidities in Multiple Sclerosis (MS).

Materials and Methods: We analysed 125 consecutive MS patients, to register any transaminases increase before disease modifying therapies (DMTs).

Results: We found sustained transaminase increase (> 1 upper normal limit) in 5 patients out of 125. The 5 patients underwent a targeted anamnesis, first level blood tests including viral and autoimmune screening and hepatobiliary ultrasound. Three patients were diagnosed as fatty liver disease, while two patients required hepatic biopsy and are described below. Case 1: A 42-years old woman with a new diagnosis of MS and two close relapses had a 20-years story of recurrent transaminase increase. Hepatic biopsy showed a nodular regenerative hyperplasia compatible with porto-sinusoidal vascular disease. Therapy with ofatumumab resulted efficient and safe. Case 2: A 21-years old woman with a new diagnosis of MS had two close relapses, the second one treated with methylprednisolone and followed, one month later, by a severe transaminase increase. Hepatic biopsy showed centrolobular necrosis and inflammatory infiltrates. ANA were positive. A drug induced liver disease was supposed, but the persistence of transaminase elevation lead to start prednisone (with enzyme normalization) and to diagnose a probable autoimmune hepatitis. The patient continued a low dose of prednisone and started natalizumab. Four year later, she developed an MS relapse treated with methylprednisolone followed by a hepatic relapse, recovered increasing the dosage of prednisone.

Discussion and Conclusions: Sustained increase of transaminases in new diagnosed MS patients impose a specific diagnostic work-up to understand the underlying condition, contributing to the choice of the most appropriate DMT. We reported the cases of a porto-sinusoidal vascular disease and of a probable autoimmune hepatitis, respectively, concurrent to MS. In the first case, hepatic biopsy was diagnostic and made theoretically administrable any DMT except Alemtuzumab because of the potential thrombotic risk. In the second case, methylprednisolone was a confounding element and, even after hepatic biopsy, the diagnosis of drug induced versus autoimmune hepatitis was difficult, orientating towards autoimmune hepatitis after follow-up. Literature analysis shows that there is a continuous spectrum between hepatoxicity with immunoallergic mechanism and autoimmune hepatitis due to immune rebound phenomenon, often without a clear line of demarcation between the two conditions. The role of natalizumab and other DMTs in toxic and autoimmune hepatitis is debated, our case suggests that natalizumab is apparently safe while methylprednisolone should be avoided.

## OFATUMUMAB USE IN A REAL WORLD ITALIAN SETTING

E. D'Amico[1], A. Zanghi'[1], S. Bonavita[2], G. Abbadessa[2], L. Lavorgna[2], E. Signoriello[3], G. Lus[3], R. Fantozzi[4], D. Centonze[4], C. Avolio[1]

[1]Department of Medical and Surgical Sciences, University of Foggia (Foggia); [2]Neurology Department, University of Campania Luigi Vanvitelli (Napoli); [3]Neurology Department, University of Naples (Napoli); [4]Neurology Department, IRCCS Neuromed (Pozzilli-IS)

Objectives: The primary outcome was to offer an overview real world practice with ofatumumab in relapsing Multiple Sclerosis (RMS) patients and to observe the first six months on therapy in terms of disease activity and disability progression.

Methods: Inclusion criteria were patients: 1) aged 18-55; 2) with a confirmed diagnosis of RMS, per the revised 2010 McDonald criteria; 2) who started OFA according to Italian Medicines Agency prescription rules and within 12 months from the RMS diagnosis.
Results: 43 patients were enrolled from 5 Italian MS centers, 67% female, mean age 33,4±8,5 years. All patients had magnetic resonance activity and at least one relapse in the previous 12 months. Out of them, 35 had at least six months of follow up. Median EDSS was 1.5 (interquartile range 1.0-2-00). During the first six months of therapy, no relapses or MRI activity were recorded. No worsening of disability was reported.

Discussion: Ofatumumab stabilizes the disease course in our highly active cohort during the first 6 months of therapy.
Conclusions: The progressive and increasing use of anti-CD20 drugs, imposes the need for larger, prospective, real-world long-term studies to characterize further its use and efficacy in different classes of RMS patients.

## SIPONIMOD-INDUCED LYMPHOPENIA IN PATIENTS WITH SECONDARY PROGRESSIVE MULTIPLE SCLEROSIS: A REAL-WORLD EXPERIENCE

U. De Marca[1], R. Capuano[1], F. Di Filippo[1], S. Scannapieco[1], V. Andreozzi[1], A. Bisecco[2], A. D'ambrosio[2], M. Conte[2], V. Conti[1], A. Filippelli[1], A. Gallo[2], M. Di Gregorio[1], P. Barone[1]

[1]Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", University of Salerno (Salerno); [2]Department of Advanced Medical and Surgical Sciences, University of Campania 'Luigi Vanvitelli' (Napoli)

Objectives: Siponimod, a sphingosine-1-phosphate receptors modulator (S1Prm), leads to a dose-dependent reduction of the peripheral absolute lymphocytes count (ALC) to 20–30% of baseline. In the pivotal phase III study (EXPAND) in Secondary Progressive Multiple Sclerosis (SPMS), only 1% of treated patients reached a grade 4 lymphopenia (ALC <200/mcL). In real world studies, low baseline ALC and previous treatment with interferon-beta have been identified as risk factors for lymphopenia in patients with Multiple Sclerosis treated with Fingolimod, the first S1Prm available for MS. Real world data regarding ALC reduction rates and predicting factors are lacking for Siponimod. We therefore aimed to evaluate Siponimod-induced lymphopenia in clinical practice.

Material and Methods: 31 patients with SPMS (pwSPMS) were included in the analysis. Clinical-demographical data, biometric values and life habits were collected. ALC was obtained before and 3-6 months after Siponimod introduction. STATA 14 was used for statistical analysis.

Results: Seventy-one percent of patients were female; the mean age was 55.2 (± 8) years, with a mean disease duration of 27 (±12.5) years; median EDSS was 6.5 (IQR25=4, IQR75=7). The mean body mass index (BMI) was 24.6 (±2.8) and 15% were smokers. All pwSPMS had previously been treated with other disease modifying therapies (DMTs): 61.3% with interferon beta. Eighty percent of patients carried the cytochrome P2C9*1*2-(CYP2C9*1*2-) and-*1*1-genotype. Mean baseline (BL) ALC was 1395 (±613)/mcL (median 1380/mcL, IQR25=1005/mcL, IQR75=1940/mcL), while average ALC within 3-6 months was 517 (±378)/mcL (median 400/mcL, IQR25=270/mcL, IQR75=660/mcL); an average reduction of 42.8 (±29.4)% of ALC was therefore measured between the baseline and short-term follow-up. Sixty-four percent of pwSPMS reached a grade 3 lymphopenia (ALC <500/mcL); 9.6% reached a grade 4 (ALC <200/mcL), conducting to Siponimod withdrawal. No differences were observed across different cytochrome P2C9 genotypes. Regression model including age, sex, EDSS, disease duration, previous DMTs, ALC before starting Siponimod, BMI, smoking, alcohol intake did not show any predictor of ALC reduction.
Discussion: In a real-world cohort, we observed a higher ALC reduction (42.8%) and a higher percentage of grade 3-4 lymphopenia (64.5 and 9.6%, respectively) compared with those observed in the EXPAND study (30% reduction of ALC and 1% grade 4 lymphopenia, respectively). We did not identify any predicting risk factor for lymphopenia, but this was probably due to our small sample.

Conclusions: Siponimod-induced lymphopenia in clinical practice is more relevant than that reported in the EXPAND study. No risk factors for lymphopenia have been identified.

Background: Compared to typical MS onset in young adulthood (ie, adult-onset – AOMS), the minority of pediatric- (POMS – ie, before age 18 years) and elderly-onset (EOMS – ie, after age 50 years) MS patients might experience faster cognitive decline. We aimed to describe cognitive phenotype (Ph) distribution and related MRI substrates in POMS and EOMS vs AOMS patients, over time.

Methods: We enrolled 1262 MS patients and 238 healthy controls (HC). All subjects underwent cognitive evaluation with Rao's Brief Repeatable Battery and Stroop Color Word Test, of whom 222 MS patients and 88 HC also underwent 3T MRI with pulse sequences for atrophy and lesion assessment. Probabilistic models were applied to attribute previously described Ph ("preserved-cognition", "mild verbal memory/semantic fluency", "mild-multi-domain", "severe-attention/executive", and "severe-multi-domain") to patients; and to estimate the probability of attribution to each Ph over increasing disease duration (DD), considering the effect of age at onset. Similar models were used to estimate the probability of MRI alterations over increasing DD.

Results: Among POMS and AOMS patients, the probability of "preserved-cognition" or "mild-verbal memory/semantic fluency" Ph decreased with increasing DD; while that of "mild multi-domain", "severe executive/attention" and "severe multi-domain" Ph increased (p from <0.001 to 0.03). Among EOMS, the probability of "cognition preserved" Ph was lowest at disease onset and it hardly changed over DD; the probability of "mild-verbal memory/semantic fluency", "severe executive/attention" and "severe multi-domain" Ph reduced over DD; while that of "mild multi-domain" increased over DD (p from 0.01 to 0.03). Compared to AOMS, POMS patients showed a steeper increase in the probability to experience deep GM and hippocampal atrophy after 20 years DD (p from <0.001 to 0.03), as opposed to similar trajectories over time for cortical GM atrophy and lesion volume. Compared to AOMS, EOMS patients showed higher probability of hippocampal and cortical GM atrophy at disease onset, and a steeper increase in this probability after 5 years DD (p from <0.001 to 0.01); moreover, they showed higher probability of greater lesion volumes and deep GM atrophy at disease onset (p from <0.001 to 0.03), but with less steep increase over DD (p from 0.01 to 0.05).

1Conclusions: Age at MS onset significantly influences Ph distribution among MS patients, as partly explained by underlying trends of regional GM atrophy.

## CARDIOGENIC SHOCK AFTER OCRELIZUMAB INFUSION: A POSSIBLE CORRELATION?

G. De Napoli[1], F. Vitetta[2], K. Smolik[1], A. Fiore[2], M. Cardi[1], E. Gotti[3], D. Ferraro[1]

[1]Department of Biomedical, Metabolic and Neurosciences, University of Modena and Reggio Emilia (Modena); [2]Neurology Unit, Azienda Ospedaliero Universitaria di Modena (Modena); [3]Cardiology Unit, Azienda Ospedaliero Universitaria di Modena (Modena)

Background: Ocrelizumab is an intravenously administered, humanized anti-CD20 monoclonal antibody authorized for the treatment of relapsing forms of multiple sclerosis or primary progressive multiple sclerosis. We report the case of a patient with remitting-relapsing multiple sclerosis (RRMS) who developed a cardiogenic shock after the second 300 mg infusion (first cycle) of Ocrelizumab.

Case report: A 42-year-old man with a history of active RRMS was started on Ocrelizumab after fingolimod discontinuation. Roughly 24-36 hours after the second infusion of Ocrelizumab, the patient started developing worsening dyspnea, associated with cough and throat irritation, without fever. On admission at the emergency department, 12 days from symptom onset, systemic oxygen saturation was low, Chest X-Ray showed pulmonary congestion and echocardiography documented left ventricle with normal volume, mild hypertrophy and severe reduction of systolic function (LVEF 25-30%). A supportive therapy with high-flow oxygen and diuretics was started. The patient was then moved to intensive care for persistent hypotension, requiring mechanical support with intra-aortic balloon pump placement. Angiography didn't reveal critical coronary stenoses and Cardiac MRI documented a non-specific picture characterized by areas of myocardial oedema of the interventricular septum with increased T1 signal, consistent with both a drug-induced cardiotoxicity and a myocarditis. However, microbial serologic tests were negative and histological findings at endomyocardial biopsy were not suggestive of myocarditis. The patient gradually improved with rapid normalization of the left ventricular systolic function.

Discussion and Conclusion: Ocrelizumab is generally well tolerated. The most common side effects reported in trials include infusion-related reactions and infections, which were mainly mild to moderate in severity. Since our patient did not show systemic allergic symptoms during or within 24 hours of infusion and symptoms had gradual progression, a hypersensitivity-associated acute coronary syndrome can be excluded. Nevertheless, the time correlation between drug administration and symptom onset, fortunately followed by complete recovery, and the exclusion of other causes, suggest Ocrelizumab may have played a role in determining the cardiac functional injury. To date, no cardiac adverse events have been reported in association with Ocrelizumab, but a few cases of myocardial infarction, atrial fibrillation, pulmonary oedema and cardiogenic shock have been described following the first infusion of Rituximab, another B cell–depleting antibody. Although the underlying mechanism of cardiac toxicity of anti-CD20 is not known, a dysregulation of the immune system can be hypothesized, as some studies suggest that depletion of B cells may induce up-regulation of proinflammatory cytokines.

## NK CELL LEVELS PREDICT DISEASE ACTIVITY IN PATIENTS WITH MULTIPLE SCLEROSIS ON OCRELIZUMAB/RITUXIMAB THERAPY

S. Dal Bello[1], S. Lorenzut[2], E. Saccomano[3], Y. Tereshko[1], D. Cargnelutti[2], D. Cutuli[2], G. Gigli[3], M. Valente[1]

[1]Clinical Neurology Unit, Department of Neuroscience, Udine University (Udine); [2]Neurology Unit, ASUFC (Udine); [3]Department of Medicine (DAME), Udine University (Udine)

Objectives: The primary objective was to identify predictors of response to treatment with infusional anti-CD20 drugs in patients with Multiple Sclerosis; the secondary objective was to study the effect of Ocrelizumab/Rituximab on laboratory immune parameters. Materials and Methods: A retrospective single-center study was conducted among patients who received infusion therapy with anti-CD20 drug for the treatment of Multiple Sclerosis.

Results: A total of 64 patients met the inclusion criteria, with 277 total cycles of therapy studied. Disease activity at 6 months after drug infusion occurred in 97 of 277 total evaluations, identifying on multivariate analysis that a reduced percent level of NK cells at 3 months after infusion is a possible predictor of disease activity at 6 months after Ocrelizumab/Rituximab administration (p=0.041). Anti-CD20 infusions result in absolute and percent decreases in B lymphocyte levels and an increase in absolute and percent levels of NK cells at 3 and 5 months after therapy compared with baseline values ($p < 0.001$). EDSS assessed before drug initiation is the only variable that predicts any disease activity at 6 months after the first Ocrelizumab/Rituximab infusion ($p = 0.044$).

Discussion: The pathogenesis of multiple sclerosis (MS) still appears to be unclear [1]. Recent years have focused on the role of B lymphocytes and the possibility of using specific drugs, such as Ocrelizumab and Rituximab, directed toward these cells to reduce inflammation and slow disease progression [2]. The effect of these therapies on NK cell and how these cells may influence disease progression is poorly understood.

Conclusions: Ocrelizumab/Rituximab therapy results in a reduction in B lymphocyte counts and an increase in NK cells. Lower percentage levels of NK cells at 3 months after anti-CD20 infusion predict the presence of disease activity at 6 months after such therapy, confirming a possible role of NK cells in the pathogenesis of Multiple Sclerosis. Repopulation of B lymphocytes at 3 months has not been shown to predict disease activity at 6 months after drug infusion.

## PSYCHOTIC ONSET OF MULTIPLE SCLEROSIS MISTAKEN FOR SCHIZOFRENIA: A CASE REPORT

M. G. Di Donna[1], V. Ferrari[2], M. Panella[2], F. Izzi[2], F. Placidi[2], N. Mercuri[2]

[1]Neurology, University of Rome Tor Vergata (Roma);[2]Institute of Neurophysiopathology, University of Rome Tor Vergata (Roma)

Introduction: Here we describe the case of a 22-year-old male presented with an episode of flue in October 2022. Ten days later, while the patient and his family were on a pilgrimage, he experienced acute onset of a mystical-religious-themed delirium associated with psychomotor agitation, verbal and physical aggression towards his mother. The patient was taken to the emergency room; head CT scan was performed, found to be normal. Due to the persistent state of psychomotor agitation, he was subjected to compulsory medical treatment. An acute onset of schizophrenic disorder was diagnosed, and the patient was treated with daily intramuscular paliperidone, with a good control on delirium; he was discharged after a week with the indication to continue oral antipsychotic therapy. At discharge, however, the patient presented a severe ideomotor slowing, with significant diffuse stiffening of trunk and limbs and a severe iatrogenic extrapyramidal rigid-akinetic syndrome was suspected. On neurological examination the patient presented severe hypomimia, hypophonic and dysarthric speech; dexterity tests revealed severe bradykinesia, plastic hypertonus in limbs and trochlea phenomenon were present. Further diagnostic investigations were performed: EEG showed fronto-temporal sharp waves and spikes focality; brain MRI showed hyperintensities in T2 FLAIR sequences in bilateral temporal periventricular areas, left frontal iuxtacorticale areas, frontal pericallosal periventricular areas, with a radial aspect as perivenular distribution. In the suspicion of CNS demyelinating disease, cervical spine MRI was also performed documenting the presence of two dorsal lesions in T2 FLAIR sequences. Visual evoked potentials were normal. Lumbar puncture revealed the presence of an isolated intrathecal oligoclonal synthesis with (type 3 profile). Anti-aquaporin antibodies on CSF were negative. Multiple Sclerosis was diagnosed, antipsychotic therapy was gradually discontinued, with total resolution of parkinsonism. The patient was referred for clinical and therapeutic follow-up at the Multiple Sclerosis Centre of this hospital.

Discussion and Conclusion: Several CNS demyelinating diseases can present with clinical manifestations of psychosis. Production of psychotic symptoms may result from functional asynchrony of interdependent regions, due to alterations in critical circuits as result of pathology. The nature, location and timing of white matter pathology seem to be crucial in the development of psychosis, especially during the critical adolescent period of association area myelination. This case report points to the pivotal role of clinical ability to differential diagnosis, considering schizophrenia-like psychosis as a possible manifestation of organic disease. White matter results fundamental in maintaining CNS connectivity and its pathology may contribute to the neurobiology of psychosis.

Annunziata University Hospital (Chieti)

Objective: Natalizumab is currently prescribed off-label for Paediatric-Onset Multiple Sclerosis (POMS), despite its well-known efficacy in

real life experiences. Conversely, Fingolimod is the only second-line treatment already approved in POMS. The aim of this study is to compare the efficacy of Natalizumab versus Fingolimod in POMS.

Materials/Methods: This is an observational longitudinal multicentric study: we included natalizumab-treated POMS (N-POMS) (retrospectively and prospectively) and fingolimod-treated POMS (F-POMS). We collected Annual Relapse Rate (ARR), Expanded Disability Status Scale (EDSS), Symbol digit Modality Test (SDMT) and MRI activity at baseline (T0), at 12-18 months (T1), and at last observation (T2).

Results: We enrolled 55 N-POMS and 28 F-POMS from 6 Italian MS centres. The two groups were well-balanced for age, gender, disease duration, number of previous disease-modifying treatments (DMT) and MRI lesion load. Compared to F-POMS, N-POMS showed higher EDSS (2.2±1.4 vs 1.4±1.1, p=0.008), higher ARR (1.01 [0-5.2] vs 1.00[0.1-4.4], p=0.045) and a lower SDMT (49.4±7.9 vs 60.2±9.2, p=0.045) at treatment start. N-POMS had a lower rate of at least one relapse between T0 and T1 (8 N-POMS [14.5%] vs 9 F-POMS [36%], p=0.03). EDSS score between T0 and T1 significantly decreased in N-POMS. (2.2± 1.4 vs 1.6± 1.3, p<0.001), but not in F-POMS. Between T1 and T2, 9 N-POMS switched to another DMT after 64±39 months (1 for inefficacy and 8 for safety concerns). Moreover, among 30 N-POMS not undergoing DMT switch, we observed a further EDSS reduction over time (1.52±1.27 vs 1.4±1.3, p=0.03).

Discussion: Notwithstanding the higher activity at baseline in N-POMS, natalizumab outperformed fingolimod in reducing the relapse rate and promoting disability improvement

Conclusions: Although a definite comparison is difficult and is hampered by the need of a larger sample size to perform a proper propensity score matching, our result suggests a better efficacy profile of natalizumab in POMS.

L. Novarese Hospital (Moncrivello-VC)

Background: COVID-19 vaccines have been recommended to people with multiple sclerosis (pwMS) and, to ensure a long-lasting immunity, a third booster dose has been administered in several countries [1, 2]. Data about potential risks associated with the third booster dose in pwMS, such as vaccine-triggered disease exacerbations [3], are still limited.

Objective: Herein, we investigated whether the administration of a third booster dose of mRNA COVID-19 vaccines was associated with an increased risk of short-term disease reactivation in a large cohort of pwMS.

Methods: Twenty Italian MS tertiary centres participated to this study. We retrospectively selected 1265 consecutive pwMS who received a third booster dose of an mRNA COVID-19 vaccine. Demographic and clinical data were collected, including the presence, number and characteristics of relapses within the 60 days before and after the administration of the third booster dose.

Results: In the selected cohort, the relapse rate in the two months following the third booster dose of mRNA COVID-19 vaccines did not increase when compared to the preceding two months. Indeed, the rate of pwMS experiencing relapses in the 60 days after the administration of the third booster dose was 2.1%, similar to the rate recorded in 60 days prior to vaccination, which was 1.9%. The incidence of relapses in the two-month period before and after vaccination was not statistically different (B= -1.42, 95% CI -2.916 to 0.076, p=0.063). Furthermore, we studied whether demographic and clinical disease characteristics influenced the occurrence of relapses in response to vaccination. We found that pwMS relapsing after the booster dose were younger, presented a higher disease activity in the year before the third dose and were more frequently untreated compared to pwMS that not relapsed after the booster vaccination.

Discussion and Conclusions: The third booster dose of mRNA COVID-19 vaccines proved safe for pwMS. Our findings suggest that the occurrence of relapses after vaccination is influenced by established risk factors for disease activity and emphasize the importance of disease modifying treatments (DMTs) in preventing relapse recurrence.

## EXTENDED INTERVAL DOSING OF OCRELIZUMAB IN MULTIPLE SCLEROSIS: A SINGLE-CENTER, REAL-WORLD EXPERIENCE

S. Diamant, V. Zancan, M. Nasello, G. Bellucci, A. Marrone, V. Rinaldi, M. Salvetti, G. Ristori, M. Buscarinu

NESMOS, AOU Sant'Andrea, La Sapienza University (Roma)

Aims: Ocrelizumab, an anti-CD20 monoclonal antibody, is approved for treating relapsing remitting (RR) and primary progressive (PP) multiple sclerosis (MS). The standard dosing regimen requires intravenous infusions every six months. Experience of extended dosing due to COVID-19 pandemic-related issues suggests that this strategy may provide comparable efficacy while reducing treatment burden and healthcare costs. This study aimed to evaluate the safety, effectiveness, B and T cell count changes associated with extended interval dosing of ocrelizumab in a real-world setting.

Methods: This retrospective study included patients with RRMS or PPMS who received ocrelizumab at our center. We included patients that had already completed 2 cycles of therapy and with at least 1 year of follow-up. Patients were divided into two groups: standard dosing (SID; every six months) and extended interval dosing (EID; ≥4 weeks delay). Outcome measures were annualized relapse rate (ARR), disability progression, changes in B and T cell counts, immunoglobulin levels, MRI activity, and adverse events. Statistical analyses included t-tests, chi- square tests or Mann-whitney U test as appropriate, correlations, linear and logistic regression models.

Results: We screened 112 patients; 24 were excluded due to insufficient data or short follow-up. Patient were divided into EID (N=35, 45% female, 3% PPMS) and SID (N=53, 54% female, 26% PPMS). Baseline age (median 45 and 43), ARR (0.41 and 0.39) and disease duration (11.8 and 11.4 years) were similar between the SID and EID groups ($p>0.05$) The mean observation time was $25 \pm 11$ months. The EID group had a median dosing interval of 7.8 months (range: 7.2-8.4 months). 9 patients (8 RR, 1 PP) had >2 delayed administrations. Preliminary analyses did not reveal significant differences in ARR, MRI activity nor disability progression between EID and SID. B cell counts were effectively suppressed in both groups ($p=0.43$). Delayed dosing did not affect CD8+ and CD4+ counts nor immunoglobulin levels. Adverse events were infrequent and comparable in both groups.

Conclusion: Extended interval dosing of ocrelizumab beyond the standard six-month regimen appears to be a feasible option in the treatment of RRMS and PPMS, with comparable outcomes to SID.
Discussion: These findings provide insights for a tailored schedule of ocrelizumab in MS. Further studies in larger cohorts are awaited to validate this option.

## CLADRIBINE AS EXIT STRATEGY FROM NATALIZUMAB: A SINGLE-CENTER RETROSPECTIVE OBSERVATIONAL STUDY

C. Dionisi[1], D. Landi[2], S. Bartolomeo[2], C. Nicoletti[2], G. Mataluni[2], G. Marfia[2]

[1]Department of Neuroscience, Tor Vergata University (Roma); [2]Multiple Sclerosis Clinical and Research Unit, Department of Systems Medicine, Tor Vergata University (Roma)

Objectives: Natalizumab (NTZ) is a highly effective treatment in patients with Relapsing-Remitting Multiple Sclerosis (RRMS) but there is a risk of disease reactivation after its withdrawal due to the rapid decay of α4β1 integrin saturation. Several exit strategies have been proposed to minimize this risk, but limited data are available regarding the efficacy, safety and immunological impact of cladribine tablets (CLAD)after treatment with NTZ, which is the aim of this study.

Methods: A retrospective observational study was conducted in RRMS patients starting CLAD after NTZ discontinuation. The main variables analyzed were: relapse rate, new T2 and Gadolinium enhancing T1 lesions, EDSS, lymphocyte count and adverse events.

Results: 14 RRMS patients (11 female, median age 43 (range 27-59) years old), with a median disease duration of 12 (5-30) years and a median EDSS of 1.25 (1.0-3.0) were enrolled. Annualized relapse rate (ARR) in the year before NTZ was 1.0 and no relapse was documented under NTZ treatment. The median number of NTZ infusions was 52 (23-138), 13/14 patients received NTZ according to an extended dose schedule. NTZ discontinuation was due to the risk of developing progressive multifocal leukoencephalopathy (PML) in all the cases. The mean wash out interval between NTZ and CLAD was $33,8 \pm 16,7$ days and the median follow up after switching to CLAD was 24 months (12-48). New MRI T2 lesions were detected in 2 asymptomatic patients within 6 months after switch while one patient had a relapse without EDSS progression four months after the second cycle of CLAD. At present, median EDSS is unchanged in the whole group (1.5, range 1.0-3). Transient grade 3 lymphocytopenia was detected in 1 patient during the first year and in 3 patients during the second year after switch. No patients experienced grade 4 lymphocytopenia. The most frequent side effects were headache (n=3), hair loss (n=2), mild upper respiratory tract infections (n=5) and candidiasis (n=1). No serious adverse events were recorded.

Conclusions: According to our results, CLAD represents an efficacious and safe exit strategy from NTZ in patients with high risk of PML. However, a larger sample size is needed to confirm these findings and to establish the prognostic factors predicting an optimal treatment response.

## DEVELOPMENT OF A WEB APP FOR THE ROUTINE CLINICAL MANAGEMENT OF INFUSION THERAPIES FOR MULTIPLE SCLEROSIS PATIENTS

R. Docimo[1], A. Bisecco, A. d'Ambrosio[1], M. Risi[1], R. Borgo[1], C. Marotta[1], C. Esilio[1], F. D'Anna[1], M. Altieri[2], R. Melisi[3], G. Tedeschi[1], A. Gallo[1]

[1]Department of Advanced Medical and Surgical Sciences (DAMSS), University of Campania "Luigi Vanvitelli" (Napoli); [2]Department of Psychology, University of Campania "Luigi Vanvitelli" (Napoli); [3]Department of Experimental Medicine, Division of Pharmacology, University of Campania "Luigi Vanvitelli" (Napoli)

The routine clinical management of infusion sessions dedicated to infusion therapies for Multiple Sclerosis (MS) is challenging because of the high number of patients being treated, the time/space constraints of the infusion room, the need to share clinical data with the MS team. From this background we aimed to develop a web app to help managing clinical data collected during infusion sessions. In order to implement the web app in the everyday clinical practice, we worked to make it user-friendly and smartphone-compatible, offering quick access to patients profiles and MS-related clinical data. To ensure the privacy and security of patients information, the web app was developed to adhere to the highest standards of data protection and comply with industry regulations, utilizing secure encryption protocols, access controls and authentication mechanisms. At the time of each patient's examination/infusion the web app allows to collect the following data: referring neurologist, date of the examination, name and cycle of the infusion therapy, medical history update, EDSS (supported by an EDSS calculator), T25FW, 9HPT, MRI report, blood chemistry tests (with a prespecified checklist for each infusion therapy), date of the next examination/infusion (calculated automatically, based on standard/personalized schedule), and open fields for further/detailed description of other relevant data (e.g. neurological examination, ongoing MS-related and non-MS-related therapies, prescribed therapies upon discharge, clinical events such as relapses, infections, pregnancies, etc). The web app has already been set for two different infusion therapies, Natalizumab and Ocrelizumab/Rituximab. For Natalizumab-treated patients is possible to enter the following data: infusion frequency (every 4 to 6 weeks, with the possibility to modify/personalize the schedule and calculate the date of the following examination/infusion), JCV index, monitoring blood tests. For Ocrelizumab/Rituximab-treated patients is possible to enter the following data: infusion frequency (every 6 months, with the possibility to modify/personalize the schedule and calculate the date of the following examination/infusion), linfocyte subsets, immunoglobulin (IgG, IgM and IgA) levels and hepatitis B markers status. Finally, the web app can: i) generate a full report of each examination, ii) create a dot graph for each available clinical measure (EDSS, T25FW, 9HPT, etc) in order to better monitor disease evolution, iii) send an email with a summary of the infusion session to the MS-team. The routine clinical management of infusion therapy sessions at the MS centers can be efficiently supported by modern-digital tools such as a web app, which facilitates standardized collection, monitoring and sharing of clinical data.

## GENETIC REGULATION OF INFLAMMATORY CYTOKINES: HOW SINGLE-NUCLEOTIDE POLYMORPHISM VARIANTS PREDICT CENTRAL INFLAMMATION, DISABILITY, AND RADIOLOGICAL MEASUREMENTS IN MULTIPLE SCLEROSIS

E. Dolcetti[1], A. Bruno[1], F. Azzolini[1], L. Gilio[1], G. Galifi[1], S. Gambardella[2], R. Furlan[3], A. Finardi[3], M. Stampanoni Bassi[1], D. Centonze[4], F. Buttari[1]

[1]Neurology Unit, IRCCS Neuromed (Pozzilli-IS); [2]Department of Biomolecular Sciences, University of Urbino "Carlo Bo (Urbino); [3]Clinical Neuroimmunology Unit, Institute of Experimental Neurology (INSpe), Division of Neuroscience, San Raffaele Scientific Institute (Milano); [4]Department of Systems Medicine, Tor Vergata University (Roma)

Background: Genetic variability of cytokines expression in multiple sclerosis (MS), a chronic inflammatory disease of central nervous system, is poorly understood. rs2227306 IL-8 polymorphism influences neuroinflammatory diseases course [1], and rs2069812 IL-5 polymorphism is associated with more severe manifestations of Th2-mediated pathologies [2], with contrasting evidence in Th1 diseases [3].

Objectives: To identify whether IL-5 rs2069812 and IL-8 rs2227306 SNPs effectively predict central neuroinflammation at diagnosis and possible clinical and radiological outcome measurements in MS.

Materials and Methods: In 202 European patients diagnosed with relapsing-remitting (RR-MS), primary progressive (PP-MS) and secondary progressive MS (SP-MS), we performed clinical and radiological assessments at diagnosis, exploring the associations between rs2069812 and a large set of inflammatory molecules, and evaluating EDSS at first (176 patients) and second year (162 patients) after diagnosis. In a second group of 141 relapsing-remitting (RR)-MS patients, rs2227306 polymorphism, CSF IL-8 levels, clinical and demographical characteristics were determined, with assessment of structural MRI measures in 50 patients.

Results: We identified in the first group an association between the presence of recessive (T) allele for rs2069812 and CSF levels of IL-2 ($p = 0.017$), IL-6 ($p = 0.015$), IL-17 ($p = 0.013$), GM-CSF ($p < 0.001$), MIP-1b ($p = 0.008$) and IL-15 ($p = 0.011$). In patients carrying the natural (C) allele, we found an association between CSF levels of IL-5 ($p = 0.012$) and IL-1ra ($p = 0.027$), while no differences emerged in clinical and radiological parameters. In C-carriers we found a negative correlation between CSF levels of IL-5 and EDSS at the first year ($r = -0.244$, $p = 0.040$) and EDSS at second year ($r = -0.314$, $p = 0.013$) after diagnosis, while no significant correlations emerged in T-carriers. In the second group, an association between CSF IL-8 and EDSS at diagnosis was found ($r = 0.207$, $p = 0.014$). CSF IL-8 concentrations were significantly higher in patients carrying the T variant of rs2227306 ($p = 0.004$), with a positive correlation between IL-8 and EDSS at diagnosis ($r = 0.273$, $p = 0.019$), and a negative correlation between CSF levels of IL-8 and cortical thickness ($r = -0.498$, $p = 0.005$).

Discussion and Conclusions: We described for the first time a role of IL-5 and IL-8 SNPs in MS central inflammation, identifying a protective function on disease progression for common variant of rs2069812 and a detrimental function for rs2227306 in terms of radiological impairment and disability.

## CHARACTERIZATION OF T-CELL RESPONSE TO RECOMBINANT VZV VACCINE IN PWMS UNDER DMTS

F. Dominelli[1], A. Zingaropoli[1], P. Pasculli[1], M. Tartaglia[2], F. Ciccone[1], L. Malimpensa[2], G. Ferrazzano[2], M. Iannetta[3], G. Alessio[3], I. Fato[3], E. Tortellini[1], M. Guardiani[1], M. Lichtner[4], L. Sarmati[3], C. Mastroianni[1], A. Conte[2], M. R. Ciardi[1]

[1]Department of Public Health and Infectious Diseases, Sapienza University (Roma); [2]Department of Human Neurosciences, Sapienza University (Roma); [3]Infectious Disease Unit, Department of System Medicine, Tor Vergata University and Hospital (Roma); [4]Department of Neurosciences Mental Health and Sensory Organs, Sapienza University (Roma)

Background: People living with MS (pwMS) are at increased risk of Herpes zoster (HZ), mainly due to DMT mechanism of action. Due to several neurological sequelae of VZV, like post herpetic neuralgia, the recombinant VZV gE vaccine has been approved for immunocompromised individuals with a schedule of two-dose administration without interrupting current DMT. However, as observed in response to other vaccines, among DMT-treated pwMS, dissimilar and reduced humoral and cellular responses to vaccination could been observed. The study aimed to characterized cellular immune responses to recombinant VZV vaccine in pwMS under different DMTs.

Materials and Methods: From February 2023, at the Neuroinfectious Unit, during the assessment of infectious risk, recombinant VZV vaccine has been proposed to pwMS. First, pwMS at increased risk of HZ have been considered, according to vaccine guidelines. Before (T0) and after two months (T1) from first dose, pwMS were enrolled. For the two time points IFNg, IL2 and TNFa production by T-cells upon VZV gE peptide library stimulation was performed. "Activated" T-cells were defined as those producing any of IFNg, IL2 and TNFa, while "triple-positive" T-cells as those simultaneously producing all 3 cytokines.

Results: Among the 76 pwMS at increased risk of VZV reactivation, 12 pwMS underwent recombinant VZV vaccine schedule (10 females/2 males, median age [IQR] 50 [40-60] years). Among them, 50% were ocrelizumab-treated, 8% fingolimod, 17% dimethyl fumarate, 8% natalizumab, 8% cladribine and 8% with peginterferon β1a. To date for 3 pwMS an evaluation at T1 has been performed. No differences in the percentages of CD4+ and CD8+ activated T-cells was observed between T0 and T1 (CD4+: 0.0 [0.0-0.0] and 0.18 [0.17-0.18], respectively; CD8+: 0.0 [0.0-0.0] and 0.0 [0.0-0.0], respectively). The same results were observed for percentages of CD4+ and CD8+ triple-positive T-cells between T0 and T1 (CD4+: 0.0 [0.0-0.0] and 0.02 [0.01-0.02], respectively; CD8+: 0.0 [0.0-0.0] and 0.0 [0.0-0.01], respectively).

Conclusion: In line with current literature on other vaccine responses, such as influenza and SARS-CoV-2, our preliminary data showed that T-cell responses to vaccination in pwMS seems to be significantly influenced by DMTs mechanism of action.

## IMPACT OF SLEEP QUALITY ON NEUROPSYCHOLOGICAL FEATURES IN MULTIPLE SCLEROSIS

M. Eliano, F. Falco, F. Lamagna, M. Petracca, M. Moccia, V. Nicolella, A. Esposito, F. Novarella, R. Lanzillo, V. Brescia Morra, A. Carotenuto

Department of Neurosciences, Reproductive and Odontostomatological Sciences, Federico II University (Napoli)

Objective: Multiple sclerosis (MS) is a chronic neurodegenerative condition characterised by a wide range of symptoms. Sleep disturbances affect most MS patients, and could present as sleep-disordered breathing, insomnia, daytime sleepiness, narcolepsy and restless legs syndrome. Sleep disturbances can contribute to pain, depression, anxiety and fatigue, which are commonly observed in patients with MS, with a negative effect on their Quality of Life. However, the impact of sleep quality on neurocognitive functions in this population is still poorly explored. Therefore, the aim of the study is to assess the interplay between sleep quality, cognition, fatigue, anxiety and depression in MS patients.

Material and Methods: Consecutive MS patients underwent clinical (EDSS, age, gender), cognitive (Symbol digit modality test [SDMT], Brief Visuospatial Memory Test [BVMRT], California Verbal Learning Test [CVLT]), and psychosocial (Modified Fatigue Impact Scale [MFIS], Beck Depression Inventory [BDI], Beck Anxiety Inventory [BAI]). Sleep quality was assessed through the Pittsburgh Sleep Quality Index [PSQI] total score. Cognition was calculated as the sum of cognitive tests failed according to Italian normative data (Cerebral Functional System [FS] score). Multiple linear regression models were applied to explore association between PSQI total score (dependent variable) and BDI, BAI, MFIS total scores and subscores and cerebral FS (independent variables) by accounting for age, gender and EDSS (covariates)

Results: We enrolled 522 MS patients (353 female; mean age 42.61 ± 13.02 years; mean EDSS 3.08 ± 1.59; 424 relapsing-remitting and 98 progressive patients). 266 patients (51%) presented with cognitive impairment. Mean physical MFIS was 9.84 ± 11.08; mean cognitive MFIS was 7.99 ± 10.02; mean psychosocial MFIS was 1.69 ± 2.39. Patients presented with a mean BDI 7.26 ± 9.73, mean BAI 4.67 ± 10.86 and mean PSQI of 2.71 ± 3.83. Higher scores at PSQI correlated with MFIS physical fatigue (coeff. 0.76, 95%CI 0.51 – 1.00, p<0.001), MFIS cognitive fatigue (coeff. 0.75, 95%CI 0.52 – 0.98, p<0.001), MFIS psychosocial fatigue (coeff. 0.12, 95%CI 0.07 – 0.18, p<0.001), BDI (coeff. 1.13, 95%CI 0.92 – 1.35, p<0.001), BAI (coeff. 0.93, 95%CI 0.64 – 1.22, p<0.001) but not with cerebral functional system score (p=0.15).

Conclusion: Sleep quality greatly influences neuropsychological features in patients with MS. A worse quality of sleep is related to higher levels of fatigue (psychosocial, physical and cognitive), depression and anxiety. These findings strongly support the need to evaluate sleep disorders in MS in order to improve its quality to reduce long-term consequences. Therefore, enhancing sleep quality could slow down disease progression.

Background and aims: Evusheld (EVS) was authorized by FDA and EMA as pre-exposure prophylaxis (PrEP) in people at high risk of severe Covid-19 outcomes, including people with Multiple Sclerosis (pwMS) on B-cell depleting (BCD) therapies - such as Ocrelizumab (OCR). In this population, no data on possible adverse drug reactions (ADRs) to EVS, B-lymphocytes (CD20+) counts pre- and post-EVS injection, and comparison of percentage increase of IgG antibodies directed against SARS-CoV-2 trimeric spike protein (anti-TSP IgG) post-Evusheld and Covid-19 vaccine was available. The aim of this study was to better characterize the efficacy and safety profile of EVS in pwMS on BCD agents.

Materials and Methods: 17 pwMS on OCR agreed to receive EVS as PrEP for Covid-19. Sera samples were collected before the first dose of Covid-19 vaccine (T0), 4 weeks after the second dose (T1), 4 weeks after third dose (T2), immediately before (T3) and 4 weeks after (T4) EVS.

Results: Covid-19 vaccine ADRs were mild-to-moderate, whereas no ADRs were reported after EVS injection. A significant increase of anti-TSP IgG was found only at T0-T1 ($Z = -3.059$, $p=.002$) and T3-T4 ($Z= -3.621$, $p<.001$) time-points. The median percentage increase between T3-T4 was significantly higher with respect to the T0-T1($Z = -3.296$, $p=.001$) and T1-T2 ($Z = -3.059$, $p=.002$) time-points.

Conclusions: These results further support EVS safety and efficacy in boosting anti-TSP IgG titers in pwMS on OCR, with a statistically greater increase than that observed after completion of a full Covid-19 vaccine cycle, plus a booster dose.

## HYPOCALORIC DIET IMPROVES FATIGUE AND ANXIETY IN OVERWEIGHT PERSONS WITH MULTIPLE SCLEROSIS

F. Felicetti[1], S. Ruggieri[2], I. Ruotolo[3], C. Livi[3], G. D'Ambrosi[3], R. Nistri[3], A. Ianniello[2], C. Pozzilli[2], M. Petracca[2]

[1]Multiple Sclerosis Center, Sant'Andrea Hospital, La Sapienza University (Roma); [2]Department of Human Neurosciences, Sapienza University of Rome (Roma); [3]MS Center, Sant'Andrea Hospital (Roma)

Objectives: Overweight and other cardiovascular risk factors are known contributors to disability accrual in Multiple Sclerosis (MS) [1,2,3]. We aimed to explore the impact of different dietetic approaches on cardiovascular risk and clinical status in overweight persons with MS (pwMS).

Material and Methods: Overweight pwMS (body mass index-BMI>25 kg/m2) were prospectively enrolled, randomly allocated to three hypocaloric dietetic plans differing in macronutrients composition (carbohydrates/proteins/lipids diet A 65%/15%/20%; diet B 35%/25%/40%; diet C 50%/20%/30%) and followed-up for 1 year (6 months of dietetic intervention and 6 months of observation). The Multiple Sclerosis Performance Test, a self-administered, iPad®-based system for quantifying cognition, upper and lower extremity motor function, and vision was performed at baseline, 6 and 12 months. Questionnaires for the evaluation of sleep quality, fatigue, anxiety, depression, stigma, social participation and satisfaction were administered. Information about cardiovascular risk parameters (BMI, waist circumference-WC, umbilical circumference-UC, hip circumference-HC, blood pressure, total, HDL and LDL cholesterol, triglycerides, glycemia) were collected. Adherence to the diet plan was quantified as days of complete to insufficient adherence across the treatment period. Between-group comparisons were performed with Chi-square and ANOVA; longitudinal analyses with one-way ANOVA for repeated measures and mixed-design ANOVA.

Results: Fifty-three patients were analyzed (diet A n=19, diet B n=18, diet C n=16). The three groups were well matched for sex, age, disease duration and EDSS. Along the 6 months of dietetic intervention, no difference in adherence was detected across the three dietetic plans ($p=0.84$). Overall, patients showed a significant weight reduction over time ($p<0.001$), with a mean weight loss of 4 kg at 6 months, and substantial weight stability from month 6 to 12. No difference in weight loss over time was observed across diets ($p=0.34$). BMI, WC, UC, HC, HDL and LDL cholesterol improved over time (p ranging from 0.03 to 0.001), with no differences across diets (p ranging from 0.16 to 0.55). Among all tested clinical variables, fatigue and anxiety improved significantly at 6 months in comparison with baseline ($p=0.004$, $p=0.013$), with no differences across diets ($p= 0.58$, $p=0.89$).

Discussion: Dietetic interventions in overweight pwMS, irrespective of the specific macronutrients composition, are able to improve their cardiovascular profile. Although no variations in objective disability scores could be detected, during the treatment period anxiety and fatigue were significantly decreased.

Conclusion: Hypocaloric dietetic interventions should be encouraged in all overweight pwMS, to ameliorate their cardiovascular profile and the perception of subjective symptoms such as anxiety and fatigue.

Neurosciences, University of Foggia (Foggia); [9]Multiple Sclerosis Centre, Neurology Unit, SS. Annunziata University Hospital (Chieti); [10]Multiple Sclerosis Centre, AOU Policlinico Vittorio Emanuele, University of Catania (Catania); [11]Multiple Sclerosis Centre, Scientific Institute, Fondazione Don Carlo Gnocchi (Milano); [12]Department of Medical and Surgical Sciences, Magna Græcia University (Catanzaro); [13]Multiple Sclerosis Center, Gallarate Hospital, ASST della Valle Olona (Gallarate-VA); [14]Department of Biomedical, Metabolic and Neurosciences, University of Modena and Reggio Emilia (Modena)

Objective: Currently, there is no consensus on the sequencing of Multiple Sclerosis (MS) therapies, resulting in variable use of disease-modifying therapies (DMTs) in routine practice. The discontinuation of lymphocyte sequestering agents such as fingolimod (FTY) is known to leave the patient vulnerable to disease reactivation, especially in case of long wash-out periods before the subsequent DMT. Since several real-world studies directly comparing dimethylfumarate (DMF) and FTY largely demonstrated similar effectiveness between these DMTs, we aimed to assess the effectiveness of DMF following FTY discontinuation using data from the Italian MS Registry.

Methods: We included MS patients who discontinued FTY and started DMF or a cell-depleting agent (ocrelizumab, alemtuzumab, cladribine or rituximab) within six months, and assessed differences in the occurrence of relapses between the groups and, among patients on DMF, between those discontinuing FTY due to lack of efficacy versus other reasons.

Results: We included 822 patients; 163 started DMF and 659 started a cell-depleting agent after a median of 10 weeks (IQR: 6-15) from FTY termination. Relapses occurred after a median of 8 months (IQR:2-18) in 61 patients (37%) on DMF compared to 87 (13%) on depleting agents ($p<0.001$). They occurred in a greater proportion of patients discontinuing FTY due to lack of efficacy (24/47-51%) as opposed to other reasons (37/116-32%) ($p=0.022$). In the latter group, a washout period >6 weeks significantly increased the risk of a relapse (OR: 2.47, 95%CI: 1.03-5.92; $p=0.042$). Predictors of relapses in the DMF-treated group at monovariable analyses were: relapses during the washout-period (OR:3.80, 95%CI:1.23-11.73; $p=0.020$), FTY discontinuation due to lack of efficacy (OR: 2.23, 95%CI: 1.11-4.45, $p=0.023$), relapses in the year preceding FTY treatment (OR: 2.25, 95%CI: 1.05-4.84, $p=0.038$) and age (OR: 0.97, 95%CI: 0.93-0.99; $p=0.042$). At multivariable analysis, only relapses during the washout-period were independently associated with relapses during DMF treatment (OR:3.43, 95%CI: 1.07-10.98; $p=0.038$).

Discussion and Conclusion: Patients de-escalating from FTY to DMF for any reason have a significantly greater risk of relapsing compared to patients transitioning from FTY to cell-depleting agents, especially in case of treatment switch to DMF due to lack of efficacy, with over half of these patients relapsing. Relapses during the washout period are independent predictors of a relapse during DMF treatment and should lead to consider the option of a high-efficacy treatment following FTY discontinuation.

## BASELINE WHOLE BRAIN VOLUME AND DISABILITY PROGRESSION IN OZANIMOD-TREATED PATIENTS WITH RELAPSING MULTIPLE SCLEROSIS

M. Filippi[1], J. Cohen[2], D. Arnold[3], H. Hartung[4], C. Cheng[5], C. Pachai[6], J. Riolo[7], D. Silva[7], B. Cree[8]

[1]IRCCS San Raffaele Scientific Institute, Vita-Salute San Raffaele University (Milano); [2]Mellen Center for MS Treatment and Research, Cleveland Clinic (Cleveland-USA); [3]NeuroRx Research and Montréal Neurological Institute, McGill University (Montréal-CND); [4]Dept of Neurology, Medical Faculty, Heinrich-Heine University (Düsseldorf-D); [5]Biostatistics, Bristol Myers Squibb (Princeton-USA); [6]Preclinical Imaging, Bristol Myers Squibb (Princeton-USA); [7]Medical Division, Bristol Myers Squibb (Princeton-USA); [8]Weill Institute for Neurosciences, Dept of Neurology, University of California San Francisco (San Francisco- USA)

Objective: In people with multiple sclerosis (MS), brain volume loss correlates with long-term disability progression. This secondary analysis assessed disability progression over 5-7 years of ozanimod treatment stratified by high or low baseline whole brain volume (WBV).

Materials and Methods: In the 24-month phase 3 RADIANCE (NCT02047734) trial, patients with relapsing MS (RMS) were randomly assigned ozanimod 0.46 or 0.92 mg/d or IFN beta-1a 30 μg/wk; completers were eligible to enrol in DAYBREAK (NCT02576717) and receive ozanimod 0.92 mg. Kaplan-Meier analyses of 3-month confirmed disability progression were performed for patients with high versus low RADIANCE baseline WBV.

Results: At the February 2, 2021, data cutoff (5-7 years of ozanimod treatment), high baseline WBV was associated with a lower proportion of patients with and slower rates to disability progression when compared with the low baseline WBV group in those who switched from IFN beta-1a to ozanimod 0.92 mg (high/low hazard ratio (HR) [95% CI]: 0.56 [0.32–0.96], nominal $P=0.0365$). A relatively similar numerical trend was observed for patients who received continuous ozanimod 0.92 mg (high/low HR [95% CI]: 0.85 [0.49–1.47], nominal $P=0.5587$).
Conclusion: In RADIANCE and DAYBREAK, high baseline WBV was associated with numerically less disability progression over 5-7 years of ozanimod treatment compared with low baseline WBV in patients with RMS; however, these subgroup analyses assessed a small sample size and are hypothesis generating rather than declarative.
Funding. This study was supported by Bristol Myers Squibb.

## HOW TO INTEGRATE PROXIMITY CARE IN MULTIPLE SCELROSIS MANAGEMENT: THE STAYHOME PROJECT EXPERIENCE

Mondino (Pavia); [7]Multiple Sclerosis Center, S. Croce e Carle Hospital (Cuneo); [8]Multiple Sclerosis Center, San Lazzaro Hospital (Cuneo); [9]Multiple Sclerosis Center (Cefalù-PA); [10]Multiple Sclerosis Center, Policlinico di Catania (Catania); [12]Neurological Department, Fermo Hospital (Fermo); [13]Multiple Sclerosis Center, Ospedale dell'Angelo (Mestre-VE);

[14]Multiple Sclerosis Center, Sassari University Hospital (Sassari); [15]Italian Multiple Sclerosis Association (AISM) (Genova); [16]IQVIA Italy, Implementation Science&Healthcare; [17]Biogen Italy

Objectives: The objective of the StayHome project is to integrate proximity care into the management of Multiple Sclerosis (MS) patients in Italy, addressing the organizational complexity that patients currently face. The project aims to identify improvement areas for proximity care implementation, define a desired care model, and implement, monitor, and support proximity care in MS Centers by adopting a bottom-up approach involving healthcare professionals and patient associations.

Materials and Method: First, a mixed method survey has been conducted involving 50 Centers to identify the main improvement areas for proximity care implementation and to build a cross-Center analysis framework. 14 Multiple Sclerosis Centers in 9 Regions were then involved on a voluntary basis to map the AS IS and define a TO BE care model, based in each Center on face-to-face interviews, collection of organizational data, on-site assessment, and roundtables. More than 150 healthcare professionals, hospital managers and regional stakeholders have been involved in such activities with a potential impact for about 14,000 patients. A Steering Committee, including KOLs, PAG and Scientific Association representatives, supervised progresses and methodologies adopted in the project, including Key Performance Indicators to monitor the patient pathway and a Maturity Model to assess and support MS Centers in the path towards proximity care.

Discussion: Implementing proximity care in MS management posed challenges due to the complex nature of the disease. It became evident that a uniform approach is suboptimal, given the influence of regional and local specificities. Instead, a bottom-up approach, which involved collaboration with local healthcare professionals and patient associations, emerged as a more effective strategy. The active involvement and support of hospital and regional managers played a crucial role in addressing the unique challenges faced by each MS Center. In addition, different areas of intervention have been identified as a priority, including the formalization of integrated Hospital – Territory pathways, the digitalization of patient pathways and the empowerment of a multidisciplinary approach especially for neurological rehabilitation.

Conclusion: The findings highlighted the limitations of a uniform approach in the implementation of proximity care for MS in Italy and underscored the importance of context-aware strategies. In addition, the findings identify the priority areas to address and provide Key Performance Indicators and Maturity Model as practical tools to assess and support the implementation of proximity care. Finally, the project outcomes provide valuable insights for scaling up proximity care models at the regional and national levels.

## IN VIVO EFFECTS OF THREE DISEASE MODIFYING THERAPIES (DIMETHYL FUMARATE, NATALIZUMAB AND CLADRIBINE) ON IMMUNOLOGICAL SUBSETS IN RELAPSING REMITTING MULTIPLE SCLEROSIS

C. Finocchiaro[1], C. Chisari[1], S. Toscano[1], S. Lo Fermo[1], N. Parrinello[2], A. Romano[2], G. Palumbo[2], M. Zappia[1], F. Patti[1]

[1]Department of Medical, Surgical Sciences and Advanced Technologies "GF Ingrassia", University of Catania (Catania); [2]Hematology Unit, Azienda Ospedaliera Universitaria Policlinico-San Marco (Catania)

Objectives: Using flow cytometry, we aimed to assess immune cell subsets differences in terms of myeloid, T- and B-cell subsets in peripheral blood of relapsing–remitting multiple sclerosis (RR-MS) patients treated with different disease modifying therapies (DMTs).

Materials: This cross-sectional, prospective, observational study was conducted at the MS Center of University of Catania, Italy.

Methods: We included follow-up RR-MS patients treated with DMTs with different mechanisms of action (cladribine [CLD], dimethyl fumarate [DMF] and natalizumab [NTZ]), in the period between July 2022 and September 2022. Each patient underwent a clinical and radiological evaluations and blood sample collection.

Results: Out of 52 RR-MS patients screened, 43 (83.7% women; mean age at diagnosis 34.7±11.1 years; median EDSS 2.0, IQR 1.0–2.8) were finally enrolled. A total of 24 (55.8%) patients were treated with DMF, 10 (23.3%) with NTZ and 9 (20.9%) with CLD. At follow-up (after a mean period of 20 ± 4 months of treatment), patients treated with DMF showed reduced percentage of total CD3+ (74±6.9 vs 64.2±12.1, p =.001), of the CD3+CD8+ (T-cytotoxic) (26.7±7 vs 18.5±6.4, p<.001), and of the CD4+CD25+CD127low/− (T-reg) (8.1±2.5 vs 5.9±3, p =.009). The DMT group also showed a significant increase of the percentage of the CD15+/CD33+/CD14-/HLADR−/low (G-MDSCs) (59.9±9.8 vs 67±7.7, p =.008), of the CD4+/CD8+ ratio (1.9±0.8 vs 2.6±0.9, p=.004), of the CD4+CD45RA+ (T-naïve) (40.3±14.7 vs 51.7±16.8, p=.02) and of the percentage of the B-naïve (56.2±11.8 vs 70.5±10.8, p< .001). In the NTZ group, a decreased percentage of total CD3+ (73.3±7.5 vs 64±7.8, p =.02) was found, while the percentage of the total CD19+ was increased (9.9±3.1 vs 16.1±8.1, p=.04). Finally, a reduction in the percentage of total CD3+ (76.4±6.3 vs 59.3±9.7, p<.001), of the CD3+CD4+ (T-helper) (46.7±8.8 vs. 33.6±6.2, p =.002), and of the CD3+CD8+ (T-cytotoxic) (29.7±8.4 vs 22.1±7.2, p=.05) was found in patients treated with CLD.

Discussion: DMTs induced significant modifications in myeloid, B-, and T-cell immunophenotypes. Conclusions. The characterization of the immunologic changes, occurring during MS and in response to DMTs, might represent a new parameter for the monitoring of disease activity, progression and therapy efficacy.

## USE OF TERIFLUNOMIDE IN YOUNG WOMEN WITH MULTIPLE SCLEROSIS: A RETROSPECTIVE STUDY ON THE DETERMINANTS OF CHOICE

M. Fois, L. Lorefice

Multiple Sclerosis Centre, Department of Medical Sciences and Public Health, University of Cagliari (Cagliari)

Objects: Teriflunomide is a once-daily oral immunomodulatory agent for relapsing–remitting multiple sclerosis (MS). While safety concerns about pregnancy historically drove the propensity to prescribe teriflunomide to men rather than women, over the years, the use of teriflunomide has changed, increasing significantly among women [1,2]. In this context, this study explored determinants of the choice of teriflunomide in MS women of reproductive age.

Materials and Methods: This retrospective study included women between 20 and 40 years of age with MS diagnosed according to

McDonald's criteria and recruited from Multiple Sclerosis Centre of University of Cagliari. Patients were classified as naive and switchers for tolerability or safety. The determinants of the choice of teriflunomide were detected with an ad hoc questionnaire aimed at assessing the presence of conditions complicating the use of other first-line disease modifying treatments (DMTs) (i.e., needle phobia, gastrointestinal problems, allergic diathesis). It was also recorded whether the MS woman already had children.

Results: A sample of 77 MS women between 20 and 40 years of age treated with teriflunomide were included in the analysis. Mean age and disease duration were 38.7 ±8.2 and 8.1±6.3 years, respectively, with mean drug exposure of 19,1±22,7 months. Mean EDSS was 1.3 ± 0.7. Seventeen (22.1%) patients were naïve, and 60(77.9%) were switched from other DMTs, of which 60(77.9%) for tolerability and safety reasons (19 after dimethyl fumarate discontinuation and 41 after injectable DMTs).The presence of needle phobia in 9(11.7%) patients,allergic diathesis in 16 (20.8%), and gastrointestinal problems in 28(36.4%), all conditions interfering with the use of other DMTs,and having already had children in 34(44.2%) patients,were the determinants of teriflunomide choice most frequently reported.

Discussion: Recent real-world experience has shown that the use of teriflunomide is constantly evolving [1,2].The efficacy, safety,and tolerability profile of teriflunomide is well established in real-world experience, and its use is associated with a high level of treatment satisfaction [3]. Based on this evidence, its use has increased in all categories of patients, older and younger ones, including women.

Conclusions: Teriflunomide is a valid therapeutic option due to its tolerability both in naïve women and in switchers. In particular, its use is to be considered for those patients with needle phobia, gastrointestinal problems or allergic diathesis, which would complicate or have complicated the use of other first-line DMTs, and for those women who have already had children or who do not want any in the short term.

## HOW TO BEHAVE IN A PEDIATRIC PATIENT WITH MYELIN-OLIGODENDROCYTE GLYCOPROTEIN ANTIBODY-ASSOCIATED DISEASE (MOGAD) AND A SUBCLINICAL RELAPSE: TREAT OR NOT? A CASE REPORT

A. Franceschini[1], E. Curti[2], M. Minetti[1], E. Tsantes[2], F. Granella[1]

[1]Neurosciences Unit, Department of Medicine and Surgery, Parma University Hospital (Parma); [2]Neurology Unit, Department of General Medicine, Parma University Hospital (Parma)

Background and Aims: Myelin oligodendrocyte glycoprotein (MOG) antibody-associated disease (MOGAD) is an inflammatory demyelinating disease of the central nervous system (CNS). MOGAD is typically associated with acute disseminated encephalomyelitis, optic neuritis, or transverse myelitis, and is less commonly associated with cerebral cortical encephalitis, brainstem presentations, or cerebellar presentations. MOGAD can present as either a monophasic or relapsing disease course.

Materials: We performed brain and spinal cord MRI, physical examination, laboratory exams and electroencephalography (EEG) with and without sleep deprivation.

Methods: We report the case of a patient with typical features of MOGAD with a subclinical relapse.

Results: In March 2022, a 3-year-old girl presented to hospital with seizures, gait imbalance, ipovisus in right eye and behavioral changes. Brain and spinal cord MRI showed occipital cortical and subcortical T2-FLAIR hyperintensities, as well as inflammatory lesions in basal ganglia, in the right optic nerve and in the spinal cord (C4-C5 and in the conus, D12-L1). Laboratory work-up showed MOG-antibody positivity (qualitative dosage), while other tests, including aquaporin4 antibody were normal. Considering MRI and laboratory findings, we made a diagnosis of MOGAD and the patient started a therapy with high dosage of methylprednisolone followed by oral tapering of prednisone for one month. Later, the patient made clinical, neuroradiological and EEG follow-ups, with and without sleep deprivation. The exams showed an improvement of patient condition. Furthermore, we repeated a quantitative dosage MOG-Ab that showed, initially, an alteration (August 2022, titer of 1:640) and, subsequently, a negativization (November 2022, titer of 1:40). The patient did not show any symptom. However, but in an EEG follow-up, (February 2022) we found a new epileptogenic focus in left occipital lobe and generalized epileptiform abnormalities. So, we made a new dosage of MOG-Ab that showed a positive titer (1:320) and a brain and spinal cord MRI, negative for new lesions.

Discussion: It is difficult, for a clinician, to treat a patient only for abnormality laboratory or electroencephalography findings, without clinical manifestations. On the other hand, we know that MOGAD could be a relapsing disease with a complete or incomplete/partial recovery.

Conclusions: The possibility of starting a treatment and the potential type of treatment were discussed. We decided to wait and evaluate the situation over time. We were also wondering whether to treat with corticosteroids (high dosage followed by tapering) or with immunoglobulin intravenous every 28 days, as seems to be effective in MOGAD with relapses, but could be a complex treatment in such a young patient.

## NEUROMYELITIS OPTICA SPECTRUM DISORDER WITH POSITIVE ANTI-AQUAPORIN-4 ANTIBODY RELATED TO THE IMMUNE CHECKPOINT INHIBITOR NIVOLUMAB

V. Francioni[1], G. Giuliodori[1], G. Jorio[1], M. Morelli[1], M. Fabi[2], L. De Dominicis[1]

[1]Neurology, Hospital of Senigallia (Senigallia-AN); [2]Neuroradiology, Hospital of Senigallia (Senigallia-AN)

Background: Immune checkpoint inhibitors (ICIs) development has greatly improved survival of patients with advanced malignancies. Nevertheless, ICIs can cause immune-related adverse effects (irAEs) involving any organ. Neurological irAEs are infrequent and mostly reported in patients with melanoma.

Case presentation: A 62-year-old man without any previous illnesses was diagnosed with melanoma of the pectoral region. Following resection, adjuvant ICIs with nivolumab (an anti-programmed cell death protein 1 antibody) was recommended. Since a bilateral immune-related pneumonitis was diagnosed, nivolumab was stopped after one year of treatment (10 cycles of therapy). Four months later, the patient developed lower extremity weakness with paresthesia and urinary retention. His neurological examination revealed paraparesis with brisk knee jerks and a sensory level at T7. Magnetic resonance imaging (MRI) of the spinal cord showed centrally located T2-hyperintensity from C2 to C7 level and from D4 to D8 with contrast enhancement and spinal cord edema. Analysis of the cerebrospinal fluid (CSF) showed an increased white cell count of 52 cells/μL (83% neutrophils), protein concentration of 275 mg/dL, normal glucose concentration; oligoclonal bands were not detected. CSF bacterial cultures were negative as well as viral panel and citology. An investigation for markers of autoimmune disorders, anti-neuronal antibodies, and myelin-oligodendrocyte glycoprotein antibodies yielded negative results. In contrast, anti-aquaporin-4 antibody (AQP4-Ab) tested positive (titer 1:10). Brain MRI and ophthalmologic examinations were normal. Neuromyelitis optica spectrum disorder (NMOSD) was diagnosed, and high-dose intravenous methylprednisolone was administered (1 g/daily for 7 days), followed by tapered oral steroids and 5 days of intravenous immunoglobulins therapy. Two weeks later, spinal MRI showed improvement in the cervical region, but remnant dorsal lesions without contrast enhancement. Also CSF improved after treatment (cell count: 5 cells/μL, protein concentration: 78 mg/dL); AQP4-Ab tested negative after one month. Nevertheless, paraparesis and sensory loss improved only minimally; after extensive discussion between oncology and neurology, mutual decision was made to move forward with rituximab.

Discussion: Our patient developed anti-AQP4 antibody-positive NMOSD after four months of nivolumab therapy discontinuation. To the best of our knowledge, this is the fourth known case of nivolumab-induced NMOSD; all described cases showed limited response to glucocorticoids and poor functional outcome.

Conclusions: The mechanism of ICIs causing NMOSD is not completely understood and predicting emergence of NMOSD after nivolumab injection is currently difficult. Therefore, clinicians should be aware of this kind of neurological irAEs and start treatment of these complications as soon as possible.

## A MULTIDIMENSIONAL SELF-REPORTED EVALUATION OF FRAILTY IN PEOPLE WITH MULTIPLE SCLEROSIS

J. Frau[1], A. Mulasso[2], G. Coghe[1], L. Beratto[2], S. Cuomo[2], L. Lorefice[1], M. Melis[1], E. Cocco[3]

[1]Multiple Sclerosis Centre, ASL Cagliari (Cagliari); [2]NeuroMuscular-Function/Research Group, Department of Medical Sciences, University of Turin (Torino); [3]Multiple Sclerosis Centre, ASL Cagliari, University of Cagliari (Cagliari)

Objective: Multiple Sclerosis (MS) is a neurodegenerative disease of the central nervous system. People with MS (pwMS) have a high risk of frailty that could be measured by different tools. We aim to evaluate frailty using the Tilburg frailty indicator (TFI), a multidimensional self-reported questionnaire, and to explore its relationship with autonomy, quality of life (QoL), and disability.

Methods: All the patients with MS enrolled completed TFI (frail with a TFI score $\geq$ 5 points), the Groningen Activities Restriction Scale to evaluate autonomy, and the Multiple Sclerosis Impact Scale-29 to evaluate QoL. We collected the Expanded Disability Status Scale (EDSS) score, age and gender. Data were analysed using descriptive analyses, hierarchical multiple regression, and ANCOVA.

Results: A total of 208 adults with MS (mean age 44 years, SD=11; 75% of women; 89.4% relapsing-remitting) were enrolled. The mean TFI total score was 5.7 points (SD=3.0; range 0-14), with the 62.5% of participants exhibiting frailty. After controlling for age and gender, the EDSS score was revealed to influence the total ($\beta$=0.469; R2=0.255; $p<0.001$) and the physical ($\beta$=0.571; R2=0.349; $p<0.001$) frailty score, with an explained variance of 25.5% and 34.9%, respectively. No effects on psychological and social frailty domains were detected. The proportion of frail patients with EDSS $\geq$ 6.0, EDSS within 3.5-5.5, and EDSS $\leq$ 3.0 was 91.7%, 83.3%, and 66.0%, respectively. Frail patients exhibited higher autonomy impairment (p=0.017) and worse QoL ($p<0.001$).

Discussion: We found a high frequency of frail patients with MS. Frailty is more common in patients with higher disability, but it affects also those with low EDSS.

Conclusion: In people with MS frailty could be influenced by factors other than disability.

## NATALIZUMAB IN THE SETTING OF PEDIATRIC-ONSET MULTIPLE SCLEROSIS: A REAL-WORLD EXPERIENCE IN COMPARISON WITH A MATCHED ADULT POPULATION

M. Gaggiola[1], F. Rinaldi[2], G. Zanotelli[1], V. Mauceri[1], F. De Napoli[1], G. Scialpi[2], M. Passamonti[1], A. Zolin[1], A. Berardi[2], A. Miscioscia[1], P. Perini[2], P. Gallo[1], M. Puthenparampil[1]

[1]Department of Neurosciences, Padua University Hospital (Padova); [2]Multiple Sclerosis Center, Padua University Hospital (Padova)

Introduction: Pediatric-Onset Multiple Sclerosis (POMS) is characterized by a more aggressive disease course and earlier development of physical and cognitive disability compared to Adult-Onset MS (AOMS). Therefore, early introduction of highly effective treatment, such as Natalizumab (NTZ), is mandatory.

Objectives: To evaluate the efficacy of NTZ in POMS on both clinical and radiological outcomes compared to an AOMS matched control group.

Methods: We enrolled 36 POMS in a single-centre retrospective study and compared them with a propensity-matched AOMS control group. Both POMS and AOMS were treatment-naïve and were matched for gender, baseline Expanded Disability Status Scale (EDSS), and disease duration. Both radiological (i.e. no evidence of new/enlarging

white matter lesions or gadolinium-enhancing lesion) and clinical (i.e. no evidence of clinical relapse or EDSS worsening) no evidence of disease activity (rNEDA and cNEDA respectively) were evaluated at 12 and 24 months. Survival analysis was conducted on whole observation period. Disease activations occurring within the first six months of NTZ were not considered.

Results: 36 POMS and 36 AOMS control patients were enrolled in this study. Baseline characteristics were as follows: (i) M/F = 14/22 in both POMS and AOMS; (ii) median EDSS = 1.0 (range 0-2.5) in both groups; (iii) median disease duration = 3 months (IQR 2-5.5) in POMS and 3 months (IQR 2-6.25) in AOMS; (iv) mean age (±SD) = 14.6 (±2.0) in POMS and 30.0 (±6.8) in AOMS; and (v) median follow-up time = 37.5 months (range 6-136) in POMS and 24 months (range 12-105) in AOMS. None of the POMS patients and one AOMS experienced a clinical relapse during the first 2 years of treatment. While at month 12 no difference was observed between AOMS and POMS (p=1.0), at month 24 93.1% (27/29) of POMS and 77.8% (21/27) of AOMS fulfilled the NEDA condition (p=0.137). Survival analysis confirmed this trend (log-rank test p=0.16). Wilcoxon's signed-rank test showed no significant changes in EDSS values among AOMS from baseline to last follow-up (p=0.52 with a median follow-up of 24 months). On the other hand, statistically significant sustained improvement on EDSS score emerged in POMS (p=0.005 with a median follow-up of 37.5 months).

Conclusion: This study provides evidence that NTZ is highly effective in treating POMS. Additionally, NTZ treatment in POMS determined a significant EDSS improvement. Our findings support the use of NTZ as the first treatment option for POMS.

## THE NEUROPSYCHOLOGICAL CORRELATES OF IMPULSIVENESS IN MULTIPLE SCLEROSIS

M. Gaita[1], M. Cropano[1], S. Miniello[2], S. Raimo[3]

[1]Department of Psychology, University of Campania Luigi Vanvitelli (Caserta); [2]Neurology and Stroke Unit, Sant'Anna e San Sebastiano Hospital (Caserta); [3]Department of Medical and Surgical Sciences, University Magna Graecia (Catanzaro)

Objective: The aim of the present study was to explore the association between impulsiveness and neuropsychological profile in people with Multiple Sclerosis (MS).

Materials: Forty-four people with MS underwent a comprehensive cognitive battery (Rao's Brief Repeatable Battery of Neuropsychological Tests1), and behavioral scales tapping impulsiveness (Barratt Impulsiveness Scale; BIS-11), apathy (Dimensional Apathy Scale; DAS), depression (Beck Depression Inventory-II; BDI-II), and interoceptive sensibility (Self-Awareness Questionnaire; SAQ).

Methods: We performed correlation and regression analyses to investigate the relation between impulsiveness and neuropsychological profile in MS.

Results: Correlational analyses showed that the BIS-11 total and Non-Planning subscale scores had high correlations with the Symbol Digit Modalities Test score (SDMT: $r \geq -0.469$, $p = < 0.001$); and with the DAS total score ($r \geq 0.493$; $p<0.001$). Moreover, the BIS-11 Attentional subscale score showed high correlations with the DAS executive subscale score ($r= 0.505$, $p< 0.001$), the BDI II total score ($r=0.584$; $p<0.001$), and SAQ total score ($r= 0.485$; $p<0.001$). All other correlations did not survive after Bonferroni's correction level of significance (p=0.001). Linear regression analyses showed that the BIS-11 total and Non-Planning subscale scores predicted the SDMT ($\beta \geq -1.272$; $t \geq -3.702$; $p \leq 0.001$) and the DAS score ($\beta \geq 0.435$; $t \geq 4.160$; $p \leq 0.001$); whereas the BIS-11 Attentional subscale score predicted the SAQ ($\beta= 2.197$, $t = 3.593$, p=0.001), the BDI-II ($\beta= 1.129$, $t = 4.664$, $p<0.001$), and the DAS executive subscale score ($\beta= 0.613$, $t = 3.794$, $p<0.001$).

Discussion: Our findings suggest that sub-traits of impulsiveness are differentially related to cognitive and behavioral aspects in MS. In particular, Non-Planning impulsiveness would be mainly related to behavior-based measure of executive functioning [1,2]; whereas Attentional impulsiveness would seem to be a significant contributing factor for behavioral disorders and to reflect an overestimation of bodily sensations [3].

Conclusions: The present study suggests a new approach for investigating the relation between neuropsychological profile in MS and impulsiveness as multi-dimensional construct. Our behavioral results fit neurofunctional evidence suggesting a disfunction of prefrontal regions subserving cognitive and emotional aspects of self-regulation.

## NON-INFECTIOUS PNEUMONITIS AS A RARE ADVERSE REACTION OF ALEMTUZUMAB TREATMENT: A CASE REPORT AND A BRIEF LITERATURE REVIEW

M. Galimberti, E. Schilke, E. Funelli, D. Cereda, C. Balducci, M. Fusco, C. Ferrarese, M. Frigo

San Gerardo Hospital, University of Milano-Bicocca (Monza)

Objective: Alemtuzumab is an anti-CD52 monoclonal antibody approved for the treatment of active Relapsing Remitting Multiple Sclerosis (RRMS) by European Medicines Agency (EMA) in 2013. Since then, post-marketing evidence has highlighted some rare but severe Adverse Drug Reactions (ADRs), including respiratory complications.

Materials and Methods: We report the case of a patient in follow up at our Neuroimmunology Centre throughout medical records, radiological imaging, and laboratory results. A literature search about alemtuzumab-induced respiratory reactions was performed.

Results: A 37-year-old male diagnosed with RRMS started alemtuzumab treatment and completed the first cycle without complications in November 2021. Twelve months later he initiated the second treatment cycle. After the second infusion he developed persistent non-productive cough and dyspnea. The treatment was discontinued. Vital signs and physical examination were normal except for diffuse bilateral harsh breath sound and rhonchi on chest auscultation. Lab analysis evidenced a slight increase of c-reactive protein and leukocyte count. A chest x-ray showed a thickening of the interstitial tissue with bilateral consolidations. CT-scan documented multiple bilateral ground-glass and pseudonodular opacities with peribronchovascular distribution. A bronchoalveolar lavage (BAL) was performed and the differential cell count revealed 49% macrophages (without hemosiderin inclusions) and 51% neutrophils. All microbiological tests on BAL and serum resulted negative. The patient was left untreated and spontaneously recovered. One month later a CT-scan showed complete resolution of the pulmonary alterations.

Discussion: All the findings in our case supported the diagnosis of an alemtuzumab-induced pneumonitis. This evidence adds to other reports that have placed greater emphasis on diffuse alveolar

haemorrhage (DAH), recently reported by EMA as a severe risk associated with alemtuzumab. However, any induced lung injury is important considering its correlation with serious complications including respiratory failure. Moreover, our case proves these complications can occur not only during the first treatment cycle as usually found. Several pathogenetic mechanisms have been proposed, among which the most significant seem to be cytokine release syndrome and cytotoxic damage mediate by innate immune system cells. These mechanisms need to be further investigated, considering the different onset-time and severity of lung injury described in the literature.

Conclusion: The identification of risk factors and the characterization of premedication/treatment for ADRs, such as pneumonitis, would improve the safety profile of alemtuzumab. Furthermore, it is crucial to increase clinicians' awareness of the potential complications of alemtuzumab for their timely identification.

## RADIAL SHOCK WAVE THERAPY FOR SPASTICITY IN MS: A PROSPECTIVE SINGLE ARM TRIAL

P. Garelli[1], M. Vercellino[2], C. Bosa[1], M. Campagnoli[3], A. Malfitano[4], A. Rolando[1], M. Spada[1], S. Marasciulo[1], G. Massazza[3,4], M. Minetto[3,4], P. Cavalla[2]

[1]Department of Neuroscience, University of Turin (Torino); [2]Department of Neurosciences, AOU Città della Salute e della Scienza (Torino); [3]Division of Physical Medicine and Rehabilitation, Department of Surgical Sciences, AOU Città della Salute e della Scienza (Torino); [4]Division of Physical Medicine and Rehabilitation, Department of Surgical Sciences, University of Turin (Torino)

Objectives/Aims: To assess the efficacy of radial shock wave therapy to improve lower limb spasticity and deambulation in MS patients.

Materials: The modified Ashworth scale was used to assess spasticity (both for the quadriceps and the triceps surae). The following test were used to evaluate deambulation: timed 25-foot walk (T25FW) test, timed up and go (TUG) test. Pain was assessed using the spasticity visual analog scale and pain visual analog scale (VAS), depression using the Beck depression inventory and finally cognition using the Brief International Cognitive Assessment for Multiple Sclerosis (BICAMS).

Methods: This is an ongoing single-arm prospective trial of radial shock wave therapy for lower limb spasticity in MS patients. Patients are treated with radial shock waves (1.5 bar, 4 Hz, 3000 shots for 15 minutes) once every week for 4 weeks. The endpoint of the study is to assess changes in lower limb spasticity, deambulation, depression and cognition from baseline (T0) to after 4 weeks of radial shock wave therapy (T4), and then every month afterwards (T5, T6, T7) up to 3 months from the last treatment.

Results: Up to March 2023, 30 patients have been recruited in the study (mean age 55.8±10.4 years, median EDSS 6.0, range 3.5-7.5). After 4 cycles of radial shock wave therapy (at T4), a significant improvement was observed for the modified Ashworth scale (both for the quadriceps and the triceps surae), timed 25-foot walk (T25FW) test, timed up and go (TUG) test, spasticity visual analog scale and pain visual analog scale (VAS), depression (Beck depression inventory), which was sustained for the 3 months of observation after the end of treatment (at T5, T6, T7). No treatment-related adverse events were reported.

Discussion: Radial shock wave therapy is used to treat pain and spasticity in patients with cerebral palsy and stroke. Previous studies suggest that it could be useful also for the treatment of spasticity in MS patients; our study confirms this data.

Conclusions: Radial shock wave therapy is effective to reduce spasticity and to improve deambulation in MS patients, with effects sustained over time and without significant adverse effects.

Background: Mucosal associate invariant T (MAIT) cells are unconventional T cells with an innate-like phenotype. They recognize microbial-derived riboflavin derivatives presented by the major histocompatibility class (MHC) I-related protein MR1 and their mature phenotype is deeply influenced by the microbiome composition [1].

Objective: The overall goal of this study was to describe the role of MAIT cells in the pathogenesis of multiple sclerosis (MS) and its animal model, experimental autoimmune encephalomyelitis (EAE).

Methods: MAIT cell activation and effect during Experimental Autoimmune Encephalomyelitis (EAE) was studied in MR1-/- mice [2], lacking completely MAIT cells, and MR1 sufficient (MR1+/+ and MR1+/-) controls by flow cytometry. The effect of the gut microbiome composition on MAIT cells phenotype was inquired in a separate set of experiments changing housing conditions. Peripheral blood (PB) and cerebrospinal fluid (CSF) samples were obtained from newly diagnosed, untreated people with MS (pwMS) and age-matched healthy controls (HCs). MAIT cell number, phenotype and cytokine production were characterized by flow-cytometry. The effect of MAIT cell activation on conventional T cell proliferation was determined by CFSE assay. Gut microbiome composition was determined by 16S, mWGS and ITS sequencing.

Results: MAIT cells are activated during EAE, they acquire a MAIT1 phenotype and have an immunomodulatory role, influenced by the gut microbiome composition. PwMS have lower numbers and defective activation of MAIT cells in both PB and CSF. Activated MAIT cells obtained from pwMS are less effective at suppressing in vitro conventional T cells proliferation compared to MAIT cells obtained from HCs. We linked MAIT cell phenotype to an altered gut bacterial and fungal microbiome composition consisting of low fungal richness, high abundance of Saccharomyces and low abundance of Prevotella.

Conclusions: Our study described a modulatory effect of MAIT cells on both innate and adaptive immunity. In pwMS we demonstrated a decrease and a dysregulation of MAIT cell number and function, possibly linked to an altered gut microbiome composition.

## EARLY USE OF ORAL CONTRACEPTIVE, MENOPAUSE AND PREGNANCY ARE ASSOCIATED WITH LESS SEVERE DISEASE COURSE IN WOMEN WITH MULTIPLE SCLEROSIS

A. Giordano[1], K. Misra[1], F. Clarelli[1], M. Sorosina[1], S. Santoro[1], L. Ferre'[1], M. Cannizzaro[1], L. Moiola[2], V. Martinelli[2], M. Filippi[2], F. Esposito[1]

[1]Laboratory of Human Genetics of Neurological Disorders, San Raffaele Scientific Institute (Milano); [2]Neurological Department and MS Center, IRCCS San Raffaele Hospital (Milano)

Objectives: Multiple Sclerosis (MS) is more common in women than men but, after the onset, women have a more favorable disease course. Evidence shows that changes in sex hormones occurring early affect the risk of MS, but their impact on future disease severity is less explored and poorly understood.

Aim: To investigate how the exposure to environmental factors (EF) provoking changes in sex hormones affects future disease severity in women with MS.

Materials and Methods: An extensive environmental questionnaire was available for 1,117 women with MS (age => 18 years; follow-up from onset =>2 years). From this, we extracted questions regarding the exposure to EF provoking changes in sex hormones: 1) use of oral contraceptive before/at the time of diagnosis; 2) pregnancy before the diagnosis; 3) menopause occurred before the diagnosis; 4) age at menarche. The latest available Expanded Disability Status Scale (EDSS) score and the age at the time of EDSS evaluation were used to calculate the Age-Related Multiple Sclerosis Severity (ARMSS) score. Mean disease duration at the time of ARMSS score was 15 years. Normalized ARMSS score was used as outcome in linear regression models.

Results: Patients who reported use of oral contraceptives prior to the diagnosis had a better outcome in terms of future MS severity (p=0.0048). Conversely, the use of oral contraceptive at time of diagnosis was not associated with disease severity (p=0.182), further suggesting the importance of an earlier exposure. Patients who reported a pregnancy before the diagnosis had lower ARMSS score (p=0.0015), as well as patients in whom menopause occurred before the diagnosis (p<0.001). When studying women reporting an age at menarche => 14 years, we found a trend for association with lower ARMSS score which was not statistically significant (p=0.076).

Conclusions: Our findings replicate previous reports from smaller studies, suggesting an influence of early changes in sex hormones and future disease severity; these results prompt prospective investigations.

## HIGHER VITAMIN D LEVELS ARE CAUSALLY ASSOCIATED WITH THE NO EVIDENCE OF DISEASE ACTIVITY-3 STATUS IN MULTIPLE SCLEROSIS

A. Giordano[1], M. Sorosina[1], E. Mascia[1], B. Pignolet[2], S. Silvia[1], F. Clarelli[1], L. Ferre'[1], K. Misra[1], M. Cannizzaro[1], R. Liblau[2], M. Filippi[3], F. Esposito[1]

[1]Laboratory of Human Genetics of Neurological Disorders, San Raffaele Scientific Institute (Milano); [2]Infinity, Institute Toulousain des Maladies Infectieuses et Inflammatoires, Universite' Toulouse III (Toulouse-F); [3]Neurological Department of Human Genetics of Neurological Disorders, San IRCCS San Raffaele Hospital Scientific Institute (Milano)

Objectives: Vitamin D (VitD) levels affect the risk of developing multiple sclerosis (MS), but studies on its effect on composite outcomes of disease activity are few and a validation of its causal role is lacking. We evaluated whether serum VitD levels at baseline have a causal role in driving disease activity measured by the No Evidence of Disease Activity-3 (NEDA-3) status at 2-years follow-up.

Materials: We included 230 patients with relapsing-remitting MS from San Raffaele Hospital in Milan (OSR) and Centre Hospitalier Universitaire de Toulouse (CHUT). At the time of sampling, patients were not on Disease-Modifying Treatment (DMT) and wash-out from previous steroid or DMT was considered.

Methods: Serum 25-OH-vitamin-D was measured through an electro-chemiluminescence competitive binding assay. Adjustment for VitD seasonal variation was applied, modelling a sinusoidal function and linear logistic regression was used to assess the association between VitD levels and the NEDA-3 status. To assess whether the association between VitD levels and disease activity is causal, we carried out an inverse-variance weighted Mendelian Randomization (MR) analysis using the TwoSampleMR tool.

Results: Higher baseline VitD serum concentration was associated with higher probability of fulfilling the NEDA-3 criteria at 2-years (p=0.019). In addition, patients having at least 2 relapses during the follow-up had significantly lower VitD levels at baseline, if compared with patients having no relapses (p<0.001) or one relapse (p=0.037). Taking advantage of a published Genome-Wide Association Study (GWAS) on genetic variation in VitD on 417,580 controls [1], we selected 15 genetic instrumental variables and explored the causal role of VitD on NEDA-3 status in an internal cohort of 1,408 MS patients. The results strongly suggested a causal effect of VitD on disease activity (inverse-variance weighted MR p-value<0.001).

Conclusions: VitD levels are associated with a causal relationship to disease activity in MS.

## CO-OCCURRENCE OF MULTIPLE SCLEROSIS AND AMYOTROPHIC LATERAL SCLEROSIS: A RARE CASE REPORT IN A LARGE NEUROLOGICAL CENTRE IN CENTRAL ITALY

B. Giovannini, F. Bianchi, M. Calverino, D. Panelli, L. Becattini, G. Siciliano, L. Pasquali

Department of Clinical and Experimental Medicine, Neurology Unit, University of Pisa (Pisa)

Introductions: In Multiple Sclerosis (MS), dissemination of demyelinating lesions in the central nervous system (CNS) is the sign of an autoimmune etiopathology. Amyotrophic Lateral Sclerosis (ALS) is instead a neurodegenerative disease characterized by a progressive loss of motoneurons in brain and in spinal cord. Two seemingly different diseases, but with something in common, since recent evidence showed connection between immunity dysregulation and ALS, as far as a higher incidence of autoimmune diseases in ALS patients. Our case report regards a patient affected by MS and ALS, seen at our Multiple Sclerosis centre.

Case report: A 73-years-old man, in 2017, suddenly developed paraesthesia in the left inferior limbs associated to a progressive gait impairment. During a day hospital at our clinic, he underwent: Brain, Cervical and thoracic MRI showing multiple demyelinating lesions; Lumbar puncture resulting in 2 oligoclonal bands; Infective, rheumatological and anti-aquaporin-4 antibody screening on serum which were unremarkable; Lower limbs electromyography which showed chronic neural injury without evidence of ongoing denervation. He was then diagnosed with MS; his EDSS score was 4,0 and he began a follow up in our centre. Annual 1,5-tesla brain and medulla MRIs were stable, while neurological examination got worse reaching an EDSS score of 7,0, in 2021. At the end of 2022, a 3-tesla brain MRI showed a bilateral thinning and hypo intensity in primary motor cortex, without any new demyelinating lesions. In the meaning time neurological conditions dramatically worsened since the patient developed a dropped head with hypophonic voice and dysphagia. At neurological examination his upper limbs strength was furtherly reduced, with spontaneous fasciculations at the four limbs and a significant muscle atrophy. An electromyography showed acute denervation, while a further cervical MRI did not show spinal stenosis. Total body CT was performed to exclude a paraneoplastic syndrome, which was unremarkable. Criteria for ALS were then met, and he started therapy with Riluzole.

Conclusions: Association of MS and ALS is reported in literature as an unusual event. Even if MS patients can show important lower motor dysfunctions, in our case the presence of a rapid progression of the motor signs or a sudden change in the previous disease course, should rise the question of the co-occurrence of another disease possibly pathologically related.

## FINGOLIMOD-ASSOCIATED PROGRESSIVE MULTIFOCAL LEUKOENCEPHALOPATHY (PML): CASE REPORT AND REVIEW OF LITERATURE

E. Giacopuzzi Grigoli, L. Brambilla, S. Crisafulli, P. Confalonieri, C. Antozzi, R. Mantegazza, V. Torri Clerici

Department of Neuroimmunology, Neurological Institute C. Besta IRCCS Foundation, University of Milan (Milano)

Objectives: To describe a patient with relapsing-remitting multiple sclerosis (RRMS) who developed a monolocalized progressive multifocal leukoencephalopathy (PML) while being treated with Fingolimod, a sphingosine-1-phosphate receptor (S1PR) modulator.

Results: This case report describes a 65-year-old female RRMS patient, previously treated with immunosuppressive therapy, that subsequently was started on Fingolimod treatment and resulted in clinical and radiological stability for four years. However, the patient presented with a solitary, paucisymptomatic, cerebellar lesion, initially mistaken for a new MS lesion, but later identified as progressive multifocal leukoencephalopathy (PML) after JC virus DNA was detected in her cerebrospinal fluid. The patient discontinued Fingolimod and showed clinical and radiological improvement, with a stability of disease without requiring any further disease-modifying therapy (DMT).

Discussion: This case describes an atypical presentation of PML, as it occurred during Fingolimod treatment, as a single, paucisymptomatic, cerebellar localization, with a favorable clinical and radiological course. Although the incidence of monolocalized PML and the differences in PML presentation during Natalizumab and Fingolimod treatment are not yet fully understood, our case seems to confirm the more favorable course of focal PML compared to the classic multifocal pattern, and the more favorable disease course in patients treated with Fingolimod compared to Natalizumab. An higher risk of Fingolimod-associated PML seems to be related to previous immunosuppressive therapies. Furthermore, some factors could predict a good PML prognosis, such as immunosenescence, a less active phase of MS, the location and extent of the PML lesion and the different mechanism of action of the ongoing DMT.

Conclusions: This case highlights the association between PML and Fingolimod in MS, and the importance of careful monitoring and risk management when using S1PR modulators, especially in patients with a history of prior use of immunosuppressive therapies. Our case confirms the possibility of a favorable outcome with monofocal, Fingolimod-associated PML and identifies some potential positive predictive factors. However, further research is needed to elucidate the mechanisms underlying PML in diverse patient populations receiving different pharmacological treatments. The different mechanisms of action of DMT may in fact play a role in the more or less favorable course of PML.

## EVALUATION OF LONG-TERM EFFECTIVENESS AND SAFETY OF OCRELIZUMAB IN PRIMARY PROGRESSIVE AND RELAPSING MULTIPLE SCLEROSIS: A SINGLE CENTER EXPERIENCE

T. Guerra, F. Caputo, A. Manni, M. Trojano, D. Paolicelli, P. Iaffaldano

Department of Translational Biomedicine and Neuroscience (DiBraiN), University of Bari "Aldo Moro" (Bari)

Objectives: To evaluate long term effectiveness and safety of ocrelizumab for primary progressive (PP), relapsing remitting (RR) and active secondary progressive (SP) multiple sclerosis (MS) patients in a clinical setting.

Material: Patients with ≥ 2 years of treatment with ocrelizumab were retrospectively recruited at the Multiple Sclerosis Center of Bari.

Methods: EDSS changes over time were evaluated using Wilcoxon paired test. 12-month confirmed disability worsening (CDW) and improvement (CDI) were calculated, annualized relapse rate (ARR) before and after ocrelizumab start was estimated and follow up magnetic resonance imaging (MRI) scans were collected. A multivariable logistic regression model was used to evaluate the association of clinical and radiological baseline factors with the risk of CDW. Adverse events were collected.

Results: The final cohort retrieved 140 patients (80 RR, 37 PP, 23 SP), with a mean (SD) follow-up after treatment start of 3.83 (0.06) years. The EDSS score after OCZ start significantly increased compared to the baseline values only in the PPMS group ($p<0.01$), but it remained stable in SP and RR groups ($p>0.05$). The mean ARR decreased from 0.61 (95% CI 0.47–0.74) in the year prior to ocrelizumab start to 0.04 (95% CI 0.01–0.09) in the first year, thereafter all patients remained free of relapses and MRI activity up to six years of follow up. The overall percentage of stable patients increased from the second to the fourth year (64.3% vs 86.4%), in parallel with a reduction in patients with CDW (26.4% vs 7.9%) and CDI (9.3% vs 5.7%). The multivariable logistic regression models revealed that a multifocal onset (OR, 95% CI: 2.96, 1.10–7.94) and the presence of >2 relapses before ocrelizumab start (3.82, 1.46–9.96) were significant ($p<0.05$) risk factors of CDW. Side effects mostly consisted of infusion-related reactions; we also reported 2 neoplasms, 1 organizing pneumonia and 4 localized zoster infections.

Discussion: The increasing amount of data available on the effectiveness and safety of B-cell-depleting therapies in MS led to a growing consideration of these treatments as a viable strategic option. [1] Strong real-word evidence, also based on disease registries [2], demonstrates that ocrelizumab reduces clinical and radiological activity over time, with a favorable safety profile and clinical benefits maintained over years of treatment. Ocrelizumab is also effective in delaying clinical progression [3].

Conclusions: In our cohort, ocrelizumab proved to stabilize disability progression and prevent disease activity over the long term. The safety profile was quite favorable.

## EVALUATION OF CLINICAL AND RADIOLOGICAL PREDICTORS OF NEDA-3 STATUS ACHIEVEMENT OVER THE LONG TERM IN RELAPSING REMITTING MULTIPLE SCLEROSIS: A SINGLE CENTER EXPERIENCE

T. Guerra, F. Amati, G. Guglielmini, A. Bianco, F. Caputo, A. Manni, M. Trojano, D. Paolicelli, P. Iaffaldano

Department of Translational Biomedicine and Neuroscience (DiBraiN), University of Bari "Aldo Moro" (Bari)

Objectives: To analyze, in a cohort of relapsing remitting multiple sclerosis (RRMS) patients, the prevalence of no evidence of disease activity-3 (NEDA-3) status achievement and to evaluate clinical, radiological, and therapeutic factors associated with its failure.

Material: We included RRMS patients, followed from 2010 at the MS center of University Hospital Policlinic of Bari, with a first visit within one year from disease onset and with ≥1 visit per year.

Methods: DMTs exposure was classified based on the efficacy of the first prescribed DMT in moderate efficacy (ME) and high efficacy (HE) DMTs. Percentages of patients exposed to ME and HE DMTs reaching NEDA-3 status at 2 and at 5 years of follow-up were compared using the chi-square test. A multivariable logistic regression model was used to estimate the association of demographic, clinical and radiological baseline factors with the risk of not achieving NEDA-3 status.

Results: A cohort of 452 patients (female patients n=295, 65%) with a mean (SD) follow-up of 6.37(0.17) years was analyzed. Patients who started their treatment history with HE DMTs (n=119, 26.3%) reached a NEDA-3 status at 2 and 5 years more frequently than those who received ME DMTs (47% vs 28%, p=0.001; 45% vs 24%, p=0.001, respectively). The multivariable logistic regression models revealed that a multifocal onset (OR, 95% CI: 1.47, 1.27–1.68; 1.53, 1.27–1.79), ≥2 relapses before DMT initiation (1.35, 1.14-1.57; 1.07, 1.04-1.10), a longer time to first DMT start (1.26, 1.12–1.40; 1.34, 1.18–1.51), treatment initiation with ME DMT (1.28, 1.14–1.42; 1.38, 1.18–1.59) and the presence of spinal cord lesions at baseline magnetic resonance imaging (1.25, 1.11–1.39; 1.22, 1.09-1.36) were significant ($p<0.05$) risk factors of not achievement of NEDA-3 status at 2 year and 5 years of follow up.

Discussion: NEDA-3 is a composite outcome defined by the absence of relapse, disability worsening and radiological activity. Also given the increasing evidence about disease progression processes independent of inflammation, the study of prognostic factors of non-activity of disease remains fundamental in orienting the choices of the neurologist. [1] HE-DMTs, especially used in an early phase of disease, revealed to play a fundamental role in delaying irreversible central nervous system damage and MS-related disability progression and accrual. [2,3]

Conclusions: Clinical and radiological baseline characteristics play a major role in predicting the NEDA-3 status over the long term. HE DMTs demonstrate superiority in preventing longer-term disability disease activity.

## COVID-19 INCIDENCE, SEVERITY, AND PROPENSITY TO VACCINATION AMONG PEOPLE WITH MULTIPLE SCLEROSIS: A POPULATION-BASED COHORT STUDY IN WESTERN SICILY

S. Iacono[1], V. Restivo[2], G. Schiro'[1], G. Lo Piccolo[1], G. Sorbello[3], M. Andolina[3], A. Cali'[1], A. Bianchi[4], S. Realmuto[5], P. Aridon[1], G. Callari[6], M. D'Amelio[1], S. Cottone[7], L. Grimaldi[6], E. Amodio[2], F. Vitale[2], A. Fallucca[2], G. Salemi[1], P. Ragonese[1]

[1]Department of Biomedicine, Neuroscience and advanced Diagnostics, Section of Neurology, University of Palermo (Palermo); [2]Department of Health promotion, Maternal and Infant care, Internal Medicine, and Medical Specialties (PROMISE), University of Palermo (Palermo); [3]Department of Biomedicine, Neurosciences and Advanced Diagnostics, Institute of Clinical Biochemistry, Clinical Molecular Medicine and Clinical Laboratory Medicine, University of Palermo (Palermo);

[4]NMR Research Unit, Queen Square MS Centre, Department of Neuroinflammation, Faculty of Brain Sciences, UCL Queen Square Institute of Neurology, University College (London-UK); [5]Neurology Unit, Azienda Ospedaliera Ospedali Riuniti Villa Sofia Cervello (Palermo); [6]Neurology and Multiple Sclerosis Center, Foundation Institute (Cefalù-PA);[7]Neurology Unit, ARNAS Civico (Palermo)

Objective: Several studies investigated Covid-19 risk and severity in people with multiple sclerosis (pwMS) by means of registry-based analyses [1-2]. On the other hand, some authors explored the relationship between disease modifying drugs and COVID-19 severity in pwMS [3]. However, population-based studies exploring the incidence of COVID-19 in pwMS are still lacking. We planned a study in western Sicily to ascertain the incidence and severity of Covid-19 among a cohort of people affected by MS derived from a population-based study. Secondary objectives were to calculate predictors of willingness to vaccination, and re-infection rates.

Materials and Methods: People diagnosed as affected by MS (pwMS) according to current diagnostic criteria were recruited by means of a previous population-based study in western Sicily. Covid-19 incidence was ascertained by direct contact of each person enrolled in the study and information about swab positivity and vaccination were abstracted by reviewing all the official charts and certification. We calculated cumulative rates of Covid-19 incidence until June 2022. Probability of severe infection, hospitalization or death were also calculated together with 95% CI and two-sided p-values.

Results: Among a cohort of 2751 (prevalent cases of pwMS enrolled in the study) 734 tested positive for SARS-COV-2 during the follow-up period with a cumulative incidence rate of 13.3/% person years. Five people deceased due to Covid-19 (0.68%), while 90.33% had an asymptomatic disease course, and 10 (1.36%) had a severe infection leading to hospitalization or ICU admission. The overall rate of re-infection was 3.41% (25/734). Sex, marital status, education nor employment status were predictors associated to higher propensity to be vaccinated.

Discussion and Conclusion: Results from this study large population-based cohort study investigating Covid-19 incidence and severity in southern Italy showed an overall incidence rate lower than previously reported in the general population in Italy and slightly lower compared to the Sicilian population. Mortality rate appeared to be lower than expected. Rates observed in present the study are probably related to the specific characteristics of the investigated population.

## INCIDENCE AND CORRELATES OF CARDIOVASCULAR COMORBIDITIES IN MULTIPLE SCLEROSIS: A PROSPECTIVE REGISTRY-BASED STUDY

S. Iacono[1], S. Costa[1], G. Schiro'[1], M. Andolina[1], G. Sorbello[2], A. Calì[2], G. Salemi[1], P. Ragonese[1]

[1]Department of Biomedicine, Neuroscience and Advanced Diagnostics, Section of Neurology, University of Palermo (Palermo); [2]Department of Biomedicine, Neurosciences and Advanced Diagnostics, Institute of Clinical Biochemistry, Clinical Molecular Medicine and Clinical Laboratory Medicine, University of Palermo (Palermo)

Objective: Multiple Sclerosis (MS) is an autoimmune disease affecting the central nervous system [1]. Cardiovascular comorbidities are common in general population although its impact in pwMS is almost conflicting. Some authors found a genetic evidence for the causal associations of MS while others showed that cardiovascular comorbidities may affect the risk of MS progression [2-3]. The aims of this study are to evaluate the frequency of cardiovascular comorbidities in pwMS, the difference between primary progressive MS patients (PPMS) and those with relapsing remitting course (RRMS) and the impact of these comorbidities among disease progression.

Materials and Methods: We collected the presence and development of cardiovascular comorbidities in our MS patients in the outpatients setting. We calculated the cumulative incidence of such comorbidities as well as the hazard ratios (HR) for secondary progression by using Cox regression models.

Results: From a total of 576 pwMS (73% female; 87.2% RRMS; age: 51 +- 9 years; follow up: 14.8 +- 10.2 years), hypertension reached a cumulative incidence of 17.2/100 person/year followed by cardiopathies (10.8/100 person/year), hypercholesterolemia (7.4/100 person/year), type 2 diabetes mellitus (5.2 /100 person7year) and stroke or TIA (0.9/100 person/year). Among cardiopathies, arrhythmias were the more common developed by pwMS (4.7/100 person/year) followed by ischemic acute cardiopathy (2.4/100 person/year). Hypertension and cardiopathies showed higher prevalence in primary progressive pwMS compared to RR MS patients (all $p < 0.05$). The presence of hypertension (HR=0.83 [95% CI: 0.6-1.2]; p=0.23), hypercholesterolemia (HR=0.83 [95% CI: 0.5-1.3]; p=0.42) and cardiopathies (HR=1 [95% CI: 0.7-1.5]; p=0.97) did not affect the risk of progression among RR pwMS whereas diabetes mellitus (HR=1.7 [95% CI: 1-2.7]; p=0.04) was found to be a risk factor for progression.

Discussion and Conclusion: Our study shows a higher prevalence of cardiovascular comorbidities among patients with PPMS compared to those with RRMS as well as the impact of type 2 diabetes mellitus in MS progression suggesting that the accurate evaluation of these comorbidities should be systematically embedded among the routinary management of pwMS, especially in those with PPMS.

Objectives: To compare the long-term effect of an early intensive treatment (EIT) versus a delayed start, after an escalation approach (ESC), of high-efficacy disease-modifying therapies (HE-DMTs) on disability trajectories and on the risk of progression independent of relapse activity (PIRA) and relapse-associated worsening (RAW).

Material: Patients with relapsing onset MS (RMS), ≥5 years of follow-up, a first DMT prescription within 3 years from disease onset and ≥3 Expanded Disability Status Scale (EDSS) score evaluations were retrieved from the Italian Multiple Sclerosis Register.

Methods: Patients were classified into EIT or ESC group according to the first prescribed DMT and propensity score (PS)-matched. On the matched cohorts, disability trajectories over a ten-year period and the risk of reaching a first PIRA and RAW were compared between the ESC and EIT groups using a linear mixed model for repeated measures (LMMRM) and multivariable Cox regression models, respectively. The recursive partitioning and amalgamation (RECPAM) algorithm was applied to the unmatched cohort to identify subgroups of patients with different risk of reaching irreversible EDSS 6.0, then LMMRM was used to evaluate differences in disability trajectories among them.

Results: The study cohort included 4878 RMS subjects, 914 exposed to a EIT approach and 3964 to an ESC strategy. The PS-matching procedure retrieved 907 pairs. Estimated annual delta-EDSS values were all significantly ($p<0.01$) higher in the ESC group compared with the EIT group. The estimated delta-EDSS (95%CI) differences increases over time, going from -0.16 (-0.25– -0.07, $p=0.0005$) at 1 year to -0.44 (-0.57– -0.31, $p<0.0001$) at 5 years and to -0.68 (-0.89– -0.47, $p<0.0001$) at 10 years. ESC strategy was associated to a significant higher risk of reaching a first PIRA and RAW event in comparison to the EIT strategy (HR, 95%CI: 1.17, 1.02-1.35, $p=0.03$; 1.73, 1.31-2.28, $p=0.0001$; respectively). RECPAM analysis identified four groups of patients with a significant different risk of reaching EDSS 6.0 based on EDSS and age at DMT start time. The ESC strategy resulted in a significant higher slope of the disability trajectories compared to the EIT approach in all subgroups.

Discussion: A recent expert opinion [1] presented the EIT as the best strategy to ensure a long-term impact on inflammatory activity and reducing the risk of progression, but until now there has been a slow adoption of this strategy [2].

Conclusions: Our results further confirmed that an early HE-DMTs start may minimize clinical disability accumulation and reduce the risk of reaching a first PIRA event.

Moscati di Avellino (Avellino); [18]Multiple Sclerosis Center, Ospedale Generale di Valduce (Como); [19]MS Unit, Institute C. Besta (Milano); [20]Department of Medical Science and Public Health, Centro Sclerosi Multipla, University of Cagliari (Cagliari); [21]Multiple Sclerosis Clinical Care and Research Center, Federico II University (Napoli); [22]Multiple Sclerosis Clinical and Research Unit, University Hospital of Rome Tor Vergata (Roma); [23]Neurology Unit, Neurorehabilitation Unit, Neurophysiology Unit, MS Center, Vita-Salute San Raffaele University and San Raffaele Scientific Institute (Milano); [24]Department of NEUROFARBA, University of Firenze (Firenze)

Objectives: To compare the risk of achieving the first 6-months confirmed progression independent of relapse activity (PIRA) and relapse associated worsening (RAW) events in a real life-cohort of naïve relapsing-remitting multiple sclerosis (RRMS) patients treated with natalizumab (NTZ) or ocrelizumab (OCR).

Materials: RRMS patients with a first visit within one year from disease onset, a first DMT prescription with NTZ or OCR and ≥ 3 Expanded Disability Status Scale (EDSS) score evaluations were extracted from the Italian Multiple Sclerosis Register.

Methods: A pairwise propensity score (PS)-matched analysis was performed to mitigate the impact of potential biases. Risk of reaching the first PIRA and RAW events were estimated using multivariable Cox proportional hazards models. The recursive partitioning and amalgamation (RECPAM) algorithm was used to evaluate subgroups of patients who can benefit most from exposure to either of the two HE-DMTs.

Results: A total of 661 subjects were included (NTZ=477; OCR=184). The median (IQR) follow-up after treatment start was 1.44 (0.73-2.49) and 1.43 (0.72-2.36) years, respectively. The PS-matching retrieved 169 pairs. A first PIRA event was reached by 13 (7.7%) NTZ exposed patients and 22 (13.0%) OCR exposed patients. No RAW events were found in the NTZ group and only 1 RAW event was reported in the OCR group. No differences between the two groups (NTZ -treated group as reference) were found in the risk (HR, 95%CI) of reaching a first PIRA (1.75, 0.88-3.48; p=0.11) event. RECPAM analysis identified 4 classes of risk of reaching a first PIRA event. In the subgroup of patients with an age at onset >38 years, a higher number of relapses before DMT start, and a longer time from disease onset to the DMT start, the exposure to OCR was associated to a significant higher risk of reaching a first PIRA event in comparison to NTZ exposure (6.72, 1.23-36.84; p=0.03).

Discussion: NTZ and OCR are commonly used as HE-DMTs for RRMS. Some recent studies have compared the two therapies in terms of effectiveness, impact on relapses and disability accrual. [1-3] No direct comparisons of the effect of these two drugs on PIRA and RAW events are currently available.

Conclusions: Both OCR and NTZ effectively suppress RAW events in RRMS patients. In short-term, the number and the risk of achieving PIRA events were not significantly different between the two groups, but differences in treatment response may exist in specific patient subgroups. A longer follow-up is essential to confirm the effect on disability progression.

## THE EFFECTS OF CUMULATIVE LIFETIME ESTROGEN EXPOSURE, PREGNANCY AND LACTATION ON MULTIPLE SCLEROSIS-RELATED DISABILITY IN THE PERIMENOPAUSAL PERIOD

A. Ianniello[1], I. Ferrante[2], C. Piervincenzi[1], R. Nistri[1], L. De Giglio[3], S. Ruggieri[1], M. Petracca[1], G. Sellitto[2], P. Pantano[1], C. Pozzilli[1]

Objectives: Gender differences in multiple sclerosis (MS) pathology emphasize the role of sex hormones. However, the role of low lifetime exposure to female sex hormones as a risk factor for poor prognosis remains uncertain. This study aims to explore the relationship between cumulative lifetime estrogen exposure (CLEE), pregnancy, lactation, and MS-related disability, particularly during the perimenopausal period.

Materials and Methods: This single-center, two-phase observational study enrolled consecutive perimenopausal women with MS. Comprehensive clinical, demographic, and reproductive history data, were collected. Neurological and neuropsychological assessments, 3T MRI, and Optical Coherence Tomography (OCT) were performed. CLEE was calculated by subtracting lactation months (or 1.5 months for pregnancies without lactation) from the reproductive window. Spearman's correlation evaluated relationships, and the sample was divided into two groups (based on the median CLEE) for comparison analysis using multivariate analysis and t-tests.

Results: Our sample consists of 32 women with stable MS (27 RMS, 5 SPMS; mean age 50.5; median EDSS 2.0; median CLEE 461 months). The number of pregnancies correlated with macular retinal nerve fiber layer (RNFL) thickness (coefficient 0.454, p 0.015). Total months of lactation showed correlation with symbol digit modalities test (SDMT) (coefficient 0.632, $p < 0.01$) and with thalamic volume (coefficients 0.618, $p < 0.01$). Age-corrected multivariate analysis showed significant differences between the two CLEE groups in both optic head and macular RNFL thicknesses (-7, -9 μm, respectively; $p < 0.05$). T-test showed significant differences in several neuropsychological tests, including 9-hole peg test (- 4.0 seconds, p 0.018), and multiple sclerosis impact scale-29 (MSIS-29) (-4.2, p 0.002), favouring the higher CLEE group. EDSS was lower in the group with the highest CLEE (- 0.9, p 0.03), while gray matter fraction was higher in the group most exposed to sex hormones (-0.26, p 0.07).

Discussion: Correlations between pregnancies/CLEE and RNFL thickness suggest a protective effect of sex hormones on axonal integrity. Lactation duration associates with improved cognitive performance and increased thalamic volume. Neuropsychological results support a potential beneficial impact of estrogens on motor function and quality of life. The group with higher CLEE exhibited less disability and a trend towards higher gray matter fraction.

Conclusions: Cumulative lifetime estrogen exposure, pregnancy, lactation, and potentially hormonal replacement therapy, may influence disease severity and disability progression in women with MS. Our findings highlight the importance of considering sex hormone influence on MS outcomes and suggest potential avenues for improving disease course in women with MS.

## THE OCRELIZUMAB AND NATALIZUMAB WEARING-OFF EFFECT IN PATIENTS WITH MULTIPLE SCLEROSIS

E. Idini, G. Coghe, L. Lorefice, J. Frau, G. Bibbò, C. Cualbu, A. Vacca, E. Cocco

Multiple Sclerosis Center, Binaghi Hospital, ATS Sardegna, Dpt od Medical and Public Health, University of Cagliari (Cagliari)

Objective: The objective of this study was to assess the prevalence and predicting factors of the wearing-off effect (WOE) in patients with Multiple Sclerosis (MS) treated with monoclonal antibodies, specifically Natalizumab (NTZ) and Ocrelizumab (OCR).

Materials and Methods: A total of 239 MS patients were included, female-to-male ratio was 3:1. The mean age was 38.6 ± 9.2 years, and the mean EDSS was 2.4 ± 1.7. The patients had received a minimum of 8 NTZ infusions or three cycles of OCR. The Multiple Sclerosis Impact Scale (MSIS-29), Short Form-12 Health Survey (SF-12), Fatigue Severity Scale (FSS), Beck Depression Inventory-II (BDI-II) and a questionnaire specifically addressing the WOE, were completed. The patients were divided into two groups based on the presence or absence of self-reported WOE. The differences between the two groups were evaluated using a two-way ANOVA. Logistic regression analysis was conducted to identify predicting factors of WOE.

Results: Out of the 239 patients, 126 (52.5%) reported WOE (53.3% in the NTZ group and 51.7% in the OCR group). The two-way ANOVA revealed statistically significant higher scores on SF-12, MSIS-29, BDI-II, FSS, EDSS, and BMI in individuals who reported WOE. Logistic regression analysis was performed separately for each treatment group. For the NTZ group, only the FSS was included in the final model: each 1-point increase on the FSS scale was associated with a 2.21 (CI95%: 1.47-3.33) times higher likelihood of experiencing WOE. The logistic regression model was statistically significant ($\chi 2(4) = 21.055$, $p < 0.001$). For the OCR group, only SF-12 was included in the final model, showing that each point increase on the SF-12 scale decreased the likelihood of WOE by 0.90 (CI95%: 0.085-0.96) times. The logistic regression model for the OCR group was statistically significant ($\chi 2(4) = 11.4$, $p = 0.001$).

Discussion and Conclusions: The study findings demonstrate that approximately half of the MS patients treated with NTZ or OCR experience the WOE. Patients who reported WOE exhibited differences in fatigue, quality of life, and disability. In the NTZ group, fatigue emerged as a significant determinant of WOE, while a poor impact of health-related quality of life seemed to influence the WOE effect in the OCR group. Based on these results, careful evaluation of the extended-dose protocol is necessary when patients report significant fatigue.

## BEING HIGHLY SENSITIVE PERSON NEGATIVELY IMPACTS ON COGNITIVE AND PSYCHOSOCIAL FATIGUE IN MULTIPLE SCLEROSIS PATIENTS

F. Lamagna[1], F. Falco[2], M. Eliano[2], M. Petracca[2], M. Moccia[2], A. Spiezia[2], D. Caliendo[2], C. Di Monaco[2], R. Lanzillo[2], V. Brescia Morra[2], A. Carotenuto[2]

[1]Psychology Department, University of Campania "Luigi Vanvitelli" (Caserta); [2]Department of Neurosciences, Reproductive and Odontostomatological Sciences, Federico II University (Napoli)

Objective: Fatigue is one of the most common symptoms in multiple sclerosis (MS), that may affect the cognitive functions. Sensory processing sensitivity (SPS) can be defined as a personality trait that includes the individual characteristics of sensitivity towards endogenous and exogenous stimuli. It is colloquially called High Sensitivity, or Highly Sensitive Person (HSP), a person with a high emotional and empathetic reactivity, and a greater depth in the processing of information. This personality trait renders the individual more vulnerable to external influences and more affected by their environments as they perceive more stimuli than they could process. The trait ultimately results in overarousal, cognitive depletion, and fatigue. Therefore, the aim of the study is to evaluate whether the HSP affects fatigue in MS patients, taking into account the ability to process stimuli, namely the cognitive status.

Material and Methods: Consecutive MS patients underwent clinical (EDSS, age, gender), cognitive (Symbol Digit Modality Test [SDMT] and Trial Making Test [TMT]), and psychosocial (Modified Fatigue Impact Scale [MFIS]) evaluation. Patients were also assessed through the Highly Sensitive Person scale (HPS scale). Linear regression were applied to explore association between HPS total score (dependent variable) and MFIS total scores and sub-scores, by accounting for age, gender, EDSS, TMT, SDMT (covariate).

Results: We enrolled 132 MS patients (84 female; mean age 44.04 ± 12.43 years; mean EDSS 2.86 ± 1.39; 112 relapsing-remitting and 20 progressive patients). 42 patients (32%) presented with a cognitive impairment and a mean TMT score of 46.45 ± 35.27. Mean total MFIS was 23.30 ± 19.6, mean physical MFIS was 11.70 ± 10.09; mean cognitive MFIS was 9.48 ± 8.82; mean psychosocial MFIS was 2.11 ± 2.37. Mean score at HPS was 101.70 ± 33.76. Higher scores at HPS correlated with MFIS total fatigue (coeff. 0.17, 95%CI 0.05 - 029, p=0.005), MFIS cognitive fatigue (coeff. 0.09, 95%CI 0.04 – 0.14, p<0.001), MFIS psychosocial fatigue (coeff. 0.02, 95%CI 0.00 – 0.03, p=0.03) but not with MFIS physical fatigue (coeff. 0.05, 95%CI -0.01 – 0.12, p=0.08).

Conclusions: HPS individuals process sensory information in a deep and complex way, which makes them easily overstimulated for demanding cognitive tasks in ecological contests. This may affect the fatigue perceived by MS patients; in fact, higher level of HPS is related with greater cognitive and psychosocial fatigue.

## PHENOTYPIC CHARACTERIZATION OF THE PLACENTA FROM WOMEN WITH MULTIPLE SCLEROSIS EXPOSED TO NATALIZUMAB DURING PREGNANCY

D. Landi[1], F. Servadei[2], I. Pisani[3], M. Montanaro[2], G. Auriemma[4], H. Valensise[5], A. Mauriello[2], G. Marfia[6]

[1]Department of the Systems Medicine, Tor Vergata University (Roma); [2]Department of Experimental Medicine, Anatomic Pathology, Tor Vergata University Hospital (Roma); [3]Department of Obstetrics and Gynecology, Policlinico Casilino Hospital (Roma); [4]Department of Gynecology and Obstetrics, IRCCS San Gerardo dei Tintori, University of Milano-Bicocca (Monza);[5]Department of Obstetrics and Gynecology, Tor Vergata University, Policlinico Casilino Hospital (Roma); [6]Department of systems medicine, Multiple Sclerosis Clinical and Research Unit, Tor Vergata University Hospital (Roma)

Aims: Recent evidence has consistently demonstrated that continuing natalizumab (NTZ) during pregnancy protects mothers with Multiple Sclerosis (MS) from relapses due to treatment suspension, without causing major fetal hematological or congenital abnormalities. Nevertheless, there is no data about the impact of Natalizumab exposure on placental pathology. The aim of this study was to describe the placental phenotype of mothers with MS exposed to NTZ throughout pregnancy compared to mothers unexposed to treatments.

Materials and Methods: Clinical data and placental pathological specimens from women with MS and growth parameters from their newborns were collected and analyzed. Macroscopic and microscopic analysis on placental specimens fixed in formalin was performed. Placental lesions were classified according to the Amsterdam Placental Workshop Group Consensus Statement.

Results: Seven women exposed to NTZ (mean age at conception 32,4+/-3, median NTZ infusion during pregnancy=4(3-4)) and 7 unexposed (mean age at conception 32,14+/-6) and their newborns were enrolled. No difference was found regarding infant gestational age (39,5±0,7 mg vs. 39,5+/-0,7 weeks, p=0.4) birthweight (3142±431,5 mg vs 3180±336; p=0.8) or placental weight (501,5±147,6 vs 431± 75 mg, p=0.3) comparing women exposed to NTZ and controls. The incidence of microscopic alterations, falling within the spectrum of maternal vascular malformation and fetal vascular malformation, was slightly higher in exposed compared to unexposed women, while inflammatory findings, like villitis or deciduitis, were less frequent.

Discussion: Our results suggest that treatment with NTZ during pregnancy is not associated with major macroscopic placental anomalies, conversely it seems to alter the microscopic placental vascularization pattern. However, these findings do not impact on pregnancy outcomes, fetal gestational age or birth weight. Our data also suggest a potentially positive role of NTZ in the creation of a less inflamed placental microenvironment. We can speculate that NTZ might be able to inhibit the migration of lymphocytes also into the placenta, similarly to the known effect at blood-brain barrier.

Conclusions: Although these results should be confirmed on larger samples to draw definitive conclusions, our preliminary data corroborate the evidence in support of the low risk of NTZ continuation during gestation.

Besta IRCCS Foundation (Milano); [8]Neuroimmunology, Center for Multiple Sclerosis, Cerebrovascular Department, Neurological Unit, ASST (Crema-CR); [9]Neuroimmunology Center, Cardiocerebrovascular, Azienda Socio Sanitaria Territoriale (ASST) of Crema (Crema-CR); [10]Multiple Sclerosis Center, Hospital of Gallarate, ASST della Valle Olona (Gallarate-VA); [11]Department of Neurology, ASST Rhodense - Ospedale "G. Salvini" (Garbagnate M.se-MI); [12]Department of Neurology, Multiple Sclerosis Center, IRCCS Ospedale San Raffaele (Milano); [13]UOSI Multiple Sclerosis Rehabilitation, IRCCS Istituto delle Scienze Neurologiche (Bologna); [14]Department of Neurology, IRCCS Ospedale Policlinico San Martino (Genova)

Objectives: Therapeutic sequencing after high-efficacy induction treatments is a matter of debate in MS. No safety and efficacy data about the switch to ocrelizumab (OCR) in patients (pts) with evidence of disease activity/progression after two alemtuzumab (ALM) courses have been reported yet. The aims of our study are to evaluate safety and efficacy of the switch from ALM to OCR in an Italian, multicentric cohort of MS patients with evidence of disease activity and/or progression after two ALM courses.

Materials and Methods: Prospective data collection from different Italian MS Centers.

Results: 73 MS patients were enrolled from May 2019 to…[at OCR start: mean age 39.2 (SD9.2) years; female, 63%; Relapsing Remitting, (RR): 78.1%, Relapsing Progressive, (RP): 13.7%; 67 (91.7%) started OCR for relapses/MRI activity, 6 (8.3%) for disability progression; cumulative number of relapses:69; mean number of new T2 and Gd+ lesions:3 (3.2) and 1 (2); median EDSS:3.5 (range 0-8)]. The mean follow-up (FU) from OCR start was 2.3±1 years. Safety: (i) Infusion Associated Reactions (IARs) occurrence was lower than in ALM ($p<0.005$); (ii) infections (n=41, 56.2%): upper airways (n=20), urinary (n=18), HSV (n=1), VZV (n=1) reactivations, appendicectomy (n=1). No patients developed severe forms of COVID19 (n=48); (iii) cancer (n=2, 1 colic, 1 cervix). Considering pts with at least 2-years FU (n=55), immunophenotype and IgG levels were available for 20 and 25 pts respectively: no pts showed evidence of T CD4 +cells lymphopenia and for all pts a complete B CD19+ cells depletion (<5/mm3) was obtained. Hypo-IgG was observed in 8 (32%) pts [with respect to 2/32 (6.25%) pts at 1-y FU]; (iv) autoimmunity: n=1 developed thyroiditis 1 month after OCR start while, out of the 15 pts with TSH abnormality at OCR start, 13 pts (86.7%) showed TSH normalization within 1-year. Efficacy: at 2-y FU (n=55), relapse-free survival was 92.7%, MRI-activity-free survival was 89.1%, progression-free survival was 76.4% [47/55 pts (85.5%) considering only pts with RRMS at OCR start.

Discussion and Conclusions: The results of our study show that the switch to OCR after 2 ALM courses is safe and effective, despite the severity of MS characterizing our patients' cohort. Infectious rate was not higher than that reported in clinical trials involving OCR. In addition, the data show a positive effect on the development/ongoing thyroidal autoimmunity.

## SAFETY OF ANTI-VARICELLA ZOSTER VIRUS VACCINATION IN PATIENTS WITH MULTIPLE SCLEROSIS TREATED WITH NATALIZUMAB: A CASE SERIES

C. Lapucci[1], D. Boccia[2], T. Sirito[2], M. Cellerino[2], M. Mikulska[3], L. Sticchi[4], M. Inglese[2]

[1]Department of Neurology, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa, IRCCS Ospedale Policlinico San Martino (Genova); [2]Department of Neurology, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa (Genova); [3]Division of Infectious Diseases, Department of Health Sciences (DISSAL), University of Genoa (Genova); [4]Hygiene Unit, IRCCS Ospedale Policlinico San Martino (Genova)

Objectives: In multiple sclerosis (MS), risk minimisation of several vaccine-preventable infectious diseases represents an essential need. However, some considerations have to be carefully evaluated when vaccinating patients with MS. Specifically, live vaccines are generally contraindicated during DMDs due to the risk of infection caused by the virus present in the vaccine. Among vaccine-preventable diseases, Varicella Zoster Virus (VZV) immunization represents a common issue in clinical practice, as it is strongly recommended before starting several MS specific DMDs. Nevertheless, the vaccination with live attenuated vaccines (LAVs, i.e., VZV) is generally not recommended during immunosuppressive therapies. Natalizumab (NTZ), despite of its mechanism of action, is currently included in this category.

Materials and Methods: After a risk/benefit evaluation, we decided to vaccinate 4 MS patients considering the following discussion points: (i) a long (i.e.- 3 months, as suggested by Spanish consensus) withdrawal of NTZ before administering LAVs is associated with a very high risk of MS rebound. (ii) in case of vaccine-induced VZV disease, a specific antiviral drug for VZV (acyclovir) can be administered (iii) maternal and fetal complications due to VZV infection during pregnancy represent a well-known phenomenon. (iv) when prescribing treatment with fingolimod and ocrelizumab, the two most common exit strategy from NTZ, a previous anti-VZV vaccination is strongly recommended. Therefore, the Disease Management Team reached a consensus on performing VZV vaccination during NTZ treatment in the following cases: A. Female MS patients who plan a pregnancy during NTZ treatment B. MS patients who withdraw NTZ treatment to switch to DMTs for which VZV immunization is strongly recommended. C. MS patients in treatment with NTZ who require anti-VZV post-exposure prophylaxis.

Results: All patients received two doses of anti-VZV vaccine with an interval of at least 1 months between them. None developed reported vaccine-associated adverse reactions of any type. The mean follow-up (FU) from the second dose of anti-VZV vaccination was 75.2±25.6 days. None of patients developed VZV infection; for 2 patients, qualitative VZV Real Time (RT) PCR on blood was performed 10 and 5 (Pt.1) and 5 and 12 (Pt.2) days after the first and second anti-VZV vaccination cycle respectively, with negative result.

Discussion and Conclusions: Our case series represents the first description of the good safety profile of anti-VZV vaccination in MS during NTZ treatment. No vaccine-related adverse events of any type nor VZV infections were observed. Larger patients' cohorts are needed to confirm our preliminary findings.

## PROTEOMIC ANALYSIS OF WHOLE SALIVA IN MULTIPLE SCLEROSIS: RELATIONSHIPS WITH DISEASE ACTIVITY IN RELAPSING REMITTING FORMS

L. Lorefice[1], A. Maccabeo[1], C. Piras[1], G. Guadalupi[2], J. Frau[1], G. Fenu[3], F. Murgia[4], G. Diaz[4], E. Cocco[1], B. Manconi[2]

[1]Multiple Sclerosis Center, Binaghi Hospital, ASL Cagliari, Department of Medical Sciences and Public Health, University of Cagliari (Cagliari); [2]Department of Life and Environmental Sciences, University of Cagliari (Cagliari); [3]Department of Neurosciences, ARNAS Brotzu (Cagliari); [4]Department of Biomedical Sciences, University of Cagliari (Cagliari)

Objectives: The challenge for the future in the field of multiple sclerosis (MS) is to improve the prediction of therapeutic responses by identifying biomarkers. Omics sciences represent an innovative approach for exploring the mechanisms underlying MS evolution [1]. The present study aimed to explore the proteomic profile of saliva, a biofluid mirror of several systemic disease processes [2], to identify biomarkers associated with disease activity in subjects with relapsing-remitting (RR) MS.

Materials: The study included RRMS patients without disease modifying therapy (DMT) for at least three months. Patients were classified as RR_active (with presence of clinical relapses in the last trimester and new/enlarged T2 lesions or gadolinium-enhancing T1 lesions) or RR_non active. A group of sex-/age-matched healthy controls (HCs) was also included.

Methods: Whole saliva was collected from participants. Proteomic data were obtained by nano-HPLC-high-resolution-MS/MS analysis bottom-up pipeline; protein identification was performed by Proteome Discoverer software, while multiple Mann—Whitney test and Random Forest (RF) statistical analysis between groups was performed with R software. Mann—Whitney tests provided indications on the panel of differentially expressed salivary proteins and peptides (p-value<0.05 and FDR<5%) among groups.

Results: Sixty RRMS patients (30 RR_active and 30 RR_not-active) and 22 HCs were enrolled. 138 proteins were found with altered levels in RR-MS_active compared to HCs (11 proteins were decreased and 127 increased); 222 proteins differed in RR-MS_not-active compared to HCs (19 proteins were decreased and 203 were increased); 27 proteins differentiated RR-MS_active versus RR-MS_non-active (21 proteins were decreased and 6 increased). Information regarding Reactome (v.3.7) pathways enrichment analysis was retrieved for unique proteins found after comparison of the three groups: saliva from RR-MS_active patients was enriched in terms related to "Formation of the cornified envelope" and "Keratinization"

while saliva from RR-MS_not-active patients was enriched in terms related to "Immune system". RF analysis evidenced a panel of salivary proteins able to classify with 100% accuracy RR-MS patients versus HCs and with an 86.2% accuracy RR-MS_active versus RR-MS_not-active.

Discussion: The bottom-up proteomic pipeline allowed evidencing the quantitative differences of salivary proteome in RR-MS with respect to HCs; RF analysis revealed the feasibility of the salivary proteome to discriminate HCs group with respect to RR-MS patients and RR-MS_active with respect to RR-MS_not-active.

Conclusion: The proteomic approach may prove useful in the stratification of MS subjects. Further studies are needed to identify proteins associated with disease activity, and how these vary during exposure to DMTs.

## MOTOR FATIGUE AND SENSORIMOTOR NETWORK EFFECTIVE CONNECTIVITY DYSFUNCTION IN MULTIPLE SCLEROSIS: INSIGHTS FROM PATIENTS TREATED WITH NATALIZUMAB

D. Maccarrone[1], G. Leodori[1,2], M. Mancuso[1], F. Certo[1], M. Tartaglia[1], A. Ianniello[1], V. Baione[1], G. Ferrazzano[1], L. Malimpensa[1], D. Belvisi[1,2], A. Berardelli[1,2], C. Pozzilli[1], A. Conte[1]

[1]Department of Human Neurosciences, Sapienza University of Rome (Roma); [2]IRCCS Neuromed (Pozzilli-IS)

Background and Objectives: Motor fatigue is a debilitating symptom in people with Relapsing-Remitting Multiple Sclerosis (RRMS). Transcranial magnetic stimulation-electroencephalography (TMS-EEG) evidence suggested that motor fatigue in RRMS is associated with abnormal post-fatigue facilitation of motor cortex (M1) effective connectivity within the sensorimotor network (SMN). This study investigated whether this SMN dysfunction is driven by inflammation-related dysfunction. We assessed changes in M1 output and effective connectivity within the SMN in patients treated with natalizumab, an inflammation-reducing treatment. We further probed correlations with clinical variables, and possible differences between natalizumab extended interval dosing (EID) and standard interval dosing (SID).

Methods: RRMS patients complaining of motor fatigue were assessed before and two weeks after natalizumab infusion. Motor fatigue was assessed through an index finger contraction task. Decrease in M1 output during the task, i.e., supraspinal fatigue, was assessed by the superimposed force evoked by TMS. Pre- and post-task M1 connectivity within the SMN was evaluated via TMS-EEG. Clinical measures included fatigue severity scales, EDSS, 9-hole peg test (NHPT), SDMT, and BDI-II scores.

Results: Forty-two patients completed the study (21 SID; 21 EID). Motor fatigue along with its supraspinal component decreased after natalizumab. Post-task modulation of M1 effective connectivity significantly changed after natalizumab. Fatigue symptoms severity, SDMT, and BDI-II scores improved after natalizumab. Significant correlations were observed between specific clinical and neurophysiological changes. No difference was found between SID and EID groups.

Discussion: Motor fatigue in RRMS is probably associated with inflammation related SMN dysfunction. Natalizumab mitigates fatigue by modulating M1 output and SMN connectivity.

## IS FATIGUE IN MS THE SAME ONE MANIFESTING AS WEARING-OFF SYMPTOM IN NATALIZUMAB TREATED PATIENTS?

G. Magro, S. Barone, A. Pascarella, J. Buonocore, C. Mummolo, R. Di Iorio, A. Saraceno, G. Spano, A. Gambardella, P. Valentino

Neurology, University "Magna Græcia" of Catanzaro (Catanzaro)

Objectives: Recent studies have demonstrated the safety of Extended Interval Dosing (EID) up to 6 weeks in patients receiving NTZ [1]. Patients receiving NTZ experience fatigue as the main Wearing-off Symptom (WoS), regardless of the dosing interval [2]. We previously demonstrated that there was no significant increase in WoS in patients with an EID of 5-6 weeks [2]. Since depression is a very frequent symptom in patients and it can often be hidden by fatigue, the primary objective of the study is to better characterize fatigue as a symptom in order to investigate a possible correlation with the symptom depression and with cognition, in patients undergoing therapy with NTZ, regardless of the dosing interval. Secondary objective of the study is the evaluation of the impact that the explored symptoms have on the patients' quality of life.

Methods and Materials: 87 patients have been evaluated. They were asked on the day of infusion to specify whether fatigue is present and if so whether is habitual or occurs only as the next infusion approaches; assessment of fatigue was done with the FSMC scale. Populations is divided in three main categories: chronic fatigue, end of does fatigue, no fatigue. All patients underwent a clinical evaluation, including EDSS, evaluation of depression with BDI-II, quality of life with MSQoL-29 scale. Anxiety was assessed with the STAI-Y scale, cognitive aspects with the Symbol Digit.

Results and Conclusions: 73 (84%) patients complained of fatigue, 14 (16%) did not. Among the 73 patients, 30 (34.5%) complained of end of dose fatigue and 43 (49.4%) of chronic fatigue. FSMC scale is higher in those who suffer chronically of fatigue compared to those who exhibit end of dose fatigue only (74.7 vs 53, $p<0.01$) with a significantly lower quality of life measured by MSQoL-29 in these patients (82.4 vs 78.4, $p<0.05$). Symbol Digit is similar in all three populations. BDI-II was higher in those complaining of chronic fatigue compared to those complaining of end of dose fatigue only (16.6 vs 9.6 $p<0.01$), while we found no difference in BDI-II between the no fatigue and the end of dose fatigue population, with a normal mean value in both populations (7.2 vs 9.6). We obtained similar results for STAI-Y trait (49.5 vs 46.5, $p<0.05$). These results show that fatigue as Wearing-off Symptom is different and probably strictly related to Natalizumab mechanism of action.

## QUALITY OF LIFE AND UNMET NEEDS IN PEOPLE WITH MULTIPLE SCLEROSIS (PWMS): PRELIMINARY RESULTS OF AN ITALIAN MULTICENTRE STUDY

E. Maida[1], G. Abbadessa[1], E. Cocco[2], P. Valentino[3], G. Miele[1], F. Bile[1], F. Patti[4], G. Borriello[5], P. Cavalla[6], L. Lavorgna[1], S. Bonavita[1]

[1]Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli" (Napoli); [2]Department of Medical Science and Public Health, University of Cagliari (Cagliari); [3]Institute of Neurology, University Magna Graecia (Catanzaro); [4]Department "GF Ingrassia", Section of Neurosciences, University of Catania (Catania); [5]MS Center, Hospital San Pietro Fatebenefratelli (Roma); [6]MS Center, Department of Neuroscience, City of Health and Science University Hospital of Turin (Torino)

Introduction: Multiple Sclerosis (MS) requires interdisciplinary management involving several clinical and administrative figures to guarantee the most appropriate path of care. People with MS (PwMS) are a heterogeneous population with different needs according to symptoms, individual experiences, and disease severity. Whenever these needs are not fulfilled, the patient is left alone to struggle with the difficulties of his/her illness.

Materials: The aim was to identify the unmet needs of a cohort of Italian PwMS and to ascertain whether they might be influenced by demographic variables, disease characteristics or perceived quality of life.
Methods: We elaborated an online anonymous questionnaire exploring socio-demographic status, MS basic information, perceived quality of life and unmet needs. Health-related quality of life (HRQoL) was measured by EQ-5D-5L, which was then converted in a utility index score, and EQ-VAS. Conversely, unmet needs were assessed with 23 questions designed to examine five aspects of perceived comprehensive care: access to information and primary care, socioeconomic aspect, need for assistance, and doctor-patient relationship.

Results: 690 PwMS responded to the survey: mean age was 43.60 years; 70.14 % were female. Overall, 95 % of subject reported at least one need being unmet; 65.79 % and 69.27 % showed one or more unmet need within the domain of the access to information and primary care; 83.04 % reported at least one socioeconomic related unmet need; 54.45 % revealed at least one assistance unmet need; lastly, 37.39 % reported one or more unmet need in doctor-patient relationship. Presence of unmet needs correlated with a lower age (p=0.029), higher PDDS (0.001) and lower utility index score and EQ-VAS (p=0.001). Moreover, results showed that across Italian regions the central ones reported a significantly lower number of total unmet needs than others (northern, southern, islands; respectively p=0.003, p=0.001, p=0.015).

Discussion: Our data show that most PwMS have unmet needs, and that these significantly correlate with reduced quality of life, younger age and greater disability. In particular, EQ-5D-5L utility index revealed to be the strongest predictor of unmet needs, as it negatively correlates with the number of unmet needs in each domain explored (except for the social aspect).

Conclusions: The general dissatisfaction revealed by our study suggests that the perception of pwMS still needs to be addressed. It is essential to act on modifiable factors that may result in reduced quality of life, since the latter is inseparably linked to the resolution of unmet needs.

## FRAILTY AND URINARY SYMPTOMS IN PEOPLE WITH MULTIPLE SCLEROSIS: WHAT POSSIBLE INTERACTION?

L. Malimpensa[1], G. Ferrazzano[1], G. Leodori[1], D. Belvisi[1], A. Zampelli[2], A. Di Santo[2], F. Forte[2], A. Conte[1]

[1]Department of Human Neurosciences, Sapienza University (Roma); [2]Urology Department, M.G. Vannini Hospital (Roma)

Objectives: Urinary symptoms represent a major source of disability in multiple sclerosis (MS). When they appear in early stages may be considered as a negative prognostic factor as well as changes in severity of urinary symptoms may predict transition towards the progressive form of MS. Therefore, presence and severity of urinary symptoms may reflect pathophysiological mechanisms responsible for disease progression in MS. Nonetheless, it remains unclear whether individual factors, not directly related to MS, may increase individual susceptibility to presence and worsening of urinary symptoms. Among these factors, frailty, an age-related condition characterized by an increased vulnerability to stressors due to accumulation of different deficits with a loss of adaptation to physiological changes, has recently been proposed as a descriptor of the health status of people with MS (pwMS). Frailty may facilitate the development and worsening of urinary symptoms in pwMS by acting as a moderator of pathophysiological mechanisms involved in disease progression. Therefore, the aim of the present study was to investigate the relationship between urinary disturbances and their perception and frailty levels in MS.

Materials and Methods: 52 pwMS were enrolled. MS severity was assessed by EDSS. All pwMS underwent the 8-item overactive bladder questionnaire (OAB-v8), the International prostate symptom score (IPSS) and the Urinary Incontinence Quality of Life Scale (I-QOL). Uroflowmetry and Ultrasound for Postvoid Residual were also performed. Frailty was assessed by a validated frailty questionnaire, which results in the fragility index (FI) calculated as the sum of the deficits over the number of variables evaluated resulting in a score between 0 and 1.

Results: FI was significantly associate with the presence and with the disability of urinary symptoms. We also found a positive correlation between FI and age, sex, disease duration, type of MS and EDSS. Two multivariable logistic regression model by using as dependent variable of interest IQoL total score and OAB respectively have showed that only FI scores resulted significantly associated with these two variables. No correlations were found between FI and the lesion load on MRI or data from Uroflowmetry and Ultrasound for Postvoid Residual.

Discussion and Conclusion: FI is associated with the presence and with the burden of disability of urinary symptoms in pwMS by suggesting new insights into the role of frailty as a potential moderator in the perception and impact on quality of life of urinary symptoms in pwMS possibly due to common pathophysiological mechanisms.

## COMPARING THE SHORT-TERM SAFETY PROFILE OF ANTI-CD20 B CELLS DEPLETING DRUGS IN MULTIPLE SCLEROSIS (OFATUMUMAB VS. OCRELIZUMAB): RESULTS OF A PROSPECTIVE STUDY

G. T. Maniscalco[1], C. Scavone[2], D. Di Giulio Cesare[1], V. Liguori[2], E. Prestipino[3], S. Salvatore[3], M. Di Battista[3], O. Moreggia[1], A. Ziello[1], V. Andreone[4], A. Capuano[2]

[1]Multiple Sclerosis Center, "A. Cardarelli Hospital" (Napoli); [2]Regional Center of Pharmacovigilance and Pharmacoepidemiology of Campania Region; Department of Experimental Medicine, University "Luigi Vanvitelli" (Napoli); [3]Neurological Clinic and Stroke Unit; Multiple Sclerosis Center, "A. Cardarelli Hospital" (Napoli); [4]Neurological Clinic and Stroke Unit, "A. Cardarelli Hospital" (Napoli)

Background: Adult patients with relapsing forms of multiple sclerosis (MS) with active disease are candidates for the treatment with ocrelizumab and ofatumumab. These drugs target CD20 in two different epitopes and differ in the method of administration. Indeed, ocrelizumab is administered through an intravenous infusion, preceded by pre-medication with steroids and antihistamines, while ofatumumab is meant to be administered by subcutaneous injection by the patient themselves, without any premedication. In order to describe and compare the short-term safety profile of ocrelizumab vs. ofatumumab, in terms of occurrence of suspected adverse drug reactions (ADRs), we carried out a prospective observational study.

Materials and Methods: This was a prospective observational study, carried out at the MS Centre of the Cardarelli Hospital (Naples, Italy) in collaboration with the Regional Center of Pharmacovigilance and Pharmacoepidemiology of Campania Region. The study enrolled all MS patients who received first dose of ocrelizumab or ofatumumab from February to May 2023. Patients were monitored for the occurrence of any ADR occurring during the first administration of the drug at the MS centre (through their direct observation) and those occurring within 24 hours following the drug administration (information on these ADRs was collected through a telephone contact). For each patient included in the analysis the following variables were collected: age, sex, Expanded Disability Status Scale (EDSS), MS diagnosis according to the 2017 McDonald criteria, type of MS, type of anti-CD20 medication. Any differences were investigated using the Fisher's Exact test.

Results: During the study period, 22 MS patients (59.1% male) were included in the study. Of these patients, 9 received ofatumumab and 13 ocrelizumab. The EDSS ranged from 1 to 7.5. The mean age of patients receiving ofatumumab and ocrelizumab was 47.9 (11.6) and 42.1 (12.1), respectively. Among patients receiving ofatumumab, 8 (88.9%) experienced at least one ADR within 48 hours vs. 5 patients receiving ocrelizumab (38.5%) (p=0.03). The most common ADRs following ofatumumab injection were flu-like symptoms, fever and gastrointestinal symptoms, while the most common ADRs following ocrelizumab injection were allergic reaction, sleepiness and flu-like symptoms.

Conclusion: Our results showed a higher number of short-term ADRs among patients who received ofatumumab compared to patients treated with ocrelizumab. In this context premedication can represent a useful strategy to mitigate the occurrence of ofatumumab-induced ADRs in the 24 hours following its administration. Our results provide additional data that support the need of additional monitoring of these drugs.

## PREDICTORS OF CLADRIBINE EFFECTIVENESS IN MULTIPLE SCLEROSIS: 2-YEARS DATA FROM A REAL-WORLD, SINGLE CENTRE COHORT

A. Manni, F. Oggiano, R. Vitobello, T. Guerra, A. Iaffaldano, F. Caputo, P. Iaffaldano, M. Trojano, D. Paolicelli

Department of Translational Biomedicine and Neurosciences, University of Bari "Aldo Moro" (Bari)

Objectives: Cladribine tablets (CLAD) for adult patients with highly active relapsing multiple sclerosis (RMS) have been available in Italy since 2018. We aimed to assess predictors of no-evidence-of-disease-activity-3 (NEDA-3) status after 24 months of the last dose of CLAD.

Materials and Methods: This is a single-centre, observational, real-world study on RMS patients treated with CLAD, with at least 24 months of follow-up after the last dose taken. Clinical and magnetic resonance imaging (MRI) activity together with disability worsening were assessed as outcomes. We evaluated the relationship between baseline characteristics and outcomes to identify predictors of response.

Results: We included 88 patients (70.5% female, mean age at CLAD start 35.4±11.4). Baseline EDSS was 2.5 (1.5-7.0), 77.3% showed MRI activity at baseline (47/88 patients presented Contrast enhancing lesions, 49/88 showed New T2 lesions). Eighteen patients were treatment naïve, 48 switched to CLAD from a First line Disease Modifying Drug (DMD), and 22 from Second line DMDs. All patients were observed for a median follow-up time of 2.4 (1-4) years after the last dose of CLAD. Seventeen patients (19.3%) showed clinical (6/17) and/or radiological (15/17) activity after a median time of 1.31aa (0.7-2.73) from the last dose of CLAD. Twenty-six (29.5%) had 6-months confirmed disability progression ≥0.5 EDSS points at the last follow-up. Forty-nine patients (55.7%) showed NEDA at the last available follow-up. Naïve patients (p=0.001), those with a lower number of previous DMDs (p<0.001) and those switching from first line DMDs (p=0.069) were more likely NEDA3 at the last available follow-up. At the multivariate analysis the number of previous therapies was confirmed as the only predictor of NEDA 3 status (P = 0.035). Twenty-one patients (23.9%) switched to other DMDs, after a median time of 1.8 (0.7-2.1) years.

Discussions: Besides long-term data from Randomised Clinical Trials, other clinical experience provided evidence of a higher efficacy of CLAD when used early in the therapeutic algorithm. To our knowledge, previous real-world follow-up, ranged from a mean of 12 to 43 months post CLAD start. Our experience, instead, provides information for the 2-years after the last dose of CLAD. However, our findings, confirmed a higher effectiveness of CLAD when placed early in the treatment algorithm.

Conclusions: In our experience, CLAD effectiveness on the 24 months follow-up from the last dose was higher with its early positioning in the therapeutic scenario.

## CSF OSTEOPONTIN IS ASSOCIATED WITH CORTICAL DAMAGE ACCUMULATION AND DISEASE ACTIVITY IN EARLY MULTIPLE SCLEROSIS

D. Marastoni[1], A. Tamanti[1], E. Colato[1], A. Scartezzini[1], V. Mazziotti[1], V. Camera[1], F. Virla[1], E. Turano[1], R. Magliozzi[1], B. Bonetti[1], L. Steinman[2], M. Calabrese[1]

[1]Department of Neurosciences, University of Verona (Verona); [2]Department of Neurology and Neurological Sciences, Stanford University (Stanford-USA)

Objectives: Accumulating evidence suggested a key role of Osteopontin (OPN,1) and other inflammatory molecules in driving chronic intrathecal inflammatory processes that have been suggested as one major pathological driver of disability accumulation in patients with multiple sclerosis (MS). Herein, we evaluated cerebrospinal fluid (CSF) inflammatory markers of accumulation of cortical damage as well as disease activity in patients with early relapsing remitting MS (RRMS).

Materials and Methods: CSF levels of OPN and other 66 inflammatory markers were assessed using an immune-assay multiplex technique in 107 patients with RRMS (82F/25M, mean age 35.7±11.8 years). All patients underwent regular clinical evaluation, including Expanded Disability Status Scale (EDSS) assessment, and yearly 3T MRI scans for at least 2 years. A subgroup of 39 patients underwent a similar 4-year clinical and radiological follow-up. White matter lesion number (WMLn) and volume (WMLv), cortical lesions number (CLn) and volume (CLv) and global cortical thickness (CTh) were evaluated together with the 'no evidence of disease activity' (NEDA-3) status, defined by no relapses, no disability worsening and no MRI activity, including CLs.

Results: After applying a random forest approach, OPN, CXCL13, TWEAK, TNF, IL19, sCD30, sTNFR1, IL35, IL16, and sCD163 were significantly associated with changes in global CTh, being Osteopontin (OPN) and CXCL13 the best related. Results were confirmed in the cohort of patients with a 4-year follow-up. In a multivariate linear regression model, CXCL13 ($p < 0.001$), OPN ($p = 0.001$) and sTNFR1 ($p = 0.024$) were increased in those patients with accumulating atrophy (adjusted R-squared 0.615). We then added the ten markers to a model that included age, sex, baseline EDSS, WMLn, WMLv, CLn, CLv, number of spinal cord lesions and Gadolinium enhancing lesions (adjusted R-squared 0.19). OPN ($p = 0.002$) and IL19 ($p = 0.022$) levels were confirmed to be significantly increased in patients developing more cortical atrophy over the follow-up and provided additional value to the abovementioned variables (adjusted R-squared 0.619). CXCL13 and OPN revealed also the best association with disease activity after two years.

Discussion: These data confirm and expand our knowledge on the prognostic role of the CSF inflammatory profile in predicting changes in cortical pathology and disease activity in early MS.

Conclusions: OPN, a molecule involved in many intrathecal inflammatory processes, has a potential key role as a marker of disease progression, providing additional value to clinical, demographic and MRI variables commonly adopted in clinical practice.

## FUNCTIONAL CONNECTIVITY MODIFICATIONS IN MONOAMINERGIC CIRCUITS UNDERPIN FATIGUE DEVELOPMENT IN MS PATIENTS

M. Margoni[1], P. Valsasina[1], A. Bacchetti[1], D. Mistri[1], N. Tedone[1], M. Filippi[2], M. Rocca[3]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [2]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [3]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: Aim of this study was to investigate changes over time of resting state (RS) functional connectivity (FC) in monoaminergic networks and concomitant development of fatigue in patients with multiple sclerosis (MS).

Materials and Methods: Eighty-nine right-handed MS patients and 49 matched healthy controls (HC) underwent clinical and 3.0T RS functional MRI assessment at baseline and after 1.26 year median follow-up (interquartile range=1.01-2.01 years). Fatigue was evaluated at baseline and follow-up using the modified fatigue impact scale (MFIS) score. MS patients were considered as fatigued if MFIS was >38. Monoaminergic-related RS FC was estimated using an independent component analysis constrained to PET atlases for dopamine, noradrenaline and serotonin transporters.

Results: At baseline, 24 (27%) MS patients were fatigued (F) and 65 were not fatigued (NF). Of these, 22 (34%) developed fatigue (devF) at follow-up and 43 remained NF. At baseline, MS patients showed abnormalities of RS FC vs HC in all three PET-guided monoaminergic networks. In particular, F MS patients were characterized by increased monoaminergic-related RS FC in hippocampal, postcentral, temporal and occipital cortices, as well as by decreased RS FC in the insular cortex. NF MS patients showed limited dopamine-related RS FC changes over time. Conversely, devF MS patients showed increased dopamine-related RS FC over time in the left hippocampus, significant at time-by-group interaction analysis. In the noradrenaline-related network, NF MS patients showed decreased RS FC over time in the left superior frontal gyrus. Conversely, the same region showed increased RS FC in both devF and F MS patients; this divergent behavior was significant at time-by-group interaction analysis. Finally, devF MS patients presented increased serotonin-related RS FC over time in the angular and middle occipital gyri, while this latter region showed decreased serotonin-related RS FC at follow-up vs baseline in the F MS group.

Discussion: Fatigue affects a large proportion of MS patients independently from disease stage. Our results suggests that dysregulation of monoaminergic networks has a role in fatigue pathogenesis, with a peculiar involvement of hippocampal, superior frontal and middle occipital cortices in patients developing fatigue.

Conclusion: Specific patterns of monoaminergic networks changes over time characterized MS patients according to fatigue status.

## DISTINCT CYTOKINE PROFILE IN INDIVIDUALS PRESENTING WITH MS FOLLOWING THE SARS-COV-2 OUTBREAK

A. Marin[1], F. De Napoli[2], V. Mauceri[2], M. Gaggiola[2], G. Zanotelli[2], P. Perini[3], F. Rinaldi[3], B. Molon[1], P. Gallo[2], M. Puthenparampil[2]

[1]Department of Biomedical Sciences, University of Padua (Padova); [2]Department of Neurosciences, University of Padua (Padova); [3]Neurology Clinic, Hospital-University Padua (Padova)

Background: Although the etiology of Multiple Sclerosis (MS) remains unknown, the hypothesis that viruses could act as potential triggers of the autoimmune process leading to brain inflammation has been repeatedly postulated. The occurrence of the SARS-CoV-2 epidemic provides an opportunity to investigate whether a neurotropic virus can impact the development of autoimmune diseases like MS and shed light on the immunological mechanism(s) underlying the chronic progression of virus-induced brain inflammation.

Aim: The objectives of this study are as follows: 1) to examine the potential association between the risk of MS and exposure to SARS-CoV-2; 2) to investigate the characteristics of the intra-cerebral autoimmune response triggered by SARS-CoV-2. Here, we present the preliminary findings from our study cohort.

Methods: We analyzed serum and cerebrospinal fluid samples from 80 patients. The cohort included 40 MS patients with symptom onset in 2020 (MS2020), 20 patients with other non-inflammatory and inflammatory disorders diagnosed in 2020 (ONIND and OIND), and 20 MS patients with symptom onset prior to 2020 (MSbefore). Initially, each serum sample was tested for the presence of anti-SARS-CoV-2 IgG antibodies using an Anti-SARS-CoV-2 ELISA kit. Subsequently, we screened both the serum and CSF samples for 49 different analytes, including cytokines, chemokines, and growth factors. We utilized a Simple Plex Cartridge Kit for 4 analytes and ProcartaPlex Multiplex Immunoassay for 45 analytes. Statistical analysis involved Kruskal-Wallis test with Dunn correction for multiple comparisons.

Results: We observed some differences in cytokine levels (CSF BAFF, CXCL-13, HGF, SCF; serum PDGF-BB) between the group with other disorders and MS, all with $p<0.05$. However, no significant differences were observed between MS2020 and MSbefore. Conversely, there was a significant difference in serum IL-18 levels among the groups ($p=0.0015$). Specifically, the concentration of IL-18 was $66.9\pm18.8$ pg/mL in ONIND and OIND, $34.4\pm24.4$ pg/mL in MS2020 ($p=0.048$ compared to ONIND and OIND), and $19.72\pm26.0$ pg/mL ($p=0.0014$ compared to ONIND nad OIND and $p=0.036$ compared to MSbefore).

Conclusions: Our preliminary findings indicate that the CSF cytokine profile differs between MS2020 and both the control group and previous MS cases. Further investigations are warranted to determine whether the SARS-CoV-2 pandemic alters the immunological characteristics in MS.

## SIPONIMOD, EXPERIENCE OF THE MS CENTER OF FROSINONE

F. Marinelli[1], M. Marziale[2], F. Ferrante[2], R. De Simone[3]

[1]Fabrizio Spaziani Hospital, Neurology Unit, ASL Frosinone (Frosinone); [2]Pharmacy Unit, ASL Frosinone (Frosinone); [3]Neurology Unit, ASL Frosinone (Frosinone)

Objective: The objective of this analysis, based on a small sample size, is to gather real-world experience with siponimod and compare it with data from pivotal studies in the treatment of secondary progressive MS (SPMS). The challenges in treating SPMS include the need for early diagnosis and evaluating treatment effectiveness, especially in patients with higher disability levels [1].

Materials: The analysis included 17 SPMS active patients who started siponimod between April 2022 and May 2023.

Methods: Descriptive statistics such as mean, standard deviation, median, minimum, maximum, frequency, and percentages were used to summarize continuous and categorical variables.

Results: The mean age at treatment start was $51 \pm 6.5$ years, with 76.5% of patients being female. The age is similar to that reported in the Expand study [2], while the proportion of female patients is higher. The mean age at MS diagnosis was $35 \pm 9.2$ years. At entry, the EDSS (mean ± SD) was $5.4 \pm 1.4$. The majority of patients (52.9%) had an EDSS score between 6.0 and 6.5, similar to the Expand study. In the year prior to siponimod treatment, 82.4% of patients had experienced one relapse, with a mean number of relapses of $0.82 \pm 0.32$, higher than that observed in the Expand population. The mean number of new/enlarged T2 lesions on the MRI performed in the 2 years before treatment start was $1.52 \pm 2.19$. Most patients had received more than two treatments before starting siponimod (35.5%). The main reasons for switching from first-line treatments were efficacy and disability progression, while safety or tolerability concerns were the primary reasons for switching from second-line treatments. Since May 2023, 12 patients have remained on siponimod treatment for 12 months, while two patients discontinued treatment after three months (11.8%) due to lymphopenia and patient's decision. The mean EDSS remained stable for the majority of patients after 6 months (93.7%) and 12 months (91.7%).

Discussion: Our patient population is similar to that in the pivotal trial Expand in terms of age and EDSS at the start of siponimod treatment. However, our population appears to have a more active disease, likely due to regulatory prescription criteria. Treatment with siponimod is generally well tolerated, with a safety profile consistent with other treatments in the same class.

Conclusions: siponimod showed a safety and tolerability profile consistent with the phase 3 clinical trial data. Larger real-world studies are needed to confirm these results.

## REAL-TIME CYTOMEGALOVIRUS (CMV) SEROCONVERSION IN A DIMETHYL FUMARATE (DMF) TREATED MULTIPLE SCLEROSIS (MS) PATIENT

A. Marrone[1], M. Picozza[2], M. Buscarinu[1], G. Bellucci[1], V. Zancan[1], M. Nasello[1], R. Reniè[1], G. Borsellino[2], L. Battistini[2], M. Salvetti[1]

[1]Department of Neurosciences, Mental Health and Sensory Organs (NESMOS), Sant'Andrea Hospital, Sapienza University of Rome (Roma); [2]Neuroimmunology Unit, IRCCS Fondazione Santa Lucia (Roma)

Objective: We describe real-time seroconversion of Cytomegalovirus (CMV) in a multiple sclerosis (MS) patient who was treated with dimethyl fumarate (DMF).

Materials: A 37-year-old male with a history of relapsing-remitting MS, diagnosed a year ago with diplopia. The patient started DMF within the context of a multicenter clinical study that involves subjects undergoing a diet characterized by a mild calorie restriction. At screening, the patient serology for CMV was negative and positive for EBV.

Method: During the study, in addition to clinical evaluations, patients undergo blood sampling with flow cytometry analysis of lymphocytes every six months. Two weeks before the 6-month sampling, the patient reported mild fever and dyspepsia. At 7 months, ad hoc resampling for Intracellular Cytokine Staining (ICS assay) was performed because of an increase in activated T cells. At 11 months, resampling was performed. The patient did not have a relapse of MS or evident clinical worsening during this period. Blood cells count never showed lymphopenia.

Results: At baseline, the patient had a normal CD4/CD8 ratio. At 6 months, the CD4/CD8 ratio was reversed and there was an increase in senescent CD8 (CD28- CD27-) cells. There was also a burst of activated CD4+, CD8+ and γδ T cells. At 7 months, ICS revealed an antigen-specific response to CMV pp65 by senescent-phenotype CD8+ T cells. At 11 months, the CD4/CD8 ratio returned to >1, and the senescent CD8 cells persisted. The patient serology for CMV was became positive.

Discussion: This case shows an in-vivo expansion of activated T cells in response to CVM infection, and the appearance and persistence of senescent-phenotype CD8+ T cells as expected in a physiological adaptive immune response. The observed phenomenon was caused by CMV and this was confirmed by both ICS and seroconversion. These phenomena are known in the literature but their observation in a real-life context is difficult.

Conclusion: In this case neither DMF nor the calorie restriction affected the immune response to CMV infection in a patient with MS. Moreover it helps solidify knowledge in the field of adaptive immune response to CMV infection. It is not clear whether CMV seroconversion affects the course of MS, certainly there is evidence that it is protective against the development of MS.

## A CASE OF CEREBRAL VENOUS THROMBOSIS IN MOGAD: CAUSAL OR CASUAL ASSOCIATION?

O. Marsico[1], S. Gasparini[1], A. Pascarella[1], E. De Santis[1], V. Bova[2], A. Mammì[1], V. Cianci[2], U. Aguglia[1]

[1]Institute of Neurology, Magna Graecia University (Catanzaro); [2]Regional Epilepsy Center, Great Metropolitan BMM Hospital (Reggio Calabria)

Objective: Myelin oligo-dendrocyte glycoprotein-associated disease (MOGAD) is a demyelinating disorder, distinct from multiple sclerosis (MS) and aquaporin-4 (AQP4)-seropositive neuromyelitis optica spectrum disorder (NMOSD). The most common clinical manifestations of MOGAD are optic neuritis, transverse myelitis, cerebral cortical encephalitis, seizures and cranial neuropathies [1]. To date, cerebral venous thrombosis (CVT) has been reported seldom in MS and in only two cases of pediatric-onset MOGAD [2-3], but the physiopathology is far to be elucidated. Here we report a case of CVT in an adult affected by MOGAD.

Materials/Methods: A previously healthy non-smoker 37-year-old male presented with a 2-week history of gait impairment, urinary urgency and hypoesthesia from the thoracic region to the inferior limbs. Spine MRI showed a STIR-hyperintense, continuous cord lesion from C2 to D1, and multiple smaller lesions in dorsal spine, with extensive contrast enhancement. A cell-based assay for anti-MOG serology resulted in a high-titer positivity (1/1280); a high-dose intravenous methylprednisolone course was performed, with improvement in ambulation and sensory disturbances. Oligoclonal bands on CSF and anti-AQP4 on serum were absent. After 3 days, he experienced 4 hours of severe headache, followed by an episode characterized by dizziness, behavioral arrest, loss of consciousness, right arm rigidity and tonic-clonic jerks lasting one minute, consistent with a focal to bilateral epileptic seizure. Somnolence and confusion were noted after the seizure. At neurological examination, the patient was drowsy and confused, with mild left hemiparesis.

Results: Infective, autoimmune and thrombophilic blood work-up was unremarkable. An urgent brain CT and MRI scan with contrast showed a right cortical frontoparietal lesion with superficial cortical veins and superior sagittal sinus congestion, associated with local absence of flow. A diagnosis of CVT was made. He started therapy with oral lacosamide and anticoagulation with subcutaneous enoxaparin followed by warfarin.

Discussion/Conclusion: CVT is a multifactorial cerebrovascular event rarely occurring in demyelinating syndromes. To our knowledge, this is the first adult case reporting the association between CVT and anti-MOG antibodies. Risk factors for CVT (lumbar puncture and corticosteroid therapy) were evident in our case. Nevertheless, a cause-effect hypothesis between MOGAD and CVT cannot be excluded. Indeed, in MS as well as in MOGAD, it has been hypothesized that a shared inflammatory-thrombotic mechanism subsists because of the evidence of lymphocytic infiltration around veins and the coexistence of multiple immunological pathways leading to inflammation of the blood vessel wall [3]. However, more documented cases are needed to better determine the link between these two rare conditions.

## LONG-TERM MISDIAGNOSIS OF PRIMARY PROGRESSIVE MULTIPLE SCLEROSIS: A CHALLENGING CASE REPORT

C. Martellino, A. Barbaccia, M. De Luca, O. Pardeo, C. Stancanelli, S. Messina, M. Russo, V. Rizzo

Department of Clinical and Experimental Medicine, University of Messina (Messina)

Purpose: Primary progressive multiple sclerosis (PPMS) represents only approximately 10 percent of MS cases and is characterized by disease progression from onset, although occasional plateaus, temporary minor improvements, and acute relapses may occur. Here we report the case of a patient with an uncommon presentation of MS, both in terms of age of onset and clinical features.

Materials and Methods: A 77-year-old woman presented to our clinic with a personal history of hypertensive cardiopathy, diabetes, kidney failure, autoimmune thyroiditis, dyslipidemia, osteoporosis, and psoriatic arthritis. Furthermore, in 2019 she had a urinary tract infection that later evolved into sepsis. At this time, she started having trouble walking requiring bilateral support. Then, she developed a progressive and worsening tetraparesis within about 1 year. Electromyography (EMG) showed neurogenic suffering with signs of denervation and reinnervation on all muscles examined. At this point, amyotrophic lateral sclerosis and polyneuropathy were among the differential diagnoses and she came to our attention. At the neurological examination she presented with normal spatial-temporal orientation, hypophonia, dysphagia and hypomobile pendulous veil. She also had a strength deficit of neck flexor and extensor muscles (MRC 3) and tetraparesis. Hoffmann's sign on both sides, bilateral Babinski's sign and Epstein sign were present. Deep tendon reflexes were normal.

Results: In our clinic, we performed brain MRI that showed approximately 10 hyperintense lesional foci in long TR scans, placed at the periventricular white matter, subcortical white matter in bilateral frontal and right temporal region, on the left anterolateral side of the pons, at the cervical cord-bulbus junction and in the D7-D8 tract of the spinal cord, not taking contrast. She also underwent an EMG that showed an axonal polyneuropathy.

Discussion and Conclusions: Although the clinical features were not diriment, radiological evidence and the presence of oligoclonal bands in cerebrospinal fluid supported the diagnosis of PPMS. Primary progressive forms of MS are less common and arise at a later age. Therefore, our clinical case highlights the need to consider MS as a differential diagnosis in elderly patients, despite we faced an unusual presentation of the disease, especially considering the very late onset, its rapidly evolving nature and the difficulty in the diagnostic process because of the comorbidities of our patient that masked MS symptoms for a long time.

## SPATIAL TRANSCRIPTOMICS ANALYSIS OF TSPO GENE EXPRESSION IN MULTIPLE SCLEROSIS BRAIN

M. S. Martire[1], E. Pedrini[1], F. Fagiani[1], J. Lin[2], D. Reich[2], M. Filippi[3], M. Absinta[1]

[1]Institute of Experimental Neurology, Division of Neuroscience, Vita-Salute San Raffaele University and Hospital (Milano); [2]Translational Neuroradiology Section, National Institute of Neurological Disorders and Stroke (NINDS), National Institutes of Health (NIH) (Bethesda-USA); [3]Institute of Experimental Neurology, Division of Neuroscience/ Neurology Unit, Vita-Salute San Raffaele University and Hospital/ IRCSS San Raffaele Hospital (Milano)

Background and aims: PET targeting mitochondrial translocator protein (TSPO) is an in vivo candidate biomarker for quantifying glia-related inflammation and phenotyping chronic lesions in multiple sclerosis (MS) (1. PMID 34993478). Recent neuropathological studies (2. PMID 34145928) showed by immunofluorescence analysis that TSPO is not increased in activated microglia in MS brains. This finding complicates interpretation of in vivo TSPO-PET imaging of microglia driven-inflammation in MS. In this study we quantified TSPO gene expression and cellular specificity in MS tissue according to pathological lesion stages by combining spatial transcriptomics and single-nucleus RNAseq (snRNAseq).

Materials and Methods: Spatial transcriptomics (Visium 10x Genomics) was performed on 16 tissue blocks (from 9 progressive MS cases, 7 women, age range 39-67), including active, chronic active, chronic inactive, and remyelinated lesions. On each sample anatomical regions (i.e., cortex vs white matter vs lesion core and edge) were defined by manual segmentation and Seurat unsupervised spatial clustering. For each sample and spatial cluster, TSPO+ spots (defined by non-zero TSPO expression) were quantified. To identify TSPO cellular specificity by spatial cluster, spot cell-type deconvolution was performed using SPOTlight and our published snRNAseq MS dataset (PMID 34497421), and the prevalent cell type was recorded for each TSPO+ spot.

Results: The percentages of TSPO+ spots were significantly different across spatial clusters (ANOVA $p<0.0001$), higher in active lesions (27.1%), followed by cortex (5.2%), lesion core (4.1%), chronic active edge (3.3%), and normal appearing white matter (1.2%). There were no significant TSPO differences in the lesion core of chronic active, inactive, and remyelinated lesions. By both snRNAseq and cell-type spatial deconvolution, TSPO was mainly expressed by endothelia, astrocytes, and immune cells. Within active lesions, most TSPO+ spots were enriched in composition by immune cells (36%) and endothelia (23%), while within the chronic lesion core, by endothelia (37%), astrocytes (30%), and, to a lesser extent, immune cells (6%).

Discussion: TSPO gene expression is not specific to immune cells. Our analysis on a limited spatial transcriptomics dataset demonstrates that TSPO gene expression is higher in active than chronic MS lesions, but its quantification was not significantly different among chronic lesion stages.

Conclusions: Our study supports the use of TSPO-PET as biomarker for acute neuroinflammation, although discrimination among chronic lesion pathological stages by quantification of TSPO+ spots was not achievable, hindering its application for the in vivo classification of chronic lesion types.

Cognitive impairment affects approximately 30% of pediatric onset Multiple Sclerosis (POMS) with a negative impact on everyday life and school activities1. No specific intervention for neuropsychological dysfunction has been proved to be effective in this age range. The aim of this multicentric randomized, double blind, controlled study, supported by a FISM research grant, is to evaluate the feasibility and effectiveness of a home-based, computer-assisted training of attention in patients with POMS. Inclusion criteria were diagnosis of MS, age 9-18 years, impairment on at least one attention test (visual attention or matrices). Subjects were randomized to specific training (ST) or non-specific training (n-ST), delivered through a customized module based on attention exercises implemented in COGNI-TRAcK2, scheduled in 5 daily sessions per week, for 8 weeks. The main feature of the ST is the implementation of automatic adaptive working load algorithms and procedures for intensiveness regulation. The effectiveness of the ST on attention has been primarily assessed on the Symbol Digit Modalities Test (SDMT)3 using an analysis of variance for repeated measures. Secondary objectives include effectiveness on other cognitive domains and everyday-life activities. The clinical and neuropsychological evaluations were performed at baseline, end of training, 3-month follow-up. 22 relapsing-remitting POMS patients were included (15 female, mean education 10.1 + 2.6 years, mean age 15.3 + 2.2 years, mean age at onset 13.3 + 2.6 years, mean Expanded Disability Status Scale (EDSS) 1.2 + 0.8). So far, data of 8 subjects in n-ST and 4 subjects in ST were available. As for the primary outcome, mean score on the SDMT improved in the ST group (from 29.75 at baseline to 39.75 after 3 months) and remained stable in the n-ST group (from 32.0 at baseline to 35.5 after 3 months). However, the difference did not reach the statistical significance (effect size 0.81). The positive effect of ST was evident in another test of attention, the number of correct answers in the matrix visual search (p=0.042). The analysis of other neuropsychological measures is ongoing. These preliminary findings point to a potential benefit of a home-based, computer-assisted training of attention in patients with POMS. Early effective rehabilitation in POMS can mitigate the negative impact of cognitive impairment in patient's lifestyle and school performance. The analysis of the effect of this training on non-trained cognitive domains and everyday functioning will be presented.

## AUTISTIC TRAIT IN ADULTHOOD IS A MAJOR DETERMINANT OF HEALTH-RELATED QUALITY OF LIFE IN PEOPLE WITH MULTIPLE SCLEROSIS: A CROSS-SECTIONAL STUDY

A. Masia[1], R. Meloni[2], M. Serra[3], S. Leoni[4], G. Farina[4], G. F. Mameli[4], E. Sechi[4], P. Solla[1], I. R. Zarbo[1]

Introduction: Multiple Sclerosis (MS) can significantly impact various aspects of quality of life. Autism Spectrum Disorders (ASD) are neurodevelopmental disorders characterized by impairments in social communication, interaction, and restricted interests. The influence of autistic traits on daily functioning is often underestimated, despite their potential impact. Consequently, there is a lack of studies examining the correlation between the severity of autistic traits and the quality of life in adults with MS.

Patients and Methods: A total of 213 adult MS patients were recruited and evaluated for cognitive deficits and anxiety. Participants completed self-assessments of quality of life using a disease-specific tool (MSQoL-54). The presence and severity of autistic traits were measured using the RAADS-14 questionnaire. Additional data on gender, age, degree of neurological disability, and education level were collected to analyze their potential role as confounders or effect modifiers. Correlations were investigated using univariate analysis of covariance, while adjusting for possible confounding factors.

Results: The analysis included 176 subjects with an average age of 46.4±12.6. The data revealed that MS patients with higher levels of autistic traits had lower health-related quality of life (HRQoL) scores in all subdomains ($p<0.001$).

Conclusions: Our findings suggest that the presence of autistic traits in individuals with MS is associated with a negative impact on their quality of life. Further research is necessary to gain a better understanding of the underlying mechanisms and to explore potential interventions that may improve outcomes for MS patients with autistic traits.

## ASSOCIATION BETWEEN HYPERREFLECTIVE FOCI COUNT AND YKL-40 CONCENTRATIONS IN CEREBROSPINAL FLUID IN PATIENTS WITH RELAPSING REMITTING MULTIPLE SCLEROSIS

V. A. Mauceri[1], A. Marin[1], E. Basili[1], A. Miscioscia[1], F. De Napoli[1], M. Gaggiola[1], G. Zanotelli[1], F. Rinaldi[2], P. Perini[2], P. Gallo[1], M. Puthenparampil[1]

[1]Department of Neuroscience, University of Padua (Padova); [2]Department of Neuroscience, University Hospital of Padua (Padova)

Objectives: To investigate in a pivotal cohort the number of Hyperreflective foci (HRF), considered clusters of activated and proliferating retinal microglia, and other OCT parameters and their association with levels of specific inflammation and neurodegenerative biological markers.

Materials and Methods: Fifty-two patients with relapsing-remitting multiple sclerosis (RRMS) were recruited in this study. These patients underwent Spectrum-domain optical coherence tomography (OCT) and cerebral spinal fluid (CSF) examination at baseline. We analized OCT parameters, including HRF count in inner nuclear layer (INL) and retinal ganglion cell layer–inner plexiform layer (GCIPL), peripapillary retinal nerve fiber layer (RNFL) thickness (circular scan centered on optic nerve head) and macular RNFL and GCIPL thickness and volumes (25 vertical scans, centered on the fovea). NfL and YKL-40 levels in CSF were measured using enzyme-linked immunosorbent assay (ELISA), in line with manufacturer's instructions. Linear Regression Analysis was applied to investigate the OCT parameters linked to both CSF molecules, then confirmed by multiple regression analysis.

Results: HRF count in INL and GCIPL correlated with YKL-40 CSF concentration (p=0.0068 and p=0.0355 respectively). Moreover, YKL-40 associated with mGCL total volume (p=0.0348) and inner ring thickness (p=0.0164), mIPL total volume (p=0.0436) and inner ring thickness (p=0.0176). No association was disclosed for CSF NfL. Multiple linear regression analysis confirmed only the association between CSF YKL-40 and INL HRF (β 3.007, p=0.0068).

Discussion: Multiple Sclerosis (MS) pathophysiology includes both inflammatory and neurodegenerative mechanisms. Microglia are the resident immune cells of the central nervous system and the retina. It is widespread activated in the brain of patients with multiple sclerosis and its activation can result in the synthesis of proinflammatory mediators, which further can stimulate astrocytic expression of chitinase (such as Chitinase-3-like protein 1, YKL-40). Neurofilament light chain (NfL) levels and thickness of inner retinal layers are both emerging biomarkers of neuro-axonal damage.

Conclusions: Our pivotal project demonstrated that YKL-40 is specifically linked to HRF INL count, further stressing the link between astrocyte and microglia activation.

## SAFETY AND EFFICACY OF OCRELIZUMAB: REAL WORLD EXPERIENCE IN A LARGE SARDINIAN GROUP

P. Mellino, J. Frau, D. Carmagnini, G. Coghe, E. Cocco, L. Lorefice

Multiple Sclerosis Center, Binaghi Hospital, Asl Cagliari, Department of Medical Sciences and Public Health, University of Cagliari (Cagliari)

Objectives: Ocrelizumab (OCR) is an anti-CD20 treatment approved for active forms of MS relapsing remitting (RR) and primary progressive (PP) patients. Despite its growing use, data on the real-world experience of OCR use are limited. Aim of this study was to examine the OCR use in PP and RR patients, and among these in naïve and switchers, evaluating the predictors of treatment response. Adverse infusion events (AIEs) were also evaluated.

Materials and Methods: MS patients exposed to OCR between 2016 and 2022 were considered. Demographic and clinical features were analyzed, and the patients were categorized as naive or switchers from I° and II° line disease modifying treatments (DMTs). NEDA-3 status at 24 months was evaluated for RR patients; determinants of NEDA 3 and AIEs were explored by regression analyses.

Results: The sample included 421 patients, of which 33(7.9%) were PP and 388(92.1%) RR. Among these, 67(17.3%) were naïve, while the switchers from I° and II° line DMTs were 199 (51.3%) and 122 (31.4%), respectively. OCR use as exit strategy from Natalizumab has been reported in 25 JCV+ patients. Among these, 5 patients had clinical or neuroradiological reactivation in the first 12 months, despite the short latency to OCR initiation (3.4 ± 2.0 months). NEDA 3 status after 24 months was calculated for 192 RR patients and achieved by 163(84.9%). Lower age (p=0.05) and the ARR in the year prior OCR (p=0.005) emerged as determinants. AIEs occurred in 128 (30.4%) patients; a relationship with previous allergic diathesis (p=0.001), reported for 37 (8.8%) patients, was observed, while the short protocol administration, used for 279 (66.8%) patients, was not related.

Discussion: A good efficacy profile was found, with significant reduction of ARR at 24 months and high percentage of patients achieving NEDA-3 status at 24 months (84.9%). Lower age at OCR start and lower ARR in the year prior emerged as significant predictors. OCR appeared also an effective and safe exit strategy from Natalizumab. As for the safety profile, the rate of AIEs appeared in line with current literature, and as expected, previous allergic diathesis emerged as a significant determinant, while the short infusion protocol appeared unrelated and thus a safe option to choose.

Conclusion: OCR is confirmed as a high efficacy option for naïve and switchers patients. Still, further real-world data are needed to better understand its efficacy and safety in different patients' groups.

## THE IMPACT OF AUTISTIC TRAITS ON SYMPTOM SEVERITY IN MULTIPLE SCLEROSIS PATIENTS: A CROSS-SECTIONAL STUDY

R. Meloni[1], A. Masia[1], M. Serra[2], S. Leoni[3], G. Farina[3], G. Mameli[3], E. Sechi[3], P. Solla[4], I. R. Zarbo[4]

[1]Department of Medical Sciences and Public Health, University of Cagliari (Cagliari); [2]Faculty of Medicine, University of Sassari (Sassari); [3]Neurology Unit, AOU Sassari (Sassari); [4]Dept of Medicine, Surgery and Pharmacy, University of Sassari (Sassari)

Introduction: Neuropsychiatric disorders, such as depression and anxiety, are prevalent among individuals with multiple sclerosis (MS). Autism Spectrum Disorders (ASD) are neurodevelopmental disorders characterized by impairments in social communication, interaction, and restricted interests. Despite their clinical significance, the presence and impact of autistic traits in adults are often overlooked. Consequently, no studies have examined the potential influence of autistic traits on the perception of symptoms in MS.

Patients and Methods: A total of 213 adult MS patients were recruited and screened for cognitive deficits and anxiety. Participants completed standardized questionnaires to self-assess fatigue, anxiety, and depression. The presence and severity of autistic traits were measured using the RAADS-14 questionnaire. Correlations were explored using univariate analysis of covariance, while adjusting for potential confounding factors.

Results: The analysis included 176 subjects. The data revealed that MS patients with autistic traits exhibited significantly higher levels of depression, anxiety, and fatigue ($p<0.001$).

Discussion and Conclusions: Our findings suggest that the presence of autistic traits in individuals with MS is associated with a negative impact on disease-related symptoms. These findings emphasize the importance of early investigation of these aspects during diagnosis.

## PROGRESSIVE MULTIFOCAL LEUKOENCEPHALOPATHY IN A PATIENT WITH MULTIPLE SCLEROSIS AND NEGATIVE SEQUENTIAL STRATIFY TESTS: A CASE REPORT

A. Messina, M. Zuccarello, P. Vullo, C. Messina, C. G. Chisari, M. Zappia, F. Patti

Department of Medical, Surgical Sciences and Advanced Technologies G.F. Ingrassia, Section of Neurosciences, University of Catania (Catania)

Progressive Multifocal Leukoencephalopathy (PML) is a rare opportunistic infection of the Central Nervous System (CNS) and a serious complication of Natalizumab (NAT) treatment, due to the reactivation of human polyomavirus 2 (HPyV-2), also known as John Cunningham Virus (JCV). Infection with JCV usually occurs in early life often as a latent and asymptomatic infection and is estimated to reach 60-80% prevalence in the general population. JCV can reactivate in patients with severe immunosuppression, as occurs in patients treated with immunosuppressive therapies like NAT. Normally, most survivors have a poor functional outcome. The most used test which allows the clinician to stratify the risk of JCV reinfection is the Stratify Test, a two-step enzyme-linked immunosorbent assay (ELISA) that detects JCV antibodies in human serum or plasma. It has been estimated the amount of Stratify test false negatives is 2.5%, although several studies show the amount is higher. Here, we present a case of a 43-year-old young woman with a 25-year history of MS treated with Natalizumab who developed PML and was always tested negative to JCV Stratify test, before and after the development of the disease. The patient arrived to our attention with psychomotor impairment, confusion and anomic aphasia disturbances in January 2022. For this reason, she underwent a brain MRI, which reported the presence of two large bihemispheric cortical lesions "consistent with a progression of Multiple Sclerosis". Thus, she was hospitalized and performed JCV Polymerase Chain Reaction (PCR) in serum and cerebrospinal fluid (CSF), that demonstrated 33600 copies/mL. During the hospitalization, numerous Stratify tests were also performed, always showing negative results. We treated the patient with five sessions of plasmapheresis with the aim of removing NAT from blood and administered mefloquine, mirtazapine, ganciclovir, interleukin-7. After a transient reduction in the copies number of JCV in CSF (15030 copies/mL) concurrently with a stabilization of neurological symptoms, the patient showed an abrupt clinical-radiological progression, until the development of a persistent vegetative state four months after the beginning of the disease. Her blood and immunological tests were always unremarkable. This is a very rare case showing permanent negativity to Stratify test disagreeing with current literature. We hypothesized that the index case did not present any immunological response and, consequently, she did not develop humoral immunity. This is important to the clinician in the way he has to consider immunological response for the development of anti-JCV antibodies.

Cardarelli Hospital (Napoli); [12]Department of Systems Medicine, Tor Vergata University (Roma)

Purpose: Several studies have shown that calorie restriction (CR) is able to improve clinical course of experimental autoimmune encephalomyelitis (EAE), the animal model of multiple sclerosis (MS) [1]. The purpose of this study is to evaluate the effect of mild controlled CR on MS progression and activity. More specifically, we aimed at evaluating the impact of CR on dimethyl-fumarate (DMF) treatment in terms of circulating immunephenotype and metabolic asset of different immune cell subsets and their correlation with the clinical status of relapsing-remitting (RR) MS patients.

Materials and Methods: We enrolled 92 naïve-to-treatment RR-MS subjects that, after inclusion in the study, started DMF treatment. After enrollment, subjects were randomized to a personalized diet among three different regimes: free diet (FD), caloric restricted (CR) diet (15% reduction of personalized calorie intake) and caloric restricted diet without milk and gluten (CRWMG), with the same 15% calorie reduction as for the CR group. Blood samples for the cellular, molecular and metabolic assessment of immune cells as well as the flow-cytometric extended analyses were obtained from all patients at baseline (T0), and after 6 (T1), 12 (T2) and 24 (T3) months of treatment.

Results: After an initial screening of the cellular and molecular analyses from the completion of the two-years follow up (n = 29), we observed that CR altered different subsets of circulating T cells and in particular those with a pathogenic pro-inflammatory phenotype. These results also associated with an overall increased in the glycolytic metabolism which associated with a better induction of anti-inflammatory regulatory phenotypes.

Discussion: These data suggest that CR could be considered as effective in decreasing the frequency of pathogenic T helper cells and interfering with intracellular metabolism.

Conclusion: Our results suggest that mild CR might influence the outcome of MS and could be a useful tool for improvement of therapeutic potential of first line drug treatments during RR-MS.

Introduction: Multiple Sclerosis (MS) may influence family functioning, with effects on both marital relationships and parental bonding. Our aim is to evaluate family functioning and related factors in patients with MS and their families.

Methods: A dedicated platform has been used for filling in the questionnaires for MS patients and their families. As controls, we selected families with no subjects referring chronic diseases. Sociodemographic and clinical information was preliminary collected. Administered questionnaires included: (1) the short form of the Family Assessment Measure Third Edition (FAM3); (2) the Hospital Anxiety and Depression Scale (HADS); (3) the Multidimensional Scale of Perceived Social Support (MSPSS); Dyadic Adjustment Scale (DAS) and the Inventory of Parent and Peer Attachment (IPPA).

Results: 129 MS patients, 93 family members (21 aged between 13 and 20 years old), and 210 control subjects (100 aged between 13 and 20 years old) completed the online questionnaires. MS family members are more anxious than control subjects (p= 0.0016) and MS partners have a higher degree of dyadic agreement (on finances, leisure time, home organization) than control subjects (p= 0.0167). Young people with ages between 13 and 20 years old who have at least one member with MS in their family, have higher quality attachments with significant others (both parents and peers), as assessed with the IPPA.

Conclusion: MS may affect the psychological state and family functioning by making MS family members more anxious, but also make more compliant partners and mature adolescents.

## PARAMAGNETIC RIM AND NON-RIM LESIONS SHOW A SIMILAR PERIVENTRICULAR GRADIENT IN MULTIPLE SCLEROSIS: EXPLORING THE CSF-MEDIATED PATHOLOGY AND ITS 7TESLA MRI AND CLINICAL CORRELATES

A. Miscioscia[1], C. Treaba[2], V. Barletta[2], E. Herranz[2], J. Sloane[2], E. Barbuti[2], C. Mainero[2]

[1]Department of Neuroscience, University of Padua (Padova); [2]Department of Radiology, A. A. Martinos Center for Biomedical Imaging, Massachusetts General Hospital (Boston-USA)

Introduction: In multiple sclerosis, paramagnetic rim lesions (PRL), which are characterized by a paramagnetic rim of iron-laden microglia visible on 7T susceptibility-weighted images, represent an important manifestation of chronic white matter (WM) pathology and indicate compartmentalized inflammation [1]. Chronic intrathecal compartmentalized inflammation has been suggested to be a mediator of a cerebrospinal fluid (CSF)–related tissue damage that can manifest with a 'surface-in' gradient of pathological changes as a function of distance from CSF [2, 3]. Whether PRL spatial development and distribution is influenced by CSF inflammatory factors is unknown.

Objectives: To investigate i) PRL distribution as a function of distance from ventricular CSF, compared to non-rim WM lesions (WML);

ii) and its relationship with clinical and imaging measures including cortical lesions, as CSF-driven inflammation with microglia activation is thought to be involved in the pathogenesis of cortical demyelination in MS.

Methods: Ultra-high resolution brain T2*-weighted gradient-echo sequences, yielding magnitude and phase images, were acquired at 7T from 61 MS patients (46 relapsing-remitting MS, RRMS, 15 progressive MS, PMS) to obtain PRL, non-rim WML, leukocortical, intracortical and total cortical lesion (LCL, ICL, TCL) volumes. The WM was divided into 1-mm-thick concentric bands radiating from the ventricular surface toward the cortex, and either PRL or non-rim WML volume was extracted from each band. Correlations between either PRL or non-rim WML and clinical and structural measures were evaluated using linear mixed-effects models and Spearman correlations.

Results: PRL volume was higher in the periventricular WM and declined with increasing distance from ventricular surface (intercept= 78 mm3, slope = -2.1, P<0.001). Non-rim WML showed a similar distribution (intercept= 235 mm3, slope = -6.5, P<0.001). In PMS, the higher the PRL volume in the bands at the closest proximity to the ventricles, the youngest age at disease onset (ρ= -0.637, P= 0.011). No correlations between PRL and cortical lesions were found. Regardless of phenotype and distance from ventricles, non-rim WML volume was significantly correlated with WM and thalamic volume, cortical thickness, and TCL volume (all p-values<0.009), as well as EDSS, disease duration and age at disease onset (all p-values<0.007).

Conclusions: PRL and non-rim WML showed a similar periventricular gradient of distribution, suggesting that CSF may influence WM MS lesion formation, but not its paramagnetic characteristics. Compared to PRL, non-rim WML volume demonstrated a stronger correlation with measures of neurodegeneration and clinical outcome. The pathogenetic basis of PRL generation necessitates further investigations.

## TOWARDS A NOVEL CLASSIFICATION OF COGNITIVE PHENOTYPES IN PEDIATRIC MULTIPLE SCLEROSIS

D. Mistri[1], M. Margoni[2], A. Meani[1], L. Moiola[3], C. Vizzino[1], M. Filippi[4], M. Rocca[5]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [2]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute (Milano); [3]Neurology Unit, IRCCS San Raffaele Scientific Institute (Milano); [4]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [5]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: Despite the considerable heterogeneity observed in the neuropsychological manifestations among pediatric multiple sclerosis (pedMS) patients, previous research has typically focused on a dichotomous classification of cognitive impairment. Aim of this study was to identify cognitive phenotypes in pedMS using an unsupervised machine learning approach and to characterize their clinical and MRI features, including structural and functional abnormalities within seven cortical networks based on Yeo's parcellation.

Materials and Methods: Seventy-three pedMS patients and 30 age-, sex- and education-matched healthy controls (HC) underwent 3.0T MRI, neuropsychological and clinical examination including Expanded Disability Status Scale (EDSS) score. A comprehensive neuropsychological battery (Selective Reminding Test, Spatial Recall Test, Trail Making Test, Symbol Digit Modalities Test and Semantic and Phonemic verbal fluency test) was administered to all patients. K-means cluster analysis was used to identify cognitive phenotypes based on neuropsychological test scores. MRI analysis included quantification of brain T2 white matter (WM) lesion volume (LV) and normalized brain volumes assessment, network metrics of lesion-related structural dysconnectivity and resting state (RS) functional connectivity (FC) between cortical regions within the seven networks.

Results: The machine learning approach proposed as optimal result a three-clusters solution including a Preserved cognition cluster (27 patients [37%]), a Mild verbal memory/semantic fluency involvement cluster (28 patients [38%]) and a Multidomain involvement cluster (18 patients [25%]). Across cognitive phenotypes, there were no differences in age, sex, disease duration and brain T2 WM LV. Patients with Multidomain involvement had higher EDSS score when compared with patients with Preserved cognition (p=0.006). Compared with HC, patients with Mild verbal memory/semantic fluency involvement exhibited lower normalized cortical volume (p=0.045), while patients with Multidomain involvement exhibited lower normalized brain, WM, cortical and thalamic volumes (p≤0.045). Higher structural dysconnectivity within multiple networks was found in Multidomain involvement phenotype when compared with Preserved cognition phenotype (p≤0.045). Compared to HC, patients with Mild verbal memory/semantic fluency involvement (p=0.045) and Multidomain involvement (p=0.045) experienced decreased RS FC within the frontoparietal network.

Discussion: By employing an unsupervised machine learning approach, this study identified three distinct cognitive phenotypes in pedMS. MRI analysis revealed a differential pattern of structural and functional MRI abnormalities across cognitive phenotypes. This novel classification provides a more comprehensive understanding of cognitive impairment in pedMS and the neural substrates of pediatric MS-related cognitive changes.

Conclusion: The findings highlight the complexity of cognitive impairment in pedMS and provide evidence for the existence of multiple cognitive phenotypes.

## COMPLETE EPSTEIN-BARR VIRUS SEROPOSITIVITY IN A COHORT OF PEDIATRIC ONSET MULTIPLE SCLEROSIS

G. Monte, L. Papetti, M. Ferilli, G. Tiralongo, M. Checchi Proietti, S. Tarantino, M. Valeriani

Developmental Neurology Unit, Bambino Gesù Children's Hospital IRCCS (Roma)

Introduction: Multiple sclerosis (MS) is a chronic inflammatory demyelinating disease of the central nervous system of multifactorial etiology. A role of Epstein-Barr virus (EBV) is supported by the increased MS risk after infectious mononucleosis. Almost all adult patients with MS have evidence of a prior infection while 12-14% of pediatric onset MS (POMS) have been reported to be EBV-seronegative questioning the role of EBV infection. The aim of this study was to retrospectively evaluate EBV infection in our POMS cohort.

Methods: MS patients with disease onset < 18 years of age seen at Bambino Gesù Children's Hospital were included. Anti-EBV nuclear antigen (EBNA) IgG and anti-viral capsid antigen (VCA) IgG and IgM were measured by automated quantitative chemiluminescence immunoassay (CLIA) and were retrospectively evaluated at disease onset. For comparison, we analyzed the EBV seroprevalence in an age-matched cohort from our hospital. Serum samples positive for EBNA-IgG and/or VCA-IgG were considered EBV seropositive. The Fisher's exact test was used to compare the two groups.

Results: Fifty-seven POMS were included and all had a previous EBV infection. Thirty-seven were female and the median age at disease onset was 14 years (range 5-17). In the comparison group, one-hundred and fifty patients were included with a median age of 13 years (range 6-17) and they had neurological (i.e. headache and epilepsy) or other autoimmune diseases (i.e. inflammatory bowel disease, juvenile idiopathic arthritis). One-hundred and two (68%) patients were EBV seropositive. The two age-matched groups were compared and EBV seropositivity was significantly higher in POMS ($p < 0.00001$).

Conclusion: Consistent evidence support the role of EBV as a strong risk factor for MS. In our POMS cohort, EBV seropositivity was 100% like adult MS – higher than prevalence reported in literature for POMS - supporting the role of infectious mononucleosis in MS pathogenesis. Further studies are needed to clarify the role of EBV infection in POMS onset and disease course.

## SAFETY OF SARS-COV2 VACCINATION AND COVID-19 SHORT-TERM OUTCOME IN PEDIATRIC ACQUIRED DEMYELINATING DISORDERS OF CENTRAL NERVOUS SYSTEM: A SINGLE CENTER EXPERIENCE

G. Monte[1], L. Papetti[1], M. Ferilli[1], F. Ursitti[1], R. Moavero[1], G. Sforza[1], S. Tarantino[1], M. Proietti Checchi[1], F. Vigevano[1], P. Palma[2], M. Valeriani[1]

[1]Neurology Ward Unit, Bambino Gesù Children's Hospital, Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS) (Roma); [2]Unit of Clinical Immunology and Vaccinology, Bambino Gesù Children's Hospital, Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS) (Roma)

Introduction: Concern of a correlation between disease relapse in patients with acquired demyelinating disorders of central nervous system (CNS) and SARS-CoV2 vaccines has been raised. In this single center study, we retrospectively evaluated safety of SARS-CoV2 vaccination and COVID-19 short-term outcome in pediatric acquired demyelinating disorders of CNS.

Materials and Methods: Patients with multiple sclerosis (MS), myelin oligodendrocyte glycoprotein antibody associated disease (MOGAD) and neuromyelitis optica spectrum disorder (NMOSD) with disease onset before 18 years of age were included. Demographic and clinical data, and information regarding previous SARS-CoV-2 infection and vaccination were collected.

Results: We included nine patients with MOGAD. Six patients received SARS-CoV2 vaccination and complained pain at injection site while only one had fever and fatigue. Median follow-up was 28 weeks (range 20-48). Seven patients had COVID-19 occurring with mild flu-like symptoms and median follow-up was 28 weeks (range 24-34). Nobody had disease relapse. Five patients with NMOSD were included. All patients received SARS-CoV2 vaccination (BNT162b2-Pfizer-BioNTech). The median follow-up was 20 weeks (range 14-24) and only two patients complained pain at injection site, fever and fatigue. Three patients had also COVID-19 with mild flu-like symptoms, despite two of them being under immunosuppressive treatment. Lastly, forty-three patients with MS were included. 35 out of 43 received SARS-CoV2 vaccination with a median follow-up of 24 weeks (range 8-36). Fourteen patients had no side effects, while 21 complained mild side effects (mainly pain at injection site) and one experienced a disease relapse with complete recovery after steroid therapy. At vaccination, all but one were under treatment. Sixteen patients had COVID-19 occurring with mild symptoms.

Discussion: COVID-19 outcome was good although many patients were under immunosuppressive treatment. Vaccine-related side effects were frequent but were mild and self-limited. Only one MS patient had a post-vaccination relapse with complete recovery after steroid therapy. In conclusion, our data support the safety of SARS-CoV-2 vaccines in pediatric MS, MOGAD and NMOSD.

## FEASIBILITY AND EFFICACY OF AN AT-HOME, TECHNOLOGY-SUPPORTED MINDFULNESS PROGRAM IN PEOPLE WITH MULTIPLE SCLEROSIS: A PROOF-OF-PRINCIPLE STUDY

F. Motolese[1], D. Stelitano[1], J. Lanzone[2], A. Cruciani[1], M. Rossi[1], G. Musumeci[1], C. Masciulli[3], V. Di Lazzaro[1], F. Capone[1]

[1]Unit of Neurology, Neurophysiology, Neurobiology and Psychiatry, University Campus Bio-Medico of Rome (Roma); [2]Neurorehabilitation Unit, Istituti Clinici Scientifici Maugeri IRCCS (Milano); [3]Department of NEUROFARBA, University of Florence (Firenze)

Background: Multiple Sclerosis (MS) is a chronic disease with great clinical heterogeneity and is characterized by significant emotional distress about the uncertainties relating to disease progression. Not surprisingly, neuropsychiatric symptoms are common in MS, occurring in almost 60% of patients over the course of the disease. Mindfulness is a practice that encourages individuals to cultivate a present-focused, acceptance-based approach to managing their symptoms and helps to reduce anxiety, depression, and stress. Its positive effect on MS has been demonstrated, but learning such a technique is expensive and time-consuming. In this study, we investigated the feasibility and efficacy of an 8-week, at-home, technology-supported mindfulness program in a cohort of MS patients.

Methods: The study included two visits, one at baseline and another after the mindfulness program. Both visits consisted of a clinical and neuropsychological evaluation, together with the recording of a high-density EEG. We measured adherence to the proposed mindfulness treatment and its effect on different neuropsychological scales and in terms of quantitative EEG parameters. All participants received a smart biofeedback device – i.e., a headband with EEG sensors placed along

the forehead – to be used during the therapeutic program consisting of daily meditative exercises.

Results: Twenty-nine patients were recruited for the present study. Among them, 27 (93%) completed the entire program and 17 (63%) completed more than 80% of the scheduled sessions. We observed a statistically significant reduction of the Ruminative Response Scale score and a significant increase in the Digit Span Backward. Regarding neurophysiological data, we found a significant reduction of the whole-scalp beta and parieto-occipital theta power after the intervention.

Conclusion: Our results show that an at-home, technology-supported mindfulness program is feasible for people with MS. Meditative exercises help patients change their perspective on their condition, improving emotional response regulation. In turn, this might help with other related aspects, such as cognition or everyday self-efficacy. The efficacy in terms of reappraisals of stress, cognitive and emotional coping responses is also supported by our neurophysiological data. The major barrier to the diffusion of such practices is that mindfulness requires long and expensive training with specialised instructors. New technologies might help to improve compliance and the efficacy of mindfulness programs, as shown in the present paper. Further studies are warranted to better explore the role of such approaches in managing the psychological impact of MS diagnosis.

## TUMEFACTIVE MULTIPLE SCLEROSIS: DIAGNOSTIC CHALLENGES AND TREATMENT CONSIDERATIONS

C. Mummolo, A. Saraceno, J. Buonocore, R. Di Iorio, G. Spano, S. Barone, A. Gambardella, P. Valentino

Institute of Neurology, Department of Medical and Surgery, Magna Graecia University (Catanzaro)

Aims: Tumefactive multiple sclerosis (TMS) is an uncommon variant of multiple sclerosis (MS), defined by lesions larger than 2 cm that may be accompanied by surrounding edema, mass effect and ring enhancement [1]. Radiological features may be difficult to distinguish from other tumefactive demyelinating lesions (TDLs) as brain tumors or abscesses and often necessitate a brain biopsy for differential diagnosis [2].

Case: A 45-year-old woman presented right limbs hypoesthesia, completely resolved without therapy about one week later. Neurological examination revealed diplopia onupward gaze and brisk deep-tendon reflexes. Brain and spinal MRI revealed one T2-hyperintense lesion with restriction diffusivity and incomplete ring enhancement in left temporal lobe with a diameter of 22 mm and one T1-hypointense and T2-hyperintense lesion in right paramedian pontine area with a diameter of 21 mm. Additional subcortical and periventricular subcentrimetic areas of T2-hyperintensities were described. Cerebrospinal fluid examination showed elevated IgG index and positive oligoclonal bands. Multimodal evoked potentials study was unremarkable. We performed intravenous methylprednisolone (at the total dosage of 5 g). Brain MRI performed after treatment evidenced reduced diameter of left temporal lobe lesion, without contrast enhancement. According to 2017 McDonalds criteria [3], a diagnosis of multiple sclerosis was made. One month later, the patient started disease-modifying therapy (DMT) with ofatumumab, with clinical-radiological stability after three months.

Discussion: Approximately 70% of individuals who initially present with TDL develop definite multiple sclerosis. Despite the estimated median EDSS score is 3.5 at the time of the first attack, our case showed a mild clinical manifestation with minimal disability. Nevertheless, owing to patient's unfavourable prognostic factors such as age (above 40 years) and severe radiological imaging (subtentorial lesion and black hole), a high-efficacy treatment approach was chosen.

Conclusion: Diagnosis of tumefactive demyelinating lesions can be difficult and not always straightforward. Due to limited studies regarding TMS, the choice of DMT may rely on physicians, personal experience. However, it appears evident that certain drugs like natalizumab, fingolimod or alemtuzumab should be avoided because of their potential negative role in triggering or worsening TDL [2].

## MANAGEMENT OF SPASTICITY IN MULTIPLE SCLEROSIS PATIENTS WITH BOTULINUM TOXIN: REAL-LIFE EXPERIENCE FROM AN ITALIAN CENTRE

M. Nasello, E. Bianchini, A. Massimiani, V. Zancan, M. Buscarinu, M. Giovannelli, M. Salvetti

Department of Neuroscience, Mental Health and Sensory Organs (NESMOS), Sapienza University of Rome (Roma)

Objectives: Spasticity is a highly prevalent and disabling symptom in Multiple Sclerosis (MS) patients. Botulinum toxin (BoNTA) is a first-line treatment, however real-world data on BoNTA use in MS patients are scarce [1]. Here we report the experience of BoNTA use in MS patients in our centre.

Materials and Methods: Data from MS patients referred to BoNTA centre at Sant'Andrea Hospital in Rome, from 2010 to 2023, were retrospectively analysed. Information regarding Expanded Disability Status Scale (EDSS), disease duration, age at diagnosis, MS phenotype, BoNTA injection sites (upper/lower limb and proximal/distal), oral spasticity treatments before and after BoNTA were extracted. Patients were grouped according to (i) age at diagnosis into adult-onset MS (AOMS, 20-49 years) and late-onset MS (LOMS, >49 years); (ii) those who continued treatment and those who dropped out; (iii) disease phenotype (relapsing-remitting, RRMS; secondary progressive, SPMS; primary progressive, PPMS).

Results: Data from 84 patients were included (median EDSS 6.5; disease duration 16.1±9.3; females 62%). The number of patients treated with BoNTA increased over time (p=0.007) while EDSS and disease duration did not change. No significant differences in BoNTA injection sites were found across groups, even though LOMS patients were more frequently treated in the proximal upper limb and none of the PPMS patients were treated in the upper limb differently from RRMS and SPMS. PPMS and SPMS had a higher median EDSS (p=0.022) than RRMS. At BoNTA initiation, 46% of patients were in treatment with oral Baclofen but only 36% of patients continued it

(p=0.001). Patients in therapy with Nabiximols at BoNTA initiation were 18% increasing to 27% at follow-up (p=0.009).

Discussion: The increased number of patients treated with BoNTA over time could reflect increased attention among neurologists. The reduced access to physiotherapy in the last year due to COVID-19 pandemics could have also played a role. The potential difference in BoNTA injection sites could reflect an underlying biological variability, disease severity, disability and functional needs across disease phenotypes. Our results suggest that oral Baclofen, opposite to Nabiximols, is frequently prescribed before BoNTA initiation and more frequently discontinued afterwards.

Conclusions: Management of spasticity through BoNTA in MS patients increased over the years. However, an earlier initiation of treatment at a lower EDSS, disease duration and disability level are warranted. Future studies will help elucidating the potential differences in spasticity pattern and therapy response across disease phenotypes and the usefulness of combined treatment with BoNTA and oral drugs.

## SPASTICITY PLUS SYNDROME MODEL IN MULTIPLE SCLEROSIS: AN OPERATIVE APPROACH IN A REAL LIFE COHORT

C. Nicoletti[1], G. Mataluni[2], M. Ponzano[3], M. Sormani[3], D. Landi[1], G. Marfia[1]

[1]Department of Systems Medicine, Tor Vergata University (Roma); [2]MS Clinical and Research Unit, Tor Vergata University Hospital (Roma); [3]Department of Health Sciences, Section of Biostatistics, University of Genoa (Genova)

Introduction: Spasticity Plus Syndrome (SPS) has been recently conceptualised to enclose several symptoms that might coexist with spasticity in Multiple Sclerosis (MS). In this study we aimed to test the SPS model through a web-based tool exploring the symptomatic profile of a cohort of patients with MS relying on patients reported outcomes (PROs).

Materials and Methods: A web-based questionnaire was sent to MS patients followed at the MS Center of Tor Vergata University to assess the symptomatic burden of spasticity, spasms, pain, fatigue, sleep disorders, depression, anxiety, bladder and bowel dysfunctions and sexual disturbances. The impact of each symptom on daily life was rated from 0 to 5 and symptoms $\geq 3$ were considered for the second level test and then for the analysis. Patients were also profiled according to clinical outcomes.

Results: Analysing 400 questionnaires we found that frequency of fatigue was 64%, depression 26% anxiety 31%, spasticity 33%, pain 25%, spasms 19%, bladder 37% and bowel 21% dysfunctions, sexual disturbances 27%, sleep disorders 29%. Defining SPS as the association of spasticity or spasms plus at least one symptom among pain, urinary dysfunction and fatigue, SPS was detected in 26% of patients with EDSS $\leq$2.5 and in 24% with EDSS 3-4 and 50% with EDSS

Conclusions: Our PROs-web-based questionnaire confirms the validity of SPS model in a real-life setting and provides an operative frame to assess SPS model. Moreover, our analysis shows that SPS can be found also in patients with low disability. Adoption of this self-reported SPS questionnaire in clinical practice might allow an earlier detection of SPS and prompt an innovative earlier model of care.

## PARAMAGNETIC RIM LESIONS IN NATALIZUMAB PATIENTS: PREVALENCE, INFLUENCE ON MSFC AND PATIENT REPORTED OUTCOMES

R. Nistri[1], C. Piervincenzi[1], C. Giannì[1], A. Ianniello[1], E. Barbuti[1], V. Bianchi[2], B. Pitzalis[1], E. Gangemi[1], M. Altieri[1], A. Conte[1], P. Pantano[1], C. Pozzilli[1]

[1]Department of Human Neuroscience, La Sapienza, University (Roma); [2]MS Clinic, La Sapienza University (Roma)

Background and Aims: Paramagnetic rim lesions (PRLs) have been gathered with severe disability and clinical worsening, as measured by EDSS, but their relation with Multiple Sclerosis Functional Score (MSFC), cognitive scores and patient-reported outcomes (PROs) have been poorly evaluated. Aim of this study is to assess whether presence and number of PRLs influence other clinical measures evaluating cognition and patient-reported clinical status in patients treated with Natalizumab.

Materials and Methods: This project plans to compare 50 MS patients treated with Natalizumab and 50 control patients treated with first line/oral Disease Modifying Therapies (DMTs). The study protocol consists of a multimodal 3T MRI scan including susceptibility weighted images (SWI) for the detection of PRLs. Clinical evaluation includes: EDSS, MSFC, Brief international Cognitive Assessment for MS (BICAMS), MS Impact Scale-29 (MSIS-29), EuroQol five-dimensional questionnaire (EQ-5D-3L), Fatigue Symptoms and Impacts Questionnaire-Relapsing MS (FSIQ-RMS), We here report the analysis of the first 42 patients studied (24 Natalizumab and 18 Controls).

Results and Discussion: No difference between Natalizumab and control groups was found in demographic and clinical characteristics. In the Natalizumab group PRL prevalence was 50% (12/24), while in controls was 67% (12/18), with an average PRL number of 1,1 (0-4) vs 2,1 (0-9). In the Natalizumab group, age, disease duration and EDSS, did not correlate with the number of PRLs, while patients with at least one PRL performed significantly worse at the 9-hole-peg-test with the dominant hand than those without PRL. Moreover, a bivariate analysis showed an association between PRLs' number and memory deficits detected by California Verbal Learning Test (CVT-z score).

Conclusions: In this preliminary analysis, Natalizumab seems to be associated with a less prevalence of PRLs compared to first line/oral DMTs. CVLT and 9-hole-peg-test are influenced by PRLs more than EDSS and PROs.

## (S)MIMIC STROKE: A CASE REPORT

F. Novarella[1], M. Moccia[2], M. Petracca[3], A. Spiezia[1], D. Caliendo[1], C. Di Monaco[1], V. Nicolella[1], A. Esposito[1], R. Lanzillo[1], A. Carotenuto[1], V. Brescia Morra[1]

[1]Multiple Sclerosis Clinical Care and Research Centre, Department of Neuroscience, Reproductive Science and Odontostomatology, Federico II University of Naples (Napoli); [2]Department of Molecular Medicine and Medical Biotechnology, Federico II University of Naples (Napoli); [3]Department of Human Neurosciences, Sapienza University (Roma)

Objectives: Multiple sclerosis (MS) is a disease usually characterized by an abrupt and recurrent onset of neurological symptoms, opening the scenario to differential diagnoses that can delay the start of disease modifying treatment (relapsing course). Although rarely, MS can also present as progressive disability accrual since inset, characterizing the so-called progressive phenotype. We present the case of a progressive MS patients presenting with an acute onset of neurological symptoms misdiagnosed for stroke.

Materials and Methods: P.G. 52-year-old man, MS diagnosis at age 22, on Siponimod therapy since 2020 affected by hypertension and diabetes under pharmacological treatment. The patient was a former smoker. EDSS 4 in March 2022. Previously the patient was treated with fingolimod, teriflunomide and interferon. Patient presented with a acute onset on December 2022 of dizziness that prevented the patient from standing after waking up, followed the next day by paresthesias and hyposthenia in the left hemilateral. The patient went to the emergency room, where he had a CT Scan. showing a hypodense area at the right brainstem level. Following the hypothesis that the patient may have experienced an ischemic stroke, treatment with Cardioaspirin 300 mg was set, continuing with a dosage of 100 mg in the following days. The patient then decided to request a second opinion at our MS clinical center. Brain MRI with contrast injection was performed. Two hyperintense lesions were found T2 sequences with contrast enhancement in T1: a right bulbar lesion with cercinate appearance and a punctiform lesion at the left superior frontal gyrus.

Results: Therefore, we withdraw the ischemic hypothesis, and we diagnosed MS relapse. Patient was discontinued from the antiplatelet therapy and then methylprednisone 1 gr therapy for 5 days has been administrated, followed by therapeutic switch from Siponimod to Natalizumab.

Discussion: Timely neurological differential diagnosis is essential as to not delay the appropriate therapeutic approach. Patients with MS have an increased cardiovascular risk, demonstrated in various studies in the literature. This is due to lower physical activity, to disability, and to the systemic inflammation status that characterizes autoimmune diseases.

Conclusions: Hence, given the possibility for MS patient to experience stroke, which shows in turn similar clinical manifestations there is a need for proper diagnostic algorithm and exams.

## LONG TERM EFFECTIVENESS AND SAFETY OF ALEMTUZUMAB IN A REAL LIFE COHORT OF PATIENTS WITH MULTIPLE SCLEROSIS

F. Oggiano, A. Manni, R. Vitobello, A. Bianco, T. Guerra, A. Iaffaldano, P. Iaffaldano, D. Paolicelli

Department of Translational Biomedicine and Neuroscience (DiBraiN), University of Bari "Aldo Moro" (Bari)

Objectives: Alemtuzumab (ATZ) is an anti-CD52 humanized monoclonal antibody approved for highly active Relapsing Remitting Multiple Sclerosis (RR-MS). Long term data from real world clinical setting are still missing. We aimed to assess the effectiveness and safety of ATZ in a single-centre cohort from Italy after 5 years of treatment.

Materials: In this retrospective, single-centre, real-world study we collected data of RRMS patients who received ATZ (n = 23).

Methods: Expanded disability status scale (EDSS), relapses, magnetic resonance imaging (MRI) parameters before and after ATZ were compared; serious adverse events (SAEs) were evaluated. All statistical analysis were adjusted for age, sex, MS history and previous treatment.

Results: Data of twenty-three RR-MS were collected [F=17 (73.9%); mean age 35.38±9.7years; median EDSS score 3.0 (1.5-7.0)]. All patients were followed up for a median time of 4.98 (3.5-5.9) years. Most of them (91.3%) had at least one clinical relapse in the year before ATZ, all of them showed new T2 hyperintense lesions at the baseline MRI scans, while sixteen (69.9%) showed contrast-enhancing-lesions. None of our patients was treatment naïve; most of them (91.3%) switched to ATZ after failure of more than two disease modifying Therapies (DMTs). Two patients were treated with an additional third course of ATZ, both after 18 months, for MRI activity. At the last available follow-up, nine patients (39.1%) achieved sustained No Evidence of Disease Activity-3 (NEDA-3); they didn't receive any other DMTs. Six patients (26.1%) showed improved EDSS at last follow-up. Among baseline characteristics, no predictive factors were identified for reaching NEDA3 status. The median time to first relapse was 2.1(0.17-3.1) years, the median time to another DMT initiation was 1.99 (0.25-3.2) years. Over 5 years, three SAEs were recorded: a case (4.3%) of breast cancer three years after the second course of ATZ, a case of Basedow disease and a case of HPV-related cervical cancer, both after one year from the second ATZ course.

Discussion: ATZ randomized clinical trials (RCTs), recruited treatment-naïve patients (CAMMS223 and CARE-MS I), or mostly patients at the first treatment failure (CARE-MS II). In real world, instead, as in our clinical experience, ATZ has often been proposed after failure of multiple DMTs. Nevertheless, the drug effectiveness was similar to long term data from RCTs.

Conclusion: In this real-world setting, more than one third of pwMS treated with ATZ showed sustained NEDA-3 status five years after treatment. Moreover, SAEs were comparable to RCTs experience.

## UP-REGULATION OF SERUM MIR-128-3P IS ASSOCIATED WITH LOW GREY MATTER VOLUME IN PATIENTS WITH RECENT DIAGNOSIS OF MULTIPLE SCLEROSIS

R. Orlandi, S. Bartiromo, R. Orlandi, F. Gobbin, M. Zanoni, E. Orlandi, M. Romanelli, M. Gomez-Lira, A. Gajofatto

Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona (Verona)

Background: MicroRNAs (miRs) are small non-coding RNAs that regulate gene expression at a post-transcriptional level. Different circulating miRs have recently emerged as candidate biomarkers in Multiple Sclerosis (MS); miR-128-3p has been associated with a progressive disease course in previous studies.

Objectives: To assess the association between miR-128-3p expression in serum samples of patients with MS and disease course, T2-lesion load and brain volumes in two independent groups of MS patients followed at Verona University Hospital.

Methods: We conducted a preliminary retrospective observational study on 74 MS patients (51 relapsing-remitting MS (RRMS), 10 clinically isolated syndrome, 9 primary progressive MS (PPMS), 4 Secondary Progressive MS) with an available brain MRI scan performed within 2 years from diagnosis. Subsequently, we conducted a cross-sectional study on 51 consecutively enrolled patients (33 females) aged 18-40 years recently (≤2 years) diagnosed with MS (45 RRMS, 6 PPMS). A brain MRI scan performed between 6 months before and 1 month after inclusion was mandatory. In both studies, clinical and demographic variables were collected, and T2-lesion, global brain, white matter and gray matter volumes, and presence of gadolinium-enhancing (Gd+) lesions were assessed. Levels of miR-128-3p on serum samples collected at diagnosis were detected by Real-Time PCR and expressed as ratio to miR-425-5p concentration as normalizer.

Results: In the preliminary study, serum miR-128-3p levels were higher in PPMS than in RRMS (median ratio 2.86 vs 0.73, p=0.036) and PPMS patients had an inverse correlation between gray matter volume and miR-128-3p levels (r=–0.807, p=0.009). In the cross-sectional study, serum miR-128-3p inversely correlated with global brain volume (r=–0.31, p=0.034) and gray matter volume (r=–0.31, p=0.035) in the whole cohort.

Discussion and Conclusions: Our data suggest a possible relationship between the expression of serum miR-128-3p and the extent of gray matter atrophy in MS patients, with a putative association with disease progression over time. To confirm these speculative inferences, longitudinal studies are mandatory to assess the possible role of miR-128-3p as a candidate biomarker for prediction of disease progression in MS patients.

## LONGITUDINALLY EXTENSIVE TRANSVERSE MYELITIS IN MS: A SINGLE CENTRE EXPERIENCE

S. Othmani[1], V. Floris[2], P. Zara[2], S. Leoni[3], P. Solla[3], E. Sechi[3]

[1]Unit of Neurology, Department of Medical, Surgical and Experimental Sciences, University of Sassari (Sassari); [2]Department of Medical, Surgical and Experimental Sciences, University of Cagliari (Cagliari); [3]Department of Medical, Surgical and Experimental Sciences, University of Sassari (Sassari)

Objective: The reported frequency of longitudinally extensive myelitis lesions - LEMs (i.e., spanning >3 contiguous vertebral body segments on spinal cord MRI) in multiple sclerosis (MS) varies, ranging from 0% to 32% [1]. Most prior studies, however, predate the discovery of aquaporin-4-IgG (AQP4-IgG) and myelin oligodendrocyte glycoprotein-IgG (MOG-IgG), potentially resulting in overestimation of LEMs [2]. We sought to determine the frequency of LEMs at first myelitis attack in a single-centre cohort of patients with central nervous system (CNS) demyelinating disorders.

Methods: We retrospectively identified adult (age ≥18 years) patients with CNS demyelinating disorders seen at the University-Hospital of Sassari from January 1, 2017 to December 31, 2022. Among these patients, we included those meeting the following inclusion criteria: 1) First myelitis attack; and 2) available spinal cord MRI during the myelitis attack. The frequency of LEMs was determined and classified according to the diagnosis at last follow-up.

Results: Among 336 patients with CNS demyelinating disorders consecutively seen over 6 years, 158 were included in the study: MS, 138 (88%); AQP4-IgG+NMOSD, 6 (4%); isolated myelitis, 5 (3%); MOG-IgG-associated disease, 3 (2%); and other demyelinating diseases of the CNS, 6 (4%). In total, eleven (7%) cases of LEMs were identified, in the context of AQP4-IgG+NMOSD (n=6), MOG-IgG-associated disorder (n=2), seronegative NMOSD (n=1), isolated myelitis (n=1), and relapsing-remitting MS (n=1). Thus, the overall frequency of LEMs in MS was 0,7% (1/138). The only MS patient with LEMs was a 55-year-old man who developed subacute weakness of right limbs, accompanied by numbness and gait instability. Spinal cord MRI showed a longitudinally extensive T2-hyperintense enhancing lesion extending from C2-D11. Brain MRI showed typical MS lesions. CSF analysis revealed moderate pleocytosis (29 white blood cells) and absence of oligoclonal bands; AQP4-IgG and MOG-IgG were absent in both serum and CSF by live cell-based assay. He was treated with intravenous methylprednisolone (1 g/d x 5 days) and plasma exchange with improvement. Natalizumab was started but after 12 weeks he had a new myelitis relapse and was switched to ocrelizumab with stabilization.

Discussion and Conclusions: LEMs is extremely rare among adult MS patients at first myelitis attack. Although our MS patient with LEMs met the 2017 diagnostic criteria for MS, he showed several atypical features that raise the possibility of an alternative aetiology of the myelitis.

## BIOMARKERS OF INTRATHECAL SYNTHESIS IN LATE ONSET MULTIPLE SCLEROSIS: KAPPA AND LINK INDEXES PERFORMED BETTER THAN OLIGOCLONAL BANDS

L. Paciolla[1], E. Virgilio[12], A. Bianchi[1], D. Vecchio[3], R. Cantello[1], C. Comi[4]

[1]Neurology Unit, Department of Translational Medicine, University of Piemonte Orientale (Novara); [2]Neurology Unit, "S. Croce e Carle" Hospital (Cuneo); [3]Neurology Unit, Department of Translational Medicine, University hospital "Maggiore della Carità" (Novara); [4]Neurology Unit, Department of Translational Medicine, "S. Andrea" Hospital, Department of Translational Medicine, University of Piemonte Orientale (Vercelli)

Objectives: Late-Onset Multiple Sclerosis (LOMS) includes those cases with onset above 50. Although clinical and radiological features have been increasingly described [1], insufficient data focused on pathogenetic mechanisms and fluid biomarkers. We aimed to compare biomarkers of intrathecal IgG synthesis in a cohort of relapsing-remitting (RR) patients with LOMS and adult-onset (AO) MS.

Materials: This retrospective three-center study included 70 patients (35 LOMS and 35 AOMS) who underwent lumbar puncture in their diagnostic work-up for biochemical cerebrospinal fluid (CSF) analysis and to detect CSF oligoclonal bands (OB) of immunoglobulin (Ig). Mean age at onset was 31 years old for AOMS (77% female) and 56 for LOMS (65% female).

Methods: CSF kappa-free light chains (KFLC) and CSF Ig were measured by nephelometry and used to calculate IgG and KFLC indexes. The OB detection was achieved by isoelectric focusing and immunofixation on an agarose electrophoresis system. The one-way ANOVA was used for quantitative data and the $\chi 2$ test for categorical variable.

Results: Despite the 88,6% of patients had OB+ in both groups, LOMS patients showed lower values of KFLC and IgG indexes. In fact, mean values (±standard deviation) were: for k-FLC index 53,76 (± 53,48) in AOMS versus 31,88 (±35,61) in LOMS (p=0.03); 0,75 (±0,3) for IgG index in AOMS versus 0,56 (±0,15) in LOMS (p=0.02). No differences were found in CSF KFLC and IgG values between the two groups.

Discussions: These data might suggest the presence of slight immunopathogenic phenotype difference among the two groups, specifically characterized by a lower inflammatory component in LOMS patients compared to AOMS ones. In addition, previous investigations had already revealed a faster evolution to the progressive phase of the disease and a lower Magnetic Resonance (MR) activity[2], in terms of new or enlarging T1 and T2 lesions at MR Imaging or new Gadolinium+ lesions, in LOMS patients.

Conclusions: Taken as a whole, these results emphasise the possibility of a predominance of neurodegenerative mechanisms to inflammatory ones in LOMS patients. A larger population is needed to confirm these data and draw up a complete profile of this particular subset of patients by integrating the clinical and radiological data with biological ones.

## TUMEFACTIVE DEMYELINATING LESIONS IN MULTIPLE SCLEROSIS AFTER SARS-COV-2 INFECTION: A DIFFERENTIAL DIAGNOSIS DILEMMA

M. C. Pantuliano[1], F. Motolese[1], V. Pozzilli[1], M. Rossi[1], A. Cruciani[1], C. Mallio[2], F. Pilato[1], V. Di Lazzaro[1], F. Capone[1]

[1]Neurology, Neurophysiology and Neurobiology Unit, Department of Medicine, Campus Bio-Medico University of Rome (Roma); [2]Campus Bio-Medico University Hospital Foundation, Research Unit of Radiology, Department of Medicine and Surgery, Campus Bio-Medico University of Rome (Roma)

Objectives: Herein we aim to describe an atypical case of multiple sclerosis (MS) manifested by the finding of tumefactive demyelinating lesions (TDL) resembling a primary central nervous system lymphoma (PCNSL).

Materials: A 39-year-old woman presented to the emergency department of our hospital reporting a one-week history of confusion, dysarthria and right-sided hemiparesis. She got infected by SARS-CoV-2 a few weeks before the onset of symptoms. The neurological examination also revealed brisk deep tendon reflexes, Hoffman's sign bilaterally and right Babinski's sign.

Method: Blood tests showed positive antinuclear antibodies, positive Viral Capsid Antigen and Epstein Barr Nuclear Antigen IgG. Cerebrospinal fluid (CSF) analysis showed 20 cells, mainly lymphocytes, with increased protein levels. CSF flow cytometry was not decisive. Brain magnetic resonance imaging (MRI) revealed tumefactive T2 hyperintense lesions with incomplete ring enhancement in the corpus callosum, the left caudate nucleus and internal capsule, and the right temporal pole near the ventricular horn and extending to the cortex. The spinal cord MRI was normal, while magnetic resonance spectroscopy was inconclusive. Since the radiological findings were ambiguous and cast doubt on the diagnosis of demyelinating disease over a possible diagnosis of PCNSL, a brain biopsy was performed. No tumour cells were found. After some time, the immunofixation showed the presence of oligoclonal bands (OCBs) with pattern III.

Results: After high-dose corticosteroid therapy, the patient clinically improved. Other brain MRI scans performed over six months showed stability of the findings with a reduction of contrast-enhancing lesions. A diagnosis of MS was done.

Discussion: TDL represent a rare form of demyelination defined as tumour-like lesions of the central nervous system (CNS). TDL can be associated with MS or other demyelinating diseases, although they can also manifest as an isolated disease. Distinguishing TDL from CNS neoplasms may be challenging. In our patient, the main reasons that led to a misdiagnosis were pleocytosis and the location and radiological appearance of the lesions.

Conclusions: A high index of suspicion is necessary to avoid unnecessary procedures as brain biopsy. Information pertaining to clinical history such as age, the presence of other autoimmune diseases and time of symptoms onset, as well as laboratory findings, such as the presence of OCBs, should be carefully evaluated in patients with tumefactive lesions of unknown aetiology. Besides, a recent history of viral infection - as COVID-19 in our case - should be considered as a potential precipitating factor of CNS demyelination in susceptible individuals.

## DRUG EXPENDITURE EVOLUTION IN THE MULTIPLE SCLEROSIS MARKET IN ITALY: A PROJECTION TO 2027

D. Paolicelli[1], M. Moccia[2], R. Clerici[3], D. Croce[4], M. Riccaboni[5], G. Agostoni[6], M. Mondino[7], A. Farina[7], C. Tortorella[8]

[1]Department of Translational Biomedicine and Neuroscience, University of Bari Aldo Moro (Bari); [2]Department of Molecular Medicine and Medical Biotechnology, University of Naples "Federico II" (Napoli); [3]Operative Unit of Neurology, Valduce Hospital (Como); [4]Centre for Research on Health Economics, Social and Health Care Management, LIUC-Università Cattaneo (Castellanza-VA); [5]AXES, IMT School for Advanced Studies Lucca (Lucca); [6]Market Access Department, Sanofi (Milano); [7]Medical Department, Sanofi (Milano); [8]Department of Neuroscience, San Camillo-Forlanini Hospital (Roma)

Objectives: The objective of this study was to estimate drugs expenditure evolution in the Italian Multiple Sclerosis (MS) market from 2022 to 2027, by the National Healthcare System perspective, to evaluate the system sustainability in sight of new launches (e.g., BTK inhibitors).

Materials: Model inputs integrated quantitative data sources, which included 3 different IQVIA proprietary databases (i.e., patient treated, net prices, negotiation dynamics), and qualitative sources, represented by interviews to Italian experts, both clinicians (4) and payers (2).

Methods: A predictive model with a 5-year time horizon (2022-2027) was built, combining clinical data on patients treated and economic data on net cost of each drug. Model baseline was based on the number of patients treated with each drug in 2020-2022 and current net costs of therapies. Evolution of patients treated was established applying compound annual growth rate, combined with manual adjustments derived from clinician insights. Future expenditure evolution was developed including new launches, losses of exclusivity and renegotiation of already marketed drugs. For each event, assumptions and inputs were based on analogue analyses, market insights and 2 rounds of interviews with expert. Results were validated through a final roundtable involving all stakeholders. Sensitivity analyses determined robustness of the model, varying more uncertain assumptions in an exploratory scenario.

Results: Despite treated patients' increase, Italian MS expenditure decreases from 659 M€ in 2022 to 590 M€ in 2027, with generic and biosimilar market entries having the highest impact on the reduction, followed by renegotiations of already marketed drugs. By 2027, 1L treatments (i.e., interferons, fumarates and teriflunomide) are expected to reduce their market shares from 54% to 33%, while BTK inhibitors are expected to reach 14% of the total patient shares in less than 2 years since launch. Sensitivity analyses showed good model robustness, with a difference in 2027 total expenditure of less than 10% considering assumptions in the exploratory scenario.

Discussion: Reduction of 1L treatment is in line with the clinical trend of anticipating the use of 2L treatments. Expectation of clinicians on BTK inhibitors are high: they will represent the main innovation in the MS treatment, thanks to their new mechanism of action and allowing to treat a population who currently have no treatment options (i.e., progressive patients).

Conclusions: Despite the increase in treated population and new launches, expenditure is estimated to decline over time, especially thanks to savings due to generic and biosimilar market entrance.

## ASSESSING SPATIO-TEMPORAL PATTERN OF THALAMIC DAMAGE IN MULTIPLE SCLEROSIS PATIENTS

V. Penati[1], E. Portaccio[1], C. Niccolai[1], A. Caporali[1], M. Betti[1], C. Ballerini[1], C. Fabbiani[1], R. Bonacchi[2], A. Biscarini[1], R. Tartarone[1], E. De Meo[1], E. Fainardi[1], E. De Meo[1], M. Amato[1]

[1]Careggi Hospital, University of Florence (Firenze); [2]San Raffaele Hospital, University Vita Salute San Raffaele (Milano)

Background: Thalamic atrophy is one of the earliest changes occurring during multiple sclerosis (MS) disease course. Thalamic structure is extremely complex being composed of gray matter nuclei and white matter bundles. Several pathogenetic mechanisms underlying thalamic damage have been hypothesized including Wallerian degeneration from white matter lesions and CSF-immunocytotoxic factors mediated damage.

Objectives: To identify long-term trajectories of thalamic nuclei damage and the contribution of its progression in determining clinical disability and cognitive impairment.

Methods: Using a 3T scanner, 3DT1- and T2- weighted images were obtained from 55 MS patients at disease onset and yearly for a maximum of 5 years, together with clinical and cognitive evaluation. Thalamic nuclei were segmented by using Freesurfer version 7.2.0. Algorithms of growth models by alternating conditional expectation were used to assess long term trajectories of thalamic nuclei volume changes, and linear regression models were used to assess the relationship of a progression index of thalamic damage with clinical disability and cognitive decline.

Results: Bilateral thalamic nuclei nearest to the CSF (reuniens, parafascicular, laterodorsal and pulvinar) showed a bimodal progression of volume loss, while the remaining ones showed progressive volume loss. By using growth models by alternating conditional expectation, we were able to identify an index of relative progression $\gamma$, considering the shared variance among thalamic nuclei volumes. Significant associations were observed between $\gamma$ and: clinical disability ($\beta$=0.16, p=0.03), information processing speed, verbal memory, visuo-spatial memory, and executive functions ($\beta$ from -3.38 to -0.87, p<0.001).

Conclusions: The different pattern of progression of volume loss between nuclei nearest to CSF and nuclei nearest to white matter confirm the hypothesis of heterogenous pathogenetic mechanisms underlying thalamic damage. The index identified has proven to represent a powerful tool to explain the contribution of thalamic damage to cognitive impairment and clinical disability, thus representing a potential biomarker for disease monitoring.

## IMPACT OF CYTOMEGALOVIRUS ON IMMUNOPHENOTYPE OF NATURAL KILLER CELLS AND CD8+ T LYMPHOCYTES IN MULTIPLE SCLEROSIS

V. Perri[1], M. Zingaropoli[2], P. Pasculli[2], F. Ciccone[2], A. Taglietti[2], M. Tartaglia[1], V. Baione[1], L. Malimpensa[1], G. Ferrazzano[1], A. Conte[1], C. Mastroianni[2], M. Ciardi[2]

[1]Department of Human Neuroscience, Sapienza University (Roma); [2]Public Health and Infectious Diseases, Sapienza University (Roma)

Aims: Cytomegalovirus (CMV) causes a persistent infection which may have a multifaceted impact in multiple sclerosis (MS) [1]. Many studies reported the close association between CMV and expansion of Natural Killer (NK) expressing the activating receptor NKG2C, as well as the expansion with senescent CD8+ T cells [2]. In this study we aimed to characterize the phenotype of NK cells and CD8+ T cells to evaluate the impact of CMV infection on MS progression.

Materials: At the Neuroinfectious Unit of Policlinico Umberto I Hospital, untreated MS patients and healthy donors (HDs) were enrolled and the following parameters were evaluated: sex, age, disease duration and EDSS (Expanded Disability Status Scale).

Methods: Serological diagnostic analysis were performed to evaluate CMV serostatus. For a patients subgroup, isolated peripheral blood mononuclear cells (PBMC) were examined by flow cytometry to characterize NK and CD8+ T cells phenotype. By median fluorescence intensity (MFI), NKG2C expression levels on CD56dimCD57+ NK cells were evaluated. Correlations between immunophenotype and clinical parameters were investigated.

Results: Overall, 74 MS patients (39 M/35 F) with median age [IQR] 51 [43-58], median disease duration 11 [6-19] and median EDSS score 5.0 [3.5-6.0] were enrolled. Results showed that 69% (51/74) of MS patients were CMV-seropositive. A significantly higher expression levels of NKG2C (409[274-1304], 318[195.5-424] respectively, p=0.041) and a lower T cells percentage in MS compared to HD (68.9[62.3-71.3], 75.3[70.4-78.9] respectively, p=0.001) were observed. According to CMV serostatus, CMV seropositive MS patients showed a significantly higher expression levels of NKG2C (600.5[375.5-1597], 197[0-399] respectively, p=0.008) and higher CD56dimCD57+ NK cells percentage (36.5[26.2-43.1], 20.0[10.3-30.1] respectively, p=0.021) compared to CMV seronegative MS patients. NKG2C expression levels were significantly higher in CMV seropositive MS patients compared to CMV seropositive HD subjects (600.5 [375.5-1597], 320 [210-750] respectively, p=0.022). Moreover, NKG2C levels were positively correlated with EDSS (p=0.022) and disease duration (p=0.028).

Discussion: Overall, we observed that CMV infection leads to marked changes in the immune system, mainly characterized by the expansion of adaptive NK cells expressing high levels of NKG2C activating receptor and the differentiation of specific subsets of T cells. The NKG2C expression levels significantly higher in MS patients appear to be related to EDSS worsening, suggesting a CMV detrimental role on MS progression.

Conclusions: CMV display a complex interaction with the immune system which can explain their suggested role as co-factors of immune-mediated diseases as MS. However, the role of CMV in MS immunopathology remains controversial and further studies are warranted to define a role of this virus as either culprit or protector.

## QUALITY OF LIFE AND PSYCHOLOGICAL DISTRESS IN A GROUP OF PATIENTS WITH MULTIPLE SCLEROSIS: LONG-TERM BENEFITS OF GROUP PSYCHOTHERAPY

I. Pesci[1], B. Biolzi[2], A. Guareschi[3], A. Pelosi[4], V. Nucera[2], B. Allegri Rossi[2], D. Medici[3], A. Alzapiedi[5]

[1]Department of Neurology, Ospedale VAIO di Fidenza (Fidenza-PR); [2]Psycology Unit, AUSL Parma (Fidenza-PR); [3]Neurology Unit, AUSL Parma (Fidenza-PR); [4]Scientific Disciplinary Sector Psychometrics (Parma); [5]Psicology Unit, AUSL Parma (Parma)

Quality of life and psychological distress in a group of patients with Multiple Sclerosis: long-term benefits of group psychotherapy.

Introduction: Neurological diseases are nowadays the most widespread pathological condition in the Western world, more than cardiovascular diseases and neoplasms. These are chronic, degenerative and constantly diseases but not yet curable pharmacologically. For this reason, appears more necessary than ever to implement psycho-social treatments.

Objective: The present study is aimed at analyzing how the CORE-OM test (Clinical Outcome in Routine Evaluation – Outcome Measures), a self-report questionnaire, consisting of 34 items indicated in the evaluation of the outcome in following a psychological treatment, can re-evaluate psychological distress in a group of patients attending a psychological support group.

Methods: The CORE-OM test was administered, in association with the BDI (Beck Depression Inventory), to 10 women, between 21 and 50 years olg aged, who received a diagnosis of Relapsing-remitting Multiple Sclerosis between 2004 and 2018, in charge of the Multiple Sclerosis Center of U.O. of Neurology at the Vaio Hospital. 7 patients take first-line therapies, while 3 second-line therapies and have an average EDSS (Expanded Disability Status Scale) score of 1.5. Patients have attended a psychological support group therapy, once a month. During the treatment only two patients discontinued the sessions.

Tools: The evaluation included the re-administration of the CORE-OM test (Clinical Outcome in Routine Evaluation - Outcome Measures) and BDI after the third year of treatment.

Results and Discussion: Patients who continued to attend psychotherapy group showed good compliance results with treatment, by asking to be able to continue the group therapy with more deferred sessions in time. The re-administered questionnaires confirmed low levels of psycho-emotional distress and depression.

## BRAIN RESERVE AND TIMING OF CLINICAL ONSET IN MULTIPLE SCLEROSIS

M. Petracca[1], S. Ruggieri[1], R. Nistri[2], I. Tomasso[2], S. Haggiag[3], C. Tortorella[3], C. Gasperini[3], C. Pozzilli[1], L. Prosperini[3]

[1]Department of Human Neurosciences, Sapienza University of Rome (Roma); [2]MS Center, Sant'Andrea Hospital (Roma); [3]Department of Neurosciences, San Camillo-Forlanini Hospital (Roma)

Objectives: Larger maximal lifetime brain volume (MLBV) provides a genetically determined brain reserve, being linked to lower risk for disability progression in multiple sclerosis (MS)[1,2]. Here, we explored whether such protective effect could also affect the timing of MS clinical onset.

Material and Methods: Clinical and MRI data of relapsing-remitting MS patients were retrospectively retrieved from the MS Centre databases of S. Andrea and S. Camillo Forlanini Hospitals in Rome. MLBV was computed from available 3D T1-weighted images and expressed as the reciprocal of the SIENAX volume scaling factor (with higher values corresponding to larger intracranial volume-ICV), regression-adjusted for sex. A time-to-event analysis was conducted to ascertain the effect of MLBV on the risk of an earlier disease onset. For this purpose, we carried out a Cox proportional hazards regression model stratified by sex. In this analysis, all patients reached the event (i.e., the disease onset) and there was no censored case; the age (years) at disease onset was set as the main time variable.

Results: 329 patients (229 women, 100 men) with a mean age at onset of 28.4 (SD ± 9.4) years (median 27, range 8 to 61) were included in the study. Larger MLBV exerted a protective effect on the time to disease onset: Hazard Ratio = 0.07, 95% CIs 0.01 to 0.51, p = 0.009; we obtained similar results by using a Spearman Rank correlation analysis (rho=0.15, p=0.01). Consistent findings were identified when repeating the same analysis after removing 10 patients with early-onset MS (<16 years) and 8 patients with late-onset MS (>50 years): Hazard Ratio = 0.11, 95% CIs 0.01 to 0.86, p = 0.036; similar findings were found by using a Spearman Rank correlation analysis (rho=0.11, p=0.056).

Discussion and Conclusion: The timing of MS clinical onset seems to be affected by brain reserve. Such relationship remains significant when excluding patients with age at onset at the extremes of the spectrum.

## CLADRIBINE USE IN MULTIPLE SCLEROSIS: A MONOCENTRIC REAL-WORLD EXPERIENCE

S. Pilotto, P. Mellino, D. Carmagnini, J. Frau, G. Coghe, E. Cocco, L. Lorefice

Multiple Sclerosis Center, Binaghi Hospital, ASL Cagliari, Department of Medical Sciences and Public Health, University of Cagliari (Cagliari)

Objectives: Clinical trials have shown that cladribine tablets are effective and safe in treating multiple sclerosis (MS) [1,2]. However, MS patients in clinical setting differ from those in clinical trials. Thus real-world, data is needed to understand the effectiveness of cladribine in a broader population. This study aimed to describe the efficacy of cladribine in the clinical setting for MS patients and to examine trends in drug use over five years.

Materials: This independent, retrospective, real-world monocentric study analyzed the cladribine use in 131 MS patients, classified as naïve or switchers, between 2018 and 2022.

Methods: Clinical and MRI data were evaluated, and the NEDA-3 status (no evidence of disease activity in three key areas: relapses, disability progression, and MRI activity) was determined at 12-and 24-months. Descriptive statistics and multivariate regression analysis were performed by using SPSS version 20.0.

Results: The study included 131 MS patients exposed to cladribine [98 women (74.8%)]. Of these, 6.9% were naïve, 85.5% were switchers from first-line disease-modifying therapies (DMTs), and 7.6% were switchers from second-line DMTs. During the study period, the use of cladribine increased, with an increase in naïve patients of approximately 10% in the last year of observation. A reduction in the mean age (37.2±9.1 years) and MS duration (8.8±6.8 years) at cladribine initiation was also observed, with use increasingly represented in younger people and early MS. The comparisons between annualized relapse rate (ARR) 12 months before and after cladribine, analyzed for 72 MS patients (naive and switchers), indicated a significant ARR reduction in the naive group (ARR pre 1.67±0.5 vs. ARR post 0.01±0.01, $p = 0.038$), switchers from first-line (ARR pre 0.9±0.8 vs. ARR post 0.1±0.4, $p = 0.001$) and switchers from second-line (ARR pre 1.0±0.7 vs. ARR post 0.1±0.3, $p = 0.006$). NEDA-3 status was achieved in 52/72 (72.2%) patients at 12 months and 24/33 (71.5%) at 24 months.

Discussion: In our court, cladribine is used more frequently in younger individuals with early-stage MS. When comparing the relapse rates before and after cladribine treatment, significant reductions in annualized relapse rates were observed in both naïve and switchers groups. A considerable proportion of patients achieved NEDA-3 status at both 12 and 24 months.

Conclusions: Cladribine is increasingly used in young people at an early stage of the disease with impressive impact on disease activity in both naïve and switcher patients.

## LEUKOCYTE TELOMERE LENGTH IN WOMEN WITH MULTIPLE SCLEROSIS: COMPARISON WITH HEALTHY WOMEN DURING PREGNANCY AND PUERPERIUM

S. Pilotto[1], M. Fronza[1], P. Caria[2], T. Dettori[2], D. Frau[2], J. Frau[1], M. D'Alterio[3], F. Murgia[4], S. Angioni[3], E. Cocco[1], L. Lorefice[1]

[1]Multiple Sclerosis Center, Binaghi Hospital, ASL Cagliari; Department of Medical Sciences and Public Health, University of Cagliari (Cagliari); [2]Department of Biomedical Sciences, Section of Biochemistry, Biology and Genetics, University of Cagliari (Cagliari); [3]Division of Obstetrics and Gynecology, Department of Surgical Sciences, University of Cagliari (Cagliari); [4]Clinical Metabolomics Unit, Department of Biomedical Sciences, University of Cagliari (Cagliari)

Objectives: Several studies indicated leukocyte telomere length (LTL) as a biomarker of multiple sclerosis (MS) evolution [1]. This study aimed to investigate LTL in women with multiple sclerosis (MS) compared to that in healthy women (HW) across different reproductive phases, and to evaluate its relationship with MS activity.

Materials: Blood samples of women with MS and healthy controls (HC) during fertile life, pregnancy and puerperium were collected. Short term lymphocyte culture for each individual was set up, following a standard protocol.

Methods: LTL on metaphase chromosomes, obtained from T cells in short term cultures, was determined using quantitative fluorescence in situ hybridization (Q-FISH), with Cy3-conjugated telomere PNA probe, according to the manufacturer's instructions. Thus, descriptive statistics and multivariate regression analysis were performed by using SPSS version 20.0.

Results: Blood samples from 68 women with MS (22 during fertile life, 23 during pregnancy, and 23 post-partum) and 52 HC (23 during fertile life, 20 during pregnancy, and 9 post-partum) were analysed. During pregnancy, LTL in MS women and HC was 84.7 ± 10.5kb and 77.6 ± 11.5kb, respectively ($p<0.005$). Regression analysis showed that shorter LTL was associated with pregnancy in HC ($p=0.021$); this relationship was not observed in MS women, for whom shorter LTL was related to a higher EDSS ($p=0.036$). A longitudinal analysis was performed in eight MS women, showing LTL shortening from pregnancy to puerperium ($p=0.003$), which was related to MS reactivation ($p=0.042$).

Discussion: Our analysis shown longer telomeres in MS women during pregnancy than in HC at the same stage and age. This could be partially explained by considering the protective action on MS activity played by immune system changes during pregnancy [2]. An inverse association between pregnancy status and LTL independently of age was found in HC and evidence suggests that pregnancy might be associated with telomeres shortening given an increased turnover-cells status [3]. Additionally, we reported an inverse association between LTL and EDSS score in MS women, independently of disease duration, age and biological stage. A cumulative effect played by the same risk factors on both MS progression and LTL shortening leading to oxidative stress might be considered [1]. Moreover, a longitudinal analysis shown that telomeres of MS women shortened after pregnancy, and this was associated with a return of clinical relapses.

Conclusions: Our results highlight the possible associations between LTL, reproductive biological phases, and MS activity after delivery.

## PEDIATRIC ONSET MULTIPLE SCLEROSIS IS ASSOCIATED TO FATHER'S SMOKING STATUS AND TO FATHER HAVING SMOKED PRIOR TO PREGNANCY OF STUDY CHILDREN: THE PEDIGREE STUDY

S. Pilotto[1], M. Fronza[1], M. Simone[2], Y. Vaia[3], S. Bova[3], A. Gallo[4], G. Tedeschi[4], R. Lanzillo[5], V. Brescia-Morra[5], M. Amato[6], E. Cocco[1], M. Trojano[7], F. Martinelli-Boneschi[8], S. D'Alfonso[9], A. Ghezzi[9], R. Bergamaschi[10], M. Pugliatti[11]

Objectives: Investigating the role of environmental exposures in determining multiple sclerosis (MS) in adults is hampered by long latency, potential for recall bias especially with regards to perinatal exposures. We aimed to investigate whether one such environmental factor, i.e., exposure to cigarette smoking, is associated to pediatric onset MS (POMS) in an Italian population.

Materials and Methods: The PEDiatric Italian Genetic and enviRonment ExposurE Study (PEDIGREE) aims to investigate the independent and interactive role environmental exposures and genetic asset in predisposing children (<18 years of age) to develop MS. The PEQ-IT questionnaire was used to prospectively collect environmental and perinatal exposures [1].

Results: Preliminary results are presented based on 88 children, 58 with MS and 30 controls, 22(25,0%) males and 66(75,0%) females, with mean (SD) age of 14,7 (2,8) years at study time (no difference by sex nor status) and mean (SD) age at MS clinical onset of 12,1 (3,3) years (no difference by sex). Mean(SD) disease duration between clinical onset and study time was 2,6(2,0) years (no difference by sex). Median EDSS was 1 (range 0,0-4,0) at study time (no difference by sex). More cases (14,3%) than controls (3,6%) were exposed to cigarette smoking at home (p=0,230). No association based on mother's smoking status was observed (p=0,274), nor with mother having smoked during pregnancy of participants (7,5% of cases vs. 3,3% of controls were smokers, p=0,438), or before pregnancy (5,6% of cases vs. 0% of controls were smokers, p=0,549). A significant crude association was observed with father's current smoking status, i.e, 76,5% in cases vs. 41,4% in controls, p=0,002; p-trend=p=0,002; OR=4,60 (95%IC 1,72, 12,30) as well as with father having smoked before pregnancy, i.e., 58,0% in cases vs. 26,7% in controls, p=0,010, p-trend=0,007, OR=3,80 (95%IC1,42, 10,17). These associations remained significant even after adjusting for father's educational level at participants' birth: OR=4,72 (IC95% 1,37, 16,23; p=0,014), and OR=4,27 (95%IC 1,18, 15,44; p=0,027), respectively.

Discussion: Our findings are in line with those from a case-control study conducted on 129 MS cases from the French KIDSEP neuropediatric cohort and 1,038 controls showing a 2-fold increased exposure and dose-response effect in POMS [2]. Second hand smoking was 3.7-fold more common in POMS than in monosymptomatic acquired demyelinating syndrome if associated to HLA-DRB1*15 [3].

Conclusions: POMS was over 4-fold associated to father's active current smoking status and over 3-fold with father having smoked prior to pregnancy. No association was observed with mother's smoking status ever.

## MENOPAUSAL TRANSITION IN MULTIPLE SCLEROSIS: RELATIONSHIPS WITH DISEASE ACTIVITY AND BRAIN VOLUME MEASUREMENTS

G. Pisano[1], S. Pilotto[1], G. Fenu[2], M. Fronza[1], J. Frau[1], G. Coghe[1], V. Sechi[3], M. A Barracciu[3], E. Cocco[1], L. Lorefice[1]

[1]Department of Medical Sciences and Public Health, Multiple Sclerosis Center, Binaghi Hospital, Ats Sardegna, University of Cagliari (Cagliari); [2]Hospital Brotzu, AOB Cagliari (Cagliari); [3]Radiology Unit, Binaghi Hospital, Ats Sardegna, University of Cagliari (Cagliari)

Background: The role of menopause in influencing multiple sclerosis (MS) trajectories represents a controversial issue. Recent evidence has shown a significant association between menopause and MS progression (Lorefice L, 2023); however, the impact of this hormonal transition on MRI findings is still poorly explored. This study investigates the possible role of menopause in influencing MS from clinical and neuroradiological perspectives. In particular, the possible association between menopause and brain atrophy has been explored.

Materials and Methods: The study included MS women of ages ranged 45-55 years. Demographic and clinical characteristics were collected, and the reproductive phase, defined as fertile, perimenopausal, and postmenopausal (Santoro N., 2005) was defined for each patient. Thus, MS activity over the past year, reported as annualized relapse rate (ARR), and MRI activity (defined as new T2 lesions and/or the presence of gadolinium-enhancing lesions) were compared between women in fertile phase and menopause. Brain volume measurements of the whole brain (WB), white matter (WM), grey matter (GM), and cortical GM were estimated using SIENAX (Smith SM, 2002) and the possible relationship with menopausal status was assessed by regression analysis.

Results: The analysis included 147 MS women. Eighty-four (57.1%) patients were menopausal, with a mean age at menopause onset of 48.5

± 4.3 years, and mean duration of menopause of 4.1 ± 1.1 years. When compared for ARR, menopausal patients reported a lower rate than the non-menopausal group (ARR of 0.29 ± 0.4 versus 0.52 ±0.5, respectively; p<0.01). Lower MRI activity, observed respectively in 13.1% of menopausal and 20.6% of non-menopausal patients was observed (p=0.03). Lower cortical GM volumes (578.1 ± 40.4 ml in menopausal patients versus 596.9 ± 35.8 ml in non-menopausal group; p<0.01), have also been reported. Finally, multivariate analysis showed a significant association between lower ARR (p=0.001) and cortical GM volume (p=0.002) with menopausal status after correction for age and other variables.

Discussion: Menopause may represent an adverse prognostic factor for MS progression. Our preliminary results suggest that menopause could facilitate cortical GM atrophy, probably due to the decline of the neuroprotective effects of estrogens, with subsequent shift into a more progressive phase of the disease.

## MISMATCH BETWEEN PERCEIVED COGNITIVE IMPAIRMENT AND REAL COGNITIVE PERFORMANCES IN PATIENTS WITH MULTIPLE SCLEROSIS

F. Pistoia[1], C. Raparelli[2], L. Evangelista[2], G. Saporito[1], F. Barbone[2], R. Totaro[2]

[1]Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila (L'Aquila); [2]Department of Neurology, Demyelinating Disease Center, San Salvatore Hospital (L'Aquila)

Objective: The aim of this study was to investigate the mismatch between perceived cognitive impairment and real cognitive performances in patients with multiple sclerosis (MS).

Materials and Methods: A cohort of patients with MS, referring to the Demyelinating Disease Center of L'Aquila from March 2022 to February 2023 was investigated through the Brief Repeatable Battery of Neuropsychological Tests (BRB-N) and the Perceived Cognitive Deficit (PCD) questionnaire, a 11 item self-reported assessment tool exploring the patient perceived degree of cognitive impairment in 6 major cognitive domains (verbal memory, visuo-spatial memory, learning, sustained attention and concentration, speed of information processing, and verbal fluency). The PCD answers, reported on the 5-degree scale, were further converted into dummy variables (yes/no) according to low (grade 1-3) or high (grade 4-5) self-perception of cognitive impairment. Domain-specific perceived cognitive scores were correlated with BRB-N subtests scores exploring verbal memory, visuo-spatial memory, learning, sustained attention and concentration, speed of information processing and verbal fluency. Data were analyzed through descriptive statistics and using the weighted Cohen's kappa (Kw) coefficient to evaluate the rate of agreement between the variables.

Results: 119 patients were included (86 women and 33 men; mean age±SD, 46.8±12.1, minimum 16 years, maximum 67 years, average years of schooling 14.2 years). The most frequent clinical form was relapsing-remitting (RR) MS (n=93; 78%), followed by secondary-progressive (SP) MS (n=26; 22%). Mean disease duration was 10.9±8.9 years for the whole group, 10.1± 8.3 years for RR-MS patients and 14.5±10.2 for SP-MS patients. One hundred and ten patients were treated with disease modifying drugs (Fingolimod n=27, Natalizumab n=21, Dimetil-fumarato n=17, Teriflunomide n=16, Ocrelizumab n=12, Siponimod n=11, Ofatumumab n=2, Interferone Beta n=2, Alemtuzumab n=1, Cladibrina n=1). The Kw coefficient was low for all the cognitive domains explored [verbal memory: Kw 0.10 (95% CI -0.05-0.31), visuo-spatial learning: Kw 0.18 (95% CI -0.02-0.38), learning deficit: Kw 0.18 (95% CI -0.02-0.38), sustained attention and concentration: Kw -0.008 (95% CI -0.15-0.19), speed of information processing: Kw 0.23 (95% CI 0.09-0.31), verbal fluency: Kw 0.01 (95% CI -0.18-0.23). There was a general trend to underestimate the real cognitive deficit in all domains, except for verbal fluency whose impairment was usually overestimated.

Discussion: For most of the cognitive domains explored, a poor agreement between subjective perceived cognitive impairment and real cognitive skills was recognized.

Conclusions: Discrepancy between perceived cognitive impairment and real cognitive performances should be carefully considered, as potentially interfering with well-being and productivity of patients.

## INCREASED SERUM MARKERS OF NEURONAL AND GLIAL DAMAGE IN PATIENTS WITH HEREDITARY OPTIC ATROPHIES

D. Plantone[1], D. Righi[1], S. Locci[1], G. Primiano[2], A. Bargagli[1], R. Cortese[1], M. L. Stromillo[1], N. De Stefano[1], A. Rufa[1]

[1]Dept of Medicine, Surgery and Neuroscience, University of Siena (Siena); [2]Department of Neuroscience, University Cattolica del Sacro Cuore (Roma)

Objectives: Non-syndromic hereditary optic neuropathies are neurodegenerative disorders of the optic nerve, resulting in central vision loss and optic atrophy. The main forms are autosomal dominant optic atrophy (ADOA) caused by OPA1 gene mutations, and Leber hereditary optic neuropathy (LHON) due to pathogenic mtDNA variants inherited maternally. Both conditions typically affect young adults, presenting as bilateral, painless, subacute central vision loss. Neurofilament light chain (NfL) and glial fibrillar acidic protein (GFAP) are well-established biomarkers that indicate neuroaxonal and glial injury, respectively. Growth/differentiation factor-15 (GDF-15), a member of the transforming growth factor β superfamily, represents a valuable biomarker of primary mitochondrial diseases caused by defects in mitochondrial translation machinery and mtDNA maintenance. The aim of this study is to assess whether levels serum NfL (sNfL), sGFAP and sGDF-15 are elevated in a cohort of 12 patients with ADOA and 8 patients with LHON when compared with a cohort of 20 age-, sex- and BMI-matched healthy controls (HCs).

Materials and Methods: Blood samples were collected and serum aliquots were stored at −80°C until assay. SNfL, sGFAP and GDF-15

levels were assessed in each serum sample of patients and controls. We used the commercially available immunoassay kits for GFAP and NfL run on the ultrasensitive SR-X™ Biomarker Detection System (Quanterix) following manufacturer instructions. GDF-15 was assessed using Abcam's GDF-15 Human ELISA kit, according to the manufacturer's instructions.

Results: sNfL levels were higher in both ADOA [median sNfL (pg/ml) 31.87, IQR 10.20-60.70] and LHON patients [median sNfL (pg/ml) 27.32; IQR 11.18-50.43] than HCs [median sNfL(pg/ml) 6.78; IQR 5.34-8.25] ($p<0.001$ for both). sGFAP levels were higher in ADOA patients [median sGFAP(pg/ml) 76.99, IQR 64.80-121.35] compared to HCs [median sGFAP(pg/ml) 47.53 IQR 25.57-72.21, $p=0.010$] and were within the normal ranges in LHON. Finally, GDF-15 levels were higher in LHON patients [median sGDF-15 (pg/ml) 896; IQR 514-1181] compared to HCs [median sGFAP (pg/ml) 454; IQR 278-682, $p = 0.033$]. No difference was found by comparing ADOA patients with the other two groups.

Discussion and Conclusions: The observed elevation of sNfL in both ADOA and LHON patients indicates that neuro-axonal degeneration is a shared characteristic of these diseases. Interestingly, the increased levels of sGFAP suggest a significant activation of astrocytes in ADOA. This finding aligns with previous studies conducted on animal models, where the presence of a mutant Opa1 gene was associated with the loss of retinal ganglion cells, accompanied by activation of astrocytes and microglia.

## INCIDENT EPILEPSY IN MULTIPLE SCLEROSIS: A META-ANALYSIS OF RANDOMIZED CLINICAL TRIALS

V. Pozzilli[1], C. Tortorella[2], A. Cruciani[1], S. Haggiag[2], C. Gasperini[2], F. Capone[1], V. Di Lazzaro[1], L. Prosperini[2]

[1]Unit of Neurology, Neurophysiology and Neurobiology, University Campus Bio-Medico (Roma); [2]Department of Neurosciences, San Camillo Forlanini Hospital (Roma)

Objectives: Epilepsy is reported to be more common in patients with multiple sclerosis (pwMS) compared to the general population, especially in those with advanced disability and progressive disease course, albeit with heterogeneous data across studies. Cortical/iuxtacortical lesions and brain atrophy are well-recognized pathological substrates associated with seizures in pwMS. However, available data about epilepsy in MS is mainly derived from observational studies, therefore susceptible to selection bias. The objective of the present study is to verify the hypothesis of an increased incidence of epilepsy in pwMS and find the associated risk factors.

Materials: A total of 62 RCTs, with the pooled cohort consisting of 53,705 patients with an average follow-up of 2 years, yielding 105,818 patient-years were considered for data extraction.

Methods: An extensive literature was performed to extract rates of adverse events (i.e. seizure, epilepsy, or convulsion) from phase 3 randomized clinical trials (RCTs) in pwMS with more than 18 years of age, and a duration equal to or above 48 weeks. A random-effect model was fitted to estimate the pooled incidence rate of seizures (effect size) in all study populations, regardless of arm allocation. Variables (moderators) affecting the pooled effect size were analyzed through meta-regressions. Given the rarity of the events of interest, estimates were inserted in equations as double arcsine transformed incidence rates.

Results: The pooled incidence rate for a new onset seizure was 34 (95% confidence intervals: 23 to 45) per 100,000 patient-years. Reporting of events of interest increased over the years (Beta = 0.06, $p = 0.031$). After correcting for the calendar year, higher incidence rates were observed in studies that enrolled patients with either a secondary progressive course (Beta = 0.043, $p = 0.005$), a greater EDSS (Beta = 0.042, $p = 0.019$), or a lower normalized brain volume (Beta = -0.24, $p = 0.028$). Out of 68 total events, 44 occurred in RCTs on sphingosine-1-phosphate agonists (S1Pa), resulting in an increased risk in treated arms versus placebo or the active comparator (odds ratio = 2.5, $p=0.018$).

Conclusion: Our study confirms a higher incidence of epilepsy in pwMS (34 versus 23-31 patient-years in the general population aged 30-60 years) and shows an association between incident epilepsy and both neurological disability and brain atrophy. Moreover, S1Pa would result in potentially epileptogenic agents, which needs further confirmation.

## CONVENTIONAL VERSUS ROBOTIC ASSESSMENT OF POSTURAL AND BALANCE DISORDERS IN MILD TO MODERATE DISABILITY MULTIPLE SCLEROSIS PATIENTS

A. Quaglia[1], A. Aleo[2], L. Venturi[3], S. Pozzi[3], L. Sabattini[4], A. Lugaresi[4]

[1]IRCCS Institute of Neurological Sciences Bologna, Bologna University (Bologna); [2]University of Bologna, School of Medicine and Surgery (Bologna); [3]DATeR Hospital Rehabilitation, Ospedale Bellaria, UOSI Multiple Sclerosi Rehabilitation (Bologna); [4]IRCCS Institute of Neurological Sciences Bologna, UOSI Multiple Sclerosis Rehabilitation, Ospedale Bellaria (Bologna)

Objective: To quantitatively assess balance disorders in Persons with Multiple Sclerosis (PwMS).

Material: Seventy adult PwMS and mild (EDSS 0-3.5, group A) to moderate (EDSS 4-6.5, group B) disability were recruited.

Method: Clinical assessment was through the robotic device (Hunova®) and the Berg Balance Scale (BBS), Timed Up and Go (TUG), 10 Meter Walk Test (10MWT), Activity Balance Confidence (ABC), Modified Fatigue Impact Scale (MFIS).

Results: The sample population consisted of 46 females and 24 males, mean age 49.27. 37 patients were included in group A (mean EDSS 2.5, mean age 46.29) and 33 patients in group B (mean EDSS 5.0, mean age 52.6). In the descriptive analysis, the clinical scales and instrumental assessment parameters (Hunova) were compared between the 2 groups; the variables were crossed with each other using the Mann-Whitney test for comparison. The most accurate indicators of a balance disorder are: the amount of trunk movement (P-value = 0.0001), the anteroposterior (P-value = 0.0009) and mediolateral

(P-value = 0.0040) sway range with eyes closed, the sway area with eyes closed and open in static balance; the amount of trunk movement (P-value = 0.0079) and mediolateral eyes open sway movements (P-value = 0.0016) in passive balance; the range of mediolateral trunk sway (P-value = 0.038) and forward stabilization time (P-value = 0.038) in "Reactive Balance"; the duration (P-value = 0.008) and rise and sit times (P-value = 0.0015) of the "Five times Sit to Stand test" (5TST). In most clinical trials, such as in the TUG and the T10MWT, the median value recorded in group A is lower than in group B, because they are mutually concordant scales; BBS performs better in group A (median value 56 out of 56) than in group B (median value 49.5 out of 56) and is discordant with EDSS because it has an inverted scale as ABC.

Discussion: Robotic assessment resulted superior to conventional scales especially in slightly impaired PwMS.

Conclusion: Assessment of stabilometric indicators has proven useful in detecting alterations in postural control as early as in unperturbed standing, even in the absence of neuro-motor and balance dysfunction (top BBS score). The robotic platform, with its greater sensitivity, shows the best performance in assessing postural changes in the early phases of MS and might allow pre-clinical identification and rehabilitation of balance disorders.

## SEXUAL AND SPHINCTER DYSFUNCTIONS IN PEOPLE WITH MULTIPLE SCLEROSIS: ASSOCIATIONS WITH CLINICAL FEATURES AND IMPACT ON QUALITY OF LIFE

C. Redemagni, E. Tavazzi, E. Colombo, E. Rigoni, R. Bergamaschi, L. Ahmad

Foundation IRCCS Neurological Institute C. Mondino (Pavia)

Background and Purpose: Sexual and sphincter dysfunctions (SSD) in people with multiple sclerosis (pwMS) are common but underestimated despite their relevant impact on quality of life. The objective of the study was to analyse SSD in a group of pwMS and evaluate their association with clinical features.

Materials and Methods: PwMs were enrolled and asked to respond to self-administered questionnaires investigating sphincter functions (Wexner scales, Neurogenic bowel dysfunction score-NBD; Constipation Scoring System-CSS; Actionable Bladder Symptom Score-ABSS), sexual functions (MS Intimacy and Sexuality Questionnaire-MSISQ-15; Female Sexual Function Index-FSFI-and the McCoy Female Sexuality Questionnaire-MFSQ for females International Index of Erectile Function-IIEF-15 for males) and quality of life (MS quality of life 54-MSQOL-54). A logistical regression model was used to identify correlation between EDSS, sex, age and SSD.

Results: 217 pwMS (154 females and 63 males; mean age 45.2-11.3 years) were recruited in the study. The following clinical features were collected: disease duration (12.9-9.2 years), disease phenotype (197 RRMS, 20 PMS), median EDSS (1.5, IQR 1-2.5). EDSS was significantly associated with disease duration (p<.005), MSQoL-54, MSISQ-15, FSFI, all the sphincter-related scales (all p<.001) and MSFQ-sexual (p<.009), whereas there was no statistical association between EDSS and IIEF-15. The correlation was still significant after correcting for age and sex, except for Wexner and FSFI. Disease duration was significantly associated only with ABSS (p=.04), FSFI, MSFQ (all p<.001). After correcting for sex and age, disease duration was significantly associated with MSISQ-15 (p<.05) FSFI (p=.02) and showed a trend towards significance with IEF (p=.06). A significant correlation was observed between the presence of sexual dysfunction (MSISQ-15) and all scales related to sphincter disorders (p< 0.001). A worse quality of life (MSQoL54) was significantly associated with higher degree of both sexual and sphincter dysfunctions (all p<.001). When comparing females to males, the formers reported significantly higher level of sexual (MSISQ-15) and sphincter disorders (Wexner, ABSS, CSS, NBD) and significantly lower quality of life in both physical and mental components of the scale.

Conclusions: Our findings confirm the relevance of both sphincter and sexual disorders in pwMS and their significant impact on quality of life. Sexual and sphincter dysfunctions are strongly associated, leading to hypothesize a common anato-functional origin. A higher disability and female sex are risk factors for developing SSD. This study highlights the importance of investigating sex and sphincter functions with proper scales, considering their clinical and socio-psychological impact in pwMS.

## VALIDATION OF SMAC (SCLEROSI MULTIPLA AUTOVALUTAZIONE COGNITIVA): NORMATIVE DATA IN THE ITALIAN POPULATION

A. Riccardi[1], V. Pucci[2], I. Meglioranzi[3], E. Carta[4], S. Mattivi[5], F. Barbadoro[6], M. Mascia[4], G. Scialpi[5], M. Puthenparampil[5], P. Perini[7], F. Rinaldi[7], E. Cocco[4], S. Mondini[2], P. Gallo[5]

[1]Multiple Sclerosis Centre, Department of Neuroscience, University Hospital of Padua, University of Padua (Padova); [2]Department of Philosophy, Sociology, Education and Applied Psychology, Human Inspired Technology Center, University of Padua (Padova); [3]Neurosciences Unit, Department of Medicine and Surgery, University of Parma (Parma); [4]Multiple Sclerosis Centre, ASL Cagliari, University of Cagliari (Cagliari); [5]Multiple Sclerosis Centre, Department of Neuroscience, University Hospital of Padua (Padova); [6]Neurology, Public Health and Disability Unit, Coma Research Centre, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [7]Multiple Sclerosis Centre, University Hospital of Padua (Padova)

Objectives: We have previously reported the results of a pilot study suggesting that SMAC could be a promising patient-reported outcome

to evaluate Multiple Sclerosis patient's perspective on their cognitive status (Riccardi et al., 2022). Aim of this work is to provide normative data for the Italian population of SMAC.

Materials: Participants were asked to fill out an online version of SMAC, a 25-item questionnaire that requires about five minutes to be completed.

Method: A sample of 1445 healthy controls (HC) equally distributed for age (mean age= 44.9± 19.3 years), gender (F/M=1:1) and education (mean =14.7±4.6 years) was enrolled in the study. Psychometric properties were calculated, and the best cut-off point was identified via ROCs, comparing the performance of HC with a sample of 130 matched MS patients (mean age=43.4±11.9; mean education=13.2±3.8; F/M=4:1).

Results: The internal consistency was very high (Cronbach's alpha=0.9). Regression analyses showed gender and education significant in predicting SMAC scores. In particular, higher scores were related to education and female gender. ROCs' analysis identified 35.5 as the best cut-off score in distinguishing patients and healthy controls, with a sensitivity of 66% and a specificity of 77% (Area Under the Curve=0.7). The Item Response Theory showed that all items detect the presence of subjective cognitive complaints (Beta range=0.8-1.7).

Discussion: SMAC showed a high internal consistency proving excellent reliability in the evaluation of the construct. Furthermore, SMAC demonstrated good sensitivity and specificity in detecting individuals with subjective cognitive complaints, highlighting its potential in clinical practice.

Conclusions: We provide SMAC normative data for the Italian population. Integrated with a thorough evaluation of psychological and neuropsychological status, SMAC help clinicians to understand the real impact of cognitive decline in MS patients.

Objectives: CogEx is a multi-site, blinded, randomized, sham-controlled trial, aimed at determining if cognitive rehabilitation (CR) and aerobic exercise (EX) are effective in people with progressive (P) multiple sclerosis (MS), and if combining CR and EX has synergistic effects. Here, we present the results of CogEx trial on MRI measures of lesions and atrophy.

Materials and Methods: Participants were randomized (1:1:1:1) to following arms: "CR plus EX", "CR plus sham EX (EX-S)", "EX plus sham CR (CR-S)", and "CR-S plus EX-S" and attended 12 weeks of intervention. Physical and cognitive (BICAMS battery) assessments were performed at baseline, immediately after intervention (week 12) and 6 months post-intervention. Participants in the MRI sub-study underwent MRI scans at the same time points. T2 lesion volume was quantified and new T2 lesions vs previous scans were counted. Normalized brain (NBV), grey matter (NGMV), cortical grey matter (NcGMV) and white matter (NWMV) volumes (FSL SIENAx), normalized thalamic and hippocampal volumes (FSL FIRST) and percentage brain volume change (FSL SIENA) were obtained. Changes of NGMV, NcGMV, NWMV, thalamus and hippocampus were calculated as percentage differences vs previous scans.

Results: 104 PMS people participated in the CogEx MRI substudy ("CR plus EX": n=25; "CR plus EX-S": n=28; "CR-S plus EX": n=25; "CR-S plus EX-S": n=26). At week 12, the number of correct responses at Symbol digit modalities test (SDMT) (p=0.64) were not significantly different among groups, nor SDMT (p=0.67), California verbal learning test (CVLT) (p=0.19) and Brief visuospatial memory test (p=0.92) Z-scores. While the time-by-group interaction for changes at week 12 vs baseline of NGMV (p=0.10) and NcGMV (p=0.09) were not statistically significant, the interactions for both NGMV (p=0.04) and NcGMV (p=0.02) were significant when considering groups performing CR vs those performing CR-S. In groups performing CR, increased NGMV (r=0.42, p=0.004) and NcGMV (r=0.36, p=0.01) at week 12 vs baseline correlated with increased CVLT. No significant differences were found for the remaining MRI variables.

Discussion: Results of the CogEx study did not show any significant synergistic effect of CR and EX on cognitive performances or structural MRI measures of PMS people. However, there was some evidence of an association between increased cortical volume and improved CVLT scores in the two groups undergoing CR.

Conclusion: CR modulated cortical GM volumes in PMS patients and correlated with concomitant improvements of cognitive performances.

## LONGITUDINAL CHANGES OF FUNCTIONAL CONNECTIVITY DYNAMISM ARE RELEVANT FOR DISABILITY WORSENING AND COGNITIVE DETERIORATION IN MULTIPLE SCLEROSIS: A 2.5-YEAR STUDY

M. A. Rocca[1], P. Valsasina[1], G. d'Amore[1], M. Margoni[2], P. Preziosa[3], M. Filippi[4]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [2]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute (Milano); [3]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [4]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: Aim of this study was to investigate changes over time of time-varying functional connectivity (TVFC) at 2.5-year follow-up in patients with multiple sclerosis (MS), and their association with clinical and cognitive worsening.

Materials and Methods: 3T magnetic resonance imaging (MRI) scans and clinical evaluations were obtained at baseline and at median follow-up of 2.5 years from 28 right-handed healthy controls (HC) and 129 MS patients. Of these, 79 patients also underwent baseline and follow-up neuropsychological assessment. At 2.5-year follow-up, MS patients were classified as clinically and cognitively stable/worsened according to disability and neuropsychological score changes. TVFC maps were produced by assessing the coefficient of variation across sliding-windows of degree centrality.

Results: At follow-up, 25/129 (19.3%) MS patients worsened clinically and 14/79 (17.7%) worsened cognitively. MS patients showed reduced baseline TVFC vs HC in orbitofrontal ($p<0.05$, corrected), cerebellar, precuneal and thalamic regions. At 2.5-year follow-up, a widespread reduction of TVFC over time ($p<0.05$, corrected) was found both in clinically and cognitively stable MS patients, especially in temporal, parietal, occipital and cerebellar lobes. Clinically and cognitively worsened MS presented TVFC reductions in default-mode network regions. Clinically worsened MS also exhibited peculiar TVFC reductions in the basal ganglia. Reduced TVFC over time in the left putamen in clinically worsened vs stable, and reduced TVFC in the right precuneus in cognitively worsened vs stable MS patients were significant at time-by-group interaction analysis.

Discussion: Overall, MS patients were characterized by decreased TVFC over 2.5-year follow-up. However, while stable MS patients presented TVFC reductions predominantly in sensorimotor and associative cortices of temporal, parietal and occipital lobes, clinically and cognitively worsened MS patients exhibited reduced TVFC over time in areas of the default-mode network. In addition, reduced connectivity dynamism in deep grey matter characterized clinically worsened MS, while precuneus involvement characterized cognitively worsened MS patients.

Conclusions: TVFC reductions in deep grey matter and precuneal regions may represent useful biomarkers to predict and monitor cognitive and clinical disability accumulation in MS.

## LONG TERM IMMUNOLOGICAL EFFECTS OF MS DISEASE-MODIFYING TREATMENTS: PATIENTS SWITCHING FROM A S1P MODULATOR TO OCRELIZUMAB OR NATALIZUMAB

A. Rolando[1], S. Marasciulo[1], C. Bosa[1], P. Garelli[1], P. Cavalla[2], M. Vercellino[2]

[1]Department of Neurosciences "Rita Levi Montalcini", University of Turin (Torino); [2]Department of Neurosciences "Rita Levi Montalcini", AOU Città della Salute e della Scienza, Molinette Hospital (Torino)

Objectives: To assess any differences in absolute lymphocyte counts and lymphocytes subpopulations in patients switching to ocrelizumab or natalizumab from a S1P modulator (fingolimod), in comparison with patients switching from another DMT and with naive patients, with a follow-up up to 48 months.

Materials: We identified 25 ocrelizumab patients switched from fingolimod vs 159 ocrelizumab patients naive or switched from other DMTs, and 20 natalizumab patients switched from fingolimod vs 132 natalizumab patients naive or switched from other DMTs. Methods: retrospective observational study of patients switching from S1P modulator (fingolimod) to ocrelizumab or natalizumab, in comparison with patients switching from another DMT to ocrelizumab or natalizumab and with naive patients starting ocrelizumab or natalizumab. Absolute lymphocyte counts and lymphocytes subpopulation were analyzed, at baseline (pre switch), and post switch at 12 months, 24 months and 48 months.

Results: Lower absolute lymphocyte counts and lower CD4+ lymphocytes counts were observed, at all time points, in ocrelizumab patients switched from fingolimod vs ocrelizumab patients naive or switched from other DMTs (with the highest difference, at all time points up to 48 months included, with patients switched from natalizumab). Number of CD8+ lymphocytes and NK lymphocytes were instead not significantly different, except at baseline (with a lower baseline number in patients switching from fingolimod). Lower absolute lymphocyte counts were also observed, at all time points, in natalizumab patients switched from fingolimod vs natalizumab patients naive or switched from other DMTs.

Discussion: Scarce data are available on the potential long term effects on the immune system of DMTs used in MS. Switching among DMTs is frequent in MS, for safety or efficacy, and frequently MS patients can be exposed to multiple DMTs in sequence over time. S1P modulators are widely used in MS and the results of our study demonstrate their long term immunological effects in MS patients up to 4 years after therapy switch.

Conclusion: A persistence of immunological effects of S1P modulators exposure, with lower absolute lymphocytes number and lower CD4+ lymphocytes number, is still observed after 4 years from fingolimod discontinuation after switching to ocrelizumab or natalizumab.

## NURSING APPROACH DURING SHORTER AND CONVENTIONAL INFUSION OF OCRELIZUMAB: A SINGLE CENTRE EXPERIENCE

E. T. Roldan[1], S. Crisafulli[1], P. Confalonieri[1], V. Torri Clerici[1], C. Antozzi[1], C. Bossi[2], R. Mantegazza[1], L. Brambilla[1]

[1]Department of Neuroimmunology, Neurological Institute C. Besta IRCCS Foundation (Milano); [2]Department Clinical Neurosciences, Neurological Institute C. Besta IRCCS Foundation (Milano)

Aim: Ocrelizumab is an anti-CD20 antibody approved for Multiple Sclerosis administered intravenously (iv) as two initial 300mg doses and subsequent 600mg doses every 6 months. For the latter, two infusion rate protocols are approved: a conventional infusion (CI, approx 3.5 hours) and a short infusion (SI, approx 2.0 hours). SI was employed to patients who did not experience significant events in previous infusions. Iv administration requires supervision by nurses to monitor infusion related reactions (IRRs). We compared the IRRs rate, type and severity during SI versus CI, to consider changes in the current monitoring protocols.

Material: We enrolled 79 patients who received one ocrelizumab 600mg SI from 2016 to 2022 at Carlo Besta Neurological Institute, as currently recommended.

Methods: We monitored blood pressure, heart rate and temperature every 15 minutes during the first hour and then every 30 minutes till infusion end. IRRs were defined as adverse events related to drug administration occurring during the infusion or up to 24h after. 5 covariates were considered for formal test hypothesis: age at ocrelizumab start, sex, comorbidity, previous MS treatments, IRRs at first cycle (300mg).

Results: 79 patient received 452 infusions (158 300mg, 215 CI, 79 SI). The mean CI duration was 233.02 ± 26.44 minutes; 145.7 ± 27.57 for SI. The overall IRRs rate was 0.23, all were grade 1 ore 2 and resolved without sequalae. IRRs were: throat irritation (60%), skin rash (14%), tachycardia (5,7%), significant blood pressure change (2.8%), fever (1.9%). IRRs rate was higher during the first 300mg administration (0.43) than during the second one (0.11). IRRs rates at CI and SI were similar (0.18; OR 0.91, 95% CI 0.34 - 2.43). Only the occurrence of IRRs at the first cycle was associated with increase IRR risk at SI (OR 11.20 95% CI 2.17 - 57.8) at the multilevel mixed-effect model. Symptomatic treatment (plus modifying infusion speed or alone) was given in 76.4% of IRRs, 23% by iv route. 15% of SI and 6% of CI needed symptomatic treatment.

Discussion: SI did not increase IRRs rate or severity and only 10% involved vital signs. IRRs at SI were more likely in patients who experienced IRR at the first 300mg infusion.

Conclusions: The ocrelizumab SI protocol optimizes MS Center nurse activities, reduces monitoring intensity without negative impact on patient safety.

## MOG-ANTIBODY ASSOCIATED DISORDER (MOGAD) MIMICKING TYPICAL MRI PATTERN OF WERNICKE ENCEPHALOPATHY: A CASE REPORT

S. Romano, A. Franceschini, S. Lazzari, R. Cancilla, G. Libelli, F. Granella, E. Chierici

Department of Medicine and Surgery, University of Parma (Parma)

Objectives: MOG antibody-associated disease (MOGAD) has a wide spectrum of clinical-MRI manifestations. We describe a unique neuroradiological presentation of MOGAD resembling typical MRI pattern of Wernicke's encephalopathy (WE).

Materials and Methods: A 42-years-old woman presented to medical attention with a 5-days history of headache followed by blurry vision. She has been suffered from diarrhea for 6 months and she underwent a cholecystectomy 4 months prior. Neurological examination only documented severe bilateral decreased visual acuity. Brain MRI showed bilateral and symmetrical hyperintense FLAIR/T2 lesions in periaqueductal grey matter, dorsomedial nuclei of thalamus, floor of the IV ventricle and mammillary bodies. WE were suspected and thiamine supplementation was promptly started. In the meantime, gastrointestinal exams led to the diagnosis of Chron's disease as a potential cause of thiamine depletion.

Results: After six days of thiamine administration, she showed no clinical improvement. Lumbar puncture detected 14 leucocytes, mostly monocytes, and no oligoclonal bands. Orbital MRI was performed, showing bilateral longitudinally extensive optic nerve lesions. A 5-day high-dose intravenous corticosteroid therapy and a plasmapheresis cycle led to a complete resolution of visual loss; brain-MRI follow-up documented T2-lesions resolution over time. Finally, serum positivity for MOG-IgG confirmed the diagnosis of MOGAD.

Discussion: In MOGAD, brain MRI can show bilateral, large, fluffy lesions located in white matter, middle cerebellar peduncle, brainstem, cortical and/or deep grey matter as features of ADEM, cerebral cortical encephalitis, brainstem and cerebellar symptoms; clinically silent brain or brainstem lesions can be present in patients with clinical optical neuritis or transverse myelitis. We documented a particularly unusual neuroradiological pattern: bilaterally symmetrical FLAIR/T2 hyperintensity in the paraventricular regions of the thalamus, hypothalamus, periaqueductal region, floor of the fourth ventricle and mammillary bodies. This brain MRI pattern has been reported to have a high specificity (93%) for the diagnosis of WE. Our case highlights the heterogenicity of brain MRI pattern in MOGAD and stressed the importance to search for MOGAD specific features like bilateral longitudinally extensive optic nerve lesions, spinal cord H-sign, T2-lesion resolution over time.

Conclusion: We reported a rare MOGAD brain MRI pattern perfectly overlapping with neuroradiological typical pattern of WE. Our case index helps to elucidate the spectrum of MOGAD MRI characteristics with the aim of assisting clinicians in the diagnosis of this heterogeneous disease.

## MRI CORRELATES OF MANUAL DEXTERITY ASYMMETRY IN PEOPLE WITH MULTIPLE SCLEROSIS

F. Romanò[1], E. Pagani[2], S. Morelli[2], M. Rocca[3], M. Filippi[4]

[1]IRCCS San Raffaele Hospital, Vrije Universiteit Amsterdam (Amsterdam-NL); [2]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [3]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [4]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: Motor, sensory and cerebellar symptoms are often lateralized in people with multiple sclerosis (pwMS). Asymmetry in hand dexterity has been reported to increase with disability. Also, uneven distributions of lesion distribution and atrophy progression have been

described. This study aimed to assess whether there is an association between asymmetry in hand dexterity and in MRI measures of structural damage in MS, and if these relationships are influenced by disability.

Materials and Methods: Three hundred thirty-four pwMS and 124 healthy controls (HC), all right-handed, underwent 3T MRI acquisition of 3D-T1-weighted and dual-echo sequences, used to extract left and right normalized brain volumes (cortical and deep gray matter and cerebellum) and lesion loads (cerebral and cerebellar). Hand dexterity was evaluated with the nine-hole peg test (NHPT). Asymmetry indexes (AIs) for volumetric and hand dexterity measures were calculated by subtracting left and right z-transformed values, computed based on the HC group. Nonparametric correlations between NHPT AI and AIs of structural measures were assessed in HC and in pwMS stratified by disability, measured with the Expanded Disability Status Scale (EDSS) (mild=0-3.5; moderate=4.0-5.5; severe=6.0-8.0). Differences in overall asymmetry between groups were compared by converting AIs in absolute values and performing one-way ANOVAs.

Results: PwMS of all disability categories had worse NHPT scores than HC ($p<0.001$). No side-specific lateralization of dexterity impairment or structural damage emerged in the examination of AIs in pwMS. Larger degrees of asymmetry (i.e. more dispersed distributions) were observed in patients with moderate/severe disability, whereas mildly disabled pwMS had values ranging closer to those of HC. No correlations between structural and NHPT AIs were found in HC and mildly disabled pwMS. In moderately disabled pwMS NHPT AI correlated with cortical ($\rho=0.31$, $p=0.02$) and deep gray matter volume ($\rho=0.40$, $p=0.001$) AIs, while in pwMS with severe disability it was associated with cerebellar lesion load AI ($\rho=0.37$, $p=0.003$). Cortical and deep GM volume asymmetries were highest in the moderate disability group, whereas NHPT and cerebellar lesion load asymmetries were highest in severely disabled pwMS.

Discussion: Manual dexterity asymmetry correlates with GM atrophy asymmetry in pwMS with moderate disability and with cerebellar lesion load asymmetry in those with severe disability.
Conclusion: Structural asymmetries are associated to asymmetry in NHPT and both increase with disability in pwMS. Different structural substrates at different levels of disability underlie asymmetry in manual dexterity impairment.

## TCD20+ KINETICS IN PATIENTS SWITCHING TO OCRELIZUMAB THERAPY FROM FINGOLIMOD VERSUS DIMETHYL FUMARATE

G. Romano[1], G. Lus[1], C. Abbondanza[2], M. D'agostino[3], G. Maglio[1], G. Miele[1], R. Missione[1], C. Coppola[1], S. Bonavita[1], E. Signoriello[1]

[1]Department of Advanced Medical and Surgical Sciences, 2nd Division of Neurology, Second University of Naples Luigi Vanvitelli (Napoli); [2]Department of Precision Medicine, University of Campania "Luigi Vanvitelli" (Napoli);[3]Clinical and Molecular Pathology, Diagnostics In Immunopathology, University of Campania "Luigi Vanvitelli" (Napoli)

Introduction: CD20+T cells have a peculiar immunophenotype because they express inflammatory cytokines and markers of effector function. Anti-CD20 treatment as ocrelizumab (OCR) exerts their action also through this lymphocytes subset. The switching strategy from sequestering or depleting DMTs to OCR could influence the T-CD20 depletion induced by OCR. Here, we investigated lymphocyte subset kinetics, including TCD20+, in patients switching to OCR from fingolimod (FTY) vs those switching from dimethyl fumarate (DMF) and the possible correlations with disease activity.

Methods: Patients switching from FTY or DMF to OCR performed blood counts and lymphocyte subsets at the time of therapy discontinuation (T0), at the first administration of OCR (T1), one month after infusion (T2) and finally at six months (T3). We collected demographic and clinical data at the baseline (number of relapses and disease activity before starting treatment and EDSS) and during treatment with OCR we collected clinical relapses, new T2 lesions, and new gd+ lesions at MRI at T3.

Results: We included 16 patients, of this 37.5% switched from FTY. Annualized relapse rate before OCR were $0.37 \pm 0.31$, 75% of patients showed disease activity, and mean EDSS at baseline was $4.25 \pm 1.83$. At six months, after the start of OCR treatment, no relapses occurred, mean EDSS was $4.12 \pm 1.64$ and 12.5% of patients show disease reactivation. No statistically significant difference was registered between groups for the trend of CD4, CD8, NK, CD20, and TCD20. At T0 we found mean TCD20+ values of 56.6 cells/uL in patient switching from DMF and 34.2 cells/uL in patients switching from FTY. At T1 in FTY, we registered an increase of the same (mean value 50.6 cells/uL). At T2 and T3 we observed a reduction of TCD20+ in both patients switching from DMF and FTY. In patients with disease reactivation in the first six months of OCR treatment, we registered an increase of TCD20 at T2 (p=0,03) independent of the previous treatment.

Discussion and Conclusions: Previous treatment with FTY or DMF does not seem influence the lymphocytes subset kinetics during OCR. Disease reactivation in the first six months of OCR could be pulled by the increase of TCD20 lymphocyt. However, given the small number of patients it is necessary to expand the sample and conduct further studies to assessing the possible correlation with early disease activity.

## COGNI-TRAIN: AN INNOVATIVE USER-FRIENDLY APPROACH FOR COGNITIVE REHABILITATION IN MS

M. Rosari[1], S. Conti[1], A. Venuti[1], M. Peresson[2], A. Canestrari[2], M. Marianetti[1], G. Borriello[2]

[1]St John of God Institute, Fatebenefratelli Roman Province (Roma); [2]St Peter Hospital, Fatebenefratelli Roman Province (Roma)

Cognitive impairment is commonly referred and disabling in multiple sclerosis (MS). Although there is now good evidence that cognitive rehabilitation is effective in MS, most healthcare providers are unaware of these treatment options and there are still no universally approved approaches for it.

Objective: To investigate the efficacy of a new cognitive rehabilitation approach in patients affected by MS.

Materials e Methods: 15 patients affected by RR MS with EDSS <4 (9F, 6M; age 34,3±8,5; duration of disease 6,8±4,3), referring subjective cognitive disturbances, underwent a six month cognitive rehabilitation program called COGNI-TRAIN that we have created in our Center. COGNI-TRAIN provides Cognitive Rehabilitation exercises through the periodic sending (once every 10 days) by email of structured Powerpoints containing verbal and non verbal material, including videos, to carry out cognitive strengthening. The exercises can be easily approached autonomously and are divided into specific work areas (memory, executive functions, visuo-spatial skills, language, attention). A professional psychoeducational counseling was also provided by a dedicated professional psychologist. One week before the beginning of the program and one after the end of

it patients were evaluated with an extensive and original cognitive-behavioral neuropsychological tests battery including Mini Mental State Examination, Clock Drawing Test, Picture Interpretation Test, Frontal Assessment Battery, Apathy Evaluation Scale, Visual Analogue Mood Scale - Sadness, Epworth Sleepiness Scale.

Results: All the patients improved their performances in at least two cognitive tests and one behavioral test. The neuropsychological domains mostly involved by the improvement were Executive functions, Attention, Apathy and Sleepiness ($p<0.01$).

Discussion and Conclusion: COGNI-TRAIN demonstrated to have positive effects on cognitive performance of patients affected by RR MS. If further research will confirm these data, COGNI TRAIN could become a precious resource for the management of a disease in which non-pharmacological approaches are often neglected.

## EFFICACY AND SAFETY PROFILES OF PERCUTANEOUS TIBIAL NERVE STIMULATION WITH THE IMPLANTABLE STIMROUTER™ NEUROMODULATION SYSTEM FOR THE TREATMENT OF REFRACTORY LOWER URINARY TRACT SYMPTOMS IN MULTIPLE SCLEROSIS PATIENTS

R. Sacco[1], P. Maino[2], E. Koetsier[3], G. Disanto[4], J. Renard[5], A. Digesu[6], C. Gobbi[7], C. Zecca[7]

[1]Neurocenter of Southern Switzerland, University of Southern Switzerland (Lugano-CH); [2]Anestesiology, Neurocenter of Southern Switzerland, Faculty of Biomedical Sciences, University of Southern Switzerland (Lugano-CH); [3]Anestesiology, Neurocenter of Southern Switzerland, Regional Hospital di Lugano (Lugano-CH); [4]Multiple Sclerosis Center (MSC), Department of Neurology, Neurocenter of Southern Switzerland (Lugano-CH); [5]Urology Service, Regional Hospital of Bellinzona (Bellinzona-CH); [6]Department of Urogynaecology, Imperial College Healthcare NHS Trust (London-UK);[7]Multiple Sclerosis Center (MSC), Department of Neurology, Faculty of Biomedical Sciences, University of Southern Switzerland (Lugano-CH)

Background and Objective: Lower urinary tract symptoms (LUTS) are common in multiple sclerosis (MS) and significantly affect quality of life. Available pharmacotherapy has often limited efficacy and/or is poorly tolerated in MS patients. Conversely growning data support the neuromodulation in the treatment of LUTSs. To investigate the efficacy and safety of the implantable, MRI compatible StimRouter™ neuromodulation system for the treatment of refractory LUTS in patients with MS.

Material and Methods: This is a prospective, single centre, 6 month-trial conducted at the tertiary MS Center, Ospedale Regionale di Lugano, Switzerland, involving MS patients affected with refractory LUTS. Patients previously responsive to PTNS neuromodulation were included. Subcutaneous electrode was implanted in the right or left lower tibia area. All patients were treated with percutaneous tibial nerve stimulation delivered by the implantable StimRouter™ neuromodulation system. Self-administered stimulation sessions of 60 minutes were performed in 5-7 days/week over 6 months. Patients underwent urodynamic assessment and filled in questionnaires concerning LUTS severity and related quality of life at baseline and 6 months after starting neuromodulation.

Results: 23 MS patients [15 females/8 males, median (IQR) age 48 (42.5-53.5) years] were recruited. Six patients had neurogenic detrusor overactivity (NDO), 5 detrusor sphincter dyssynergia (DSD), 12 had both NDO and DSD. Within patients with NDO, median bladder volume at first uninhibited contraction significantly increased from baseline to week 24 (median=136 ml, [IQR 101-244 ml] vs 343 ml [IQR 237-391 ml]; $\beta=138.2$, $p=0.001$). No significant changes of urodynamic parameters were found in patients with DSD. OAB-q symptoms scores progressively decreased and OAB-q quality of life scores increased ($\beta=-0.50$, $p<0.001$ and $\beta=0.47$, $p<0.001$, respectively), while MSQoL-54 scores did not significantly change ($\beta=0.24$, $p=0.084$) in the overall population. Treatment satisfaction was overall high (median=8, IQR 6-9). No serious adverse events were recorded.

Discussion and Conclusion: Neuromodulation through StimRouter™ led to objective and subjective improvements of OAB symptoms and related quality of life in MS patients with refractory LUTS (especially NDO). StimRouter™ represents a minimally invasive, MRI-compatible, wireless self-administered neuromodulation treatment for MS patients suffering from refractory LUTS.

## SAFETY AND EFFECTIVENESS OF OCRELIZUMAB TREATMENT IN A COHORT OF PATIENTS TREATED IN A MEDIUM MULTIPLE SCLEROSIS CENTRE OF MILAN

G. Santuccio, S. Tonietti, M. Suardelli, S. Canella, M. Massaro, F. Frediani

Department of Neurology, San Carlo Hospital, ASST Santi Paolo e Carlo, Statale University of Milan (Milano)

Objective: Multiple Sclerosis (MS) is an inflammatory/degenerative disease of central nervous system (CNS). MS onset is mainly between 20-45 years of age. Many modifying drug diseases (DMD) are now available. Ocrelizumab is a humanised monoclonal antibody that targets anti-CD20 B lymphocytes, determining B cell depletion. It is approved by EMA and AIFA for Relapsing-Remitting (RR) and Primary Progressive (PP) MS with high disease activity [1-2]. Its efficacy is very high and sustained over time. Safety is currently good. Aim of the study was to evaluate the safety and efficacy in a patient cohort followed in our MS centre.

Materials: 18 MS patients (11 females, 7 males) were consecutively treated with ocrelizumab one infusion every 6 months, as scheduled by EMA and AIFA. 10 patients were RR-MS, 5 PP-MS and 3 SP-MS. Age was 20-63 years (mean 43); disease duration 1-30 years (mean 10.5). 7/18 patients were naïve to any treatment. First patient was enrolled in September 2018, last patient in November 2022. All patients performed clinical evaluation every 6 months and brain MRI every year.

Methods: In this retrospective study we compared clinical and MRI activity pre (1 year before) versus post Ocrelizumab treatment. Clinical measures were cumulative relapse number, patients with confirmed progression and mean EDSS score, MRI measures were cumulative number of new T2 lesions and Gd+ lesions post. We also recorded any AE occurred during Ocrelizumab treatment.

Results: Infusions ranged from 1 to 10 (mean 5.1) Cumulative Relapses pre were 16 (mean 0.9), post 0; mean EDSS score pre 3.3,

post 2.6. Progression was confirmed in 4 versus 14 stable/improved patients. Cumulative MRI T2 Lesions pre- were 39 (mean 3.3), post 0. Cumulative MRI Gd+ lesions were pre- were 23 (mean 1.4), post 0. 3 Adverse Event (AE) occurred: sinusitis, bronchitis covid+ and cystitis, all with good outcome. No AE required Hospitalization. All patients are still on treatment.

Discussion: Almost all patients are responder to Ocrevus therapy regardless MS course, disease duration and previous treatments. None of them had relapses and MRI activity during treatment. Better responders are RRMS patients with previous recent high clinical and MRI activity. Progression occurred mainly in SPMS with longer disease duration. No severe safety issues were observed in our cohort.

Conclusions: With the limits of a retrospective study in a small cohort, we confirm previous observation that ocrelizumab is highly effective and a safe treatment for all active MS patients.

## BEYOND NEGATIVE ONSET MRI: DIAGNOSTIC AND THERAPEUTIC CHALLENGE OF INFLAMMATORY MYELOPATHY IN A PATIENT WITH CROHN'S DISEASE

A. Saraceno, J. Buonocore, R. Di Iorio, E. Fratto, C. Mummolo, G. Spano, S. Barone, P. Valentino, A. Gambardella

Institute of Neurology, Department of Medical and Surgical Sciences, Magna Graecia University (Catanzaro)

Aims: Spinal cord involvement can sporadically occur with Crohn's disease (CD), due to various mechanisms such as abnormal immunological status and side effects of medications, including biological drugs [1]. Magnetic resonance imaging (MRI) of myelopathy can be negative even months after onset, implying a delayed diagnosis and treatment [2].

Case: A 57-year-old man presented three-weeks before a subacute-onset of abdominal numbness spread to lower limbs and distally to upper limbs, with gait imbalance. He was affected by monoclonal gammopathy of undetermined significance and CD, treated with azathioprine and biological drugs. Brain and spine MRI performed at onset resulted negative. Neurological examination showed ataxic gait, positive Romberg test with lower limbs and distal upper limbs hypoesthesia and lower limbs apallesthesia. Blood test revealed anaemia (10,9g/dl,n.v.:14-18) and lymphopenia (0,35x10^3/uL,n.v.:0,9-5,2). Cerebrospinal fluid examination (CSF) showed blood brain barrier dysfunction, but negative oligoclonal bands. Somatosensory evoked potentials (SEP) in upper and lower limbs revealed bilateral increased latency. Brain and spine MRI were again unremarkable. Electroneurography showed decreased velocity of all sensory nerve and lower limbs motor nerve conduction, with prolonged F-wave latencies; needle-electromyography demonstrated distal muscles abnormal spontaneous activity. In suspicion of sensory-motor demyelinating polyneuropathy autoimmune disease-associated, we attempted therapy with 5-day (0.4gr/kg/day) intravenous immunoglobulin (IVIg), with partial benefit. Three weeks later, he complained lower limb weakness and spasms with worsening of gait, possible only with bilateral support, Lhermitte's sign, a T5-sensory level and bowel incontinence. CSF, electromyography and SEP were superimposable, lower limbs motor evoked potentials were absent bilaterally. Spine MRI revealed multiple cervicodorsal T2-hyperintensities, some with contrast enhancement. Aquaporin-4 and myelin-oligodendrocyte-glycoprotein antibodies on serum and CSF were negative. We performed a therapy with intravenous methylprednisolone (at total dosage of 5g), followed by IVIg, with remarkable improvement of gait and limbs strength. One month later, he had a clinical-radiological relapse, successfully treated with intravenous methylprednisolone. Afterwards, he started rituximab achieving clinical-radiological stability during one-year follow-up.

Discussion: We report an inflammatory myelopathy with initial negative MRI plus peripheral demyelinating polyneuropathy associated to CD and successfully treated with rituximab. Despite concerns about rituximab exacerbating CD, its use was justified due to CD clinical remission and high risk of residual disability associated with relapsing myelitis.

Conclusion: This case highlights the importance of accurate clinical and paraclinical evaluation, as well as repeat spinal cord imaging when there is mismatch between clinical symptoms and initial MRI findings, to ensure early and appropriate treatment, minimizing potential disability.

## TOCILIZUMAB TREATMENT IN PROGRESSIVE MOGAD MIMICKING LEUKODYSTROPHY: A CASE REPORT AND LITERATURE REVIEW

G. Schirò, S. Iacono, M. Andolina, A. Bianchi, P. Ragonese, G. Salemi

Department of Biomedicine, Neuroscience and Advanced Diagnostics, University of Palermo (Palermo)

Introduction: Myelin oligodendrocyte glycoprotein-immunoglobulin G associated disease (MOGAD) is an autoimmune demyelinating disorder of the central nervous system (CNS) which usually occurs with recurrent optic neuritis, transverse myelitis, acute disseminating encephalomyelitis or brainstem encephalitis. To date, the anti-CD 20 drug Rituximab (RTX) is employed in MOGAD although some authors reported the efficacy of Tocilizumab (TCZ) in refractory patients.

Aim: We present the case of a woman affected by refractory MOGAD who was treated with TCZ after therapy with RTX had failed to prevent relapses. We also conducted a current review literature on TCZ use in MOGAD.

Results: A 57-years-old Caucasian woman affected by MOGAD with severe motor impairment and cognitive dysfunction was treated from 2020 to February 2022 with RTX. However, during the follow-up, she experienced progressive clinical and cognitive worsening associated with white matter lesions mimicking leukodystrophy. In February 2022, the patient started therapy with TCZ administered every four weeks with subsequent improvement of cognitive performance, walking ability and brainstem functions. During TCZ (last follow-up considered was on March 2023) our patient reached the condition of NEDA-3 (no relapse, no increase in disability, no MRI activity on neuroimaging follow-up performed in October 2023). Moreover, during TCZ treatment, the patient experienced pauci-symptomatic SARS-CoV-2 infection that did not modify disease course or TCZ schedule. To date, there are few evidence on the efficacy and safety of TCZ in MOGAD. However, all the reviewed cases showed that TCZ represent an effective therapy in drug resistant MOGAD with subsequent improvement of symptoms and disease course.

Discussion and Conclusions: Our case highlights the efficacy of TCZ in drug resistant MOGAD and strengthens previous reports of TCZ safety and efficacy in MOGAD.

Giglio (Cefalù-PA); [11]Department "GF Ingrassia", Section of Neurosciences, University of Catania (Catania); [12]Unit of Neurology, IRCCS Neuromed (Pozzilli-IS)

Introduction: Cladribrine is an oral pulsed therapy for relapsing multiple sclerosis (RMS). Hormonal and immune changes are responsible for the decline of disease activity in the third trimester of pregnancy and disease reactivation in the early post-partum period. To date there are no available studies on the pregnancy effect on disease activity in women with MS who conceived after cladribrine treatment.

Methods: We recruited women of childbearing age with RMS who became pregnant or not after being treated with cladribrine. For both groups, demographic, clinical and radiological data were collected one year before and after treatment to compare the disease activity.

Results:47 childbearing women mean age 35.05 ys were included. 24 women had a pregnancy after a mean of 1.75 years from the first treatment cycle, 5 pregnancies occurred between the first and second cycle. Women with or without pregnancy did not differ for demographics or disease activity pre cladribrine. No significant differences in disease activity post cladribrine were found between women with or without pregnancy (0.12 vs 0.04 for ARR p=0.36;1.9 vs 1.1 p=0.65 for new T2 lesions and 0.29 vs 0.3 p= 0.60 for new gd+ lesions). No significant differences were found between women with pregnancy occurred between the first and second cycle or after the second cycle.

Discussion and Conclusion: Pregnancy does not appear to influence disease activity in women previously treated with cladribrine; further studies with larger numbers are needed to confirm this finding and to identify the best timeframe to conceive after cladribine treatment that guarantees to be still protected from reactivation in the post-partum period.

## AUTONOMIC NERVOUS SYSTEM (ANS) INVOLVEMENT: A NEW MARKER OF DISABILITY IN PATIENTS WITH MULTIPLE SCLEROSIS

C. Siniscalchi, E. Cassano, A. Russo, D. Dell'Aversana, M. Nolano, R. Iodice

Department of Neuroscience and Reproductive and Odontostomatological Sciences, University of Naples Federico II (Napoli)

Objectives: The aim of the study was to investigate the incidence of autonomic dysfunction in people with MS (pwMS). In addition, we tried to evaluate if Expanded Disability Status Scale (EDSS), disease duration and different subtype of MS correlate with the severity of autonomic dysfunction.

Materials and Methods: 73 out of pwMS underwent to Wexner Scales on bowel function, SNF-SIQ and SCOPA-AUT. Ewing tests, Sympathetic Skin Response SSR and Dynamic Sweat Test DST were performed in 22 pwMS.

Results: It was found an elevated incidence of autonomic disfunction symptoms among patients affected by MS (in our study 90% of the total group had at least one autonomic domain affected). The most common affected domains were the genitourinary, gastrointestinal and thermoregulation ones. Furthermore, it was found that scores obtained from the clinical scales correlated with disability but not with disease duration nor type of MS. On the other hand, it was found that data obtained from the diagnostic procedures didn't correlate with disability nor with disease duration nor with type or MS.

Discussion and Conclusion: it is still not clear the involvement of the Autonomic Nervous System in pwMS. Moreover, there are still no validate procedures to study this impairment. Our study confirms this involvement, but a bigger cohort of patients is needed.

## THE EARLY EFFECT OF CLADRIBINE VERSUS FINGOLIMOD ON CLINICAL AND MRI MEASURES IN RELAPSING REMITTING MULTIPLE SCLEROSIS

T. Sirito, G. Boffa, C. Lapucci, D. Boccia, K. Aluan, L. Castellan, A. Uccelli, A. Laroni, E. Capello, M. Cellerino, M. Inglese

Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa (Genova)

Background and Aims: A treatment protocol with cladribine tablets (CLAD) requires two courses of treatment in Year 1 and Year 2. Data regarding its efficacy during the first 12-months of treatment in comparison with fingolimod (FINGO) in the real-life setting are still sparse. The aim of this study is to compare the early impact of CLAD (I course) and FINGO in terms of clinical and MRI outcomes in a cohort of relapsing-remitting multiple sclerosis (RRMS) patients (pts).

Materials and Methods: A total of 63 patients were included in the analysis, [32 CLAD and 31 FINGO; females: 65.1%; mean age, disease duration, ARR two previous years: 39.4+14.2, 8.6+9.6 years, 0.47+0.56; median (range) EDSS and number of previous DMTs: 1.5 (0-5.5) and 1 (0-3)]. No differences in terms of age, sex, disease duration, ARR two previous years, number of previous treatments, EDSS, total brain volume and lesion load were found between the two groups at baseline. In this ongoing study, RRMS patients underwent complete clinical evaluation [including assessment of Expanded-Disability-Status-Scale (EDSS), annualized relapse rate (ARR), nine-hole-peg–test (9HPT) and timed-25-foot-walk (T25FW] and 3T-MRI (Siemens MAGNETOM) at baseline and after 12-months follow-up. NIH toolbox standing balance test was used to quantify balance impairment. Changes in percentage-brain-volume-change (PBVC) were measured. The probability of disability-/relapse- /MRI activity-free survival, NEDA-3 and NEDA-4 status (defined as NEDA3 + PBVC<0.4% per year) were calculated with Kaplan-Meier estimator.

Results: At 1-year FU, MRI-inflammatory-activity-free survival was 81.3% and 74.2% (p=0.55) and relapse-free survival was 93.8% and 100% (p=0.16) in CLAD and FINGO treated pts, respectively. Progression-free survival was 100% in both groups. Mean PBVC was -0.6+1.5% (-0.48+1.6% in CLAD vs -0.76+1.4% in FINGO pts; p=0.82). NEDA-3 status was achieved in 81.3% and 74.2% (p=0.57) while NEDA-4 in 35.7% and 27.3% (p=0.53) of pts in CLAD and FINGO groups, respectively. Although not statistically significant, there was a decrease of 0.63+3.0 vs an increase of 0.9+3.8 seconds at 9HPT test (p=0.13), an increase of 0.46+3.2 vs 1.3+3.3 (p=0.51) seconds at T25FW tests and a decrease of 0.19+0.55 vs 0.06+0.74 (p=0.57) of NIH Toolbox Standing Balance theta value in CLAD vs FINGO treated pts, respectively.

Discussion and Conclusions: Although a complete CLAD treatment course requires the 2-dose 2-year protocol, our findings suggest that its efficacy is comparable to FINGO even during the first 12-months, though should be confirmed by larger analysis.

Background: Hypogammaglobulinemia (HG) is a known adverse event of treatment with anti-CD20 monoclonal antibodies (mAbs). Information on the safety profiles of the different anti-CD20 mAbs used in the treatment of Multiple Sclerosis (MS) can be useful for therapeutic decisions and for the implementation of de-risking strategies.

Objectives and Methods: Main aim of this retrospective multicentre study was to assess the frequency of HG in MS and Neuromyelitis Optica Spectrum Disorder (NMOSD) patients treated for at least one year with either ocrelizumab (OCR) or rituximab (RTX) and its association with the occurrence of severe infections (SI). Secondary aims were to identify predictors of HG and SI.

Results: We included 556 patients (533MS, 23NMOSD; 190M, 366F, mean age: 47 years) with a mean follow-up of 29 months (range: 12–90). Compared to OCR-treated patients (nr=399), patients on RTX (nr=157) were older (53 vs 45 years), more frequently progressive (67% vs 36%), had a higher disability (EDSS 5 vs 4) and a longer treatment duration (33 vs 28 months). IgG HG occurred in 21% of patients, while IgM HG occurred in 34%. Both were significantly more frequent in the RTX group (27% vs 18% and 45% vs 29%, respectively), and occurred earlier during RTX treatment, but there was no difference in the incidence rate ratio between the two drugs. The risk of IgG HG was influenced by age≥50 years (OR: 1.64) and by the number of treatment cycles (OR: 1.10). The risk of IgM HG was increased by the RTX therapy (OR: 1.78) and the number of treatment cycles (OR: 1.09). A total of 357 infections were recorded during treatment (rate per 100 person years -100PY: 26.3). Of these, 25 were severe, requiring hospitalization (100PY rate: 1.8). The majority (76%) were Covid-related pneumonias. At multivariable analysis, only athe disease phenotype (OR 1.50, 95%CI:1.02-2.20; p=0.039) and IgG HG (OR 2.51, 95%CI: 1.09-5.80; p=0.031) at any time during treatment increased the risk of a SI. The co-occurence of IgG and IgM HG further increased the odds of a SI (OR 3.17, 95%CI:1.27-7.92; p=0.013).

Conclusion: IgG and IgM HG occurred in a substantial proportion of MS patients treated with ant-CD20 mAbs and increased the risk of a SI, highlighting the importance of monitoring immunoglobulin levels at baseline and throughout treatment. IgG and IgM HG were more frequent in RTX-treated patients compared to those treated with OCR, but baseline characteristics and treatment duration differed between the two populations. Further studies, with longer follow-up periods, are necessary to inform on the safety profiles of the different anti-CD20 mAbs.

## A COMPREHENSIVE PICTURE OF FUNCTIONAL DISORDERS IN NON-DISABLED PEOPLE WITH MULTIPLE SCLEROSIS: A LONGITUDINAL STUDY

C. M. Solaro[1], E. Gervasoni[2], D. Anastasi[2], R. Di Giovanni[3], M. Rovaris[2], G. Brichetto[4], P. Confalonieri[5], A. Tacchino[4], I. Carpinella[2], D. Cattaneo[2]

[1]Neurology Unit, Galliera Hospital (Genova); [2]IRCSS Fondazione Don Carlo Gnocchi (Milano); [3]Rehabilitation Department, CRRF Mons L. Novarese (Moncrivello-VC); [4]Scientific Research Area, Italian Multiple Sclerosis Foundation (FISM) (Genova); [5]Multiple Sclerosis Center, IRCCS Foundation (Milano)

Objective: Functional disorders appear early in the course of the disease and develop gradually over time impacting on social participation and quality of life. Investigating the progression of disability, walking, fatigue, manual dexterity, and cognition in a cohort of People with Multiple Sclerosis (PwMS) in the early stage of the disease.

Methods: We performed a longitudinal 2-year study to unravel functional disorders of 82 non-disabled PwMS with Expanded Disability Status Scale (EDSS) < 2.5 points, disease duration < 5-year, and aged (Mean±Standard Deviation) 39.5±10.6 years.

Materials: Participants were assessed at baseline and after 2-year with clinical and instrumented evaluations. Data on disability and functional disorders were collected using EDSS, Six-Minute Walk Test (6MWT), Multiple Sclerosis Walking Scale-12 (MSWS-12), Fatigue Severity Scale (FSS), Nine Hole Peg Test (NHPT), Brief International Cognitive Assessment (BICAMS), while instrumented data were extracted from 6MWT using wearable devices.

Results: EDSS changed from 1.5±0.7 points to 1.8±0.9 points with 34% of PwMS showing deterioration beyond the Minimally Important Changes of deterioration (MICdet EDSS = 1-point). Conversely, the 6MWT, FSS, and MSWS-12 did not change (6MWT from 559.35±84.5m to 577±93.5m, FSS from 3.3±1.8 points to 3.1±1.8 points, and MSWS-12 from 31.3±15.3 points to 30.0±14.9 points) with 10% and 11% PwMS showing walking deterioration beyond MICdet (MICdet 6MWT= 55m; MICdet MSWS-12= 6 points). We observed similar results considering instrumented variables: stride regularity (from 0.86±0.07 [au] to 0.88±0.08 [au]), antero-posterior gait symmetry (from 81.88±6.60 [au] to 83.74±6.06 [au]) and gait instability (from 0.69±0.11 [au] to 0.74±1.12 [au]). No relevant changes were observed for 9HPT and BICAMS.

Discussion: Even if EDSS deteriorated over time, fatigue, cognition, and upper/lower limb functions were on average spared 2 years after baseline assessment.

Conclusion: The large between-subject variability suggests the use of artificial intelligent techniques to predict subjects prone to deterioration.

## DEVELOPMENT OF THE HEAT SENSITIVITY IMPACT QUESTIONNAIRE (HSI-Q): AN ONGOING VALIDATION STUDY

C. M. Solaro[1], R. Di Giovanni[2], E. Grange[3], M. Rolla[2], M. Zidaric[2], R. Bertoni[4], D. Anastasi[4], E. Gervasoni[4], D. Cattaneo[4], G. Merati[4]

[1]Neurology Unit, Galliera Hospital (Genova); [2]Rehabilitation Department, CRRF Mons L. Novarese (Moncrivello-VC); [3]Scientific Research Area, Italian Multiple Sclerosis Foundation (FISM) (Genova);[4]Fondazione Don Carlo Gnocchi Onlus IRCCS (Milano)

Objectives: An estimated 60–80% of People with MS (PwMS) have been reported as being sensitive to environmental heat. Clinically, increased body temperature in PwMS can result in experiencing a temporary worsening of clinical signs and neurologic symptoms (Uhthoff's phenomenon). There is a lack of validated tools to assess the patients' perspective on heat sensitivity in this population. Through consensus conference of expert and PwMS and content validity analysis, we developed the Heat Sensitivity Impact Questionnaire (HSI-Q). The aim of the study is to validate and test the psychometric properties of the HSI-Q in a sample of PwMS.

Materials: HSI-Q (38 items) was administered to a preliminary sample of PwMS. Subjects completed HSI-Q, Modified Fatigue Impact Scale (MFIS) and Multiple Sclerosis Walking Scale-12 (MSWS-12); a subgroup also 2 Minute Walk Test (2MWT) and Timed Up and Go (TUG).

Methods: We assessed criterion validity, using a general question ("are you heat-sensitive?"), and construct validity, analysing the correlations (Spearman rank correlation coefficient) between HSI-Q total score and EDSS, MFIS and MSWS-12. We reported the correlations between HIS-Q total score and 2MWT, TUG on a subgroup of PwMS.

Results: 70 PwMS completed the HSI-Q (38F/32M, mean age 51.32(10.62) years, mean disease duration 13.90(9.90) years, mean EDSS 5.68(1.70), 30 RRSM, 23 SPSM, 17 PPSM). Scores obtained: HSI-Q tot 3.99(2.58), general question 5.97(3.02), MFIS 34.09(20.49), MSWS-12 33.94(19.52), 2MWT 83.4(54.85), TUG 22.54(17.11). Total HSI-Q score showed high correlation ($r=0.644$, $p<0.000$) with the general question "are you heat-sensitive?", low correlation with EDSS ($r=0.294$, $p=0.013$), moderate correlations with MFIS ($r=0.497$, $p<0.000$) and MSWS-12 ($r=0.430$, $p<0.000$). Regarding the subgroup of 50 PwMS, no significant correlations were found between HSI-Q total score and 2MWT and TUG.

Discussion: The preliminary assessment of HSI-Q validity showed high criterion validity and moderate construct validity.

Conclusion: This is an ongoing study and the sample of PwMS will be implemented in the upcoming months.

## DOES THE TARGET NEDA COMPLY WITH FUNCTIONAL MEASURE CHANGES AFTER 2 YEARS IN EARLY PHASE OF MULTIPLE SCLEROSIS?

C. M. Solaro[1], R. Di Giovanni[2], E. Grange[3], E. Gervasoni[4], D. Anastasi[4], M. Rovaris[4], P. Confalonieri[5], I. Caprinella[4], M. Rolla[2], M. Zidaric[2], D. Cattaneo[4]

[1]Neurology Unit, Galliera Hospital (Genova); [2]Rehabilitation Department, CRRF Mons L. Novarese (Moncrivello-VC); [3]Scientific Research Area, Italian Multiple Sclerosis Foundation (FISM) (Genova); [4]IRCCS Fondazione Don Carlo Gnocchi (Milano); [5]Multiple Sclerosis Center, IRCCS Foundation (Milano)

Objectives: Few studies investigated the longitudinal changes of functional measures in people with MS (PwMS) with low disability. The aim of the study is to evaluate after two years of follow-up (2FU) the evolution of clinical and functional measures stratified for NEDA (no-evident-disease-activity; evidenced by lack of clinical relapses, of disease progression measured by expanded disability status scale and absence of new disease activity on magnetic resonance imaging (MRI)).

Methods: We assessed PwMS at baseline and after 2FU. We analysed the worsened and increased scores at different evaluations in the two subgroups NEDAgroup and noNEDAgroup.

Materials: Evaluation measures: Six Minute Walking Test (6MWT), Timed up and Go test (TUG), Timed-25 Foot Walking (T-25FW), Fatigue Severity Scale (FSS), Twelve-Multiple Sclerosis Walking Scale (MSWS_12), Fullerton Advanced Balance-short (FAB-s), 9-Hole Peg Test (9-HPT), Manual Ability Mesure-36 (MAM-36), Brief International Cognitive Assessment for Multiple Sclerosis (BICAMS).

Results: 57 PwMS were enrolled [baseline: 35F, mean age 38.97 (SD=10.76) years, mean disease duration 2.14 (SD=1.84) years, mean EDSS 1.41), 57 relapsing-remitting MS course; 2FU: mean EDSS 1.83]. At 2FU, 25 PwMS were in NEDAgroup while 32 in noNEDAgroup. In the NEDAgroup the number of PwMS worsened: 12 at 6MWT, 9 at TUG, 11 at FSS, 12 at T-25FW, 7 at MSWS-12, 9 at FAB, 33 at 9-HPT, 3 at MAM-36, 12 at SDMT, 11 at CVLT-II, 8 at BVMT-R. In the noNEDAgroup the number of improved: 11 at 6MWT, 17 at TUG, 16 at FSS, 14 at T-25FW, 11 at MSWS-12, 13 at FAB, 24 at 9-HPT, 8 at MAM-36, 15 at SDMT, 19 at CVLT-II, 13 at BVMT-R.

Discussions: Several subjects showed a clinical improvement underline the importance of an extensive clinical evaluation beyond the EDSS.

Conclusions: Overall, 24 MS subjects classified as NEDA showed a decrease of function in at least one domain at 2FU.

## TO EVALUATE THE ACTIVITY AND THE EFFICACY OF TRADITIONAL SWALLOWING THERAPY (TST) PLUS NEUROMUSCULAR ELECTROSTIMULATION (NMES) VS TST PLUS SHAM-NMES IN MS PATIENTS WITH DYSPHAGIA

C. M. Solaro[1], G. Brichetto[2], F. Patti[3], M. Rovaris[4], C. Tassorelli[5], M. Grasso[6]

[1]Neurology Unit, Galliera Hospital (Genova); [2]Scientific Research Area, Italian Multiple Sclerosis Foundation (FISM) (Genova); [3]Department of Medical and Surgical Sciences and Advanced G.F. Ingrassia, University of Catania (Catania); [4]Scientific Institute Santa Maria Nascente, Fondazione Don Carlo Gnocchi (Roma); [5]IRCCS C. Mondino Foundation and University of Pavia (Pavia); [6]IRCCS "Fondazione S. Lucia" (Roma)

Objectives: Dysphagia is a disabling, life-threatening symptom that can cause death in people with Multiple Sclerosis (PwMS) through aspiration pneumonia. To date, no randomized clinical trials have shown that rehabilitative strategies are effective. Only one study applied Neuromuscular electrical stimulation (NMES) to swallowing function on PwMS. The aim of this study is to determine whether NMES added benefit to standard swallowing rehabilitation program in PwMS.

Methods: This is a multicentre double blinded, randomized clinical trial with two arms: standard rehabilitative plus Active NMES vs standard rehabilitative with Sham NMES. Inclusion criteria: MS diagnosis, stable disease activity, ASHA score <6 and DYMUS score >2.

Materials: We performed an ad-interim analysis in order to assess if the two groups (NMES vs. sham NMES) are balanced for age, gender, disease duration (DD), disease course and EDSS, and if it is possible to assess a preliminary effect of the treatment.

Results: A total of 125 PwMS were screened, 80 were included in the study, of which 8 dropped out. Till now, 75 subjects completed the treatment. Thirty-three subjects were allocated to the NMES group and 32 in the sham-NMES group. Demographic and clinical characteristics of the two groups: NMES [age 55.9(11.3), DD 17.7(8.9), 7 RRMS, 7 PPMS, 19 SPMS, EDSS 6.8(1.0)] and Sham-NMES [age 56.0(11.8), DD 18.9(9.0), 6 RRMS, 4 PPMS, 22 SPMS, EDSS 7.0(1.2)]. The two groups do not statistically differ for gender, age, disease duration, disease course and EDSS ($p>0.05$). Pre and post-treatment clinical scores: NMES [pre: ASHA=4.67(0.74), DYMUS=4.15(2.2), DOSS=4.63(0.71); post ASHA=5.30(0.73), DYMUS=2.76(2.5), DOSS=5.41(0.89)] and Sham-NMES [pre: ASHA=4.53(0.87) , DYMUS=4.75(2.1), DOSS=4.76(0.79); post ASHA=4.94(0.91), DYMUS=3.56(2.3), DOSS=5.21(0.90)].

Conclusion and Discussion: The two groups are balanced for disease course, age and EDSS. Ad interim analysis highlighted that the use of the device is well tolerated (5 drop-out are unrelated to the treatment).

## THE TOPOCHRONIC MAP OF THE LARGE-SCALE BRAIN DYNAMICS

P. Sorrentino[1], S. Petkoski[2], M. Sparaco[3], E. Troisi Lopez[4], E. Signoriello[3], F. Baselice[5], S. Bonavita[3], M. Pirozzi[6], M. Quarantelli[6], G. Sorrentino[4], V. Jirsa[2]

[1]Department of Biomedical Sciences, University of Sassari (Sassari); [2]Institut de Neurosciences des Systèmes, Aix-Marseille Université (Marseille-F); [3]Department of Advanced Medical and Surgical Sciences, University of Campania Luigi Vanvitelli (Napoli); [4]Department of Motor Sciences and Wellness, University of Naples Parthenope (Napoli); [5]Department of Engineering, University of Naples Parthenope (Napoli); [6]Biostructure and Bioimaging Institute, National Research Council (Napoli)

Background and Objectives: Large-scale brain activity dynamically evolves over time across multiple time-scales. The structural connectome, which represents the spatial network of brain regions, plays a crucial role in coordinating activity through its influence on signal transmission delays and oscillatory signals [1,2]. In this study, we provided a map of the functional delays characterizing the connections across the human brain [3] using in vivo magneto/electroencephalography and integrated them with the structural connectome derived from magnetic resonance imaging (MRI) in patients affected by multiple sclerosis (MS) and healthy controls.

Materials: 18 MS patients and 20 controls were recruited in the study. We combined source-reconstructed magnetoencephalography (MEG) signals and tractography to non-invasively estimate signal transmission delays across the network of white matter bundles.
Method: Integration of functional delays derived from MEG signals with the structural connectome derived from MRI was evaluated. We also performed a statistical analysis and comparison with random surrogate delays to validate the findings.

Results: We found higher signal transmission delays in MS patients compared to controls. Analyzing these delays, we observed that they correlated with the length of the structural bundles, indicating a relationship between structural organization and timing of interactions in the brain network. Moreover, we found that edges directly affected by demyelinating lesions exhibited significantly slower delays compared to healthy edges. However, the delays were not solely determined by bundle length, as demonstrated by using surrogate data obtained from randomized neuronal avalanches. Comparing these random surrogates to the observed delays, we found that the observed delays were significantly correlated with bundle lengths, unlike the random surrogates.

Discussion: In summary, our study provides a practical non-invasive technique for estimating functional transmission delays at the individual level, demonstrating that delays in the brain network are influenced by factoris beyond distance alone. Furthermore, our approach detects and quantifies the impact of myelin lesions on signal transmission delays in MS.

Conclusions: In conclusion, our findings could offer new possibilities for diagnostic and therapeutic interventions in MS. In fact, by considering subject-specific constraints, our technique contributes to the refinement of brain models. Additionally, our findings shed light on the longer delays induced by myelin lesions in multiple sclerosis, contributing to a better understanding of the disease.

## PAROXYSMAL DYSARTHRIA: AT ONSET AND AFTER A RELAPSE OF MULTIPLE SCLEROSIS. A CASE SERIES

G. Spano, A. Saraceno, J. Buonocore, R. Di Iorio, C. Mummolo, S. Barone, P. Valentino, A. Gambardella

Institute of Neurology, Department of Medical and Surgical Sciences, University Magna Graecia (Catanzaro)

Background: Paroxysmal dysarthria (PD) syndrome is an uncommon neurological symptom in multiple sclerosis (MS), characterized by brief, stereotyped episodes of slurred speech. The underlying cause is a localized lesion in the cerebellotalamocortical pathway, particularly in the midbrain, which can have various etiologies (inflammatory, vascular, neoplastic). PD is commonly observed during the course of MS or as an initial symptom. Treatment with Carbamazepine has shown positive results. In our center's experience, we encountered two cases of PD: one in a woman who developed it after 10 years of MS and another in a woman with the initial onset of MS.

Case presentation: Case 1: A 34-year-old woman, an elementary school teacher, has been suffering from relapsing-remitting multiple sclerosis (MS-RR) for 10 years. For approximately a month, she experienced multiple daily episodes characterized by difficulty articulating words and writing, lasting only a few seconds, which significantly affected her work. This symptom appeared to be preceded by a subjective sensation of warmth that gradually ascended from her feet to her head. Case 2: A 30-year-old woman with no comorbidities. Two months ago, she began experiencing bilateral visual blurring and a numb sensation in her tongue and upper right dental arch. This symptomatology spontaneously regressed after a week. However, a few days later, she developed a sensation of heaviness in her left upper and lower limbs, accompanied by multiple daily episodes of difficulty articulating words. These episodes also lasted a few seconds, but the woman did not report any prodromal symptoms. Magnetic resonance imaging (MRI) and lumbar puncture confirmed the diagnosis of multiple sclerosis.

Results: The MRI of both patients, despite differing lesion loads, revealed a common lesion affecting the midbrain region. In case 1, the lesion was located in the right paramedian midbrain region, while in case 2, it was in the left paramedian midbrain region. Treatment with CBZ was initiated. However, in case 1, carbamazepine failed to produce improvement, whereas Lamotrigine demonstrated a significant improvement in paroxysmal dysarthria, resulting in nearly complete suppression of the attacks. Conversely, in case 2, carbamazepine proved effective.

Conclusions: It is crucial to pay close attention to patients presenting with paroxysmal symptoms, as they may signify the onset of a more complex neurological condition. In the case of PD, careful examination of the dentatorubroolivary pathway's location is advisable. Importantly, there is symptomatic treatment available for this paroxysmal disorder, which, in addition to carbamazepine, may include lamotrigine.

## EFFECT OF SIPONIMOD ON LYMPHOCYTES SUBSETS IN ACTIVE SECONDARY PROGRESSIVE MULTIPLE SCLEROSIS AND CLINICAL IMPLICATIONS

A. L. Spiezia[1], R. Lanzillo[1], V. Cerbone[2], M. Petracca[3], D. Caliendo[1], A. Fiore[2], G. Scalia[2], M. Marcello[4], V. Brescia Morra[1], A. Carotenuto[1]

[1]Department of Neuroscience, Reproductive Sciences and Odontostomatology, Federico II University of Naples (Napoli); [2]Centre for Advanced Biotechnology (CEINGE), Federico II University of Naples (Napoli); [3]Department of Human Neurosciences, Sapienza University (Roma); [4]Department of Molecular Medicine and Medical Biotechnology, Federico II University of Naples (Napoli)

Background and Objectives: Circulating immune cells play a pathogenic role in multiple sclerosis (MS). However, the role of specific lymphocyte subpopulation is not unveiled yet, especially in progressive stages. We aimed to investigate lymphocyte changes in active secondary progressive MS (aSPMS) and association between specific changes in immune cells and worse clinical outcomes during siponimod treatment.

Methods: This was a mono-centric prospective longitudinal study. We enrolled 46 aSPMS patients with 2-years follow-up after the start of siponimod treatment, along with 14 sex- and age-matched healthy controls (HCs). Clinical and laboratory data were collected at baseline, 3rd, 6th, 12nd, and 24th month for MS patients, and at baseline for HCs.
Results: At baseline compared with HCs, SPMS patients presented with reduced T lymphocyte (p=0.05), reduced memory regulatory lymphocytes (p=0.04), increased naïve regulatory T lymphocytes (p=0.02) and a trend toward an increase in CD3+CD20+ lymphocytes (p=0.07). Over time, SPMS patients treated with siponimod showed T, CD4+, B, and memory regulatory B lymphocytes and CD4/CD8 ratio from month 3 thereafter vs baseline. Patients experiencing disability progression while on siponimod treatment showed no B, memory regulatory and CD3+CD20+ lymphocytes reduction nor CD8+ and and naïve regulatory lymphocytes increase vs patients not experiencing progression.

Discussion: Patients treated with siponimod showed a sustained T lymphocytes reduction, especially CD4+, CD3+CD20+ and naïve regulatory T cells as well as B lymphocytes and memory regulatory B cells reduction. In addition, we reported that disability progression while on siponimod treatment was associated with the lack of drug effect on B and CD3+CD20+ lymphocytes.

## ANTI-GABAAR ANTIBODY-MEDIATED ENCEPHALITIS AFTER ALEMTUZUMAB TREATMENT

G. Sportelli[1], I. Del Negro[1], S. Lorenzut[2], D. Cutuli[2], D. Cargnelutti[2], M. Spatola[3], M. Valente[1], A. Vogrig[1]

[1]Clinical Neurology, Department of Medicine, University of Udine Medical School (Udine); [2]Neurology Unit, Department of Neurosciences, Azienda Sanitaria Universitaria Friuli Centrale (ASU FC) (Udine); [3]Neuroimmunology Program, August Pii Sunyer Biomedical Research Institute (IDIBAPS), Hospital Clinic, University of Barcelona (Barcelona-E)

Objectives: To present a case of anti-GABAAR encephalitis triggered by alemtuzumab (anti-CD52 monoclonal antibody for high active relapsing-remitting multiple sclerosis (MS)) presenting with refractory status epilepticus (SE).

Materials: Immunological studies, brain magnetic resonance imaging (MRI), continuous electroencephalogram (EEG).
Methods: Case report and review of the literature.

Results: A 38-year-old woman with relapsing remitting MS treated with alemtuzumab was admitted complaining sensory disturbances in her left leg; new-onset aphasia was also noticed. Subsequently she manifested a generalized tonic-clonic seizure and a progressive worsening of the neurological state with ensuing encephalopathy. Brain MRI revealed several new T2-weighted and DWI hyperintense lesions, which were not compatible with MS nor with a Progressive Multifocal Leucoencephalopathy. Cerebrospinal fluid (CSF) biochemical, microbiological and autoimmune testing performed at the Udine University Hospital were negative. EEG was consistent with left frontotemporal SE. Despite Intensive Care Unit admission, intravenous antiseizure and anaesthetic drugs administration, there was no effect on SE. In light of the suspected autoimmune pathogenesis, treatment with anti-IL6R tocilizumab was started with SE resolution. Given the strong clinical suspicion for anti-GABAAR encephalitis, CSF/serum samples were sent to IDIBAPS (Barcelona, Spain), which resulted positive. Considering the likely pathogenic antibody, treatment with Rituximab was started. At last follow-up, 3 months after onset, the patient is still severely affected (mRS=5). So far, four cases of autoimmune encephalitis triggered by Alemtuzumab were described [Giarola et al. 2019; Buscarinu et al. 2019; Maniscalco et al. 2020; Ratuszny et al. 2023], two of them anti-GABAAR positive (50%) [1;2], suggesting that alemtuzumab could be a relevant trigger.

Discussion: Anti-GABAAR encephalitis is a very rare neurological condition which often leads to refractory SE. Autoimmune encephalitis is a possible, although rare, consequence of Alemtuzumab treatment.

Conclusion: Our case highlights the importance of anti-GABAAR antibody testing in cases of post-alemtuzumab encephalitis and the high risk of refractory SE in this setting. High index of suspicion is mandatory as anti-GABAAR is not present in commercial kits for autoimmune encephalitis diagnosis.

## COGNITIVE PERFORMANCE, PSYCHOLOGICAL SYMPTOMS AND FATIGUE IN PEDIATRIC PATIENTS WITH MULTIPLE SCLEROSIS: THE ROLE OF THE TREATMENT

S. Tarantino[1], M. Proietti Checchi[1], L. Papetti[1], M. Ferilli[1], G. Monte[1], M. Valeriani[1,2]

[1]Developmental Neurology Unit, Bambino Gesù Hospital (Roma);[2]Center For Sensory-Motor Interaction, Aalborg University (Aalborg-DK)

Objectives: Although Multiple Sclerosis (MS) is a rare condition in pediatric age, an increasing rate of patients are diagnosed under the age of 18. The disabling nature of the disease cannot be reduced only to physical symptoms. Cognitive impairment, fatigue and psychological symptoms are also common features of MS [1]. Studies investigating the impact of pharmacologic interventions on cognitive, psychological and fatigue outcomes, in children and adolescents, with MS are limited. We evaluated: 1) the evolution of cognitive skills, fatigue and psychological symptoms in one year follow up; 2) the role of treatment received on patients' cognitive performance and psychological symptoms; 3) the association between cognitive profile, fatigue, psychological symptoms.

Methods: In this retrospective study, thirty-seven children and adolescents with MS were included (13 boys, 24 girls; mean onset age=14; ± 2.05). The cognitive profile was assessed by Rao's Brief Repeatable Battery (SDMT, CLRT, LTS, SPART, PASAT and LWG subtests). The Patient Health Questionnaire-9 (PHQ-9), General Anxiety Disorder-7 Questionnaire (GAD-7) and the Fatigue Severity Scale (FSS), were used to explore depression, anxiety and fatigue. Seventeen patients received infusion treatment (n= 12 Natalizumab; 4 Ocrelizumab; 1 Rituximab) and 20 received non-infusion treatment (n= 2 Glatiramer Acetate; 6 Interferon beta 1a; 2 Dimethyl Fumarate; 10 Fingolimod). Every patient underwent a baseline evaluation (T1) and second evaluation (T2).

Results: Our data showed a general improvement in several subtests of the Rao battery (p=<0.05). Thirty patients (81%) showed significant higher scores in processing speed (SDMT) in T2 compared with T1 (p=< 0.001). An improvement emerged in both patients receiving infusion treatment (p=0.053) and non-infusion treatment (p=0.006). Moreover, our data showed higher scores in T2 in short-term verbal memory (SRT- LTS, p=0.003), short-term visuo-spatial memory (SRT, p=<0.001) and executive functions (LWG, p=< 0.001). A positive association between fatigue and SDMT in T2 was found (p=0.029). Moreover, our data showed a significant association between depression, visuo-spatial memory (p=0.009) and its delayed recall (p>0.001). Depression and anxiety symptoms were very common (>50%) in T1 and T2. No difference (T1 vs T2) according to the treatment in fatigue and psychological symptoms was found.

Conclusions: Our study evidenced a positive cognitive evolution in patients with pediatric MS. Improvements in cognitive skills emerged in both patients receiving infusion and non-infusion treatment. Given the impact that MS can have on emotional development, a special attention should be paid to young patients' psychological symptoms.

## NMOSD ATYPICAL ONSET WITH TONIC SPASMS AND AREA POSTREMA SYNDROME

F. Tazza. I. Lagorio

Neurology, San Paolo Hospital (Savona)

Case Report: A 72-year-old female patient with a history of breast neoplasm and rheumatoid arthritis presented to the hospital with subacute onset of nausea, vomiting, and tonic spasms affecting the left limbs. She had not been taking any medications. In her left upper limb, she experienced tonic spasms characterized by flexion of the wrist and metacarpophalangeal joints, resembling the "hand of the obstetrician." The patient also reported tonic contraction of the calf in her left lower limb. These movements occurred simultaneously in both limbs, lasting approximately 10 seconds and recurring 2-3 times per hour, with increased frequency associated with anxiety and hyperventilation. Neurological examination revealed subtle left hemiparesis, increased left deep tendon reflexes, and a positive left Babinski sign. Complete blood count, liver and kidney function tests, electrolyte levels, ionized blood calcium, arterial pH, and C-reactive protein were all within normal range. Trousseau and Chvostek signs were negative. Brain and cervical spine MRI showed a large hyperintense lesion in T2-weighted sequences and isointensity in T1-weighted sequences, with modest enhancement by gadolinium-based contrast agent in the lower brainstem and upper cervical cord. Thoracic and lumbar spine MRI were unremarkable. Cerebrospinal fluid examination showed a normal total protein concentration, absence of cells, and a few oligoclonal bands with a pattern type 4. Electromyographic study of the tonic spasms revealed simultaneous contraction of agonist and antagonist muscles, with an asymmetric pattern observed in the flexor digitorum profundus and extensor digitorum communis muscles. No abnormal spontaneous electromyographic activity was detected before or after the episode. Additionally, serum antinuclear and anti-SSA antibodies were detected. A high titer of anti-aquaporin-4 immunoglobulin G (anti-AQP-4-IgG) was also identified, leading to the diagnosis of anti-AQP-4-IgG positive neuromyelitis optica spectrum disorder (NMOSD). Nausea completely resolved with symptomatic treatment (levosulpiride 25mg three times a day orally), while the tonic spasms responded well to a low dose of carbamazepine (100mg once a day). To investigate a paraneoplastic cause of NMOSD, total body CT and PET scans were performed, ruling out neoplastic lesions.

Discussion: Our patient exhibited tonic spasms and area postrema syndrome as the primary symptoms at the onset of NMOSD. Spinal movement disorders are recognized in up to 40% of NMOSD patients, with tonic spasms being the most common phenotype. These spasms typically occur during the recovery phase, associated with remyelination processes. The atypical presentation could lead to a delayed diagnosis. Treatment with carbamazepine resulted in excellent and rapid clinical response.

## A DYNAMIC INTERPRETATION OF KFLC INDEX FOR THE DIAGNOSIS OF MULTIPLE SCLEROSIS: ARE OLIGOCLONAL BANDS STILL REQUIRED?

S. Toscano[1], C. Chisari[2], S. Lo Fermo[2], G. Gulino[3], M. Zappia[2], F. Patti[2]

[1]Department of Biomedical and Biotechnological Sciences, University of Catania (Catania); [2]Department of Medical, Surgical Sciences and Advanced Technologies "GF Ingrassia", University of Catania (Catania); [3]Central Laboratory, University Hospital Policlinico-San Marco (Catania)

Aim: To evaluate the diagnostic accuracy of different cut-off values and ranges of κFLC index in a miscellaneous cohort of neurological patients, finally proposing a diagnostic procedural flowchart for the diagnosis of MS.

Materials and Methods: We consecutively enrolled patients admitted to the Neurology Clinic of the University Hospital "Policlinico G. Rodolico" of Catania, who underwent a diagnostic lumbar puncture in the period between January 2017 - February 2022. We analyzed data from 607 patients diagnosed with MS (179), CIS (116), other inflammatory neurological diseases (94) or non-inflammatory neurological diseases (218). Se, Sp and other measures of diagnostic accuracy were reported for κFLC index, IgG OCB and IgG Index. Potential thresholds and ranges were identified for κFLC index and compared with cut-off values proposed in scientific literature.

Results: The highest diagnostic accuracy in our sample was reported for κFLC index cut-off of 5.0 (Se=85.4%, Sp=90.4%, AUC=0.88, Youden index=0.75). A κFLC index threshold of 11.0 exhibited higher Sp (95.5%, 95% CI 93.1-97.1) than IgG OCB (95.2%; 95% CI 93.1-96.7), allowing to restrict the analysis of IgG OCB to patients with κFLC between 5.0-11.0, halving costs and reducing the time needed for the procedure by ten times. The odds of being diagnosed with MS/CIS was 2.2-fold higher for each increase of 5 units in κFLC index value (OR=1.17; 95% CI 1.12-1.23; p<0.001), independently from values assumed by IgG index and IgG OCB detection.

Discussion: κFLC index is considerably sensitive and specific in supporting the diagnosis of MS/CIS, performing better than IgG OCB

and IgG Index, with the advantage of being a quantitative variable. Among different thresholds, a cut-off value of 5.0 proved to be the most accurate in discriminating between MS/CIS and other neurological diseases. Patients exhibiting κFLC index values higher than 11.0 do not need any further assessment, since κFLC index exhibits a higher specificity than IgG OCB and IgG Index for the diagnosis of MS in this range of values. IgG OCB could be used as a second-line assessment in patients with κFLC index values between 5.0-11.0 in case of diagnostic doubts, in order to further increase specificity, saving time and reducing costs.

Conclusion: We propose to use κFLC index as a preliminary test, considering all subjects with values higher than 5.0 as positive results, and thus possible MS. The analysis of IgG OCB could be restricted only to subjects with borderline values between 5.0-11.0, in order to increase specificity and solve diagnostic doubts about other inflammatory conditions.

## CEREBROSPINAL FLUID NEUROFILAMENT LIGHT CHAINS: A SHORT-TERM PROGNOSTIC BIOMARKER FOR MULTIPLE SCLEROSIS

S. Toscano[1], V. Oteri[2], C. Chisari[2], C. Finocchiaro[2], S. Lo Fermo[2], P. Valentino[3], A. Bertolotto[3], M. Zappia[1], F. Patti[1]

[1]Department of Biomedical and Biotechnological Sciences, University of Catania (Catania); [2]Department of Medical, Surgical Sciences and Advanced Technologies "Gf Ingrassia", University of Catania (Catania); [3]Neuroscience Institute Cavalieri Ottolenghi (Nico), University of Turin (Torino)

Aim: To explore the predictive role of cerebrospinal fluid neurofilament light chains (cNFL) in patients with a recent diagnosis of Multiple Sclerosis (MS), naïve to any disease-modifying treatment.

Materials and Methods: We retrospectively collected data of patients diagnosed with MS, referred to the Neurology Clinic of the University-Hospital G. Rodolico of Catania between January 2005 and December 2015. All patients underwent cerebrospinal fluid (CSF) collection at the time of MS diagnosis and clinical and radiological follow-up for at least three years afterwards. cNFL levels were measured in CSF samples with Simoa NFLight advantage kit at the CRESM (University Hospital San Luigi Gonzaga, Orbassano, Torino). A neuropsychological evaluation with Symbol Digit Modalities test (SDMT) was performed at baseline, at 1-year and at 3-year follow-up. Multivariate logistic regression analysis was performed to investigate cNFL as a potential risk factor for different clinical outcomes.

Results: 244 MS patients (230 relapsing-remitting, RRMS; 94.3%), with a mean age at diagnosis of 37.0±11.1 years, were recruited. cNFL levels did not correlate neither with the Expanded Disability Status Scale (EDSS) at diagnosis and at subsequent evaluations up to 12 years, nor with SDMT performed at diagnosis, at 1 year and at 3 years. cNFL were an independent factor for the occurrence of at least one relapse during the first two years after MS diagnosis (OR=2.75; 95% CI 1.19-6.31; p=0.02) and for the occurrence of gadolinium-enhanced (Gd+) lesions during the first 2 years from diagnosis at brain and spine magnetic resonance imaging (MRI) scans (OR=3.45, 95% CI 1.81-6.57; p<0.001).

Discussion: According to our results, cNFL levels detected at the time of MS diagnosis seem to be a good predictor of short-term disease activity, being associated with the occurrence of clinical relapses and Gd+ lesions at MRI brain and spine scans within two years from MS diagnosis. Conversely, the level of cNFL was not associated with EDSS score and cognitive performance tested with SDMT neither at the time of diagnosis nor at follow-up.

Conclusion: The detection of cNFL at the time of MS diagnosis can be a useful support to predict the two-year risk of clinical and radiological relapses, thus affecting therapeutic choices in the very early phases of the disease.

## COGNITIVE IMPAIRMENT AND RETINAL THICKNESS IN NEWLY DIAGNOSED MULTIPLE SCLEROSIS PATIENTS: RESULTS FROM A CROSS-SECTIONAL STUDY

S. Toscano[1], C. Chisari[2], M. Zappia[2], F. Patti[2]

[1]Department of Biomedical and Biotechnological Sciences, University of Catania (Catania); [2]Department of Medical, Surgical Sciences and Advanced Technologies "Gf Ingrassia", University of Catania (Catania)

Aim: To explore the role of retinal nerve fiber layer (RNFL) thickness as a predictor of physical and cognitive disability in patients with Multiple Sclerosis (pwMS).

Materials and Methods: We screened all newly diagnosed pwMS referred to the MS centre of the University Hospital "Policlinico-San Marco" in the period 2015-2019. All patients were evaluated at baseline and after 3 years of follow-up. RNFL and ganglionar cell layer (GCL) thickness for right eyes (r.e.) and left eyes (l.e.) were measured with Optical Coherence Tomography (OCT). Disability level and cognitive profile were assessed, using the Expanded Disability status scale (EDSS) and the Brief International Cognitive Assessment for Multiple Sclerosis (BICAMS) battery, respectively.

Results: We consecutively enrolled 487 pwMS, including 68 (14.0%) with primary progressive MS (PPMS). At baseline, both RNFL and GCL were bilaterally thinner in PPMS (r.e. 90.4±12.7; l.e. 90.2±13.5, and r.e. 80.1±11.2; l.e. 80.3±12.6, respectively) compared to relapsing-remitting MS (RRMS) (r.e. 94.6±13.1; l.e. 94.3±14.8, and r.e. 85.1±9.5; l.e. 84.9±9.3, respectively) (p<0.01). PPMS patients recorded lower scores at Symbol Digit Modalities Test (SDMT) (24.9±7.7 vs 36.1±12.2; p<0.01, respectively) and both groups performed worse at 3-years follow-up compared with baseline evaluations. A RNFL thickness ≤88.0 μm was an independent predictor of cognitive

impairment (CoI) (OR=5.32; 95% CI=1.84-9.12; p=0.02) and disability worsening (OR=3.18; 95% CI=1.21-10.33; p=0.05), regardless of previous history of optic neuritis (ON) and use of disease-modifying treatment.

Discussion: All MS patients exhibited a significant reduction in both RNFL and GCL over a 3-year follow-up and those with RNFL thickness lower than 88.0 µm exhibited a 5-fold risk to develop CoI in our population. Compared with RRMS, patients with PPMS exhibited thinner RNFL and GCL bilaterally at baseline and at 3-year follow-up and performed worse in motor assessments and SDMT at all time points. CoI at 3-years was independently predicted by EDSS at diagnosis, disease duration, progressive phenotype, annualized RNFL loss and a RNFL thickness lower than 88 µm.

Conclusion: RNFL thickness, as a biomarker of neurodegeneration, could be considered a predictive biomarker of cognitive degeneration and physical disability in MS.

Montichiari, Multiple Sclerosis Regional Center, Department of Neurology, Asst Spedali Civili Di Brescia (Montichiari-BS); [18]Child Neurology Unit, Buzzi Children's Hospital (Milano); [19]Department of Children Neuropsychiatry, University Hospital of Sassari (Sassari); [20]School of Medicine, Italian Multiple Sclerosis And Related Disorders Registry, University of Bari (Bari); [21]Department of Neurology, University of Florence (Firenze); [22]Multiple Sclerosis Regional Center, Ospedale Binaghi (Cagliari); [23]University Hospital of Ferrara (Ferrara); [24]Department of Health Sciences, University of Eastern Piedmont (Novara)

Aims: Multiple Sclerosis (MS) is a chronic inflammatory multifactorial disease that occurs between 20 and 40 years of age. We focused on MS with onset before 18 years (paediatric MS-PedMS), which is a rare and more aggressive form of MS, that offers a unique opportunity to gain clinical and biological data in proximity to the actual disease onset, lifestyle and environmental information. An Italian multicentric study group was realized aiming to enroll paediatric MS patients, matched healthy controls (HC), and MS adults with a disease onset < 18 years in order to analyse genetic, epigenetic, transcriptomic, environmental factors, their interactions, and gut microbial composition.

Methods: In a case-control experiment, we performed 16S sequencing, primary analyses by SmartSeq-MicrobAT software, and more complex and comparative analyses by MicrobiomeAnalyst and Qiime2 pipeline that produced analogous outcomes.

Results: We analysed 87 PedMS and 55 HC. Preliminary results showed a similar composition at phylum level between groups, with Firmicutes (44%) and Baciteroidetes (33%) being the most abundant phyla. The heat tree method revealed a significant different abundance ($p<0.05$) at species level: unclassified_Blautia, unclassified_Lachnospiraceae, Butyrate_producing_bacterium_L2_12 and unclassified_Firmicutes were enriched in PedMS, while Bacteroides sp. Smarlab_3302996, Odoribacter and Unclassified_Rikenellaceae were decreased. Alpha-diversity, measured by Observed index, resulted significant in HC compared to PedMS ($p=0.02$), while beta-diversity showed similarity between the two groups.

Discussion: So, we profiled gut microbial composition of PedMS patients and HC. We found significant abundance differences at species level that were confirmed in paediatric and adult literature: Blautia and Odoribacter were respectively found to be increased and decreased both in our study and in PedMS literature, while Lachnospiraceae were increased in our study but decreased in other paediatric studies.

Conclusion: We plan to add new samples, expanding our cohort, and to perform again the analysis. Moreover, we will perform an integration with host-genetic data (GWAS-SNP) and other host-omics, together with clinical and environmental information to explore gene-environment interaction that could lead to a paediatric disease onset.

## REDUCTION OF GANGLION CELL-INNER PLEXIFORM LAYER THICKNESS IN MS: COMPARISON BETWEEN LOW-MODERATE EFFICACY AND HIGH EFFICACY DMT

A. F. Vacca[1], G. Coghe[1], C. Cordano[2], E. Idini[1], L. Lorefice[1], E. Cocco[1], J. Frau[1]

[1]Multiple Sclerosis Centre, Binaghi, University of Cagliari (Cagliari); [2]Division of Neuroimmunology and Glial Biology, Weill Institute for Neuroscience, University of California San Francisco (UCSF) (San Francisco-USA)

Introduction: Optical coherence tomography (OCT) is a diagnostic tool useful to investigate neurodegeneration associated with MS progression by measuring retinal layers thickness.

Objectives: To assess the impact of disease-modifying treatments (DMTs) on ganglion cell-inner plexiform layer (GCIPL) thickness, measured by optical coherence tomography (OCT).

Material and Methods: We analyzed 47 MS patients (female to male ratio 3:1, mean age 38.8 ± 8.65 years, median EDSS at baseline 2.0 with range from 0 to 6.5, mean disease duration 9.38 ± 9.04) who underwent longitudinal spectral-domain OCT imaging (Spectralis, Heidelberg Engineering, Germany) at the MS Centre of Cagliari between 2017 and 2021. OCT scans were performed for both eyes at baseline (T0) and at two-year follow-up (T1). The primary outcome parameter was macular ganglion cell–inner plexiform layer (GCIPL) volume. Based on the DMT the patients were divided in low-moderate efficacy group (interferon beta, glatiramer acetate, teriflunomide, and dimethyl-fumarate), or high efficacy group (fingolimod, cladribine, ocrelizumab, natalizumab, alemtuzumab). Differences in GCIPL for macular sectors between T0 and T1 were evaluated with mixed ANOVA, setting the treatment groups as independent variables and correcting for age of onset, EDSS and disease duration.

Results: 93 eye scans were acquired from 47 patients, 22 on low-moderate efficacy and 25 on high efficacy DMT. At baseline, low-moderate efficacy group displayed a mean GCIPL global thickness of 67,7 µm and 69,1 µm in outer temporal sector, while high-efficacy group exhibited thicknesses of 65,5 µm and 64,3 µm, respectively. Mixed ANOVA showed a significant difference in the reduction of GCIPL (T0 vs T1) between low-moderate efficacy and high-efficacy DMTs. The high efficacy group showed less GCIPL atrophy compared with the low-moderate efficacy group in both outer temporal sector (66,8 µm vs 64,9 µm, $p<0.001$) and the global thickness (65,6 µm vs 66 µm, $p<0.001$). After correcting for demographic and clinical variables, differences between T0 vs T1 for the two groups were confirmed ($p<0.002$).

Conclusions: According to our data, high-efficacy DMTs can reduce GCIPL atrophy in a two-year follow-up. Hence we confirmed the ability of high-efficacy treatments to potentially alter the trajectory of neurodegeneration in MS and the usefulness of retinal imaging in monitoring treatment efficacy.

## KAPPA FREE LIGHT CHAINS AS MARKERS OF MULTIPLE SCLEROSIS DIAGNOSIS: A 10-YEAR MONOCENTRIC STUDY

D. Vecchio[1], P. Chiara[2], E. Virgilio[1], G. Bellomo[2], I. Crespi[2], P. Naldi[1], U. Dianzani[2], C. Comi[1], R. Cantello[1]

[1]Neurology Unit, Department of Translational Medicine, University of Piemonte Orientale (Novara); [2]Clinical Biochemistry, Department of Translational Medicine, University of Piemonte Orientale (Novara)

Background: Cerebrospinal fluid (CSF) kappa free light chain (KFLC) are becoming a diagnostic biomarker for multiple sclerosis (MS).

Aims: To compare the efficiency of KFLC to oligoclonal bands (OB) in diagnosing MS and radiological and clinical isolated syndromes (RIS-CIS).

Methods: We collected 802 patients (59% females) in 10 years, who underwent CSF analysis for intrathecal synthesis in the diagnostic work-up and were classified according to their diagnosis: 296 MS, 170 with other neurological inflammatory diseases (including 28 RIS-CIS), and 336 non-inflammatory. Lymphoproliferative and infective diseases were excluded. KFLC index cut off was 5.

Results: KFLC index were significantly higher in MS patients compared to those with other neurological diseases (mean ±standard deviation: 68.6±154.1 versus 4.7±12.4; $p<0.001$) with high sensitivity (91% similar to that of OB) and moderate specificity (85% if compared to 90% of OB) in diagnosing MS. A KFLC index above 5 was demonstrated in 6/27 MS cases with no OB, and in 4/28 RIS-CIS cases.

Conclusions: The KFLC index markers confirmed the accuracy in MS diagnosis, also in those patients with no OB and in the RIS-CIS population.

## AN ATYPICAL CASE OF PROGRESSIVE DISEASE IN MOGAD

M. U. Verza, A. Mariottini, E. Schiavo, S. Cornacchini, L. Massacesi, V. Damato

Department of Neurosciences, Psychology, Drugs Research and Child Health (NEUROFARBA), University of Florence (Firenze)

Introduction: The myelin oligodendrocyte glycoprotein antibody (MOG-IgG) is a biomarker found in a subset of patients with central nervous system inflammation. The MOG antibody-associated disease (MOGAD) may be associated with a monophasic or relapsing disease course, but clinical progression independent of relapse activity is rare. Herein we describe a patient with a progressive course, initially misdiagnosed as Multiple sclerosis (MS), in which MOG-IgGs were found to be positive after 5 years of clinical follow-up.

Case Description: A 45-year-old woman diagnosed with MS in 2018 based on progressive gait impairment, MRI evidence of inflammatory lesions in the cerebellar hemispheres, (right middle cerebellar peduncle, pons, thalamocapsular region, periventricular white matter) and in spinal cord (C1-C2, C4-C5 and D8 levels) with the presence of oligoclonal bands in cerebral spinal fluid (CSF). The patient started on Natalizumab, suspended after one year for a progression of disability with assistance required to walk for more than 150m (EDSS 5.5). Given the progressive disease course, Siponimod was started on February 2020 with further disability progression in the absence of relapses or new MRI lesions (EDSS 6.5). It was withdrawn in February 2022 for Sars-CoV-2 infection. Notably the patient experienced transient clinical improvement lasting more than 12 weeks after Siponimod was stopped. The patient was referred to our clinic for a second opinion in September 2022 (EDSS at visit 7.0). Given the unusual disease course with several red flags (including severe itching and bilateral VEP alteration), anti-AQP4 and anti-MOG antibodies were requested on serum, which were negative using fixed commercial assays, but anti-MOG antibodies resulted positive at live cell-based assay at high level (End point titre 1:640), confirming the diagnosis of MOGAD.

Discussion: This case report contributes to expand the clinical spectrum of MOGAD, which should be considered when patients present with unexpected response to disease modifying therapies for MS. In these cases, MOG-IgG should be always tested and live

cell-based assays should be recommended in case of negativity for MOG-IgG by commercial fixed tests. Doing a literature review, we found at least 7 other cases very similar to this one, which confirms that a progressive trend, though rare, should be considered in MOGADs.

## PRELIMINARY RESULTS OF A REAL LIFE MULTIPLE SCLEROSIS COHORT TREATED WITH OFATUMUMAB

R. Vitobello, A. Manni, F. Oggiano, A. Bianco, A. Iaffaldano, P. Iaffaldano, D. Paolicelli

Department of Translational Biomedicine and Neurosciences (DiBraiN), University of Bari "Aldo Moro" (Bari)

Objectives: Ofatumumab is a fully human anti-CD20 monoclonal antibody approved for the treatment of highly active Relapsing Remitting Multiple Sclerosis (RR-MS). There is few evidence about its effectiveness in the real life. Therefore, we identified a cohort of ofatumumab treated patients, to evaluate the quickness of its effect in a real life cohort.

Materials: The study population included RRMS patients who received ofatumumab in a Southern Italy MS Center, from July 2022. Methods: Descriptive statistical analysis was performed using Statistical Package for Social Science (SPSS) software. We analyzed the following variables: Expanded Disability Status Scale (EDSS), Gadolinium enhancing (GD+) lesions and T2 new lesions, clinical relapses at baseline and at 6 months of follow-up.

Results: We enrolled 52 RRMS patients (14 Male (26.9%), mean age 30.5±10.9, median time from MS onset 8.0 (1-32) years). Thirty-three of them (63.5%) were treatment-naive; the baseline EDSS was 3.0 (1.0-6.5) and the median number of relapses before ofatumumab beginning was 2 (1-4). Only 2 of 52 patients (1.04%) presented clinical relapses at the subsequent follow-up. Of the 19 patients (63.5 %) who had a MRI control at six months, 5 (9.6%) had persistence of radiological activity with new T2-lesions (2 of these GD+). Instead, 14 patients (26.9 %) obtained 6 months NEDA-3. The median EDSS at the 6 months follow-up was 2.0 (1.0-5.0). We have not identified potential predictive factors for persisting clinical or radiological activity.

Discussion: Ofatumumab demonstrated a reduction of clinical and radiological disease activity, according to the current evidence of randomized clinical trials (ASCLEPIOS I/II and ALITHIOS open-lable extension).

Conclusion: Our data confirmed Ofatunumab efficacy in the short term. In consideration to its recent approval, research is needed to confirm these data on the long term and in a larger populations.

## GUT, SKIN AND ORAL MICROBIOME IN MULTIPLE SCLEROSIS: A MENDELIAN RANDOMIZATION ANALYSIS

V. Zancan[1], G. Bellucci[2], R. Bigi[3], M. Nasello[2], V. Rinaldi[2], A. Marrone[2], M. Buscarinu[2], R. Mechelli[4], G. Ristori[2], M. Salvetti[2]

[1]Department of Neurosciences, Mental Health and Sensory Organs, AO Sant'Andrea, Sapienza University of Rome (Roma); [2]Department of Neurosciences, Mental Health and Sensory Organs, Sapienza University of Rome (Roma); [3]Neuroimmunology Unit, Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS) Fondazione Santa Lucia (Roma); [4]Department of Human Science and Promotion of Quality of Life, San Raffaele Roma Open University (Roma)

Objectives: Growing evidence links the microbial communities inhabiting the gut and other body surfaces to pathophysiological processes underlying MS. Here we aimed to assess causality between the gut, skin and oral microbiomes and Multiple Sclerosis (MS), by performing Mendelian Randomization (MR) analyses.

Materials: We extracted genetic instruments from summary statistics from 3 large genome-wide association studies (GWAS) on gut microbiome (18340, 8959 and 7738 subjects), 1 GWAS on skin flora (1656 skin samples), and 1 GWAS on oral microbiome (1915 subjects). Exposure data derived from the latest GWAS on MS susceptibility (47429 patients and 68374 controls).

Methods: MR represents an epidemiological study design that allows to estimate the causal relationship between a risk factor and an outcome of interest using genetic variants as proxies for environmental exposures.

Results: Genetically predicted abundance of Ruminococcus (Odds Ratio, OR=2.89, p=0.001), Bacteroides (OR= 1.16, p=0.02), Actinobacteria (OR 1.48, p=0.02) and Bifidobacteriaceae (OR= 1.46, p=0.01) in the gut, Veillonella species (OR=1.06, p=0.02) in the skin, Lachnospiraceae (OR=1.41, p=0.02) and Saccharimonidales (OR=1.33, p=0.03) in saliva are causally linked with MS. Furthermore, we found that microbial lactose and galactose degradation processes (OR=0.71, p=0.0006) in the gut, and abundance of Flavobacteriales Capnocytophaga (OR=0.60, p=0.0006) in saliva may exert a protective effect towards MS susceptibility.

Discussion: Our results provide compelling evidence that specific microbial taxa in the gut, skin, and saliva may play a causal role in the development of MS. Importantly, beyond confirming the role of gut species previously associated with the disease, we highlight other taxa and body sites deserving further investigation.

Conclusion: This work underscores the relevance of the microbiome-brain axis in MS etiology and opening wider perspectives on host-environmental interactions in MS. Targeted modulation of the gut, skin, and saliva microbiota may hold promise for the development of novel therapeutic strategies aimed at mitigating MS risk and progression.

## MIRNA 106A-5P IN CEREBROSPINAL FLUID AS SIGNATURE OF EARLY RELAPSING REMITTING MULTIPLE SCLEROSIS: A CROSS SECTIONAL STUDY

A. Zanghì, V. Manuti, G. Serviddio, C. Avolio, E. D'Amico

Department of Medical and Surgical Sciences, University of Foggia (Foggia)

Objectives: Aim of the study was to compare the levels of expression of circulating microRNA (miRNAs) 21-5p, miRNA 106a-5p, miRNA146a-5p, miRNA223-3p in cell-free cerebrospinal fluid (CSF) in Relapsing Remitting Multiple Sclerosis (RRMS) patients and other neurological diseases (OND).

Materials and Methods: A cross sectional study conducted at MS centre of Foggia, Italy. We enrolled patients with (1) age between 18 and 55 years, (2) a definitive diagnosis of RRMS per the revised McDonald criteria, and (4) naïve to any disease modifying therapy or 5) patients with other OND. Investigated MiRNAs were extracted, retro-transcripted and then assessed by real-time polymerase chain reaction assay (q-PCR). A receiver-operator characteristic (ROC) curve was used to test MiRNAs as a biomarker for the diagnosis of MS. A linear regression analysis was done to find any association with disease characteristics at the time of diagnosis.

Results: A total cohort of 70 subjects (70% women) was analyzed. Out of them, 35 had a RRMS diagnosis. MiRNA 106a-5p (7.8±3.8 vs 1.3±0.9, p=0.03) had higher levels in RRMS patients when compared to OND. The ROC curve indicated that MiRNA 106a-5p could be considered as disease biomarkers with an area under the curve of 0.812 (p<.001; 95% CI 0.686-0.937). Linear regression analysis showed an association between the number of oligoclonal bands and MiRNA 106a-5p levels (B coeff 2.6, p<.001; 95% CI 1.3-4.9).

Discussion: In our cross-sectional real-world study, we found that CSF miRNA106a was upregulated in RRMS patients at the time of diagnosis and that it was associated to a higher number of OCBs. The altered miRNAs expression in early MS phases would lead to the modulation of inflammation. The major strength of this study is to suggest CSF MiRNAs as useful disease biomarkers because of their easy extraction and stability.

Conclusions: Further studied are needed to characterize their role in early MS as disease biomarker.

## PLATELET TO LYMPHOCYTE RATIO AND DISEASE COURSE IN MULTIPLE SCLEROSIS PATIENTS

A. Zanghì, P. Di Filippo, F. De Vita, C. Avolio, E. D'amico

Department of Medical and Surgical Sciences, University of Foggia (Foggia)

Objectives: Aim of the study was to describe if any association between platelet to lymphocyte ration and disease course in a cohort if Multiple Sclerosis patients.

Materials and Methods: A cross sectional study conducted at MS centre of Foggia, Italy. We enrolled patients with (1) age between 18 and 55 years, (2) a definitive diagnosis of RRMS per the revised McDonald criteria, and (4) treated with disease modifying therapy. We have collected platelet lymphocyte ratio (PLR) during routinary clinical practice. It was converted to log10 to normalize values. A linear regression analysis was done to find any association with disease characteristics.

Results: A total cohort of 120 subjects (61.8% women, mean age 43.2±12.2 years) was analysed. Out of them, 71.7% were switchers from other DMTs. The mean value of log10 PLR was 2.2±0.3. A correlation was found between PLR and the level of disability measured with Expdanded Disability Status Scale (B coeff 1.3, p<.001; 95% CI .1.1-1.9)

Discussion: In our real-world study, we found that the PLR could be associated to level of disability in a cohort of MS patients.

Conclusions: Further studied are needed to characterize the role of chronic inflammation measured with peripheral biomarkers and disease course.

## NEUROCOVID

## CEREBRAL VENOUS SINUS THROMBOSIS IN THE VACCINE-INDUCED IMMUNE THROMBOTIC THROMBOCYTOPENIA (VITT): AN ACUTE COVID-19 VACCINATION SYNDROME (ACVS)

V. Annese, A. Danese, A. Lupato, M. Turazzini

COU of Neurology, Mater Salutis Hospital (Legnago-VR)

Background: SARS-CoV-2 can lead to acute disease and post-acute-syndrome (PACS-long COVID). Side effects of COVID-19-vaccines have been increasingly noted and studied. Post-COVID-19-vaccination-syndrome (PCVS) needs to be distinguished between acute-COVID-19-vaccination-syndrome (ACVS) and post-acute-COVID-19-vaccination-syndrome (PACVS). Moreover, there are mixed forms of disease caused by natural SARS-CoV-2-infection and COVID-19-vaccination.

Case report: We describe a case-study of a 61-year-old woman, affected by migraine, paroxysmal-supraventricular-tachycardia. She was previously treated with atenolol. On May 8th2021 she underwent vaccination with adenovirus-vector–based-vaccine (ChAdOx1/nCoV-19). In the following two days, she reported fever. On May 11th, she'd an onset of headache with intensity up to 10NRS, unresponsive to NSAIDs. On May 18th, she was admitted to Emergency-Room. Neurological evaluation was initially normal. After few hours, aphasia, right hemianopsia and mental confusion appeared. Few tests performed were reported below.

Blood-tests: PLT 41,000/mmc, INR 1.41, D-dimer 32.000 ug/l.
Cerebral-CT: Hyperdensity of the sulci in the left temporo-parietal-region and ipsilateral transverse sinus.

Cerebral angio-CT: Transverse and sigmoid sinus thrombosis. She was admitted in Stroke-Unit for cerebral venous sinus thrombosis in thrombocytopenia post-COVID-19-vaccination. After excluding HIT and thrombotic microangiopathy she performed transfusion of 1 bag of PLT, IVIG 1g/kg (which inhibits FcRγIIA-mediated-platelet-activation), dexamethasone 8 mg, fondaparinux 2.5 mg. She was transferred to Intensive-Cure-Unit of Neurosurgery in order to evacuate the hematoma. Dexamethasone 8 mg was administered 4 times a day, mannitol and another transfusion of PLT (platelet level rising to 110,000 /mmc). Levetiracetam was started after the onset of seizures. On May28th, the angio-CT showed a greater patency of the sigmoid-transverse sinus. On June4th, the T-P-O hematoma was almost completely reabsorbed at the cerebral CT. Ab anti-complex-heparin-PF4 were positive. The suspicion of brain sinus thrombosis associated with the adenovirus-vector–based-vaccine was finally confirmed (five diagnostic-criteria-of-the-UK-Haematology-Expert-Group-developed-consensus for VITT). On June15th, she came back to our ward. She was alert, collaborating, understands simple delivery, spoke poorly, fairly fluent and communicative, notes of ideo-motor-apraxia, right mild hemianopsia.

Conclusion: We describe an acute vaccine-induced-immune-thrombotic-thrombocytopenia (VITT) with cerebral-venous-sinus-thrombosis. It's a rare but severe immunological reaction particularly associated to the adenovirus-vector-based-COVID-19-vaccines that can afford in low-middle-income countries. A possible mechanism for side effects could be that the vaccine triggers the formation of anti-platelet factor-4-antibodies, which cross-react with membrane-bound or soluble proteins involved in thrombus formation. Extreme activation of platelets and the coagulation system leads to a high risk of death from venous or arterial thrombosis or secondary hemorrhage. Rapid recognition and treatment of VITT could reduce the brain damage.

## HYPOSMIA AFTER SARS-COV2 INFECTION: WHEN THE SIMPLEST ANSWER IS NOT THE RIGHT ONE

E. Biassoni[1], L. Lombardo[1], A. Donniaquio[1], R. Mancini[1], F. Calizzano[1], M. Losa[1], F. Germano[1], S. Grisanti[2], D. Arnaldi[1], S. Morbelli[3], L. Benedetti[1], F. Massa[1], M. Pardini[1]

[1]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DiNOGMI), University of Genoa (Genova); [2]Neurology, P.O. Ponente, Santa Corona Hospital (Pietra Ligure-SA); [3]Department of Health Sciences (DISSAL), University of Genoa (Genova)

Background: Hyposmia is a non-specific symptom associated with both local conditions and neurodegenerative diseases, including Lewy body disease (LBD) [1]. During the COVID-19 pandemic, hyposmia gained significant attention as a possible consequence of Sars-CoV-2 infection [2]. It is crucial to recognize and evaluate hyposmia within a comprehensive clinical framework to prevent overlooking other potential etiologies.

Case Report: In 2020, a 77-year-old woman developed ageusia and anosmia during Sars-CoV-2 infection. Despite recovery from the infection, she continued to experience hyposmia along with concentration and memory difficulties, occasional postural instability, asthenia, and depression. Neurological and cognitive assessments conducted at an outpatient clinic did not reveal any abnormalities. However, the Sniffing test confirmed the presence of hyposmia. Further investigations, including brain magnetic resonance imaging (MRI) and [18F]FDG PET scans as part of Neurocovid research, demonstrated millimeter chronic vascular lesions and bilateral moderate hypometabolism in the lateral temporal and posterior parietal lobes, respectively. Upon evaluation in a specialized Memory Clinic, the patient also reported insomnia, constipation, and a history of visual and auditory hallucinations. A slight visuospatial deficit and mild asymmetric parkinsonism with left-side predominance were detected. To explore the possibility of a LBD, additional diagnostic tests were conducted. DaT-SPECT revealed reduced dopamine transporter uptake in the putamen (predominantly in the right side), polysomnography showed REM sleep without atonia, and [123]I-MIBG myocardial scintigraphy demonstrated low uptake. These biomarkers were indicative of probable mild cognitive impairment with Lewy bodies (MCI-LB) based on current diagnostic criteria [3]. Therapy with Rivastigmine 4.6 mg/24h was initiated.

Discussion: The exacerbation of likely pre-existent hyposmia in association with Sars-CoV-2 infection led the patient to medical consult. The heightened awareness of hyposmia during the COVID-19 pandemic played a pivotal role in recognizing this symptom. Visiting a specialized center enabled a comprehensive evaluation of this non-specific symptom within the context of a complex disorder that could have otherwise been overlooked. The presence of cognitive impairment, depression, visual hallucinations, and subtle parkinsonism may suggest early-stage MCI-LB and should be considered in patients with hyposmia [3].

Conclusions: This case report serves as a reminder not to underestimate hyposmia, particularly in the post-COVID-19 pandemic phase when it is associated with cognitive or depressive symptoms. Improved recognition and thorough evaluation of hyposmia can contribute to the early detection and appropriate management of neurodegenerative disorders, including LBD. Clinicians should maintain a high index of suspicion for underlying neurologic conditions when assessing patients presenting with hyposmia.

## CEREBRAL POLYOPIA/DIPLOPIA WITH ONSET DURING ACUTE SARS-COV-2 INFECTION

F. Brigo

Department of Neurology, Hospital of Merano (SABES-ASDAA) (Merano-BZ)

Objectives: Cerebral polyopia (or cerebral diplopia) is a visual perceptual disorder where two or multiple images are perceived while fixating on a single object, even with one eye closed (monocular vision) [1]. It is important to differentiate cerebral polyopia/diplopia from other causes of monocular diplopia, particularly ocular refractive abnormalities. Cerebral polyopia/diplopia is extremely rare and is usually due to lesions involving the associative visual cortex, such as multiple sclerosis, stroke, trauma, encephalitis, brain tumors, epileptic seizures, and migraine [2]. The infection by SARS-COV-2, and its related COVID-19 disease, has been associated with many neurological and ophthalmological manifestations. Herein, I describe the first case of cerebral polyopia with onset during SARS-CoV-2 infection.

Materials and methods: Case report.

Results: The patient was a 50-year-old right-handed colorblind man without relevant medical history. Six months earlier, during a Sars-COV-2 infection (confirmed by nasopharyngeal swab with rapid antigen test) he experienced headaches, associated with high fever and diplopia. The diplopia was present and remained unchanged both when either one eye was closed (monocular vision) and when both eyes were open (binocular vision). The two images had equal characteristics in terms of visual resolution, size, and color; they were separated from each other by the same amount of space and with the same angular degree. The diplopia persisted unchanged after the infection had resolved. An extensive ophthalmological evaluation excluded primitive eye causes of monocular diplopia. The neurological examination was unremarkable. Serology for EBV, CMV, HIV, tick-borne encephalitis, Toxoplasma gondii, and Borrelia burgdorferi was negative. Serum autoimmune screening was unremarkable, acetylcholine receptor antibodies were negative, and cerebrospinal fluid examination yielded normal results (no oligoclonal bands or neurotropic viruses were detected). The serological test for COVID-19 confirmed prior infection. Ocular optical coherence tomography, visual field testing, visual evoked potentials, and electroencephalogram were normal. A contrasted brain MRI showed several subcortical T2-hyperintense blurry lesions in frontal and parietal white matter, without involvement of occipital region.

Discussion: The symptoms suggest that polyopia could have arisen within the context of a viral SARS-CoV-2 encephalitis. This hypothesis is supported also by the lack of any further etiological explanation and by the subcortical lesions seen on MRI, compatible with previous multifocal encephalitis.

Conclusion: Although extremely rare, cerebral polyopia/diplopia should be promptly differentiated from monocular diplopia due to refractive disorders. It can be the symptom of an acute brain lesion or dysfunction, including viral encephalitides, such as that due to SARS-CoV-2 infection.

## RELAPSING DOUBLE SERONEGATIVE NEUROMYELITIS OPTICA SPECTRUM DISORDER POST-COVID VACCINATION

S. D. M. Camerer, V. Camera, F. Virla, E. Turano, D. Marastoni, M. Tinazzi, M. Calabrese

Department of Neuroscience, Biomedicine and Movement Sciences, University of Verona (Verona)

Introduction: In this report we will discuss a rare case of relapsing double seronegative neuromyelitis optica spectrum disorder (DN-NMOSD) post-Covid vaccination.

Case-report: A 28-year-old man presented with diplopia, vomiting and hiccups within one week from the first jab of Pfizer vaccine (January 2021) persisting for longer than 10 days. Blood tests, abdominal ultra-sounds and MRI did not find signs of gastrointestinal tract infections. The symptoms regressed spontaneously. In February 2021, two days after the second jab of Pfizer vaccine, the patient complained again diplopia associated with dizziness, asthenia, and a skin rash in the right hemiface, interpreted as a VZV reactivation. While the skin rash improved with famciclovir treatment, the diplopia worsened, and the patient was admitted in the Neurology Unit. Bilateral gaze-evoked nystagmus and drowsiness were found. Brain MRI showed a T2/FLAIR hyperintense area at the medulla-cervical spinal cord junction and at the pavement of the IV ventricle. Serum anti-myelin oligodendrocytes glycoprotein (MOG)-IgG and aquaporin4(AQP4)-IgG were negative as well as cerebrospinal fluid (CSF) standard exam, film arrays for viral and bacterial infections and oligoclonal bands. He was treated with high-dose intravenous steroids (methylprednisolone 1g for 5 days) with a complete recovery. In December 2021, he suffered from a sudden right optic neuritis (visual acuity 1/10) and high-dose intravenous steroids were administrated with complete recovery of the right eye vision. MOG-IgG and AQP4-IgG were again negative. Oral steroids tapering off was started. In February 2022, few days after the oral steroids suspension, the patient experienced a left optic neuritis (visual acuity 4/10). CSF analyses were repeated and OCB and film Array on CSF as well as serum AQP4-IgG and MOG-IgG were found negative. MRI showed a new T2/FLAIR hyperintense swelling of the right optic hemichiasm, while PEVs showed bilateral slowing in conduction speed (left>right). This time the patient was left with reduction of the left eye visual acuity after high-dose steroids. DN-NMOSD was diagnosed, and rituximab treatment was started empirically without additional relapses.

Discussion: DN-NMOSD is a rare condition requiring the exclusion of both AQP4-IgG and MOG-IgG [1]. In this case AQP4-IgG and MOG-IgG were tested before the steroid therapy was started, confirming the double-seronegative phenotype of NMOSD. Five cases of DN-NMOSD after Pfizer vaccine were reported recently [2], however none of these cases presented with brainstem syndrome nor with a relapsing course and requiring rituximab treatment. The greater autoreactivity may be attributed to the viral vector of the vaccine [3].

## ESSENTIAL TREMOR WORSENING AFTER SARS-COV-2 INFECTION: A SECOND CASE REPORT

D. Costa[1], L. Angelini[1], M. Passaretti[1], D. Birreci[1], D. Colella[1], A. Cannavacciuolo[2], G. Paparella[2], A. Berardelli[2], M. Bologna[1]

[1]Department of Human Neurosciences, Sapienza, University of Rome (Roma); [2]IRCCS Neuromed (Pozzilli-IS)

Aim: Neurological manifestations following SARS-CoV-2 infection are widely recognized. However, the potential effects of SARS-CoV-2 infection on essential tremor (ET) have not been extensively studied. We previously reported a case of ET worsening following SARS-CoV-2 infection1. In this report, we present a second case showing a substantial worsening of tremor in a 63-year-old woman diagnosed with ET after contracting SARS-CoV-2 infection.

Materials and Methods: We conducted clinical and kinematic assessments to evaluate various tremor features, including postural, kinetic and rest tremor. Additionally, cognitive and psychiatric evaluations were performed using clinical scales at two time points: 2 months (T2) and 1 year (T3) after the infection. The data were compared with the measurements taken 1 month before the infection (T1). Blood laboratory exams were also conducted before and after infection.

Results: At T2, we observed a significant increase in postural tremor amplitude in the upper limbs compared to T1 (average percent variation: +45%). Furthermore, there was a substantial increase in head tremor amplitude (average percent variation: +284%). At T3, we observed a reduction in both postural tremor amplitude (-24%) and head tremor amplitude (-48%) compared to T2. However, the values remained higher than those at T2 (+11% in upper limb postural tremor amplitude; +99% in head tremor amplitude). There were no significant variations in tremor frequency (Hz) or differences in rest and kinetic tremor features. The trends observed in the kinematic analysis were consistent with the clinical evaluation, as indicated by the total score obtained on the Fahn-Tolosa-Marin Tremor Rating Scale (FTMTRS). In T3, the score was 32, whereas it was 41 in T2 and 28 in T1. Additionally, there were no changes in cognitive and psychiatric status compared to the previous evaluation. Lastly, the results of blood laboratory exams did not significantly differ among the three evaluations.

Discussion: The observations overall indicate that the initial worsening of tremor is not solely attributed to the natural course of the disease, but rather to infection. It is plausible to hypothesize that the SARS-CoV-2 virus induced long-lasting neuroinflammation in the structures involved in the pathophysiology of ET, particularly the cerebello-thalamic network, resulting in a significant deterioration of tremor symptoms.

Conclusion: To the best of our knowledge, this is the second reported case of tremor worsening in ET following SARS-CoV-2 infection. Longer follow-up and measurement of neuroinflammation biomarkers could provide a better understanding of the causal role of SARS-CoV-2 infection in patients with ET.

## FATAL POSTERIOR REVERSIBLE ENCEPHALOPATHY AS THE ONLY MANIFESTATION OF COVID 19

M. S. Cotelli[1], P. Lavezzi[2], A. Tomasoni[2], F. Manelli[3], S. Bonetti[4], G. Tomasini[5], G. Bonetti[6], R. Furloni[7], V. Palomba[8], M. Mendeni[7], F. Zanardi[5], V. Bertasi[1], M. Turla[1]

[1]Neurology Unit, Valcamonica Hospital (Esine-BS); [2]Radiology Unit, Valcamonica Hospital (Esine-BS); [3]Emergency Unit, Bolognini Hospital (Seriate-BG); [4]Emergency Unit, Spedali Civili Hospital (Brescia); [5]Emergency Unit, Valcamonica Hospital (Esine-BS); [6]Clinical Pathology Laboratory, Valcamonica Hospital (Esine-BS); [7]Medicine Unit, Valcamonica Hospital (Esine-BS); [8]Neurology Unit, Desenzano Hospital (Desenzano-BS)

Background: The novel human coronavirus disease (COVID-19) infection has been associated with many neurological complications vascular and thrombotic complications, some of which may result from endothelial dysfunction, including the posterior reversible encephalopathy syndrome (PRES). We describe a case report of a PRES a solely manifestation of COVID 19 and one week after first dose of COVID 19 vaccination.

Materials and Methods: We report the case of a 79 years-old caucasian woman, who was evaluated at the emergency department of our hospital due to malaise, dull and gravative headache, fever, cognitive impairment from three days. She had received administration of first dose SARS-COV2 vaccine (Spikevax) seven days before. At evaluation patient presented generalized tonic-clonic seizures (bilateral seizure foci at electroencephalogram) responsive to intravenous infusion of levetiracetam. She was clearly confused, with global aphasia, cortical blindness without motor or sensory defects or meningeal signs. Body temperature was 38°C while arterial pressure resulted 130/80 mmHg. Nasopharyngeal swab revealed COVID 19 infection. Chest tomography excluded respiratory involvement or pulmonary embolism. Oxygen saturation levels resulted normal. Her medical history was unremarkable, especially for cognitive impairment or psychiatric disorders. She suffered from arterial hypertension, stable and well-controlled. Lumbar puncture with film - array resulted normal. Blood exams resulted all normal except for high levels of ferritin (1278 ug/l), reactive C protein 44.6 mg/l (0-5), D dimer 1380 ug/l, Interleuchin 6 16.67 pg/ml. Autoimmune panel and paraneoplastic markers resulted normal.

Results: She performed brain magnetic resonance imaging showed 2/fluid-attenuated inversion recovery (FLAIR) symmetrical hyperintensities areas involving both occipito-frontal -parietal hemisphere with vasogenic edema and without contrast enhancement or haemorrage lesions. She was diagnosed with PRES. Despite intravenous steroid therapy, levetiracetam, empirical antiviral treatment, hydratation patient conditions worsened (state of coma) and she died after 2 days. Blood pressure and renal function remained normal until death.

Discussion: Final diagnosis was PRES due to COVID 19 infection in an old patient who had been exposed and infected either through the end-to-end or shortly after process of vaccination rather than a vaccine adverse event. PRES resulted the only clinical manifestation of COVID 19 (respiratory parameters and chest evaluations and remained normal, repeated chest radiography excluded pulmonary involvement) and the main cause of death.

Conclusion: We report a fatal PRES case due to COVID 19 infection, expanding current literature. Especially in the first wave of

pandemic prompt evaluation of neurological symptoms and treatment was necessary in order to save lives.

## PREDICTORS AND IMPACT ON DISABILITY OF DELIRIUM IN COVID-19: AN OBSERVATIONAL STUDY ON 2288 CONSECUTIVE HOSPITALIZED PATIENTS

V. Cristillo[1], A. Pilotto[1], M. Locatelli[1], S. Gipponi[1], E. Cottini[1], C. Rossi[2], M. Lombardo[2], F. Castelli[3], M. Metra[4], A. Padovani[1]

[1]Department of Clinical and Experimental Sciences, University of Brescia (Brescia); [2]General and Health Direction, ASST Spedali Civili di Brescia (Brescia); [3]Division of Infectious and Tropical Diseases, University of Brescia (Brescia); [4]Department of Medical and Surgical Specialties, Radiological Sciences, and Public Health, University of Brescia (Brescia)

Backgrounds: Delirium is a common event among Covid-19 hospitalized patients. In this work, we aim at evaluate the predictors of delirium and its impact on in-hospital mortality and disability in a large population of consecutive patients hospitalized for Covid-19.

Methods: Two thousand two hundred eighty-eight Covid-19 patients were admitted to single tertiary COVID-19 hospital from March 2020 to May 2022. Premorbid conditions, severity of COVID-19, incidence of delirium, mortality and disability at discharge were extracted from digital medical records. Univariate and multivariate regression analysis were implemented to evaluate predictive factors associated with delirium, mortality and disability at discharge.

Results: Out of 2288 patients, 223 (9.7%) experienced delirium (Del+). Compared to patients without delirium (Del-), Del+ subjects were older, exhibited more comorbidities and worse premorbid conditions, worse COVID-19 severity and higher mortality rates (31.4% vs 12.9%, p p<0.001) and discharge outcomes (mRS 2.78+1.3 vs 1.57+1.3 - p<0.001). Age, premorbid disability and Covid-19 severity were the strongest predictors of both delirium and poor outcomes. Patients with delirium appeared to be at higher risk of mortality and poor outcomes regardless the COVID-19 severity at variance with COVID+ patients.

Discussion and Conclusion: The study highlighted those elderly and frail patients, hospitalized for Covid-19, are at higher risk of delirium, which is an important predictor of in hospital mortality and poor outcomes, independently from COVID-19 severity.

## POST-COVID19 AND POST-SARS-CoV2 VACCINATION MYELITIS IN COMPARISON: A CASE SERIES

F. De Napoli[1], F. Berti[1], A. Miscioscia[1], P. Perini[1], M. Puthenparampil[1], F. Rinaldi[1], D. Bonifati[2], P. Gallo[1]

[1]Department of Neuroscience DNS, University of Padua (Padova); [2]Neurology, Ca' Foncello Hospital (Treviso)

Introduction: The incidence of acute transverse myelitis (ATM) associated with Sars-CoV2 is not clear, ranging from 0.5 per million to 1.4%. We can distinguish two forms of ATM based on the latency period from the Sars-CoV2 infection to the first neurological manifestation: para-infectious cases (15 hours to 5 days) and post-infectious cases (10 days to 6 weeks). Furthermore, many cases of ATM post-Sars-Cov2 vaccination are described. The exact pathological mechanism that correlates infection or vaccination with myelitis is debated, considering viral neurotropism or immune-mediated reactions through molecular mimicry, epitope spreading, bystander activation or polyclonal B-cell activation. We report six cases of patients who developed myelitis correlated to Sars-CoV2 infection or vaccination admitted to our ward. The aim of this work is to compare clinical, neuroimaging, CSF pattern, response to therapies and outcomes in these patients, distinguishing three subgroups: para-infectious, post-infectious and post-vaccination.

Results: We observe that patients who developed SARS-CoV-2 para-infective myelitis showed a more severe clinical course refractory to several therapies and developed clear spinal lesions on MR study. The post-infective group seems to respond better to therapies and showed a mild illness compared to the first ones. Post-vaccination cases exhibited an even more benign course.

Conclusions: The differences recorded between the three groups suggest that there may be different pathogenic mechanisms underlying them. Moreover, it points out the importance of recognizing the type of ATM related to Sars-Cov2 in order to start promptly the more effective therapy.

## SMALL FIBRE NEUROPATHY IN POST COVID-19 SYNDROME: A CASE- CONTROL STUDY

P. Falco, G. Di Stefano, D. Litewczuk, E. Galosi, C. Leone, G. Di Pietro, G. De Stefano, A. Truini

Department of Human Neuroscience, Sapienza University (Roma)

Objectives: Patients with a post COVID-19 condition often complain of sensory symptoms and pain. Previous retrospective clinical observations raised the possibility that small fibre neuropathy may underlie these post COVID-19 related disturbances [1]. In this case-control study, we aimed to definitely diagnose small fibre neuropathy in patients with painful post COVID-19 condition.

Materials and Method: To definitely diagnose small fibre neuropathy, we collected clinical data (e.g., pain and autonomic symptom questionnaires) and investigated quantitative sensory testing (QST) and skin biopsy in 26 selected patients with painful post COVID-19 conditions. We also screened 100 previously ill COVID-19 survivors and selected 30 control participants without any post COVID-19 symptoms. Then, we compared the main demographic and clinical variables between groups.

Results: Of the 26 patients with painful post COVID-19 condition, 12 had skin biopsy and/or QST abnormalities, compatible with a small fibre neuropathy. In patients with post painful post COVID-19 condition (with and without small fibre neuropathy), demographic and clinical data (including COVID-19 severity) were comparable to those of previously ill COVID-19 survivors without any post COVID-19 symptoms.

Discussion: This case-control study shows that approximately 50% of our patients complaining of sensory symptoms and pain after the acute phase of COVID-19 received a diagnosis of small fibre neuropathy. In patients with small fibre neuropathy demographic and clinical data were comparable to those in previously ill COVID-19 survivors without a post COVID-19 condition. Of the 100 unselected participants with a previous SARS-CoV-2 infection, five suffered from a painful post COVID-19 condition; these five patients were eventually diagnosed with a small fibre neuropathy, expanding previous data on post COVID-19 small fibre neuropathy prevalence [2]. We found that our patients with small fibre neuropathy had a mechanical hyperalgesia (8 patients) and a sensory loss QST phenotype (4 patients). These findings are in line with previous studies showing that mechanical hyperalgesia and sensory loss are the most frequent QST phenotypes in patients with small fibre neuropathy. We therefore hypothesize that in our patients with small fibre neuropathy, pain might predominantly reflect central sensitization phenomenon; nevertheless, in some patients, pain might be also triggered by second order neuron deafferentation [3].

Conclusion: Our case-control study showed that small fibre neuropathy is relatively common in patients suffering from painful post COVID-19 condition; in our patients, however, this specific post COVID-19 complication was unrelated to demographic and clinical variables (e.g., COVID-19 severity or the duration of hospitalization) related to COVID-19.

## CLINICAL CHARACTERISTICS OF SMALL FIBER NEUROPATHY FOLLOWING SARS-COV2 INFECTION OR VACCINATION: RESULTS FROM SKIN BIOPSY AND MULTIPLE SCALE ASSESSMENT

A. Furia, A. Incensi, S. Parisini, R. Liguori, V. Donadio

Institute of Neurological Sciences of Bologna, University of Bologna (Bologna)

Objectives: The study aims to characterize patients reporting with symptoms compatible with Small Fiber Neuropathy (SFN) temporally related to either SARS-CoV2 infection or vaccination, as already suggested by reports [1].

Materials: Patients were selected if they presented with a clinical picture compatible with SFN in close temporal connection ($\leq 2$ months) with either SARS-CoV2 infection or vaccination.

Methods: Skin biopsy was performed in all patients to assess intraepidermal nerve fiber density (IENFD). Large fiber neuropathy was excluded by neurological examination and nerve conduction studies. Clinical data, comprising time from infection or vaccination to symptoms, pain characteristics and localization, type of vaccination and response to therapy were collected. Additionally, the Douleur Neuropathique-4 Questionnaire (DN4) was administered to characterize the pain, as well as the Composite Autonomic Symptom Score (COMPASS) in order to assess autonomic fiber involvement and Short Form Health Survey-36 for assessment of quality of life.

Results: 66 (33 post-vaccination, 33 post-COVID) patients were enrolled (42 females, 33 males). Onset from event to clinical presentation was on average 248 hours (range 1-1440) in post-vaccination and 445 hours (range 24-2880) in post-COVID patients. Skin biopsy revealed reduced intraepidermal nerve fiber density compatible with SFN in 25/33 post-vaccination (75%) and 31/33 post-COVID (94%) patients. When assessable (28/33 post-vaccination, 31/33 post-COVID, total 59), DN4 was positive in 50/59 patients) and mean COMPASS score was 40.86 post-vaccination, 56.09 post-COVID.

Discussion: The majority of patients, moreso in the post-COVID category, showed reduced IENFD compatible with SFN. Moreover, clinical scores characterized pain as likely neuropathic, associated to autonomic symptoms.

Conclusions: In line with other studies, these results suggest a link between SFN and SARS-CoV2 infection or vaccination. A possible explanation could be the immune response against the Spike glycoprotein of SARS-CoV2 causing small fiber damage.

## SMALL FIBER NEUROPATHY AFTER ANTI-COVID VACCINATION OR COVID INFECTION: A CASE SERIES

A. Furia, A. Incensi, S. Parisini, R. Liguori, V. Donadio

Institute of Neurological Sciences of Bologna, University of Bologna (Bologna)

Objectives: The aim of this case series is to describe two cases of Small Fiber Neuropathy (SFN) diagnosed by a congruent clinical picture and reduced intraepidermal nerve fiber density (IENFD), one occurring after anti-COVID vaccination and the other after COVID infection, as already suggested by reports [1].

Materials: Patient 1 is a 33-year-old female who first presented with severe back and lower limb burning pain 4 weeks after treatment with botulinum injections. Lumbosacral MRI, as well as blood exams for autoimmune disorders, was negative. Pain did not respond to gabapentin 100 mg/die, but slowly remitted over time. A first skin biopsy was negative. Successively, 4 days after the second dose of anti-COVID vaccination, she presented with burning pain localized to limbs and trunk. Skin biopsy was then repeated, showing reduced IENFD

compatible with SFN. Patient 2 is a 31-year-old male who presented with burning pain localized to both calfs, 4 days after the first dose of anti-COVID vaccination. Skin biopsy was negative; subsequently, around 2 months after COVID infection, he presented with burning paresthesia affecting both hands and forearms. Skin biopsy was then repeated, indicating reduced IENFD.

Methods: Clinical data of the 2 patients were collected concerning medical history, treatment and clinical examination, as well as skin biopsy results.

Results: Patients without previous SFN, as shown by negative skin biopsies, developed neuropathy, the first after vaccination and the second after infection.

Discussion: While studies concerning post-COVID/vaccination SFN cannot usually exclude previously reduced IENFD at skin biopsy, these two cases show a stronger correlation between these two events and SFN.

Conclusion: SFN is a potential complication of either COVID infection or vaccination and a coherent clinical picture should prompt assessment of small fibers.

## EFFICACY OF INTRAVENOUS IMMUNOGLOBULINS (IVIG) ON COVID-19-RELATED NEUROLOGICAL DISORDERS OVER THE LAST 2 YEARS: AN UP-TO-DATE NARRATIVE REVIEW

G. Garascia, P. Manganotti, G. Furlanis, A. Buoite Stella

Clinical Unit of Neurology, Department of Medicine, Surgery and Health, University Hospital and Health Services of Trieste, ASUGI, University of Trieste (Trieste)

Introduction: IntraVenous Immunoglobulins (IVIg) are a preparation of human antibodies. They represent a consolidated therapeutic tool for the treatment of various immune-mediated neurological diseases. SARS-CoV-2 infection has been reported to determine several clinical manifestations, including neurological disorders. In recent years, the use of IVIg in these conditions has gradually increased, with an impact not only on the treatment of neurological complications, but even on the comprehension of their causal mechanisms.

Methods: We openly explored the available topic-specific indexed medical literature in order to answer the question of whether IVIg could be considered a valid tool to address the clinical management of COVID-19-induced neurological disorders. We collected the found studies in an extensive table, by indicating for each of them details about the subjects treated, the IVIg regimen employed and the therapeutical results obtained.

Results: In the first part of this narrative review, the mechanisms both of interaction of SARS-CoV-2 with the nervous system and of IVIg action were discussed. In the second part, we collected scientific literature data over the last years to discuss the use of IVIg therapy in different neuro-COVID conditions, in order to provide a critical summary of the possible strategies of treatment. As concerns our experience, we have dealt with and published cases of COVID-19-related Guillain-Barré and new onset refractory status epilepticus. They turned out to respond to IVIg treatment, even when disease-specific and other immunomodulating treatment had failed, without the appearance of side effects. In all cases we used the classical dosage regimen of 0.4 g/kg/day for 5 days. Virtually all reviewed studies are in agreement to detect an acceptable to great efficacy of IVIg employment in COVID-19-related neurological diseases, with no or mild adverse effects.

Discussion: IVIg therapy is a versatile tool with multiple molecular targets and mechanisms of action that might contribute to explain some of the underlined processes of Sars-CoV-2 infection, indeed its efficacy has to be linked with its immunomodulatory effects. As such, IVIg therapy has been used in several COVID-19-related neurological diseases, including polyneuropathies, encephalitis, and status epilepticus, reaching an improvement of symptoms even in the most severe cases, without the development of important side reactions, thus suggesting IVIg treatment can be both effective and safe.

Conclusion: In most treated cases, sometimes even when other medications had failed, IVIg proved to be simultaneously an effective, safe and often decisive therapy against several COVID-related neurological conditions, virtually without provoking adverse effects.

## COVID-19 MULTI-ORGAN PATHOLOGY: A SPECIAL FOCUS ON AGING BRAIN

A. Gatti[1], V. Medici[2], G. Profka[2], M. Rossi[2], M. Ceroni[1,2], A. Costa[1], A. Guaita[2], E. Poloni[3]

[1]National Neurological Institute C. Mondino, University of Pavia (Pavia); [2]Golgi-Cenci Foundation, University of Pavia (Abbiategrasso-MI, Pavia); [3]Golgi-Cenci Foundation, ASP Golgi-Redaelli, University of Pavia (Abbiategrasso-MI, Milano, Pavia)

Objective: We describe COVID-19 pathology across different tissues to clarify the disease's pathophysiology, focusing on the brain.

Materials: Clinical and pathological data from COVID-19 cases.

Methods: Lung, kidney, heart, and brain from nine COVID-19 autopsies were compared by using antibodies against SARS-CoV-2, macrophages-microglia, T-lymphocytes, B-lymphocytes and activated platelets. Alzheimer's Disease pathology was also assessed. PCR techniques were used to verify the presence of viral RNA in the brain.

Results: COVID-19 cases had a short clinical course (0–32 days) and a mean age of 77.4 y/o. Hypoxic changes and inflammatory infiltrates were present across all tissues. The lymphocytic component in lungs and kidneys was predominant over that of other tissues ($p < 0.001$), with a significantly greater presence of T-lymphocytes in the lungs ($p = 0.020$). Microthrombosis was significantly higher in COVID-19 lungs ($p = 0.023$) compared with controls. The heart showed scant SARS-CoV-2 traces in the endothelium–endocardium, foci of activated macrophages and rare lymphocytes. All COVID-19 brains showed non-SARS-CoV-2-specific changes including hypoxic-agonal alterations, a variable degree of neurodegeneration and/or pre-existent small vessels disease. The neuroinflammatory picture was dominated by ameboid CD68 positive microglia, while only scant lymphocytic presence and scarce SARS-CoV-2 traces were detected. Microglial activation in the brainstem was significantly greater in COVID-19 cases ($p = 0.046$). Microglial hyperactivation in the frontal cortex and hippocampus was clearly associated to AD pathology ($p = 0.001$), regardless of SARS-CoV-2 infection. In COVID-19 cases complicated by delirium (all with neurocognitive disorders), there was a significant enhancement of microglia in the hippocampus ($p = 0.048$). The pons exhibited the highest microglial activation ($p = 0.017$).

Discussion: The most characteristic pathological features of COVID-19 were an abundance of T-lymphocytes and microthrombosis in the lung and microglial hyperactivation in the brainstem. Although higher in cases with both Alzheimer's pathology and COVID-19, cortical neuroinflammation is mostly related to pre-existing neurodegeneration. COVID-19 brains seem to manifest a boosting of innate immunity with microglial reinforcement, and adaptive immunity suppression with a low number of brain lymphocytes probably related to systemic lymphopenia. No neuropathological evidence of SARS-CoV-2-specific

encephalitis is detectable. Probably, the microglial hyperactivation represents the neuropathological basis of the "COVID-19 encephalopathic syndrome" in the elderly, favored by the microglial priming due to neurodegeneration. The prominent neuroinflammation in the brainstem is as a specific topographical phenomenon.

Conclusions: The long-term consequences of COVID-19 seem to represent a complex phenomenon arising from persistent inflammation, rather than persistent viral replication.

## INVESTIGATING THE IMPACT OF SARS-COV2 INFECTION ON ESSENTIAL TREMOR: A SURVEY-BASED STUDY AND RETROSPECTIVE ANALYSIS OF CLINICAL AND KINEMATIC DATA

A. S. Grandolfo[1], D. Costa[1], D. Birreci[1], G. Paparella[2], L. Angelini[1], A. Cannavacciuolo[2], M. De Riggi[1], M. Passaretti[1], A. Berardelli[2], M. Bologna[1]

[1]Department of Human Neurosciences, Sapienza University of Rome (Roma); [2]IRCSS Neuromed Institute (Pozzilli-IS)

Objectives: Over the past three years, SARS-CoV-2 infection has had a significant impact on people's health. Apart from the well-known manifestations, some individuals have experienced new neurological symptoms or worsening of existing neurological conditions. However, there is a lack of studies investigating the effects of SARS-CoV-2 on tremor in a large sample. This retrospective study aims to analyze longitudinal data from patients diagnosed with Essential Tremor (ET) to investigate the impact of SARS-CoV-2 infection on tremor features. The objective is to examine how the infection may have influenced the progression or changes in tremor over time.

Materials: This study consisted of a cohort of forty patients diagnosed with Essential Tremor (ET), with 21 females and a mean age of 69±12,25. A survey was conducted to assess the clinical progression of SARS-CoV-2 infection, identify any new neurological symptoms, and evaluate changes in tremor experienced by the patients.

Methods: The clinical features of tremor collected with the Fahn-Tolosa-Marin Clinical Rating Scale for Tremor (FTM) and The Essential Tremor Rating Assessment Scale (TETRAS) were retrospectively evaluated. Additionally, we retrospectively analyzed kinematic data, including rest, postural, and kinetic tremor, which were collected using an optoelectronic motion system.

Results: Out of the twenty-five patients who reported a SARS-CoV-2 infection, eleven (44%) experienced a subjective worsening of tremor. Only one patient reported the emergence of tremor in a previously unaffected body part. Among those who reported subjective worsening of tremor, a significant number (72%) also reported experiencing "Long-Covid" symptoms such as brain fog, fatigue, and myalgia, whereas this prevalence was much lower (7%) in those without worsening (P=0.002). However, when considering clinical and objective kinematic measurements, a notable worsening of tremor was confirmed in only two cases (18%) among those who subjectively reported worsening symptoms.

Discussions: While a considerable number of patients reported subjective worsening of tremor following the infection, objective measurements only confirmed this change in a minority of cases.

Conclusions: These findings suggest that significant tremor worsening may occur in a limited number of patients. Further research is needed to gain a clearer understanding of the impact of SARS-CoV-2 infection in patients with ET.

## POSTERIOR REVERSIBLE ENCEPHALOPATHY SYNDROME AND REVERSIBLE CEREBRAL VASOCONSTRICTION SYNDROME IN PATIENTS WITH COVID-19 INFECTION. IS THERE A LINK? A SYSTEMATIC REVIEW AND CASE REPORT ANALYSIS

G. Iaccarino[1], A. Bonura[1], S. Rossi[1], F. Capone[1], F. Motolese[1], R. Calandrelli[2], V. Di Lazzaro[1], F. Pilato[1]

[1]Neurology, Campus Bio-Medico (Roma); [2]Radiology, Policlinico A. Gemelli (Roma)

Aim: During the SARS-CoV-2 pandemic, several cases of PRES and RCVS have been reported in patients with COVID-19, but the link between these clinical-radiological syndromes and COVID-19 has not yet been defined. This review aims to investigate whether SARS-CoV-2 infection or the therapies used to treat COVID-19 can be potential risk factors for the development of PRES or RCVS.

Methods: A systematic review was conducted on PubMed, Scopus, and Web of Science for case reports concerning patients with COVID-19 who developed PRES and/or RCVS. The clinical characteristics of the two populations were analyzed separately, and statistical analyses were performed to identify additional risk factors beyond those already known.

Results: 70 articles concerning 105 patients (85 with PRES, 20 with RCVS) were found. Our analysis revealed a lower incidence of common risk factors for PRES and RCVS in patients with COVID-19, suggesting that COVID-19 may be an independent risk factor for both conditions. This could be due to the ability of SARS-CoV-2 to cause endothelial dysfunction, which is the common pathophysiological mechanism for both RCVS and PRES. Additionally, our analysis found a statistically significant increase in antiviral therapy with ritonavir or darunavir in individuals without known risk factors for PRES. Since antiviral drugs can also cause endothelial damage by reducing the bioavailability of nitric oxide, they too may act as independent risk factors for the development of PRES.

Conclusions: In conclusion, a correlation has been found between PRES, RCVS, and COVID-19, as well as between PRES, COVID-19, and antiviral therapy used to treat SARS-CoV-2 infection. Further research is needed to confirm these results using larger sample sizes and randomized control groups.

## AN OBSERVATIONAL STUDY OF PAINFUL POST COVID-19 CONDITION

D. Litewczuk[1], P. Falco[1], G. Di Stefano[1], E. Galosi[1], C. Leone[1], G. De Stefano[1], G. Di Pietro[1], P. Pasculli[2], M. Zingaropoli[2], M. Ciardi[2], A. Truini[1]

[1]Department of Human Neuroscience, Sapienza University (Roma); [2]Department of Medicine, Infectious Disease, Sapienza University (Roma)

Studies now show that about 10-20% of people previously infected by SARS-CoV-2 may develop a post COVID-19 condition, manifesting with a collection of different physical and mental health symptoms, including pain. In this observational study, we aim to identify frequency and risk factors for painful post COVID-19 conditions. We consecutively screened 100 previously ill patients referred to a COVID-19 unit for the routine follow-up visit. The participants underwent a detailed neurological examination, and we collected the main demographic and clinical data, including information about any painful condition, regardless whether previously diagnosed or newly developed. We distinguished patients into three categories: patients without pain, patients with a pre-existing pain condition, patients with pain triggered by COVID-19. All patients with possible or probable neuropathic pain grading system for neuropathic pain underwent Quantitative Sensory Testing (QST) and skin biopsy. Of the 100 participants, 49 had chronic pain (i.e. pain persisting in the last 30 days). In 26 patients chronic pain followed the COVID-19. Conversely, 23 patients suffered from a previously diagnosed chronic pain condition; the severity of pain, nevertheless, increased after COVID-19. Of the 26 patients with painful post COVID-19 condition, five had possible neuropathic pain and seven probable neuropathic pain. Five patients were eventually diagnosed with a small fibre neuropathy. Unexpectedly, we found that our patients with painful post COVID-19 condition had similar demographic and clinical data compared to previously ill patients without a painful post COVID-19 condition. This study extends current knowledge about the frequency of neuropathic pain in previously ill COVID-19 patients. Previous systematic studies indicated that the overall frequency of possible neuropathic pain due to COVID-19 infection is 10%. Our study, showing a 5% frequency of definitely diagnosed small fibre neuropathy in unselected participants with a previous SARS-CoV-2 infection, now suggests that a considerable proportion of post COVID-19 neuropathic pain is due to small fibre neuropathy.

## MULTI-DIMENSIONAL ASSESSMENT OF COGNITIVE AND PSYCHIATRIC BURDEN IN PEOPLE WITH LONG-COVID: A CROSS-SECTIONAL OBSERVATIONAL STUDY

F. Masserini[1], V. Cucumo[2], G. Cirnigliaro[3], C. Scarpa[3], M. Boscacci[3], B. Dell'Osso[3], S. Pomati[2], L. Pantoni[1]

[1]Neuroscience Research Center, Department of Biomedical and Clinical Sciences, University of Milan (Milano); [2]Center for Treatment and Study of Cognitive Disorders, Neurology Unit, Luigi Sacco Hospital (Milano); [3]Department of Biomedical and Clinical Sciences, University of Milan (Milano)

Cognitive and psychiatric symptoms have been increasingly reported after SARS-CoV-2 infection. These sequelae develop soon after infection and persist for several months. We aimed to study this syndrome and start implementing strategies for their objective assessment. One-hundred-thirty-five consecutive patients (mean age 55.4±12.3, 62% females), referred to the neurologist by the infectious disease department because of cognitive complaints after COVID-19, were evaluated. Neurological evaluation including a cognitive screening test [Montreal Cognitive Assessment (MoCA)] was performed; patients were also invited to answer a general symptom questionnaire and a self-administered multidimensional assessment of psychiatric symptoms, which was then followed by full psychiatric assessment if scores resulted above validated cut-off. Ninety-nine patients completed the cognitive screening and self-administered psychiatric questionnaire. Subjects were referred after a mean of 13.5±5.6 months from acute infection, which was of low severity for most patients (56% treated as outpatients, only 9.1% requiring ICU). The most common persisting symptoms were fatigue (92%), sleep problems (69.5%), and headache (52.4%). MoCA outlined cognitive deficits in at least one cognitive domain in 34% of patients, mainly in memory and attention. About 60% presented depressive, anxiety, or stress-related symptoms. Psychiatric scales scores correlate significantly with overall symptom burden and MoCA score. No significant correlation was found between cognitive scores at MoCA and overall symptom burden. Cognitive complaints after COVID-19 were confirmed by cognitive screening tests in only one third of cases and were associated with high levels of psychiatric symptom burden. While MoCA scores and overall symptom burden correlated significantly with psychopathological burden, no reciprocal correlation between these two variables was found. We hypothesize that persistent cognitive complaints after COVID-19 might be the reflection of a concomitant or reactive psycho-pathological condition, possibly coupled with an infection-related impact on cognitive functions. The application of a combined neurological and psychiatric assessment of patients who have suffered a COVID-19 patients seems crucial.

## BICKERSTAFF ENCEPHALITIS PRESENTING WITH A STROKE-LIKE ONSET IN COVID-19 INFECTION

S. Montella[1], R. Bruno[1], V. D'Agostino[2], L. Durante[1], M. Lieto[1], R. Scala[1], M. Mazzaferro[1]

[1]Neurology Unit, Ospedale del Mare, ASL Napoli 1 Centro (Napoli); [2]Department of Neuroradiology, Ospedale del Mare, ASL Napoli 1 Centro (Napoli)

Objective: Description of a particular case of Bickerstaff encephalitis (BBE) in Covid-19 infection.

Materials: Neurological manifestations of Covid-19 infection are observed frequently, in more than one third. [1] Headache, nausea, and vomiting, for example, are mild neurological symptoms. Other syndromes such as ADEM, meningo-encephalitis, GBS are described.

Methods: Here we describe the case of C.A., a 55-year-old man with an acute onset of ptosis in the left eye and dizziness. Cranial CT scan as well as brain MRI showed no abnormal results, given the partial occlusion left Cerebral Posterior Artery's P1 trait, the patient was treated as a stroke. At neurological examination, consciousness, language and speech were normal; limitation of vertical eye movements and impairment of smooth pursuit eye movements and accomodation were present, with bilateral ptosis; severe ataxia was present. The following day, the patient developed four limbs weakness and confusional state. PCR to SARS-CoV-2 was positive but he did not develop any respiratory symptoms. A second brain MRI showed hyperintense lesions in brainstem and basal ganglia. Electroencephalogram test showed right high-amplitude theta waves. CSF exam showed a leukocyte count of 5/mm3, glucose level of 50 mg/dl, protein level of 40 mg/dl, sterile cultures, and absence of oligoclonal bands. Anti-Hu, anti-Yo, anti-Ri, and anti-amphiphysin antibodies were absent in serum and CSF. Blood HIV test, IgM for Varicella-zoster virus, Epstein Barr virus, Cytomegalovirus were negative. Antithyroid, antinuclear antibodies were negative. Electromyography showed rieduced frequency of F-wave with no denervation. The patient received IVIG therapy without substantial improvements of clinical conditions while administration of high dose corticosteroids induced rapid and full recovery.

Results: Our case is an example of BBE (with a particolar onset) in Covid-19 infection.

Discussion: The coronavirus enters the nervous system either through the blood or via the olfactory nerves. Pathogenesis of neurological manifestations of human coronavirus infection includes direct neuronal damage, apoptosis, production of pro-inflammatory cytokines, immunopathological mechanisms. [1] GBS, Miller Fisher syndrome, acute necrotizing encephalitis, myelitis, acute disseminated encephalomyelitis (ADEM), and myasthenia gravis have been reported [2]. As in our patient, corticosteroids seemed to have a beneficial effect on several of these cases.

Conclusions: Recent evidence suggests that a wide range of neurological complications of SARS-CoV-2 infection could be explained by enhanced immune response [2]. Successful management of BBE is dependent upon a high clinical index of suspicion and early diagnosis. BBE widens the spectrum of para-infectious neurological disorders related to COVID-19.

Objectives: We explored whether COVID-19 is associated with an increased risk of disease activity, disability worsening, neuropsychological distress and cognitive dysfunction during the 18-24 months following SARS-COV-2 infection.

Materials: We enrolled 174 PwMS with history of COVID-19 (MS-COVID) between March 2020 and March 2021 and compared them to an age, sex, disease duration, EDSS, line of treatment-matched group of 348 PwMS with no history of COVID-19 in the same period (MS-NCOVID). We collected clinical, MRI data and SARS-CoV2 immune response in the 18-24 months following COVID-19 or baseline evaluation. At follow-up, PwMS also underwent a complete neuropsychological assessment with Brief Repeatable Battery of Neuropsychological Tests, and optimized scales for fatigue, anxiety, depression and post-traumatic stress assessment.

Methods: Descriptive statistics and univariate logistic regression analyses were employed to evaluate the association between the group (MS-COVID and MS-NCOVID) and a change in clinical characteristics. Comparison of neuropsychological variables: Continuous variables were compared between the two groups by using the Mann-Whitney test, while categorical variables with the Fisher's exact test. P-values were adjusted with Bonferroni's correction to account for multiple testing.

Results: 136 MS-COVID and 186 MS-NCOVID accepted the longitudinal evaluation. The two groups did not differ in terms of EDSS worsening (15% vs 11%), number of relapses (6% vs 5%), need to change DMT (7% vs 4%), new T2 lesions (9% vs 11%) and gadolinium enhancing lesions (7% vs 4%) on brain MRI (p values range: 0.18-0.68). 22% of MS-COVID and 23% MS-NCOVID were cognitively impaired at follow-up, with no between-group difference in the prevalence of cognitive impairment (p=1.000). The z-scores of global and domain-specific cognitive functions, and the prevalence of neuropsychiatric manifestations were also similar between the two groups (p values range: 0.19-1.00). No difference was seen in term of SARS-CoV2 immune reactivity.

Discussion: Based on these findings, it may be appropriate to suggest that PwMS can begin to return to their normal lives with less fear of COVID-19. Of course, caution and good hygiene practices should still be encouraged, as the virus can still pose a risk to anyone, regardless of their immune status.

Conclusion: COVID-19 has no impact on disease activity and cognitive performance among PwMS 18-24 months after infection.

Funding This study has been partially Supported by Fondazione Italiana Sclerosi Multipla (FISM 2021/C19-R-Single/005) and financed or cofinanced with the '5 per mille' public funding.

## STROKE IN COVID-19 PATIENTS FROM 2020 TO 2022 IN CIRIE' NEUROLOGY UNIT

M. Narracci, C. Chiavazza, C. Baima, S. Gasverde, E. Gentile, D. Papurello

Neurology Unit, Cirie Hospital (Torino)

Objectives: Sars-cov2 can cause multiorgan disease due to altered coagulability and microangiopathy. Patients have an increased risk of cerebrovascular events both ischemic and hemorrhagic [1]. The aim of our study was to compare clinical characteristics of Covid-19 stroke patients with data of larger metanalysis reported in literature [2].

Materials and Methods: Data of 1599 patients with Sars-cov2 infection admitted to our Hospital from 2020 to 2022 were collected. In 42/1599 stroke patients we analyzed the incidence cardiovascular risk factors (hypertension, coronary artery disease - CAD, atrial fibrillation, diabetes), stroke etiology (large vessel disease - LVD, small vessel disease - SVD, multiple embolic stroke - ME or intravascular bleeding - IB), ischemic stroke treatment (intravenous thrombolysis and/or endovascular treatment) and concomitant respiratory involvement.

Results: The annual incidence of stroke in Covid-19 patients was similar to the one reported in literature (2,5%). Our patients were older with a median age of 78.9 years versus 65.3 [2] and mostly female. Cardiovascular risk factors in Covid-19 patients developing acute cerebrovascular disease were hypertension in 76,2% of cases versus 62,2% in literature, CAD in 11,9% versus 15.9%, atrial fibrillation was more frequent in our population (33,3% versus 13.9%) and diabetes less represented (16,7% versus 36.7%). Considering stroke etiology, LVD was found in 57% of patients and SVD in 23,8% versus 10.6% and 3.3% respectively. ME strokes were 9,5% versus 21.9%. IB was described in 9,5% of cases compared to 11.6% in metanalysis data [2]. Acute stroke treatment was intravenous thrombolysis in 26,3% versus 19.1% while endovascular treatment was performed in 7,8% versus 25.9%. Stroke patients with Covid-19 and mild respiratory symptoms were 58,3% in 2020 and 2021, 54,5% in 2022; patients with severe respiratory symptoms were 65% in 2020, 36,4% in 2021 and 45,4% in 2022; cases of death were 60% in 2020 while in 2021 and 2022 no deaths were registered. In literature, severe Covid-19 disease was reported in 60.5% [2].

Discussion and Conclusions: Stroke incidence in our Covid-19 patients was the same described in metanalysis but our patients were older and prevalently female. Hypertension and CVD were similarly represented but we found more LVD and SVD related strokes and less ME events, probably due to gender difference [1] and milder Sars-cov2 respiratory disease in 2020-2022 compared to 2019-2021, after vaccination campaign, triggering lower prothrombotic activity [1,3]. Endovascular treatment was less performed probably due to longer timing to Hospital access in early pandemic phase.

## A CASE OF PARSONAGE-TURNER SYNDROME AFTER COVID-19 VACCINATION IN A PATIENT AFFECTED WITH PARKINSON'S DISEASE AND A BRIEF REVIEW OF THE LITERATURE

S. Perillo, R. Bencivenga, A. Giglio, L. Baratto, E. Cassano, N. Cuomo, R. Iodice, F. Manganelli, A. De Rosa

Department of Neurosciences and Reproductive and Odontostomatological Sciences, Federico II University (Napoli)

Objectives: We aimed to describe a case of Parsonage-Turner syndrome (PTS) in a patient affected with Parkinson's disease (PD) following COVID-19 vaccination. We also analyzed PTS cases reported in the literature so far.

Materials and Methods: Cases of PTS following COVID-19 vaccination were reviewed, and epidemiological, clinical and electrophysiological features were collected.

Results: A 69-year-old man affected with PD presented to our department due to acute and intense pain in the right shoulder and arm two weeks after the booster dose of mRNA COVID-19 vaccine (Pfizer-BioNTech BNT162b2) inoculation into the right deltoid. He did not benefit from treatment with non-steroid anti-inflammatory drugs. A few days later, he developed weakness on abduction and elevation of the right upper limb. He denied previous vaccine adverse reactions, trauma, or infections. Neurological examination showed muscular atrophy of the proximal right upper limb, and severe weakness of the shoulder rotation and abduction, elbow flexion and forearm supination. Biceps tendon reflex was decreased. Hypoesthesia of the right shoulder was present. Nerve conduction study revealed reduced bilateral sensory responses of median, ulnar and radial cutaneous nerves. Needle electromyography showed fibrillations, positive sharp waves and decreased motor unit recruitment in deltoid and brachial biceps muscles. As it had been more than a month since the onset of symptoms, only physical therapy was recommended. Six months later, the upper limb weakness and the hypoesthesia dramatically improved. Until now, forty-two cases of PTS following immunization with all types of COVID-19 vaccine have been reported. Most cases were male (69%) aged between 15 and 84 years (49.6 $\pm$ 16.3 years). Time of symptoms onset ranged from 13 hours to 8 weeks after the vaccination. The symptoms were ipsilateral to the side of inoculation in 29 cases (50%) and bilateral in two patients (4%). Pathological findings compatible with PTS have been described in all the cases that underwent electrophysiological study. All patients had amelioration of the symptoms, independently of treatment with corticosteroids.

Discussion: The pathophysiology of PTS is unknown, but it may involve genetic, environmental, and immune-mediated components. The mRNA vaccines may be associated with increased risk of autoimmune diseases, triggering type I interferon responses. As the patients can develop symptoms contralateral to the injected side, it is unlikely that INA is secondary to direct nerve insult from inoculation.

Conclusion: PTS may be associated with COVID-19 immunization. Electrophysiology is a useful to rule out other diseases. There is no specific treatment available, but it may resolve independently of pharmacological treatment.

## LONGITUDINAL EVALUATION OF SERUM MARKERS OF NEURONAL AND GLIAL DAMAGE AFTER FULL CLINICAL RECOVERY FROM MILD COVID-19 INFECTION

D. Plantone[1], A. Stufano[2], D. Righi[1], I. Iavicoli[3], P. Lovreglio[2], N. De Stefano[1]

[1]Dept of Medicine, Surgery and Neuroscience, University of Siena (Siena); [2]Department of Interdisciplinary Medicine, University of Bari Aldo Moro (Bari); [3]Department of Public Health, University of Naples Federico II (Napoli)

Objectives: Neurofilament light chain (NfL) [1] and glial fibrillar acidic protein (GFAP) [2] have been demonstrated to increase in the peripheral blood of patients during the acute phase of COVID-19, regardless of the presence of neurological manifestations. [3] In this 10-month longitudinal study, we assessed the trend of serum levels of biomarkers of neuronal and glial damage in a cohort of patients after mild COVID and investigated their associations with cognitive and working performance.

Material and Methods: 147 previously healthy university workers were recruited after SARS-CoV-2 infection (T0, one week after negative swab). The Cognitive Failure Questionnaire (CFQ) was administered and sNfL and sGFAP concentrations were assessed. 49/147 patients experienced the persistence of at least one symptom of long-COVID syndrome 10 months after swab negativization (T1). For all these patients the CFQ, sNfL, and sGFAP were repeated. In addition, a cohort of 82 age- and BMI-matched healthy controls (HCs) was recruited.

Results: Age and BMI-corrected sNfL and sGFAP concentrations at T0 were higher in patients after COVID-19 than in HCs (median sNfL 22.8 vs 7.2 pg/mL; median sGFAP 146.3 vs 63.5 pg/mL; $p< 0.001$ for both). 11/147 patients had an impaired CFQ (score < 43) at T0, showing higher levels of sNfL and sGFAP than those with normal CFQ (median sNfL 45.0 vs 22.4 pg/mL; median sGFAP 194.0 vs 131.3 pg/mL; $p=0.005$ for both). The 49 patients examined also at T1 had significantly reduced levels of sNfL and sGFAP at T1 (median sNfL 18.3 pg/ mL; median sGFAP 77.2 pg/mL; $p<0.001$ for both) compared to T0 and their mean CFQ values were significantly higher than the values observed at T0 (18.1 vs 27.1; $p<0.01$, 6/49 patients had impaired CFQ score). However, sNfL and sGFAP levels at T1 remained significantly higher than in HCs ($p<0.001$). No difference was found in sNfL and sGFAP levels when patients with normal and impaired CFQ at T1 were compared.

Discussion and Conclusions: In sum, inflammatory-related neuronal and glial degeneration characterizing the acute phase of COVID still persists months after full clinical recovery and is more pronounced in patients with cognitive difficulties during the period immediately after swab negativization. Moreover, these two biomarkers significantly decrease but do not return back to normal levels in those patients with at least one symptom suggestive of long COVID syndrome.

## MBL LEVELS IN PATIENTS EXPERIENCING "BRAIN FOG" AS LONG-COVID SYMPTOM

L. Rossi[1], R. Bulla[2], G. Furlanis[1], C. Agostinis[3], M. Toffoli[4], A. Balduit[5], A. Mangogna[5], M. Liccari[1], G. Morosini[2], U. Kishore[5], P. Manganotti[1]

[1]Neurology Unit, Department of Medical, Surgical and Health Science, Cattinara University Hospital, ASUGI, University of Trieste (Trieste); [2]Department of Life Sciences, University of Trieste (Trieste); [3]Institute for Maternal and Child Health, IRCCS Burlo Garofolo (Trieste); [4]Department of Medical, Surgical and Health Science, University of Trieste (Trieste); [5]Institute for Maternal and Child Health, IRCCS Burlo Garofolo (Trieste); [6]Department of Veterinary Medicine, United Arab Emirates University (Al Ain-U.A.E)

Objectives: To evaluate the potential relation between the long-COVID syndrome "brain fog" (BF) and the complement pathway; in particular between BF and Mannan-Binding Lectin (MBL) levels and activity.

Materials: Patients referring to the Neuro-Long-COVID ambulatory service were screened for the presence of neurological symptoms that were persistent or occured ex novo at least after 4 weeks from acute COVID-19 manifestations. Patients without previous history of cognitive deficits, who reported persistent inattention, lack of concentration, short-term memory loss or impaired cognition were included in the BF group (BF+ve), patients who reported only persistent hyposmia/hypogeusia were included in the "without BF" group (BF-ve). Volunteers without persistent symptoms but with history of COVID-19 were included in the BF-ve group, volunteers without history of COVID-19 were included in the control group (CTRL). General anamnestic data, including comorbidities, were collected. An extensive neurological assessment of the patients was performed, including the Montreal Cognitive Assessment (MoCA) for BF+ve. All participants underwent a blood sample.

Method: Commercial ELISA kits were used for the determination of serum levels of MBL and of the activation of classical, alternative and lectin pathways of all participants. T-test was used to evaluate the differences between the groups (BF+ve, BF-ve, CTRL).

Results: A total of 66 subjects were included in the study: 32 BF+ve, 16 BF-ve, 18 CTRL. Significantly lower levels of MBL were observed in the sera of BF+ve patients compared to BF-ve group ($p<0.01$). Sera belonging to the BF+ve group presented a lower percentage of lectin pathway activation compared to BF-ve patients, whereas no differences were found for classical and alternative pathways.

Discussion: The pathogenic mechanisms of BF remain still unknown. The complement system could have an ambivalent role: enhancing virus elimination in the early stages of infection and leading to hyperinflammation and endothelial injury as a consequence of an excessive or aberrant activation. MBL act, in the innate immune defense system, as an opsonin and as a recognition molecule in complement activation via lectin pathway. Reduced MBL levels in BF+ve group could suggest a reduced capacity to inhibit SARS-CoV-2 infection in this group of patient and could suggest a predisposition to long-Covid BF in patients with lower levels of MBL.

Conclusions: MBL level is significantly lower in patients experiencing BF in the post-acute phase of COVID-19. Long-COVID-associated BF can be considered as one of the manifestations of increased susceptibility to infections and diseases induced by MBL deficiency.

## A MULTI-RELAPSING SERONEGATIVE AUTOIMMUNE ENCEPHALITIS TRIGGERED BY SARS-COV-2 INFECTION: A CASE REPORT

E. Virgilio[1], L. Solero[1], F. Franchino[1], I. Pastore[1], E. Torre[1], A. Dutto[1], S. Servo[1], A. Dinoto[2], S. Carta[2], S. Mariotto[2], M. Capobianco[1]

[1]Neurology Unit, Department of Medicine, Santa Croce e Carle Hospital (Cuneo); [2]Neurology Unit, Department of Neurosciences, Biomedicine, and Movement Sciences, University of Verona (Verona)

Background: In recent decades, autoantibodies with high specificity for autoimmune encephalitis (AE) have improved diagnosis [1,2,3]. However, AE diagnosis in seronegative patients is challenging, and treatments are potentially harmful, emphasizing the importance of accurate clinical history, examination, and supportive paraclinical diagnostic tests. SARS-CoV-2 infection has been reported to trigger limbic encephalitis and anti-NMDA receptor AE, but the mechanisms are still poorly understood [1]. Moreover, due to AEs low frequency, their long-term prognosis and relapse risk is still unknown. Here we report the case of a multi-relapsing seronegative AE with onset after paucisymptomatic SARS-CoV-2 infection.

Case Presentation: A 60-year-old man with a negative medical history experienced paucisymptomatic SARS-CoV-2 infection (fever and sore throat, no hospitalization needed) in December 2021. He reported anxious behaviors and paranoia weeks later, progressively worsening despite psychiatric treatments. In March 2022, generalized seizures and cognitive impairment occurred. Brain MRI, lumbar puncture (LP), CSF Tau, p-Tau, beta-amyloid, and serum and CSF AE autoantibodies were negative. Brain PET revealed severe hypometabolism in bilateral temporal lobes and steroids and antiepileptic drugs were started. A diagnosis of possible AE according to 2021 diagnostic criteria was formed [2,3]. Six months later, we observed a partial improvement in cognitive and psychiatric manifestations while he continued to experience seizures despite the administration of different antiepileptics drugs. Brain PET was stable. Steroids were tapered, and he clinically relapsed with psychiatric manifestations and cognitive and memory deficits. LP and autoantibodies resulted once again negative. IVIG and rituximab were started. Cancer screening was negative. In February 2023 a third relapse occurred one month after the second semestral rituximab infusion. CSF 14.3.3 was negative at LP, CSF Tau was increased, and serum and CSF AE autoantibodies were analysed in a third-level expert laboratory. immunohistochemistry revealed a mild positivity on vessel walls and cytoplasmatic Purkinje cells, further supporting a possible autoimmune pathogenesis. Cyclophosphamide was started with clinical improvement.

Discussion: AE diagnosis and treatment in seronegative patients is challenging. Our case highlights the long-term difficulties in disease control despite the administration of high-efficacy therapies. SARS-CoV-2 infection, particularly severe infection, can trigger AE, which is usually seronenegative for well-known antibodies.

Conclusions: Seronegative AE is still underdiagnosed, but properly recognizing this condition has important consequences for patients' prognosis and treatment.

## PLASMA BIOMARKERS OF NEUROLOGICAL DISORDERS: FROM ACUTE STAGE TO POST-ACUTE SEQUELAE OF COVID-19

M. A. Zingaropoli[1], P. Pasculli[1], C. Barbato[2], C. Petrella[2], M. Fiore[2], F. Dominelli[1], F. Ciccone[1], M. Antonacci[1], M. Lichtner[3], G. Galardo[4], F. Pugliese[5], C. Mastroianni[1], A. Minni[6], M. Ciardi[1]

[1]Department of Public Health and Infectious Diseases, Sapienza University of Rome (Roma); [2]Institute of Biochemistry and Cell Biology (IBBC), National Research Council (CNR), Department of Sense Organs, Sapienza University of Rome (Roma); [3]Department of Neurosciences, Mental Health, and Sense Organs, NESMOS, Sapienza University of Rome (Roma); [4]Medical Emergency Unit, Sapienza University of Rome (Roma); [5]Department of Specialist Surgery and Organ Transplantation "Paride Stefanini", Sapienza University of Rome (Roma);[6]Department of Sensory Organs, Sapienza University of Rome (Roma)

Background: We examined biomarker levels of brain injury (GFAP and NfL) and monocyte/macrophage activation markers (sCD163) with the presence of neurological symptoms (NS) during the acute phase of the disease (baseline) and after three months from hospital discharge (postCOVID, Tpost)

Materials and Methods: Hospitalized COVID-19 patients were enrolled. Plasma samples were collected for the evaluation of NfL and GFAP and sCD163 levels at both time-points. According to COVID-19 severity at acute stage of the disease, patients were stratified into severe and non-severe groups as well as based on the NS presence at both time-points into with and without NS groups.

Results: Study population included: 144 hospitalized COVID-19 patients and 53 heathy donors (HD). At baseline, higher NfL, GFAP and sCD163 levels in severe compared to the non-severe group were observed ($p<0.0001$, $p<0.0001$ and $p<0.0001$, respectively). At baseline, higher NfL and GFAP levels in patients with NS on hospital admission compared to those without in both groups were observed (severe group: $p=0.0575$ and $p=0.0051$, respectively; non-severe group: $p=0.0427$ and $p<0.0001$, respectively). At Tpost, a significant reduction in NfL, GFAP and sCD163 levels compared to baseline was observed ($p<0.0001$, $p<0.0001$ and $p=0.0413$, respectively) although levels were almost higher compared to HD ($p<0.0001$, $p=0.0045$ and $p=0.0418$). At Tpost, higher NfL levels in both severe and non-severe groups compared to HD was observed ($p<0.0001$ and $p=0.0046$, respectively) while GFAP and sCD163 levels were still higher compared to HD only in the severe group ($p=0.0040$ and $p=0.0003$, respectively). At Tpost, patients with NS in the severe group showed higher NfL and GFAP levels compared to those with NS in the non-severe one ($p=0.0357$ and $p=0.0351$, respectively) as well as patients without NS in the severe group compared to patients without NS in the non-severe one ($p=0.0464$ and $p<0.0001$, respectively). Conversely, a higher sCD163 levels in patients with NS in the severe group compared to patients with NS in the non-severe one was observed ($p<0.0001$).

Conclusion: High NfL and GFAP plasma levels in COVID-19 could be due a proinflammatory systemic and brain response that involves microglial activation and sub-sequent neuronal damage. Our data highlight the association between myeloid activation and CNS perturbations. The recognition and diagnosis of these neurologic complications at both acute stage and post-COVID are challenging, particularly in the context of overstrained medical systems, where an under recognition or delays in diagnosis may contribute to poor outcomes.

## NEUROEPIDEMIOLOGY

### POSITIVE PREDICTIVE VALUE OF ACETYLCHOLINE RECEPTOR AUTOANTIBODY TESTING BY RADIOIMMUNOPRECIPITATION ASSAY

P. Chessa[1], P. Zara[1], G. Deiana[2], A. Morette[2], M. Puci[2], G. Sotgiu[2], P. Solla[2], E. Sechi[2]

[1]Department of Medical Sciences and Public Health, University of Cagliari (Cagliari); [2]Department of Medical, Surgical and Experimental Sciences, University of Sassari (Sassari)

Background and Objective: Antibodies against the acetylcholine receptor (AchR-IgG) confirm a diagnosis of autoimmune myasthenia gravis (MG) when detected in serum of patients with compatible clinical phenotypes. Radioimmunoprecipitation assay (RIPA) is the gold standard for AchR-IgG detection with a reported specificity of ≈99%. However, its accuracy in large, unselected populations has not been fully elucidated. We determined the positive predictive value (PPV) and risk of false AchR-IgG positivity in a real-life setting.

Materials and Methods: We retrospectively identified patients consecutively tested for AchR-IgG by RIPA at the University-Hospital of Sassari between January 2003-March 2022 (n=4795). Medical records of patients with AchR-IgG positivity (antibody titer of ≥0.5 nmol/L) were independently reviewed by two neurology investigators to determine true vs false antibody positivity, based on clinical phenotype and/or presence of clear alternative diagnoses at last follow-up. AchR-IgG-positive patients with insufficient clinical information were excluded (n=84). Diagnostic performance was summarized with point specificity, positive predicted values and their 95% confidence intervals (CIs). Results: Of 362 AchR-IgG-positive patients included in the study, 50 (13.8%) were designated as false positives. Specificity and PPV were 98.9% (95% CI, 98.5-99.2) and 86.2% (95% CI, 82.2-89.6), respectively. Alternative diagnoses in patients with false AchR-IgG positivity included ocular diseases (n=8), rheumatic diseases (n=7), pseudoptosis (n=5), myopathy (n=4), isolated cranial nerve palsy (n=2), parkinsonism (n=2), migraine (n=2), demyelinating diseases (n=2), and others (n=18). Main reasons for antibody testing included isolated diplopia (n=18), nonspecific asthenia (n=16), isolated eyelid ptosis (6), or others. Compared to patients with true AchR-IgG positivity, false positive patients were younger (median age, 65 [range, 7-91] vs 38 [range, 5-80] years), more frequently female (155/312 [49.8%] vs 37/50 [74%]), and had a lower antibody titer (median, 6 [range, 0.5-28] vs 0.7 [range, 0.5-5.5] nmol/L); $p<0.01$. After stratification by AchR-IgG titers of ≥1 nmol/L, specificity and PPV increased to 99.8% (95% CI, 99.6-99.9) and 96.6% (95% CI, 94-98.3), respectively.

Discussion and Conclusions: Despite the high specificity of AchR-IgG testing by RIPA, the risk of false antibody positivity is not negligible in clinical practice (14% in this study). Caution is needed when low titer AchR-IgG positivity (0.5-0.9 nmo/L) is detected in patients with symptoms that are nonspecific for MG or explainable by more common alternative etiologies.

Ingrassia", Section of Public Health, University of Catania (Catania); [3]Neurology Unit, Cannizzaro Hospital (Catania)

Background: Multiple Sclerosis (MS) is defined as Late Onset Multiple Sclerosis (LOMS) when the onset occurs after 50 years. LOMS patients might be underdiagnosed or misdiagnosed because they usually display a different disease phenotype compared to classical MS with a higher prevalence of Progressive forms (either primary or secondary), a more frequent motor or sensory symptom of onset and a faster disease progression. Across MS cohorts, the prevalence ranges from 0.6% to 12%, however little is known on the incidence of LOMS in the general population.

Aim: To study the annual incidence of LOMS in a population-based cohort.

Materials and Methods: Case ascertainment was conducted using as main sources the registries of all the MS centers of the province of Catania. Inclusion criteria were MS diagnosed according to McDonald criteria (2005) or subsequent revisions (2010, 2017); patients older than 50 years at the disease onset; onset between 2005-2020; resident in the province of Catania at the time of the onset. Incidence rates (IR) have been calculated for all the study period, according to sex, age classes and five years interval. Incidence rate ratios (IRR) have been computed to compare incidence rates.

Results: During the study period, 171 patients with LOMS were identified (104 women; 60.8%). The mean age at onset was 56 ± 6 years and the main phenotype was Relapsing Remitting MS (n=110; 64.3%), followed by Primary Progressive (n=34; 19.9%). The average annual crude IR was 2.7/100,000 person-years (pyar) (95% Confidence Intervals, CI 2.31-3.13). IR was 3.0/100,000 (95% CI 2.45-3.64) for women and 2.34/100,000 (95% CI 1.81-2.96) for men, with a female to male ratio of 1.29 (95% CI 0.94-1.77; p value = 0,11). Overall incidence risk was quite stable during the entire study period 2005-2020 (2.7/100,000 pyar). Nonetheless we observed an increased risk in the group aged 60-69 from 1.12/100,000 pyar during 2005-2010 to 3.12 during 2016-2020. When comparing the last quinquennum 2016-2020 to the first 2005-2010 the IRR was 2.79 (95%CI 1.13-7.81; p-value 0.01).

Conclusions: This is the first Italian population-based study exploring the incidence of LOMS. An increased IR over the time was observed in the age-group 60-69, possibly reflecting an increased age at onset of MS over the time. Although this increasing incidence in older people may be due to a better accuracy in diagnosis as well as to the aging of the general population, possible role of environmental factors cannot be excluded.

## INCIDENCE OF MULTIPLE SCLEROSIS IN THE CITY OF CATANIA: A 45-YEARS OBSERVATIONAL POPULATION-BASED STUDY

C. E. Cicero[1], C. Chisari[2], S. Toscano[2], F. Manno[1], G. Salafica[1], R. Marziolo[3], D. Maimone[3], S. Lo Fermo[1], M. Zappia[1], F. Patti[1], A. Nicoletti[1]

[1]Department of Medical and Surgical Sciences, and Advanced Technologies "G.F. Ingrassia", Section of Neurosciences, University of Catania (Catania); [2]Department of Medical and Surgical Sciences, and Advanced Technologies "G.F. Ingrassia", Section of Public Health, University of Catania (Catania); [3]Neurology Unit, Cannizzaro Hospital (Catania)

Background: Incidence of Multiple Sclerosis (MS) has been progressively increasing in Europe, with values ranging from 1.9/100,000 person years (pyar) in the fifties to 8.5/100,000 pyar in the years 2003/2007. However, in the last decades differences in temporal trends across European countries, especially considering high incidence areas, have been described. We have previously analyzed the incidence rates of MS in the city of Catania for a 30-years period (1975-2005), finding an increasing incidence.
Aim: To describe the incidence rates and temporal trends of MS in the city of Catania from 1975 to 2020.

Materials and Methods: Incident cases of MS have been ascertained using the registries of the main MS centers of the municipality of Catania. To be enrolled patients had to be diagnosed either with the Poser's criteria (cases between 1975 to 2001) or McDonald's criteria and subsequent revisions (cases between 2001 to 2020) and had to be resident in the city of Catania at disease onset. The onset adjusted annual incidence risk was based on the year of the clinical onset. Age and sex-specific annualized incidence rates have been calculated.

Results: From 1975 to 2020 a total of 718 incident cases were diagnosed in the city of Catania. Incidence steeply increased from 1.3/100.000 during 1975-1979 to 7.0/100.000 pyar during quinquennium 2000-2004 and showing a plateau soon after with substantially stable rates from 2004 to 2020 with an average annual crude incidence risk of 7.3/100,000 pyar. The average female to male ratio was 1.6 (95% CI 1.4-1.8, p value<0.0001) ranging from 0.8 (95% CI 0.35–1.61) in 1975-1979 to 1.8 (95% CI 1.2-2.8 p value<0.003) in 2016-2020. The mean age at onset increased steadily over the incidence study-periods from 23.9± 8.6 during 1975–1979 to 36.0±11.4 during 2016-2020.

Conclusions: MS incidence increased over time, reaching a plateau after 2004, possibly reflecting the effect of improvements in diagnosis and consequently a reduction in the time interval between clinical onset and diagnosis. The observed increasing age at onset might be the result of either improvement in diagnosis (through the use of MRI) or due to the effect of several environmental risk factor, whose relevance has changed over the years.

## DISPARITIES AND INEQUALITIES FOR NEUROLOGICAL PATIENTS IN ITALY (DIS-NE-I)

M. Leonardi, P. Sismondo, A. Marcassoli, M. Lanza, A. Fornari

Neurology, Public Health, Disability Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano)

Objective: Health disparities and inequalities are important and a too long overlooked public health concern worldwide. These differences in health and health care can affect people with any disease, including neurological disorders. The aim of this systematic review was to provide an overview of the main health inequalities faced by neurological patients in Italy and identify the modifiable determinants of health injustice.

Methods: The main databases (PubMed, EMBASE) were searched systematically. Quality was assessed with the Mixed Methods Appraisal Tool. This review followed the standard guidelines of Preferred Reporting items for Systematic Reviews and Meta-Analyses (PRISMA).
Results: 1797 records was obtained with the search string and, after the title and abstract screening, we have included 215 studies eligible for the full-text screening. The studies included in the final round, of the review, will be subjected to quality appraisal. Finally, the results will be analysed and clustered by topic.

Conclusions: The expected results could highlight the current inequalities in neurological care in Italy. This information's can contribute to implement specific interventions to reduce differences and injustice and can be a useful start point for supporting policy maker in decision process.

## DRUG USE IN PRESENCE OF CONTRAINDICATIONS IN MYASTHENIA GRAVIS: A REAL-WORLD COHORT STUDY IN ITALY - THE CAESAR STUDY

N. Lombardi [1,2], M. Finocchietti[3], G. Crescioli[1,2], O. Paoletti[4], P. Brunori[5], F. Sciancalepore[6], M. Tuccori[2,7], A. Addis[3], A. Vannacci[1,2], U. Kirchmayer[3], the CAESAR study group

[1]Department of Neurosciences, Psychology, Drug Research and Child Health, Section of Pharmacology and Toxicology, University of Florence (Firenze); [2]Tuscan Regional Centre of Pharmacovigilance (Firenze); [3]Department of Epidemiology Lazio Regional Health Service (Roma); [4]Regional Health Agency of Tuscany, Pharmacoepidemiology Unit (Firenze); [5]Neurophysiopathology, Perugia Hospital (Perugia); [6]National Center for Disease Prevention and Health Promotion, Italian National Institute of Health (Roma); [7]Department of Clinical and Experimental Medicine, Unit of Pharmacology and Pharmacovigilance, University of Pisa (Pisa)

Aims: To evaluate the use of pyridostigmine (Py) in presence of contraindications, and the use of concomitant potentially contraindicated drugs in a cohort of patients affected by Myasthenia Gravis (MG) in the Italian Regions of Lazio, Tuscany, and Umbria.

Materials: Administrative healthcare data were used to identify adults affected by MG (period 2013-2019). Among incident users of Py, the presence of contraindications (mechanical gastrointestinal/urinary obstruction, obstructive respiratory diseases, cardiovascular diseases, and mechanical ventilation) in the 2 years before the first prescription was evaluated. Among MG patients, the use of drugs with potential contraindications in the first year after enrolment was evaluated.

Methods: This is a retrospective cohort study. A multivariate logistic regression model was used to evaluate the determinants of Py and of potentially contraindicated drugs use in MG patients.
Results: Among 591 incident Py users affected by MG, 91 (15.4%) reported at least one of the contraindications considered at the first prescription of Py. Patients prescribed with Py in presence of contraindications were more frequently affected by diabetes, obesity, and renal diseases ($p<0.05$). Age 75+ years (odds ratio, OR 4.94, 95% confidence interval, CI 1.60-15.22 for Latium; OR 3.78, 95%CI: 1.26-11.34 for Tuscany; OR 5.83, 95%CI 1.19-28.52 for Umbria), the presence of at least one specific comorbidity (OR 3.93; 95%CI 1.68-9.17 for Latium), and polytherapy (6+ drugs, OR 4.90, 95%CI: 1.35-17.85 for Tuscany) were found to be significantly associated with Py use in presence of contraindications. Among patients affected by MG, 1,483 (62.6%) were treated with potentially contraindicated drugs in the first year of follow-up (66.9% in Latium; 59% in Tuscany; 57.6% in Umbria). Patients aged 75+ years, those with at least one specific complication or comorbidity, and those exposed to polytherapy were more likely to be treated with a potential contraindicated drug.

Discussion: The analysis of the determinants of Py use in presence of contraindications, and the use of concomitant potentially contraindicated drugs highlighted indicators of greater frailty, in particular for the covariates older age, comorbidities, and polytherapy.

Conclusion: Among incident users of Py, more than 15% of patients have at least one of the contraindications considered, and among patients diagnosed with MG, in the first year of follow-up >60% of subjects were treated with potentially contraindicated drugs.

## POINT PREVALENCE OF EPILEPSY IN DEMENTIA: A "REAL WORLD" ESTIMATE

M. I. Pateri[1], G. Floris[1], G. Borghero[1], S. Ardu[2], S. Pilotto[2], G. Pisano[2], G. Defazio[3], A. Muroni[1]

[1]Institute of Neurology, University Hospital of Cagliari (Cagliari); [2]Department of Medical Sciences and Public Health, University of Cagliari (Cagliari); [3]Department of Translational Biomedicine and Neurosciences, University of Bari "Aldo Moro" (Bari)

Background: Several studies have demonstrated a higher frequency of seizures and epilepsy in Alzheimer's disease and other forms of dementia as compared with healthy elderly individuals [1,2]. However, incidence and prevalence of epilepsy in the general population of dementia are unknown since most previous studies were performed in secondary-tertiary referral centres. In addition all prior studies but one provided "period" rather than "point" prevalence estimates [3].

Materials and Methods: We assessed point prevalence estimate of epileptic manifestations requiring antiepileptic medication in patients Alzheimer's disease, vascular dementia, and frontotemporal dementia from a secondary clinical setting.

Results: Point prevalence estimates were 6.4% in Alzheimer's disease, 8.9 % in vascular dementia, and 6% in fronto-temporal dementia ($p=0.8$), rates that were greater than those observed in the healthy elderly population. Regardless of the etiology of dementia, epilepsy was characterized by unprovoked seizures that lacked distinguishing clinical features.

Discussion and Conclusions: These findings support epilepsy as part of the spectrum of dementia. The similar point prevalence of definite epilepsy requiring anti epileptic treatment in Alzheimer's disease and non-Alzheimer dementias raised the possibility of similar underlying mechanism of epileptogenesis. Although this was not a population-based study, accurate point prevalence data from clinic setting would be important to better define the burden of epilepsy in dementia and the demands on health services to manage the condition.

## COVID-19 PANDEMIC IMPACT ON STROKE MANAGEMENT IN TRIESTE: A LOOK IN 2020, 2021 AND 2022 EMERGENCY EVOLUTION

I. Scali, M. Naccarato, F. Palacino, G. Prandin, E. Vincis, L. Mancinelli, P. Caruso, G. Furlanis, P. Manganotti

Clinical Unit of Neurology, Department of Medicine, Surgery and Health Sciences, Clinical University Hospital and Health Services, University of Trieste (Trieste)

Background and Aims: COVID-19 pandemic has been the most impactful health event of the last century. Most worldwide studies have focused on the pandemic consequences on stroke management during first infection wave (spring 2020). In Italy COVID-19 pandemic went through various management phases adopted by Italian government following the infection waves, and emergency measures lasted until March 31st, 2022. Our aim was to expand the epidemiological investigation to the whole pandemic period.

Materials: We selected all patients admitted to Trieste Stroke Unit from January 1st, 2018 until December 31st, 2022.

Methods: We divided all the patients into seven groups, according to COVID government restriction measures: pre-COVID-19 phase (2018/01/01-2020/03/08), 1st COVID-19 wave (2020/03/09-2020/05/03), post-lockdown phase (2020/05/04-2020/06/14), phase of easing measures (2020/06/15-2020/11/05), 2nd COVID-19 wave (2020/11/06-2021/04/25), "green-pass" phase (2021/04/27-2022/03/31), post-emergency phase (2022/04/01-2022/12/31).

Endpoints were admission, treatments, and outcomes at various stages. We evaluated differences using Kruskal–Wallis test for numeric or Chi-square test for nominal variables. A level of $p < 0.05$ was considered statistically significant.

Results: We collected 1694 patients, 757 thrombolysis and 221 thrombectomies. The number of patients hospitalized per day reached the minimum during most restrictive measures (0,68 in 1st and 0,77 in 2nd wave vs 0,97-0,98 in pre-/post-emergency). Treatment was preserved all over the pandemic's various stages (p=0.415). Compared to pre-pandemic situation, 1st COVID-19 wave showed a decrease of patients with mRS 0-2 at discharge (34% vs 52%): functional independence returned to usual frequency in 2nd COVID-19 wave (47% vs 52%) but the amount of patients with mRS 5-6 increased (36% vs 26%, p=0.001).

Discussion: COVID-19 pandemic changed stroke management far beyond 2020: after a first decrease in admission, the following phases showed gradual recovery to a classical contest even if the pre-emergency situation is still returning. Nevertheless, neurological emergency treatment was preserved all over the pandemic: dedicated protected rooms, specific training for operators and quick Swab tests for each new stroke patient didn't affect the possibility of reperfusive therapies. As shown by mRS score, 1st COVID-19 wave showed a decrease in the percentage of patients with functional independence at discharge: this frequency returned to pre-pandemic condition in 2nd COVID-19 wave but the amount of totally dependent or dead patients increased.

Conclusions: Stroke management experienced other changes beyond the shocking first impact of the pandemic in 2020: although in different ways in its two main waves, the COVID-19 Era had an important impact on stroke patients' health in Trieste.

## AN 8-YEAR, POPULATION-BASED STUDY IN CENTRAL ITALY: INCIDENCE OF ALS IN MARCHE REGION BEFORE AND DURING THE COVID-19 PANDEMIC

F. M. Sopranzi[1], A. Faragalli[2], M. Pompili[3], F. Carle[2], R. Gesuita[2], M. Ceravolo[1]

[1]Department of Experimental and Clinical Medicine, Polytechnic University of Marche (Ancona); [2]Center of Epidemiology, Biostatistics and Medical Information Technology, Polytechnic University of Marche (Ancona);[3]Regional Health Agency of Marche, Marche Region (Ancona)

Objectives: We sought to conduct a population-based longitudinal study in the Marche Region of central Italy to estimate Amyotrophic Lateral Sclerosis (ALS) incidence in this region, evaluate its trend between 2014 and 2021, and look for any variation during the COVID-19 pandemic (2020-2021).

Materials and Methods: We designed a longitudinal, population-based study of adults residing in Marche and listed in the regional registry as beneficiaries of the National Health System. Patients hospitalized for the first time with an ALS diagnosis (code 335.20 ICD-9 CM) or tagged with the disease-specific exemption code (RF0100) between 2014 and 2021 were considered incident cases. ALS cases residing for less than 3 years before the index date in the Marche Region, with a hospitalization for ALS, or with an exemption for ALS active in 2011-2013 were excluded. We used secondary sources to identify new diagnoses of ALS, in patients meeting the revised El Escorial criteria. The accuracy of secondary sources in identifying ALS incident cases was tested against the information included in the clinical database of the regional referral center for ALS. ALS mean incidence was computed as the ratio between the total incident cases and the regional population (12,223,809 p-y). A heatmap served to show the distribution of incidence rates according to the municipality of cases' residence. Incidence rate trend adjusted by sex and age was evaluated using Poisson regression model. ALS incidence in Marche Region was compared to that reported in similar studies conducted in other Italian regions.

Results: 425 new ALS cases (median age: 70y) were detected in the entire 2014-2021 period. The mean ALS incidence in the study period was 3.5 per 100,000 py (95%CI: 3.2-3.8; M:F = 1.22). No significant trend was observed during 2014-2019 period, but a significant mean decrease of 5.8% (95% CI 2.0%; 9.5%, p = 0.003) was observed after adding the 2020-2021 period to the Poisson regression model. ALS incidence in Marche was significantly higher compared to most similar studies conducted in other Italian regions.

Discussion and Conclusion: This observational study revealed a higher incidence of ALS in Marche, compared to other Italian regions, whose factors should be better investigated considering the role of environmental factors, occupational exposures and genetic features. We describe a significant decrease in ALS incidence over time. The understanding of the causes underlying this finding warrants a longer follow-up looking into ALS incidence trends after the pandemic.

## MOVEMENT DISORDERS IN THE EMERGENCY ROOM: A NOT SO RARE OCCURRENCE FROM A PROSPECTIVE, OBSERVATIONAL STUDY

F. Spagnolo, G. Di Maggio, E. Leopizzi, V. De Marco, S. La Spada, S. Vergine, M. Modesto, V. Durante, L. Celli, M. Ferrara, A. Pati, V. Pinto, A. Rini

Department of Neurology, Antonio Perrino's Hospital (Brindisi)

Objectives: Although management of Movement Disorders (MD) is primarily outpatient, the recent identification of several dysimmune conditions mainly showing MD as a clinical phenotype has raised attention towards the association between Emergency Room (ER) and MD. This is a single-center, prospective, observational study exploring the acute MD occurrence and their associated clinical phenotype.

Subjects and Methods: Over a six-month-period (June-December 2021) data concerning subjects attending the ER for a new-onset MD or for worsening of a pre-existing MD were collected and analyzed. A pre-set questionnaire exploring: demographic data, information on past and present medical history (using Charlson Comorbidity Index) and therapy, MD-phenotype (hypokinetic, hyperkinetic, mixed), MD-severity (mild, moderate, severe), MD-distribution (generalized, axial, appendicular), MD-development pattern (acute, subacute, chronic); MD-duration (<24h; 24-48h; >48h); MD-awareness (anosognosic,

moderately anosognosic, fully aware) were utilized. Information about MD-fluctuations, MD-associated pain, ability to walk and indication for subject's hospitalization were also prospectively collected. Etiopathogenetic hypotheses on MD were also formulated according to the more common etiologies: vascular, dysmetabolic, infectious/inflammatory, worsening of pre-existing MD, epileptic, iatrogenic, lesional, functional, other. A Fisher's exact test was used to test the differences in proportions for categorical variables.

Results: Over a 6-month period, 1651 subjects admitted in ER were referred for an urgent neurological evaluation. Of these, 37 subjects (2.24%) had a new onset MD (n=25, 1.5%) or showed a worsening of a preexisting MD (n=12, 0.7%). Over two-thirds of acute MD were hyperkinetic in nature, tremor and corea being the most represented phenotypes (30% and 27% respectively). Autonomous gait was impaired in 62% of patients with acute MD, often leading to hospitalization (43% of acute MD-subjects). The iatrogenic, dysmetabolic and inflammatory origin were the most frequently hypothesized etiologies (in 27%, 10% and 10% of cases, respectively).

Discussion: Previous studies described a very low frequency of MD emergencies, ranging between 0.2% [1] and 0.073% [2]. According to our study, the occurrence of MD in emergency setting should not be considered rare, as it ranges between 1.5 and 2.24% of all subjects requiring urgent medical attention. Hyperkinetic movement disorders are undoubtedly the hallmark of acute MD and a particular sensitivity to detect hyperkinetic phenomenology should be encouraged also among ER personnel, to not miss severe and treatable conditions.

Conclusion: This study highlights that acute MD represent an important clinical entity in emergency settings despite the fact that literature on the frequency and underlying etiologies of acute MD is very scarce.

## CLINICAL COURSE AND DEMOGRAPHIC FEATURES OF VEGETATIVE STATE/UNRESPONSIVE WAKEFULNESS SYNDROME PATIENTS IN A LONG-TERM RESIDENTIAL FACILITY

L. Tinti, E. Pupillo, E. Bianchi, E. Beghi

Laboratory of Neurology, Mario Negri Institute for Pharmacological Research IRCCS (Milano)

Objectives: We aimed to characterize the clinical course and demographic features of Vegetative State/Unresponsive Wakefulness Syndrome (VS/UWS) patients in a long-term residential facility (RSD San Pietro, Monza).

Materials: Clinical registries of resident patients in a long-term facility with a diagnosis of VS/UWS from January 2014 to December 2021.

Method: Monocentric retrospective cohort study.

Results:113 patients with a new diagnosis of VS/UWS in the study period were included. The mean age at admission was 61,3 ± 16,2 years (range 18,7 – 88,3); 51,8% were female. According to ICD-9 codes, etiologies were cerebral hemorrhage (42,3%), including intraparenchymal, subarachnoid and traumatic mechanisms; trauma without hemorrhage (19%); anoxic brain injury (9,5%); ischemic stroke (6,9%); others including epilepsy, hydrocephalus, metabolic encephalopathies (22,3%). The Coma/Near Coma scale (CNC) categories were extreme coma (2,8%); marked coma (31,8%); moderate coma (39,3%); near coma (25,2%); no coma (0,9%). The Glasgow Coma Scale (GCS) at admission was 8 in 46,3% of cases, following a gaussian distribution of values in the interval 4 – 12. Survival probability by Kaplan-Meier curves at the maximum available follow-up was 12,6%, with a median survival of 100,7 months, grossly following a linear decrease.

Discussion: Compared to similar studies in other countries, we found hemorrhages to be the most common etiology of VS/UWS in our cohort. Pichler and Fazekas analyzed data from 19 VS/UWS patients in a single year and found anoxic brain injury to be the most frequent cause (63%), followed by hemorrhages (21%), and brain trauma (16%); a single case was due to ischemic stroke, while they did not report about other etiologies. This was in contrast to older studies, conducted in a timeframe between the late 1970s and the early 1990s, which indicated a predominance of traumatic brain injuries as causes of chronic disorders of consciousness (DoC). Both our and Pichler's findings could possibly reflect changing attitudes towards the withdrawal of life sustaining treatments in the acute stage after devastating brain injuries, as well as substantial advances in intensive care practices. Of note, our study was not designed to accurately stratify DoC patients into VS/UWS and minimal conscious state, due to the retrospective nature of the data.

Conclusions: Available epidemiological estimates show contrasting results about the predominant causes of VS/UWS. This knowledge gap would require future studies to follow a prospective, population-based design, to better inform stakeholders about resource allocation and care organization.

[1]Department of Medical Sciences and Public Health, University of Cagliari (Cagliari); [2]Multiple Sclerosis Center, ASL Cagliari, University of Cagliari (Cagliari); [3]Department of Medical, Surgical, and Experimental Science, University of Sassari (Sassari); [4]Department of Neurology, San Francesco Hospital (Nuoro);[5]Department of Neurology, Azienda Ospedaliera G. Brotzu (Cagliari)

Objective: The Italian region of Sardinia (population, 1,587,413 people on December 2022) is a high-risk area for multiple sclerosis (MS), with an estimated prevalence of 330 per 100,000. It is unknown, however, whether the epidemiological burden of other demyelinating diseases of the central nervous system (CNS), such as aquaporin-4-IgG positive neuromyelitis optica spectrum disorder (AQP4-IgG+NMOSD), is similarly higher compared to other geographical settings. In this

study we aimed to determine the incidence and prevalence of AQP4-IgG+NMOSD in Sardinia.

Materials and Methods: Incidence was calculated between January 1, 2013, and December 31, 2022; whereas the prevalence day was December 31, 2022. Patients with a diagnosis of AQP4-IgG+NMOSD based on 2015 international diagnostic criteria were retrospectively identified using two different sources: 1) Archives of the MS Center Laboratory in Cagliari (reference and only laboratory for AQP4-IgG testing in the island); and 2) medical records of the four Sardinian reference units for treatment of MS and other CNS demyelinating disorders. Serum AQP4-IgG positivity was assessed by cell-based assay.

Results: A total of 45 cases were included in the study (incident, 30; prevalent, 41). The median age (range) at disease presentation was 51 (6-78) years and 96% were Caucasian. Female/male ratio was 9:1. The crude (95% CI) incidence and prevalence were 1.9 (1.3-2.6) per million person-years and 2.6 (1.9-3.5) per 100,000, respectively. Crude prevalence significantly increased from January 2013 (1.1 per 100,000; 18 cases over 1,640,379 people) to December 2022 (2.6 per 100,000; 41 cases over 1,587,413 people); p=0.002. After age-standardization to the world population, incidence and prevalence (95% CI) estimates decreased to 1.3 (0.8-1.9) per million and 1.8 (1.2-2.5) per 100,000, respectively. Among incident cases, the clinical syndromes at disease onset were longitudinally extensive myelitis in 21 (70%), optic neuritis in 4 (13%), brain/brainstem dysfunction in 3 (10%), or combinations in 2 (7%). Coexisting autoimmunity (either neurologic or systemic) were reported in 50% (mostly autoimmune thyroiditis). One incident case (4%) presented before 18 years of age.

Conclusions: Incidence and prevalence of AQP4-IgG+NMOSD in Sardinia are comparable to those reported in other Caucasian populations (≈1 per million and 0.8-3.3 per 100,000, respectively). The higher geographical MS risk in the island seems disease-specific and not associated with a higher risk of other CNS demyelinating disorders.

## NEUROGENETICS AND RARE DISEASES

### APOLIPOPROTEIN E (APOE) HAPLOTYPES IN HEALTHY SUBJECTS: A WORLDWIDE POPULATION GENETICS AND SEX-BASED PERSPECTIVE FOR ANCESTRY-INFORMED GENDER MEDICINE

P. Abondio[1], F. Bruno[2], A. Bruni[2], D. Luiselli[1]

[1]aDNA Lab, Dept. Cultural Heritage, University of Bologna (Ravenna); [2]Regional Neurogenetic Center (CRN), Department of Primary Care, ASP Catanzaro (Lamezia Terme-CZ)

Human APOE is a 299-amino acid long protein expressed and secreted in several tissues and body districts, where it exerts different functions mainly related to lipid metabolism, with specific activities around cholesterol transport and absorption/elimination. It has three main isoforms, determined by the pair of mutations rs7412-C/T and rs429358-C/T, which gives rise to the functionally different APOE variants ε2, ε3, and ε4. These have a distinct impact on lipid metabolism and are differentially implicated in Alzheimer's disease and neurodegeneration, cardiovascular disease, and dyslipidaemia. A plethora of other single nucleotide variants along the sequence of the APOE gene have been studied in cohorts of affected individuals, where they also modulate the influence of the three main isoforms to determine the risk of developing the disease. However, no contextual analysis of gene-long haplotypes has been carried out so far, and never extensively in cohorts of healthy individuals from different worldwide populations. Leveraging a rich, publicly available population genomics dataset, this study elucidates the distribution of APOE variants and haplotypes that are shared across populations and specific to macroareas, revealing a variety of risk-allele associations that distinguish peculiar ancestral backgrounds and can be leveraged for specific ancestry-informed screenings in medicine and public health. Moreover, when a dichotomous sex-based analysis is performed at a population and macroarea level, more subtle differences emerge in the distribution, frequency and sharing of haplotypes carrying protective and risk alleles that may be informative for a gendered approach to personalized medicine.

Health (Bethesda-USA); [13]The Global Parkinson's Genetics Program (Gp2)

Background and Aims: The Global Parkinson's Genetics Program (GP2) is an international collaborative program that focuses on improving our understanding of the role of genetics in Parkinson Disease (PD) and on making this knowledge globally available and actionable. A substantial proportion of risk for PD is driven by genetics and these genetic links have advanced disease understanding and therapeutic development. Although much progress has been made, a majority of the heritable component of PD remains unknown. GP2 addresses these gaps, by working collaboratively and globally to collect and characterize hundreds of thousands of people representing diverse backgrounds and disease experiences. The three main scientific outcomes are: 1) enabling a dramatic expansion of knowledge on genetic PD risk 2) accelerating and improving genetic discovery of monogenic PD forms, and 3) making these findings globally relevant. Methods: Clinical data and blood/DNA samples of PD subjects and families, from existing global consortia and cohorts from around the globe are being collected and subjected to Neurobooster Array and, in a subset, to short and long-read whole-genome sequencing (WGS). For monogenic cases, we also developed the GP2 Monogenic Portal, an easy-to-use online electronic case report form (eCRF), to submit pseudonymized data of patients/families in whom a monogenic cause of PD is suspected. The collection of rich patient/family data will facilitate prioritization of samples for WGS, enable deeper analysis of genetic, clinical-demographic and environmental factors influencing disease expression. GP2 enables large scale data collection, production, analysis, and dissemination. Patients' genetic data generated in the project is returned to the referring clinician; moreover, harmonized data are made available to the scientific community at large for further research.

Results: To date, the GP2 has contacted ~150 potential contributors from >50 different countries. In Italy, 9 centers across the country are already registered to GP2. Array genotypes now consist of a total of 24,935 genotyped participants, while 722 individuals already underwent whole genome sequencing. More recently, GP2 is expanding to recruit at-risk populations for PD, such as individuals diagnosed with REM sleep behavior disorder or idiopathic hyposmia, as well as "atypical" parkinsonism cases.

Conclusion: GP2, with another seven years of project efforts ahead, will deepen and extend global understanding of the genetic basis of PD across diverse populations, including those currently underrepresented. Findings and data generated from GP2 will have wide implications for research and care of PD and other neurodegenerative diseases.

## CHARCOT-MARIE-TOOTH DISEASE 2C: A NOVEL MISSENSE MUTATION IN THE TRPV4 GENE

S. Avventura[1], S. Magri[2], F. Balistreri[2], L. Bevilacqua[3], G. De Biasi[3], V. Sarro[3], A. Toriello[4], A. Iovino[4], C. Vinciguerra[4], A. Landolfi[3], P. Barone[3], G. Piscosquito[4]

[1]Neurology Unit, University Hospital "San Giovanni di Dio e Ruggi d'Aragona", Department of Medicine and Surgery, "Scuola Medica Salernitana", University of Salerno (Salerno); [2]Unit of Medical Genetics and Neurogenetics, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [3]Neurology Unit, Department of Medicine and Surgery, "Scuola Medica Salernitana", University of Salerno (Salerno); [4]Neurology Unit, University Hospital "San Giovanni di Dio e Ruggi d'Aragona" (Salerno)

Objective: With this study, we investigated the pathogenetic role of a novel heterozygous missense mutation (c.617G>A, p.Arg206His) in the TRPV4 gene, found in a Southern-Italy family with an axonal Charcot Marie Tooth disease (CMT). CMT type 2C is a peripheral neuropathy which is transmitted with an autosomal dominant manner caused by a mutation in TRPV4 gene, encoding for a Ca2+-permeable, nonselective cation channel.

Materials: Neurological examination, nerve conduction study, genetic analysis was performed in the proband and her family. Bioinformatic study of the mutation was also reported.

Results: We present a 32-year-old woman suffering from weakness of distal lower limbs, causing progressive walking disturbances and milder hand impairment. She underwent bilateral calcanear osteotomy and Achilles tendon lengthening (age 12 years). Neurological examination showed: mild pes cavus with hammertoes, stepping gait, positive Romberg sign, mild hypostenia of the intrinsic musculature of the hand (APB, ADM and FDI MRC 4/5) and more severe leg paresis (AT MRC=4/5; BDE and LAE MRC= 0/5), absence of deep tendon reflexes, bilateral needle hypoesthesia of the distal leg (CMTES= 10/28, CMTNS= 11/36). Electrodiagnostic studies showed an axonal, length-dependent sensorimotor polyneuropathy. The CMT panel showed a c.617G>A variant (p.Arg206His) in the TRPV4 gene. Family screening was performed: her mother and brother presented a milder clinical (CMTES 8 and 6, respectively) and electrophysiological phenotype. The same TRPV4 variant was identified in the affected family members.

Discussions: The c.617G>A (p.Arg206His) variant was never previously reported. Exome sequencing was negative for further pathogenetic known CMT genes. Its frequency in general population is lower than 0.01% (1/13,006 GO-ESP; 3/251,204 GnomAD). The CADD score is 19.69, predicting to be amongst the 1% most deleterious substitutions in human genome. Data collected about this gene seem to depose for a co-segregation familial model. Furthermore, this variant falls into the ARD2 (Ankyrin Repeat Domain) region, which is considered very important for regulation of cytoskeletal activity. Moreover, although the clinical and electroneurographic neuropathic phenotype is consistent with classical CMT2 cases, the affected members lack the auditory, vocal cord or respiratory system involvement, which are often reported in the disease [1].

Conclusions: According to ACMG guidelines [2], this variant is classified as probable pathogenetic in determining the disease.

## SEIZURES, HYPOTONIA, MILD INTELLECTUAL DISABILITY AND DISMORFIC FACIAL FEATURES: A NOVEL MUTATION IN PRPS1 FOUND IN A 25-YEARS OLD MAN

G. Beneduce[1], C. Lo Rizzo[2], M. Rispoli[1], N. De Stefano[1], C. Battisti[1]

[1]Department of Medicine, Surgery and Neurosciences, University of Siena (Siena);[2]Medical Genetics Department, University of Siena (Siena)

The PRPS1 gene codes for the enzyme phosphoribosyl-pyrophosphate synthetase-1 (PRS-1) that is a crucial enzyme in the de novo synthesis of purines and pyrimidine nucleotides. Mutations in PRPS1 may result in gain or loss of function for the protein. The spectrum of PRPS1-related disorders associated with loss-of-function mutations

includes Arts syndrome, Charcot – Marie – Tooth disease-5 and X-linked nonsyndromic sensorineural deafness. The phenotypes associated with gain-of-function mutations include PRPS-related hyperuricemia and phosphoribosylpyrophosphate synthetase superactivity. We report the case of a 25 years – old man who presented seizures, hypotonia, mild intellectual disability and dismorfic facial features, in which we identified a novel mutation in PRPS1. His pregnancy was characterized by prenatal growth restriction. At the age of 6 he presented a generalized epileptic seizure which was followed by other episodes. School support was needed from primary school. The patient experienced asthenia and muscle weakness even after minor efforts. In 2008 analysis of the karyotype and of the FMR1 gene was carried out, both reported within the norm. A EMG in 2019 showed mild signs of myogenic suffering in the lower limbs. When he referred to our department the neurological examination carried out during hospitalization showed bilateral distal weakness, loss of deep tendon reflex in the lower limbs and slight telekinetic tremor. The physical examination presented high and broad forehead, simplified ears, synophry, clinodactyly of the fifth toe bilaterally, sandal gap bilaterally, hollow left foot, kypho-scoliosis and stuttering. Consanguinity in the family was denied. The EEG showed episodic short sequences of theta activity at 5 hz in the left temporal region in the context of which sharper graphoelements are inscribed, without epileptiform abnormalities. Brain MRI were normal. A biopsy of quadriceps was within limits except for a predominance of type II fibers. A blood sample was acquired from the boy to perform analysis of genes associated with the clinical condition presented. The analysis carried out highlighted a hemizygous variant of uncertain clinical significance of the PRPS1 gene: c.307-3delT. The variant was inherited from the mother by a X – linked recessive condition. Mutations in PRPS1 is responsible of different effect in proliferating cells and postmitotic cells, resulting in an array of phenotypic presentations. The spectrum of recognized disorders caused by disruption of PRS-1 function is broad and more and more new mutations are being identified. With this novel mutation identified in our patient, we expand the already wide spectrum of PRPS1-related disorders.

## DIFFUSE RADIOLOGICALLY ISOLATED LEUKOENCEPHALOPATHY (DRIL)

C. Benzoni[1], E. Salsano[1], S. Fenu[1], D. Mandia[2], S. Magri[3], D. Di Bella[3], M. Moscatelli[4], D. Pareyson[1], Y. Nadjar[2], F. Taroni[3]

[1]Unit of Rare Neurological Diseases, Department of Clinical Neurosciences, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [2]Neuro-Metabolism Unit, Reference Center for Lysosomal Diseases, Neurology Department, Pitié-Salpêtrière University Hospital (Paris-F); [3]Unit of Medical Genetics and Neurogenetics, Department of Diagnostic and Applied Technology, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [4]Unit of Neuroradiology, Department of Diagnostic and Applied Technology, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano)

Background and Aims: In adulthood, many (> 50%) leukoencephalopathies (LKENs) remain of unknown cause, despite extensive laboratory investigations [1]. In some cases, clinical and radiological findings can be sufficiently homogeneous to allow a classifying diagnosis useful for clinical practice. Objective of our work is to describe a condition we named "diffuse radiologically isolated leukoencephalopathy (DRIL)".

Materials and Methods: We reviewed the clinical and laboratory features of the asymptomatic adults with LKENs of unknown origin assessed from January 2004 to December 2018 in the Unit of Rare Neurological Diseases of Carlo Besta Neurological Institute, Milano, Italy, and in the Neuro-Metabolism Unit of Hôpital Pitié-Salpêtrière, Paris, France.

Results: We identified 19 subjects, 11 Italian (9 females) and 8 French (5 females), among 57 Italian (~20%) and 50 French (~15%) patients with unclassified LKENs assessed at our Institutions. These subjects underwent brain MRI at a mean age of 56 years (range 39-71) because of head trauma, headache, or nonspecific symptoms, and were referred to us for a supposed leukodystrophy. They all exhibited a supratentorial, diffuse, T2/FLAIR-hyperintense and T1-hypointense LKEN. There was evidence of neither brain injury at birth nor vascular risk factors. Neuropsychological assessment and neurophysiological testing were unremarkable. T2-star sequences, and, when performed, proton magnetic resonance spectroscopy, spinal cord MRI, gadolinium contrast-enhancement sequences, CSF analysis and muscle biopsy were normal. In the 15 followed-up patients no clinical sign or MRI change were observed after a median follow-up of 3 years (range 0.5-20). No mutation was identified using LKEN targeted-gene panels.

Conclusions: Our observations suggest the existence of a group of subjects, mostly middle-aged females, with a diffuse LKEN with stable demyelinating-like features on MRI that remains asymptomatic over the years. In all these subjects, LKEN was discovered when a brain MRI was performed for unspecific symptoms, likely unrelated to the widespread white matter abnormalities. The brain MRI findings lead to extensive, unsuccessful investigations, and cause anxiety to the patients by mimicking severe leukodystrophies, which were excluded by comprehensive next-generation sequencing testing. This condition could be referred to as "diffuse radiologically isolated leukoencephalopathy (DRIL)". As to the pathogenesis, myelin damage or neuronal loss seem unlikely based on lack of clinical abnormalities and unremarkable neurophysiological studies, and we speculated that the condition may reflect a brain water content increase due to blood-brain barrier permeability changes, as seen in the mitochondrial neurogastrointestinal encephalopathy syndrome TYMP-related (MNGIE) [2].

## A NEW MUTATION DETECTED BY NGS IN MT-ATP6 GENE ASSOCIATED WITH MELAS AND IN SILICO 3D PROTEIN ANALYSIS

F. Cavalcanti, L. Citrigno, P. Spadafora, S. De Benedittis, O. Gallo, G. Di Palma, A. Qualtieri

Institute for Biomedical Research and Innovation (IRIB), National Research Council (Mangone-CS)

Introduction: The possibility to utilize today tools for the 3D structural analysis of proteins based on artificial intelligence such as AlphaFold, allows to obtain with relative ease, very useful functional indications related to the modifications caused by gene mutations, comparable with those that can be obtained experimentally.
Objective: The aim was to understand the impact of mitochondrial gene mutations identified by NGS on protein stability by means of an in silico structural approach.

Materials and Methods: Thirdy DNA samples, previously analyzed for canonical diagnostic mitochondrial DNA mutations were deep sequenced in order to identify the possible mtDNA genetic determinants. The Precision ID mtDNA Whole Genome Panel was utilized and an Ion 318 Chip Kit v2 was subjected to the ION Torrent PGM sequencing machine. The sequences were reviewed by IGV, v2.1.13 software. The variants were annotated and filtered considering the type of pathogenic variants, the population frequencies and presence in database and an heteroplasmy >5%. Protein structures of interest were loaded as PDB files from UniProt on-line database ((www.expasy.org/). The PDB files by AlphaFold, were open and analysed using SPDBV viewer software version 4.1.

Results: After the alignment, the coverage analysis reported 100% of the on target reads, with a uniformity of the 99.9% and a mean coverage of 574x. We identified 27 non-synonymous variants with a MAF <1%. Among these variants, we focused our attention on the MT-ATP6 gene carrying the mutation m.9124A> G; p.T200A and associated with MELAS. The related protein belongs to the ATP sinthase intramembrane unit F0. The 3D structure of this protein with a polar non-polar variation (T200A) shows a loss of the intrachain H-bond at the H6 domain between residue 200 and 197.

Discussions and Conclusions: The new gene variant let us to suggest that at protein level the resulting alteration could distorce the H6 helical structure inducing an anomalous protein functionality related to Melas. Of interest is the observation that an analogous variant already identified, the A177T, on the H5 domain, associated with MELAS, determines also an H-bond alteration. Because the H5 and H6 alpha-helical are in a very near region, we therefore suggest that the protein functionality linked to this region (H5-H6) may be related to the MELAS phenotype.

## ABNORMALITIES OF TRUNK ACCELERATION-DERIVED GAIT INDEXES IN SUBJECTS WITH GLUT-1 DEFICIENCY

M. Corrado[1], R. De Icco[1], V. Grillo[1], V. De Giorgis[1], V. Vacchini[1], C. Varesio[1], M. Celario[1], D. Trabassi[2], S. Castiglia[2], M. Serrao[2], C. Tassorelli[1]

[1]IRCCS Mondino Foundation, University of Pavia (Pavia); [2]Department of Medical and Surgical Sciences and Biotechnologies, "Sapienza" University of Rome (Roma)

Objectives: Gait disturbances and movement disorders are frequent in patients with GLUT-1 deficiency, mostly represented by pyramidal, cerebellar, and extrapyramidal dysfunction. This study aimed to assess the ability of a set of trunk acceleration-derived gait indexes to identify gait unbalance in subjects with GLUT-1 deficiency, and to detect potential correlations with clinical and biochemical parameters.

Materials and Methods: We recorded a 30 meters gait of 10 subjects with GLUT-1 deficiency and of 10 age-, sex- and gait speed-matched healthy subjects (HS). Gait analysis was performed via an inertial measurement unit (IMU) placed at the lower back. Based on trunk acceleration patterns in the antero-posterior (AP), medio-lateral (ML), and vertical (V) directions, we calculated: spatio-temporal gait parameters, pelvic kinematics, harmonic ratios (HR), recurrence quantification analysis (RQA), stride length coefficient of variation (CV), the longest short term Lyapunov's exponent (sLLE), and the log dimensionless jerk score (LDLJ).

Results: When compared to the HS group, the GLUT-1 subjects showed lower values of HR AP, HR ML, single support (SS) phase, and cadence. Moreover, they showed higher values of CV, LDLJ AP, LLE AP, and double support (DS) phase duration. In the GLUT-1 group, HR AP negatively correlated with a positive history of recurrent falls ($r = -0.88$, $p = 0.03$), while CV negatively correlated with ketonemia ($r = -0.64$, $p = 0.04$).

Discussion: Subjects with GLUT-1 deficiency exhibited multiple alterations in the trunk acceleration-derived gait indexes. Interestingly some of these alterations correlated with clinical/biochemical features, such as history of falls and ketonemia.

Conclusions: IMU derived gait indexes are reliable in the detection of gait dysfunction in GLUT-1 deficiency syndrome. Hopefully we will be able to use these instrumental markers for the long-term follow up of patients and to monitor treatment response.

## PHACE SYNDROME: CASE REPORT

M. S. Cotelli[1], P. Lavezzi[2], F. Manelli[3], S. Bonetti[4], R. Furloni[5], A. Madureri[6], G. Tomasini[7], G. Bonetti[8], M. Turla[1]

[1]Neurology Unit, Valcamonica Hospital (Esine-BS); [2]Radiology Unit, Valcamonica Hospital (Esine-BS); [3]Emergency Unit, Bergamo Est Hospital (Seriate-BG); [4]Emergency Unit, Spedali Civili Hospital (Brescia); [5]Medicine Unit, Valcamonica Hospital (Esine-BS); [6]Cardiology Unit, Valcamonica Hospital (Esine-BS); [7]Emergency Unit, Valcamonica Hospital (Esine-BS); [8]Laboratory of Clinical Pathology, Valcamonica Hospital (Esine-BS)

Objectives: PHACE syndrome (posterior fossa anomalies, hemangioma, arterial lesions, cardiac abnormalities/coarctation of the aorta, eye anomalies) is a rare condition whose etiology is still unknown, characterized by infantile large hemangiomas of face or neck and neurodevelopmental defects of heart, eyes, arteries and brain. Over 400 cases have been reported in scientific literature. Clinical trials are still open to consider a possible genetic involvement. We report the case of a 46 years-old caucasian woman who was diagnosed with PHACE.

Materials and Methods: She was evaluated at emergency department of our hospital due to epileptic seizure. Her medical history was positive for cerebral haemorrage at birth, epilepsy successfully treated with valproic acid and lamotrigine. She also underwent surgery due to infantile strabismus and was followed by psychiatrists due to persistent mood disorder. Her familial history resulted negative. She was unmarried and lived with her mother. She presented neurodevelopmental retardation (Wechsler Adult Intelligence Scale -WAIS IV score: 60). She attended compulsory education with support teacher and was right-handed.

Results: Neurological examination showed left moderate hemiparesis and sensory impairment. General examination showed short stature, left cheek cutaneous hemangioma extending to the left neck, bilateral proptosis. She performed brain computer tomography (CT) due to magnetic resonance imaging intolerance, which showed pontomesencephalic and right cerebral hemisphere hypoplasia, foramen Monroe colloid Cyst, right fronto-temporo-parietal lobes malacic area with ex -vacuo dilatation of right ventricle. Electroencephalography showed diffuse bilateral spike waves prevalent on the right hemisphere, consistent with neuroradiological pattern. According to 2016 revised diagnostic criteria (cutaneous hemangioma + 1 major criteria) diagnosis of PHACE syndrome was performed.

Discussion: PHACE syndrome is usually diagnosed during infancy, but also adult cases have also been reported (we recently described another adult caucasic patient with the same disease). Our patient has always been simply considered "mentally retarded" but a possible syndrome has never been taken into consideration. Unfortunately, she refused to perform brain magnetic resonance due to claustrophobia and psychosis while she is currently performing cardiovascular and ocular screening examinations. Sternal defects have been excluded such as thyroid disorders. We think that our case report can expand current literature.

Conclusion: We recommend to evaluate patients with segmental infantile hemangioma, expecially on the face, scalp and cervical region with clinical and imaging workup and considered PHACE among possible etiologies.

## AUTOSOMAL DOMINANT SPG18: THE FIRST LARGE ITALIAN FAMILY

N. Cuomo[1], M. Migliaccio[2], M. Piciocchi[3], V. Valente[3], A. Iovino[1], M. Esposito[4], G. Pierantoni[3], V. Menchise[5], C. Caccavale[3], S. Paladino[3], C. Criscuolo[1]

Introduction: Hereditary Spastic Paraplegias (HSP) are clinically and genetically heterogeneous and are classified as "pure", when spastic paraplegia is the only symptom or "complex" when other clinical features are present. SPG18 is due to endoplasmic reticulum lipid raft associated protein 2 (ERLIN2) gene mutations. It was initially described as autosomal recessive HSP, but later two cases with an autosomal dominant (AD) inheritance were identified. Currently, 8 AR, 5 AD and 3 sporadic SPG18 cases have been reported.

Objectives: To describe clinical and molecular findings of a large Italian AD SPG18 family.

Materials and Methods: A detailed medical history inquiry, neurological examinations of the proband and family members were conducted. Patients underwent brain and cervical magnetic resonance imaging (MRI), electromyography (EMG), neuropsychological examination and whole exome sequencing. Sanger sequencing was performed to verify the genetic variation in the proband and family members. Velocity gradient assay on proband's fibroblasts was performed to investigate propensity of the mutated ERLIN2 to form oligomers.

Results: Five affected family members underwent neurological examination showing progressive spastic paraplegia. Age at onset ranged from four years old to 18. Brain MRI and EMG were unremarkable. Neuropsychological evaluation pointed out a borderline intellectual functioning in one patient. One patient reported generalized epilepsy. The proband's father died at 58 years old with a diagnosis of amyotrophic lateral sclerosis (ALS). Some of his siblings also died around 60 years old with an anamnestic history ascribable to ALS. Genetic analysis revealed the heterozygous missense mutation, c.502G>A (p.V168M), in ERLIN2 gene. It cosegregated with the disease in the affected patients and was not present in the healthy subjects. Velocity gradient assay indicated no differences in oligomerization between mutated and wild-type protein

Conclusion: We report a large Italian SPG18 kindred spanning three consecutive generations and supporting AD transmission pattern. While the AD SPG18 families, reported up to now, showed a pure phenotype, our kindred shows a complex phenotype characterized by intellectual disability in one and epilepsy in another patient. It came to light a broad intrafamilial phenotypic variability spanning from pure to complex HSP and to ALS. Our data strength p.V168M more frequent association to ALS. Biochemical assays unravelled that V168M does not affect the ability of erlin-2 to oligomerize, therefore, not supporting a dominant negative effect of the mutated protein. ERLIN2 mutations should be considered in Italian HSPs cases, particularly in patients with ALS positive familiar history.

## A TREATABLE INHERITED METABOLIC DISEASE AS RARE CAUSE OF HEREDITARY SPASTIC PARAPLEGIA

G. M. I. Falcone[1], F. Santorelli[2], A. Toscano[1], O. Musumeci[1]

[1]Neurology and Neuromuscular Disorders Unit, University of Messina (Messina); [2]Molecular Medicine and Neurogenetics, IRCCS Stella Maris Foundation (Pisa)

Severe 5,10-methylenetetrahydrofolate reductase (MTHFR) deficiency is a rare but treatable inherited metabolic disease associated with hyperhomocysteinemia leading to a neurological syndrome with variable age of onset and phenotypes including spastic paraplegia. We describe two unrelated adult males who presented to our Unit because of progressive gait disturbances with rigidity and mild weakness of lower limbs. The first case started to complain of stiffness at lower limbs and cramps at 33 years of age. He also suffered from depression. One year later he was

hospitalized because of generalized tonic-clonic seizures. Lab exams showed severe hyperhomocysteinemia, low folic acid and vitamin B12. EMG showed a sensorimotor neuropathy, Brain MRI showed cerebral and cerebellar atrophy and peritrigonal leukoencephalopathy. He underwent an NGS panel for HSPs and he was found compound heterozygous for the variants MTHFR c.1752+1G>T and c.1160G>A (p.Gly387Asp). The second case started experiencing gait difficulties since 16 years of age. One year later he was hospitalized due to a cerebral venous sinus thrombosis. Lab exams showed severe hyperhomocysteinemia, low folic acid and vitamin B12. Brain MRI showed periventricular leukoencephalopathy and a thin corpus callosum. He was affected by bipolar disorder and under treatment with lithium. The patient was found compound heterozygous for the variants MTHFR Arg345Cys and Asn483Ser. Both patients are currently under treatment with high dosage betaine, folic acid and vitamin B12 with stabilization of symptoms. MTHFR deficiency should always be considered as a possible cause of hereditary spastic paraplegias especially in the setting of an atypical, more accelerated clinical course and the presence of psychiatric disorders. Given the possibility of treatment, screening homocysteinemia should always be part of the diagnostic work-up of spastic paraplegias.

## DELETION 15Q21.3-22.31 RELATED TO CEREBELLAR VERMIS HYPOPLASIA. A CASE REPORT

P. Flace[1,4], A. de Bartolomeis[2], L. Pascazio[3], G. Papagni[4], M. Gelato[5], G. Liaci[3], S. Zeppetella[6], D. Galletta[7]

[1]Medical School, University of Bari 'Aldo Moro' (Bari); [2]Section on Clinical Psychiatry and Psychology, Laboratory of Molecular and Translational Psychiatry and Unit of Treatment Resistant Psychosis, University of Naples Federico II (Napoli); [3]Stroke Unit, Section of Neurology, Department of Translational Biomedicine and Neuroscience "DiBraiN", University of Bari 'Aldo Moro' (Bari); [4]Hospital Structures, Universo Salute Opera Don Uva (Bisceglie-BT); [5]Frangi Rehabilitation Center, Korian - Group (Acquaviva delle Fonti-BA); [6]Unit of Human Pathology, 'Sea Hospital'ASL-NA1 Centre (Napoli); [7]Unit of Psychiatry and Psychology, Federico II University Hospital (Napoli)

Cerebellar vermis hypoplasia (Vm-Hyp) is characterized by an elective reduction of this portion of the cerebellum, which conserved its overall shape. Vm-Hyp is a rare malformative condition related to a wide variety of causes. Although, studies highlight a role of the cerebellum in not only sensory-motor functions, but also non-motor functions such as cognition, language and emotions. However, with difficulty, non-motor deficits are related to cerebellar malformations. In fact, Vm-Hyp is a rare and heterogeneous malformative condition which due to its etiological, clinical and neuroradiological characteristics is often overlooked and not considered. In fact, much more often Vm-Hyp is associated with clinical conditions in which there is a malformation of other portions of the central nervous system such as the brainstem or the basal ganglia. Here we report the clinical case of a young 29-year-old woman presenting an elective Vm-Hyp and a specific 15q21.3-22.31 deletion of about 7Mb. In fact, the neuroimaging investigation demonstrated the absence of malformations of other brain regions. In addition, other imaging analyses have evidenced the absence of malformative alterations in other regions of the body. The neuropsychological evaluation highlighted a serious impairment of practical-concrete skills, aimlessness, reduced social adaptation, medium-severe cognitive impairment. Although the correlation between the genetic deletion and Vm-Hyp is quite evident, further investigations are necessary to understand which cerebellar circuits are mainly compromised and which neuropsychological functions are most damaged.

## CANVAS AND SLEEP DISORDERS: A PROSPECTIVE CROSS-SECTIONAL STUDY

A. Funcis, S. Rossi, F. Madia, G. Dalla Zanna, G. Silvestri, V. Brunetti

Institute of Neurology, Catholic University of the Sacred Heart (Roma)

Objective: Cerebellar ataxia, neuropathy and vestibular areflexia syndrome (CAVANS) is a recessive late-onset ataxia caused by biallelic AAGGG expansions in the second intron of replication factor complex subunit 1 (RFC1) gene [1-2]. The aim in this study is to characterize, for the first time, sleep and its disorders in patients with genetically confirmed CANVAS.

Methods: Sleep was assessed by means of self-administered questionnaires and home-based polysomnography (PSG). Subjective sleep quality was assessed with Pittsburgh sleep quality index (PSQI), daytime sleepiness was assessed with Epworth sleepiness scale (ESS), and insomnia symptoms were assessed with Insonnia severity index (ISI). The presence of restless leg syndrome (RLS) was investigated with the administration of IRLS diagnostic clinical interview; in case of symptoms consistent with RLS, patients filled the IRLSSG severity scale. Symptoms of anxiety and depression were evaluated by means of Zung Self-Rating Anxiety Scale and Beck Depression Inventory short form, respectively.

Results: Eight patients with genetically confirmed CANVAS were enrolled (5 males, mean age: 64.1±7.3 years) with an average duration of disease of 13.9±7.2 years. Sensory axonal polyneuropathy and chronic spasmodic cough were present in all patients. Dysautonomia was reported in 5/8 patients. For what concern subjective sleep assessment, 5/8 patients complained poor sleep quality, 3/8 complained daytime sleepiness, 4/8 patients reported insomnia symptoms, 5/8 patients met the diagnostic criteria from moderate to very severe RLS. Four out to five patients with subjective poor sleep quality used sleep aids. The anxiety and depressive symptoms were present in 4/8 and 3/8 patients, respectively. PSG results showed a reduction of Slow Wave Sleep (N3/TST=15.2±13.0%) and REM (REM/TST=14.4±7.1%) and an increased wake after sleep onset (WASO=57.3±46.7 minutes). Obstructive sleep apnea (OSA) was present in 7/8 patients, ranging from moderate to severe (mean AHI=29.0±18.7), while 1/8 patients showed significant number of central sleep apnea; only one patient, with shorter disease duration (3 years from onset), did not show sleep-disordered breathing; only 2/7 patients with OSA reported daytime

sleepiness. Finally, 3/8 patients showed a periodic limb movement index over the cut-off.

Conclusions: Our data showed that patients with CANVAS have poor sleep quality, altered sleep architecture, and a high prevalence of sleep disorders, particularly of OSA, insomnia, and RLS. Although OSA is the most common disorder, daytime sleepiness was not reported in all patients [3]. Therefore, given the high prevalence of sleep disturbances, sleep assessment should be routinely performed in patients with CANVAS.

## ERLIN 2 MUTATIONS IN AN ITALIAN SERIES OF PATIENTS: PHENOTYPIC AND GENETIC VARIABILITY

V. Gioiosa[1], E. Cioffi[1], A. Petrucci[2], A. Tessa[3], F. Santorelli[3], C. Casali[1]

[1]Department of Medico-Surgical Sciences and Biotechnologies, University of Rome Sapienza (Latina); [2]Departement of Neurology and Neurophysiopathology, Azienda Ospedaliera San Camillo Forlanini (Roma); [3]IRCCS Stella Maris Foundation (Pisa)

Objectives: ERLIN2 gene mutations are associated to rare forms of hereditary spastic paraplegia (HSP) either autosomal recessive (AR) or dominant (AD), collectively known as type 18 (SPG18) [1]. The encoded protein is localized to lipid rafts of the endoplasmic reticulum and plays a critical role in inositol 1,4,5-trisphosphate signaling by mediating ER-associated degradation of activated IP3 receptors. About 13 families have been described worldwide (eight AR-SPG18 families, five AD-SPG18 families, and three sporadic cases have been reported) [2]. Clinical phenotype depends on the mode of transmission with AD-SPG18 as a juvenile-adolescent onset pure HSP, while AR-SPG18 is mostly a complicated HSP with earlier onset and more severe course. In rare cases, the initial spastic paraplegia could evolve to rapidly progressive motor neuron disease similar to amyotrophic lateral sclerosis (ALS) [3]. Brain MRI may display white matter alterations (WMA), thin corpus callosum. Herein, we report five patients with ERLIN2/SPG18, the largest series so far described in Italy.

Materials and Methods: Five patients were enrolled in 3 Italian centres, and underwent neurological examination, clinical cognitive assessment, brain MRI, and genetic analysis.

Results: Four subjects harboured a heterozygotic ERLIN 2 mutation (AD), with no family history in three, onset in childhood (1/4), 20-50 years (3/4). One patient harboured a double heterozygotic ERLIN2 mutation and infantile onset (AR). All showed a rather uniform phenotype including lower limb weakness and spasticity, mild impairment of vibration sense (2/4). One of the AD patients, the mother of another, after many years of spastic paraparesis developed rapidly evolving ALS-like with bulbar signs and lower motor neuron syndrome. Extra neurological manifestations included congenital cataract (1/5). Brain MRI showed WMA in 1/5.

Discussion and Conclusion: ERLIN2 was initially mapped in an autosomal recessive Turkish family with intellectual disability, motor impairment, and multiple joint contractures in 2011. Later ERLIN2 mutations were also identified in an autosomal recessive family with the complicated form of HSP in Saudi Arabia, which was designated as SPG18. Early reported families were all recessively inherited, complicated HSP. In 2018, two AD-HSP families caused by heterozygous ERLIN2 missense mutations [2]. This is the largest series of ERLIN2/SPG18 patients reported in Italy. In our series AD SPG18 seems to be more frequent than AR. The clinical phenotype ranges from early onset complicated HSP, both AD and AR, to mild adult onset HSP. In addition we observed one instance of HSP-ALS conversion phenotype. This confirms the wide phenotypic variability and raises the question of genetic counseling and prognosis.

## USE OF LENADOGENE NOLPARVOVEC GENE THERAPY FOR LEBER HEREDITARY OPTIC NEUROPATHY IN EARLY ACCESS PROGRAMS

C. La Morgia[1], C. Vignal-Clermont[2], V. Carelli[1], R. Hage[3], R. Sergott[4], S. Donahue[5], P. Yu-Wai-Man[6], H. Dollfus[7], T. Klopstock[8], V. Smirnov[9], C. Cochard[10], C. Ponce[11], F. Munier[12], M. Taiel[13], J. Sahel[14]

[1]IRCCS Institute of Neurological Sciences of Bologna, Neurology Unit, University of Bologna (Bologna); [2]Centre Hospitalier National d'Ophtalmologie des Quinze-Vingts (Paris-F); [3]Hopital Rothschild (Paris-F); [4]Wills Eye Hospital (Philadelphia-USA); [5]Vanderbilt Eye Institute (Nashville-USA); [6]John van Geest Centre for Brain Repair (Cambridge-UK); [7]CHRU de Strasbourg (Strasbourg-F); [8]Ludwig-Maximilians-Universitat Munchen (Munchen-D); [9]Centre Hospitalier Universitaire de Lille (Lille-F); [10]Centre Hospitalier Universitaire de Rennes (Rennes-F); [11]University Medical Center of El Paso (El Paso-USA); [12]Hopital Ophtalmique Jules-Gonin (Lausanne-CH); [13]GenSight Biologics (Paris-F); [14]Institut de la vision (Paris-F)

Objectives: Lenadogene nolparvovec is a novel, as yet unapproved, gene therapy for patients with Leber hereditary optic neuropathy (LHON) due to the m.11778G>A MT-ND4 mutation. Through early access programs, patients with MT-ND4-LHON can benefit from lenadogene nolparvovec prior to marketing authorization.

Materials and Methods: Lenadogene nolparvovec was provided based on unsolicited requests and authorized for use by local regulations. Patients with confirmed MT-ND4-LHON received lenadogene nolparvovec as a unilateral or bilateral intravitreal injection at the dose of 9x1010 viral genomes/eye. Baseline characteristics, efficacy, and safety data were collected.

Results: Between August 2018 and March 2022, 63 MT-ND4-LHON patients received lenadogene nolparvovec in early access programs; 35 (55.6%) in France, 9 (14.3%) in Italy, 1 (1.6%) in the UK and 18 (28.6%) in the US. Overall, 42 (66.7%) patients were administered bilaterally; all but one received both injections on the same day. At first lenadogene nolparvovec injection, the mean (SD) age was 33.7 (16.6) years (median=31.0; range=13.0-74.0) and the loss of vision in the first affected eye had lasted for a mean of 11.30 (9.66) months. Idebenone therapy was ongoing in 81% of patients at the time of injection. Among the 63 patients, 45 patients have available data at one-year post-treatment. For these 45 MT-ND4-LHON patients, the mean (SD) change in BCVA from baseline to 1 year was 0.21 (0.69) LogMAR

(+10.5 EDTRS letters equivalent), and 29 were bilaterally treated and improved their BCVA at 1 year by -0.27 (0.76) LogMAR (+13.5 ETDRS letters equivalent). The safety of lenadogene nolparvovec was favorable with data comparable to those of the 189 patients treated in clinical studies.

Conclusion: Patients receiving lenadogene nolparvovec in the early access programs were predominantly European and received therapy mostly in both eyes. Preliminary efficacy and safety analyses show that lenadogene nolparvovec injection was associated with a clinically meaningful improvement of visual acuity and a favorable safety similar to that observed in clinical studies.

## NEUROLOGICAL MANIFESTATION AND GENETICS OF PHACOMATOSES: A RETROSPECTIVE STUDY FROM UNIVERSITY OF PISA ADULT NEUROLOGICAL INSTITUTE

P. Lopriore[1], A. Meli[1], M. A. Caligo[2], E. Manni[3], V. Montano[1], G. Siciliano[1], M. Mancuso[1]

[1]Neurological Institute, Department of Clinical and Experimental Medicine, University of Pisa (Pisa); [2]Laboratory of Molecular Genetics, Azienda Ospedaliero-Universitaria Pisana (Pisa); [3]Dermatology Unit, Azienda Ospedaliero-Universitaria Pisana (Pisa)

Phacomatoses are a broad group of rare genetic multisystem conditions characterized by the development of slow-growing neoplastic formations of neuroectodermal and mesodermal origin. Tuberous sclerosis complex (TSC) and Neurofibromatosis (NF) (type I and type II) are among the most common types of phacomatoses and result from germline mutations in TSC1/2, NF1 and NF2 genes, respectively. Mutations can be de novo (most commonly) or familial with an autosomal dominant inheritance pattern. Intellectual/learning disability, seizures, sensorineural hearing loss and headache are among the most common neurological manifestations. In this study the aim was to assess the neurological manifestation and the genetic characterization of patients with phacomatoses referring to our adult neurological centre. A cohort of 39 patients (male 38.5%, female 61.5%) with a clinical suspect or a clinical/molecular diagnosis of TSC or NF was retrospectively studied. Genetic testing was performed using single gene or panel next-generation sequencing and Multiplex ligation-dependent probe amplification. Clinical and neuroradiological data were collected from the patients medical records. In our cohort a positive family history was present in 33,3% of cases. A clinical diagnosis was established mainly in adolescence (7 to 22 years old, 31.0%) or adult age (40 to 59 years old, 20.7%). A molecular diagnosis was reached in 27 cases, 5 resulted negative; 4 genetic testing are ongoing, in 2 cases molecular diagnosis performed in another center was unknown, 1 patient refused genetic tests. Mutations in NF1, NF2, TSC1, TSC2, and LZTR1 were found, establishing a molecular diagnosis of NFI (19), TSC (4), NFII (3) and Schwannomatosis (1). For NF1 mutations, the most represented were single nucleotide variants (68.4%), followed by deletions, duplications and insertions (6,9% each). NF1 most common mutation type were frameshift and missense (31.6% each) followed by stop codon, splicing and intronic variants (26.3%, 5,3% and 5.3% respectively). Neurological manifestations were present in about 50% of patients, the most common were epilepsy (35%), pediatric intellectual/learning disability (25%), headache (20%) and adult mood disorders (10%). A neuroradiological central nervous system involvement was present in 19/32 confirmed or suspected NF/Schwannomatosis and 7/7 confirmed or suspected TSC. Phacomatoses are complex genetic disease which commonly have neurological manifestations. Given the relative frequency of NFI (the most common autosomal dominant disorder of the nervous system) and the presence of recently approved drug able to control TSC-associated clinical manifestations, a deep understating of these conditions is needful for adult neurologists for a timely diagnosis and optimized management.

## OCULODENTODIGITAL DYSPLASIA: DEEP NEUROLOGICAL PHENOTYPING FROM A TUSCAN PEDIGREE

P. Lopriore[1], M. Vista[2], L. Bassani[3], A. Tessa[4], F. M. Santorelli[4], D. Orsucci[2]

[1]Neurological Institute, Department of Clinical and Experimental Medicine, University of Pisa (Pisa); [2]Unit of Neurology, San Luca Hospital (Lucca); [3]Unit of Radiology, San Luca Hospital (Lucca); [4]Molecular Medicine, IRCCS Stella Maris Foundation (Pisa)

Oculodentodigital dysplasia (ODDD) is a rare congenital malformation syndrome characterized by craniofacial, ocular, dental, digital anomalies, and neurological symptoms with less than 300 cases described worldwide. ODDD is caused by mutations in the GJA1 gene (6q22-q23), encoding connexin-43, a gap junction protein. Inheritance is mostly autosomal dominant (AD) with high penetrance and variable expression. Neurological manifestations are thought to occur in approximately 30% of patients, including late-onset spastic paraparesis, ataxia, dysarthria, prominent bladder disturbances, hyperreflexia, seizures and developmental delay or mild intellectual disability. Brain MRI may show a mild hypomyelination leukodystrophy pattern and/or gray matter T2 hypointensity. The aim of this study was to describe the neurological phenotypes and neuroradiological features of 10 patients from a single Tuscan pedigree. We analyzed a large ODDD three-generations pedigree. Clinical and neuroradiological features were retrospectively collected from patients medical records. Brain MRI were performed in 5/10 patients (multiple time points from 2006), in 2 is scheduled. In June 2023 we performed a full neurological examination, collecting motor and cognitive scales. Patients harbored a heterozygous missense single nucleotide variant (c.416T>C, p.Ile139Thr) in GJA1 exon 2, classified as likely pathogenic (ACMG criteria). The pedigree was made up of 5 males and 5 females from three generations, 2 elderly patients (70 and 75 years old), 4 adults (from 43 to 55 years old), 3 adolescent (from 8 to 21 years old) and 1 infant (14 months old). Clear neurological symptoms were present in 5 of 10 patients. Neurological onset was characterized by late-onset slow-progressive gait disturbances (ataxia and spastic paraparesis) in 2 patients, neurogenic bladder (in the form of urinary urgency or urinary retention) in 2 patients, slight learning disability in 1 patient. The most common neurological features were spastic paraparesis/sign of lower limb pyramidal involvement (4/5), spastic ataxia (2/5), postural tremor (2/5), isolated ataxia (1/5) and mild cognitive decline (1/5). 2 adults had psychiatric disturbances (mild bipolar disorder and depression). Out of neurological features and typical syndromic characteristics, lower limb lymphedema was present in 3/5 females and bowel dysfunction (chronic diarrhea and fecal incontinence) reported in 3/10 patients. A

mild hypomyelination leukodystrophy pattern was recognized in 5/5 patients. ODDD diagnosis is often missed. Thus, the recognition of neurological manifestations, including lower limb slow-progressive pyramidal involvement and ataxia, and peculiar brain MRI patterns, in association with typical syndromic features should trigger the genetic evaluation of undiagnosed patients.

## NOVEL PATHOGENIC VARIANTS INVOLVED IN AUTOPHAGY IN FRONTOTEMPORAL DEMENTIA: A WHOLE EXOME SEQUENCING STUDY

A. Marcinnò, F. Roveta, S. Boschi, E. Piella, F. Ferrandes, A. Grassini, P. Provero, D. Marnetto, I. Rainero, E. Rubino

Department of Neurosciences "Rita Levi Montalcini", University of Turin (Torino)

Aim: Frontotemporal dementia (FTD) etiology has an important genetic component, the three most frequently involved genes, (MAPT, GRN and C9orf72) are implicated in about 5-10% of cases. The discovery of other causative genes opened new etiologic and therapeutic perspectives. Autophagy is one of the main intracellular mechanisms through which genetic alterations may converge on neurodegeneration. Beyond C9orf72, other autophagy associated genes mutations (in TBK1, OPTN, SQSTM1, UBQLN2, TDP43 and VCP) were demonstrated to cause FTD. The present study aims to identify gene variations by WES (whole exome sequencing) in a cohort of FTD patients with specific focus on genes involved in autophagy.

Materials and Methods: 78 patients (38 females, 40 males) were involved. They received a diagnosis included in FTD spectrum. The most frequent genetic variants known at the time of the diagnosis (MAPT, GRN and C9orf72) resulted negative. WES data were used to detect unknown variants in eight autophagy genes already associated with FTD and in twenty-three other autophagy genes. The American College of Medical Genetics and Genomics (ACMG) criteria were used to define novel variants as pathogenic, likely pathogenic or VUS (variants of uncertain significance).

Results: 4 novel variants classified as pathogenic were detected: three frameshift mutations (two in CHMP2B, one in UBQLN2) and one splice site variant of TBK1. Other two variants in UBQLN2 were classified as likely pathogenic. There were also 61 VUS affecting C9orf72, SQSTM1, TBK1, VCP, OPTN, CCNF, mTOR, ATG9, NDST3, AMPK, WDR41, TAX1BP1, WIPI2, YKT6, FIP200, STX17, ATG2A, ATG13, TMEM41B, TOLLIP, ULK1, BECN1, NBR1, NDP52 and STAU1. In five patients, we found the coexistence of pathogenic or probably pathogenic variants or VUS in autophagy genes already or not yet associated with FTD.

Discussion: Considering only autophagy genes, six patients are carriers of mutations classified as pathogenic or likely pathogenic. Five of them are oligogenic case, in which VUS and pathogenic variants coexist, involving gene products whit functional interactions. Together with subsequent confirmation by segregation and in vitro analysis, these novel variants will be reevaluated also considering the convergence on the same intracellular process and its effect on neurodegeneration.

Conclusions: Using WES in FTD cases not associated with the most frequent genetic variants could have an important clinical and research impact. Novel pathogenic variants will be further investigated to confirm their etiologic role. Moreover, this study deepens our knowledge about the association between FTD pathogenesis and autophagy, focusing on oligogenic cases.

## NEUROLOGICAL AND NEUROPSYCHOLOGICAL CORRELATES OF KLIPPEL-FEIL SYNDROME

S. Melchiorre, M. Santilli, M. Russo, G. Polito, C. Ciprietti, D. Calisi, F. Dono, M. Onofrj, S. L. Sensi

Department of Neuroscience, Imaging and Clinical Sciences, University G. D'Annunzio of Chieti-Pescara (Chieti)

Background: Klipplel-Feil syndrome (KFS) is a rare congenital malformation characterized by the fusion of at least two cervical vertebrae. This condition leads to a classic triad of short neck, low hairline, and limited neck mobility, found in approximately half of all patients [1]. In KFS, neurological deficits are relatively common, primarily due to spinal stenosis, cervical spinal deformity, and vertebral instability [2,3].

Case presentation: A 66-year-old right-handed married man was referred to our neurological outpatient clinic. The man was a nurse and a drummer and only complained of dizziness after laughing. The neurological examination revealed multidirectional gaze-evoked nystagmus, more prominent on the left side, which was also inexhaustible. Hyperreflexia in the lower limbs was present and associated with an inconstant Babinski reflex. Ataxic gait was not evident, but he could not walk in tandem. At the inspection, the typical triad was found; thus, a diagnosis of KFS was hypothesized. Thus, an MRI scan of the brain was prescribed. The exam showed a complex cervical-occipital malformation, including the rise of the epistropheus above the line of Chamberlain, the fusion of the posterior arch of the atlas with the occipital squama, basilar impression, and downwards dislocation of the cerebellar tonsils. Platibasia (with the medulla and the pons compressed on the right lateral wall by a meningioma) was also evident. The fusion of multiple cervical vertebrae, associated with spinal canal stenosis and C4-C5 disc degeneration with myelopathy signs, were also present. A radicular cyst was finally reported. The patient also underwent neuropsychological evaluation, in which normal global cognition was found. However, borderline visuospatial scores emerged when performing the copy of the Osterrieth-Rey figure and the Trail-making tests.

Conclusions: Despite the extent of the underlying malformation, subjects with KFS may have a normal life and even perform complex motor tasks, as in the case of our patient, able to play drums at semiprofessional levels. Our patient's visuospatial functions showed borderline cognitive performance, but only follow-up will tell the possible evolution to full-course cognitive decline. The case demonstrates the remarkable levels of compensatory plasticity that the brain can set in motion even in the presence of major congenital defects.

## HEREDITARY ATAXIAS: DIAGNOSTIC YIELD WITH NEXT-GENERATION SEQUENCING

A. Meli[1], P. Lopriore[1], A. Fogli[2], A. Lo Gerfo[2], A. Rocchi[2], M. A. Caligo[2], V. Montano[1], G. Siciliano[1], M. Mancuso[1]

[1]Neurological Institute, Department of Clinical and Experimental Medicine, University of Pisa (Pisa); [2]Laboratory of Molecular Genetics, University Hospital of Pisa (Pisa)

Hereditary ataxias (HAs) are a group of progressive monogenic rare neurodegenerative disorders characterized by a wide spectrum of ataxia-dominated phenotypes. Despite the identification of many causative genes, up to 50% of HAs cases still remain without a molecular diagnosis, mainly due to their vast clinical and genetic heterogeneity. Massive parallel next-generation sequencing (NGS) analysis broadened our knowledge of HAs genetic aetiology, consequently stimulating the trend toward genetically specific therapies. In this study, we aimed to assess the diagnostic yield of NGS panel and exome analysis in the clinical practice of our setting. A cohort of 111 patients with a clinical diagnosis of HA but no molecular confirmation was studied. In 7 patients the segregation analysis was performed to determine the genetic diagnosis. NGS panel (26 genes) and/or clinical exome sequencing (CES) were performed in the case of inconclusive first-line genetic tests for spinocerebellar ataxias (SCA1-3, 6-8,12,17), DRPLA, Friedreich's ataxia (FRDA) or phenotype-guided specific single gene sequencing ("traditional genetic tests"). By means traditional genetic tests a molecular diagnosis was achieved in 35,3 % of patients. 86,1% were short tandem repeats and the three most common were FXN (35,5%), ATXN2 (25,8%), and RFC1 (12,9%). Of 61 patients with HAs of indeterminate genetic origin, 43 underwent new molecular evaluation using NGS approach; for 2 patients NGS was performed directly. In 8 of 45 (17,8%) pathogenic or likely pathogenic variants were found. In 7 of these 8 patients, the diagnosis was made by CES. Genes mutations identified as causative of hereditary ataxia were found in SPG7 (1), CACNA1G (1), EEF2 (1), PRKCG (1), KCNC3 (1), ADCK3 (1), SYNE1 (1), ITPR1 (1). Finding ADCK3 and ITPR1 mutations by CES in two probands, allow us to identify the same mutations in other affected family members by Sanger sequencing. Furthermore, in 13,3% of patients (6/45) one or more heterozygous variants classified as VUS were detected in genes correlated with autosomal dominant form of HAs, particularly in FAT3 (1), FAT2 (1), STUB1 (1), ITPR1 (1), CTBP1 (1), IFRD1 (1) and CACNA1A (1). Overall, we present daily practice evidence that for about 20% of the patients with a clinical diagnosis of HA, but no molecular diagnosis on routine genetic testing, a definitive diagnosis can be reached with the NGS approach, especially using CES.

## DNA APTAMER-BASED APPROACH: AN EMERGING TOOL TO FIGHT HUNTINGTON'S DISEASE

M. Melone[1], D. Fasano[2], B. Bellastella[3], L. De Rosa[3], V. Valente[3], C. Riccardi[4], F. D'Aria[5], F. Digilio[6], M. Carillo[6], J. Amato[5], D. Montesarchio[4], C. Giancola[5], G. Pierantoni[3], S. Paladino[3]

[1]Department of Advanced Medical and Surgical Sciences, 2nd Division of Neurology, Center for Rare Diseases and InterUniversity Center for Research in Neurosciences, University of Campania Luigi Vanvitelli (Napoli); [2]Department of Advanced Medical and Surgical Sciences, Center for Rare Diseases, 2nd Division of Neurology, University of Campania Luigi Vanvitelli (Napoli); [3]Department of Molecular Medicine and Medical Biotechnology, University of Naples Federico II (Napoli); [4]Department of Chemical Sciences, University of Naples Federico II (Napoli); [5]Department of Pharmacy, University of Naples Federico II (Napoli); [6]Research Institute on Terrestrial Ecosystems (IRET), CNR (Napoli)

Introduction: Aptamers, comprising single-stranded DNA or RNA, are molecular-recognition agents, predominantly emerged in the last years as valuable therapeutic candidates for several human diseases. Despite the exceptional advances made in Huntington's disease (HD) research, nowadays no definitive treatment is available for this invalidating progressive neurodegenerative disease, caused by elongation of CAG repeats in huntingtin (HTT) gene. Recently, a set of guanine-rich aptamers (named MS1 to MS4) able to preferentially recognize full-length HTT with an expanded polyglutamine tract has been identified, pointing out the use of these aptamers as promising approach in HD [1,2].

Methods: Biological characterization of MS3, which was emerged the best aptamer in this series, and its two truncated variants (named MS3-33 and MS3-17) was performed in SH-SY5Y cells, the widely used human neuronal cell line derived from neuroblastoma. Moreover, the biological impact of MS3 and MS3-17 aptamers was evaluated in the widely used immortalized striatal cell line model of HD stably expressing human expanded HTT (STHdhQ111/111) in comparison with wild-type counterpart (STHdhQ7/7) as well as on a well-established Drosophila melanogaster model for HD (Q128HD-FL).

Results: By confocal microscopy analysis we show a rapid, dose-dependent uptake of fluorescein-conjugated aptamers in SH-SY5Y cells, demonstrating their effective internalization with no general cytotoxicity. In addition, they are stable over time as evidenced by the presence of fluorescent signal 72 hrs after their wash out of medium, further supporting the feasibility of their in vivo use. Remarkably, these aptamers are readily taken up and persist even in STHdhQ111/111 cells, in comparable manner to STHdhQ7/7 cells. Since mitochondrial dysfunction seems to play a fundamental role in the pathogenesis of HD, by imaging and biochemical assays we have investigated the effect of the aptamer treatment on mitochondrial dynamics and functions. Interestingly, we observed that the tubular morphology of mitochondria was restored in STHdhQ111/111 MS3- and MS17- treated cells, indicating that the aptamer treatment promotes mitochondrial network organization Consistently, the expression of the mitochondrial fusion machinery was increased in treated cells. Finally, a significant improvement in the motor neuronal function and lifespan of transgenic flies fed with these aptamers was observed, proving their in vivo efficacy.

Conclusions: Overall, these data unravel the efficacy of these targeting mutant huntingtin aptamers both in vitro and in vivo. Thus, they highlight the relevant therapeutic potential of DNA aptamer-based approach for HD.

## EFFECT OF GBA MUTATIONS AND GENDER ON NEUROPSYCHOLOGICAL FEATURES OF PARKINSON DISEASE AT DIFFERENT DISEASE STAGES

P. Mitrotti[1], M. Avenali[1], I. Palmieri[2], G. Cuconato[3], L. Gallo[4], R. Calabrese[5], C. Galandra[3], C. Tassorelli[1], C. Pacchetti[6], F. Blandini[7]

[1]Neurorehabilitation Unit, IRCCS Mondino Foundation, University of Pavia (Pavia); [2]Neurogenetics Research Centre, IRCCS Mondino Foundation (Pavia); [3]Department of Molecular Medicine, University of Pavia (Pavia); [4]Department of Brain and Behavioral Sciences, University of Pavia (Pavia); [5]Neurorehabilitation Unit, IRCCS Mondino Foundation (Pavia); [6]Parkinson's Disease and Movement Disorders Unit, IRCCS Mondino Foundation (Pavia); [7]Ca' Granda IRCCS Foundation, Ospedale Maggiore Policlinico (Milano)

Objective: To investigate the contribution of GBA mutations and gender on depressive and anxiety symptoms in patients with Parkinson Disease at different stages.

Methods: GBA-mutated (GBA-PD) and non-mutated (NM-PD) patients underwent a comprehensive clinical characterization (MDS-UPDRS I-II-III-IV, MOCA, SCOPAUT, UPSIT, RBDSQ, Pain, BDI and HADS-A). Clinical scores were compared between the two groups. To further investigate the neuropsychological profile of GBA-PD patients, subgroup analyses were performed upon stratification for disease duration (early stage: <6 years, intermediate: between 6 and 10 years, and advanced: > 10 years) and for gender. Correlation analyses were also investigated.

Results: 52 GBA-PD (56% males) and 84 NM-PD (64% males) were enrolled. Within GBA-PD, 9 subjects carried mild (17.31%), 18 severe (34.62%), 15 risk (28.85%) and 10 unknown (19.23%) variants. Overall, 45% (n=23) GBA-PD presented a clinically relevant depressive burden (BDI cut-off>13) compared to 19% (n=15) of NM-PD. BDI and HADS-A scores were also significantly higher in GBA-PD than NM-PD. Interestingly, when stratifying by gender, such higher BDI and HADS-A scores emerged only in GBA-PD males compared to their NM-PD counterparts, while scores were similar in females from both groups. Indeed, this observation was further substantiated when comparing genders within each group, as NM-PD males showed lower BDI and HADS-A scores compared to females, while no differences emerged in the GBA-PD group. The use of antidepressants and anxiolytics drugs was comparable between both PD groups and gender subgroups. When PD groups were stratified by disease duration, at early disease stage both BDI and HADS-A scores were significantly higher in GBA-PD than in NM-PD, while no differences were noted in intermediate and advanced stages. Moreover, differences in BDI and HADS-A scores between GBA-PD males and NM-PD counterparts were even more significant in the early stage while they were lost in the other disease stages. Finally, BDI and HADS-A scores in GBA-PD did not correlate with other clinical motor and non-motor parameters.

Conclusions: GBA-PD patients showed a greater burden of depressive and anxious symptoms, especially in the early disease stage. Noteworthy, this difference was mainly driven by GBA-PD males compared to NM-PD counterparts. This worse neuropsychiatric profile was unrelated to the severity of motor and non-motor symptoms. These data underscore the importance of early detecting and properly treating neuropsychiatric symptoms in GBA-PD, since GBA mutations confer a greater risk of mood disorders and male gender may affect this association.

## EMERGING ROLE OF SERUM MIRNAS AS NOVEL LIQUID BIOPSY BIOMARKERS IN NEUROFIBROMATOSIS TYPE 1 AND RELATED CLINICAL COMPLICATIONS

F. Napolitano[1], M. Dell'Aquila[1], M. Ravo[2], G. Ventola[2], G. Franzese[1], T. Esposito[3], S. Sampaolo[1], S. Paladino[4], M. Melone[1]

[1]Department of Advanced Medical and Surgical Sciences, 2nd Division of Neurology, Center for Rare Diseases and InterUniversity Center for Research in Neurosciences, University of Campania Luigi Vanvitelli (Napoli); [2]Genomix4Life Srl, Genome Research Center for Health-CRGS (Baronissi-SA); [3]Molecular Genetics and Genomics Laboratory, Institute of Genetics and Biophysics, Italian National Research Council (CNR) (Napoli); [4]Department of Molecular Medicine and Medical Biotechnology, University of Naples Federico II (Napoli)

Aims: Neurofibromatosis type 1 (NF1) is a neuro-cutaneous genetic disorder caused by dominant mutations in the NF1 gene and characterized by heterogeneous clinical presentation with increased susceptibility to developing benign and malignant tumors. Dysregulation of gene expression can cause complex disease phenotypes. MicroRNAs (miRNAs) function in post-transcriptional gene regulation acting as both tumor suppressors and oncogenes in a wide variety of human cancers. Several studies have reported the potential role of circulating miRNAs to mirror physiological and pathophysiological conditions functioning as biomarkers for various diseases. To date, the role of circulating miRNAs in NF1 remains poorly investigated. We aimed to identify serum miRNAs profiling as novel diagnostic and prognostic biomarkers associated with NF1 phenotype and with disease severity. Material and Methods: The study included 126 NF1 patients, enrolled at Division of Neurology of AOU Luigi Vanvitelli and diagnosed based on the NIH Consensus Conference criteria of 1988. We stratified the patients into clinical severity progression groups (G1-G5), ranged from mild to severe phenotype, as reported in our recent NF1 genotype-phenotype correlation study [1]. To identify miRNA as circulating biomarkers of NF1 disease, small noncoding RNA sequencing (sncRNA-seq) for pooled serum samples, followed by qRT-PCR validation analysis for the best miRNA signature in independent samples were performed. miRNA-gene network analysis was investigated using IPA (Ingenuity Pathway Analysis) tool.

Results: sncRNA-seq results showed 87 deregulated serum miRNAs. A concordance expression pattern between sncRNA-seq and qRT-PCR data for seven miRNAs was found, suggesting their association with NF1 disease. IPA analysis revealed that the candidate miRNAs regulate multiple genes biologically connected to each other and mainly involved in the molecular signaling linked to development and progression of cancer, such as MAPK and PI3K/AKT/mTOR signaling, that are the most studied downstream pathways of neurofibromin, protein encoded by NF1.

Discussion: NF1 is characterized by a highly clinical variability. This study revealed for the first time the role of a panel of seven miRNAs as novel liquid biopsy biomarkers of NF1 and related clinical complications, paving the way for the exploration of their influence in the NF1 disease. Future studies should validate these results in a larger multi-centric cohort of patients.

Conclusions: Our findings highlight a role of circulating miRNAs in NF1 pathogenesis, thus representing future therapeutic targets of NF1disease.

## A CASE OF MOG ANTIBODY DISEASE IN A PATIENT WITH HISTORY OF RECURRENT ADEM AND ATAXIN 1 GENE EXPANSION

M. Nasello, V. Zancan, G. Bellucci, R. Reniè, M. Buscarinu, G. Ristori, M. Salvetti

Department of Neuroscience, Mental Health and Sensory Organs (NESMOS), Sapienza University of Rome (Roma)

Introduction: Myelin oligodendrocyte glycoprotein (MOG) antibody-associated disease (MOGAD) is an autoimmune disease of CNS. Here we describe a case of MOGAD in a patient with expansion of ataxin-1 gene (ATX-1).

Case presentation: A 29 year-old-girl was admitted to our hospital with paraesthesia in both feet, hypoesthesia of left limbs and gait ataxia, occurring few days after SARS-COV-2 infection. She inherited a 44-long CGG triplets expansion in ATX-1 gene from her father who had a diagnosis of spinocerebellar ataxia type 1 (SCA1). The patient had a history of recurrent acute disseminated encephalomyelitis (ADEM) and bilateral optic neuritis during childhood following infectious diseases. During each relapse, brain MRI showed typical post-contrast enhancing white matter lesions, completely disappearing after corticosteroid therapy. Repeated lumbar punctures revealed transient oligoclonal bands, while antibodies against MOG and Aquaporin-4 (AQP4) always tested negative, as well as genetic tests for LHON, MELAS and CADASIL. During the hospitalization in our department, brain and spine MRI showed a new lesion in right semi-oval center and a C3-C4 white matter lesion in the posterior columns without post-contrast enhancement as well as unchanged gliotic lesions and cerebellar atrophy. Laboratory tests showed IgM and IgG positive for Herpes Simplex virus 1. Intravenous methylprednisolone was administered, with progressive complete resolution of symptoms. Serum anti-MOG IgG was detected by cell-based assays (CBA) and confirmed by a second test. Based on the clinical history (ADEM, optical neuritis and transverse myelitis) and the anti-MOG antibodies positivity a diagnosis of MOGAD was made [1]. A 9-month follow-up showed the disappearance of spinal cord lesion at MRI and an unremarkable neurological examination with no relapses.

Discussion: To the best of our knowledge this is the first report of a patients with MOGAD and ATX-1 gene expansion. Even though gene ATX-1 is strictly related to SCA1, recent studies have suggested its role in other degenerative and autoimmune neurologic diseases. Indeed, ATX-1 seems to have an immunomodulatory mechanism by regulating B-cells functions and protecting from demyelination in animal models [2].

Conclusion: Since the genetic component in the pathogenesis of MOGAD is still unknown, future studies on patients with coexisting ATX-1 mutations could help elucidating this gene's possible role in the development and clinical course of the disease.

## CALPAIN1-RELATED HEREDITARY SPASTIC PARAPLEGIA: NOVEL EVIDENCES FROM A SOUTHERN ITALIAN PATIENT

V. Nicolella[1], M. Migliaccio[1], R. Lanzillo[1], S. Tozza[1], L. De Rosa[2], G. M. Pierantoni[2], S. Paladino[2], F. M. Santorelli[3], V. Brescia Morra[1], C. Criscuolo[1]

[1]Department of Neurosciences, Reproductive and Odontostomatological Sciences, University of Naples "Federico II" (Napoli); [2]Department of Molecular Medicine and Medical Biotechnology, University of Naples Federico II (Napoli); [3]Molecular Medicine for Neurodegenerative and Neuromuscular Diseases Unit, IRCCS Stella Maris Foundation (Pisa)

Introduction: Hereditary spastic paraplegias (HSPs) are a group of clinically and genetically heterogeneous neurodegenerative diseases, characterized by progressive spasticity and weakness of lower limbs. More than 80 causal genes have been associated to HSP with all classical modes of monogenic inheritance reported. Clinically, HSPs are classified as pure when spastic paraplegia is the only symptom or complex when it is associated with other clinical features, such as ataxia, seizure, cognitive decline, extrapyramidal symptoms and peripheral neuropathy. Recessive mutations in the CAPN1 gene have recently been identified in spastic paraplegia 76 (SPG76), a complex hereditary spastic paraplegia (HSP) often combined to cerebellar ataxia [1].
Objective: To describe clinical and molecular findings of an Italian patient affected by SPG76.

Materials and Methods: Neurological, neuroradiological, neurophysiological and neuropsychological examination was conducted in a HSP patient from Southern Italy. Next generation sequencing-based HSP gene panel testing was performed and the causative variant was confirmed by Sanger sequencing. Furthermore, we investigated protein expression by Western blot analysis.

Results: The patient was a 43-years-old man born from first cousins. Onset was at 15 years old with running impairment and falls. Neurological examination disclosed sever spastic gait possible only with bilateral supports with increased muscle tone and weakness in lower limbs, brisk upper and lower limbs reflexes, bilateral ankle clonus and Babinski signs. No sensory alterations were detected, while cerebellar ataxia signs were present. Notably, the patient presented spastic dysarthria, urinary urgency and a cyclothymic disorder in a borderline personality. Nerve conduction studies were normal. Motor evocated potentials showed an impaired central conduction in the four limbs. Brain MRI showed thinning of the splenium of the corpus callosum. Genetic analysis revealed a homozygous truncating mutation in CAPN1 (c.1153C>T; p.R385*). As expected, at western blotting analysis the truncated protein was not detectable in patient fibroblasts.

Discussion: We describe a new Italian SPG76 patient with a complex form of HSP characterized by cerebellar signs less evident than pyramidal ones. Up to now, 50 families have been reported worldwide [2]. Only few Italian patients have been described; one of these with the same mutation as our case, suggesting a possible founder effect [2,3]. This patient showed an overlapping neurologic phenotype except of sensory deficit, not present in our patient, and absence of psychiatric disturbances.

Conclusions: Taken together, these evidences suggest an increasing role of CAPN1 in the pathogenesis of HSP, particularly in the Italian population.

Background and Objectives: Early-onset Parkinson disease (EOPD) commonly recognizes a genetic basis, thus EOPD patients are often addressed to diagnostic testing based on next-generation sequencing (NGS) of PD-associated multigene panels. However, NGS interpretation can be challenging in a diagnostic setting, and few studies have addressed this issue so far.

Methods: We retrospectively collected data from 648 PD patients with age-at-onset (AO) less than 55y who underwent NGS of a minimal shared panel of 15 PD-related genes as well as PD-MLPA in eight Italian diagnostic laboratories. Data included a minimal clinical dataset, the complete list of variants included in the diagnostic report. and final interpretation (positive/negative/inconclusive). Patients were further stratified based on AO≤40y (vEOPD, n=157). All variants were reclassified according to the latest ACMG criteria. For classification purposes, PD-associated GBA1 variants were considered diagnostic.

Results: In 186/648 (29%) patients, the diagnostic report listed at least one variant, and the outcome was considered diagnostic (positive) in 105 (16%). After reanalysis, diagnosis changed in 18/186 (10%) patients, with five shifting from inconclusive to positive and 13 former positive being reclassified as inconclusive. A definite diagnosis was eventually reached in 97 (15%) patients, of whom the majority carried GBA1 variants or, less frequently, biallelic PRKN variants. In 89 (14%) cases, the genetic report was inconclusive.

Conclusions: This study attempts to harmonize reporting of PD genetic testing across several diagnostic labs and highlights current difficulties in interpreting genetic variants emerging from NGS-multigene panels, with relevant implications for counselling.

## RETINAL VASCULOPATHY WITH CEREBRAL LEUKOENCEPHALOPATHY: A CASE WITH A NEW TREX1 MUTATION

M. G. Pin[1], L. Corrado[2], G. Strigaro[1], C. Comi[1], S. D'Alfonso[2], R. Cantello[1], D. Vecchio[1]

[1]Neurology Unit, Department of Translational Medicine, University of Piemonte Orientale, and Azienda Ospedaliero-Universitaria "Maggiore della Carità" (Novara); [2]Genetic Laboratory, Department of Health Sciences, University of Piemonte Orientale (Novara)

Aims: We report the case of a 46-year-old Italian man with a retinal vasculopathy with cerebral leukoencephalopathy (RVCL-S), initially misdiagnosed as glioma, and to underline the red-flags of this rare disorder.

Materials and Methods: A 46-year-old Italian man presented with a 5-day history of mild ideo-motor slowdown, subacute mild left hemiparesis and dysarthric speech. Brain MRI showed a right temporo-insular large lesion with surrounding edema and inhomogeneous enhancement that suggested cerebral lymphoma or glioma. He underwent cerebral biopsy revealing focal necrosis with reactive gliosis and modest perivascular lymphoid infiltrate. One month later he presented focal motor to bilateral tonic-clonic seizures and he started lacosamide. He repeated a brain MRI showing a dimensional increase of the lesion (restricted at diffusion weighted imaging and peripheral enhancement). Medical history included microvascular liver disease since 11 years before, microvascular kidney disease since 10 years before, anemia and a 13-year of scleroderma with Raynaud's phenomenon. Family history was negative (two healthy sisters, no children).

Results: Infective/autoimmune and tumoral screenings were unremarkable, and cerebrospinal fluid analysis negative. On oral steroids, a third brain MRI demonstrated volumetric reduction of the lesion with small nodular enhancement. Considering the pseudotumor onset and the multisystemic involvement, RVCL-S was suspected and confirmed by the identification of an heterozygous novel frameshift mutation (p.S267Qfs*57) in the C-terminal of the three-prime repair exonuclease (TREX1) gene.

Discussion: RVCL-S is a rare autosomal dominant vasculopathy caused by heterozygous C-terminal truncating mutations in TREX1 gene. The clinical spectrum includes vascular retinopathy, focal brain dysfunctions and other systemic manifestations, including Raynaud phenomenon, anemia with gastrointestinal bleeding, hypothyroidism, liver and kidney diseases. In our patient systemic symptoms developed several years before the onset of neurological manifestations. To date, there is no specific disease modifying treatment for RVCL-S. Our patient was treated with a course of intravenous methylprednisolone followed by oral glucocorticoids gradually tapered, anti-seizure drug, iron supplementation, blood transfusions for anemia and antihypertensive drugs. He started clinical and radiological follow-up: the last brain MRI, performed in May 2023, showed a severe dimensional increase of the lesion and the surrounding edema. Genetic counseling was discussed with family members (one healthy sister tested was negative for the mutation).

Conclusions: A pseudotumoral brain lesion might suggest RVCL in patients with ongoing systemic diseases. Recognition of this entity may help avoid unnecessary invasive examinations and therapeutic interventions.

## JUVENILE ALEXANDER DISEASE: A CHALLENGING CASE OF A FAMILIAR PROGRESSIVE ATAXIA

C. Romano[1], E. Morena[2], S. Petrucci[3], S. Diamant[2], M. Marconi[2], L. Travaglini[4], G. Zanni[5], M. Salvetti[2], S. Romano[2], G. Ristori[2]

[1]Department of Human Neuroscience, Sapienza University of Rome (Roma); [2]Department of Neurosciences, Mental Health and Sensory Organs, Sant'Andrea Hospital, Sapienza University of Rome (Roma); [3]Department of Clinical and Molecular Medicine, Faculty of Medicine and Psycho, Sapienza University of Rome (Roma); [4]5 Laboratory of Medical Genetics, Bambino Gesù Children's Hospital IRCCS (Roma); [5]Genetics and Rare Diseases Research Division, Unit of Neuromuscular and Neurodegenerative Disorders, Bambino Gesù Children's Hospital IRCCS (Roma)

Case presentation: A 20 years old female came to our attention for gait ataxia and subtle involuntary movements. Moreover, she had scoliosis and history of enuresis and began some years before. The neurological examination evidenced difficulties in balance and walking, nystagmus in the horizontal gaze bilaterally, clonus at ankles with plantar cutaneous reflex in extension bilaterally and sporadic dystonic movements in her face and upper limbs. Her mother experienced since childhood ataxia with a rapidly progressive course, diagnosed as Primary Progressive Multiple Sclerosis. The similar phenotype, made an inherited cause highly probable. However, no other know relatives suffered from neurologic syndromes. Both autosomal dominant (AD) and autosomal recessive (AR) ataxic syndromes were considered, lacking a part of proband's pedigree, but not causative genetic alterations were found. Then, brain MRI evidenced T2 symmetric hyperintensities in medium cerebellar peduncles, basal ganglia, bilateral insula, and periventricular white matter, with thalamus sparing. Basing on these MRI findings and on the presence of cerebellar involvement and dystonia, we investigated Wilson Disease, a rare AR disorder of copper metabolism, which resulted negative too. Considering the strong suspect for an inherited condition, we performed a clinical exome sequencing (CES), that analyzes more than 4500 genes associated with diseases. CES evidenced the new heterozygous missense variant c.260T>A in exon 1 of glial fibrillary acidic protein (GFAP) gene (NM_002055.4), that causes the valine to aspartate aminoacidic substitution at codon 87 (p. Val87Asp) in the GFAP. The same heterozygous variant was detected in her mother.

Discussion: Damaging variants in GFAP are responsible for Alaxander's disease (AxD, MIM # 203450), a rare AD neurodegenerative disorder caused by the glial fibrillary acidic protein accumulation in astrocytes. AxD presents an age-related clinical spectrum with well-defined characteristics in both children (neurodevelopmental regression) and younger (seizure, ataxia, spasticity, scoliosis, autonomic dysfunction), with non-specific neurological manifestations in adults [1]. The c.260T>A in GFAP we found has never been described to date, either in general population or AxD cases. However, it it is in a mutational hot spot domain of the protein and is considered pathogenic by the most relevant pathogenicity scores (MetaLR 0.94; Revel 0.93). Moreover, different aminoacidic changes at the same codon (p. Val87Ile p.Val87Leu; p.Val87Gly) were previously described in late onset AxD patients [2]. This data, together with the maternal segregation and the phenotypes of the two women, are in favor of a pathogenic role of the p.Val87Asp substitution in determining the disease [3].

Introduction: SCA7 is a very rare form of dominant cerebellar ataxia, caused by the expansion of a CAG repeat within the ataxin 7 (ATXN7) gene. Encouraging data on riluzole effects in patients with cerebellar ataxias [1,2] prompted us to try an off-label use of riluzole in an Italian and an American family with SCA7.

Methods and Results: A Peruvian-Algerian family had five members (4 female, 1 male) with progressive vision impairment and ataxia associated to abnormally expanded CAG repeat within the SCA7 gene in one allele. At baseline, before the onset of riluzole treatment, the SARA scores of Patients I-1, II-1, II-3 were respectively 20, 11, 9 while patient II-2 was 0; visual acuity was less than 1,0 logMAR in patients I-1 and II-1, equal or better than 1,0 logMAR in patients II-2 and II-3. It shows that after riluzole treatment the only patient treated before ataxia onset (patient II-2) had a significantly slowing of visual deterioration and no ataxia is yet occurring at last follow-up after 3,5 years. The remaining three patients, in whom riluzole therapy was introduced after ataxia onset, showed a clear stop of the pre-treatment steep increase of SARA

scores, showing decrease/stability of neurological deficit for 2-3 years, before the restart of ataxia worsening. No effect on visual function was observed in patients II-1 and II-3, while an improvement/stability was evident in patient I-1. Two female siblings (51 and 60 year-old), assessed at Tampa Center (US) reported visual disturbances and were diagnosed as SCA7 (39 and 40 repeats respectively). They were followed up by ophthalmological examinations and neurological examination for several years. In late 2010 they started riluzole After one year of therapy cerebellar and visual functions improved (respectively from 8 to 6 at SARA score and from 0.6 to 0.4 at logMAR) in both siblings. SARA score remained stable for 3 years and then started to increase (13 at the last evaluation - 6 years after the beginning of the treatment in both siblings), while ophthalmologic status remained practically stable in both siblings, since they started the drug. None of treated patients had adverse events or abnormal laboratory findings all over the follow-up.

Conclusions: Data from these families suggest some efficacy and safety of riluzole, even on long-term follow-up. A controlled trial is ongoing in Italy, and open to foreign Centers, that was granted by the Agenzia Italiana del Farmaco.

## SPASTIC ATAXIA AND MOTORNEURON DISEASE AS POSSIBLE MANIFESTATIONS OF ATP13A2 VARIANTS

S. Rossi[1], A. Conte[2], M. Sabatelli[3], K. Patanella[2], F. Santorelli[4], G. Silvestri[5]

[1]Department of Neurosciences, University Cattolica del Sacro Cuore (Roma); [2]Centro Clinico NeMO, Policlinico Universitario A. Gemelli (Roma); [3]Centro Clinico NeMO, University Cattolica del Sacro Cuore, Policlinico Universitario A. Gemelli (Roma); [4]Fondazione Stella Maris (Pisa); [5]Department of Neurosciences, University Cattolica del Sacro Cuore, Policlinico Universitario A. Gemelli (Roma)

Aim: To describe 5 late-onset sporadic cases carrying either biallelic or monoallelic variants in ATP13A2, showing either spastic ataxia (Spatax) or primary lateral sclerosis (PLS) as core phenotype.

Materials and Methods: Two Spatax patients (Patient 1 and 2) resulted negative for FXN, FMR1 and polyglutamine expansion-associated cerebellar ataxias and three patients with upper motor neuron features (Pt 3-5) underwent next-generation sequencing (NGS) targeted resequencing panels for ataxia and motor neuron disease, respectively.

Results: Spatax cases comprised two females with late-onset (63 and 52 years, respectively) gait difficulties. Neurological examination showed cerebellar and spastic signs in both patients, with more severe spasticity in Pt1, who was wheelchair-bound after 7 years from onset. Brain MRI showed cerebellar atrophy in Pt1, while was normal in Pt2. Pt1 carried the monoallelic p.Gln382Ter variant in ATP13A2, while Pt2 had the p.Met766Val variant. Pt3-5 had upper motoneuron features as core phenotype, with mean age at onset of gait difficulties at 57 years. Pt3 was a 72-year female showing PLS phenotype with mixed cerebellar and spastic dysarthria and cerebellar atrophy at brain MRI. Pt4 was a 56-year male with PLS and nystagmus, mixed cerebellar and spastic dysarthria and white matter abnormalities (WMA) at brain MRI, evolving to amyotrophic lateral sclerosis (ALS) in about 6 years. The last case, Pt5, was a 73-year female with HSP phenotype at onset, evolving to ALS after about 5 years from onset, with WMA at brain MRI. Pt3 carried the p.Arg1158Cys ATP13A2 variant, Pt4 was a compound heterozygous for p.Gly1115Cys and p.Pro1074=, whereas Pt5 carried the c.1039+6C>T and p.Gln1103Arg variants (segregation analysis was unavailable). Except for the p.Gln382Ter, which was predicted to be pathogenic, all the other variants in ATP13A2 were classified as variants of uncertain significance (VoUS).

Discussion: ATP13A2 is a lysosomal P5-type transport ATPase, whose transported substrate remains unidentified, with a pivotal role in both lysosomal function and mitochondrial network integrity. Biallelic pathogenic variants in ATP13A2 have been associated to Kufor-Rakeb disease, ALS, HSP, and neuronal ceroid lipofuscinosis. More recently, also a possible causative significance for monoallelic variants has been suspected, with a role as a risk factor for Parkinson's disease and Multiple System Atrophy.

Conclusions: Even in the heterozygous state, functional impairment of ATP13A2 might predispose to accelerated age-associated mitochondrial dysfunction. Functional studies on fibroblast-patient derived cells are needed to define pathogenicity of these VoUS in ATP13A2. If confirmed, this will expand spectrum of ATP13A2 variants associated phenotypes.

## A NOVEL MUTATION IN MFN2 IS ASSOCIATED WITH ALS-FTD IN AN ITALIAN FAMILY

M. C. Russillo[1], C. Vinciguerra[1], A. Di Fonzo[2], E. Monfrini[2], D. Ronchi[2], S. Cuoco[1], G. Piscosquito[1], P. Barone[1], M. Pellecchia[1]

[1]Center for Neurodegenerative Diseases (CEMAND), Department of Medicine, Surgery and Odontology "Scuola Medica Salernitana", University of Salerno (Salerno); [2]Neurology Unit, IRCCS Ca' Granda Ospedale Maggiore Policlinico (Milano)

Introduction: MFN2 gene encodes the protein Mitofusin 2, involved in essential mitochondrial functions such as fusion, trafficking, turnover, and cellular interactions. Mutations of MFN2 gene have recently been identified as the cause of approximately one-third of dominantly inherited cases of the axonal Charcot-Marie-Tooth disease (CMT type 2A) and of rarer clinical variants, including a severe, early-onset axonal neuropathy, in some instances associated with pyramidal tract involvement (CMT type 5), optic atrophy (CMT type 6), and, occasionally, alterations of cerebral white matter [1,2]. More recently, in a mouse model of ALS, MFN2 protein has been found to interact in complex with Transactive response DNA-binding protein of 43 kDA (TDP-43), involved in frontotemporal lobar degeneration (FTLD) and ALS [3].

Objective: We describe a family carrying a novel MFN2 mutation associated with an ALS-frontotemporal dementia (FTD) phenotype in the mother and a CMT2A in her son.

Methods: Patients underwent a multidimensional assessment including neurological and neuropsychological evaluation, structural and functional imaging, and genetic screening.

Results: The mother, a 67-year-old woman, referred to us for a three year-history of mood disturbance and gait impairment, and a more recent hypophonia, dysarthria, dysphagia, and diffuse muscle wasting. Family history was positive for psychiatric disorders and gait

disturbances. Brain 18F-FDG PET showed severe hypometabolism in the fronto-temporal brain cortex bilaterally. Electrodiagnostic studies (EDX) showed severe motor axonopathy in the bulbar, cervical and lumbosacral districts. Her 41-year-old son had a history of mood depression and sensory disturbances in the limbs, along with mild muscle wasting, weakness, and reduced reflexes. Nerve conduction studies revealed a moderate sensory-motor polyneuropathy, while brain MRI was normal. Whole exome sequencing of the patients' DNA identified a novel mutation in the MFN2 gene (NM_014874.4 c.581A>C p.(Asp194Ala).

Discussion: Our findings provide evidence for the significance of a newly discovered MFN2 mutation observed in two family members, each displaying distinct clinical manifestations. Additionally, we present the first documented case of ALS-FTD associated with an MFN2 mutation, thereby expanding the range of MFN-related disorders.

Conclusions: Further research involving larger cohorts of patients will be needed to better understand the role of MFN2 as a contributing gene in the development of ALS-FTD.

## A NOVEL SPAST-MUTATION IN HEREDITARY SPASTIC PARAPARESIS SPG4

E. Sbragia[1], E. Di Maria[2], C. Solaro[3], A. Assini[3]

[1]Neurology Department, Galliera Hospital, DiNOGMI, University of Genoa (Genova); [2]University Unit of Medical Genetics, Galliera Hospital (Genova); [3]Department of Neurology, Galliera Hospital (Genova)

Introduction: Hereditary spastic paraparesis (HSP) defines a wide variety of inherited neurological diseases affecting the upper motor neuron sustained by heterogeneous genetic mutations corresponding to diverse clinical phenotypes [1]. To date [1], over 100 loci/88 genes and 83 different clinical forms have been been associated to HSP. Nevertheless, SPAST (encoding for spastin) remains so far the most common gene mutated in HSP, identified in over 40% of cases. SPAST-associated forms (called SPG4) have usually an adult-onset result as a pure corticospinal degeneration. In this study, we characterize a novel homozygous SPAST mutation in an italian woman who presented a lower limb predominant spastic paraparesis and suspect but not characterized familiar history.

Materials and Methods: A 56-years-old italian woman was referred to our clinic for clinical and genetic evaluation. Molecular analysis was performed in 2022 by the means of a targeted massive sequencing panel (Illumina NextSeq).

Results: Patient's mother presented progressive difficulties in ambulation at 46 years old, one of mother's brothers was referred to walk "on toes' tip" since young age and one mother's female nephew (daughter of a brother) had multiple sclerosis. At 57 years old, the patient started to complain subtle onset of left lower limb weakness, specifically after an accidental fall. The symptoms became more pervading in 2019, when the patient started with the first exams (motor evoked potentials -MEP-, MRI), negative. In 2020 MEP resulted alterated and at the begin of 2021 the patient came at our attention. Neurological examination revealed a modest bilateral spastic paraparesis and diffuse brisk tendon reflexes. MRI studies resulted again negative while MEP resulted highly alterated. Therefore the patient was addressed to our genetic unit. Molecular analysis showed a novel c.1617-2A>C splicing variant in the SPAST gene, never reported on current databases.

Discussion: In this report, we described a novel SPAST-gene mutation. We assume an association to SPG4 since a single substitution of the same nucleotide was reported as pathogenic in a case of SPG4 [2], an adjacent variant is reported with low frequency [2] and patient's clinical presentation is consistent SPG4-phenotype. Nevertheless, our patient is the only affected member of the family that could be studied. We would then conclude that this novel SPAST variant is responsible for the clinical picture observed in the present case and could be classified as a novel pathogenic variant. However, further observations are needed.

## MATERNAL UNIPARENTAL ISODISOMY IN A PATIENT WITH AUTOSOMAL RECESSIVE SPASTIC PARAPLEGIA TYPE 20

C. Scuderi[1], M. Lo Giudice[1], S. Santa Paola[1], M. Giuliano[1], O. Galesi[2], M. Fichera[3], E. Borgione[1]

[1]Unit of Neuromuscular Diseases, Oasi Research Institute IRCCS (Troina-EN); [2]Laboratory of Medical Genetics, Oasi Research Institute IRCCS (Troina-EN);[3]Medical Genetics, Department of Biomedical and Biotechnological Sciences, University of Catania (Catania)

Background: Hereditary spastic paraplegia (HSP) refers to a group of rare neurodegenerative disorders with the predominant clinical manifestation of spasticity in the lower extremities. A complicated form is identified by the presence of other neurological or non-neurological manifestations such as seizures, dementia, muscle atrophy, ataxia, intellectual disability, peripheral neuropathy, extrapyramidal disturbance, gastroesophageal reflux, Dupuytren's disease, or varicose veins. Autosomal recessive spastic paraplegia type 20 (SPG20) is a form of complicated HSP characterized by an onset in infancy of progressive lower extremity spasticity and weakness associated with distal amyotrophy, pseudobulbar palsy, motor and cognitive delays, mild cerebellar signs (dysarthria, dysdiadochokinesia, mild intention tremor), short stature and subtle skeletal abnormalities. SPG20 is due to mutations in the SPART gene (13q13), which encodes the protein spartin.

Objective: We studied a 10 years old boy with spastic paraparesis, dystonic movements, mild intellectual disability, speech impairment, multiple congenital anomalies, white matter abnormal signs and sensorimotor neuropathy. Array-CGH 60K showed a deletion in chromosome 17p12 including PMP22 gene, inherited from the father. This deletion, associated with hereditary neuropathy with liability to pressure palsies (HNPP), was not sufficient to explain the complex phenotype of the patient, therefore we extended molecular genetics studies.

Methods: We performed mutation analysis using whole exome sequencing (WES) and homozygosity mapping using SNPs-array.

Results: WES analysis showed the homozygous nonsense variant c.1120C>T (p.Q374X) in the exon 4 of the SPART gene. While segregation analysis in the mother, as expected, identified the SPART variant in a heterozygous state, it could not be displayed in the father. High resolution SNPs-array analysis provided evidence that the homozygosity of the SPART variant in the patient is due to maternal uniparental isodisomy (UPiD) in chromosome 13q.

Conclusions: Uniparental disomy (UPD) occurs when a person receives two copies of a chromosome, or of part of a chromosome, from one parent and no copy from the other. UPD can result in clinical conditions by producing either homozygosity for recessive mutations or aberrant patterns of imprinting in humans. Both UPiD and uniparental heterodisomy (UPhD) could result in imprinting disorders, while only UPiD or UPiD/UPhD could result in autosomal recessive disorders through the inheritance of deleterious alleles from a carrier parent. Our result highlights the importance of segregation analysis in both parents of a patient, especially in cases of homozygous recessive mutations, as UPD has significant implications for genetic counselling with a very low recurrence risk assessment in such families.

## CEREBELLAR ATAXIA WITH OCULOMOTOR APRAXIA TYPE 1: CLINICAL AND GENETIC STUDIES

G. Stufano[1], V. Arnao[2], S. Iacono[1], G. Salemi[1], P. Ragonese[1], M. D'Amelio[1], P. Aridon[1]

[1]Department of Biomedicine, Neuroscience and Advanced Diagnostics (BiND), University of Palermo (Palermo); [2]Neurology and Stroke Unit, A.R.N.A.S. Civico (Palermo)

Objective: To describe the clinical and genetic features of a family with a non-Friedreich progressive ARCA.

Design/Methods: Two brothers of a consanguineous marriage with progressive cerebellar ataxia were recruited in this study. After written informed consent a genome sequencing were performed.

Results: A 47 year old man was unsteady since the age of 10 years and three years later he developed cerebellar ataxia and ocular abnormalities. He presented with a slowly progressive gait impairment. Neurological examination was characterized by ataxia, oculomotor apraxia and dystonia. There was decreased deep tendon reflexes and neuropsychological tests were normal. Brain magnetic resonance imaging showed cerebellar atrophy. A genetic panel sequencing for AOA including APTX (aprataxin), SETX (senataxin), PIK3R5, PNPK genes was performeds and disclosed a pathogenic homozygous variant (p.Ala198Val, c.593C>T ) in the APTX gene, confirming the diagnosis of AOA1. The same APTX variation (p.Ala198Val, c.593C>T) and a heterozygous variation in SETX (p.Arg2098Ter, c.6292C>T) were identified in the brother of the proband. In the neurologic examination, dysarthric speech, dysmetria, dysdiadokinesis, instability and ocular apraxia were present. The symptoms began in adolescence and slowly progressed into adulthood. There was evidence of cerebellar atrophy on cranial magnetic resonance imaging.

Conclusions: This is the first report of an Italian family with c.593C>T mutation in APTX gene. In our patients, AOA1 typically manifests with gait ataxia in the first decade of life, followed by dysarthria and upper limb dysmetria and oculomotor apraxia. This description validate concept that the diagnosis of some movement disorders should rely on genetic testing and clinicians should consider this when reporting cases of inherited movement disorders.

## COMBINING MT-TL1 AND MT-ND1 GENE MUTATION: CASE REPORT OF MELAS DURING PREGNANCY AND LITERARY REVIEW

M. F. Tepedino[1], M. Russo[2], A. Toriello[2], C. Vinciguerra[2], P. Penza[2], G. Piscosquito[2], M. Picillo[2], P. Barone[2]

[1]Center for Neurodegenerative Diseases (CEMAND), Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", University of Salerno (Salerno); [2]Neurology Unit, Department of Medicine and Surgery, "Scuola Medica Salernitana", A.O.U. San Giovanni di Dio e Ruggi D'Aragona (Salerno)

Objective: Mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes (MELAS) syndrome is one of the most frequent mitochondrial disorder [1]. We present a 36-year-old pregnant woman with stroke like episode (SLE) who received a genetic diagnosis of MELAS syndrome during hospitalization. The peculiarity of our patient consisted in presenting together the heteroplasmic m.3243A>G mutation in the MT-TL1 gene and homoplasmic mutation m.3394T>C in the MT-ND1 gene. Moreover, we reviewed the cases of pregnant women with MELAS present in the literature.

Methods and Materials: We performed a systematic review using keywords as "MELAS" or "mitochondrial disease" and "pregnancy".

Results: A 36-year-old woman at 6th week pregnant was admitted to our hospital for SLE, presented with migraine, followed by sudden acute onset of bilateral neurosensorial hearing loss, and bilaterally asymmetrical temporal cortico-subcortical hyperintensity in T2/FLAIR and DWI weighted sequences on brain magnetic resonance imaging (MRI). Arterial blood gas analysis presented elevated lactate levels. Genetic analysis showed both abovementioned mutations. At 10th week appeared coma, breathing failure and severe metabolic acidosis with spreading of cerebral lesions to parieto-occipital and cerebellar cortices on brain MRI. We identified 15 case reports (mean age 31.5±5.65, mean week of pregnancy 23.13±10.02) of pregnancy-induced worsening of MELAS. MELAS syndrome was diagnosed during pregnancy in 5(33,3%) cases due to abrupt worsening of clinical condition. The reason of hospitalization were obstetric complications in 7 cases (47%), neurological symptoms in 4 cases (27%), cardiovascular complications in 2, medical evaluation before childbirth and for chronic kidney disease in other ones.

Discussion: The physiological change of pregnancy, with its increased respiratory demands, suggests that women who already have mitochondrial dysfunction may be at risk of worsening symptoms [2]. Frequently, pregnant women with MELAS have obstetric complications and these are patients with a known diagnosis (40%). Among the women who received a diagnosis during pregnancy (n=5), as in our case, neurological symptoms are more frequent (60%) (2 had myopathy, 1 epilepsy). Therefore, despite the approach to patients with MELAS must be multidisciplinary, the neurologist plays a central role in the management. M.3394T>C mutation is a rarely associated with Leber's hereditary optic neuropathy, but the significance of this mutation is not fully understood [3].

Conclusion: Our findings suggest that m.3394T>C mutation may contribute to the MELAS phenotype. Furthermore, we confirm pregnancy is a risk factor for worsening of symptoms in MELAS.

## QARS-RELATED EPILEPTIC ENCEPHALOPATHY CAUSED BY A NOVEL MISSENSE VARIANT: A CASE REPORT

V. Yahya[1], E. Monfrini[1], R. Del Bo[2], A. Di Fonzo[1], R. Dilena[3]

[1]Neurology Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico (Milano); [2]Department of Pathophysiology and Transplantation, Dino Ferrari Center, University of Milan (Milano); [3]Neurophysiopathology Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico (Milano)

Aim: To identify the genetic cause of developmental and epileptic encephalopathy in a 5-year-old female patient.

Materials and Methods: Neurological exam, EEG, brain MRI, and trio-based whole-exome sequencing were performed.

Results: The patient was born 45.5 cm long (<3rd centile) at 41 weeks. At 11 months, she was 67.9 cm long (-2.2 SD). Head circumference and body weight remained around the 3rd centile. Brain ultrasonography showed two little subependymal germinolytic cysts around the left caudo-thalamic groove. At 3.5 years, she displayed focal epilepsy with occipital paroxysms and autonomic involvement (resembling Panayiotopoulos syndrome); recurrent occipital spikes and spike-wave were recorded during non-REM sleep EEG; brain MRI was normal. At 5 years, a viral pharyngitis triggered an acute encephalopathy with psychomotor slowing. EEG showed fronto-temporal θ activity and recurrent occipital spikes on a middle-high amplitude δ-rhythm background activity. Brain MRI showed subcortical white matter T2-hyperintensity and DWI restriction compatible with intramyelinic edema and hypomyelination, mild cerebellar-prevalent global atrophy, and minimal cerebellar tonsil elongation. She was treated with corticosteroids and improved within two weeks. She is currently seizure-free with carbamazepine and levetiracetam, displays a constitutional growth delay, and a mild language delay allowing her to pronounce simple sentences. Whole-exome sequencing revealed two compound heterozygous variants in the QARS gene (NM_005051.3): c.1304A>G (p.Y435C) and c.799C>T (p.R267W). The p.Y435C is a known pathogenic variant. The p.R267W is extremely rare (gnomAD allele frequency: 0.0000159), is predicted pathogenic in silico (MetaRNN: 0.9368) and affects a conserved aminoacidic residue (phyloP100: 9.206).

Discussion: Biallelic loss-of-function variants in QARS, encoding glutaminyl-tRNA synthetase, cause an autosomal recessive encephalopathy with 23 cases reported to date. Its clinical features include neonatal-onset pharmaco-resistant epilepsy, intellectual disability, constitutional growth delay, speech delay, brain atrophy with cortical structural abnormalities and hypomyelination. Phenotypic severity correlates with Qars enzyme aminoacylation activity, solubility, and affected domain: some missense variants allow a residual aminoacylation activity though lowering solubility, resulting in milder phenotypes. The p.Y435C affects the catalytic domain impairing the interaction between Qars and its tRNA. The p.R267W, also in the catalytic domain, has never been associated with disease, however, its rarity, the presence of supportive in silico predictions, and its combination with a known QARS pathogenic variant in a patient with a compatible phenotype, strongly supports its pathogenic role.

Conclusions: We expand the spectrum of QARS-related disease to a milder form displaying infection-triggered acute reversible encephalopathy in association with two missense variants, of which one is novel.

## RARS2-RELATED ENCEPHALOPATHY: A CASE OF ATAXIA-EPILEPSY DUE TO A NOVEL SPLICING VARIANT AND REVIEW OF THE LITERATURE

V. Yahya[1], R. Dilena[2], R. Del Bo[3], M. Magni[1], F. Biella[1], S. Salani[1], F. Fortunato[3], A. Di Fonzo[1], E. Monfrini[1]

[1]Neurology Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico (Milano); [2]Neurophysiopathology Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico (Milano); [3]Department of Pathophysiology and Transplantation, Dino Ferrari Center, University of Milan (Milano)

Aim: To identify the genetic cause of ataxia-epilepsy in a 16-year-old patient and draw a genotype-phenotype correlation for this rare disease.

Materials and Methods: The patient was evaluated by a pediatric epileptologist and movement disorders expert neurologists. Electroencephalograms and a brain MRI were performed. Whole-exome sequencing (WES) was followed by segregation analysis with Sanger sequencing. Functional analyses included cDNA sequencing, western blot, and mitochondrial respiratory chain activity assessment on peripheral lymphocytes.

Results: Disease appeared at 3 years with mild cerebellar ataxia and cognitive impairment. At 13 years, the patient was hospitalized for focal-to-bilateral tonic seizures with unresponsiveness. EEG displayed sharp waves and 3 Hz spike-wave discharges. Levetiracetam was started with complete seizure control. Brain MRI showed an isolated cerebellar vermis atrophy. At 15 years, neurological examination showed cerebellar dysarthria, gaze impairment, dysdiadochokinesia, dysmetria, postural and kinetic tremors, multidirectional oscillations at Romberg's test, gait ataxia with tandem gait inability. WES revealed two heterozygous variants of RARS2 (NM_020320.5), encoding mitochondrial arginyl-tRNA synthetase. Segregation analysis demonstrated their biallelic status: c.685C>T (p.Arg229*) is a known pathogenic variant, while c.972C>T (p.Thr324=), affecting the third-to-last nucleotide of exon 11, is extremely rare (gnomAD allele frequency = 0.000004), reported likely benign in ClinVar, but predicted in silico to likely impact splicing. cDNA analysis demonstrated that c.972C>T is a splice-disrupting variant excluding exon 11, though allowing the synthesis of some wild-type transcript, consistently with the patient's mild phenotype in comparison to other patients with RARS2-related encephalopathy. Mitochondrial respiratory chain activity was not significantly different from two healthy controls. Western blot in triplicate revealed a moderate reduction (~39%) of normal-length Rars2 protein in patient's lymphocytes compared to two healthy controls.

Discussion: A clinical phenotype compatible with a mild form of RARS2-related encephalopathy and the presence of the compound

heterozygous status with the p.Arg229*, led us to reclassify the c.972C>T splice-disrupting variant as likely pathogenic (ACMG criteria: PM2, PM3, PS3) and hypothesize that the phenotypic severity is negatively correlated with the amount of residual functional Rars2 protein. Hence, we reviewed scientific literature on RARS2-related encephalopathy delineating a genotype-phenotype correlation, as variant severity, including protein impact (e.g., missense, nonsense, splice-disrupt) and affected domain (e.g., catalytic core, anticodon-binding domain), is well correlated with disease onset, survival, neurological and systemic features, neuroradiological and biochemical profiles (e.g., respiratory chain activity).

Conclusions: A prompt genotypic characterization of RARS2-related encephalopathy is important to predict the phenotype, improving diagnostic counselling, follow-up, and assistance for patients and caregivers.

## NEUROIMAGING

### CHOROID PLEXUS ENLARGEMENT AS MARKER OF CHRONIC INFLAMMATION AND NEURODEGENERATION IN MULTIPLE SCLEROSIS: A COMBINED 3- AND 7-TESLA IMAGING STUDY

E. Barbuti[1], C. Traeba[2], A. Miscioscia[3], V. Barletta[2], E. Herranz[2], J. Sloane[4], E. Klawiter[5], C. Mainero[2]

Martinos Center for Biomedical Imaging, Department of Radiology, Massachusetts General Hospital, Harvard Medical School (Boston-USA); [3]Department of Neurology, University of Padua (Padova); [4]A. A. Martinos Center for Biomedical Imaging, Department of Neurology, Massachusetts General Hospital, Beth Israel Deaconess Medical Center (Boston-USA); [5]A. A. Martinos Center for Biomedical Imaging, Department of Neurology, Massachusetts General Hospital (Boston-USA)

Aim: Choroid plexus (CP) enlargement has been recently evaluated in multiple sclerosis (MS) as a novel imaging marker of compartmentalized inflammation. We investigated, in a heterogeneous MS cohort, the association between CP enlargement and imaging metrics of neurodegeneration and compartmentalized inflammation, including cortical and paramagnetic lesions (CL, PRL) on 7T MRI, and neurological disability, measured by Expanded Disability Status Scale (EDSS).

Methods: One-hundred MS patients (74 relapsing-remitting, 26 secondary progressive MS, RRMS, SPMS) and 41 age and sex-matched healthy controls (HC) were recruited. Longitudinal clinical and MRI data were available respectively for 71 and 46 patients. All subjects underwent 3T anatomical imaging to obtain cortical thickness, thalamic and white matter (WM) volumes and 7T susceptibility MRI for PRL, leukocortical, intracortical and total cortical lesion (LCL, ICL, TCL) volume and count. Volumes of CP of lateral ventricles were extracted from Freesurfer segmentation, manually edited and normalized by total intracranial volume to estimate CP ratio (CPR). Univariate associations between CPR and neuroradiological/clinical measures were assessed by Spearman correlation. Forward stepwise regressions were performed to evaluate imaging metrics predicting EDSS, CL volume and PRL count at baseline and follow-up. A linear mixed effect model was built to explore time-dependent changes in CPR in a subgroup (n=26) of the longitudinal cohort, adjusting for age and sex.

Results: CPR was abnormally increased in MS patients, both RRMS and SPMS, relative to HC, also adjusting for ventricular volume, age, and sex ($p<0.001$). CPR inversely correlated with thalamic volume, cortical thickness, and WM volume ($p<0.05$). CPR positively correlated with non-rim WML volume, PRL and CL volume and count at baseline and follow-up ($p<0.05$). In the stepwise regressions non-rim WM lesions and ICL volumes were predictive of EDSS at baseline and follow-up ($p\leq0.001$), non-rim WM lesions and PRL volumes of CL volume at baseline and only WML-non rim at follow-up($p\leq0.001$), TCL volume and WM volume of PRL count ($p<0.008$). No time-driven CP enlargement was found ($p=0.76$).

Discussion: We confirm the finding of CP enlargement in MS compared to HC, and its correlation with measures of neurodegeneration and inflammation. We also report a new modest association with 7T CL and PRL volume and count. However, CPR does not seem to have a main role in predicting neurological disability or, indirectly, MRI metrics associated with disease progression.

Conclusion: Choroid plexus enlargement is a feature of MS but only marginally accounts for the complexity of the pathological processes underlying disease progression.

### CHARACTERIZATION OF FTLD SPECTRUM THROUGH ADVANCED DIFFUSION-WEIGHTED MRI METRICS: A CONNECTOME APPROACH

Objective: To investigate structural alterations in brain network of FTLD spectrum using connectome analysis with advanced diffusion-weighted MRI metrics.

Materials: Thirty-four behavioral-variant frontotemporal dementia (bvFTD), 11 semantic variant primary progressive aphasia (svPPA), 11 nonfluent variant primary progressive aphasia (nfvPPA)

and 18 motor neuron disease (MND) patients and 48 controls were enrolled and underwent multi-shell diffusion MRI.

Methods: Fractional anisotropy (FA) maps were computed. Intra-cellular Volume Fraction (ICVF) maps were estimated using the NODDI model, providing a direct quantification of neurite morphology and its integrity. Graph analysis and connectomics assessed global and local structural topological network properties and regional structural connectivity. In particular, mean distance (MD), eigenvector centrality (EC), degree centrality (DC) and sum of node weights (SN) metrics were extracted.

Results: Overall, widespread structural changes were observed in bvFTD patients relative to controls, MND and svPPA patients. nfvPPA patients showed altered FA properties (higher DC, SN and EC and lower MD) at global level compared to controls and MND patients. This condition was also verified at a lobar level, in particular in frontal, basal ganglia, parietal, and temporal areas. In addition, ICVF graph analysis measures showed that svPPA had a lower DC and SN in the temporal lobe compared to healthy controls and MND patients. Considering the regional connectivity analysis, bvFTD patients showed widespread decreased FA compared to MND patients and controls in all brain areas. In addition, bvFTD patients showed marked decreased FA strength relative to svPPA patients particularly in the right hemisphere, involving frontal lobe, supplementary motor area, putamen, parietal and temporal areas. nfvPPA patients showed a decreased FA in the left hemisphere relative to controls and MND patients, in particular involving precentral gyrus, supplementary motor area, insula, putamen and temporal lobe. Considering ICVF, greater alterations were detected compared to FA maps, showing differences also between svPPA and nfvPPA patients.

Discussion: Conventional diffusion-tensor measures are sensitive to highlight connection damage along the FTLD spectrum. However, ICVF demonstrated to be a clinically relevant biomarker more specific to differentiate pathologies of FTLD spectrum. Specifically, the benefit emerged in the differentiation between svPPA patients and other groups.

Conclusions: Connectome-analysis based on advanced diffusion-weighted models is useful to evaluate structural brain disruptions with greater differentiation among FTLD syndromes compared to diffusion-tensor derived measures.

## DECODING THE AGING PROCESS: UNVEILING AGING FEATURES THROUGH CONNECTOME ANALYSIS AND ADVANCED DIFFUSION-WEIGHTED METRICS WITH A MACHINE LEARNING APPROACH

S. Basaia[1], S. Pisano[1], E. Sibilla[1], E. Spinelli[2], E. Canu[1], M. Filippi[3], F. Agosta[2]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [2]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [3]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: To develop an advanced machine learning (ML) algorithm combining brain connectome analysis and advanced diffusion-weighted metrics to classify different features underlying aging process.

Materials: Forty-eight young healthy controls (YC), aged 20-31 years, and 21 middle-aged [MC] and 44 elderly healthy controls [EC], aged 41-85 years, were enrolled and underwent brain multi-shell diffusion MRI and cognitive evaluation.

Methods: Fractional anisotropy (FA), Intra-cellular Volume Fraction (ICVF) and Orientation Dispersion Index (ODI) maps were estimated. TBSS and connectomics were performed to estimate structural connectivity differences between groups (FA, ICVF and ODI). A feature selection algorithm, applied to a support-vector machine (SVM) model trained on mean FA, ICVF and ODI values of all connections that resulted different in TBSS and connectome analysis in the following comparison YC vs MC, YC vs EC, MC vs EC, was used for the identification of features (TBSS- or connectome-related) of the aging process. The features that better distinguished the three groups were then used as variables in a multivariate polynomial regression model to predict subject's age. Pearson's correlation coefficient was obtained to evaluate the association between the predicted age by the model and the actual age of the subjects.

Results: SVM models showed a 99.7% and 100% accuracy in the correct classification of YC relative to MC and EC with mean ODI values of TBSS-related connections as best selected feature. SVM models demonstrated an accuracy of 83.4% between MC and EC groups, identifying mean FA values of connectome-related connections as the most informative feature for classification. Mean ODI of TBSS- and FA of connectome-related connections were used in the construction of multivariate polynomial regression model to predict subject's age, utilizing a quadratic term to capture non-linear relationships. Correlation analysis indicated robust linear relationship between age predicted by the model and actual age of subjects ($r= 0.93$; $p<0.001$).

Discussion: SVM models, based on advanced diffusion weighted (ODI) measure and connectomics, provided strong discriminatory power in classifying different groups. Correlation analysis implies that the model's predictions align well with the true ages of subjects, providing evidence of effectiveness in estimating age based on the selected neuroimaging features.

Conclusions: Combination of SVM models with neuroimaging features achieved high accuracy in group classification and age prediction, highlighting the potential of these methods for understanding brain connectivity patterns and age-related changes. These findings pave the way for improved diagnostic and prognostic tools in neuroimaging research.

## MODELING PATHOLOGICAL SPREAD THROUGH THE STRUCTURAL CONNECTOME IN THE FTLD SPECTRUM

S. Basaia[1], F. Facente[1], C. Cividini[1], E. Spinelli[2], E. Canu[1], V. Castelnovo[1], A. Ghirelli[1], G. Cecchetti[2], F. Caso[3], G. Magnani[3], P. Caroppo[4], S. Prioni[4], C. Villa[4], L. Tremolizzo[5], I. Appollonio[5], F. Verde[6], N. Ticozzi[7], V. Silani[7], M. Filippi[8], F. Agosta[2]

University of Milan (Milano); [8]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objective: To explore the relationship between network vulnerability and longitudinal atrophy progression in patients within the frontotemporal lobar degeneration (FTLD) spectrum, using Network Diffusion Model (NDM) of pathology spread.

Materials: Thirty-four behavioural-variant frontotemporal dementia (bvFTD), 11 semantic-variant primary progressive aphasia (svPPA) and 11 nonfluent/agrammatic-variant primary progressive aphasia (nfvPPA) patients underwent longitudinal T1-weighted MRI. Forty-eight young healthy subjects (20-31 years) underwent multishell diffusion MRI scan.

Methods: NDM was developed to assess whether the progression of FTLD pathology might be modeled by a spreading process, originating from a seed and then proceeding through the healthy structural connectome. The connectivity measures used to create the structural connectome were fractional anisotropy (FA) and intra-cellular volume fraction (ICVF). Three disease epicenters were identified from the peaks of atrophy of each FTLD variant: right orbitofrontal cortex (bvFTD), left inferior temporal gyrus (svPPA), and left supplementary motor area (nfvPPA). Correlations were tested between longitudinal atrophic changes estimated by NDM and those empirically obtained in FTLD patients over a follow-up of 24 months.

Results: In the case of bvFTD, NDM showed an early spread to frontal lobe and basal ganglia (6 months) and to right sensorimotor, parietal, temporal and occipital lobes (12 months), with an involvement of the left hemisphere between 18 and 24 months. In svPPA, NDM predictive maps in young controls suggested an early spread of pathology to the left occipital (6 months) and inferior frontal lobe (12 months). At 18 months, left parietal lobe would be reached, whereas only few regions in the right parietal and occipital lobes would be affected at 24 months. In nfvPPA, NDM predicted a pathology spread through all brain regions, except for the occipital lobe, which would be involved after 12 months. NDM-predicted atrophy of each region was positively correlated to longitudinal atrophy empirically observed in all three FTLD variants. Overall, NDM applied on ICVF connectome provided higher correlation values relative to NDM applied on FA maps.

Discussion: The strong correlations that were found between the atrophy estimated by NDM and the real atrophy support the hypothesis that healthy structural architecture can influence the spatiotemporal atrophy progression in FTLD. The accuracy values of each model also showed that ICVF had a greater specificity than FA to model pathology spread.

Conclusion: The NDM implementation to cross-sectional structural connectome is a valuable tool to predict atrophy patterns and pathology spreading in FTLD variants.

## THE ROLE OF MAGNETISATION TRANSFER RATIO IN EVALUATING THE PATHOLOGICAL MECHANISMS IN OPTIC NEURITIS

A. Bianchi[1,2], F. Prados[2], S. Kodali[2], C. Tur[3], A. Ianniello[4], R. Raftopoulos[5], M. Moccia[6], M. Yiannakas[2], M. Koltzenburg[7], R. Samson[2], C. Gandini Wheeler-Kingshott[2], S. Hickman[8], R. Kapoor[2], A. Toosy[2]

[1]Queen Square Multiple Sclerosis Centre, University College London (London-UK); [2]Department of Neuroinflammation, University College London (London-UK)); [3]Vall d'Hebron Institute of Research, Vall d'Hebron Barcelona Hospital Campus (Barcelona-S); [4]Department of Human Neurosciences, "Sapienza" University of Rome (Roma); [5]King's College Hospital NHS Foundation Trust (London-UK); [6]Department of Neuroscience, "Federico II" University (Napoli); [7]Clinical and Movement Neurosciences, University College London (London-UK); [8]Royal Hallamshire Hospital (Sheffield-UK)

Background and Aims: Acute optic neuritis (ON) frequently occurs in multiple sclerosis (MS) and can cause permanent neuroaxonal damage to the anterior visual pathway. Magnetisation transfer ratio (MTR) is a quantitative technique that measures the capacity of macromolecules to exchange magnetisation with the surrounding water, indirectly estimating tissue integrity. While MTR has been strongly associated with myelin content, it has also been suggested that axonal loss may play a role in its changes. The aim of our study was to investigate the pathological substrates of MTR evaluating the relationship between MTR values in the optic nerve versus visual evoked potentials (VEP) and optical coherence tomography (OCT) data.

Methods: We analysed data from the Phenytoin Neuroprotection Study, a randomized, placebo-controlled, double-blind phase 2 trial. Patients with acute ON aged 18–60 years, presenting within 2 weeks of onset, with visual acuity of 6/9 or worse, were randomly assigned (1:1) to oral phenytoin or placebo for 3 months. Measurements from 60 patients were included in this study (28 phenytoin, 32 placebo). MTR maps of the anterior visual pathway, OCT peripapillary retinal nerve fibre layer (pRNFL) and macular ganglion cell-inner plexiform layer (mGCIPL) thicknesses, and latency and amplitude VEP data were obtained at baseline and 6-months follow-up. Multilevel mixed models adjusted for possible confounders were built to evaluate the associations between VEP and OCT measures and the affected optic nerve MTR.

Results: At 6-months follow-up, anterior to the lesion (pre-lesion), greater MTR was associated with higher VEP amplitude (coeff = 0.434; p=0.001, 95%CI = 0.184 to 0.683) and thicker pRNFL (coeff = 0.797; p=0.024, 95%CI = 0.107 to 1.488). Within the lesion, greater MTR was associated with higher VEP amplitude (coeff = 0.195; p=0.048, 95%CI = 0.001 to 0.389), shorter VEP latency (coeff = -0.141; p<0.001, 95%CI = -0.201 to -0.081), and higher thickness in both pRNFL (coeff = 0.555; p=0.030, 95%CI = 0.054 to 1.055) and mGCIPL (coeff = 0.144; p<0.001, 95%CI = 0.064 to 0.223). Higher post-lesional MTR was associated with higher thickness in mGCIPL (coeff = 0.093; p=0.026, 95%CI = 0.011 to 0.173]).

Discussion: We found that myelination associations were localised to the lesion at 6 months, while neuroaxonal associations were more robust within the lesion, but also found pre/post-lesionally.

Conclusion: Our results demonstrate that MTR is a valuable technique for evaluating the pathological processes underlying optic nerve damage, and that it reflects both myelin content and axonal integrity.

## TIME-VARYING CONNECTIVITY CORRELATES OF COGNITIVE PERFORMANCE DIFFER IN LATE-ONSET VS ADULT-ONSET MS: A STUDY OF THE PRECUNEUS AND POSTERIOR CINGULATE CORTEX

D. Biondi[1], P. Valsasina[1], N. Tedone[1], A. Gallo[2], P. Pantano[3], M. Margoni[4], P. Preziosa[5], M. Filippi[6], M. Rocca[5]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [2]Department of Advanced Medical and Surgical Sciences, and 3T MRI-Center, University of Campania "Luigi Vanvitelli" (Napoli); [3]Department of Human Neurosciences, Sapienza University of Rome (Roma); [4]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute (Milano); [5]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [6]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: Around 5-20% of multiple sclerosis (MS) patients exhibit an age at onset after 45 years, a condition named late-onset MS (LOMS). Prevalence of cognitive deficits in LOMS vs adult-onset (AO) MS is still debated; also, resting state (RS) functional connectivity (FC) abnormalities of LOMS patients were never described. We explored abnormalities of static (sFC) and time-varying functional connectivity (TVFC) of precuneus and posterior cingulate cortex (PCC) in LOMS and AOMS patients, and their association with cognitive profile.
Materials and Methods: From three Italian sites, we enrolled 39 LOMS, 281 AOMS and 156 healthy controls (HC), divided into two groups (n=45/111) to match LOMS and AOMS patients, respectively, and perform disease-by-age interaction analysis. Subjects underwent neuropsychological (Rao's battery) and 3T RS fMRI assessment. TVFC was estimated through sliding-window correlation analysis using the bilateral precuneus and PCC as seeds. For this latter region, three seeds were placed in the dorsal (dPCC), ventral (vPCC), and retrosplenial cortex (RSC). sFC was assessed by standard seed-to-voxel correlation analysis.

Results: AOMS and LOMS patients showed similar global and domain-specific cognitive performances (p=0.07-0.5). Both AOMS and LOMS showed circumscribed fronto-temporal sFC decrease, and parietal, parahippocampal (PHG) and deep grey matter sFC increase, with limited disease-by-age effects. Conversely, pronounced disease-by-age effects were found for TVFC, indicating specific TVFC abnormalities for LOMS and AOMS patients. In particular, AOMS showed decreased TVFC between the precuneus and the left (L) lingual gyrus, as well increased TVFC of the RSC with the L middle occipital gyrus (MOG) and L precuneus. Conversely, LOMS patients showed significantly decreased TVFC between the vPCC and L precuneus, and between the RSC and L thalamus. They also showed increased intra-precuneal TVFC, as well as increased TVFC between the dPCC and right (R) precuneus, L MOG, L PHG and R inferior frontal gyrus. In AOMS, increased TVFC between the RSC and L precuneus correlated with better visuo-spatial memory (r=0.14, p=0.02), while in LOMS patients increased TVFC between the dPCC and L MOG correlated with better cognitive scores (r=0.4-0.6, p=0.001-0.02).

Discussion: Despite similar cognitive profiles, specific TVFC abnormalities characterized LOMS and AOMS. In both groups, higher TVFC was associated with better performance, suggesting the presence of compensatory mechanisms.

Conclusions: Altered TVFC of the precuneus and the PCC seems to have a role in the maintenance of an adequate cognitive performance in both LOMS and AOMS patients.

## FDG-PET AND ASL MRI DEMONSTRATE CORRESPONDING METABOLIC AND PERFUSION CHANGES IN LIMBIC AUTOIMMUNE ENCEPHALITIS

D. Cerne[1], G. Rebella[2], F. Massa[3], S. Morbelli[4], M. Resaz[5], L. Benedetti[1], L. Roccatagliata[6]

Introduction: Metabolic abnormalities in autoimmune encephalitis (AE) can be detected using 2-deoxy-2-[18F]fluoro-D-glucose positron emission tomography ([18F]FDG PET), with relative hypermetabolism indicating disease activity. While evidence of pulsed arterial spin labeling (PASL) perfusion MRI to identify hyperperfusion changes in AE is still anecdotal, its potential to track the disease course relies on the close coupling of metabolism and perfusion. We compared PASL perfusion changes with [18F]FDG PET metabolic alterations in patients with definite AE to evaluate the correspondence between these metrics during the acute stage and after immunotreatment.

Material and Methods: Among 23 patients with confirmed autoimmune encephalitis (AE) admitted to our hospital in the 2018-2022 timeframe, a retrospective cohort of 5 patients with either antibody-associated AE (n=2 NMDAR, n=1 LGI1, n=1 Ma2) or seronegative AE (n=1) underwent both PASL-MRI and [18F]FDG-PET during the acute stage. In 4 out of the 5 patients, these scans were repeated after six months after initial immunotreatment. Scans were visually assessed by two independent raters. Following consensus, regions with hypermetabolism ([18F]FDG-PET) or hyperperfusion (PASL-MRI) were manually delineated, referencing the contralateral hemisphere, and their spatial overlap was evaluated by DICE analysis at either baseline or 6-month follow-up. Clinical assessment scale in AE (CASE) and modified Rankin Scale (mRS) scores were obtained at baseline and every 3 months, with an average follow-up duration of 15.8 months.
Results: At baseline, three patients demonstrated hypermetabolism on both [18F]FDG PET and hyperperfusion on PASL (DICE coefficient: Pt1, 0.2; Pt.2, 0.5; Pt.5, 0.35), while the other patients showed no abnormalities. After immunotreatment, the hypersignals decreased with a similar concordance Pt.5 (DICE=0.25) or completely solved (pts 1 and 2) in both modalities, paralleling clinical improvement (-4 points in CASE and -1.8 mRS score as a mean).

Discussion: We observed full concordance between negative scans in PASL and [18F]FDG-PET, while moderate spatial concordance was observed in regions exhibiting hypersignals. Following immunotreatment, metabolic and perfusion changes consistently demonstrated a decrease, aligning with clinical improvement. Although these techniques may identify slightly different underlying processes, leading to incomplete concordance, they are coupled in their ability to monitor the progression of the disease.

Conclusion: Although confirmation in larger cohorts is needed, PASL-MRI shows promise as an indicator of disease activity, treatment response, and recovery in AE, making it a favorable alternative to FDG-PET due to its concordance with metabolic abnormalities, cost-effectiveness, safety, and wide availability.

Objectives: Hippocampal atrophy is significant in multiple sclerosis (MS), especially related to memory impairment. Research has suggested that different hippocampal subfields are affected to varying extents during different disease stages. However, studies examining the functional consequences of subfield-specific hippocampal damage in early MS are limited. We studied a relatively large population of early RRMS patients (≤5 years from onset) to gain insights into the relationship between hippocampal atrophy and memory function by i) assessing whether there is global and regional hippocampal atrophy at this early stage, ii) investigating the correlation between hippocampal atrophy and memory performance in patients with different degrees of impairment.

Materials and Methods: From the Italian Neuroimaging Network Initiative (INNI) dataset, we selected 3D-T1W brain images acquired at 3T of 219 early RRMS (150 F, mean [±SD] age: 34 [±10] years, median [range] disease duration: 2 [0-5] years) and 246 HC (133F, mean age: 34 [±9] years). Patients underwent Selective-Reminding-Test (SRT) and Spatial-Recall-Test (SPART) and were classified as mildly (MMI-MS: n.110) or severely (SMI-MS: n:109) memory impaired, according to recently proposed cognitive phenotypes. We employed the EADC-ADNI protocol to segment hippocampus, and voxel-based morphometry to identify regionally atrophic areas within the hippocampus and to select voxels correlating with memory scores. We used Freesurfer to segment hippocampal subfields and identify the subfields containing the previously identified atrophic voxels. Finally, we used generalised linear models to compare volumes and Spearman test to correlate volumes with memory performance.

Results: Early RRMS showed lower volumes in the whole, right and left hippocampi compared to HC ($p<0.001$), while hippocampal volumes did not differ between MMI-MS and SMI-MS. In MMI-MS, lower hippocampal volumes correlated with worse memory tests ($p\leq0.01$, R from 0.23 to 0.37), while in SMI-MS, only a weak correlation was found between left hippocampal volume and SRT-LTS ($p=0.04$, $R=0.189$). Atrophic hippocampal voxels were detected in all subfields (from 79% in CA2-3 to 21% in tail). In MMI-MS, decrease subfield volumes correlated with decrease in memory performances, with the closest correlation with right CA1 volume (SRT-recall: $R=0.38$; SPART: $R=0.34$, $p<0.01$). In SMI-MS, no correlations were found between subfield volumes and memory tests.

Conclusion: Hippocampal atrophy is a distinctive feature of MS, spreading from the CA to the tail since the early stages. This seems to be associated with memory impairment in MMI-MS, while this correlation is lost in SMI-MS suggesting a limited adaptive functional reorganization of hippocampi in MS, even at early phases.

## GENERALIZED SPINAL CORD ATROPHY: CASE REPORT

M. S. Cotelli[1], F. Manelli[2], S. Bonetti[3], G. Bonetti[4], G. Tomasini[5], A. Tomasoni[6], P. Lavezzi[6], A. Madureri[7], R. Furloni[8], M. Ghirardelli[8], G. Pedersoli[9], M. Michelini[5], M. Bianchi[1], M. Turla[1]

[1]Neurology Unit, Valcamonica Hospital (Esine-BS); [2]Emergency Unit, Bolognini Hospital (Seriate-BG); [3]Emergency Unit, Spedali Civili Hospital (Brescia); [4]Laboratory of Clinical Pathology, Valcamonica Hospital (Esine-BS); [5]Emergency Unit, Valcamonica Hospital (Esine-BS), [6]Radiology Unit, Valcamonica Hospital (Esine-BS), [7]Cardiology Unit, Valcamonica Hospital (Esine-BS); [8]Medicine Unit, Valcamonica Hospital (Esine-BS); [9]Rehabilitation Unit, Valcamonica Hospital (Esine-BS)

Background: Spinal cord atrophy is a rare condition. Generally, spinal cord atrophy may be focal or generalized. Focal spinal cordatrophy may be due to Chiari malformation, previous CNS infection, trauma, radiotherapy, spinal surgery, immunological disorder, vascular abnormality or CNS tumour. Generalized spinal cord atrophy is rare and may caused by Chiari malformation, luetic CNS infection, and hereditary disorders like arthrogryposis multiplex congenita, Chediak-Higashi syndrome, adrenoleucodystrophy, Sjogren syndrome, familial spastic paraparesis, and hereditary motor and sensory neuropathy with pyramidal signs (HMSN-V), multiple sclerosis. We report the case of a 62 years old caucasian woman with generalized spinal cord atrophy in which all known causes have been excluded.

Materials and Methods: A 50 years-old caucasian woman has been evaluating due to persisting gait disorder started at the age of 20 and remaining stable over time without weakness or sensory symptoms. Her medical history was positive for arterial hypertension and familial history resulted unremarkable. Neurological exam showed brisk lower limb reflexes, paraparetic gait, lower liomb hypopallesthesia with distal apallesthesia, mild proximal lower limb weakness (3/5 medical research council). She denied bulbar or sphincter disorders. No fasciculations or muscle hypotrophy were obeserved; Babinski and Hoffman were normal and clonus of the ankles was absent.

Results: She performed spine magnetic resonance imaging (MRI) showing generalized and homogeneous spinal cord atrophy with marked lumbar spinal stenosis (L3-L4); brain MRI resulted normal. Both were superimposable on previous ones performed 10 years before in another hospital. Electromyography and electroneurography

resulted normal. Somatosensory evoked potentials resulted normal, while evoked motor potential showed four limbs prolonged central motor conduction time. Genetic evaluation of known spastic paraparesis resulted normal. Blood exams with immunological panel resulted normal. Syphilis was excluded.

Discussion: All known causes of spinal cord atrophy have been excluded. Gait disorders started at the age of 20 seems to exclude a congenital malformation (but two different MRI performed 10 years apart from each other were superimposable). Gait disturbance and paraparesis could be also related to marked lumbar spinal stenosis (for which she was recently surgically treated with mild benefit on both gait disorder and paraparesis).

Conclusions: To our knowledge this case of spinal cord atrophy is still idiopathic and can expand existing literature. Follow-up with neurological examination, neuroimaging exams can be helpful in excluding differential diagnoses and monitoring disease progression.

## LONG-TERM ACCUMULATION OF SLOWLY EXPANDING LESIONS IS ASSOCIATED WITH GREY MATTER ATROPHY AND DISABILITY WORSENING IN MS: A 10-YEARS FOLLOW-UP STUDY

A. De Mauro[1], G. Gentile[2], F. Cacciante[2], N. Cantavella[2], M. L. Stromillo[1], R. Cortese[1], M. Leoncini[2], L. Luchetti[2], F. Aprile[1], F. Sforazzini[2], M. Battaglini[2], N. De Stefano[1]

[1]Department of Medicine, Surgery and Neuroscience, University of Siena (Siena); [2]Siena Imaging Srl, Department of Medicine, Surgery and Neuroscience, University of Siena (Siena)

Aims: Multiple sclerosis (MS) is associated with progressive tissue damage of the central nervous system and consequent clinical disability worsening. Recently, slowly expanding lesions (SELs) have emerged as a reliable MRI marker of chronic inflammation in MS. Long-term assessment of SELs and their relationship with measures of regional brain atrophy and disability progression has not been investigated yet. To assess SELs volume and number over a 10-year follow-up and explore the relationship between SELs, grey and white matter (GM/WM) atrophy and disability accumulation in patients with relapsing-onset MS.

Materials and Methods: Longitudinal MRI scans (acquired using a 1.5 T Philips scanner) of 97 MS subjects (number of females: 71; mean [SD] age: 34.21±7.66; median [range] baseline EDSS 1.5 [0-5.5]; median [range] follow-up: 10.1 [1.4-14.5] years) were retrospectively analysed. Using an in-house developed pipeline, SELs were identified as T2 lesions showing constant and concentric local expansion assessed by the Jacobian of the nonlinear deformation field between the T1- and T2-weighted scans across all the available timepoints. Normalized brain (NBV), GM and WM volume was obtained using SIENAX tool. General linear model with negative binomial regression was applied to investigate the relationship between SEL burden (volume and number) with both EDSS change and annualised regional GM and WM volume change assessed between baseline and the last available follow-up. Analyses were corrected for age, sex, baseline NBV and T2 lesion number and volume.

Results: A total of 138 SELs were found in 41 (49%) MS patients (mean [SD] SELs volume: 1.51±3.3; mean [SD] SELs number: 3.36±3.08). In this long-term study, a higher number of SELs was associated with increased EDSS over time ($p<0.01$, $B=0.41$) and with greater GM atrophy ($p<0.01$, $B=-1.72$). A greater volume of SELs was associated with increased GM atrophy ($p<0.01$, $B=-0.23$). A trend was found for the relationship between SELs' volume and EDSS change ($p=0.06$, $B=0.05$). No association was found between SELs and WM volume change.

Discussion and Conclusion: We showed here that SELs are associated in the long-term with GM volume changes and disease progression. This suggests that chronic inflammatory activity and sustained GM tissue loss are two related mechanisms, progressively leading to disability worsening.

## METRONIDAZOLE-INDUCED CENTRAL AND PERIPHERAL NEUROTOXICITY. DIAGNOSIS AND 1-MONTH FOLLOW-UP

A. Di Pietro[1], L. Basili[2], S. D'Aniello[3], C. Costa[4], G. Giussani[4]

[1]Department of Neurology II, University of Campania Luigi Vanvitelli (Caserta); [2]Neurology Department, Ospedale San Giuseppe MultiMedica IRCCS (Milano); [3]Neuroradiology Department, Ospedale San Giuseppe MultiMedica IRCCS (Milano); [4]Neurology Department, ASST Valtellina (Sondrio)

Objectives: Metronidazole is an antibiotic widely used to treat protozoan and anaerobic bacterial infections. Although metronidazole is generally safe and well-tolerated, rare cases of neurotoxicity have been reported. Central nervous system involvement is usually characterized by highly suggestive abnormalities on neuroimaging. Herein, a case of metronidazole-induced central and peripheral neurotoxicity with encephalopathy, cerebellar ataxia, and sensorimotor polyneuropathy is described.

Materials and Methods: A 71-year-old man was admitted to our Emergency Department with a 3-week history of rapidly progressive gait impairment, somnolence, and speech disturbance. His past medical history was remarkable for a bladder and a colorectal tumor treated 15 years earlier. He was recently hospitalized for a suspected cancer relapse, associated with a purulent pelvic collection and received 3 months of antibiotic polytherapy, including metronidazole. On admission, neurologic examination revealed impaired arousal, moderate dysarthria, tetraparesis with severe distal muscle weakness, mild trunk and limb ataxia, deep tendon hyperreflexia, and severe sensory deficit.

Results: The head CT scan was negative for any acute findings. Blood tests, including metabolic, immunological, and infection screening were unremarkable. Electromyoneurography examination revealed subacute severe symmetric sensorimotor polyneuropathy, with predominantly axonal features. Lumbar puncture revealed no albuminocytological dissociation or oligoclonal bands in the CSF. Brain MRI detected T2/ FLAIR-hyperintensity of the dentate nuclei and splenium of the corpus callosum, whereas spine MRI didn't show any relevant findings. Based on the history and MRI findings, a diagnosis of metronidazole neurotoxicity was made. Stopping metronidazole therapy, the encephalopathy progressively improved over the following weeks, whereas the polyneuropathy showed no significant improvement. One-month MRI follow-up showed complete regression of the abnormalities.

Discussion and Conclusions: We described a patient with a long exposure to metronidazole, who suddenly developed encephalopathy and severe sensorimotor axonal polyneuropathy. The clinical history of the tumor complicated by recent superinfection led to a complex differential diagnosis including possible infectious, autoimmune, paraneoplastic, and toxic-dysmetabolic causes. The MRI findings, taking into account the anamnestic informations, prompt the diagnosis. Metronidazole is a little-known, but probably underestimated, iatrogenic cause of encephalopathy and neuropathy. The case we reported points out the need for neurological monitoring during metronidazole therapy and the diagnostic role of neuroimaging when neurotoxicity is suspected. Timely diagnosis is crucial to avoid extensive and futile treatment and to promote rapid drug discontinuation.

## SPONTANEOUS SPINAL CSF LEAKAGE PRESENTING WITH ISOLATED MYELOPATHY

A. Esposito[1], L. Ugga[2], E. Tedeschi[2], R. Iodice[3], M. Moccia[4]

[1]Medicine and Surgery, Federico II University (Napoli); [2]Department of Advanced Biomedical Sciences, University of Naples "Federico II" (Napoli); [3]Department of Neuroscience, Reproductive Science and Odontostomatology, University of Naples "Federico II" (Napoli); [4]Department of Molecular Medicine and Medical Biotechnology, University of Naples "Federico II" (Napoli)

Objective: Spontaneous intracranial hypotension (SIH) is characterized by postural headache and could be caused by cerebrospinal fluid (CSF) leak, mostly in thoracic spinal cord. We report on a case of a 33-year-old woman with CSF leak presented with rapidly progressive myelopathy causing right leg weakness, brisk reflexes, reduced superficial and pain sensation, and urinary retention. Patient complained of neither headache nor history of trauma.

Materials/Methods: Brain and whole spine MRI with and without gadolinium contrast and CT-myelography were performed. Neurophysiological assessment included transcranial magnetic stimulation and somato-sensory evoked potentials.

Results: Sagittal and axial T2-weighted MRI showed anterior displacement of the spinal cord due to epidural CSF longitudinal collection with dural detachment, likely from thoracic disc-osteophytic complex. Brain MRI was normal. Both transcranial magnetic stimulation and somato-sensory evoked potentials confirmed involvement of motor and somatosensory pathways of the right lower limb. The patient was hence immediately treated with methylprednisolone 500 mg/day for 5 days, showing clinical improvement. After 7 days from the end of steroids, a CT myelography study was performed and it did not show any CSF collection nor leakage. After 21 days from first MRI, CSF collection spontaneously disappeared on MRI. Further clinical improvements followed.

Discussion: CSF leakage from disrupted spinal meninges can cause epidural collections, usually leading to intracranial hypotension and postural headache. Accordingly, MRI frequently shows such CSF collections in association with brain abnormalities including pachymeningeal enhancement, subdural effusions and sagging brainstem. [1-2] Conversely, our case presented with compressive myelopathy caused by CSF dorsal epidural collection.

Conclusions: We report on a rare clinical presentation of CSF leakage characterized by isolated spinal cord clinical and MRI findings, suggesting that spinal epidural collection could be an uncommon cause of myelopathy.

Objective: The response to transcranial magnetic stimulation (TMS) of cortical networks captured by electroencephalography (EEG), i.e., the TMS-evoked potential (TEP), relies on the integrity of the cortex and its white matter (WM) connections to distant areas. [1] The network-specific gray matter and WM degeneration occurring in Alzheimer's disease (AD), may be depicted in changes of TEP amplitude and topography. Demonstrating that TEPs can track neurodegeneration within cortical networks would make TEPs a novel biomarker for AD and possibly for other neurodegenerative disorders.

Materials: In the present cross-sectional study, we collected TEPs, resting state functional MRI (rs-fMRI), diffusion tensor imaging (DTI), and an extended neuropsychological evaluation in healthy elderly individuals and patients with AD at various stages of the disease. TEPs were elicited by stimulating the parietal nodes of the default mode network (DMN) and the frontal nodes of the executive control network (ECN), as both networks are known to be affected by AD.

Methods: We tested for differences in cognition, WM microstructural tract integrity and early TEP amplitudes (<50ms) across groups. Finally, we verified if TEP components altered in AD pathology were associated with intrahemispheric and interhemispheric WM structural connections.

Results: Two early TEP components generated for DMN stimulation, i.e., P20P and N20F, showed significantly higher amplitude after left stimulation than after right stimulation in mild cognitive impairment (MCI) due to AD, and not in other groups. Moreover, the N20F following a left DMN stimulation was stronger in MCI patients compared to healthy controls and to AD patients in dementia stage.

Finally, these TEP components were associated with the WM integrity of healthy controls: the parietal component P20P was positively associated with the integrity of the corpus callosum (CC), and the frontal component N20F was positively associated with the integrity of the CC and the contralateral superior longitudinal fasciculus. Importantly, this association was absent in AD cases.

Discussion and Conclusions: In the early stages of the disease, AD is associated with asymmetric alterations of neurophysiological responses in the DMN, in line with previously reported vulnerability of this network and of the left hemisphere in AD cases. [2] The increased TEP responses only in the MCI group indicate that neurophysiological alterations within the DMN are not linearly related with the disease staging. Early TEP components from DMN stimulation have the potential to differentiate MCI due to AD from healthy individuals.

## DIABETES IMPACT ON NIGROSTRIATAL VULNERABILITY IN PARKINSON'S DISEASE

A. Galli[1], A. Pilotto[1], C. Zatti[1], M. Toffali[1], A. Rizzardi[1], C. Tirloni[2], A. Lupini[1], E. Premi[3], B. Paghera[4], A. Padovani[1,2]

[1]Department of Clinical and Experimental Sciences, University of Brescia (Brescia); [2]Department of Clinical and Experimental Sciences, ASST Spedali Civili (Brescia);[3]Stroke Unit, ASST Spedali Civili (Brescia);[4]Nuclear Medicine Unit, University of Brescia and ASST Spedali Civili (Brescia)

Objectives: Several studies suggested a possible association between diabetes mellitus (DM) and Parkinson's disease (PD) [1,2]. Aim of the study was to investigate in vivo whether diabetes mellitus influences motor function via its impact on nigrostriatal dopaminergic vulnerability in two independent cohorts of drug-naïve patients with early-stage Parkinson's Disease (PD).

Materials: The study included two independent prospective cohorts of drug naïve PD patients: n=54 patients from the single -center DNA-PD study and n=112 patients from the PPMI dataset (PD-PPMI cohort). Each cohort comprised two subgroups of patients with diabetes mellitus (PD-DM) or without diabetes mellitus (PD-noDM), which were matched 1:1 for age, sex, motor and cognitive impairment at baseline. All subjects underwent a neurological examination and Brain SPECT to measure dopamine transporter (DAT) density at baseline. A subset of the PD-PPMI cohort (n=46 PD-noDM; n=18 PD-DM) underwent a dopaminergic imaging follow-up after 12 months.

Methods: In order to test the impact of diabetes to nigrostriatal function, PD patients with and without diabetes were matched for motor severity, age, sex. The ANCOVA test was applied to test whether diabetes may enhance nigrostriatal vulnerability (i.e., differences in striatal binding) – adjusting for age, sex, handedness, and SSRI treatment. In the PPMI cohort, the annual difference in striatal binding was entered in an ANCOVA model – adjusted for age, sex, and handedness- to test differences in progression trajectories driven by diabetes mellitus.

Results: In both PD-BS and PD-PPMI cohorts, PD-DM and PD-noDM were matched for motor severity and comparable for non-motor symptoms. In both independent cohorts, PD-DM patients had higher dopamine uptake in left putamen, as compared to PD-noDM with the same disease severity. In PD-PPMI cohort, the follow-up evaluation revealed that PD-DM had a faster annual decline of left putamen binding than PD-noDM (-20% vs. -9%).

Discussion: Findings showed that diabetes mellitus may impact on motor presentation by increasing the vulnerability of the nigrostriatal systems. This result was further confirmed by the follow-up evaluation showing a greater annual difference in left putamen binding.

Conclusions: The diabetes mellitus has an impact on nigrostriatal vulnerability. Results were confirmed in both an Italian monocentric cohort and in the multicentric PPMI cohort.

Objectives: Both post-mortem and in vivo data suggested dopamine dysfunction in patients with Alzheimer's Disease (AD) [1,2]. However, the role and timing of dopaminergic systems alterations in AD is still under debate. Aim of the study was to evaluate in vivo dopaminergic changes using DATSCAN imaging in AD patients in prodromal and dementia stages.

Materials: 60 A+T+N+ AD patients (n=22 MCI-AD; n=38 AD-DEM) and n=60 age-matched controls (CG) entered the study and underwent DATSCAN imaging.

Methods: The occipital binding was used as reference region to obtain single-subject binding in different brain regions. Between-groups differences in 123I-FP-CIT binding were assessed using ROI-based and voxel-wise analyses-adjusting for the effect of centre, age and sex. Functional covariance analysis was applied to evaluate the covariance of a brain region- or "seed"- with other brain regions.

Results: In all AD patients, nigrostriatal imaging resulted negative according to cut-off used in clinical practice [3]. Compared to age-matched controls, the whole AD sample exhibited significant dopamine deficits within caudate, putamen, globus pallidus, amygdala and hippocampus in ROI-based and voxel-wise analyses. Specifically, MCI-AD showed alterations limited to caudate, putamen and globus pallidus, while AD-DEM patients also exhibited the involvement of amygdala and hippocampus bilaterally. Functional covariance analysis

using caudate as seed showed a related pattern of reduced dopamine binding in striatal, frontal and temporal regions progressively decreasing from CG to MCI-AD and dementia stages.

Discussion: This study indicate that subtle basal ganglia alterations are a common feature of AD already in prodromal stages, whereas hippocampal and cortical deficits were prominent in later stages of the disease. Further longitudinal studies are warrented to evaluate the clinical impact of dopaminergic deficits on cognitive and motor/behavioral progression over time.

Conclusions: We managed to find in vivo dopaminergic alterations in Alzheimer's Disease, both in MCI and dementia phases.

## EXPLORING THE NEURAL BASIS OF MILD MOTOR IMPAIRMENT IN PRODROMAL ALZHEIMER'S DISEASE: INSIGHTS FROM [18F]FDG PET AND ENGINEERED GLOVE ASSESSMENT

W. Kreshpa[1], F. Massa[1], M. Hamedani[1], B. Orso[1], D. Arnaldi[1], P. Mattioli[1], L. Lombardo[1], M. Losa[1], E. Biassoni[1], N. Girtler[1], A. Brugnolo[1], G. Mancardi[1], A. Schenone[1], S. Morbelli[2], A. Chincarini[3], M. Pardini[1]

[1]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa (Genova); [2]Department of Health Science (DISSAL), University of Genoa (Genova); [3]National Institute of Nuclear Physics (INFN), Genoa Section (Genova)

Objective: Mild motor impairment (MMI) often emerges in neurodegenerative diseases before cognitive decline[1]. Using an engineered glove enables objective assessment of motor performance, particularly during finger-to-thumb opposition movements, facilitating identification of individuals in the prodromal phase of dementia. However, the neural underpinnings of MMI remain inconsistent, with variable alterations observed in brain cortical areas and the cerebellum[2]. To enhance our understanding of the metabolic correlates of MMI in mild cognitive impairment due to Alzheimer's disease (MCI-AD), we employed [18F]FDG PET analysis during tasks involving the engineered glove. Our goal is to contribute to existing knowledge on MMI in this patient population.

Materials: We retrospectively identified 23 patients with MCI (age 78.13±8.05 years; education 8±4.6 years; MMSE 22.26±4.22) and an intermediate likelihood of AD who underwent [18F]FDG PET and performed finger-to-thumb opposition sequences at maximum velocity while wearing the engineered glove within 3 months from the baseline assessment.

Methods: Four main indices were extracted for each hand (dominant versus non-dominant, and their mean), including rate at maximum speed, number of correct sequences, tapping delay, and intertapping interval. Voxel-based analysis correlated these indices with cerebral metabolism values and identified hypometabolic areas in patients compared to 40 matched healthy subjects (nuisance: age). The statistical threshold was set at <0.001 at the voxel level, with less conservative thresholds explored additionally. Clusters with at least 100 voxels, family-wise error (FWE) corrected at the cluster level, were deemed significant.

Results: The dominant hand's intertapping interval negatively correlated with metabolism in an area primarily including the left pulvinar and bilateral thalamic ventral posterior lateral nucleus, and marginally left putamen and right parahippocampal gyrus (p=0.007 at voxel level). Importantly, these regions were separate from hypometabolism encompassing left temporo-parietal areas.

Discussion: Our findings suggest that dysfunctional visual and somatosensory integration should be accounted for MMI in prodromal AD. The posterior thalamic nuclei serve as relay regions for somatosensory pathways and contribute to visual attention and motor activities like saccades, reaching, and grasping. Previous research has indicated heightened thalamic activity with increasing movement complexity, highlighting its role in the integration of signals towards the association cortices to control hand dexterity. Early dysfunction of these thalamic areas may contribute to fine motor deficits of the dominant hand in prodromal AD, even in the absence of overt hypometabolism.

Conclusions: This research reveals some neural correlates of MMI in MCI-AD, aiding the development of objective measures for assessing motor impairments and predicting cognitive progression.

## ASSESSMENT OF CNS DISEASE ACTIVITY IN SUSAC SYNDROME: INTRACRANIAL VESSEL WALL IMAGING (VWI) VERSUS STANDARD MRI SEQUENCES

A. Lotti[1], A. Barilaro[1], A. Mariottini[1], E. Fainardi[2], L. Massacesi[1]

[1]Department of Neurology 2, Careggi University Hospital (Firenze);[2]Neuroradiology Unit, Careggi University Hospital (Firenze)

Aims: Evaluate the accuracy of three-dimensional (3D)-vessel wall imaging (VWI) compared to standard sequences and contrast enhancement-3D T2-fluid attenuated inversion recovery (CE-FLAIR) to assess central nervous system (CNS) disease activity in two cases of definite Susac Syndrome (SS).

Material and Methods: Brain magnetic resonance imaging (MRI) scan and retinal fluorescein angiogram (RFA) were performed at disease onset and at one, three and six months after induction therapy start. CE-FLAIR and VWI based on 3D black-blood proton density weighted with and without gadolinium were added to standard sequences on a 3 Tesla MRI scanner.

Results: Contrast enhancement-VWI (CE-VWI) detected an abnormal diffuse leptomeningeal enhancement (LME) in both cases at onset and during follow-up. Pathological enhancement on CE-VWI persisted at six-month brain MRI, despite absence of new lesions and disappearance of LME on CE-FLAIR. Follow-up RFA revealed new arterial wall hyperfluorescence (AWH) in both cases.

Discussion: SS is a rare immune-mediated vasculitis affecting retina, inner ear and brain. Currently, the following are considered as markers of suboptimal therapeutic response: the presence of new or persistently enhancing lesions on brain MRI scan, residual LME and

new branch retinal artery occlusion (BRAO) and/or AWH on RFA, being the latter the most sensitive exam to evaluate disease activity. In our two cases we demonstrated that the stability of lesion load is not enough accurate to establish absence of disease activity in the CNS, and that the use of VWI may add valuable information for SS monitoring. Despite absence of new lesions, or even a reduction in lesion number (Case 1) at standard examination, a pathological enhancement was detected with CE-VWI in both cases, and this was consistent with evidence of disease activity at RFA. LME assessment on CE-FLAIR is considered another tool useful to diagnosis and monitoring of disease activity in SS, but its regression did not seem sufficient to predict a complete suppression of CNS involvement, as suggested in case 2. Moreover, in our cases, CE-VWI seems to be at least as sensitive as CE-FLAIR in detecting LME compared to CE-T1.

Conclusions: VWI may represent a useful tool for diagnosing and monitoring CNS disease activity in SS, as confirmed by concordance with RFA, leading treatment's choice and timing. Moreover, CE-VWI seemed at least as sensitive as CE-FLAIR in detecting LME, possibly being superior to the latter in posterior fossa. LME remission might be not accurate in predicting suppression of CNS inflammation in SS.

## NON-STENOSING INTRACRANIAL ATHEROSCLEROTIC LESIONS IN EMBOLIC STROKE OF UNDETERMINED SOURCE: A PROSPECTIVE VESSEL WALL MRI STUDY

F. Mazzacane[1,3], E. Rognone[2], B. Del Bello[3], F. Ferrari[3], A. Persico[1], R. De Icco[3], A. Pichiecchio[3], A. Cavallini[1]

[1]Department of Emergency Neurology and Stroke Unit, IRCCS Mondino Foundation (Pavia); [2]Department of Neuroradiology, IRCCS Mondino Foundation (Pavia); [3]Department of Brain and Behavioral Sciences, University of Pavia (Pavia)

Background: Despite standard diagnostic approach, 30% of ischemic strokes remain cryptogenic, most of them being classified as embolic stroke of undetermined source (ESUS). Artery to artery embolization from non-stenosing complicated atherosclerotic intracranial plaques has been suggest being relevant in ESUS aetiology, possible more than occult atrial fibrillation but it is often undetected by conventional imaging. Vessel wall MRI (VWMRI) can identify high-risk atherosclerotic plaques and other culprit intracranial arterial lesions. However, prospective studies of VWMRI in ESUS patients are lacking.

Materials and Methods: We prospectively evaluated all consecutive patients with acute ischemic stroke admitted to IRCCS Mondino Stroke Unit from July 2022. All patients underwent standard diagnostic workup including CT angiography of intracranial and epiaortic vessels, transthoracic echocardiogram and 72 h ECG monitoring. All patients respecting ESUS criteria and with no contraindication to MRI were included in the study and underwent VWMRI with gadolinium contrast agent administration within 1 month from enrollment.

Results: We have enrolled 31 patients; one patient was not able to complete the whole MRI protocol and was excluded from the analysis. The mean (± SD) age was 64.5 (± 12.75) years, 16 (53.33%) patients were female. VWMRI revealed culprit intracranial vessels lesions in in 30% (n=10) of patients. Particularly, 9 patients had non-stenotic complicated atherosclerotic plaques with contrast enhancement; 1 patient had an intracranial vertebral artery dissection. Patients with symptomatic intracranial atherosclerosis were older (71 vs 63 years, p-value = 0,018), more likely to have hypertension (89 % vs. 38 %, p-value = 0.016), and more frequently smokers (78 % vs. 33 %, p-value = 0.046).

Discussion: VWMRI was well tolerated in acute stroke patients and was able to identify culprit intracranial arteries lesions undetected by luminal-based imaging in the 30% of our ESUS patients, in particular non-stenosing complicated atherosclerotic plaques. Clinical factors associated with symptomatic intracranial atherosclerosis were older age, smoke exposure and hypertension. These would be useful to select patients at higher risk of symptomatic intracranial atherosclerotic disease who would benefit more from the adjunction of VWMRI to the diagnostic workup.

Conclusions: Our preliminary data suggest a potential role of VWMRI in improving the diagnostic workup of ESUS, reducing the percentage of cryptogenic strokes. Particularly, VWMRI was able to reveal the presence of a culprit non-stenosing intracranial atherosclerotic lesion in a significant portion of ESUS patients. Clinical factors as age, smoking and hypertension may be useful to select patients at higher risk. Our data needs to be confirmed in larger samples before translating them to clinical practice.

## A RARE CASE OF ASYMPTOMATIC TWIG-LIKE MIDDLE CEREBRAL ARTERY

S. Perillo[1], T. Perillo[2], M. Fasolino[3], A. Serino[2], A. Manto[2]

[1]Department of Neurosciences and Reproductive and Odontostomatological Sciences, Federico II University (Napoli); [2]Neuroradiology Unit, "Umberto I" Hospital (Nocera Inferiore-SA); [3]Neurology Unit, "Umberto I" Hospital (Nocera Inferiore-SA)

Objectives: Congenital middle cerebral artery (MCA) anomalies, including aplastic MCA or Twiglike MCA (T-MCA), are very rare.

Materials: We describe a case of congenital aplastic MCA in a patient with a history of hydrocephalus and brain trauma.

Methods: The patient underwent clinical evaluation, brain computed tomography (CT), CT angiography (CTA), brain magnetic resonance imaging (MRI) and MR angiography (MRA).

Results: A 48-year-old woman presented to the Emergency Department for acute onset of altered mental status and urinary incontinence. She had a positive past medical history for a brain trauma 4 months before. Neurological examination showed confusion and lethargy, without any focal neurological deficit. She underwent brain and spine CT which showed an odontoid process fracture and hydrocephalus. Subsequently a brain MRI was performed, that confirmed tetraventricular hydrocephalus; MRA showed absent left MCA signal. Either recent or chronic ischemic lesion in MCA

vascular territory were absent, and only some gliotic spots due to small vessel disease were present. To better characterize these alterations, the patient underwent a CTA, that confirmed the absence of MCA, which was replaced by a prominent network of dilated small arteries supplying M2 territory. No associated aneurysm or other vascular abnormality were seen. A ventriculoperitoneal shunt (VPS) was implanted, which resolved the hydrocephalus, with dramatic improvement of patient's mental status.

Discussion: These radiological findings were consistent with developmental T-MCA. It is a rare vascular anomaly characterized by replacement of the M1 segment of MCA by a plexiform network of small vessels. Few cases have been described in the literature so far, and it is detected in 0.11%–1.17% of people who undergo angiography. Nearly all cases are unilateral. The pathogenesis is unknown, but it has been hypothesized to result from an interruption of plexiform network fusion into MCA trunk during the embryogenesis. T-MCA can be asymptomatic, being an incidental finding, as the case described above. However, it can also be associated with intracranial hemorrhage, cerebral infarction, as well as epilepsy, vertigo, headache, or focal neurologic deficits. In our case the diagnosis was made with MRA and TCA; meanwhile, she did not perform a conventional angiography because of her poor clinical status.

Conclusion: T-MCA is a rare congenital MCA anomaly, which can be asymptomatic as well as being associated with ischemic and hemorrhagic complications. Because of its rarity, it can be easily confused with other pathologies. However, correct diagnosis is fundamental for prognostic and therapeutic implications.

## STRUCTURAL BRAIN NETWORK CONNECTIVITY GRADIENTS IN STROKE: A LONGITUDINAL ANALYSIS

L. Pini[1], M. Aarabi[1], M. Corbetta[2]

[1]Padova Neuroscience Center, University of Padova (Padova); [2]Department of Neuroscience, University of Padova (Padova)

Objective: Stroke is a major cause of death and disability globally, resulting in significant neurological impairments. Brain damage from stroke involves both local cellular changes and connectivity diaschisis affecting distant brain regions. While research has primarily focused on the former, understanding the latter is crucial for a comprehensive view of the mechanisms underlying recovery and disabilities. In this study, we conducted a cross-sectional and longitudinal analysis of structural connectivity patterns to unravel connectivity changes in stroke patients.

Materials: Multi-shell diffusion-weighted imaging (DWI) were acquired in a sample of first-stroke patients, from the Washington University in St. Louis. Data were preprocessed according to standard procedure. We employed a probabilistic tractography model to reconstruct the number of fibers passing through each brain voxel. These fibers were then projected onto a parcellation scheme (Schaefer 100 parcels) to create a symmetric connectivity matrix representing fiber counts between each parcel pair. We separately considered inter- and intrahemispheric fibers. The structural connectivity matrix was subjected to diffusion map embedding analysis, generating a low-dimensional connectivity axis where parcels with similar connections were grouped together. Parcels were categorized based on Yeo's network template to compute network-gradient patterns, which were compared between stroke patients and controls, as well as between baseline and 3-month follow-up measurements within stroke patients.

Results: We included 50 stroke patients followed at two-week and three-month intervals from the event. A total of 29 age-matched healthy controls (HC) were included. Three main connectivity structural gradients were identified. Network-gradient patterns exhibited differences extending beyond the lesional and perilesional regions to distal networks. These alterations worsen during recovery. Notably, we found that right-hemisphere lesions resulted in more pronounced network-gradient alterations compared to left-hemisphere lesions. Finally, network-gradient for inter-hemispheric structural connections were less disrupted than gradient patterns computed using intra-hemispheric connections, regardless of lesion location.

Discussion: Our findings demonstrate a broad reorganization of large-scale structural connectivity following stroke, extending beyond the immediate lesion site. Notably, right-hemisphere lesions showed more severe network-gradient alterations than left-hemisphere lesions. This information has implications for developing targeted interventions based on lesion location and severity.

Conclusion: This study provides valuable insights into the impact of stroke on the brain's structural connectivity, offering potential avenues for developing new treatments and interventions. By understanding the reorganization of connectivity patterns following stroke, we can enhance our ability to tailor therapies and improve outcomes for stroke patients.

## COMPARATIVE ANALYSIS OF SUPRA AND INFRATENTORIAL ATROPHY IN CEREBELLAR ATAXIAS: UNVEILING DISTINCTIONS ACROSS DIFFERENT NEURODEGENERATIVE ATAXIAS

S. Pisano[1], S. Basaia[2], O. Tamas[3], S. Mesaros[3], N. Dragasevic[3], V. Kostic[3], F. Agosta[4], M. Filippi[5]

[1]Department of Medical Sciences and Public Health, University of Cagliari (Cagliari); [2]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [3]Clinic of Neurology, Faculty of Medicine, University of Belgrade (Belgrade-SRB); [4]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [5]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objective: This study examined structural alterations in gray matter (GM) and white matter (WM) in patients with different neurodegenerative cerebellar ataxias (CA).

Materials: Twenty-eight autosomal dominant (AD) CA patients (including cases of genetic spinocerebellar ataxia and patients without a known mutation but with an AD transmission pattern), 17 autosomal recessive (AR) CA patients (including cases of Friedreich's ataxia, CANVAS, ANO10 mutation, Oculomotor Apraxia Type 2, ARSACS, and patients with an AR pattern of inheritance without a known mutation), 29 sporadic cases of CA (including 16 idiopathic late-onset CA), 8 multiple system atrophy patients (MSAc) and 20 controls were included. MRI and clinical assessment were conducted.

Methods: Whole-brain Voxel-Based Morphometry (VBM) and cerebellar-optimized VBM (SUIT toolbox) were used to assess GM atrophy. Brainstem and superior cerebellar peduncles (SCP) volumes were estimated and compared between groups using Freesurfer.

Results: CA groups showed widespread GM cerebellar atrophy compared to controls. AD and AR groups showed significant supratentorial GM atrophy compared to controls in: (i) bilateral medial temporal gyri, insula, calcarine cortex, and right orbitofrontal cortex in AR; and (ii) right inferior orbitofrontal cortex, postcentral, and superior temporal lobe gyri, left superior temporal gyrus, and cingulate cortex in AD. No significant GM differences were found in whole brain, except for GM alterations in right calcarine cortex in AR relative to MSAc. Moreover, MSAc showed more involvement in the medial Crus-I and II compared to AD. Concerning brainstem analysis, AD, AR, and MSAc groups exhibited reduced whole-brainstem, pons, and medulla volumes compared to controls. Moreover, AD and MSAc groups demonstrated reduced whole-brainstem and pons volumes compared to sporadic cases. AD and AR groups displayed significantly reduced midbrain volume compared to controls, and only AD exhibited a reduction compared to sporadic cases. SCP volume was reduced in CA groups compared to controls. In addition, AD showed reduced SCP volume compared to sporadic cases.

Discussion: CA groups showed diffuse cerebellar atrophy, while AD and AR groups showed also distinct supratentorial patterns of atrophy, suggesting different underlying pathophysiology. The sporadic group showed less involvement in brainstem compared to CA groups, potentially aiding in distinguishing sporadic CA from inherited forms.

Conclusions: Our study provides evidence of distinct structural alterations involving both GM and WM in CA patients of different neurodegenerative ataxias, contributing to a better understanding of the underlying degenerative processes and having implications for diagnostics and future therapeutic approaches tailored to the specific CA causes.

## CEREBRAL SMALL VESSEL DISEASE LOAD AND PROGRESSION IN A COHORT OF OLDER PATIENTS WITH ATRIAL FIBRILLATION ON ANTICOAGULANTS: STRAT-AF STUDY

A. Poggesi[1], B. Formelli[1], E. Barucci[1], C. Barbato[1], F. Pescini[2], F. Cesari[3], B. Giusti[3], A. Gori[3], A. Ginestroni[4], E. Fainardi[4], R. Marcucci[3], E. Salvadori[1]

[1]NEUROFARBA Dept., University of Florence (Firenze); [2]SOD Stroke Unit, AOU Careggi (Firenze); [3]Atherothromobotic Disease Centre, AOU Careggi (Firenze); [4]Neuroradiology Dept., AOU Careggi (Firenze)

Aims: In atrial fibrillation (AF), anticoagulants reduce the risk of thromboembolism at the cost of increased bleeding risk. Treatment decision should consider the estimate of such risk. Available risk stratification schemes rely on gross clinical information and attempts to refine them are under way. Unfortunately, none of such schemes are directed toward the most feared hemorrhagic complication, i.e. intracerebral hemorrhage (ICH). In AF, neuroimaging has led to increased detection of "asymptomatic" changes, particularly those related to small vessel disease (SVD), the main pathologic substrate of ICH. SVD might serve as surrogate marker of a bleeding-prone state. Despite this, debate is ongoing on how to consider such "brain" information in treatment decision-making. Our aims were to describe, in a cohort of older AF patients on anticoagulants, baseline SVD load and progression, and to evaluate predictors of such progression.

Methods: Strat-AF was a single center, longitudinal, observational study evaluating older (>/=65 years) patients with AF on anticoagulants. Patients were recruited from the outpatient clinic Center for Thrombosis at Careggi University Hospital and assessed by means of a comprehensive clinical evaluation and brain MRI, both repeated after 18 months. SVD was assessed according to visual scales: white matter hyperintensities (WMH; Fazekas, Scheltens scales), Microbleeds (MB; MARS), lacunar infarcts (LI; number), enlarged perivascular spaces (EPVS; 4-point scale). SVD total score was calculated (0-4 point). Face to face comparison between the baseline and follow-up scan was used to measure SVD progression: Rotterdam scale for WMH; incidence of new MB and LI; 1-point increase of EPVS scale. Predictors of progression were assessed by logistic regression.

Results: At baseline, 170 patients were enrolled (mean age 77.7+/-6.8, 110 males), of whom 114 had complete follow-up information (mean age 76.7+/-6.5, 77 males). At baseline, 67% of the cohort had moderate severe WMH, 60% had moderate severe EPVS, 22% and 17% had >/=1 LI and MB. SVD total score: 0=18%, 1=24%, 2=38%, 3=13%, 4=4%. At follow-up, two thirds of the study cohort progressed in at least one lesion type; 53% WMH, 17% EPVS, 5% LI, 12% MB. Baseline WMH (Scheltens score) and MB (number) were the independent predictors for their individual progression [OR1.09(95%CI,1.03-1.15) and OR1.76(95%CI,1.18-2.63) respectively].

Discussion: In Strat-AF, neuroimaging detected a considerable proportion of AF older patients on anticoagulants with high SVD burden, and confirms that baseline SVD load predicts future progression, corroborating the hypothesis of a useful surrogate marker.

## POLIOMYELITIS-LIKE ACUTE FLACCID PARALYSIS DUE TO WEST NILE VIRUS 1 STRAIN: CLINICAL AND NEUROIMAGING FINDINGS

A. Porsio[1], G. Sansone[1], R. Manara[1], L. Barzon[2], E. Tramarin[3], P. Santurelli[1], L. De Rosa[1], C. Briani[1], M. Corbetta[1], A. Cagnin[1]

[1]Department of Neurosciences, University of Padua (Padova); [2]Department of Molecular Medicine, University of Padua (Padova); [3]Department of Radiology, University of Padua (Padova)

Introduction: The West Nile virus (WNV) is an arbovirus than can infect human beings and caused neuroinvasive disease (WNND) in more than half of reported cases to CDC in past years (53% reported as encephalitis, 37% as meningitis, 7% as acute flaccid paralysis or AFP). Despite the low sensitivity of MRI (20 to 70%), lesions affecting basal ganglia, thalami, brainstem, cerebellum are often detected. In AFP anterior horns and/or anterior spinal nerves roots have been sometimes found affected.

Aim: To report clinical and imaging findings for neuroinvasive disease due to WNV lineage 1 during the outbreak occurred in Veneto in 20223.

Materials and Methods: Forty-seven patients with WNV infection diagnosed at our center, between 12/07/22 to 21/09/22 (45 definite WNND, 2 probable WNND; 29 males; mean age 71 +/- 14.1 years)

were collected. 38/47 patients underwent brain MRI and 19/47 a whole spinal cord MRI. Statistical analyses included descriptive statistics, Pearson's correlation, and chi-square tests (Bonferroni corrected for multiple comparisons). Three patients underwent brain and spinal autopsy.

Results: AFP was the most frequent clinical phenotype (42.6%), followed by encephalitis (34%), paucisymptomatic disease (12.8%) and meningitis (10.6%). The most common imaging finding was the diffuse gadolinium enhancement of anterior spinal nerves roots, especially those of cauda, in 10/19 of total cases and 10/14 of AFP cases. In fewer cases, MRI showed hyperintensity foci in T2-weighted sequences in cerebellum (5/38), brainstem (3/38), cranial nerves (3/38), thalamus (2/38), basal ganglia (1/38), mesial temporal lobe (1/38) and dorsal spinal cord (1/19), sometimes associated to alterations in diffusion-weighted sequences and/or gadolinium enhancement. The spinal nerves roots involvement, AFP phenotype and motor deficit severity were predictors for ICU admission, death, and correlates positively with post-event mRS and length of hospitalization. The overall 3- and 7-month mortality were 35% and 45% in AFP cases. Pathologic studies in three patients with AFP demonstrated extensive inflammatory infiltration in cerebral hemispheres, brainstem, anterior horns and in one case also in the anterior roots of the spinal nerves.

Discussion and Conclusions: The new WNV-1 strain appeared to be associated with an increased risk of severe AFP, worse prognosis, and higher mortality. MRI shows a sensitivity of 50-70%, especially in cases of AFP. Further studies need to define whether the WNV-1 can cause a more severe form of WNND due to major tropism toward anterior horns and/or spinal nerve roots, or maybe if damage at these levels is also due to reactive immune-mediated attack.

Objectives: Heterogeneous pathological processes, possibly influenced by specific regional gene expression differences, may contribute to a non-random and clinically-relevant grey matter (GM) atrophy progression in multiple sclerosis (MS). In this study, we aimed to investigate the spatial associations between regional GM atrophy and gene expression in MS.

Material and Methods: Brain 3T magnetic resonance imaging (MRI), neurological evaluation and neuropsychological assessment were obtained from 286 MS patients and 172 healthy controls (HC). Patterns of regional GM atrophy in MS patients compared to HC and according to clinical disability and cognitive status were investigated using voxel-based morphometry (VBM) ($p<0.05$, family-wise error-corrected). Genes associated with MS were identified from Open Target Platform (n=2710). The spatial cross-correlations between VBM-derived GM maps and gene expressions provided by Allen Human Brain Atlas were explored using the MENGA platform. Using ToppGene Suite, enrichment analyses were performed to explore over-represented molecular functions and cellular components involving gene expressions significantly associated with VBM-derived GM maps ($p<0.05$, Bonferroni-corrected).

Results: Compared to HC, MS patients showed widespread GM atrophy being significantly associated with the regional expression of 74 genes, involved in synaptic GABA receptor functions and mitochondrial oxidoreductase activities and mainly expressed in neurons and astrocytes. Lower volume in bilateral deep GM nuclei and cerebellum, and left insula was significantly associated with a higher Expanded Disability Status Scale score and with the expression of 44 genes being enriched in the mitochondrial and cellular nucleoids of all central nervous system (CNS) resident cells. Cognitively-impaired (n=113) vs cognitively-preserved (n=173) MS patients had distributed GM atrophy being significantly associated with the expression of 64 genes, that are involved in protein heterodimerization and oxidoreductase activities of mitochondrial and organelle membranes/envelopes and are expressed by microglia and endothelial cells.

Discussion: A clinically-relevant regional GM atrophy occurs in MS patients, especially in those with a more severe disability and cognitive impairment. This regional GM atrophy pattern is non-random and is associated with different regional expressions of genes that are mainly involved in synaptic GABA receptor activity and mitochondrial oxidoreductase functions.

Conclusions: Specific gene expression differences may influence regional susceptibility to excitatory/inhibitory imbalance and oxidative stress not only in neurons, but also in other resident CNS cells. This may accelerate neurodegenerative processes and, ultimately, GM atrophy.

## DIFFERENTIATING BETWEEN COMMON PSP SUBTYPES USING STRUCTURAL MRI: A MACHINE LEARNING STUDY

A. Quattrone[1], A. Sarica[2], J. Buonocore[1], M. Morelli[1], M. Bianco[2], C. Calomino[2], F. Aracri[2], M. De Maria[2], B. Vescio[3], M. Vaccaro[2], A. Quattrone[2]

[1]Institute of Neurology, Department of Medical and Surgical Sciences, University Magna Graecia of Catanzaro (Catanzaro); [2]Neuroscience Research Center, Department of Medical and Surgical Sciences, University "Magna Graecia" (Catanzaro); [3]Biotecnomed S.C.aR.L. (Catanzaro)

Background: Differentiating Progressive supranuclear palsy-Richardson's syndrome (PSP-RS) from PSP-Parkinsonism (PSP-P) may be extremely challenging [1-2]. In this study, we aimed to distinguish these two PSP subtypes using MRI structural data.

Methods: Sixty-two PSP-RS, 40 PSP-P patients and 33 control subjects were enrolled in the study. All patients underwent a brain 3T-MRI; cortical thickness and cortical/subcortical volumes were extracted using Freesurfer 7 on T1-weighted images. We calculated the Automated MR Parkinsonism Index (MRPI) and MRPI 2.0 and tested their classification performance. Machine learning (ML) models (eXtreme Gradient Boosting [XGBoost] and Random Forest) using different combinations of structural MRI data were also tested in differentiating between PSP subtypes.

Results: MRPI and MRPI 2.0 showed AUC >0.97 in distinguishing PSP patients from controls but had AUC of 0.88 and 0.81, respectively in differentiating PSP-RS from PSP-P. ML models demonstrated that the combination of MRPI and volumetric/thickness data was more powerful than each feature used alone. The best ML model in differentiating between PSP subtypes was XGBoost which showed AUC: 0.93(0.04) using a combination of MRPI, cortical thickness and subcortical volumes. Similar performance (AUC: 0.93[0.06]) were also obtained by XGBoost in a sub-cohort of 59 early PSP patients.

Conclusion: The combined use of MRPI and volumetric/thickness data was more accurate than MRI features used alone in differentiating between PSP-RS and PSP-P. Our study supports the use of structural MRI to improve the early differential diagnosis between common PSP subtypes, which may be relevant for prognostic implications and patient inclusion in clinical trials.

## A CASE OF MARCHIAFAVA-BIGNAMI DISEASE

R. Renna, W. Di Iorio, A. Ranieri, V. Andreone

UOSC Neurology, Stroke Unit, AORN A. Cardarelli (Napoli)

Introduction: Marchiafava-Bignami disease (MBD) is a very rare disorder discovered in 1903 by Italian pathologists Ettore Marchiafava and Amico Bignami. It is caused by demyelination/necrosis of the corpus callosum and the near subcortical white matter and is especially predominant in ill-fed alcoholics. The clinical picture is characterized by dementia, dysarthria, spasticity, and walking inability. [1]

Clinical case: A 47 years-old man with severe alcohol use disorder (per DSM-5 criteria) presented to the Emergency Department of our Hospital for a tonic-clonic generalized seizure. He had a two-months history of severe impairment of attention, imbalance, postural tremor, and walk difficulties. At neurological evaluation he was awake, displayed disorientation in time and space, postural tremor of upper limbs, severe imbalance with impossibility to walk. Laboratory tests showed decreased hemoglobin (12.5 g/dL), increased mean globular volume (99.1 fL), increased γ-glutamyl transferase (71 U/L), and increased creatine-kinase (1666 UI/L). A brain CT scan demonstrated no pathologic finding, while a brain MRI showed bilateral ovaloid areas in the splenium of the corpus callosum and in the left-side of the genu of corpus callosum that appeared hyperintense on T2-weighted images and diffusion-weighted images and hypointense on T1-weighted images, consistent with MBD. B-complex vitamins were administered, and alcohol use was forbidden.

Conclusion: Alcohol consumption is the most relevant risk factor for MBD. However, its etiology remains unclear. The symptoms of MBD are nonspecific and common in other alcohol-related diseases, such as alcohol withdrawal syndrome, Wernicke's encephalopathy, delirium, and dementia, thus making the differential diagnosis wide ranging. The distinctive element of MBD lies on the MRI characteristic presentation consisting of T1-hypointense and T2-hyperintense bisymmetric lesions involving the corpus callosum. There is no specific therapy for this disease. Some case reports have shown a favorable response to high-dose parenteral thiamine and oral B-complex vitamins. An early diagnosis and adequate treatment may provide a favorable outcome for a potentially fatal disease. MBD should be considered in the differential diagnosis of patients with heavy alcohol consumption presenting with imbalance, memory and/or behavioral abnormalities, hallucinatory phenomena, and gait disturbances. Although therapy significantly overlaps with that of Wernicke-Korsakoff syndrome or alcohol withdrawal syndrome, one should always bear in mind that a high-dose thiamine course might be required.

## ALTERED FUNCTIONAL NETWORKS IN CORTICOBASAL SYNDROME AND PROGRESSIVE SUPRANUCLEAR PALSY: A COORDINATE BASED ALE METANALYSIS

F. Ricci[1], L. Mencarelli[2], C. Motta[1], A. Martorana[1], G. Koch[2]

[1]Memory Clinic, University of Rome Tor Vergata (Roma); [2]Non-invasive Brain Stimulation Unit, Santa Lucia Foundation IRCCS (Roma)

Corticobasal Syndrome (CBS) and Progressive Supranuclear Palsy (PSP) are neurodegenerative diseases characterized by movement disorders and progressive cognitive decline, belonging to the Fronto-Temporal Lobar Degeneration (FTLD) spectrum. In this study, we analyzed these two diseases for their common underlying neuropathology and their concurrent evolution in dementia and movement impairment. To better define diagnostic and pathophysiological differences between them, we extrapolated their radiological traits through a neuroimaging coordinate based meta-analytic approach. Then, we used a functional connectivity (FC) analysis to identify altered brain resting-state networks (RSNs) associated with the resulting imaging maps. We selected 32 functional imaging studies using Fluoro-Deoxy-Glucose Positron Emission Tomography (FDG-PET) and Tecnetium-99 Single Photon Emission Computed Tomography (ECD-SPECT), following the Preferred Reporting Items for Reviews and Meta-analysis (PRISMA) statement, and analyzed them through the activation likelihood estimate statistical framework to identify syndrome-specific hypofunctional regions. Neurosinth software were used to determine FC maps of these areas. PSP is distinguished by much underactivated subcortical regions: Mid-brain, Putamen, Caudate Nucleus and Thalamus. Also cortical areas were found dysfunctional, precisely Anterior and Middle Cingulate Cortex, Anterior Insular Cortex and Superior Frontal Gyrus. CBS showed hypofunctional areas corresponding to Thalamus and left Inferior Parietal Lobule. Conjunction analysis between syndromes showed the Thalamus as the only region affected in both diseases. Subtraction analysis confirmed Mid-brain, Striatum and Fronto-Insular areas as abnormal in PSP, while Inferior Parietal Lobule characterizing CBS. Analyzing the RSNs implicated in each resulting underactivated region, it emerged that PSP have a remarkable involvement of the Basal Ganglia Network (BG), but also of cortical networks: Ventral Attention Network (VAN), Fronto-Parietal Control Network (FPCN) and anterior Default Mode Network (aDMN). The

RSNs associated with CBS were BG and Dorsal Attention Network (DAN). As expected, PSP demonstrated an abnormal functioning of the BG, predominantly associated with Mid-brain and Striatum. Furthermore, also VAN, FPCN and aDMN are involved, reflecting the executive and goal-directed behavior dysfunctions which characterize the disease. Interestingly, CBS did not show Striatum impairment, more commonly associated with movement disorders, but abnormal thalamic activity, although still belonging to the BG. The concomitant dysfunctional DAN suggests the possible presence of a complex attentional-perceptive deficit underlying the great variety of movement disturbances and dysexecutive symptoms featuring this syndrome. The present study identifies brain regions of hypofunctional activity in PSP and CBS, highlighting the related altered RSNs. The resulting maps could help to isolate brain target regions for future non-invasive brain stimulation applications.

## CSF-IN GRADIENT OF THALAMIC AND CORTICAL DAMAGE IN MULTIPLE SCLEROSIS: A 3T MAGNETIZATION TRANSFER RATIO AND R2* STUDY

M. Rubin[1], E. Pagani[1], A. Meani[1], P. Preziosa[2], L. Storelli[1], M. Margoni[3], M. Filippi[4], M. Rocca[2]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [2]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [3]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute (Milano); [4]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: A cerebrospinal fluid (CSF)-in gradient in cortical and deep gray matter (GM) damage has been found in multiple sclerosis (MS). However, the combined evaluation of gradient of cortical and deep GM damage has not been explored yet. We analyzed the concomitant patterns of cortical and deep GM microstructural abnormalities in MS at progressive distances from CSF using a multiparametric MRI approach.

Materials and Methods: Brain 3T MRI scans were acquired from 52 MS patients (33 relapsing-remitting [RR], 19 progressive [P]) and 70 healthy controls (HC). From 3DT1-weighted, we sampled cortical layers at 25%-50%-75% depths from pial to cortical-white matter (WM) interface and thalamic and caudate bands at 2-3-4 voxels from ventricular- GM interface. We tested between-group comparisons of magnetization transfer ratio (MTR) and R2* layer-specific z-scores and CSF-in across-layers z-scores changes, as well their correlations with clinical and structural measures (linear mixed models).

Results: Compared to HC, RRMS patients showed significantly lower MTR values in the outer cortical layer (FDR-p=0.025) and lower R2* values in all three cortical layers (FDR-p≤0.027). Compared to HC, PMS patients had significantly lower MTR values in the outer and middle thalamic layers (FDR-p≤0.048), in the outer caudate layer (FDR-p≤0.024), and in the outer and middle cortical layers (FDR-p≤0.016). They also showed lower R2* values in the outer thalamic layer (FDR-p=0.046) and in the outer cortical layer (FDR-p=0.003) as well as higher R2* values in all three caudate layers (FDR-p≤0.031). A significant gradient of damage, with lower values closer to the CSF, was found for thalamic MTR in both RRMS and PMS patients (FDR-p≤0.042), thalamic R2* and caudate MTR only in PMS patients (FDR-p≤0.013), cortical MTR in both RRMS and PMS patients (FDR-p≤0.002) and cortical R2* only in PMS patients (FDR-p=0.005). Lower MTR and R2* values of outer thalamic, caudate and cortical layers and steeper gradient of damage towards the CSF were significantly associated with older age, higher brain WM lesion volume and lower brain volume (absolute β≥0.08, all FDR-p<=0.040). No correlations with choroid plexus volume were found.

Discussion: We identified different CSF-in gradient of damage in the thalamus, caudate nucleus and cortex, being more substantial in PMS patients and possibly reflecting heterogeneous pathological substrates, such as demyelination, iron loss or accumulation, that differently affect these GM structures.

Conclusions: The analysis of MTR and R2* at different layers may contribute to disentangle the heterogeneous pathological processes occurring in the deep GM and cortex of MS patients.

## SURFACE-BASED BUT NOT VOXEL-BASED MORPHOMETRY REVEALS STRUCTURAL ABNORMALITIES IN INDIVIDUALS WITH SUBJECTIVE COGNITIVE DECLINE

L. Serra[1], G. Giulietti[1], S. Bonarota[1], C. Di Domenico[1], G. Caruso[1], M. Assogna[2], M. Rodini[1], L. Mencarelli[3], F. Di Lorenzo[3], G. Koch[3,4], L. Fadda[5], C. Caltagirone[6], M. Bozzali[7]

Objective: Subjective cognitive decline (SCD) is a condition that defines individuals who perceive a decrease in their cognitive functioning in the absence of any detectable deficit on neuropsychological testing [1]. SCD may be regarded as the earliest clinical stage of Alzheimer's Disease (AD) [2]. Brain structural changes have been reported inconsistently across previous studies [3]. The aim of the present study was to assess both grey matter (GM) volumes and patterns of cortical folding across the AD spectrum.

Methods: 107 individuals (31 patients with AD and 23 with Mild Cognitive Impairment (MCI, 25 individuals with SCD, and 28 Healthy Subjects [HS]) underwent neuropsychological assessment and a 3T-MRI scan to collect T1-weighted volumes (MEMPRAGE sequence). MEMPRAGE images were pre-processed using CAT-12 to obtain structural maps to perform both voxel-based (VBM) and surfaced-based morphometry (SBM). The former analysis allows the investigation of regional GM volumetrics, while the latter allows the extraction of cortical thickness, gyrification, fractal dimension, and the so-called sulcus depth. A full factorial design was used in SPM-12 to assess between-group differences in each metric separately.

Results: VBM showed the expected pattern of regional GM atrophy in AD and MCI patients compared to HS, but also to individuals with SCD. Conversely, no volumetric differences were detected in SCD individuals compared to HS. Patients with AD, compared to all other groups, showed cortical surface abnormalities in all SBM measures. MCI patients showed reduced thickness compared to both SCD subjects and HS with a bilateral distribution, alongside reduced gyrification in the left hemisphere. Moreover, MCI patients compared to HS showed reduced gyrification also in the right hemisphere. When considering fractal dimension, MCI showed reduced complexity compared to both SCD and HS in the left hemisphere. In addition, they showed reduced sulcal depth compared to SCD in the left hemisphere and to HS in the right hemisphere. Finally, SCD individuals compared to HS showed reduced gyrification bilaterally and reduced sulcal depth in the right hemisphere.

Discussion: VBM confirms its high sensitivity in detecting GM changes in the clinical categories of AD and MCI only. Conversely, cortical surface abnormalities can be detected at earlier stages, thus providing an objective measure of brain damage to be used for patient stratification and monitoring in future clinical trials for disease modifying treatments.

Objectives: The spectrum of frontotemporal lobar degeneration (FTLD) encompasses a wide variety of clinical phenotypes, with predominant behavioural and/or language presentations. Each frontotemporal dementia (FTD) syndrome is characterized by specific patterns of atrophy underlying clinical symptoms. Recently, an emerging variant with distinctive clinical features has been described1 with the name of semantic behavioural variant FTD (sbvFTD). The main aim of the study was to provide a comprehensive overview of the structural neuroimaging correlates of each specific FTD variant at baseline and describe longitudinal patterns of disease progression for each syndrome, with a particular focus on sbvFTD, which remains relatively poorly characterized in the current literature.

Materials: Our cohort included a total of 73 patients with a clinical diagnosis of behavioral variant of FTD (bvFTD, n=38), sbvFTD (n=8), semantic (svPPA, n=13) or non-fluent/agrammatic variants of primary progressive aphasia (n=14), who underwent serial neurological evaluations, neuropsychological assessments and at least two MRI scans on a 3T scanner. Fifty-two healthy controls underwent the same protocol. Methods: For each group, vertex-based and regional cortical thickness analyses were performed at baseline and longitudinally to identify patterns of atrophy at baseline and regions of cortical atrophy progression compared to healthy controls. Longitudinal mixed effect models were corrected for multiple comparisons, and adjusted for sex, age and education levels.

Results: At baseline, both vertex-wise and regional cortical thickness analyses identified specific patterns of atrophy for each FTD variant, with bvFTD showing extensive bilateral frontotemporal involvement, svPPA presenting selective left temporal lobe atrophy with initial spread to contralateral temporal pole, and nfvPPA displaying frontoparietal atrophy, mostly lateralized to left hemisphere. Patients with sbvFTD had an intermediate atrophy pattern between bvFTD and svPPA, with right-predominant temporal pole involvement associated to significant right frontal atrophy. Longitudinally, bvFTD patients were found to progress widely bilaterally, while svPPA continued steady progression restricted to the temporal lobes, nfvPPA showed limited foci of disease progression and sbvFTD showed progression only in the left temporal lobe with limited further volume loss in the right hemisphere.

Discussion: Our study has characterized structural neuroimaging hallmarks of each FTD variant and recognized variant-specific patterns of disease progression.

Conclusions: These findings could aid in the identification of imaging biomarkers able to improve FTD diagnosis and prognostic stratification. Moreover, our results singled out sbvFTD as a relatively distinct entity, despite its partial overlap with both bvFTD and svPPA.

## STUDY OF CEREBRAL PERFUSION IN NEWBORNS WITH MRI AND PCASL SEQUENCE

M. Treddenti[1], M. Caulo[2]

[1]Istituto Auxologico San Luca, Università Statale (Milano); [2]Istituto di Tecnologie Biomediche Avanzate (ITAB), Department of Neuroscience Imaging and Clinical Sciences, G. D'Annunzio University (Chieti)

Objectives: The term "perfusion" refers to the supply of oxygen and nutrients to the tissues via the bloodstream. Cerebral perfusion is quantified in terms of cerebral blood flow (CBF). Previous studies estimated neonatal cerebral perfusion by means of techniques with limitations, such as invasiveness, reduced sensitivity or the inability to obtain regional but only global flow measurements. Arterial Spin Labelling (ASL) is a non-invasive magnetic risonance imaging (MRI) sequence without contrast medium, able to provide CBF colorimetric maps. Our study aims at measuring the regional CBF in neonates by means of ASL and at identifying possible correlations between regional CBF values and the gestational age at birth (EG).

Materials: One hundred three subjects were initially recruited. From those we excluded subjects with ASL movement artifacts and encephalic pathologies relevant enough to compromise cerebral perfusion. The remaining 63 subjects were studied at term equivalent age (the MRI was performed at the fortieth week of corrected gestational age). Subjects were then divided into gestational age groups.

Methods: Ten regions of interest were identified via a morphological sequence (with care to include as little white matter and large vessels as possible and to maintain for all regions the same size, with a 5% variability). Regional CBF values were then estimated. T-tests were performed to compare the values between the two hemispheres, and an ANOVA model was applied to compare the CBF values in the various brain regions. Finally, Pearson correlation was used to evidence a CBF-EG relationship.

Results: No significant differences between CBF values in the two hemispheres were found. The highest perfusion values were found at the level of the thalamus and the frontal cortex, the lowest at the level of the parietal cortex. The most interesting data of our study is the demonstration that higher gestational ages correspond to higher perfusion values.

Discussion: Our study shows that, as already reported in the literature, CBF is higher in regions that can be associated with the greater motor rather than sensory activity of the fetus, in an environment relatively protected from external sensory stimuli.

Conclusions: Moreover, we showed the positive correlation between CBF and EG, not yet demonstrated in subjects in vivo. This finding can be explained by the importance of maturation of vascular and brain structures during fetal development.

## MOTOR BAND SIGN AS AN ULTRA-EARLY NEURORADIOLOGICAL FINDING IN PROGRESSIVE MULTIFOCAL LEUKOENCEPHALOPATHY (PML)

F. R. Vodret, U. Pensato, S. Marcheselli

Neurology, Humanitas Research Hospital, Humanitas University (Milano)

Introduction: Progressive multifocal leukoencephalopathy (PML) is a demyelinating central nervous system infectious disorder caused by the reactivation of the JC virus (JCV), that usually present in immunocompromised patients. Together with HIV-related PML, iatrogenic PML accounts for an increasing proportion of cases due to the rising number of patients who received immunosuppressive treatments [1]. The diagnosis relies on the American Academy of Neurology (AAN) criteria, yet the JCV-related disease spectrum of presentations has evolved and may challenge the current diagnostic criteria [2]. An early diagnosis is of utmost importance for rapid workup and management, especially in the iatrogenic form of PML.

Case report: We describe a patient presenting with a progressive right-hand sensorimotor deficit and gait imbalance. His medical history was relevant for multiple myeloma treated with different chemotherapies lines and myelodysplastic syndrome treated with allogeneic bone marrow transplantation ten months before presentation. A brain MRI performed two weeks after the onset of symptoms showed two bilateral edematous lesions localized in the primary motor cortex characterized by FLAIR hyperintensity and low signal on susceptibility-weighted sequence (SWI) without contrast enhancement. The MRI also revealed three areas of FLAIR hyperintensities in the left centrum semiovale. A follow-up brain MRI performed one week later revealed a slight spatial progression of the lesions mentioned above. Even though an initial cerebrospinal fluid (CSF) analysis was unremarkable, with no JCV DNA copies detected, a subsequent lumbar puncture a few days later was positive; thus, the patient fulfilled the AAN criteria for definite PML.

Conclusions: Unilateral or bilateral hypointense SWI rims associated with FLAIR hyperintensity within the primary motor cortex ("motor bands") are not classically reported as a neuroradiological finding of PML. The underpinning biologics is still unrevealed, yet recent studies suggest that the motor bend sign can appear even in the presymptomatic stage of the disease as a consequence of initial iron accumulation in infected oligodendrocytes at the cortical-subcortical junction [3]. The "motor band sign" may herald an early PML onset, therefore, CSF analysis to confirm the diagnosis should be performed, and in some case repeated, even in the atypical clinical context.

Background and Objectives: Ocrelizumab is an anti-CD20 agent with beneficial effects in Relapsing Multiple Sclerosis (RMS), prevalently due to a specific B-cell depletion [1]. Other immune cells could be modulated by this treatment, thus contributing to its therapeutic efficacy [2]. Experimental evidence suggests B cell infection by Epstein-Barr virus (EBV) as one of the promoters of a dysregulated cytotoxic CD8+ T cell response and consequent central nervous system (CNS)

tissue damage [3]. To evaluate the effect of ocrelizumab on phenotype and function of CD8+ T lymphocytes in patients affected by RMS, with a focus on EBV-specific response.

Methods: RMS subjects undergoing ocrelizumab treatment were consecutively enrolled and prospectively followed-up. Blood samples were collected just before ocrelizumab initiation and after 6 and 12 months of treatment. Immune profile and cytotoxic function of CD8+ T lymphocytes were assessed; further, CD8+ T cell anti-viral proliferative response was evaluated.

Results: Forty RMS subjects (mean age 41,95 ± 5,26 years; female sex 45,45%) were enrolled. We noticed an increase of naive (p=0.004) and a decrease of effector memory (p=0,0202) CD8+ T cells, upon ocrelizumab treatment. CD8+ T cells showed a reduced expression of the activation marker CD69 (p=0,0429), the exhaustion marker PD-1 (p=0,0019) and the effector molecule granzyme K (p<0.0001) after ocrelizumab treatment; we also noticed a significant reduction of different migration molecules on CD8+ T lymphocytes, such as CCR5 (p=0,0035), CXCR6 (p=0,0408) and CD49d (p=0,0055). Functional assays revealed an impaired CD8+ T cell cytotoxic function in RMS individuals six months after ocrelizumab administration. Indeed TCR-activated CD8+ T cell presented a reduced expression of CD107a (p=0.0313), IFN-gamma (p=0.469) and granzyme B (p=0.0156) after the treatment. Concerning virus-specific CD8+ T cell expansion, we found that ocrelizumab administration determined a selective reduction of CD8+ T cell proliferation upon EBV peptides stimulation (p=0.0464), whereas no differences were observed upon cytomegalovirus peptides and Sars-CoV-2 spike antigen stimulation.

Conclusion: Our results provide novel insights on the capability of ocrelizumab to modulate CD8+ T cell activation/migration profile and cytotoxic activity. Further, the selective impact of this agent on EBV-specific CD8+ T cell proliferation suggests a possible impact of ocrelizumab in the trialogue among CD8+ T cells, EBV and B cells, central in the pathogenesis of MS.

## LONG-TERM NEUROLOGICAL SEQUELAE IN PATIENTS PRESENTING WITH ENCEPHALITIS

D. Arici[1,2], A. Pilotto[1,2], G. Pedersoli[1], V. Cristillo[1,2], I. Volonghi[1,2], F. Castelli[3], A. Padovani[1]

[1]Neurology Unit, Department of Clinical and Experimental Sciences, University of Brescia (Brescia); [2]Neurology Unit, Department of Continuity of Care and Frailty, ASST Spedali Civili Brescia Hospital (Brescia); [3]Department of Infectious and Tropical Diseases, Spedali Civili and University of Brescia (Brescia)

Background and Aims: Advances in encephalitis research in the last decade have led to a better definition and assessment to define autoimmune or infectious etiologies. A few works investigated the use of antiepileptic drugs [1,2] and cognitive outcome [3] of different subtypes of encephalitis but no large studies evaluated the difference between subtypes of encephalitis in term of long-term neurological sequalae.

Objectives: To analyze long-term clinical outcome in patients with autoimmune encephalitis (AEs), to underline whether they present a different risk of relapse and clinical sequelae/ burden when compared to other subtypes of encephalitis, and to evaluate whether CSF marker on admission could predict long-term outcomes.

Methods: The retrospective study included all patients discharged from the Neurology Unit of "Spedali Civili di Brescia" with a diagnosis of encephalitis of any kind from 01.01.2011 to 16.11.2022. Patients were evaluated by phone interview using "Neurocheck list", a 16-item questionnaire evaluating the severity and frequency of neurological symptoms after hospitalization. Encephalitis cases were classified according to standard guidelines into autoimmune (AI), infectious (IE) and of unknown origin (UE)

Results: A total of 117 patients with encephalitis were consecutively evaluated and 70 of them included in follow-up (Mean age 51,29 years; mean follow-up duration 3,28 years; AE n=32, IE n=12, UE n=26). Nine patients presented a clinical relapse resulting in hospitalization (AE n=8, (16.0%);, UE n=1 (2,13%) , p=0.001). The most common symptoms reported were memory loss (n=35; 50,00%) and depressive symptoms (n=29; 41,42%). Although mRS at dismission was significantly worse in AE compared with UE (p=0,017), no significant differences were observed neither in cognitive-behavioural domains nor in non-motor symptoms. However, AI exhibited the best long-term prognosis in terms of vertigo/dizziness and headache (9,4% AE 31,6% IE+UE; 9,4% AE 31,6% IE+UE p=0,038; p=0,038). Eventually, nor higher CSF cell count neither higher CSF proteins appeared to predict long-term clinical outcome.

Discussions: In this long-term study AE have been associated with higher risk of recurrent poussèes but possibly lower burden compared to other encephalitis. Further studies are needed in order to understand the predictors of long-term sequelae in order to identify those patients who might benefit from cognitive and behavioral training after discharge.

## THE INSIDIOUS CLINICO-RADIOLOGICAL FEATURES OF NEUROINFECTIOUS DISEASES IN EMERGENCY: TWO CLINICAL CASES

M. R. Bagnato[1], M. Di Donna[2], M. Di Ruzza[3], C. Del Bianco[3], M. Ferrante[3], T. Lo Giudice[3], E. Saggese[3], M. Plocco[3]

[1]Stroke Unit, Tor Vergata University (Roma); [2]Neurology, Tor Vergata University (Roma); [3]UTN, Spaziani Hospital (Frosinone)

Introduction: Below we present two clinical cases that highlight the great clinical and laboratory variability of neuroinfectious diseases.

Discussion: A 18-year-old girl comes to E.R. because of frontal intense headache. It had started 2 months earlier and had worsened. The primary physician concluded for sinusitis and started antibiotic therapy a week earlier. She hasn't flue. Neutrophilia is present (11.000 WBC/mm3). At neurological examination she is akathisiac, confused and

hypostenic to left limbs. Brain-CT shows two large areas of bifrontal hypointensity, surrounded by edema. The 2-months story of headache together with images may indicate tumor or infectious disease. Gd-MRI illustrates two T2-FLAIR hyperintense bifrontal expansive formations, abundant edema, with marked signal restriction in DWI/ADC. The walls show marked contrastographic impregnation with intense meningeal enhancement. Both lesions appear contiguous with frontal hemisenus, with focal erosion of the bony cortical. The frontal sinus present abundant inflammatory material. Clinical-radiological data are suspicious for brain abscess [1]. The girl is taken to the neurosurgical room for abscess drainage and begins intravenous antibiotic therapy for S. Pneumoniae. A 32 year-old man comes to the E.R. for subentrant seizures and confusional state. A month earlier, after car accident, the patient had a subdural hematoma, without cranial bone fractures and neurological symptoms. He denies epilepsy previously. He has no fever. CRP is 40 mg/dl at blood exams (cut-off < 5 mg/dl). He is uninhibited, disoriented, with incongruous speech. Presents mild hyposthenia in the left arm. Brain CT shows partially regressed right hemispheric subdural hematoma, and the appearance of a small hypodense area in the right temporal lobe of likely ischemic-compressive nature. The following day, another CT shows enlargement of the hypodense area. This rapid change let us hypotize a possible infectous disease. Lumbar puncture is normal in protein and cellular count, with negative bacteriological and virological exams. Brain MRI shows signal restriction in DWI/ADC and T1 hyperintense signal in subdural space, surrounded by vasogenic edema in right temporo-frontal white matter. Findings depose for evolution into empyema of the subdural hematoma [2]. The man underwent urgent neurosurgical surgery and broad-spectrum antibiotic therapy.

Conclusions: Both patients recovered without sequelae. These clinical cases underline the importance to consider, especially in young people, infectious etiology, even in the absence of fever, or changes on hematochemical or CSF examinations. Accurate and rapid differential diagnosis is important so that the correct antibiotic and possibly surgical treatment can be carried out to ensure an optimal prognosis.

## EXPLORING THE ROLE OF EBV IN MS PATHOGENESIS STARTING FROM EBV INTERACTOME

C. Ballerini, E. Portaccio, A. Caporali, V. Penati, M. Amato, E. De Meo

Department NEUROFARBA, Careggi University Hospital (Firenze)

Epstein-Barr virus (EBV) infection has been described as one of the main risk factors for developing multiple sclerosis (MS), and recently, new epidemiological evidence has reinforced this premise. The molecular mechanisms of this association are complex and may involve different immunological routes, however the ultimate role of EBV in the pathogenesis of MS is not fully understood. To identify MS associated genes overlapping with EBV interactome and their expression in immune cell subtypes. We obtained EBV interactome from p-HIPSTER, a structure-informed atlas of human-virus interactions, the MS associated genes from NHGRI-EBI Catalog of human genome-wide association studies and the single cell gene expression from B and T-cells, astrocytes, macrophages, granulocytes, monocytes, microglia, dendritic and natural killer cells from the Human Protein Atlas. We overlapped the lists thus obtained by using the geneOverlap R package. We observed significant overlap between EBV interactome and MS associated genes in 45 genes [odds ratio (OR): 2.1, $p<0.001$]. Among the different immune cell populations, we identified a "core" group of 15 genes resulting from the overlap between EBV interactome and MS associated genes and expressed in all immune cell type selected ($p<0.001$). This "core" included ARHGAP27, ASAP1, CD226, COPB1, JAK1, JAK2, MAPK1, MAPK3, MEF2C, MINK1, NFKB1, RPS6KB1, STAT3, TYK2, YWHAG, genes expressed not only by B and T cells, but also by glial cells and cells belonging to innate immune system. The present findings suggest a broad range immune system involvement in mediating EBV effect on MS pathogenesis. In details, our results raise the hypothesis that EBV could contribute to MS pathogenesis even through its interaction with innate immunity.

## A CASE OF SERONEGATIVE AUTOIMMUNE ENCEPHALITIS WITH A FAVOURABLE COURSE – THE IMPORTANCE OF EARLY THERAPY

F. Baroni, S. Mozzetta, P. Gallo

Department of Neuroscience, University of Padua (Padova)

Background: Autoimmune encephalitis (AE) comprise a variety of inflammatory diseases of the central nervous system (CNS) with heterogeneous clinical manifestations and etiology [1]. Differential diagnosis of AE is often challenging thus entailing a possible delay of an early and adequate therapy.

Case report: A 29 y.o. girl, with no previous relevant clinical history, presented with the sub-acute onset of fever (39°C) following a week of mild upper respiratory tract symptoms, together with confusion and speech disturbances rapidly evolving to severe non-fluent aphasia. During neurological examination emotional distress increased, oscillating between intense crying/fast breathing periods and generic unease and restlessness. No neck rigidity or ulterior symptoms were observed. Blood tests showed increased neutrophils count (15.000 cells/uL) and high CRP levels. CT and MRI scans were normal. The clinical picture evolved in a temporal status epilepticus with respiratory distress and the patient was intubated and transferred to the ICU. Cerebrospinal fluid (CSF) revealed increased cell count (1250 cells/μL, all lymphocytes) [2], and CSF-proteins (176 mg/dL), while lactic acid and glucose were in range. Microbiological work-up in serum and CSF was negative. Waiting for the results of blood and CSF tests for AE, treatment with broad-spectrum antibiotic, antiviral and antiepileptic drugs, together with high-dose steroids (Methylprednisolone 1 g per day) was immediately started. A cycle of 5 PEX (one every three days) was also performed. EEG showed fronto-temporal epileptic figures with left prevalence. CE-MRI revealed a subtle increase in intensity through the peri-optical nerve CSF, fronto-parieto-temporal sulci, as well as diffuse cortical contrast-enhancement. Full-body 18F-FDG PET-MRI showed irregular cortical glucose absorption, with a slight front-to-back gradient and hypercaptation

in the basal ganglia and amygdala, confirming encephalitic involvement. No sign of systemic pathology was found. Following treatment, improvements in clinical, EEG and CSF examination (lymphocytes: 222 cells/uL) were observed. Immunological tests and neoplastic markers in blood were negative. The patient completly recovered after three weeks. Neuropsychological evaluation as well as serial EEG were normal. The possible infectious trigger, the clinical picture, the disease course and the response to treatments allowed the diagnosis of "Probable Seronegative Autoimmune Encephalitis" [3].

Discussion: Auto-antibody-negative AE constitute a challenging diagnosis. In the presence of no better explanation for symptoms and signs, the prompt initiation of high-dose steroid and PEX is strongly recommended.

Introduction: Guillain–Barré syndrome associated with coronavirus-2-related severe acute respiratory syndrome (COV-GBS) occurs as para-, or post-infectious forms, depending on timing of disease onset. In these two forms, we aimed to compare the cerebrospinal fluid (CSF) and serum proinflammatory cytokine profiles, to evaluate differences that could possibly have co-pathogenic relevance.

Materials and Methods: We studied a retrospective cohort of 26 patients with either post-COV-GBS (n=15), with disease onset occurring >7 days after SARS-CoV-2 infection, or para-COV-GBS (n=11), with disease onset 7 days or less. TNF-α, IL-6, and IL-8 were measured in the serum with SimplePlexTM EllaTM immunoassay. In addition to the para-/post-COV-GBS patients, serum levels of these cytokines were determined in those with non-COVID-associated-GBS (NC-GBS; n=43), paucisymptomatic SARS-CoV-2 infection without GBS (COVID, n=20), and in healthy volunteers (HV; n=12). CSF cytokine levels were measured in patients with para-/post-COV-GBS, and in those with NC-GBS (n=29), or with Alzheimer's disease (AD; n=24).

Results: Serum/CSF cytokine levels did not differ in para- vs. post-COV-GBS. We found that SARS-CoV-2 infection raises the serum levels of TNF-α, IL-6 and IL-8, as well as an increase of IL-6 (in serum and CSF) and IL-8 (in CSF) in either NC-GBS or COV-GBS than controls. CSF and serum cytokine levels resulted independent one with another.

Discussion: This study shows that the para- and post-infectious forms of COVID-19-related GBS are not associated with a different CSF or serum profile of some cytokines previously described as specifically associated with SARS-CoV-2 infection.

Conclusions: The change of cytokines linked to SARS-CoV-2 in COV-GBS appears to be driven by viral infection, although it has unique characteristics in GBS as such and does not account for cases with para- or post-infectious onset.

Objective: To describe the risk and outcomes of COVID-19 infections, in patients receiving inebilizumab, an anti-CD19, B cell depleting monoclonal antibody approved for the treatment of aquaporin-4 seropositive neuromyelitis optica spectrum disorder.

Materials: Adverse reaction reports of COVID-19 infections were analyzed for participants receiving inebilizumab in the N-MOmentum clinical trial during the COVID-19 pandemic (March-November 2020), and in a post- approval safety database (data cutoff July 31, 2022) in the United States.

Methods: Demographics, comorbidities, date of COVID-19 infection, duration of treatment with inebilizumab, seriousness, hospitalization, outcomes, and action taken with the drug were summarized.

Results: In all, there were 17 reports of confirmed COVID-19 infections among inebilizumab treated NMOSD patients (women,

n=15, unknown, n=2) from March 2020-July 2022. Median (range) age was 57 (32-68) years (n=15). Among 182 patients in N-MOmentum, 2 COVID-19 infections were reported between March-November 2020, prior to vaccine availability. The incidence rate was 0.024 (E/PY). In the safety database, 15 events were reported as of July 31, 2022. Median inebilizumab exposure in the overall group was 207.5 days (range 10-2379 days, n=12) from first infusion to COVID-19 diagnosis. Of the total 17 events, 10 events were reported as serious. COVID-19 vaccination status was not known. Five patients were had pneumonia. Of 10 patients with known outcomes 6 were reported as "recovered/resolved", 2 as not recovered/resolved at the time of reporting, and 2 died: 1 patient, 62 years, in Peru, died May 2020 before vaccine availability, possible COVID pneumonia, possible renal failure, received antibiotics, hydroxychloroquine and ivermectin; and 1 patient, 32 years, in US, died Feb 2021, possibly partially vaccinated, history of obesity, deep vein thromboembolism (DVT), sickle cell trait, treated for possible COVID pneumoniae complicated by pulmonary embolism (PE) with acute cor pulmonale. Inebilizumab treatment was reported as "not changed" in 3 patients, "withdrawn" in 1 patient, and action was unknown for the rest.

Discussion: In a 28-month period, a low incidence of COVID-19 infections was reported in patients with NMOSD receiving inebilizumab in the trial and in clinical settings in the US. Due to the nature of reporting, milder COVID cases could possibly be under-reported.

Conclusion: Inebilizumab treatment was not related to a high incidence of COVID 19 infections.

Objective: To determine the impact of long-term depletion of CD19+ B-cells on childhood vaccine-generated humoral responses in participants from N-MOmentum.

Methods: Participants received INEB (300mg, intravenous) or placebo (PBO, 3:1 randomization) on Days 1 and 15 of the 28-week randomized controlled period (RCP) then every six months during the optional open label period (OLP). The median percent change from baseline (CFB) at week 156 was evaluated for measles, mumps, rubella, and varicella; all IgG mg/dL and tetanus toxoid IgG IU/mL.

Materials: Measles, mumps, rubella, and varicella IgG levels were measured in a central laboratory via sandwich enzyme-linked immunosorbent assay (ELISA). Anti-tetanus toxoid IgG levels were measured in a central laboratory via enzyme Immunoassay.

Results: The median (min, max) % CFB to week 156 for measles was 3.4 (-97.1, 204.7, n = 47) for INEB and -5.4% (-92.7, 69.2; n=10) for PBO. Mumps median (min, max) % CFB was 5.9% (-59.3, 158.2; n=47) for INEB and 11.3% (-26.1, 94.8; n=12) for PBO. Rubella median (min, max) % CFB was 3.9% (-69.2, 204.1; n=55) for INEB and -19.7% (-86.1, 111.1; n=15) for PBO. Varicella median (min, max) % CFB was 9.6% (-86.3, 280.6; n=40) for INEB and 11.5% (-25.9, 133.6; n=13) for PBO. Tetanus toxoid median (min, max) was -1.5% (-92.9, 160.7; n = 64) for INEB and -13.5 (-61.3, 45.2), n=19 for PBO. The IgG levels decreased over the study duration with a median (min, max) decrease of -13.1% (-73.2%, 192.6%) at week 52, p = 0.005 and -20.5 (-81.1, 21.8) at week 156, p = 0.0004 for INEB participants.

Discussion: Inebilizumab (INEB), a selective anti-CD19 B-cell depleting monoclonal antibody, is approved for treatment of adults with aquaporin-4 seropositive neuromyelitis optica spectrum disorder (NMOSD). A robust depletion of circulating B-cells impacting NMOSD was observed within 4 weeks of INEB treatment in the phase 2/3 N-MOmentum trial (NCT02200770) and maintained over ≥4 years with continued dosing every 6 months. This posthoc analysis assessed whether selective B-cell depletion over the long term affects antibody titers from prior measles, mumps, rubella, varicella-zoster, and tetanus toxoid vaccinations.

Conclusions: Vaccine titers did not show a meaningful reduction after 3.5 years of INEB treatment even with nearly complete peripheral B cell depletion throughout this period.

## WEST NILE NEUROINVASIVE DISEASE: A CASE SERIES FROM THE 2022 ITALIAN OUTBREAK

F. Boscain, C. Borsato, M. Volpe, E. Mampreso

Neurology, ULSS6 Euganea (Piove di Sacco-PD)

Introduction and Aims: A markedly steep increase in West Nile virus (WNV) infections was reported in Italy in summer and fall 2022; overall, 588 cases were confirmed, 295 of them presented in the neuroinvasive form and 37 deaths were notified to the Italian National Institute of Health. The province of Padova, in the Veneto region, was the most severely affected [1]. While WNV is already considered endemic in many European countries, such a significant increase in neuroinvasive infections had never been experienced in Northern Italy. Here, we would like to present 15 cases of West Nile neuroinvasive disease (WNND) managed at our institution between July and September 2022 and to report their neurological status at follow-up.

Materials and Methods: Data on 15 consecutive patients who were diagnosed with WNND were collected. All patients were > 18 years

old and they were admitted to the Neurology, Medicine and Intensive Care Units of the "Immacolata Concezione" Hospital of Piove di Sacco (Padova). All diagnoses were confirmed according to the National Surveillance Plan guidelines, released by the Italian Ministry of Health in 2019. Follow-up information was obtained through telephone interviews to patients and/or their family members by staff physicians.

Results: 11 out of 15 patients (73.3%) were diagnosed with encephalitis or meningoencephalitis, 2 (13.3%) with isolated meningitis, 1 (6.7%) with encephalitis associated with acute flaccid paralysis and 1 (6.7%) with encephalitis associated with facial diplegia; 7 patients (46.7%) required Intensive Care Unit (ICU). Most patients (12/80%) experienced one or more severe complications and 3 patients died (20%). While median pre-hospital mRS was 0, 8 patients out of 15 (53.3%) were completely dependent, bedridden or dead (mRS 4 or worse) at early follow-up; at late follow-up, this proportion reduced to 6 cases (40%). Most patients (88.9%) reported persistent symptoms at the 7-9 months follow-up, the most frequent being fatigue, persistent bilateral upper extremity tremor and unstable gait. One patient developed immuno-mediated ocular flutter.

Discussion and Conclusions: In the 2022 Italian outbreak, WNV has shown an increasing propensity to cause neuroinvasive disease with subsequent severe or fatal outcomes. Anthropogenic changes, with their effect on climate change, may play a role in this emerging public health problem. It is relevant to gain understanding of how WNV enters the central nervous system; moreover, efforts should be undertaken to prompt public health measures to reduce WNV circulation and to provide effective treatments.

## ANTI-MA2 ENCEPHALITIS TRIGGERED BY GASTRIC CANCER: CHALLENGING CURRENT DIAGNOSTIC CRITERIA FOR PARANEOPLASTIC NEUROLOGICAL SYNDROMES

A. Burini, A. Marziali, M. Valente, A. Vogrig

Clinical Neurology, Department of Medicine (DAME), University of Udine (Udine)

Objectives: To present a rare case of anti-Ma2 encephalitis in a patient with compatible clinical features but highly atypical cancer association, highlighting possible pitfalls in the updated diagnostic criteria for paraneoplastic neurological syndromes (PNS).

Case presentation: A 71-year-old man with no significant medical history presented with an abrupt onset of oscillopsia, vertical nystagmus, and gait instability. His blood examinations were unremarkable, and a brain CT was negative. An ischemic stroke was excluded with brain magnetic resonance imaging (MRI). As the patient's symptoms were getting worse, an autoimmune encephalitis was suspected, therefore serum and cerebrospinal fluid (CSF) were tested for autoantibodies. High-titer anti-Ma2 antibodies were found positive on both samples, and this finding was confirmed on another CSF sample in a referral center. While starting immunotherapy (intravenous steroid bolus followed by intravenous immunoglobulins), we screened the patient for cancer and found a gastric adenocarcinoma (pT1b N0). Total gastrectomy with lymphadenectomy was performed and the patient required no chemo- or radiotherapy. The patient's symptoms persisted (severe oscillopsia and gait ataxia), and he also manifested REM sleep behavior disorder. Treatment with cyclophosphamide as a second-line immunotherapy was initiated (600 mg/m2 monthly for 6 months). At one year from symptoms onset, minor improvement was noticed, with reduction of nystagmus and opsoclonus. His oncological follow-up is normal, and no other tumors were found.

Discussion: Anti-Ma2 encephalitis is a paraneoplastic neurological syndrome that usually affects the limbic system, diencephalon, and brainstem; less frequently, patients may show cerebellar involvement. It is mostly associated with testicular or lung tumors. [1,2] An abrupt (stroke-like onset) is uncommon, and the association with gastric cancer is extremely rare and not included in the criteria for definite anti-Ma2 paraneoplastic neurological syndrome. [3]

Conclusion: An abrupt onset and an atypical cancer association in this case highlight the potential issues in relying on the updated diagnostic criteria for clinical diagnosis, considering that they were designed for research purposes to increase specificity, with the potential to miss atypical cases.

## PROGNOSTIC RELEVANCE OF QUANTITATIVE AND LONGITUDINAL CASPR2 AND LGI1 ANTIBODY TESTING AND NEUROFILAMENT LIGHT CHAIN LEVELS IN PATIENTS WITH AUTOIMMUNE ENCEPHALITIS

P. Businaro[1,2], S. Masciocchi[2], R. Barnabei[2], S. Scaranzin[3], C. Morandi[3], P. Bini[1], L. Diamanti[1], E. Vegezzi[2], S. Bernini[4], P. Barone[5], C. Arbasino[6], M. Risi[7], S. Cenciarelli[8], E. Marchioni[1], D. Franciotta[3], M. Gastaldi[3]

[1]Neuroncology Unit, IRCCS Mondino Foundation (Pavia); [2]Department of Brain and Behavioral Sciences, University of Pavia (Pavia); [3]Neuroimmunology Laboratory, IRCCS Mondino Foundation (Pavia); [4]Dementia Research Center, IRCCS Mondino Foundation (Pavia); [5]Department of Medicine and Surgery, Neuroscience Section, University of Salerno (Salerno); [6]Department of Medical Area, Neurology, ASST Pavia (Pavia); [7]Department of Advanced Medical and Surgical Sciences, University of Campania 'Luigi Vanvitelli' (Napoli); [8]Department of Neurology and Stroke Unit, USL Umbria 1, Gubbio and Città di Castello Hospital (Perugia)

Introduction and Objective: Autoantibodies against leucine-rich glioma-inactivated 1 (LGI1) and anti-contactin-associated protein-like 2 (CASPR2) are diagnostic and pathogenic markers of autoimmune encephalitis (AE). Increased neurofilament light chain levels indicate axonal damage. We aimed to study the relevance of longitudinal anti-LGI1/CASPR2 titres and neurofilament light chain levels as biomarkers in autoimmune encephalitis.

Material and Methods: Retrospective cohort study including patients with anti-LGI1/CASPR2 definite AE, and at least one available longitudinal sample > 60 days from onset. Titers were measured with endpoint dilution using a live cell-based assay. 28/142 samples (20%) were classified as from "acute phase", 15 (10%) as "postacute" and 99 (70%) as "remission". Neurofilament light chain levels (Nfl) were measured on 82 serum samples (51 acquired during "remission"). Outcome was measured with modified Rankin Scale (mRS) and with Clinical Assessment Scale in Autoimmune Encephalitis (CASE).

Results: We enrolled 23 patients (anti-CASPR2=7; LGI1=15, double positive=1) and 10 were females. Median age at diagnosis was 63 (range 45-82). Manifestations at onset included seizures (22/23), psychiatric symptoms (15/23) and cognitive dysfunction (14/23). Median follow-up was 37 months (range 3-64). 8/23 patients had relapses. Acute phase samples had higher median titres (1:8000, range 20-102400) compared to post-acute (1:4000, range 500-51200) and remission (1:800, range 0-51200) samples (p<0.001), even analyzing separately anti-LGI1 (p<0.001) and CASPR2 (p=0.007) sera. Titres did not correlate with disease severity at onset/follow-up. Relapses always occurred with a positive sample (n=8), and in 3/5 patients with pre-relapse samples available titres increased at relapse. Seven patients became seronegative (2 with anti-CASPR2, 4 after rituximab) after a median time from diagnosis of 12 months (range 5-58), and none experienced post-seroconversion relapses. Median AE Nfl levels (31,5, range 5,4-164) were higher than healthy controls (15,4, range 5,4-29,3) (p<0.001) and Nfl levels at onset (45,95, range 5,4-109) were significantly higher (p=0,01) than Nfl levels measured at 10 months follow-up (25,8, range 5,4-60,6).

Conclusion: Anti-CASPR2/LGI1 titres correlate with disease phase and decrease over time. Seroconversion-to-negative might associate with reduced relapse risk. Nfl levels were significantly higher than controls and correlate with disease phase. Our preliminary data warrant further study evaluating antibody titres and Nfl as biomarkers in LGI1 and CASPR2 encephalitis.

## PREDICTORS AND CLINICAL CHARACTERISTICS OF RELAPSES IN LGI1-ANTIBODY ENCEPHALITIS

L. Campetella[1], A. Farina[1], M. Villagran-Garcia[1], M. Villard[1], M. Benaiteau[1], N. Timestit[2], A. Vogrig[3], G. Picard[1], V. Rogemond[1], D. Psimaras[4], M. Rafiq[5], E. Chanson[6], C. Marchal[7], D. Goncalves[8], B. Joubert[1], J. Honnorat[1], S. Muniz-Castrillo[9]

[1]French Reference Center for Paraneoplastic Neurological Syndromes and Autoimmune Encephalitis, Hospices Civils de Lyon (Lyon-F); [2]Department of Biostatistics, Hospices Civils de Lyon (Lyon-F); [3]Clinical Neurology, Santa Maria Della Misericordia University Hospital (Udine); [4]Neurology Department 2, Mazarin - Hôpitaux Universitaires La Pitié Salpêtrière-Charles Foix, APHP (Paris-F); [5]Neurology Department, Hôpital Pierre Paul Riquet, CHU de Toulouse (Toulouse-F); [6]Neurology Department, Centre Hospitalier Universitaire Gabriel Montpied (Clermont-Ferrand-F); [7]Neurology Department, Centre Hospitalier Universitaire de Bordeaux (Bordeaux-F); [8]Immunology Department, Hôpital Lyon Sud, Hospices Civils de Lyon (Lyon-F); [9]Stanford Center for Sleep Sciences and Medicine, Stanford University (Palo Alto-USA)

Objectives: Relapses occur in 15-25% of patients with leucine-rich glioma-inactivated 1 antibody autoimmune encephalitis (LGI1-Ab encephalitis) and may cause additional disability. Herein, we aim to clinically characterize the relapses and identify factors predicting their appearance.

Materials: Retrospective chart review of patients with LGI1-Ab encephalitis diagnosed at our center between 2005 and 2022. Relapse was defined as worsening of previous or appearance of new symptoms after at least 3 months of clinical stabilization. Additionally, patients with LGI1-Ab encephalitis without relapses were identified and included as a control group.

Methods: Univariate analysis was performed to compare the relapsing patients with the control group and the initial encephalitis episode with the relapse. A Cox proportional hazards regression model was built to identify potential predictors of relapse.

Results: Among 216 patients, 30 (14%) experienced a total of 33 relapses. Median time to first relapse was 23.9 months (range 4.9-110.1). During relapses, clinical manifestations included memory impairment (70%), seizures (45%), psychiatric/behavioral symptoms (30%), and faciobrachial dystonic seizures (30%). Brain MRI was abnormal in 16/26 (62%), CSF was inflammatory in 11/25 (44%), LGI1-Abs positive in 16/23 sera (70%) and in 11/23 CSF (48%). Compared to the initial episode, relapses manifested with fewer symptoms (p<0.001) and lower maximal modified Rankin Scale (mRS) score (p=0.001). However, median mRS at last follow-up after relapse was significantly higher than after the initial episode (2 versus 1, p=0.005). Patients with relapses did not differ in their initial clinical and paraclinical features from 85 patients without relapses. Nevertheless, residual cognitive dysfunction after the initial episode was significantly associated with an increased risk of relapse (hazard ratio = 9.5, 95% CI 1.7-182.0, p=0.038).

Discussion: Relapses in LGI1-Ab patients present with fewer and milder symptoms compared to the initial encephalitis episode, and thus may be subtle and difficult to recognize. We observed herein that persisting cognitive dysfunction after the initial episode was a risk factor for relapse, and consequently patients with cognitive sequelae should be closely monitored. Additionally, mRS scores were significantly higher after the relapse than after the initial episode, implying that some patients develop additional disability after the relapse. Thus, preventing relapse occurrence would be of the utmost importance to improve patient outcomes.

Conclusions: Relapses may occur years after the initial encephalitis episode, are usually milder but cause additional disability. Residual cognitive dysfunction after the initial episode increases the risk of future relapses.

Background and Objectives: Glial fibrillary acid protein (GFAP) and neurofilament light chain (NfL) serum levels are increased in patients with aquaporin-4 antibodies positive NMOSD (AQP4+NMOSD) during clinical attacks suggesting a concomitant axonal and glial damage. [1] However, there are contradictory results in double seronegative NMOSD (DS-NMOSD). [1,2] The aim of this study is to characterise the neuronal, axonal, and glial damage of DS-NMOSD, in comparison with AQP4+NMOSD.

Methods: Patients with DS-NMOSD and age-matched AQP4+NMOSD with available serum samples obtained within 3 months from onset/relapse were retrospectively enrolled. Clinical and radiological data were collected. Serum NfL, GFAP, Tau and UCH-L1 levels were determined using an ultrasensitive paramagnetic bead-based enzyme-linked immunosorbent assay (SIMOA). Statistical analysis was performed using non-parametric tests and Receiver Operating Characteristic (ROC) curve analysis.

Results: We included 25 AQP4+NMOSD patients and 26 DS-NMOSD. Median age at disease onset was 35.1 years [IQR 27.4-48] in AQP4+NMOSD and 39 years [24.1-50.5] in DS-NMOSD(p=0.611). Female sex was more common in both groups (84% vs. 61.5%, p=0.072). The most common syndromes at sampling in both AQP4+NMOSD and DS-NMOSD were myelitis (56% vs. 38.5%) and optic neuritis (34.6% vs 32%, p=0.716). Median EDSS at sampling of the whole group was 3.5 [IQR 2.5-7.0] and was similar in the two groups(p=0.974). Serum GFAP, Tau and UCH-L1 levels were higher in AQP4+NMOSD patients compared to DS-NMOSD (median 308.3 vs. 103.4 pg/mL p=0.001; median 1.2 vs. 0.5 pg/mL, p=0.001; median 61.4 vs 35 pg/mL, p=0.006, respectively). The ROC curve analysis showed that GFAP, Tau and UCH-L1, but not NfL values were able to discriminate between AQP4+ and DS-NSMOSD (area under the curve -AUC- tau:0.782, p=0.001, AUC GFAP:0.762, p=0.001, AUC UCH-L1:0.723, p=0.006).

Conclusions: Serum GFAP, Tau, and UCH-L1 levels discriminate between AQP4+NMOSD and DS-NMOSD. The different biomarkers profile of AQP4+NMOSD vs. DS-NMOSD provides useful data to improve our understanding of this disease.

Annunziata" University Hospital (Chieti); [25]Department of Neurology, AULSS 6 Euganea Cittadella Hospital (Padova); [26]Department of Neurology, Stroke Unit, San Maurizio Hospital (Bolzano); [27]Neurology Unit, AULSS8 Berica (Vicenza); [28]Neuroimmunology Group, Paediatric Research Institute (Padova)

Background and Aim of the study: The recently published MOG antibody-associated disease (MOGAD) diagnostic criteria are based on the combination of peculiar clinical/radiological features and MOG-Abs positivity. The international experts panel designed the criteria to help clinicians in the correct interpretation of MOG-Abs results to guide the diagnostic process. We provide the first validation of the MOGAD diagnostic criteria in an Italian cohort of patients with MOG-Abs positivity.

Methods: Patients with serum and/or CSF MOG-Abs positivity were retrospectively identified from 29 Italian centers. Clinical data were collected by referring physicians in a dedicated database and the 2023 MOGAD diagnostic criteria were applied. Four groups were identified: true positive (TP: MOGAD criteria fulfilled, final diagnosis of MOGAD provided by the enrolling centre), true negative (TN: MOGAD criteria not fulfilled, final diagnosis different from MOGAD), false positive (FP: MOGAD criteria fulfilled, final diagnosis different from MOGAD) and false negative (FN: MOGAD criteria not fulfilled, final diagnosis of MOGAD confirmed). Sensitivity (ratio TP/TP+FN) and specificity (ratio TN/TN+FP) were calculated. False negative and

false positive cases were revised by two neuroimmunologists blinded to the provided final diagnosis.

Results: 155 patients were included, mean age at onset was 40.5 years (SD 16.7), and 89 (57.4%) were females. Live-CBA was the most common assay used for MOG-Abs detection (n=135, 86.8% of cases). CSF was tested in 63 (40.6%) of cases. Overall, 66 (42.8% of cases) had serum low positive titers, 66 (42.8%) serum high positive titers, 13 (8.6%) had an unknown serum positive titer, while 10 (5.8%) were CSF only positive for MOG-Abs. Final diagnoses were: MOGAD in 139 patients (85.2%), MS in 9 (5.8%), other monophasic inflammatory diseases in 5 (5.8%), and other recurrent inflammatory diseases in 2 (1.3%). After the application of 2023 MOGAD diagnostic criteria, the patients were grouped as: TP, 126 (81.3%); FP, 6 (3.9%); FN, 13 (8.4%); and TN, 10 (6.5%). MOGAD criteria had a sensitivity of 90.6% [CI 0.86-0.95] and a specificity of 62.5% [CI 0.39-0.86].

Conclusion: The 2023 MOGAD diagnostic criteria have an overall good sensitivity but only moderate specificity for MOGAD. This first validation of MOGAD diagnostic criteria supports their utility in the clinical practice to identify MOGAD cases, but also underlines the relevant role of clinicians in selecting suggestive cases, to increase pre-test probability and reduce the risk of misdiagnosis.

## HEARING HOOFBEATS, THINKING ZEBRAS: UNEXPECTED IGG4-RELATED PACHYMENINGITIS IN AN ELDERLY MAN

A. Cascianelli[1], F. Ceriello[1], D. Chiffi[2], L. Leonardi[1], L. Fionda[1], P. Tisei[1], M. Salvetti[1]

[1]Department of Neuroscience, Mental Health and Sensory Organs (NESMOS), Sapienza University (Roma); [2]Department of Human Neuroscience, Sapienza University (Roma)

Introduction/Objectives: IgG4-related disease (IgG4-RD) is a fibro-inflammatory disorder with a synchronous or metachronous multi-organ involvement and three histopathological hallmarks: lymphoplasmacytic IgG4 plasma-cells infiltration, storiform fibrosis and obliterative phlebitis. The involvement of the central nervous system by the disease is rare but increasingly recognized, and it consists of focal/diffuse hypertrophic pachymeningitis (HP) of the vault/base of the brain or of the spinal cord, or hypophysitis.

Materials/Methods/Results: We present a case of 82-year-old caucasian man, with a history of high blood pressure, diabetes mellitus, ischemic heart disease, autoimmune pancreatitis, left parietal meningioma and acute left hemispheric post-traumatic subdural hematoma. The patient referred to our Clinic in December 2022 for an acute onset of focal to bilateral tonic-clonic seizures and sub-acute onset of cognitive decline. The clinical examination, after seizures control, consisted of an altered mental status and hemiparesis of the right limbs. A CT scan was negative for acute ischemic/hemorrhagic lesions an electroencephalogram (EEG) showed a slowing of background activity, theta and sharp waves in the centro-temporal regions. The hemiparesis resolved within 1 day (Todd's paralysis). The brain-MRI showed an extra-axial mass at the left parietal convexity with signs of active inflammation of the left parieto-temporal dura mater, compatible with pachymeningitis with leptomeningeal and cortical involvement. Lumbar puncture, blood tests for infectious/immunological diseases and meningeal biopsy of the lesion were therefore performed. A comprehensive immunologic and infective assessment (including tuberculosis and treponema screening) performed on serum and CSF was unremarkable; IgG4 plasma levels were normal (63,8 mg/dL), IgE were elevated (231 kU/I). A meningeal biopsy was performed showing storiform fibrosis and perivascular inflammatory infiltrate, rich in IgG4+ plasma-cells. Immunostaining showed more than 10 IgG4+ plasma cells per HPF with a IgG4/IgG ratio > than 40%. Staining for pathogens was negative (Gram, Gomori-Grocott, Ziehl stains). Treatment with oral steroids was started with clinical and radiological improvement.

Discussion/Conclusions: Although the known left parietal meningioma, the atypical course and the finding of inflamed pachymeninges at brain MRI led to the suspicion of an IgG4-related pachymeningitis, then confirmed by histopathology. This treatable condition has been rarely described as a tumor-like mass, mimicking a meningioma. Despite the confounding factors such as a known lesion and history of subdural hematoma, the meningeal biopsy was clarifying, and a diagnosis of IgG4-related disease was made. Histologic confirmation by meningeal biopsy is required for correct diagnosis and appropriate therapy setting, especially in the presence of possible mimics, confounding comorbidities, and non-diriment laboratory investigations.

## A CASE OF CAVERNOUS SINUS SYNDROME DUE TO SPHENOIDAL SINUS MUCORMYCOSIS

M. Cervigni, M. Angeletti, F. Cancellieri, C. Di Felice, S. Malatini, A. Riva, N. Zannotti, M. Bartolini, M. Silvestrini, G. Viticchi

Neurological Clinic, Marche Polytechnic University (Ancona)

Introduction: Mucormycosis ("the black fungus") is a rare, opportunistic fungal infection, reported usually in immunocompromised patients with underlying diseases such as diabetes mellitus, organ transplant or with extensive use of corticosteroids. Extension of fungal infection to cavernous sinus leads to cavernous sinus syndrome (CSS), defined as the involvement of two or more among Third, Fourth, Fifth or Sixth cranial nerves or one with radiological involvement of cavernous sinus. Patients affected may present headache, ptosis, proptosis, ophtalmoplegia, orbital pain, diplopia, visual loss, nasal discharge, and fever. Multidisciplinary competences are necessary to recognize it and perform optimal medical e surgical treatment.

Case report: We present a case of a 59-year-old man with persistent headache, non-responsive to FANS since several days, without any neurological signs at the first clinical examination at Emergency Department. In past medical history he was affected by hypertension, dyslipidemia and ischemic cardiopathy. After two days, he developed acute and progressive ptosis, proptosis, ophthalmoplegia, fever, photophobia and visual loss in the right eye with radiologically documented bilateral purulent collection in sphenoid sinus and thrombosis of right cavernous sinus. He was treated in emergency with sphenoidal sinus endoscopic debridement; based on histological results from a surgical resection, we started intravenous amphotericin B, later switched to oral isavuconazonium for elapsing acute kidney injury. Excavated pulmonary thickenings as septic likelihood type were detected in chest CT, while cerebral angiography and echocardiography did not show

respectively mycotic aneurism and endocardial vegetation. For the cavernous sinus thrombosis, he started anticoagulation therapy. After 3 months he had complete clinical and radiological recovery, so he stopped antifungal drug and continued only with anticoagulant therapy.

Discussion: According to clinical symptoms and radiological signs, we made a diagnosis of CSS due to sphenoidal sinus mucormycosis in a patient without risk factors. He showed a complete resolution, probably for his immunocompetence and prompt combination therapy. In literature most patients have a poor prognosis with complete visual loss, eye resection or death by septic state. Recently, a growing number of cases was detected probably due to the extensive use of corticosteroids in patients with Sars-Cov2 infection, especially in developing countries.
Conclusions: Acute and progressive onset of unilateral ocular symptoms needs to exclude CSS and underlying fungal infection, in particular if patients may have risk factor for immunocompromise state, because prompt treatment allows preserving life and vision and sparing mutilating surgeries.

## SINGLE FIBER EMG IN THE DIAGNOSTIC WORKUP OF DIPLOPIA AND PTOSIS

S. Cornacchini[1], M. Verza[1], M. Bastianelli[2], A. Cassardo[2], C. Mei[2], A. Barilaro[3], L. Massacesi[1], A. Grippo[2], V. Damato[1]

Diplopia and ptosis are common neuro-ophthalmologic signs. Yet identifying the specific aetiology can be challenging due to the different potential causes. In this prospective study, we evaluated the reliability of the stimulated single fiber electromyography (SFEMG) in supporting the diagnosis of myasthenia gravis (MG) presenting with diplopia and ptosis. We included 66 patients who presented with diplopia (n=27), ptosis (n=13), or both (n=26), and underwent SFEMG. Patients received a comprehensive diagnostic workup involving detailed history investigation, physical examination, orbital and brain imaging, thyroid function and antibody screening, orthoptic evaluation, ice pack test (when applicable) and repetitive nerve stimulation test (RNS). SFEMG yielded positive results in 23 of 66 (34.8%) patients of the cohort. Among the patients diagnosed with MG (n=29), SFEMG showed a sensitivity of 72.4% (95% CI: 0.55 – 0.86) and specificity of 94.6% (95% CI: 0.84 – 0.99) with a positive predictive value of 91.3% (95% CI: 0.76 – 0.99) and a negative predictive value of 81.4% (95% CI: 0.68 – 0.91). Notably, SFEMG was positive in 7 seronegative MG cases and in 11 cases with negative RNS. In the non-MG group (37/66 patients), SFEMG was negative in the majority (35 patients, 94.6%) of cases, further supporting its value in ruling out MG. A relevant proportion (17/37) of these cases remained undiagnosed. Our findings suggest that SFEMG is a valuable tool in the diagnostic workup of diplopia and ptosis and in the differential diagnosis of MG, especially in seronegative MG cases and in those with negative RNS results.

## EXTENSIVE SPINAL HYPERTROPHIC PACHYMENINGITIS IN IGG4-RELATED DISEASE

V. Costa[1,2], L. Argenti[1], E. Pedemonte[2], A. Murialdo[2], G. Zocchi[2], I. Fasce[2], M. Del Sette[2], G. Novi[2]

[1]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa (Genova); [2]IRCSS Ospedale Policlinico San Martino (Genova)

Objectives: We describe a 66-year-old woman previously healthy with a two-month history of neck stiffness, limbs dysesthesias and progressive weakness to inability to walk, diagnosed as an isolated extensive spinal hypertrophic pachymeningitis (HP) due to IgG4-related disease (IgG4-RD).

Materials and Method: Hypertrophic pachymeningitis (HP) is a rare disease-causing thickening of the dura mater and it is often a neurological manifestation of rheumatologic, infectious, and neoplastic diseases. Immunoglobulin G-4-related disease (IgG4-RD) is a systemic inflammatory disorder that results in fibrous inflammation of virtually any organ. In some cases, HP has emerged as a rare presentation of IgG4-RD.

Results: Upon admission, neurological examination showed: neck stiffness, upper limbs muscle weakness (medical research council, MRC 4) hands paresthesia, severe lower limbs muscle weakness (MRC 2) with diffuse sensory impairment starting from a mid-abdominal level; bilateral Babinski sign and lower limbs hyperreflexia was also noted. Cervicothoracic-MRI disclosed almost complete obliteration of cerebrospinal fluid signal in the entire spinal tract, with marked contrast enhancement of the meningeal envelopes, signal alteration in the cervical-thoracic spinal cord due to compressive myelopathy. A complete workup disclosed high serum concentration of IgG4, total body CT scan and FDG-PET showed signs of subclinical aortitis. Meningeal biopsy revealed lymphoplasmacytic infiltrate, with high-level-per-field plasma-cells and an IgG4+/IgG+ ratio >40%, confirming HP due to IgG4-RD. Our patient was treated with high-doses steroids, followed by rituximab (two-1g infusions 15 days apart), with clinical and radiological improvement. At the 1-year follow up the patient walked with minimal assistance, spinal cord MRI showed dramatic improvement and FDG-PET showed no meningeal nor aortic hypermetabolism.

Discussion: Only few cases of HP with isolated spinal involvement due to IgG4-RD have been described, however, such an extensive spinal involvement is quite unique. Spinal cord compression due to IgG4-RD is a very rare cause of myelopathy and may progress rapidly, leading to severe and irreversible neurological deficits, therefore early recognition is of utmost importance. HP diagnosis due to IgG4-RD could be challenging because clinical features are non-specific. Medical assessment should include comprehensive evaluation to exclude differential diagnosis and histopathological exam represents the diagnostic gold standard.

Conclusion: In patients with "high-risk" manifestation of IgG4-RD, such as neural involvement, aggressive immunosuppression must be used as first-line treatment: in particular, rituximab, a B-cells depleting

monoclonal antibody, has shown to induce long-lasting disease remission. In our case, rituximab has stopped disease progression, in addition to dramatically changing the patient clinical condition.

Objectives: Encephalitis is defined by the presence of an inflammatory process of the brain in association with clinical evidence of neurologic dysfunction. The diagnosis and treatment are still challenging and prognostic studies are currently lacking. We aimed to investigate the predictive factors associated with poor outcomes in a large spectrum of subjects with different subtypes of encephalitis.

Methods: In this observational multicenter study, 216 patients diagnosed with 4 different types of encephalitis were recruited. The four groups were compared through ANOVA and k2 test, were appropriate. Linear and logistic regression models explored predictors of mortality and worse progression of the disease.

Results: The different types of encephalitis showed several clinical and laboratory differences. Linear regression analysis confirmed lymphocytes at admission (p=0.025) and CSF cells count (p=0.035) as the strongest predictive factors of poor outcomes, independently from demographic, clinical and laboratory characteristics. Logistic regression analysis identified apathy (p=0.018) as the most significant predictor of mortality, adjusting for demographic features and neurologic/systemic symptoms.

Discussion and Conclusion: In patients with encephalitis, CSF cells count and blood lymphocytes value appear to indicate worse disability at discharge. Apathy, on the other hand, is the strongest predictor of mortality, independently from the diagnosis. Further prospective studies are needed to confirm our findings, to identify patients at high risk of mortality and poor outcomes, and to develop specific strategies for prognostic improvement.

## CASPR2 ANTIBODY–ASSOCIATED DISEASE: THE IMPORTANCE OF KNOWING TYPICAL CLINICAL PATTERNS OF A RARE DISEASE

F. D'Ammora[1], V. Todisco[1], L. Lavorgna[1], M. Gastaldi[2], D. Franciotta[2], G. Tedeschi[1], A. Bisecco[1]

[1]Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli" (Napoli); [2]Neuroimmunology Laboratory and Neuroimmunology Research Unit, IRCCS Mondino Foundation National Neurological Institute (Pavia)

Background and Aims: A 41-years-old man was admitted to our Neurology Unit for the onset of pain in the lower limb two years before, stocking and gloves burning paresthesia, hyperidrosis and insomnia. After few months the patients experienced onset of cramps, subcutaneous vermicular movements, tremor, hypertension, tachycardia, syncopal episodes, akathisia, anxiety, behavioral changes, hyporexia and weight loss. The patient has consulted many specialists over time without a precise diagnostic framework and underwent various treatment (including SSRI, opioids, antiepileptic drugs) without clinical response.

Methods: We performed brain and spinal cord MRI with contrast, routine blood tests, extended autoimmune, infectious and hormonal screening (including urinary metanephrines), autoantibodies vs intracellular and surface neuronal antigens, electroencephalography, electroneuromyography, and total body PET-CT.

Results: Blood and urinary exams performed showed: hyponatremia, increase of renin and urinary metanephrines; electroneuromyography showed signs of neuromyotonia in all examined muscles. Surface neuronal antigens antibodies screening were positive for anti-Contactin-associated protein-like 2 (Caspr2) and anti- leucine-rich glioma-inactivated1 (LGI1) Abs. Total body PET-CT sowed normal findings.

Discussion: The association between neuromyotonia, autonomic dysfunction and central nervous system involvement in association with the relief of anti-Caspr2 and anti-LGI1 Abs supported the final diagnosis of Morvan Syndrome. Nine plasmapheresis cycles were administrated with partial clinical improvement. Afterwards, intravenous high dose steroid therapy was administrated, with improvement of hyporexia, and hyperidrosis, but persisted cramps, fasciculations, and myokymia. At one month-follow up we retest the patient for anti-CASPR and anti-LGI1 Abs, still positive. For this reason, the patient underwent second line treatment (rituximab).

Conclusion: The presence of antibodies to VGKC is reported in patients with acquired neuromyotonia (Isaac Syndrome), Morvan syndrome, and limbic encephalitis. Precisely, antibodies are not directed against the VGKC subunits but to associated proteins. Two of these proteins are LGI1 and Caspr2. In less 30% of cases, this Abs are associated with neoplasms, that in 50% of cases of Caspr2 positivity is thymoma, and in 10% of LGI1 positivity is neuroendocrine neoplasm. For the heterogeneity of their symptoms, these syndromes are often undiagnosed or diagnosed later. The knowledge of the core symptoms of these syndromes will improve their early recognition, that is important because immunotherapy and tumor treatment (if needed) are often effective.

## ORBITAL INFLAMMATORY DISEASE IN A PATIENT WITH PSORIATIC ARTHRITIS TREATED WITH ADALIMUMAB: A PARADOXICAL ADVERSE EVENT?

F. D'Anna, A. Tessitore[2], M. Cirillo, G. Tedeschi, A. Bisecco

Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli" (Napoli)

Background and Aims: A 71-year-old woman with a diagnosis of psoriatic arthritis since 2019 under treatment with Methotrexate and Adalimumab was admitted to our Neurology Unit for an acute/sub-acute onset of ocular pain, swelling, conjunctival injection and progressive visual loss in right eye. The patient reported also a concomitant onset of right-sided pulsating headache of moderate intensity (NRS 6/10) responsive to common NSAIDs. The neurological examination showed, in right eye: amaurosis, proptosis, exotropia and partial ophthalmoplegia, miosis.

Materials and Methods: Diagnostic protocol included brain and orbital MRI with Gadolinium, routine blood tests and an extended autoimmune (including IgG4), infectious, hormonal, paraneoplastic screening.

Results: MRI showed enlargement and increased T2 -signal with contrast enhancement within the right inferior rectus muscle, mildly in the right lateral and medial rectus muscles without tendon involvement; inhomogeneous signal of the right orbital adipose tissue at the orbital apex with congestion of perivenous and vascular structures of the optic nerve. Other tests were negative.

Discussion: The abovementioned findings supported the diagnosis of Orbital Inflammatory Disease (OID). Steroid therapy with methylprednisolone 1gr for 10 days was administered with slowly taper in 3 months; after two weeks, she has a clinically important improvement in extraocular motility and a minor improvement in visual acuity. The etiology and pathogenesis of IOIS are currently unknown, but the pathogenesis can be idiopathic, post-infectious/immunization and associated with autoimmune disease or systemic disease (i.e. sarcoidosis, systemic lupus erythematosus, hyper-IgG4 related disease). Nonetheless, anti-TNF-α agents (such as adalimumab), despite being effective management options in various inflammatory and autoimmune diseases, have been associated with new onset or exacerbation of autoimmune diseases (uveitis, optic neuritis/neuropathy, scleritis, demyelinating diseases and others).

Conclusions: In the present case report, the onset of Orbital Inflammatory Disease in a patient with psoriatic arthritis under treatment with Adalimumab suggest the possibility of a link between the administration of anti-TNF-α agents and the onset of this autoimmune condition. Physicians using these medications should be aware of this serious vision-threatening paradoxical adverse events, in order to recognize them early and establish an appropriate treatment.

## FACIAL DIPLEGIA: A RARE VARIANT OF GUILLAN BARRE' SYNDROME FOLLOWING ADENOVIRUS VECTOR COVID 19 VACCINES

B. D'Arco[1], A. Vogrig[2]

[1]AOU San Giovanni di Dio e Ruggi D'Aragona, University of Salerno (Salerno); [2]Neurological Clinic, University of Udine (Udine)

Introduction: Guillain-Barrè syndrome (GBS) is an acute immune-mediated neuropathy, possibly triggered by a recent infection or vaccination, and driven by an immune attack targeting the peripheral nervous system. Although an increasing number of case reports of Guillan Barrè Syndrome (GBS) in patients receiving COVID-19 vaccination have been reported both during the pre-clinical phase and after large-scale authorities' approval [1)] it's noteworthy the emerged potential association between adenovirus-based COVID-19 vaccines and a GBS specific phenotype with facial diplegia [2].

Objective: We herein report 4 cases of GBS with facial diplegia occurring 7 to 21 days after administration of ChAdOx1-nCoV-19 vaccination.
Methods: Patients underwent a multidimensional assessment including neurological, neurophysiological and laboratoristic evaluation, with a longitudinal follow up.

Results: Four patients developed facial diplegia within the 6-week period after ChAdOx1-nCoV-19 vaccination (range 7-21 days). In all cases, electrophysiological study revealed multifocal demyelinating sensorimotor polyradiculoneuropathy consistent with the diagnosis of GBS, AIDP variant; lumbar puncture revealed albumin-cytological dissociation; screening for other infectious, autoimmune, metabolic, or systemic diseases was unremarkable except for serum positivity to GM3(IgM) antibody in one patient. Autoantibody characterization is on going.

Discussion: The link between GBS atypical variant with facial diplegia and ChAdOx1-nCoV-19 vaccination is suggested by the temporal association between vaccine administration and clinical manifestations and by the lack of other known factors able to trigger GBS. Besides, the specific phenotype of this rare neurological condition supports a causal relationship between such exposure and this syndrome. An antibody-mediated autoimmune mechanisms may be relevant in the pathogenesis of GBS with facial diplegia after adenovector vaccines.

Conclusions: Future research should aim to determine the predisposing host factors and biological mechanisms underlying this association and the high frequency of facial nerve involvement.

## CHARACTERISTICS OF PATIENTS WITH AN ELEVATED KAPPA INDEX AND ABSENT CEREBROSPINAL FLUID IGG OLIGOCLONAL BANDS

G. De Napoli[1], K. Smolik[1], R. Bedin[1], P. Natali[2], M. Cardi[1], D. Franciotta[3], A. Simone[4], P. Immovilli[5], M. Santangelo[4], M. Gastaldi[6], F. Vitetta[7], P. Sola[7], D. Ferraro[7]

[1]Department of Biomedical, Metabolic and Neurosciences, University of Modena and Reggio Emilia (Modena); [2]Department of Laboratory Medicine, Azienda Ospedaliero-Universitaria and Azienda Unità Sanitaria Locale (Modena); [3]Autoimmunology Laboratory, IRCCS Ospedale Policlinico San Martino (Genova); [4]Neurology Unit, Ramazzini Hospital (Carpi-MO); [5]Neurology Unit, G. da Da Saliceto Hospital (Piacenza); [6]Neuroimmunology Laboratory, IRCCS Mondino Foundation (Pavia); [7]Neurology Unit, Azienda Ospedaliero-Universitaria di Modena (Modena)

Objective: The kappa index (cerebrospinal fluid -CSF/serum kappa free light chains -KFLC- divided by the CSF/serum albumin ratio) is a marker of intrathecal immunoglobulin synthesis (IS). Contrarily to CSF IgG oligoclonal bands (OCB), the current gold standard for IS detection, KFLC are not specific for the IgG isotype, as they also include contributions by IgM, IgA, IgD and IgE. Aim of the study was to assess the intrathecal IgM/IgA production in consecutive patients with an elevated kappa index (≥5.8, hereafter named kappa+) and absent CSF IgG OCB (OCB-), and to ascertain their diagnoses.

Methods: IgM/IgA IS was determined using quantitative methods (Optilite turbidimetric analyser) and by calculating the IgM/A index (CSF/serum IgM/A divided by the CSF/serum albumin ratio). Intrathecal IgM OCB were sought using isoelectric focusing. Control groups were randomly chosen OCB+/kappa+ and OCB-/kappa- patients. Diagnoses were classified as Multiple Sclerosis (MS), other inflammatory central nervous system (CNS) diseases (INFL), infectious CNS diseases (INFECT) and miscellaneous non-inflammatory disorders (OTHER).

Results: Of 119 patients (58M, 61F), 69 were OCB-/kappa+, 24 OCB-/kappa- and 26 OCB+/kappa+. Mean kappa index was 16.37, 1.33 and 116.67, respectively. OCB-/kappa+ were mostly patients with MS (nr=30), followed by INFECT (nr=16); OCB+/kappa+ were mostly MS/INFL (20/26) and OCB-/kappa- OTHER (15/24). Median IgM index and the frequency of CSF IgM OCB did not differ between the three groups, while IgA index was higher in the OCB-/kappa+ group (0.32) compared to the OCB-/kappa- group (0.25) (p=0.008). The vast majority of INFECT (16/18) belonged to the OCB-/kappa+ group. Median IgM/A indexes were higher (0.34/0.36) in INFECT (nr=18) compared to MS (0.06/0.27) (nr=49), INFL (0.08/0.3) (nr=19) and OTHER (0.09/0.27) (nr=33) (p<0.001/p=0.004). IgM/A indexes were greater than the cut-off (of 0.1 and 0.4, respectively) in a greater proportion of INFECT (17/18 for IgM and 6/18 for IgA) compared to the remaining patients (41/101 for IgM and 15/101 for IgA)(p<0.001). CSF IgM OCB were more frequent in INFECT (10/18) compared to the remaining patients (19/101) (p=0.001).

Conclusion: OCB-/kappa+ patients mostly had a diagnosis of MS or of an infectious CNS disease and showed an intrathecal IgM or IgA synthesis in 54% of cases. Increased IgM/IgA indexes and CSF IgM OCB were more frequent in patients with infectious CNS diseases compared to the remaining patients.

## A RETROSPECTIVE MULTICENTER STUDY ON CLINICAL AND SEROLOGICAL PARAMETERS IN MUSK MYASTHENIA GRAVIS PATIENTS WITH AND WITHOUT GENERAL IMMUNOSUPPRESSION

A. De Rosa[1], I. Koneczny[2], M. Mané-Damas[2], S. Zong[2], S. De Haas[2], S. Huda[3], M. Maestri[1], M. Guida[1], P. Van Damme[4], S. Tzartos[5], R. Ricciardi[1], M. Losen[2], P. Martinez-Martinez[2]

[1]Department of Clinical and Experimental Medicine, Neurology Unit, University of Pisa (Pisa); [2]Research group neuroinflammation and autoimmunity, Department of Psychiatry and Neuropsychology, School for Mental Health and Neuroscience, Maastricht University (Maastricht-NL); [3]Neurosciences Group, Nuffield Department of Clinical Neurosciences, Weatherall Institute of Molecular Medicine, University of Oxford (Oxford-UK); [4]Neurology Department, University of Leuven (Leuven-B); [5]Department of Immunology, Hellenic Pasteur Institute (Athens-GR)

Aim: To investigate the effects of immunosuppressive treatment on IgG4 and MuSK IgG4 levels in Muscle-specific kinase (MuSK) Myasthenia Gravis (MG).

Materials and Methods: We analysed the clinical data and sera from 52 MuSK-MG patients (45 female, 7 male, mean age 48 years ) from Italy, the Netherlands, Greece and Belgium, and 43 AChR-MG patients (22 female, 21 male, mean age 58.44 years) from Italy, that were receiving Prednisone, Azathioprine, Cyclosporine, Intravenous immunoglobulin (IVIG), combinations thereof or no immunosuppression, and sera from 45 age- and sex-matched non-disease controls (with no diagnosed diseases, 38 female, 8 male, mean age 47.8 (range 20-68) years) from the Netherlands. We analysed the disease severity (assessed as MGFA or QMG score), and measured concentrations of MuSK IgG4, MuSK IgG, total IgG4 and total IgG in the sera by ELISA, RIA and nephelometry.

Results: We observed that MuSK-MG patients showed a robust clinical improvement and reduction of MuSK IgG after therapy, and that MuSK IgG4 concentrations, but not total IgG4 concentrations, correlated with clinical severity. MuSK IgG levels and MuSK IgG4 concentrations were reduced after immunosuppression in 4/5 individuals with before-after data, but data from non-linked patients showed no significant difference. Total serum IgG4 levels were within the normal range in most MG patients, and we observed a mild relative enrichment of IgG4 in both AChR-MG and MuSK-MG patients. MuSK-MG patients improved within the first four years after disease onset, but longer disease duration (>4 years) did not lead to further clinical improvement or MuSK IgG4 reduction, and only 14/52 (26.92%) patients in total, of which 13 (93.3%) received general immunosuppression, reached clinical remission.

Discussion and Conclusions: Based on our observations, we conclude that MuSK-MG patients improve clinically with general immunosuppression, especially during the first four years of treatment, but may require further treatment to reach remission. Inter-assay variability may hide individual changes of MuSK IgG4 levels, therefore longitudinal testing of individual patients may be clinically more useful than single measurements. Since no significant differences in the serum IgG4 concentrations and IgG4/IgG between AChR- and MuSK-MG patients were observed, previous observations of a MuSK-MG specific enrichment of IgG4 could not be reproduced. This suggests that further study with larger patient and control cohorts are necessary.

## AUTOIMMUNE MOVEMENT DISORDERS IN THE ERA OF IMMUNE CHECKPOINT INHIBITORS

A. Dinoto, M. Trentinaglia, S. Carta, S. Ferrari, M. Tinazzi, S. Mariotto

Neurology Unit, Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona (Verona)

Objectives: The aim of this study is to characterize autoimmune movement disorders (MDs) occurring as an immune-related adverse event (irAE) of immune checkpoint inhibitors (ICIs).

Materials: Systematic literature review.

Methods: A systematic review of the literature was performed including patients who developed autoimmune MDs (excluding the distinct entity of isolated cerebellar ataxia) after exposure to ICIs. Clinical, paraclinical, and oncological accompaniments were analysed and collected by two independent investigators.

Results: From 1654 eligible papers, 24 articles with 26 patients were included. 18 patients were male and median age at onset was 66 years-old (range 18-77). Non-small cell lung cancer (n=7) and melanoma (n=6) were the most frequent oncological accompaniments. These iRAEs were frequently associated with anti PD-1 treatments (n=14, 54%) and occurred after a median of 5 doses. Features of movement disorders were myoclonus (n=9), tremor (n=7), hyperkinetic MDs (n=5), opsoclonus (n=5), stiff person syndrome (n=3), parkinsonism (n=2), dystonia (n=1), and unspecified movement disorder (n=1). 5 patients presented >1 core feature and onset was either acute (n=10) or subacute (n=8). MDs occurred in isolation in 6 patients, while in the remaining cases were frequently associated with encephalitis-iRAE. Brain imaging was unfrequently abnormal (9/24), with more common basal ganglia involvement, whereas an inflammatory CSF profile was frequently encountered (increased cell count 12/21, increased protein concentration 11/17, and CSF-restricted oligoclonal bands 5/11). Autoantibodies were detected in 12/19 patients being Hu, PDEA10A, and Ri the most frequently identified. Patients were treated either with steroids (n=22), immunoglobulins (n=6), plasma exchange (n=4) or other treatments (n=6). Median number of treatments per patient was 1 (0-3) with 12 patients receiving >1 treatment. ICIs were discontinued in 21/22 cases and 3/10 patients were rechallenged. At last follow-up (median 5 months, range 1-27) 11/24 patients improved, 7/24 deceased, 3/24 obtained neurological remission, 2/24 were stable, and 1/24 worsened. Relapses were reported in 4 patients in association with rapid steroid tapering/ICI rechallenge.

Discussion: ICI-related MDs usually occur in association with anti PD-1 treatment and lung cancer or melanoma. Clinical features are heterogeneous and frequently overlaps with those of other iRAEs. Treatment and ICI discontinuation led to improvement in most cases. Acute/subacute onset, coexistence of other iRAEs, MRI imaging involving basal ganglia, and an inflammatory CSF profile support the diagnosis.

Conclusion: Autoimmune MDs are a rare complication of cancer immunotherapy, but neurologist should be aware and recognize this condition to offer patients a prompt diagnosis and treatment.

## INVESTIGATING THE SPECTRUM OF DIFFERENTIAL DIAGNOSES AND MISDIAGNOSES OF AUTOIMMUNE ENCEPHALITIS

A. Dinoto[1], P. Zara[2], S. Mariotto[1], S. Ferrari[1], E. Flanagan[3], A. Buddhram[4], D. Orellana[5], D. Turilli[2], P. Solla[2], G. Day[5], E. Sechi[2], A. Lopez-Chiriboga[5]

[1]Neurology Unit, Department of Neurosciences, Biomedicine and Movement Sciences - University of Verona (Verona); [2]Department of Medical, Surgical and Experimental Sciences, University of Sassari (Sassari); [3]Department of Neurology and Laboratory Medicine and Pathology, Mayo Clinic (Rochester-USA); [4]Department of Clinical Neurological Sciences and Clinical and Neurological Sciences, Western University, London Health Sciences Centre (London-CDN); [5]Department of Neurology, Mayo Clinic College of Medicine (Jacksonville-USA)

Aims: The diagnosis of autoimmune encephalitis (AE), beside the fulfillment of clinical, paraclinical and radiological criteria, requires the reasonable exclusion of other conditions. Indeed, an erroneous diagnosis of AE may delay a correct treatment and expose patients to inappropriate immunotherapies. Thus, the proper identification of potential confounding factors is of utmost importance. The aim of this study is to characterize mimickers and misdiagnoses of AE.

Materials: Systematic review of the literature.

Methods: A systematic review including 1) patients with other neurological disorders but mimicking AE, or 2) patients with alternative neurological disorders misdiagnosed as AE was performed according to PRISMA guidelines by two independent investigators. Relevant clinical, therapeutic, and paraclinical data were extracted and diagnostic criteria for AE were applied. A comparison across the different diseases and age groups was performed (Fisher's exact test or Chi-square test).

Results: After screening 3669 records, 58 studies incorporating data from 66 patients (52 adults and 14 children) were included in the analysis. Median age at onset was 43.5 years (range 4-48) and 44 patients were male. Neoplastic (n=17), infectious (n=15), genetic (n=13), neurodegenerative (n=8), and other neurological (n=8) or systemic autoimmune (n=5) disorders were the main misdiagnoses. Thirty-eight patients fulfilled the diagnostic criteria for "possible AE", 11 for "definite limbic AE", and 4 for "antibody negative but probable AE". MRI showed lesions in 61 cases. Isolated temporal EEG abnormalities were found in 7 cases. Increased CSF white blood cells, protein concentration, and the presence of oligoclonal bands were reported in 27, 26, and 5 cases, respectively. Non-specific autoantibodies were detected in 12 patients. Forty-two patients received immunotherapy, with improvement reported in 21. Neoplastic disorders were more frequent in adults, whereas genetic conditions were more common in children.

Discussion: The spectrum of AE mimics is broad, and the recognition of these disorders is crucial as they can present paraclinical findings and treatment response similar to that observed in AE, leading to misdiagnosis and inappropriate treatment. The lack of fulfillment of the diagnostic criteria for AE, the presence of atypical neuroimaging lesions, non-inflammatory CSF findings, non-relevant autoantibodies,

and a partial response to immunotherapy are major red flags suggesting a possible misdiagnosis.

Conclusions: The present study provides a characterization of mimics and misdiagnoses of AE and clues to aid their identification. The recognition of these conditions is crucial for a correct treatment and to prevent unnecessary exposure to side effects of immunotherapies.

## KELCH-LIKE PROTEIN-11 (KLHL11) PARANEOPLASTIC SYNDROME: A REPORT OF THE FIRST ITALIAN CASES

A. Dinoto[1], P. Alboini[2], V. Chiodega[1], S. Ferrari[1], E. Sabatelli[3], C. Reale[2], G. d'Orsi[2], S. Mariotto[1], R. Iorio[3]

[1]Neurology Unit, Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona (Verona); [2]Neurology Unit, Fondazione IRCCS Casa Sollievo della Sofferenza (San Giovanni Rotondo-FG); [3]UOC Neurology, Fondazione Policlinico Universitario A. Gemelli IRCCS, University Cattolica del Sacro Cuore (Roma)

Introduction: Antibodies directed against Kelch-like protein-11 (KLHL11) are markers of a recently described paraneoplastic neurological syndrome (PNS). An ongoing multicenter Italian study (Network Italiano Neurologia Autoimmune-NINA-) is currently aiming to characterize this syndrome in the Italian population. As preliminary data, we herein describe the first two Italian cases with anti-KLHL11-associated PNS.

Materials: Serum and/or CSF of patients with suspected PNS or compatible phenotype according to the most recent diagnostic criteria were tested.

Methods: Patients' serum and CSF samples were tested at the Neuropathology Laboratory, University of Verona, using an in-house cell-based assay employing HEK293T cells transfected with a plasmid encoding KLHL11 protein. Samples were also tested locally or centrally with in-house immunofluorescent tissue-based assays to confirm the peculiar "sparkling" pattern. Clinical, video-EEG/polygraphic, demographic, and oncological data were collected.

Results: Two patients resulted positive for anti-KLHL11 antibodies (one in serum which was the only specimen available, the other one in both serum and CSF) on both cell- and tissue-based assays.

Discussion: Patient#1 is a 72-years-old man who developed subacute cerebellar ataxia two years after surgical treatment of testicular seminoma. Brain MRI demonstrated microangiopathic changes and CSF analysis showed increased protein and cell concentrations. He was treated with steroids with partial improvement. A total body CT scan showed enlarged pelvic and abdominal lymph nodes that were hypermetabolic on 18FDG-PET scan. The lymph nodes were treated with local radiotherapy. He was then re-evaluated and repeated a CSF analysis (increased protein concentration) and audiometric testing demonstrating moderate-to-severe sensorineural hearing loss. KLHL11 antibodies were positive in serum. He was treated with intravenous steroids and immunoglobulins. Patient#2 is a man with a previous history of azoospermia who underwent testicular resection in the suspect of malignancy, then not confirmed. At the age of 42, he developed subacute cerebellar ataxia and was diagnosed as seronegative autoimmune cerebellitis. Five months later, memory loss and focal (left temporal) nonconvulsive status epilepticus occurred. CSF analysis revealed increased protein concentration, a total body 18FDG-PET scan was normal, whereas brain PET scans showed a left temporal inflammatory hypercaptation, which was confirmed on MRI scans. KLHL11 antibodies tested positive in serum and CSF. Treatment with intravenous steroids and immunoglobulins led to partial improvement.

Conclusion: We herein describe the first two Italian cases of anti-KLHL11 asssociated paraneoplastic syndrome. Anti-KLHL11 PNS typically presents as a rhombencephalitis that occurs in men with testicular neoplasms, even though the spectrum of clinical phenotypes and oncological accompaniments is progressively expanding.

## CONCORDANCE BETWEEN RADIOIMMUNOASSAY AND CELL-BASED ASSAY IN RIA-ACHR POSITIVE ASYMPTOMATIC SUBJECTS

S. Falso[1], E. Sabatelli[2], S. Marini[1], A. Evoli[2], R. Iorio[2]

[1]Department of Neurosciences, Catholic University of the Sacred Heart (Roma); [2]Neurology Institute, IRCCS Fondazione Policlinico Agostino Gemelli (Roma)

Objective: Detection of acetylcholine receptor antibodies (AChR Abs) is crucial in myasthenia gravis (MG) diagnosis and currently radioimmunoassay (RIA) is the gold standard. It is well known that RIA can be positive in non-MG thymoma and in patients in complete stable remission (CSR). Aim of this study was to evaluate the concordance between RIA and fixed cell-based assay (CBA) in asymptomatic RIA-AChR positive subjects.

Materials and Methods: 604 AChR-positive subjects were consecutively seen at the Neurology Unit of IRCCS Fondazione Policlinico Gemelli in Rome between January 2000 and May 2023; clinical follow-up was $\geq$ 1 years. MG diagnosis was based on clinical examination, electrophysiological studies and Abs detection. AChR Abs were tested by RIA in the whole cohort. Serum samples from RIA-positive asymptomatic subjects were re-tested by fixed-CBA. The two assays were performed at the same time in each sample.

Results: Serum samples of 6 RIA-positive subjects were tested. Four subjects were RIA-positive for AChR Abs although they had never suffered from MG symptoms (repetitive nerve stimulation studies were negative). Two of these 4 subjects had undergone thymectomy for B2 thymoma (with a follow-up of 12 and 10 years, respectively), 1/4 had thymic hyperplasia and 1/4 had never undergone chest imaging. Two additional samples were collected in 2023 from MG patients: one who has been in CSR since 2016 and a 26-year-old woman who presented transient ptosis in 2019. AChR-Abs were not detected by fixed CBA in four samples (vs 4.80, 5.07, 5.90 and 1.47 nM/L by RIA). The two non-MG thymoma cases resulted positive for both fetal and adult AChR Abs (vs 8.70 and 5.50 nM/L by RIA).

Discussion: RIA has almost 100% specificity and false positivity for AChR Abs is extremely rare (< 1%) [1]. CBA is thought to be more sensitive than RIA in confirming MG diagnosis, especially in ocular cases, as it can detect low-affinity Abs [2]. On the other hand, RIA can detect Abs against intracellular epitopes and thus not pathogenic. Our

preliminary results show that CBA can be more specific than RIA in detecting pathogenic Abs. However, CBA resulted positive in non-MG thymoma patients, suggesting that these subjects can present Abs binding AChR without symptoms.

Conclusion: From our data, AChR detection by CBA may have a better correlation with clinical status than RIA. Future studies should assess if there is binding to intracellular epitopes of the AChR by these likely non-pathogenic Abs.

While the spectrum of neurological immune checkpoint inhibitor-related adverse events is expanding, patients outcomes are not well documented. This study aimed to assess outcomes of neurological immune-related adverse events and to identify prognostic factors. All patients experiencing grade ≥2 neurological immune-related adverse events identified at two clinical networks (French Reference Center for Paraneoplastic Neurological Syndromes, Lyon; and OncoNeuroTox, Paris) over five years were included. Modified Rankin scores were assessed at onset, 6, 12, 18 months, and last visit. A multi-state Markov model was used to estimate the transition rates between minor disability (mRS <3), severe disability (mRS 3-5), and death (mRS 6), over the study period. The state-to-state transition rates were estimated using maximum likelihood and variables were introduced into the different transitions to study their effects. A total of 147 patients were included out of 205 patients with a suspicion of neurological immune-related adverse events. Median age was 65 years (range 20-87), and 87/147 patients (59.2%) were male. Neurological immune-related adverse events involved the peripheral nervous system in 87/147 patients (59.2%), the central nervous system in 51/147 (34.7%), and both systems in 9/147 (6.1%). Paraneoplastic-like syndromes were observed in 30/147 patients (20.4%). Cancers included lung cancers (36.1%), melanoma (30.6%), urological cancers (15.6%), and others (17.8%). Patients were treated with PD(L)1 inhibitors (70.1%), CTLA4 inhibitors (3.4%), or both (25.9%). Severe disability was reported in 108/144 patients (75.0%) at onset, and in 33/146 patients (22.6%) at last visit (median follow-up duration: 12 months, range 0.5-50); 48/147 (32.7%) patients died, from cancer progression (17/48, 35.4%), neurological toxicity (15/48, 31.2%), other causes (10/48, 20.8%), or unknown causes (6/48, 12.5%). The rate of transition from severe to minor disability independently increased with melanoma (compared to lung cancer, HR=3.26, 95%CI [1.27; 8.41]) and myositis/neuromuscular junction disorders (HR=8.26, 95%CI [2.90; 23.58]), and decreased with older age (HR=0.68, 95%CI [0.47; 0.99]) and paraneoplastic-like syndromes (HR=0.29, 95%CI [0.09; 0.98]). In patients with neurological immune-related adverse events, myositis/ neuromuscular junction disorders and melanoma increase the transition rate from severe to minor disability, while older age and paraneoplastic-like syndromes result in poorer neurological outcomes; future studies are needed to optimize the management of such patients.

## EFFECTIVENESS AND SAFETY OF INTRAVENOUS IMMUNOGLOBULIN FOR PERIPHERAL NEUROPATHY IN EGPA PATIENTS: A RETROSPECTIVE STUDY

C. Fasano[1], A. Bettioli[2], M. Vastola[1], E. Silvestri[2], A. Barilaro[1], L. Massacesi[1], G. Emmi[2]

[1]Department of Neurology 2, University of Florence (Firenze); [2]Department of Experimental and Clinical Medicine, University of Florence (Firenze)

Introduction: Eosinophilic granulomatosis with polyangiitis (EGPA), is a small-vessel vasculitis belonging to the spectrum of small-vessel vasculitis associated with antineutrophil cytoplasmic antibodies (ANCAs), also characterized by eosinophilic infiltration of target organs. Peripheral neuropathy (PN) represents a vasculitic involvement, affecting about 2/3 of the patients as a presenting symptom, mainly in the form of mononeuritis multiplex. Few studies have addressed the role of intravenous immunoglobulin (IVIg) for the treatment of PN. This monocentric retrospective study aims at assessing the effectiveness and safety of IVIg in patients with PN as the main acute manifestation at EGPA onset.

Materials and Methods: Out of 93 EGPA patients followed at the Vasculitis Centre of the Careggi University Hospital, we collected data from 39 patients with disease onset characterized by PN. Minimum follow up was of 6 months and last follow up of 18 months. All patients were treated with high dose corticosteroid (CS) alone or associated with other immunosuppressive or immunomodulatory drugs at disease onset. 18 (46%) patients were treated with IVIg at disease onset and throughout the maintenance of remission (IVIg group), while the other 21 (54%) with other therapies (no IVIg group). The two groups were compared by risk of relapse and long-term disability, measured by the modified Ranking Scale (mRS).

Results and Discussion: During the 18 months follow-up, 33% (7/21) of the patients in the no IVIg group developed a relapse, versus only 5% (1/18) in the IVIg group. IVIg treatment significantly reduced the frequency of neurological and systemic relapses and it also reduced the long term neurological disability, due to a stable improvement of peripheral neuropathy. Although no significant difference was observed between the two groups in mRS at disease onset (3-3), there is a statistical difference after 18 months follow-up (2-1; p-value= 0,019). None of the patients treated with IVIg experienced serious adverse reactions.

Conclusion: These exploratory data support the effectiveness of the IVIg treatment as an add-on therapy at onset in EGPA patients developing PN as presenting symptom. The treatment with IVIg appears to be effective in reducing the risk of relapse and long-term disability.

## NIVOLUMAB-RELATED SERONEGATIVE ENCEPHALITIS IN A PATIENT WITH SQUAMOUS CELL ESOPHAGEAL CANCER. A CASE REPORT

A. Fattorello Salimbeni[1], V. Munerati[2], M. Carecchio[1], A. Salvalaggio[1]

[1]Department of Neurology, Padua University Hospital (Padova); [2]Department of Neurology, San Bassiano Hospital (Bassano del Grappa-VI)

Immune checkpoint inhibitors (ICIs) like nivolumab have become important in cancer treatment due to their effectiveness and apparent safety. However, the use of ICIs has led to several complications, particularly in the autoimmune spectrum. This report presents a case of nivolumab-related encephalitis, with abrupt onset and spontaneous recovery after discontinuing treatment. A 63-year-old man with a history of stage IIA squamous cell esophageal cancer and previous diffuse large B-cell lymphoma, started nivolumab as adjuvant immunotherapy six weeks after esophagectomy. Six weeks later, the day after the second dose, he experienced fever, dizziness, gait instability, cognitive impairment and expressive aphasia. In the following days due to progressive worsening and onset of right hemiparesis he underwent an urgent brain MRI at his local hospital in the suspicion of a cerebrovascular event, but the results were negative. He was discharged on antiplatelet therapy. A subsequent evaluation at our center one week later showed gradual motor recovery, but persistent cognitive impairment, temporal disorientation and anomic aphasia. EEG results indicated diffuse encephalopathic patterns, leading to admission one week later. Neurological assessment showed mild cognitive impairment while laboratory tests, including tumor markers and immunological assessments, were normal. A control EEG showed partial improvement, despite diffuse slow tracing still persisted. Cerebral MRI with Gadolinium and CSF analysis were within limits, except for mild pleocytosis and hyperproteinorrhaquia and a mirror pattern. CSF immunophenotyping revealed abnormal T-cell levels with a reduced CD4+CD3+ count (173.1 cells/uL, normal range 510-1270/uL). Antineuronal and neuronal surface antibodies were negative both in serum and CSF and neither viruses or bacteria were detected. Over four days his neurological status gradually improved, with only slight psychomotor retardation at discharge. Nivolumab was discontinued and one month later his follow-up neurological examination was normal. Neurological disorders, accounting for 7.2% of ICI-related complications, can range from myasthenia gravis to encephalitis. They usually manifest within weeks of starting treatment and often recover after discontinuing the drug and administering steroids. In this case, the patient's symptoms were initially misdiagnosed as a stroke. The pathogenesis is thought to be T-cell mediated, which may explain the infrequency of antineuronal antibody detection. Except for preexisting autoimmune conditions, which relapse in 20-40% of patients undergoing treatment, no clear demographic or clinical features are associated with increased risk of ICI-related neurological complications. Clinicians should be aware of these potential complications to ensure timely diagnosis and improve multidisciplinary approach to cancer patients.

## AUTOIMMUNE LIMBIC ENCEPHALITIS: BEYOND THE KNOWN – CASE REPORT

F. Favruzzo[1], C. De Luca[2], A. Marangi[2], A. De Boni[2], F. Perini[2]

[1]Neurology, Padua University Hospital (Padova); [2]Neurology, San Bortolo Hospital (Vicenza)

Introduction: Paraneoplastic limbic encephalitis (PLE) associated with Ma2 antibodies is a rare neurocognitive disorder, usually presenting with a subacute onset of the symptoms. The presentation of these syndromes regularly precedes the diagnosis of cancer, complicating their recognition as a PLE [1]. They are usually associated with small cell lung carcinoma and testicular carcinoma [2].

Case Report: Here, we report the case of a 82-year-old woman with a history of arterial hypertension, dyslipidemia and Hashimoto's thyroiditis who presented with an acute onset of subjective vertigo and disequilibrium since awakening. Neurological examination showed left cerebellar signs, left VI cranial nerve palsy, inexhaustible up-beating nystagmus and a severe retropulsion causing gait instability. CT angiography and perfusion CT showed no large vessel occlusion and/or areas with hypoperfusion and brain MRI was unremarkable. After 20 days of rehabilitation, a worsening of symptoms was detected. A repeated brain MRI showed left hippocampus and uncus T2-hyperintensity with no diffusion restriction and no gadolinium enhancement. Testing onconeural antibodies, both CSF and serum anti-Ma2 autoantibodies were positive. Total body PET-CT displayed a left-hypochondrium hypermetabolic solid lesion resulting in epitheliod-type peritoneal mesothelioma. No other primary and/or secondary lesions were found. Despite a 5-day intravenous high dose corticosteroid therapy (methylprednisolone 1g/die) the patient showed no clinical improvement. While waiting for surgical evaluation, she suddenly died from oncological disease-related complications.

Discussion and Conclusions: This case shows a PLE with acute onset of symptoms associated with pleural mesothelioma. The diagnosis was confirmed by the typical neuroradiological images and the findings of onconeural antibodies. The acute onset is atypical, but previous similar cases have been described in literature [3]. On the other hand, to our knowledge, our case is the first in the literature describing the association between peritoneal mesothelioma and anti-Ma2 PLE.

## HERPES SIMPLEX ENCEPHALITIS MIMICKING ISCHEMIC STROKE IN A PATIENT WITH ANATOMICAL VARIANT OF WILLIS CIRCLE

G. Fiume, D. Cosenza, E. Portera, G. Vita, F. Sottile, R. Lo Presti, A. Pugliese, R. Grugno

Neurology Unit, Piemonte Hospital, IRCCS Neurolesi Bonino-Pulejo (Messina)

Aim: To report an atypical case of Human Herpesvirus 6 (HHV6) encephalitis mimicking ischemic stroke in a patient with an anatomical variant of Willis Circle.

Materials and Methods: We describe herein a 62-year-old man who arrived at the emergency department with altered mental status and behavioral changes since a few hours. After having excluded toxic and metabolic diseases we apply the diagnostic work-up for cerebrovascular accidents and infective diseases. Neurological examinations, blood tests, neuroimaging (brain CT and MRI), Electroencephalogram (EEG), neuropsychological tests, and Cerebrospinal Fluid analysis (CSF) were performed.

Results: Neurological examination revealed disorientation, motor aphasia, and uncertain gait. Blood tests including Reactive C Protein (RCP) and Procalcitonin (PCT) were negative. Brain MRI showed symmetric bilateral frontal and on-vertex hyperintensity with mild meningeal contrast graphic impeachment. These lesions revealed a high signal in T2, FLAIR, and DWI sequences and a low signal in Gradient Echo as laminar necrosis. EEG presented sporadic spikes on the left central derivation. CT angiography showed a fusion of the Anterior Cerebral Arteries (ACAs) over a short distance. Neuropsychological tests showed deficits in autobiographic, recent, and past memory, in verbal and praxis function. The patient underwent lumbar puncture with evaluation of standard analysis and a FilmArray Meningitis/Encephalitis panel, revealing the presence of HHV6. Treatment with acyclovir was started at a standard dose (10mg/Kg Intravenous, every 8 hours), combined with corticosteroid therapy for 14 days. Neuropsychological evaluation was repeated, detecting an improvement in patient's verbal and executive functions. Furthermore brain MRI, performed twelve days after therapy starting, showed a global reduction of cerebral lesions and swelling.

Discussion & Conclusions: HHV6 can cause different neurological manifestations, depending on the patient's immunological status. [1] Most commonly HHV6 cerebral lesions are localized at temporal lobes[2]. In contrast, our case presented an atypical involvement of frontal lobes which represented a confounding element together with the presence of the ACAs variant. However, the appearance of the laminar necrosis since the first day and the neuroradiological lesions evolution led to a correct diagnosis. We encourage to consider HHV encephalitis in case of patients with clinical and instrumental findings suggesting an infective disease, even if radiological lesions localization is uncommon. Moreover, a good response to antiviral and corticosteroid therapy could support the diagnosis as an ex-adiuvantibus criterion.

## IMMUNE CHECKPOINT INHIBITOR-RELATED NEUROMUSCULAR TOXICITY: AN OBSERVATIONAL MONOCENTRIC STUDY

I. Florean[1], M. Dentoni[1], D. Iacono[2], M. Cinausero[2], M. Valente[1], A. Vogrig[1]

[1]Clinical Neurology Unit, Department of Medicine (DAME), University of Udine (Udine); [2]Department of Oncology, Azienda Sanitaria Universitaria Friuli Centrale (ASU FC), Santa Maria della Misericordia Hospital (Udine)

Objectives: To characterize severe (grade III-IV CTCAE) neuromuscular toxicity following Immune Checkpoint Inhibitor (ICI) administration including clinical and paraclinical features, response to immunosuppressive therapy, neurological and oncological outcome.

Materials and Methods: We included 6 adult patients developing new-onset neuromuscular symptoms within 12 months from the last ICI infusion that were treated at a tertiary referral center (2019-2022).

Results: Most patients were male (5/6; 83.3%) and the median age was 77 (range 55-85). Associated tumors were melanoma (n=2), non-small cell lung cancer (NSCLC, n=2), renal clear cell carcinoma (n=1) and concomitant NSCLC and thymic squamous carcinoma (n=1). Two patients had a pre-existing autoimmune disease (chronic gastritis and thyroiditis). Pembrolizumab was the ICI adopted in most cases (4/6, 66.7%). Neuromuscular symptoms developed a median of 6 weeks (range: 4-30.6) after ICI onset. Neurological involvement was peripheral in 5/6 patients (83.3%), central and peripheral in 1/6 (16.7%). Myositis-myocarditis overlap syndrome was diagnosed in 2/6 (33.3%) patients, myasthenia-myositis overlap syndrome in 1/6, myasthenia-myocarditis overlap syndrome in 1/6, myasthenia in 1/6 and myositis in 1/6. Concomitant unilateral optic neuritis was diagnosed in one patient. Four patients developed other non-neurologic immune-related Adverse Events (irAEs) (1) (66.7%). Laboratory tests within two weeks after symptoms onset showed increased levels of creatine kinase (CK) in 5/6 patients (83.3%), AST and ALT in 6/6 (100%), and positive Troponin I in 3/6 (50%). Myositis-specific and -associated autoantibodies were found in 2/6 (33.3%) patients. Anti-acetylcholine receptor antibodies were not detected. ICI was withdrawn in all patients and all cases received immune-modulating therapy: 4/6 (66.7%) corticosteroids and IVIg (two of which also received a second-line immunotherapy including one patient treated with anti-IL6R tocilizumab) and 2/6 (33.3%) corticosteroids only. Concerning neurological outcome, 4/6 (66.7%) patients improved with residual disability, 1/6 (16.7%) did not improve and 1/6 worsened. A complete tumor response was observed in 1/6 (16.7%) patients, while in 5/6 (83.3%) disease stability or progression was recorded.

Discussion: The time lag between ICI initiation and symptoms onset appears to be short and the disease course severe. Interestingly, the only patient who is currently disease free at 14-months follow up also developed CNS toxicity. It would be worth investigating the relationship between neurological and oncological outcome in patients experiencing neuromuscular toxicities.

Conclusions: In our case series, ICI-related neuromuscular toxicity more commonly associated to male sex and pembrolizumab therapy, developing early after ICI onset. Most patients developed concomitant iRAEs.

## TEMPORAL LOBE GLIOMA: AN UNCOMMON MIMIC OF AUTOIMMUNE LIMBIC ENCEPHALITIS

V. Floris, P. Zara, P. Solla, E. Sechi

Unit of Neurology, Department of Medical, Surgical and Experimental Science, University of Sassari (Sassari)

Background and Objective: The aetiologic spectrum of autoimmune encephalitis (AIE) mimics is broad. Primary brain tumors can present with clinical and MRI features that can resemble AIE, making the differential diagnosis challenging. Herein we describe a case of temporal lobe glioma mimicking AIE.

Materials and Methods: The clinical presentation and diagnostic approach leading to the diagnosis of glioma are presented.

Results: A 41-year-old man presented to the emergency department for rapidly progressive vertigo, confusion and language disturbances, followed by focal, refractory status epilepticus (oculogyric crisis) within 24 hours, and was admitted to the ICU. Brain MRI revealed a T2/FLAIR cortical-subcortical hyperintensity involving the right temporal pole (mostly in its ventral and lateral surface), extending to the insular cortex and frontal lobe, not accompanied by gadolinium enhancement or restricted diffusion. CSF analysis was unremarkable. Treatment with acyclovir and ceftriaxone was empirically started, but later discontinued due to negative HSV-PCR and bacterial infectious screening. Repeat lumbar puncture 5 days later revealed 12 white blood cells, normal proteins and absence of oligoclonal bands. Search for common antineuronal antibodies in serum and CSF was negative. Whole body CT failed to reveal occult malignancies. A diagnosis of possible seronegative AIE was considered based on the Graus 2016 diagnostic criteria. During the first two weeks, he was treated with intravenous methylprednisolone (1 g daily for 5 days) and intravenous immunoglobulin (IVIG) in addition to levetiracetam (3000mg/die), lacosamide (400mg/die) and sodium valproate (1200mg/die), with resolution of the status epilepticus. Repeat MRI and brain MRI spectroscopy showed stability of the lesion and increased Cho/NAA ratio suggestive for neoplasm. A brain biopsy confirmed a low-grade astrocytoma.

Discussion and Conclusions: Temporal lobe gliomas are rare but well recognized mimics of AIE. Our patient met the diagnostic criteria for possible seronegative AIE (rapid progression of altered mental status and unexplained seizures, absence of well characterised autoantibodies in serum and CSF, MRI abnormalities compatible with autoimmune encephalitis and inflammatory CSF). However, the limited involvement of the mesial part of the temporal pole, and lack of improvement of MRI abnormalities after treatment represented major red flags.

Background and Aims: Neurofilament light chain protein (NfL) is a blood biomarker of neuroaxonal injury, the levels of which are increased in hospitalized COVID-19 patients, even without major COVID-19- associated CNS manifestations and seem to be associated

with poor clinical outcomes. [1,2,3] Our study aimed to investigate the prognostic value of blood NfL levels in the acute phase of COVID-19.

Methods: We conducted an individual participant data (IPD) meta-analysis after screening on MEDLINE and Scopus to 23 May 2022. We included studies with hospitalized adult COVID-19 patients without major COVID-19-associated CNS manifestations and with a measurement of blood NfL in the acute phase and data regarding at least one clinical outcome including ICU admission, need of mechanical ventilation (MV) and death. We derived the age-adjusted measures NfL Z scores and conducted mixed-effects modelling to test associations between NfL Z scores and other variables, encompassing clinical outcomes. Summary receiver operating characteristic curves (SROCs) were used to calculate the area under the curve (AUC) for blood NfL.

Results: We identified 382 records, of which 7 studies were included with a total of 669 hospitalized COVID-19 cases (mean age 66.2±15.0 years, 68.1% males). Median NfL Z score at admission was elevated compared to the age-corrected reference population (2.37, IQR: 1.13–3.06, referring to 99th percentile in healthy controls). NfL Z scores were significantly associated with disease duration and severity. Higher NfL Z scores were associated with higher likelihood of ICU admission, MV, and death. SROCs revealed AUCs of 0.74, 0.80 and 0.71 for mortality, MV and ICU admission, respectively.

Conclusions: Blood NfL levels were elevated in the acute phase of COVID-19 and associated with clinical severity and poor outcome. The marker might ameliorate the performance of prognostic multivariable algorithms in COVID-19.

## HIV-ASSOCIATED VACUOLAR MYELOPATHY: A CASE OF SENSITIVE ATAXIA AND SPASTIC PARAPARESIS MIMICKING SUBACUTE COMBINED DEGENERATION

V. Gasparini, L. Sacchi, M. Pintus, M. Creta, S. Boldrini, A. Pietroboni, L. Ghezzi, M. De Riz, M. Bolis, A. Liparoti, A. Muscatello, A. Genovese, F. Lorusso, F. Triulzi, D. Galimberti, G. Comi, A. Arighi, T. Carandini

Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, University of Milan (Milano)

Background: HIV-associated vacuolar myelopathy is an increasingly rare manifestation of HIV, especially following the introduction and diffusion of the Highly Active AntiRetroviral Therapy (HART). In this clinical case, we reported MRI findings of a 52-year-old man, with subacute spastic paraparesis and sensitive ataxia due to Human Immunodeficiency Virus (HIV)-associated vacuolar encephalomyelopathy in newly diagnosed Acquired Immune Deficiency Syndrome (AIDS).

Case report: A 52-year-old male presented with a 2-month-long history of progressively worsening spastic paraparesis, lower limbs dysesthesias and sensitive ataxia leading to gait instability. Urinary hesitation and loss of sexual function were present. He could not walk on his toes or heels, fell in Romberg, and exhibited hypo-pallesthesia at the hips, ultimately resulting in a loss of vibration and statokinesic sensation in his feet. Cranial nerves and upper limbs were normal, except for a slight telekinetic tremor in the left hand. Deep tendon reflexes were hyperexcitable. The patient denied any use of drugs, contact with toxins, or exposure to any professional risks. Somatosensory and motor evoked potentials were altered, indicating a prolonged central conduction time. Brain-MRI showed T2/Fluid Attenuated Inversion Recovery (FLAIR)-hyperintensities in the optic chiasm and optic tracts without gadolinium-enhancement or diffusion restriction. Similar FLAIR-lesions were found in the pyramids within the brainstem and in the lateral and posterior funiculi of the cervical and dorsal spinal cord. A metabolic or toxic etiology was excluded, and no vitamin deficiencies were found. In particular, the patient had normal levels of B12 vitamin and methylmalonic acid. We hypothesized an infective origin due to lymphopenia at blood sample, and indeed HIV-testing resulted positive, with CD4+-count of 129 cells/μL. There were no other viral or bacterial infections and even HTLV I/II antibodies were negative. Therefore, we diagnosed an HIV-associated vacuolar myelopathy in a newly diagnosed of AIDS. HART was started with no significant clinical improvement at 3-month-follow-up.

Discussion and Conclusions: HIV-associated vacuolar myelopathy is clinically resemblant to subacute combined degeneration of spinal cord, due to impaired B12 vitamin utilization and neurotoxic effects of HIV. Therefore, it is important to consider it in the differential diagnosis of subacute myelopathy. [1] Interestingly, our case report presented also subclinical involvement of the brainstem and optic tract/chiasm, as previously described. [2]

Objectives: Nodding syndrome (NS) is a complex neurological disorder of unknown aetiology. A previous study suggested a role for Onchocerca volvulus induced antibodies cross reacting with human proteins such as leiomodin-1 in the pathogenesis of the disease [1].

Here we investigated the role of autoimmunity to neuronal antigens in NS patients.

Material: We screened for the presence of leiomodin-1 as well as neuronal antibodies in plasma and CSF of 240 NS patients enrolled in a phase II trial of doxycycline for the treatment of nodding syndrome.

Methods: Plasma obtained on enrolment were tested for circulating antibodies to both Onchocerca volvulus (Ov16 and Ov3261) and to leioimodin-1. The mean duration of symptoms was 8.3 (SD 2.8) years. Infection by this filarial worm was defined as a positive antibody test to any of the two Onchocerca volvulus antigens. Antibodies to leioimodin-1 were tested using a standard luciferase immunoprecipitation system (LIPS) assay. For CSF, we initially screened 50 sera and 50 CSF samples for IgG binding to rodent brain tissue by immunohistology and to specific antigens including leiomodin-1; the sera bound widely but non-specifically. For specific testing, the presence of neuronal antibodies was investigated by immunohistochemistry (IHC) on mouse brain sections and by antigen specific cell-based assays for neuronal proteins and leiomodin-1. Antibody levels in the 240 NS CSF samples were compared to 40 CSFs from European controls.

Results: A total of 232/240 (96.7%) plasma samples tested positive for Onchocerca volvulus (228/240 to Ov16 and 25/240 to Ov3261) and leiomodin-1 antibodies were detected in 77/240 (32.1%) plasma samples and in 26/240 (10.8%) of CSF samples. Circulating leioimodin-1 antibodies (76/232 [32.8%] Ov16/Ov3261 positive vs 1/8 [12.5%] Ov16/Ov3261 negative, p=0.044) but not CSF leioimodin-1 antibodies (25/232 [10.8%] Ov16/Ov3261 positive vs 1/8 [12.5%] Ov16/Ov3261 negative, p=1.0) was associated with infection by Onchocerca volvulus. However, CSF leiomodin-1 antibodies were more likely to be present in patients with myoclonic seizures or drop attacks. Neuropilar staining by IHC was found in 28/240 (11.7%) NS CSFs. Among them, 2 had GABAbR antibodies and one had CASPR2 antibodies. Only 8/28 (28.6%) patients had both leiomodin-1 and neuropilar antibodies.

Conclusion: NS is associated with infection by Onchocerca volvulus and circulating antibodies to leioimodin-1. In addition, patients with CSF leioimodin-1 antibodies present with myoclonic seizures and drop attacks. Further studies are needed to understand the pathogenesis of disease.

## ATYPICAL PRESENTATION OF ANTI-LGI1 ENCEPHALITIS: A CASE REPORT

F. Gragnani, I. Pestalozza, F. Gilio, A. Biasiotta, B. Petolicchio, S. Almonti, E. Giacomelli

Sandro Pertini Hospital, ASL Roma2 (Roma)

Objectives: Anti-LGI1 encephalitis is characterized by subacute and progressive disturbance with cognitive and behavior symptoms, seizures and sleep disorders [1]. Faciobrachial dystonic seizures are very specific for this disease, although not always present [2].

Materials and Methods: An 63-year-old man developed axial rigidity and autonomic dysfunction within the last 4 months. In that period, he presented one tonic-clonic seizure. He was diagnosed with atypical parkinsonism (multiple system atrophy) and the episode of loss of consciousness was interpreted as convulsive syncope. He was admitted to the emergency department following the acute onset of confusion, agitation and cognitive impairment. Neurological examination showed mild axial rigidity, myoclonus in the 4 limbs (with lower limbs predominance) and pyramidal signs. A complete blood count were unremarkable; his cerebrospinal fluid (CSF) analysis revealed high values for protein (115 mg/dl) without pleocytosis. Polymerase chain reactions for neurotropic viruses, bacteria and mycetes on CSF were normal. An EEG revealed diffuse slow waves, without any specific epileptogenic activity; Brain magnetic resonance imaging showed mild hyperintensities in the bilateral mesial temporal lobes and cortical atrophy. Antibodies for autoimmune and paraneoplastic encephalitis were sent and while awaiting the results, the patient started on steroid. After about three weeks his serum autoimmune encephalitis panel returned positive for anti-LGI-1 antibodies. He also started on intravenous Immunoglobulin. The CT chest-abdomen and pelvis were performed and were negative for malignancy. During the course of his hospital stay, he presented an improvement of motor disorders with complete regression of pyramidal deficit and myoclonus; cognitive and autonomic dysfunction (low blood pressure, tachycardia) persisted, and these symptoms had a fluctuating course. He was discharged from the hospital in quite good conditions but unfortunately after few weeks he presented a sudden death, presumably due to his severe haemodynamic instability.

Discussion and Conclusions: Diagnosis of encephalitis can be challenging. Our patient developed LGI-1 encephalytis with an atypical presentation with diffuse myoclonus and pyramidal signs, which are hardly described in this form, in the absence of faciobrachial dystonic seizures which are usually more frequent; moreover, it is possible that the previous diagnosis of multisystem atrophy was a misdiagnosis, and that the onset of LGI-1 encephalitis itself was characterized by atypical parkinsonism that would have preceded the more classic symdrome. To date, only one case of autoimmune encephalitis presenting with atypical parkinsonism has been described [3], but in the case of that patient LGI-1 antibodies were negative.

diseases - IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [8]Unit of Immunology, Rheumatology, Allergy and Rare Diseases & Division of Immunology, Transplantation and Infectious Diseases, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [9]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: Choroid plexus (CP) enlargement has been suggested as a marker of neuroinflammation, for instance in multiple sclerosis [1]. CP involvement has also been hypothesized in the immunopathology of systemic lupus erythematosus (SLE) [2]. However, the associations between CP volume, neuropsychiatric involvement, auto-antibody status and brain structural damage have not been fully explored yet. We investigated whether CP enlargement occurs in SLE patients compared to healthy controls (HC) and whether it is associated with neuropsychiatric involvement. Additionally, we explored the abnormalities along the glymphatic network in SLE patients through enlarged perivascular spaces (PVS) quantification in basal ganglia (BG) and centrum semiovale (CS).

Materials: Brain dual-echo and 3D T1-weighted MRI sequences of 32 SLE patients and 32 sex- and age-matched HC were acquired using a 3 Tesla scanner, together with a clinical evaluation.

Methods: CPs were manually segmented on 3D T1 sequence and enlarged PVS were assessed on paired T2 and T1 sequences through Potter's score [3].

Results: Compared to HC, SLE patients showed higher normalized CP volume (nCPV) ($p=0.023$), with neuropsychiatric SLE patients (NPSLE) showing significantly higher CP enlargement than non-NPSLE patients ($p=0.027$). SLE patients with antiphospholipid antibodies (APA) positivity had higher nCPV compared to HC ($p=0.012$), while APA negative ones did not. SLE patients had also higher Potter's score than HC both in BG and CS regions ($p<0.001$), with NPSLE patients showing a tendency to higher Potter's score in BG, compared to non-NPSLE, without reaching statistical significance ($p=0.09$). Among the demographic, clinical and MRI variables tested by means of a random forest analysis, nCPV emerged as a significant predictor of NPSLE, together with brain T2-hyperintense white matter (WM) lesion volume (LV) and APA positivity (out-of-bag AUC 0.81).

Discussion: CP enlargement occurs in SLE, especially in patients with neuropsychiatric involvement. CP volume also proved to be a predictor of NPSLE together with brain T2-hyperintense WM LV and APA positivity. Enlarged PVS are more prevalent in SLE patients, with a potential greater alteration in NPSLE, which needs to be further investigated.

Conclusions: CP and PVS abnormalities, which could reflect the impairment of blood-cerebrospinal fluid barrier and glymphatic system, point out the possible role of these structures in the pathophysiology of NPSLE.

## HUMAN HERPESVIRUS 6 RELATED FOCAL PACHYMENINGITIS IN AN IMMUNOCOMPETENT ADULT

M. Gullà, M. Salvetti, L. Fionda, F. Giubilei, L. Leonardi

Department of Neuroscience, Mental Health and Sensory Organs (NESMOS), Sapienza University (Roma)

Introduction: Human herpesvirus 6 is the etiological agent of Roseola Infantum and, rarely, meningoencephalitis in infants. Reactivation of the infection with central nervous system involvement may occur in immunocompromised adults whereas it is rare in immunocompetent patients [1]. In this report we describe a case of a HHV-6 related focal pachymeningitis occurred in an immunocompetent adult.

Case presentation: A 76-year-old woman presented in the Emergency Department with new-onset left body focal motor seizures. She reported a history of fever and weakness of the left limbs in the week prior to hospitalization. Head CT-scan was unremarkable, while EEG showed bilateral frontotemporal theta activity. Admitted in our unit, the patient presented another left-sided focal motor seizure and anticonvulsant therapy (Levetiracetam 500 mg twice day PO) was started with the resolution of seizures. Neurological examination was unremarkable. A brain MRI was indicative of frontoparietal pachymeningitis. CSF analysis revealed lymphocytic pleocytosis with normal glucose levels and hyperproteinorrachia. Polymerase chain reaction (PCR) was negative for several viral agents except for HHV-6. Inflammatory, autoimmune, infectious, and neoplastic causes of focal pachymeningitis were excluded. To confirm HHV6 acute infection, a hair follicle genomic integration test was carried out, which resulted negative. Intravenous Ganciclovir and Ampicillin was started, and 5 days after a new brain MRI showed a slight reduction in the thickening of the pachymeninges. A new lumbar puncture documented 1/mm3 cells and normal protein level, while the HHV-6 PCR was still positive. After 21 days, Ganciclovir was interrupted due to the significant improvement of brain MRI findings. At three months from the discharge, the patient remained seizure-free.

Conclusions: In our case some peculiar feature emerged: 1. HHV-6 meningeal involvement occurred in a immunocompetent patient. 2. Focal pachymeningeal involvement has never been reported as related to HHV-6 reactivation. 3. The clinical course of our patient was benign with complete remission, in contrast with more severe clinical pictures reported in literature. HHV6 has the unique ability to incorporate itself into host DNA. According to literature reports, PCR is unable to distinguish between active viral DNA replication and DNA already integrated into the host chromosome, leading to an increase in false positive results in screening tests. Thus, more infectious and non-infectious etiologies need to be excluded before diagnosing HHV-6 meningitis [2]. Due to the lack of standard treatment guidelines for the management of HHV-6 meningitis in immunocompetent adults [3], we relied on the data provided by case reports, showing good clinical, radiological and CSF response to Ganciclovir therapy.

## ROZANOLIXIZUMAB RESPONDER AND MINIMAL SYMPTOM EXPRESSION RATES IN GENERALISED MYASTHENIA GRAVIS: POOLED PHASE 3 AND EXTENSION STUDIES

F. Habetswallner[1], J. Vissing[2], A. Drużdż[3], J. Grosskreutz[4], A. A Habib[5], R. Mantegazza[6], S. Sacconi[7], K. Utsugisawa[8], T. Vu[9], M. Boehnlein[10], B. Greve[11], F. Woltering[12], M. Gayfieva[13], V. Bril[14]

[1]Clinical Neurophysiology Unit, Antonio Cardarelli Hospital (Napoli); [2]Department of Neurology, Rigshospitalet, University of Copenhagen (Copenhagen-D); [3]Department of Neurology, Municipal Hospital (Poznań-PL); [4]Precision Neurology, Department of Neurology, University of Lübeck (Lübeck-D); [5]MDA ALS and Neuromuscular Center, University of California (Irvine-USA); [6]Department of Neuroimmunology and Neuromuscular Diseases, Fondazione IRCCS, Istituto Nazionale Neurologico Carlo Besta (Milano); [7]Université Côte d'Azur, Peripheral Nervous System & Muscle Department, Pasteur 2 Hospital, Centre Hospitalier Universitaire de Nice (Nice-F); [8]Department of Neurology, Hanamaki General Hospital (Hanamaki-J); [9]Department of Neurology, University of South Florida Morsani College of Medicine (Tampa-USA); [10]Clinical Development, UCB Pharma (Monheim-D); [11]Clinical & Regulatory Strategy, UCB Pharma (Monheim-D); [12]Biostatistics, UCB Pharma (Monheim-D); [13]Patient Safety, UCB Pharma (Slough-UK); [14]Division of Neurology, University Health Network (Toronto-CND)

Objectives: The Phase 3 MycarinG (MG0003/NCT03971422) trial demonstrated efficacy of one 6-week cycle of rozanolixizumab in generalised myasthenia gravis (gMG). [1] We aimed to assess the long-term efficacy and safety of repeated cycles of rozanolixizumab using data pooled across MycarinG, MG0004 and MG0007.

Materials and Methods: After 6 weeks of weekly rozanolixizumab/placebo in MycarinG, patients entered MG0004 (NCT04124965: ≤52 weeks of weekly rozanolixizumab) or MG0007 (NCT04650854: initial 6-week cycle; subsequent cycles administered on symptom worsening as determined by investigator's discretion, e.g., Myasthenia Gravis Activities of Daily Living [MG-ADL] increase ≥2/Quantitative Myasthenia Gravis [QMG] increase ≥3; "symptom-driven cycles"). The efficacy pool included data for patients with ≥2 symptom-driven cycles pooled across MycarinG, MG0004 (first 6 weeks) and MG0007 (interim analysis). The safety pool included data for patients with ≥1 cycle across MycarinG (symptom-driven) and MG0007 (fixed/symptom-driven).

Results: In total, 127 patients received ≥2 symptom-driven cycles of rozanolixizumab 7 mg/kg (initial dose, n=69) or 10 mg/kg (initial dose, n=58). MG-ADL change from baseline to Day 43, responder rates at Day 43 for MG-ADL, Myasthenia Gravis Composite and QMG and minimal symptom expression at any visit were consistent across cycles. Treatment-free intervals (time from previous dose to first dose in symptom-driven Cycle 1) were <4 weeks for 9.0%, 4–<8 weeks for 35.9%, 8–<12 weeks for 22.8%, 12–<24 weeks for 13.8% and ≥24 weeks for 4.8% of patients, with similar proportions at the next cycle. Treatment-emergent adverse events (most mild to moderate) occurred in 169 (89.9%) patients receiving ≥1 cycle of rozanolixizumab: 103 (77.4%) and 120 (91.6%) patients receiving rozanolixizumab 7 mg/kg and 10 mg/kg, respectively.

Discussion and Conclusions: Rozanolixizumab efficacy was maintained over symptom-driven cyclical treatment and multiple endpoints.

Funding: UCB Pharma.

## ANTI-GABABR ENCEPHALITIS PRESENTING AS ISOLATED DYSAUTONOMIA: LACK OF CANCER AND ANTI-KCTD16 PREDICT RECOVERY

F. Kuris[1], M. Fabris[2], J. Honnorat[3], L. Verriello[4], M. Valente[1], A. Vogrig[1]

[1]Clinical Neurology, Department of Medicine, University of Udine Medical School (Udine); [2]Department of Laboratory Medicine, Azienda Sanitaria Universitaria Friuli Centrale (ASUFC) (Udine); [3]French Reference Center for Paraneoplastic Neurological Syndromes and Autoimmune Encephalitis, Hospital for Neurology and Neurosurgery Pierre Wertheimer, Lyon University Hospital (Lyon-F); [4]Neurology Unit, Department of Neurosciences, Azienda Sanitaria Universitaria Friuli Centrale (ASUFC) (Udine)

Objectives: (i) To describe a case of anti-GABABR encephalitis mimicking vasodepressor syncope at onset and (ii) the possible role of cancer and ancillary antibody (anti-KCTD16) status to determine prognosis.

Materials: The patient underwent a comprehensive screening for antibodies against extracellular/synaptic neuronal antigens and intracellular antigens in serum and CSF using commercial kits (Euroimmun, Lübeck, Germany), which revealed an anti-GABABR positivity confirmed by indirect immunofluorescence assay (IIFA). In addition, the samples were also tested at the French Reference Center using inhouse cell-based assays for anti-GABABR confirmation and for anti-KCTD16 testing, a novel antibody that was found to associate to paraneoplastic anti-GABABR cases.

Methods: Case report.

Results: A previously healthy 43-year-old man presented with isolated syncope of undetermined origin, occurring without prodromes. No associated cognitive, epileptic, or psychiatric symptoms were noted. Brain computed tomography (CT) and routine laboratory tests were negative/normal. During the overnight stay in the Emergency Department, he developed severe bradycardia (30 bpm) followed by tachycardia (133 bpm) and was found unconscious. Echocardiogram and brain magnetic resonance imaging (MRI) with gadolinium were normal. Tilt-test resulted positive for vasodepressor syncope and the patient was discharged. Two weeks later, he was re-admitted for recurring episodes of loss of consciousness. He became aggressive and confused and a single generalized tonic-clonic seizure was observed. Electroencephalogram (EEG) showed sharp theta-delta activity and sharp waves in the left temporal region. Antiseizure medications were started. Cerebrospinal fluid examination showed pleocytosis (14/μL). Microbiological screening was negative. GABABR antibodies were positive in both CSF and serum, while KCTD16 antibodies were negative. Immunotherapy with intravenous immunoglobulin (IVIG) and steroid bolus was started, with gradual improvement. Total body CT and PET-CT scans performed every 4 months for 1 year were negative. After an additional IVIG cycle, he fully recovered. Complete neurological and neuropsychological evaluation at last follow-up were normal.

Discussion: Anti-GABABR encephalitis typically presents with prominent epileptic symptoms, including status epilepticus. Some patients develop cognitive and behavioural symptoms. [1] Conversely, dysautonomia as an early symptom is rare. [2,3] Only another case of anti-GABA-B-R encephalitis mimicking syncope has been described. [2]

Conclusions: Non-paraneoplastic anti-GABA-B-R encephalitis may have a better response to immunotherapy and an atypical clinical onset (e.g. dysautonomia). The diagnosis can be challenging as the neuroimaging studies can be negative. Testing KTCD16 antibodies may help to exclude a paraneoplastic association and to support a favourable prognosis.

## GASTRO-INTESTINAL DYSFUNCTION AS FIRST SYMPTOM OF FATAL DOUBLE POSITIVE (SOX1, HU) ENCEPHALITIS

G. Magro[1], L. Mumoli[2], A. Fratto[2], E. Colosimo[2], R. Iannacchero[2], E. Le Piane[2], M. Pantusa[2], A. Clodomiro[2], D. Pirritano[2], A. Lucisano[2], T. Tallarico[2], G. Frontera[2], D. Bosco[2]

[1]Neurology, University "Magna Græcia" of Catanzaro (Catanzaro); [2]Neurology, Pugliese Ciaccio Hospital (Catanzaro)

Objectives: Here we report a man with subacute gastro-intestinal symptoms (diarrhea and vomiting) followed by chronic intestinal pseudo-obstruction (as typically described in DPPX encephalitis), who had encephalitis correlated to a double positivity of anti-Sox1 and anti-Hu antibodies, without evidence of cancer with fatal course.

Methods: A 73 years-old male, with no other relevant past medical history, complained for a month of epigastralgia, loss of appetite, hiccups and vomiting and diarrhea. He presented to our hospital for acute intestinal obstruction. The night before presentation he had an episode of absence with fluctuating state of consciousness, and subsequently developed a non-convulsive status epilepticus (NCSE).

Results: Neurological examination showed: altered vigilance, with no other neurological signs. Only a moderate hyponatremia (127) was found. Extensive infectious, paraneoplastic, biochemical panel was normal. EEG showed sub-continue left temporal discharges, and brain MRI confirmed an unilateral left limbic involvement. Lumbar puncture was negative for infectious causes. He was started immediately on high dose methyl-prednisolone plus IV-immunoglobulin therapy. No evidence of intestinal obstruction on total-body-CT, gastroscopy and colonoscopy was found. Three days after initial recovery he died. Positivity of Anti-Hu and anti-Sox1 antibodies were found, on serum and CSF.

Conclusion: Gastro-intestinal manifestations are notoriously associated with anti-DPPX encephalitis [1]. Recently, also anti-Hu encephalitis has been reported to cause gastro-intestinal motility impairment [2]. Clinicians should keep in mind that isolated gastroparesis could be the initial sign of an encephalitis, moreover multiple antibody positivity is increasingly recognized as predictive of a worse outcome [3].

## STEROID-RESPONSIVE ENCEPHALOPATHY ASSOCIATED WITH AUTOIMMUNE THYROIDITIS (SREAT): A DIAGNOSIS OF EXCLUSION

S. Malatini, S. Paolucci, A. Riva, F. Cancellieri, M. Cervigni, C. Di Felice, G. Marini, M. Bartolini, M. Silvestrini, G. Viticchi

Azienda Ospedaliero-Universitaria delle Marche, Marche Polytechnic University (Ancona)

Introduction: Steroid-responsive encephalopathy associated with autoimmune thyroiditis (SREAT) is an uncommon neurological syndrome associated with autoimmune thyroid disease. The pathogenesis of SREAT is uncertain even if the last evidence point towards a probable autoimmune etiology due to vasculitis or other inflammatory processes. Clinical manifestations of SREAT are various and unspecific. Due to the lack of any specific diagnostic investigations, SREAT is mainly a diagnosis of exclusion to be considered in the setting of subacute onset encephalopathy with high titers of anti-thyroid peroxidase (anti-TPO) and/or anti-thyroglobulin (anti-Tg) antibodies and responsiveness to glucocorticoid therapy in the absence of other neural autoantibodies [1].

Case report: A 56-year old woman arrived to our hospital complaining a ten days history of speech arrest, impairment in executive and attentional functions, dizziness and postural tremor of the limbs. The EEG showed diffuse slow sharp waves. The brain MRI and the body CT did not show significant finds. Her cerebrospinal fluid (CSF) analysis was normal. We found in the clinical history an hypothyroidism treated by specific therapy. During hospitalization, thyroid hormones title was normal but thyroid peroxidase antibody (anti-TPO-Ab) resulted higher than normal. All other blood investigations, including antinuclear antibodies titers and serological and virologic tests, were negative [2]. The patient was treated by intravenous methylprednisolone with a dramatic symptoms improvement within 72 hours.

Discussion: The majority of SREAT cases presents a fluctuating course with variable features such as cognitive impairment, seizures, tremor, ataxia, sleep disturbance, headache, focal neurological deficits, depression or psychosis. Disease manifestations of SREAT occur independently to the thyroid status. High titers of anti-TPO-Ab are found in nearly all reported cases till to be considered a hallmark of the disease even if its role in pathogenesis of SREAT is still uncertain. Our patient had elevated anti-TPO-Ab titers and also showed a dramatic improvement following intravenous steroid therapy which are both described as typical clinical characteristics of SREAT.

Conclusions: The diagnosis of SREAT is primarily based on the exclusion of other infective, inflammatory, autoimmune and neoplastic etiologies of encephalopathy. A subacute onset of symptoms compatible with an encephalopathy, an high anti-thyroid antibodies level and a dramatic clinical response to steroid therapy should suggest a possible diagnosis of SREAT. This case also emphasizes that patients with subacute encephalopathy should be screened for antithyroid antibodies despite their euthyroid status.

## ISOLATED RETROGRADE AMNESIA IN ANTI-CASPR2 ENCEPHALITIS: A CASE SERIES AND SYSTEMATIC LITERATURE REVIEW

A. Malvaso[1], D. Cerne[2], S. Bernini[3], E. Marchioni[4], C. Cerami[5], V. Esposito[1], F. Massa[1], D. Franciotta[6], S. Bottiroli[7], L. Benedetti[2], M. Gastaldi[6]

Mondino" National Neurological Institute (Pavia); [4]Neurooncology and Neuroinflammation Unit, IRCCS "C. Mondino" National Neurological Institute (Pavia); [5]Center for Neurocognition, Epistemology and Theoretical Syntax, Scuola Universitaria Superiore IUSS Pavia (Pavia); [6]Neuroimmunology Research Unit, IRCCS "C. Mondino" National Neurological Institute (Pavia); [7]Headache Science Center, IRCCS "C. Mondino" National Neurological Institute (Pavia)

Introduction and Aims: Anti-leucine-rich glioma inactivated 1 (LGI1) and anti-contactin-associated protein-like 2 (CASPR2) antibodies can associate with limbic autoimmune encephalitis (LAE) typically manifesting as anterograde amnesia, behavioral disorders and seizures. Retrograde amnesia has also been rarely described. We report a case series of CASPR2-positive pure episodic-autobiographical retrograde amnesia and we systematically review the literature data on memory impairment in CASPR2/LGI1 encephalitis.

Materials: Clinical data have been collected from medical records.

Methods: A systematic literature search of all published CASPR2 and LGI1 encephalitis with memory impairment was performed.

Results: A 72-year-old male patient presented with seizures and behavioral changes. Brain Magnetic Resonance Imaging (MRI) revealed bilateral temporomesial abnormalities. Anti-CASPR2 antibodies were found in both cerebrospinal-fluid (CSF) and serum. He additionally complained of retrograde amnesia involving the 6 months preceding the onset of LAE, during which his behavior was completely unaffected according to his wife. A 52-year-old male patient presented with seizures, behavioral changes, and retrograde amnesia dating back more than 12 months to the onset of LAE. Brain MRI showed blurred hyperintensity of limbic structures. Anti-CASPR2 antibodies were found only in serum. Among 21 studies describing 452 patients with LGI/CASPR2 LAE, retrograde amnesia was reported in only 7/415 anti-LGI1 (1,69%), 5/452 (0,92%) with anti-VGKC and in none with anti-CASPR2, and always in association with anterograde amnesia.

Discussion: Retrograde amnesia is a rare entity mostly attributed to post-traumatic-stress-disorder and has been associated with high Ca2+ levels due to neuroplastin loss interfering with signal transmission in Cornu Ammonis 3 (CA3) hippocampal region. We report the first two cases of pure retrograde amnesia in CASPR2 LAE. This manifestation is extremely rare in LGI1/CASPR2 LAE, where it commonly associates with anterograde amnesia. We suggest an integrated model of the pathogenesis characterized by alteration of plasma membrane Ca2+ ATPase proteins, abnormal signal transmission in GABA-A and AMPAR synapses, and higher voltage-gated potassium channel (Kv1) expression in the CA3 hippocampal region.

Conclusions: Exploring the effects of CASPR2 antibodies on CA3 might provide insight into the pathophysiology of retrograde amnesia.

## NEUROINFLAMMATION AND BASAL GANGLIA CIRCUIT DYNAMICS: A STUDY ON THE EFFECTS OF ACUTE PERIPHERAL INFLAMMATION ON DOPAMINERGIC NEURONS

A. Mancini[1], L. Bellingacci[1], J. Canonichesi[1], C. Costa[1], L. Parnetti[1], N. Tritsch[2], M. Di Filippo[1]

[1]Section of Neurology, University of Perugia (Perugia); [2]Neuroscience Institute, New York University Grossman School of Medicine (New York-USA)

Background: The basal ganglia (BG) circuit is a neuronal network mediating locomotor activity and movement execution, emotional states, social behavior, reward, and motivation. The activity of the nucleus striatum, the input station of the circuit, is strongly regulated by dopamine (DA)-releasing midbrain neurons [1]. An abnormal activation of the immune system (IS) characterizes the pathogenesis of both psychiatric and neurological disorders and is known to influence neuronal network functioning in the cerebral cortex [2,3]. To date, the influence of IS activation on DA-releasing cells and BG circuit dynamics is poorly understood.

Materials and Methods: Electrophysiological analyses of midbrain DA neurons activity and striatal synaptic plasticity were performed in lipopolysaccharide- (LPS) treated animals, 24 hours after treatment, and in control animals. Local inflammation patterns and dopamine neuron markers were assessed through immunohistochemistry.

Results: Acute peripheral inflammation increased midbrain DA neurons' firing rate and excitability state and was associated with impaired striatal synaptic plasticity. Immunohistochemical analysis showed an unaltered number of midbrains DA cells, while it showed increased activation of microglial, but not astroglial markers at the level of the substantia nigra and no changes in inflammatory markers at the level of the nucleus striatum.

Discussion: The obtained data suggest that acute systemic inflammation results in functional alterations of the BG circuit at multiple levels.

Conclusions: The involvement of DA neurons after IS activation could underlie cognitive and psychiatric symptoms in neuroinflammatory brain disorders.

## A RETROSPECTIVE COMPARATIVE STUDY OF AUTOIMMUNE COMORBIDITIES IN AUTOIMMUNE ENCEPHALITIS AND MULTIPLE SCLEROSIS

G. T. Maniscalco[1], A. Dinoto[2], G. Servillo[1], V. Manzo[1], K. Longo[1], M. Di Battista[1], S. Salvatore[1], E. Prestipino[1], O. Moreggia[3], D. Di Giulio Cesare[3], S. Miniello[4], F. Romano[5], S. Ferrari[2], V. Andreone[1], S. Mariotto[2]

[1]Neurological Clinic and Stroke Unit, "A. Cardarelli" Hospital (Napoli);[2]Neurology Unit, Department of Neurosciences, Biomedicine, and Movement Sciences, University of Verona (Verona); [3]Multiple Sclerosis Regional Center, "A. Cardarelli" Hospital (Napoli); [4]Neurology and Stroke Unit, "Sant'Anna e San Sebastiano" Hospital (Caserta); [5]Multiple Sclerosis Center, CTO Hospital, AORN "Ospedale dei Colli" (Napoli)

Background: Autoimmune comorbidities and anti-nuclear antibodies (ANA) may provide a diagnostic clue in the diagnosis of autoimmune encephalitis (AE). The aim of this study is to evaluate the prevalence of ANA in patients with AE.

Materials and Methods: In this retrospectively study we included consecutive patients with "definite AE" (defined as seropositive AE) and "possible AE" or "antibody negative, but probable AE" or "definite limbic encephalitis" (defined as seronegative AE) diagnosed according to 2016 Graus' criteria. A group of patients with multiple sclerosis (MS) was included as controls. ANA were tested with indirect immunofluorescence (IIF) using human epithelial type 2 cells, neuronal antibodies were tested with immunohistochemistry, cell-based assays and immunoblots, as appropriate. Autoimmune comorbidities, clinical, paraclinical and demographic data were retrospectively collected. A comparison between groups was performed using Mann-Whitney U and chi-square tests, as appropriate.

Results: 48 patients with AE (34 seronegative, 14 seropositive) and 50 patients with MS were included. Mean age at sampling was 54.3 ±17.1 and 40.4 ±12.4 years-old respectively ($p<0.0001$), with no differences in terms of gender (25 and 32 females, respectively, $p=0.85$). ANA positivity was reported in 35 (72.9%) patients with AE and in 24 (48%) cases with MS ($p=0.01$), whereas autoimmune comorbidities were reported in 20 (41.7%) and 10 (20%) patients, respectively ($p=0.01$). Either one between ANA positivity or autoimmune comorbidities were reported in 40 (83.3%) patients with AE versus 31 (62%) patients with MS ($p=0.01$). Paired ANA positivity and autoimmune comorbidities were more frequent in AE group (n=15, 31.3% vs n=3, 6% $p=0.001$). Lastly, seronegative AE showed increased ANA/autoimmune comorbidities compared to seropositive cases (n=9, 64.3% vs n=31, 91.2%, $p=0.02$).

Conclusion: Our study shows that patients with AE have more frequent positive ANA/autoimmune comorbidities when compared to patients with MS. This finding may be related to the loss of B cell tolerance that leads to the production of autoantibodies. The presence of autoimmune comorbidities or positive ANA may be useful in the diagnostic process of seronegative AE.

## COGNITIVE PROFILE IN ADULT PATIENTS WITH MYELIN OLIGODENDROCYTE GLYCOPROTEIN ANTIBODY-ASSOCIATED DISEASE (MOGAD): A COMPARATIVE STUDY WITH MULTIPLE SCLEROSIS

G. T. Maniscalco[1], A. Ziello[1], A. Dinoto[2], E. Mantovani[2], D. Di Giulio Cesare[1], O. Moreggia[1], M. Di Battista[3], E. Prestipino[3], S. Salvatore[3], S. Carta[2], S. Ferrari[2], S. Tamburin[2], V. Andreone[1], S. Mariotto[2]

[1]Multiple Sclerosis Center, A. Cardarelli Hospital (Napoli); [2]Neurology Section, Department of Neurosciences, Biomedicine, and Movement Sciences, University of Verona (Verona); [3]Multiple Sclerosis Center; Neurological Clinic and Stroke Unit, A. Cardarelli Hospital (Napoli)

Background: Myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) is a recently defined antibody-mediated disorder of the central nervous system (CNS). In the last decade, several studies defined the clinical and radiological phenotypes of the disease, but data on neurocognitive outcomes are limited. We herein compared the cognitive performance of patients with MOGAD to those with MS.

Methods: The Brief Repeatable Battery of Neuropsychological Test (BRB-N) and the Stroop Color Word Test (SCWT) were administered to 15 patients with MOGAD (age: 38.7±16.4; females: 60%; disease duration: 22.8±11.7 months) and 13 with MS (age: 33.4±8.2; females: 77%; disease duration: 39.9± 32.6 months). Descriptive statistic was generated for demographic variables. The Mann-Whitney U test was used to compare the BRB-N and SCWT outcomes between groups ($p < 0.05$, two-sided).

Results: MOGAD patients performed slightly worse than MS patients in the Long Term Storage (MOGAD: 39.6, MS: 45.1, $p=0.19$), Consistent Long-Term Retrieval (MOGAD: 31.2, MS: 36.4, $p=0.10$) and Symbol Digit Modalities (MOGAD: 44.4, MS: 49.5, $p=0.26$), and slightly better in the Paced Auditory Serial Addition Test (MOGAD: 39.6, MS: 37.5, $p=0.44$), but the difference did not reach statistical significance.

Discussion: MOGAD patients showed a trend towards more difficulties in verbal immediate learning and concentration skills that did not reach statistical significance. The small sample size and the imbalance in baseline conditions might have contributed to the present results.

Conclusions: MOGAD patients seem to have a specific cognitive profile, further demonstrating the peculiarity of this condition.

## EPSTEIN-BARR VIRUS-SPECIFIC ANTIBODIES IN MOGAD COMPARED TO MULTIPLE SCLEROSIS

G. T. Maniscalco[1], A. Dinoto[2], M. Foglia[3], S. Salvatore[4], E. Prestipino[4], M. Di Battista[4], O. Moreggia[1], D. Di Giulio Cesare[1], S. Carta[2], V. Chiodega[2], S. Ferrari[2], A. Viola[5], V. Andreone[4], S. Mariotto[2]

[1]Multiple Sclerosis Center, "A. Cardarelli" Hospital (Napoli); [2]Neurology Unit, Department of Neurosciences, Biomedicine, and Movement Sciences, University of Verona (Verona); [3]Clinical Pathology and Microbiology Laboratory, "A. Cardarelli" Hospital (Napoli); [4]Neurological Clinic and Stroke Unit, Multiple Sclerosis Center, "A. Cardarelli" Hospital (Napoli); [5]Molecular Biology Laboratory, Hematology and Transplantation CSE, "A. Cardarelli" Hospital (Napoli)

Background: Myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) is an antibody-mediated disorder of the central nervous system (CNS) with distinct pathomecnanisms, clinical

phenotypes, and treatment response. Recent evidence demonstrated an association between multiple sclerosis (MS) and an antecedent Epstein Barr virus (EBV) exposure. The possible association between EBV and MOGAD has not been studied, yet. We performed a retrospective study comparing the EBV serological status of MOGAD versus MS patients at diagnosis. Additional cases are now on recruitment.

Materials and Methods: We enrolled 18 patients with MS and 9 patients with MOGAD referred to our Neuroimmunology Center. Epstein-Barr nuclear antigen (EBNA)-1 and viral capsid antigen (VCA) antibodies were measured in diluted sera by chemiluminescence immunoassays (CLIAs) at "A. Cardarelli" Hospital Laboratory. Antibodies to MOG were detected with an in house live cell-based assays at the Neuroimmunology and Neuropathology Laboratory, University of Verona.

Results: No differences in gender (6 females in the MOGAD cohort, 12 in the MS group, 66.7%, p=1.0) nor in age distribution (mean 38.1 ± 15.4 vs 38.9 ±10.4) were observed in the two groups. All included patients were positive at the VCA IgG test (limit value >20 U/ml). In addition, 88.9% of MOGAD patients and 94.4% MS cases were also positive for EBNA IgG, with no differences between the two groups (p=1.0). Mean VCA IgG values was higher in the MOGAD group, with no differences compared to the MS group (424 U/ml vs 324 U/ml, p=0.418). EBNA IgG mean value (±sd) was 464 U/ml (±256) for MOGAD patients and 475 U/ml (±199) for MS cases, with no differences (p=0.611).

Conclusion: Our data suggest that EBV might play a pathogenetic role in MOGAD, similarly to MS. Further prospective studies are needed to clarify the causal link between EBV and MOGAD.

## A CASE OF ACUTE HYPERTENSIVE HYDROCEPHALUS IN A QUANTIFERON-POSITIVE PATIENT WITH AN INFLAMMATORY MENINGOENCEPHALITIS

E. Mannini[1], B. Pancaldi[1], I. Florindo[2]

[1]Neurology Unit, University of Parma (Parma); [2]Unit of Neurology, University Hospital of Parma (Parma)

The diagnosis of neuroinflammatory diseases is still challenging in some cases. In addition, exclusion of mimics (especially infections) remains an important aspect of management to avoid inappropriate treatment. Hydrocephalus can be one of the acute manifestations of neuroinfectious and neuroinflammatory diseases and has been reported in almost 5-10% of neurosarcodosis cases. We present a particularly challenging case. An Indian patient was admitted to our hospital after 1 week of fever and headache only partially responsive to symptomatic drugs. He had a silent medical history. The neurological examination revealed an alert patient, oriented to person and space, with a marked neck stiffness. The lumbar puncture revealed a limpid cerebrospinal fluid with elevation of mononucleated-cell count (320 cells), no red cells, slightly reduced level of glucose (34 mg/dl) and elevated total proteins (138 mg/dl). A broad-spectrum antibiotic and antiviral therapy was started and then stopped after the negative results of bacterial and viral PCR on CSF. After a few days the patient developed acute mental confusion, drowsiness and the palsy of the right 6th cranial nerve was noted. An urgent CT showed acute hypertensive hydrocephalus and an external ventricular shunt was immediately positioned. Meanwhile, interferon-y release assay for tuberculosis resulted positive and BK culture on CSF was required. An antitubercular therapy was initiated. A thorax CT showed a solid non- calcified nodule in the superior right pulmonary lobe with a few enlarged lymph nodes. The MRI revealed abnormalities in the mesencephalic tegmen, quadrigeminal tubercles, left hypothalamic region and bilateral hippocampal alterations. After 3 weeks the results of the BK culture excluded tubercular infection. Clinically, the patient progressively worsened becoming comatose. Unfortunately, it was not possible to carry out either a meningeal biopsy or a lung biopsy. Therefore, according to the criteria of 2018 (Stern et al.) a diagnosis of possible neurosarcoidosis was formulated after having excluded a tubercular and brucellar meningitis, neurobehcet, neuromyelitis optica spectrum disorder (NMOD) and CNS lymphoma. A therapy with high dose corticosteroids was finally started with success. At the three-month follow-up, the patient had recovered almost completely except for bilateral hearing loss and mild memory impairment. Radiological improvement was also noted. This case highlights the importance of a differential diagnosis among the possible causes of acute hypertensive hydrocephalus in order to start the most appropriate therapy as early as possible.

General Hospital (Hanamaki-J); [13]Department of Neurology, Leiden University Medical Center (Leiden-NL); [14]Department of Neurology, The University of North Carolina (Chapel Hill-USA)

Goal: Efgartigimod is a human IgG1 antibody Fc-fragment that reduces total IgG and pathogenic IgG autoantibody levels through neonatal Fc receptor blockade. ADAPT was a 26-week, global, multicentre, randomized, controlled, phase 3 trial evaluating efgartigimod in patients with generalized myasthenia gravis (gMG). Patients who completed ADAPT were eligible to enroll in the ADAPT+ open-label extension study to evaluate the long-term safety and efficacy of efgartigimod.

Methods: Efgartigimod (10 mg/kg IV) was administered in cycles of once-weekly infusions for 4 weeks, with subsequent cycles initiated based on clinical evaluation. The primary objective in ADAPT+ was to evaluate long-term safety and tolerability of efgartigimod in patients with gMG. Long-term efficacy was also assessed utilizing Myasthenia Gravis Activities of Daily Living (MG-ADL) and Quantitative Myasthenia Gravis (QMG) scales.

Results: 90% of patients (151/167) from ADAPT entered ADAPT+ and 145 (111 anti-AChR-Ab+/34 anti-AChR-Ab-) received ≥1 cycle as of 30 June 2022. With 229 patient-years of follow-up (mean duration per patient: 610 days), the most common adverse events were headache (25%), concomitant COVID-19 infection (16%), nasopharyngitis (14%), diarrhea (10%), and urinary tract infections (9%) which were mostly mild-moderate and did not increase in frequency with subsequent cycles. AChR-Ab+ patients with ≥1 year of follow-up across ADAPT/ADAPT+ (n=95) received a median (range) 5.2 (0.5–7.5) cycles per year. In anti-AChR-Ab+ patients (n=111), consistent improvements in MG-ADL (mean[SE] change week 3 of cycle 1: -5.0[0.33]; up to 16 cycles) and QMG (-4.7[0.41]; up to 7 cycles) scores were observed during each cycle, mirroring repeatable reductions in total IgG (mean[SE] reduction: -55.9%[1.15]; up to 7 cycles) and anti-AChR autoantibody levels (-56.1%[1.43]; up to 7 cycles).

Conclusions: These analyses of ADAPT+ suggest long-term efgartigimod treatment is well-tolerated and results in consistent and repeatable reductions in IgG antibody levels and clinical outcomes (MG-ADL and QMG) in patients with gMG.

## LONG-TERM SAFETY, EFFICACY & SELF-INJECTION SATISFACTION WITH ZILUCOPLAN IN MYASTHENIA GRAVIS: RAISE-XT INTERIM ANALYSIS

R. Mantegazza[1], M. I Leite[2], S. Bresch[3], M. Freimer[4], A. Genge[5], C. Hewamadduma[6], Y. Hussain[7], A. Maniaol[8], M. Śmiłowski[9], K. Utsugisawa[10], T. Vu[11], P. W. Duda[12], B. Boroojerdi[13], M. Vanderkelen[14], G. de la Borderie[15], J. Bloemers[16], J. F Howard Jr[17] on behalf of the RAISE-XT study team

[1]Department of Neuroimmunology and Neuromuscular Diseases, Fondazione IRCCS, Istituto Neurologico Carlo Besta (Milano); [2]Nuffield Department of Clinical Neurosciences, University of Oxford (Oxford-UK); [3]Service de Neurologie, Hospital Pasteur - Centre Hospitalier Universitaire de Nice (Nice-F); [4]Department of Neurology, The Ohio State University Wexner Medical Center (Columbus-USA); [5]Clinical Research Unit, The Montreal Neurological Institute (Montreal-Canada); [6]Academic Neuroscience Unit, Sheffield Teaching Hospitals Foundation Trust (Sheffield-UK); [7]Department of Neurology, Dell Medical School, The University of Texas at Austin (Austin-USA); [8]Department of Neurology, Oslo University Hospital (Oslo-N); [9]Department of Hematology and Bone Marrow Transplantation, Medical University of Silesia (Katowice-PL); [10]Department of Neurology, Hanamaki General Hospital (Hanamaki-J); [11]Department of Neurology, University of South Florida, Morsani College of Medicine (Tampa-USA); [12]Global Development, UCB Pharma (Cambridge-USA); [13]Medical Solutions, UCB Pharma (Monheim-D); [14]Safety and Risk Management, UCB Pharma (Braine-l'Alleud-B); [15]Biostatistics, UCB Pharma (Brussels-B); [16]Patient-Centered Outcomes, UCB Pharma (Brussels-B); [17]Department of Neurology, The University of North Carolina at Chapel Hill (Chapel Hill-USA)

Objectives: Long-term data from RAISE-XT (NCT04225871), a Phase 3, multicentre, open-label extension study, will enhance our understanding of the safety, efficacy and self-injection satisfaction of zilucoplan, a C5 complement inhibitor with dual mechanism of action,[1] in patients with generalised myasthenia gravis (gMG).

Materials and Methods: Adults (aged 18–75 years) with gMG who completed a qualifying zilucoplan study (Phase 2 NCT03315130/Phase 3 NCT04115293 [RAISE] [1]) self-administered daily subcutaneous injections of zilucoplan 0.3 mg/kg. Primary outcome was incidence of treatment-emergent adverse events (TEAEs). Secondary efficacy outcomes included change from qualifying double-blind study baseline in Myasthenia Gravis Activities of Daily Living (MG-ADL) score. The Self-Injection Assessment Questionnaire (SIAQ; domain scores 0–10; higher scores indicate more positive experience) was completed by US patients directly after self-injection and measured patient satisfaction with self-injection.

Results: At data cut off (8 September 2022), 200 patients had enrolled in RAISE-XT. Median (range) exposure was 1.2 (0.11–4.45) years. TEAEs occurred in 188 (94.0%) patients; 64 (32.0%) patients experienced a serious TEAE. Mean (standard deviation) changes from double-blind study baseline in MG-ADL score continued to decrease through Extension Week 12 and were maintained through to Extension Week 48 (Week E48) for the zilucoplan and placebo-switch groups: −5.95 (4.14) and −6.85 (5.13) at Week E48, respectively. In the SIAQ domain of satisfaction with self-injection, median score was 8.20 (range: 3.9–10.0; n=63).

Discussion and Conclusions: In this interim analysis of RAISE-XT, zilucoplan demonstrated a favourable long-term safety profile and sustained efficacy through to Week E48. High satisfaction rates with self-injection were reported. Funding: UCB Pharma.

Jana Pawla II (Kraków-PL); [7]Argenx (Ghent-B); [8]Curare Consulting BV (Liempde-NL); [9]Department of Neurology, Cleveland Clinic (Cleveland-USA); [10]Department of Neurology, Hanamaki General Hospital (Hanamaki-J); [11]Department

of Neurology, University of Naples Federico II (Napoli); [12]Department of Neurology, University of Münster (Münster-D); [13]Faculty of Medicine and Health Sciences, Ghent University Hospital (Ghent-B); [14]Department of Neurology, The University of North Carolina (Chapel Hill-USA)

Goals: Evaluate long-term safety, tolerability, and efficacy of subcutaneous (SC) efgartigimod PH20 (coformulated with recombinant human hyaluronidase PH20) in patients with generalized myasthenia gravis (gMG) enrolled in the ADAPT-SC+ open-label extension study. In ADAPT-SC, efgartigimod PH20 SC 1000 mg was shown to have non-inferior total IgG reduction to efgartigimod IV 10 mg/kg (approved in US, Japan, and EU) resulting in similar clinical improvement in patients with gMG. Patients completing ADAPT-SC, or enrolled in ADAPT+, were eligible to participate in the ongoing open-label extension, ADAPT-SC+.

Methods: Efgartigimod PH20 SC 1000 mg was administered in cycles of 4 weekly injections. Subsequent cycles were initiated at least 28 days from the last dose based on clinical evaluation. Clinical efficacy was assessed utilizing the Myasthenia Gravis Activities of Daily Living (MG-ADL) scale.

Results: As of March 2022, 164 participants received ≥1 dose of efgartigimod PH20 SC. Patients received ~3 cycles over a mean (SD) study duration of 170 (59) days, resulting in 72 patient-years of observation. Adverse events (AEs) were predominantly mild to moderate. The most frequent AEs were injection site erythema (25.6%), headache (15.2%), and COVID-19 (11.6%). All injection site reactions (ISRs) were mild/moderate and did not lead to treatment discontinuation. ISRs typically occurred within 24 hours of administration, resolved spontaneously, and incidence decreased with subsequent cycles. Two deaths were reported (metastatic renal cancer and COVID-19); neither were deemed efgartigimod-related per investigator. Improvement from cycle baseline in MG-ADL total score (mean [SE] improvement at week 4: –4.0 [0.25]) was observed in cycle 1, with consistent and repeatable improvements seen in subsequent cycles. Long-term treatment with efgartigimod PH20 SC 1000 mg can reduce disease severity, as assessed by the MG-ADL scale, and improve the quality of life of patients with gMG. Speed of onset, magnitude, and repeatability of improvements in MG-ADL were similar to those with efgartigimod IV during ADAPT/ADAPT+.

Conclusions: Results demonstrate that efgartigimod PH20 SC treatment was well tolerated, with no safety concern identified. Treatment with efgartigimod PH20 SC led to consistent and repeatable reductions in MG-ADL total score, and the observed safety and efficacy profile was consistent with ADAPT/ADAPT+.

## INVESTIGATING THE EFFECT OF ANTI-MENINGOCOCCAL VACCINE IN PATIENTS ON ECULIZUMAB THERAPY

S. Marini, S. Falso, E. Sabatelli, R. Iorio

Department of Neurosciences, Catholic University of the Sacred Heart (Roma)

Objectives: To evaluate the response to meningococcal vaccination in patients receiving Eculizumab therapy.
Materials: Serum samples were collected from five patients candidate for Eculizumab therapy. Four patients (pt 1-4) with a diagnosis of refractory generalized myasthenia gravis (gMG) associated with acetylcholine receptor (AChR) antibodies (Ab) and one patient (pt 5) with both neuromyelitis optica spectrum disorder associated with aquaporin 4 (AQP4) Ab and AChR-Ab+ gMG were recuited. All patients received meningococcus B and ACWY conjugate vaccination at least two weeks before sample collection, without receiving a booster dose.

Methods: Immunogenicity was assessed using the Serum Bactericidal Assay (SBA) for serogroups A, C, W, and Y with an exogenous source of rabbit complement. A titer of 1/8 was considered protective for neutralizing antibodies (NAb). Immunogenicity for serogroup B was not assessed since the assay employs the endogenous human C5 fraction that is inhibited by Eculizumab.

Results: In all patients, the response to meningococcal vaccine for serogroups A, C, W, and Y was incomplete. Patient 1 showed high antibody titers to serogroups A and C (NAb titer for serogroup A: 1/1024; for serogroup C: 1/128) and a poor response to vaccination for serogroups W and Y (NAb titers <1/4 in both cases). Patient 2 showed a good response to serogroups A, W, and Y (NAb titers A: 1/512; W: 1/256; Y: 1/256) and no response to serogroup C vaccination (NAb titer <1/4). The meningococcal serology of patient 3 showed a protective response to all tested serogroups (NAb titers A: 1/512; C: 1/128; W: 1/128; Y: 1/1024). Patient 4 and Patient 5 showed a poor response to all four serogroups (NAb titers less than 1/4 for all serogroups).

Discussion and Conclusions: Patients receiving Eculizumab infusions are at increased risk of systemic infections caused by encapsulated bacteria. Fatal meningococcal infections have been reported in patients receiving complement inhibitors. Therefore, meningococcal vaccination for serogroups A, C, W, Y, and serogroup B is required at least two weeks before starting therapy. Alternatively, antibiotic coverage must be prescribed. Booster doses are mandatory only for serogroup B, while booster doses of tetravalent vaccine are not usually administered. Four out of five patients on Eculizumab therapy did not develop a protective antibody response against ACWY meningococcal serogroups. Monitoring antibody levels may be useful in-patient management to assess the need for booster doses of the ACWY vaccine.

## SATRALIZUMAB, A NEW THERAPEUTIC CHANCE IN NEUROMYELITIS OPTICA SPECTRUM DISORDER

F. Masuzzo, M. Matta, M. Torrieri, R. Ferri, M. Clerico

San Luigi Hospital, University of Turin (Torino)

Background: Satralizumab is the first monoclonal antibody that acts blocking interleukin-6 (IL-6) receptor, approved for the treatment of neuromyelitis optica spectrum disorder (NMOSD) in patients seropositive for aquaporin-4 immunoglobulin G (AQP4-IgG). Interleukin-6 (IL-6), a multifunctional cytokine, is thought to play a key role in NMOSD pathophysiology. IL-6 signaling stimulates B-cell differentiation into plasmablasts that produce pathogenic AQP4-IgG.

Case report: In April 2022, a 50 years-old woman came to our Emergency Department for a subacute walking impairment and feet burning dysesthesia. She was hospitalized and she attended an electromyography that resulted negative and a brain and spine MRI that underlined a multimetameric central dorsal (D2-D6) T2-STIR lesion with contrast enhancement. No brain lesions. The visual evoked potentials showed bilateral prolonged P100 latency. She completed the diagnostic plan with rheumatic screening test not significative, a lumbar puncture that showed negative cerebrospinal fluid analysis and

isoelectrofocusing. We also tested serum antibodies to AQP4 and MOG (myelin oligodendrocyte glycoprotein), finding a high-titer AQP4 positivity. She started high dose of steroids for 7 days without results, so we decided for PLEX (plasmapheris). After a long hospitalization she moved into a rehabilitation.

Discussion: In June 2022, after a complete screening for viral infections, she started Rituximab, a chimeric antibody that targets CD20+ B cells. Few days later, she did routine blood tests that showed very high elevations of transaminases suggesting acute hepatitis. She was hospitalized again and underwent screening for autoimmune hepatitis, resulting a doubtful positivity for antibodies against PML (promyelocytic leukaemia protein) and gp210 (nuclear pore membrane glycoprotein 210). Gastroenterology Consultants concluded for Rituximab-Related Reversible Hepatocellular damage. She discontinued Rituximab and after a period of observation we registered a decrease of liver enzymes. We were afraid about clinical and radiological relapses so we thought about an alternative. Even though in previous studies mild and moderate elevations of liver enzymes in patients treated with IL6-inhibitors have been observed, we had high hope that this drug might be the right opportunity. In November 2022, she started Satralizumab with a strict supervision. She repeated routine blood examinations twice a month and everything was in range. No clinical attacks were noticed. In April 2023 she did a new brain and spine MRI that was stable.

Conclusion: Satralizumab has been shown to be a well tolerated and safe drug. The most common adverse events are infection, headache, arthralgia, decreased white blood cell count, hyperlipidaemia and injection-related reactions.

## RECURRENT "CLOCC" LESION RELATED TO URINARY INFECTION: A CASE REPORT

V. A. Mauceri[1], M. Gaggiola[1], A. Fortuna[1], P. Perini[2], M. Puthenparampil[1]

[1]Department of Neuroscience, University of Padua (Padova); [2]Department of Neuroscience, University Hospital of Padua (Padova)

Background: Reversible lesions in the splenium of the corpus callosum (SCC) are a clinical and radiological phenomenon characterized by a hyperintense signal on T2- weighted, fluid-attenuated inversion recovery (FLAIR), and diffusion-weighted images (DWI) and diffusion coefficient (ADC) decreased on ADC maps. Because of these radiological features, these lesions have been recently redefined as "cytotoxic lesions of the corpus callosum" or "CLOCC" lesions. Their clinical presentation is usually a mild encephalitis/encephalopathy with reversible splenial lesion (MERS). Causative factors include epilepsy, infections, metabolic disorders, malignancies, vascular or traumatic brain diseases.

Case report: A 49 years-old man, affected by severe tetraparesis due to C3-C4 cervical fracture occurred four years before, presented to our emergency department for involuntary arms movements and a gradual worsening of upper limbs strength in the last month. Three days after admission to our neurological department he developed a sudden severe sensory deterioration (GCS 3). Blood examinations (D-dimer, troponin, blood gas analysis) and instrumental findings (electrocardiogram and electroencephalogram) were normal. After two hours there was a spontaneous recovery of the state of consciousness, immediately followed by an acute onset of a psychotic state characterized by visual hallucinations and delusional ideas with a religious content. CSF examination (including physical chemistry, film array and DNA of the main pathogens) was normal. Brain MRI showed a T2, FLAIR and DWI hyperintensity of the body, genu and splenium of the corpus callosum and of the corona radiata bilaterally, characterized by severe restriction in ADC. On the same day he developed fever up to 40° and Cytrobacter freundii was isolated in urine cultures. During the hospitalization, he was transferred to the intensive care unit for respiratory failure and generalized seizures. After antibiotic therapy, he underwent a gradual clinical and cognitive improvement. Brain MRI performed after 12 days showed disappearance of the previous signal alterations, except for a more tenuous but still present hyperintensity in the splenium of corpus callosum. Two other hospitalizations were made for psychomotor slowdown related to urinary infection. Brain MRI performed during the second hospitalization showed a recurrence of signal alteration in the splenium of the corpus callosum, which then disappeared again.

Conclusion: Our clinical case highlights how reversible lesions of the corpus callosum have a heterogeneous clinical spectrum with even severe life-threatening encephalopathies. Recurrence, correlation with urinary infection and normal CSF examination support the hypothesis of a reversible cytotoxic edema caused by systemic cytokine release.

## ONE YEAR FOLLOW-UP OF HUMORAL AND CELLULAR RESPONSE AFTER THE THIRD DOSE OF BNT162B2 MRNA COVID-19 VACCINE IN MULTIPLE SCLEROSIS PATIENTS TREATED WITH B-CELL DEPLETING THERAPY

P. Mellino[1], C. Deiana[2], G. Costanzo[2], G. Sanna[2], A. Perra[2], M. Campagna[2], R. Littera[2], F. Coghe[2], L. Manzin[2], L. Chessa[2], M. Melis[3], L. Lorefice[1], D. Firinu[2], G. Fenu[3]

[1]Department of Medical Sciences and Public Health, University Of Cagliari, Multiple Sclerosis Center, Binaghi Hospital, ASL Cagliari (Cagliari); [2]Department of Medical Sciences and Public Health, University Of Cagliari, and Unit Of Internal Medicine, Policlinico Universitario Di Monserrato, AOU Di Cagliari, Azienda Ospedaliero-Univeristaria (Monserrato-CA); [3]Department of Neuroscience, ARNAS Brotzu (Cagliari)

Introduction and Objectives: Vaccination against SARS-CoV-2 virus has been the most effective way of containing the COVID-19 pandemic. However, its efficacy and durability in patients undergoing immunosuppression with B-cell depleting therapy is less known. This study aimed to assess the immunization to SARS-CoV-2 and to analyze humoral and cellular response in a cohort of multiple sclerosis (MS) patients treated with Ocrelizumab (OCR).

Materials and Methods: In this prospective observational study, we measured humoral and cellular immunity using neutralization assay and specific interferon-gamma (IFN-g) release assay (IGRA) respectively, before and after the third or fourth dose of BNT162b2 and/or after COVID-19. Data were then compared with healthy controls (HC) using independent-samples t-test.

Results: The study included 8 MS patients treated with OCR and 13 HC. As for the patient's group, all of them received at least 3 doses of BNT162b2, only two 4 doses and none received the fifth. Two patients developed COVID-19, both with mild symptoms. The median of total exposures in included subjects group (vaccine shots and/or infections) was 3 and vaccination was the last event for 75% of patients. None of

the patients and the HC were found negative for neutralizing assay or IGRA test after the third dose and in early 2023 Independent-samples T test showed a statistically significant difference (p=0.047) between the mean delta of neutralizing antibodies (after 3rd dose and in early 2023) of the two groups. The same comparison for IGRA test did not show significant differences between the two groups (p=0.49).

Discussion: The results show how humoral response significantly decreased during the follow up period in the Anti-CD20 group compared to HC, while similar evolution resulted for cellular immunity in both groups. None of the patients nor the HC presented negative results in both tests, confirming the immunogenicity of three doses of BNT162b2 vaccine with both cellular and humoral response.

Conclusions: Patients undergoing OCR therapy showed comparable responses in terms of cellular immunity, while, as expected for a CD20-depleting therapy, humoral response appeared reduced, even though not entirely absent, during the follow up period.

## ANTI-RECOVERIN ANTIBODIES IN A CEREBELLAR SYNDROME WITHOUT RETINAL INVOLVEMENT

M. Minetti[1], G. Balella[1], L. Zinno[2]

[1]Department of Medicine and Surgery, University of Parma (Parma); [2]Department of General and Specialized Medicine, AOU Ospedale Maggiore (Parma)

Objective: This case report aims to describe a rare case of anti-recoverin positive cerebellar syndrome in a patient without any evidence of malignancy or retinopathy. The objective is to discuss the underlying pathophysiology and clinical management of this condition.

Materials: The materials used for this case report include the medical records, neuroimaging data, and laboratory results of a 57-year-old male patient. The patient had a history of drug addiction, uncontrolled hypertension, and obesity. He presented to our hospital with subacute dizziness, ataxia, and a feeling of light-headedness. Despite prior treatment for labyrinthitis, his symptoms persisted and he also developed dysarthria and dysphagia. Neurological evaluation revealed a left VII cranial nerve deficit, dysarthria, left lower limb hyposthenia, bilateral dysmetria and dyssynergy at limbs, severe ataxia with multidirectional oscillations and widened base in orthostatic position, requiring bilateral support.

Methods: The patient underwent a neurological evaluation to assess the extent and nature of his symptoms. Radiological examinations were performed, such as brain MRI to investigate the brain structure, a chest-abdomen CT with ultrasound completion of the thyroid and testicles to investigate a possible paraneoplastic syndrome. Diagnostic lumbar puncture was carried out to analyze cerebrospinal fluid for protein levels, leukocyte counts and oligoclonal bands. Laboratory tests, electroneurography and blink reflex test results were considered. The patient was treated with intravenous immunoglobulins and, subsequently, received high-dose steroid therapy. Follow-up assessments were conducted after the initial treatment, including re-evaluation of symptoms and monitoring of clinical improvements.

Results: Radiological examinations did not show any abnormalities. Lumbar puncture revealed mild protein elevation and lymphocytic pleocytosis. Serological tests were positive for anti-recoverin antibodies. Treatment with intravenous immunoglobulins and high-dose steroids led to clinical improvement, including regression of the cranial nerve deficit and improved trunk control.

Discussion: The absence of retinopathy or cancer posed challenges in the diagnosis and treatment of this case. Despite the patient's multiple comorbidities, other potential causes were ruled out. The presence of anti-recoverin antibodies in the patient's serum, along with the positive response to immunomodulatory therapy, suggests a possible association between anti-recoverin antibodies and cerebellitis.

Conclusion: This case report highlights an unusual case of anti-recoverin positive cerebellitis without retinopathy or neoplasia. Although the absence of these antibodies in the cerebrospinal fluid is a limitation, the clinical improvement with immunomodulatory therapy supports an autoimmune etiology. Further research is necessary to better understand the underlying mechanism and establish diagnostic and therapeutic guidelines for similar cases.

## A REAL-LIFE EXPERIENCE WITH ECULIZUMAB AND EFGARTIGIMOD IN GENERALIZED MYASTHENIA GRAVIS PATIENTS

C. Pane, N. Cuomo, A. Sarnataro, M. Campanile, G. Puorro, A. Marsili, F. Saccà

NRSO Department, Federico II University of Naples (Napoli)

Introduction: Eculizumab, a complement active monoclonal antibody, is reimbursed in Italy for anti-acetylcholine receptor antibody positive (AChR-Ab+) patients showing persistent symptoms, despite therapy with corticosteroids (CS) and ≥2 non-steroidal immunosuppressants (NSISTs). Efgartigimod, a human IgG1 antibody Fc-fragment that blocks neonatal Fc receptor, is available in Italy through an expanded access program and treatment can be administered to both AChR-Ab+ and seronegative patients.

Methods: We included patients receiving either Eculizumab or Efgartigimod as part of our clinic practice and retrospectively collected data on their MG status using the MG activities of daily living (MG-ADL), quantitative MG scale (QMG), previous and current therapies, adverse events, and concomitant medication use.

Results: We enrolled 16 patients treated with Eculizumab and 14 with Efgartigimod. Of the Efgartigimod group, 7 were Ab-AChR positive and 7 were seronegative. Both treatments were well tolerated, with minor adverse events. Overall, MG-ADL decreased by -6.9 points (p<0.001), and qMG by -5.9 (p<0.001). Eculizumab reduced the

MG-ADL by -6.6 points (p=0.002), and the qMG by -7.4 (p<0.001). Efgartigimod reduced the MG-ADL by -7.3 points (p<0.001), and the qMG by -4.7 (p<0.001). MG-ADL responders were 15/16 (94%) of patietns treated with Eculizumab and 10/14 (71%) of those treated with Efgartigimod. For the Efgartigimod group, respoders were identical between Ab-AChR positives and negatives (5/7, 71% for each group). Mean prednisone reduction was -13.75 mg for the Eculizumab treated group ad -8.5 in the Efgartigimod group (p=NS).

Conclusion: Eculizumab and Efgartigimod proved to be both effective treatments in a real world setting. Both treatments reduced MG-ADL and qMG in difficult to treat gMG patients. For both treatments responder rate was higher than previously reported in clinical trials. Responder rate was higher in Eculizumab than Efgartigimod treated patients. This was paralleled by a non-significant higher prednisone reduction effect.

## HBV RISK MANAGEMENT IN MULTIPLE SCLEROSIS PATIENTS

P. Pasculli[1], M. Zingaropoli[1], F. Dominelli[1], E. Tortellini[1], M. Tartaglia[2], G. Ferrazzano[2], M. Lichtner[3], C. Mastroianni[1], F. Pauri[2], M. Altieri[2], A. Conte[2], M. Ciardi[1]

[1]Department of Public Health and Infectious Diseases, Sapienza University of Rome (Roma); [2]Department of Human Neurosciences, Sapienza University of Rome (Roma); [3]Infectious Diseases Unit, Santa Maria Goretti Hospital, Sapienza University of Rome (Latina)

Background: Hepatitis B virus (HBV) reactivation during immunosuppressive/immunomodulatory therapy is still a hot topic worldwide. In case of serological signs of current or past HBV infection, appropriate therapeutic or preventive strategies are suggested, according to the risk of HBV reactivation [1]. Anti-HBc antibodies, together with HBsAg, play an important role in identifying patients with a need for a more intensive follow-up or a prophylaxis against HBV reactivation, especially as anti-HBc antibodies are considered to persist lifelong, except in immunocompromised patients [2].

Objective: In a 4-years follow-up, people with MS were longitudinally evaluated each 6 months during DMTs, focusing on HBV reactivation with HBV-DNA and HBV surface antigen periodic assessment.

Methods: Serological parameters such as HBsAg, anti-HBs, and anti-HBc (IgM and IgG), were periodically measured by chemiluminescence immunoassays. HBV-DNA was investigated by real-time PCR in each subject showing previous resolved HBV exposure. A preemptive strategy was chosen to manage people with previous resolved exposure to the virus.

Results: In this four-year observational cohort study, we collected real-world data on the infectious risk before starting or switching or during DMT in people with MS patients. Two hundred and twenty-seven people with MS were enrolled (135 women, 92 men) with a median age of 49 [41-59]. Among them, 80 patients were ocrelizumab-treated. At baseline 3 patients candidates to ocrelizumab treatment, were HBsAg+ with HBV-DNA detectable and started antiviral therapy before starting DMTs; 18 patients were anti-HBc+. No patients with anti-HBc+ showed a detectable HBV-DNA and all started DMT. During DMTs, two ocrelizumab-treated patients with HBsAg- and anti-HBc+ developed HBV reactivation. After 4 years of follow-up, 2 of 18 patients with anti-HBc+ treated with ocrelizumab, lost Hbc antibodies.

Conclusion: Screening of infectious diseases in DMT candidate MS patients helps to mitigate the infectious risk and choose the most appropriate treatment in MS management. HBV screening should be performed at the beginning to know patient's serological status to decide the most appropriate therapy and/or follow-up for MS patient. Moreover, as in solid orgarn transplant recipients, MS patients treated with anti-CD20 can lose anti-HBc maybe due to an inefficient immune response. Permanent or intermittent anti-HBc loss is common in immunocompromised hosts (i.e hematologic/oncologic patients). To date, no data on people with MS and permanent or intermittent anti-HBc loss were reported. Periodic HBV screening is mandatory to highlight an active or past HBV infection in patient with high risk HBV reactivation.

## TOSCANA VIRUS MENINGO-ENCEPHALITIS: AN INFECTIOUS DISEASE TO INCLUDE IN DIFFERENTIAL DIAGNOSIS IN ELDERLY PATIENT WITH CONFUSIONAL STATE AND ALTERED CONSCIOUSNESS

A. Pes, V. Carlucci

Neurology Department, University of Padua (Padova)

Introduction: Acute confusional state and alertness disturbances are frequent neurological presentations of a plethora of diverse underlying diseases, including central nervous system infections. These ones are most commonly due to viral diseases and, among these, Toscana virus is the 3rd etiologic agent of aseptic meningitis after enteroviruses and herpesviruses. Despite this evidence, Toscana virus is not routinely considered in patients with altered consciousness level and disorientation.

Aim: To describe a case of meningo-encephalitis due to Toscana virus infection in an 82-year old man presented with headache, confusion and drowsiness.

Methods and Results: An 82-year old dyslipidemic and diabetic man, living in the countryside of North-East Italy, came to our attention for orbitofrontal headache and photophobia in the last three days followed by fever, confusion and drowsiness. Suspecting a central nervous system infection, the patient has been hospitalized. On admission, cerebrospinal fluid (CSF) examination documented hyperproteinorrachia (1.11 g/L) and pleocytosis (monocytes 109 u/L). Microbiological assays of common central nervous system pathogens, including Toscana virus in both CSF and blood were performed. A cerebral MRI with contrast and an electroencephalogram were unremarkable. In the meanwhile, an empiric intravenous antibiotic and antiviral therapy was started. After three days polymerase chain reaction (PCR) for Toscana virus resulted positive either in CSF and blood, in association with a high titer of specific IgM and IgG in blood, so that the diagnosis of meningo-encephalitis due to Toscana virus was made. Therefore, it was possible to withdraw the ongoing unnecessary empiric therapy. Supportive care measures were adopted and, after one week, the patient

showed a complete remission of symptoms. CSF analysis was repeated and documented the absence of Toscana virus RNA.

Conclusion: Toscana virus infections should be considered in the differential diagnosis of confusional states in the elderly, especially during summer in the Mediterranean area, when the vector's activity is higher. Nowadays, thanks to advanced diagnostic methods it is possible to make a diagnosis of Toscana virus meningoencephalitis quickly, reducing unnecessary use of antibiotics and unuseful medical resources.

Disclosures: I hereby certify that, to the best of my knowledge, no aspect of my current personal or professional circumstance places me in the position of having a conflict of interest with this presentation.

## AFFECTIVE AND EMOTIONAL CHANGES AS ONSET SIGNS IN AUTOIMMUNE ENCEPHALITIDES

M. Proietto, A. Battiato, V. Todaro, R. Sgroi, D. Fatuzzo, L. Giuliano, M. Zappia

Department of Medical, Surgical Sciences and Advanced Technologies "GF Ingrassia", University of Catania (Catania)

Introduction and Aims: Over the last years great attention has been given to psychiatric manifestations in autoimmune encephalitides (AEs). There is a new consensus on the definition of the entity of autoimmune psychosis. However, there is little evidence about behavioral, affective, emotional changes and cognitive impairment in those conditions. During a revision of the patients with AE admitted to our Clinic we evidenced how these symptoms, usually underestimated, can precede the clinical manifestation by months. Here, we present a sub-group of patients with a diagnosis of AE with specific behavioral, cognitive and psychic symptoms at the onset.

Materials and Methods: We selected 14 patients with a diagnosis of AE (according to 2016 Graus et al. diagnostic criteria) and admitted to our department between 2010 and 2023. Patients with pre-morbid psychiatric conditions have been excluded. All patients underwent electroencephalography (EEG), MRI, CSF analysis and a thorough neuropsychological examination.

Results: Fourteen patients with a diagnosis of probable AE (mean age 51.7±20.1 years, 57% women) have been enrolled in the study. Fifty percent of patients (n=7) presented seizures at the onset. Nine patients (64%) presented affective and emotional changes before the onset of the disease (depression, unexplained feel of fear), with a mean of 3 months before the admission to the hospital. Five patients (36%) presented behavioral changes (apathy, irritability, fatuous behavior) at the onset of the disease. Seven patients (50%) presented cognitive symptoms (memory and attention impairment, arithmetical problems) before the admission. EEG showed some abnormalities in 86% of patients (n=12). Nine patients (64%) presented fronto-temporal abnormalities, with left prevalence in 5 cases, right prevalence in 2 cases, no prevalence in the remaining 2 cases. One patient presented diffuse slow rhythm, one temporo-occipital abnormalities and one diffuse triphasic waves. Positivity for antibodies has been found in half cases (anti PNMA2, GAD, LG1, NMDA, HU in 2 cases, and against a novel intracellular antibody in one case). MRI was suggestive of encephalitis in 11 cases (79%).

Discussion and Conclusions: Our data, in line with previous published data, show that autoimmune encephalitides, even with different autoantibodies and etiology, present common clinical, EEG and MRI features. In particular, affective and emotional changes can precede of about three months the onset of the disease, representing a red flag of an encephalopathic process. Therefore, these changes in previous healthy patients should raise the suspicion of AE and induce the begin of a diagnostic workup. Further studies are needed to confirm these findings.

## AUTOIMMUNE ENCEPHALITIS WITH PSYCHIATRIC ONSET AND POSITIVITY FOR AN UNKNOWN ONCONEURONAL ANTIBODY: A CASE REPORT

M. Proietto[1], S. Ferrari[2], S. Mariotto[2], V. Todaro[1], A. Battiato[1], F. Ligato[1], P. Vullo[1], P. Crimi[1], E. Vinciguerra[1], L. Giuliano[1], M. Zappia[1]

[1]Department of Medical, Surgical Sciences and Advanced Technologies "GF Ingrassia", University of Catania (Catania); [2]Department of Neuroscience, Biomedicine and Movement Sciences, University of Verona, Policlinico GB Rossi (Verona)

Introduction: Among autoimmune encephalitides (AE) a subgroup is related to a paraneoplastic mechanism. An exact diagnosis is necessary for adequate treatment. However, paraneoplastic syndromes, such as paraneoplastic encephalitides, may even appear several years before the detection of malignancy. Here we describe the case of a woman with a psychiatric presentation. An onconeuronal antibody against intracellular antigens has been found in the cerebrospinal fluid (CSF) of the patient with no evidence of tumors.

Clinical Case and Discussion: A 48-year-old woman was admitted to our clinic for the appearance of confusion, irritability and fluctuating consciousness. In the last year, the patient had presented feelings of unexplained fair, anxiety, anorexia and insomnia. The first brain magnetic resonance imaging (MRI) showed hyperintensity of temporo-parietal cortex and white matter on FLAIR sequence. EEGs showed aspecific slow-wave rhythms. A CSF analysis evidenced hyperproteinorrachia (927 g/dL) and neutrophilic pleocytosis (78 cells). A standard panel for known autoimmune antibodies on CSF and blood serum resulted negative. With a clinical suspicion of paraneoplastic encephalitis, an extensive oncologic screening has been performed and resulted unremarkable. Patient showed a good clinical response to intravenous methylprednisolone at high dose, with resolution of the behavioral and cognitive fluctuations. However, twenty days after discontinuation of steroids, she presented irritability, muteness and drowsiness. At this stage, patient had a partial recovery after high dose steroids, and immunotherapy with azathioprine was started. At that point, even if the patient presented a full recovery in terms

of movement and alertness, she continued to present irritability and occasional paranoid ideas. After two months, patient was readmitted for infective pyelonephritis, right hemiplegia and global aphasia. MRI at that time showed bilateral hippocampal and left thalamic hyperintensity on long TR sequences. Treatment with steroids at first and plasma-exchange therapy were unsuccessful. At that time, an indirect immunohistochemistry on cerebellar cells of rat revealed the positivity of CSF on Purkinje cells' cytoplasm. Finally, patient started therapy with rituximab with improvement of speech and partial recovery of strength in her right side.

Conclusions: Psychiatric manifestations in AE are common, and commonly lead to misdiagnosis. Clinical suspicion of AE should be made when a patient presents with a new-onset and atypical psychosis and necessitates an extensive diagnostic work-up. There is no consensus yet about treatment of these conditions. In our case, an onconeuronal antibody has been found after several attempts and months. Patient responded to rituximab when no other immunosuppressive treatments were successful anymore.

## HEAD-TO-HEAD COMPARISON OF FIXED VERSUS LIVE CELL-BASED ASSAYS FOR AQP4-IGG DETECTION IN REAL-LIFE DIAGNOSTIC SETTING

M. Risi[1], S. Scaranzin[2], S. Masciocchi[2], P. Businaro[2], G. Greco[2], C. Morandi[2], D. Franciotta[2], M. Gastaldi[2]

[1]Division of Neurology, Department of Internal Medicine, Geriatrics and Neurology, AOU Luigi Vanvitelli, University of Campania "Luigi Vanvitelli" (Napoli); [2]Neuroimmunology Laboratory and Research Unit, IRCCS Mondino Foundation (Pavia)

Background: Neuromyelitis Optica Spectrum Disorders (NMOSD) is an inflammatory demyelinating disease of the central nervous system in differential diagnosis with MS, from which is distinguished by prognostic features and response to specific treatments. The presence of pathogenic anti-aquaporin 4 (AQP4) IgG is highly specific for NMOSD diagnosis and, considering the relevant clinical implication, laboratory assays with the highest accuracy are of the utmost importance. To date, both commercial fixed cell-based assay (CCBA) and in-house live cell-based assay (LCBA) have been used for AQP4 detection, but there are only few data on the concordance of these two tests, especially in a real life setting.

Objective: To compare the analytic performances of CCBA and LCBA in routine diagnostic practice.

Materials and Methods: We included patients whose samples were sent to our centre for AQP4-IgG testing from 2018 to 2023. Serum samples from each patient were analyzed in parallel with CCBA and LCBA. Medical records were reviewed to assess if patients fulfilled 2015 NMOSD criteria.

Results: We included 1882 consecutive samples. A total number of 104/1882 samples (5.5%) from 71 patients were positive in at least one diagnostic test. A concordant positive result was found in 87 samples from 71 patients, all diagnosed with NMOSD. Seventeen/104 samples from 13 patients showed discrepant results, and 7 patients were diagnosed with NMOSD. CCBA+/LCBA- results were found in 5 sample from 4 patients, 2 diagnosed with NMOSD, and CCBA-/LCBA+ results were found in 12 samples from 10 patients, 5 diagnosed with NMOSD. Cohen's kappa for LCBA and CCBA was 0.91 (agreement of 99.1%). PPV for LCBA and CCBA was respectively 0.89 and 0.94.

Conclusions: Both LCBA and CCBA have high analytic performances and are reasonable alternatives for AQP4-IgG testing, with a slightly higher PPV for CCBA. As discrepant results are more frequently associated with false positives, testing selected patients with a second assay might be helpful in improving accuracy.

## A CASE OF THYMOMA-ASSOCIATED ENCEPHALITIS AFTER THYMECTOMY

F. Rossi[1], F. Crescenzo[1], D. Ajena[1], L. Ferigo[1], A. Sottini[2], M. Turazzini[1]

[1]Neurology Unit, "Mater Salutis" Hospital, Aulss9 Scaligera (Verona); [2]Clinical Chemistry Laboratory, Asst Spedali Civili of Brescia (Brescia)

Objectives: To describe an atypical case of thymoma-associated encephalitis.

Materials and Method: A 50-year-old woman with a past medical history of a surgically removed thymoma, thyroiditis and pemphigus vulgaris successfully treated with corticosteroids and two courses of rituximab was admitted to our department for a generalized seizure preceded by headache, sleep disturbances and recurrent right hemifacial spasm (HFS). Electroencephalography showed left frontal-temporal slow waves.

Results: The laboratory examination showed microcytic anaemia and raised serum ferritin without sign of systemic infection; cerebrospinal fluid (CSF) examination was unremarkable, and neuroinfectious aetiology was ruled out by multiplex-PCR assay. Prolonged drowsiness, expressive aphasia and persistent HFS characterized the postictal seizure phase. The initial brain MRI imaging showed multifocal cortical ill-defined T2/ FLAIR hyperintense lesions with contrast enhancement, leading to a diagnosis of possible autoimmune encephalitis. Combined immunotherapy with intravenous methylprednisolone and immunoglobulins was started. Serological rheumatologic screening test showed an abnormal title of antinuclear antibodies of 1:1280 without other indicative findings of systemic autoimmune disease. Further serum and CSF analysis for an expanded paraneoplastic/autoimmune encephalitis panel revealed the presence of autoantibodies (Abs) anti-collapsin response mediator protein 5 (CRMP5, also known as CV2), anti-titin and anti-acetylcholine receptor (ACh-R) without signs of cerebellar ataxia and myasthenic syndrome. Contrast CT and PET-CT total body scans

did not reveal occult neoplasm, including residual thymoma. Despite first-line immunomodulatory treatment, a repeat brain MRI showed new and enlarged T2/FLAIR lesions with persistent enhancement after one month. After a second cycle of high-dose steroid treatment, long-term immunosuppression with azathioprine was started with a complete resolution of the lesions in two months. After a year of clinical stability, she complained again about HSF, and a new brain MRI revealed a breakthrough in the disease. Therefore, she started rituximab with clinical and MRI improvement.

Discussion: The Abs anti-AchR, anti-titin and anti-CRMP5/CV2 suggested the loss of self-tolerance usually associated with thymoma. Therefore thymoma-associated paraneoplastic/autoimmune encephalitis diagnosis was supposed to be. Nevertheless, two following PET-CT scans conducted six months apart for cancer screening were consistently negative. For this reason, we conducted T cell receptor excision cyrcles (TRECs) quantification and CD31 expression on CD4+ T cells evaluation, which are suitable markers for thymic function evaluation.

Conclusions: This case highlights how thymoma-related paraneoplastic/autoimmune CNS disorders can develop even after thymectomy but still underlie a permanent thymic output detectable by TRECs, the evaluation of which could play a role in cases without a instrumental detectable thymoma recurrence.

## EFFICACY OF INNOVATIVE THERAPIES IN MYASTHENIA GRAVIS: SYSTEMATIC REVIEW, META-ANALYSIS AND NETWORK META-ANALYSIS

F. Saccà[1], C. Pane[1], P. Espinosa[2], M. Sormani[2], A. Signori[2]

[1]NSRO Department, Federico II University (Napoli); [2]Department of Health Sciences, University of Genoa (Genova)

Introduction: Therapy of Myasthenia Gravis (MG) is undergoing a profound change with new treatments being tested. These include complement inhibitors and neonatal Fc receptor (FcRn) blockers. Objective of the study was to perform a meta-analysis and network meta-analysis of randomized and placebo-controlled trials of innovative therapies in MG with available efficacy data.

Methods: We assessed statistical heterogeneity across trials with Cochrane Q test and I2 values. We pooled mean differences with the random effect model. We derived treatment efficacy after 26 weeks of treatment with Eculizumab and Ravulizumab, 28 days with Efgartigimod, 43 days with Rozanolixizumab, 12 weeks with Zilucoplan, and after 16, 24 or 52 weeks with Rituximab.

Results: We observed an overall mean MG-ADL change of -2.17 points (95% CI -2.67, -1.67; p<0.001) as compared to placebo. No significant difference emerged between complement inhibitors and anti-FcRns (p=0.16). The QMG change was -3.46 (95%CI -4.53, -2.39; p<0.001), with a higher reduction with FcRns (-4.78 vs -2.60; p<0.001). Rituximab did not significantly improve the MG-ADL (-0.92, CI95% -2.24, 0.39; p=0.17), or QMG (-1.9, 95%CI -3.97, 0.18, p=0.07). At the network meta-analysis, Efgartigimod had the highest probability to be the best treatment, followed by Rozanolixizumab.

Interpretation: Anti-complement and FcRn treatments proved to be both effective in MG patients, whereas Rituximab did not show a significant benefit for patients. With the limitations of this meta-analysis, including efficacy time-points, FcRn treatments showed a short-term higher effect on the QMG. Real-life studies with long-term measurements are needed to confirm our results.

## EVIDENCE-BASED EXPERT CONSENSUS GUIDANCE FOR ONGOING ASSESSMENT OF GENERALISED MYASTHENIA GRAVIS

F. Sacca[1], A. Meisel[2], J. Spillane[3], J. Vissing[4]

[1]Department of Neurology, University of Naples Federico II (Napoli); [2]Department of Neurology, Charité Universitätsmedizin Berlin (Berlin-D); [3]Department of Neurology, UCL Institute of Neurology, Queen Square (London-UK); [4]Department of Neurology, Copenhagen Neuromuscular Center, Copenhagen University Hospital Rigshospitalet (Copenhagen-DK)

Goal: Regular and consistent disease assessment could provide a clearer picture of burden in generalised myasthenia gravis (gMG) and improve patient outcomes; however, there is lack of standardisation on use of assessment tools in practice. This modified Delphi consensus was conducted to review current evidence on assessment tool use in gMG and propose expert-derived guidance for good practice.

Methods: A European expert panel comprising 15 experienced gMG neurologists contributed to development of this guidance, four of whom formed a lead Sub-committee. The PICO (population, intervention, control, outcomes) framework was used to define six themes on gMG assessment tools and a systematic literature review was conducted. Consensus was reached when >=70% of the experts rated agreement with a statement as >=8 on a scale of 1–10.

Results: 18 guidance statements were developed based on evidence and expert opinion covering six themes: 1) tools for understanding gMG burden in clinical practice, clinical trials/research, and telemedicine; 2) use of depression, anxiety, and fatigue scales in patient assessment; 3) outcomes/symptoms excluded from existing gMG assessment tools; 4) thresholds for clinically important/meaningful differences; 5) assessment of treatment-related burden; 6) assessments supporting treatment decisions. Expert panel consensus was reached on 16/18 statements after one voting round.

Conclusion: This process provides evidence- and expert consensus-based guidance for use of objective and subjective assessment tools across gMG care to improve outcomes for patients.

## ISOLATED CENTRAL NERVOUS SYSTEM WHIPPLE'S DISEASE: THE ROLE OF BRAIN BIOPSY IN A DEMANDING DIAGNOSIS

Spallanzani" National Institute of Infectious Diseases (Roma); [9]Department of Clinical Experimental Unit, University of Milan (Milano); [10]Department of Health Sciences, University of Milan (Milano);[11]Department of Health Sciences, ASST Santi Paolo e Carlo (Milano)

Background and Aims: Whipple's disease (WD) is considered a very rare systemic disease caused by gram-positive bacillus Tropheryma whipplei (TW). However, a recent study reported a surprisingly high prevalence (4.9%) of TW in stool samples from Italian patients attending the Sicilian Center for Tropical Diseases [1], thus suggesting that WD might be more common than previously thought. These findings stress the importance of sharing uncommon or atypical cases of WD, in order to improve diagnostic accuracy of this clinically variable condition.

Case description: We report the case of a 64-year-old woman who complained of recurrent short-lasting episodes of confusion and epigastric pain followed by numbness in her left arm. A few months later, hypersomnia and slowly progressive cognitive impairment were documented; due to an episode of generalized seizure, she was then admitted to the hospital. Brain MRI showed bilateral contrast-enhanced lesions in the medial temporal lobe. Initial suspicion of herpetic encephalitis was not confirmed by poor response to steroids and acyclovir treatment. Because of persistence of neurologic symptoms, the patient was referred to our tertiary centre for further evaluation. Brain MRI documented volume increase of lesions causing secondary hydrocephalus; EEG revealed epileptiform activity in the right temporal lobe. The suspicion of viral encephalitis and autoimmune/paraneoplastic disease were rejected respectively due to normal results at CSF investigations, lengthy clinical presentation and negative screening for autoimmune disorders and malignancies. With further progression of patient's symptoms, brain biopsy of the right hippocampus was performed. Histological examination showed the presence of numerous perivascular foamy histiocytes with cytoplasmic intensely positive Periodic acid-Schiff (PAS) stain, a feature strongly suspicious of WD. The diagnosis was subsequently confirmed by a Tropheryma whipplei-specific PCR analysis of the brain tissue that, interestingly, was negative on CSF. Importantly, the patient had no diarrhoea, abdominal cramps, arthralgia, weight loss, or cardiac/pulmonary symptoms. General physical examination showed no lymphadenopathy or skin hyperpigmentation and duodenal biopsy was normal. Intravenous ceftriaxone followed by oral trimethoprime-sulfamethoxazole were administered for 12 months with good neurological recovery.

Conclusions: This report highlights the difficulties in diagnosing brain-isolated forms of WD due to their variable clinical presentation and their shared features with more common viral and autoimmune/paraneoplastic encephalitis [2]. Brain imaging and CSF examinations might not be informative [3]. As WD is a treatable condition, a missed diagnosis may have catastrophic consequences on patient's management. Our experience supports the role of cerebral biopsy in the diagnostic process of atypical encephalitis.

## ACUTE FLACCID PARALYSIS DUE TO WEST NILE VIRUS NEUROINVASIVE DISEASE IN THE 2022 VENETO OUTBREAK: CLINICAL AND PROGNOSTIC IMPLICATIONS

G. Sansone[1], A. Porsio[1], L. Barzon[2], P. Santurelli[1], L. De Rosa[1], C. Briani[1], D. Seppi[1], R. Manara[1], M. Corbetta[1,3], A. Cagnin[1]

[1]Department of Neuroscience, Neurology Unit, University Hospital of Padua (Padova); [2]Department of Molecular Medicine, Microbiology and Virology Unit, University Hospital of Padua (Padova); [3]Padova Neuroscience Center (PNC), Venetian Institute of Molecular Medicine (VIMM), Fondazione Biomedica (Padova)

Objectives: The West Nile Virus Neuroinvasive Disease (WNND) can present as meningitis, encephalitis, or acute flaccid paralysis (AFP). The overall mortality is 9%, while it reaches 13-14% in AFP [1]. The 2022 WNV outbreak in Veneto was particularly severe and characterised by co-circulation of the new WNV strain 1, along with the endemic strain 2 [2]. The present study aims at describing the clinical phenotypes, the main clinical and pathological findings of patients evaluated during this outbreak.

Materials and Methods: We included all patients hospitalised in the Azienda Ospedale-Università di Padova, between 12/07/22 and 21/09/22 with definite or probable WNND [3], collecting anamnestic, clinical, laboratory, imaging, and pathological data in 3 patients. Statistical analyses included descriptive statistics, Pearson's correlation and chi-square tests.

Results: Forty-seven patients were included (45 definite, 2 probable WNND; 29 males, mean age: 71±14 years), all diagnosed with WNV strain-1. At onset (mean: 4.5 days before hospitalisation), symptoms included fever (91%), flu-like symptoms (45%), headache (30%), gastrointestinal symptoms (28.3%), rash (11%). Neurological symptoms at onset included confusion (30.4%), impaired vigilance (17.5%) and motor deficits (2.2%). The clinical phenotypes included AFP (42.6%), encephalitis (34%), paucisymptomatic disease (12.8%) and meningitis/meningo-encephalitis (10.6%). Liquor analysis showed CSF pleocytosis with both mononuclear and polymorphonuclear cells (mean 158.5 elements/microliter), increased proteins and lactates (mean values: 100 mg/dl and 2.93 mmol/L, respectively). The most common MRI finding was the multi-level enhancement of the anterior ± posterior spinal nerve roots (10/19 patients), especially the cauda equina. All had AFP phenotype. The overall 3-month and 7-month mortalities were 19.1% and 25.5%, reaching, 35% and 45% in AFP cases. Mean mRS changed from 1.2 pre-event to 3.3 at hospital discharge. Post-event mRS and length of hospitalisation correlated positively ($p<0.05$) with CSF lactate levels, the severity of motor and tendon reflex deficits, and were significantly higher in AFP. Predictors of death and ICU admission ($p<0.05$) were: AFP, encephalopathy, motor and tendon reflexes deficit, spinal nerve roots' involvement, and, for ICU admission only,

the encephalitic phenotype. All AFP patients underwent intravenous immunoglobulins and/or steroid treatments, yet this was not associated with better outcomes. Autopsies revealed multifocal extensive inflammatory infiltrate with microglial nodules in the brain and spinal cord.

Discussion and Conclusions: The 2022 Veneto WNND outbreak had outstandingly high AFP frequency and mortality. This aggressive phenotype is probably conveyed by the new WNV strain-1. The mechanisms underlying the different "neuro-virulence" of distinct WNV strains require further studies.

## AUTOIMMUNE THROMBOCYTOPENIA IN A PATIENT WITH GENERALISED MYASTHENIA GRAVIS IN TREATMENT WITH ECULIZUMAB: A CASE-REPORT

A. Sarnataro[1], N. Cuomo[1], N. Conte[2], C. Pane[1], F. Saccà[1]

[1]Department of Neurology, AOU Federico II (Napoli); [2]Department of Immunology, AOU Federico II (Napoli)

Objective: Myasthenia Gravis is an autoimmune disorder caused by an inflammatory response directed towards the neuromuscular junction. In the last few years, the therapy of Myasthenia Gravis has experienced a profound change with the introduction of complement inhibitors and FcRn blockers. However, no study has been conducted on the management of these new therapies in patients with polyautoimmunity which are up to 15-20% of patients with Myasthenia Gravis. We report a case of a gMG patient treated with Eculizumab developing a SLE-mediated thrombocytopenia after prednisone reduction.

Case description: We describe the case of A.B.K. female, 43 y.o. diagnosed with Sjogren disease in 2009 and Myasthenia Gravis AchR+ in 2015. She underwent treatment with Eculizumab in November 2022 together with pyridostigmine and prednisone 25 mg. In January 2023 she was admitted to our Center due to thunderclap headache resulting from a subarachnoid haemorrhage confirmed after a CT exam. At the moment of admission, the patient was on prednisone 5 mg after progressive down-tapering, and her platelet count was 0. We administered daily platelet infusion, a 5-day cycle of IVIg and prednisone 75 mg for 10 days with no benefit and suspended the scheduled infusion of Eculizumab. We also performed an autoimmunity panel, that showed positivity to ds-DNA and ANA 1:512 so diagnosis of SLE was made according to EULAR criteria. We then introduced Romiplostim with slight but encouraging benefit. We discharged the patient as a SLE-induced thrombocytopenia and a home-therapy with Romiplostim and prednisone 25 mg.

Results: After the introduction of Romiplostim and Prednisone, platelet count was increased to 20.000 units. After one-month she was re-scheduled for Eculizumab infusion as her MG symptoms were deteriorating. After two infusions of Eculizumab her platelet count went back to normal (235.000 units).

Discussion: Our patient suffered from a SLE-induced thrombocytopenia which was reasonably fostered by the progressive reduction of Prednisone. Pre-Eculizumab prednisone helped keep SLE latent and undiagnosed. The precautionary suspension of Eculizumab was unnecessary as MG symptoms worsened and platelet count returned to normal after its re-administration.

Conclusion: In conclusion, although new treatments allow a reduce of corticosteroids and immunosuppressants, we should use caution in patients with polyautoimmunity. We demonstrate that Eculizumab is safe in gMG patients with immunological comorbidities.

## AN UNCOMMON CLINICAL-RADIOLOGICAL PRESENTATION OF ANTI-NMDAR ENCEPHALITIS: A YOUNG ADULT WITH LOUDNESS INTOLERANCE AND CLOCCS

C. Sorrentino[1], R. Matrullo[1], M. Tepedino[1], A. Toriello[2], P. Pagliano[1], P. Barone[1]

[1]Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Neuroscience Section, University of Salerno (Salerno); [2]Neurology Unit, Department of Medical Area, San Giovanni di Dio e Ruggi D'Aragona Hospital (Salerno)

Objective: Aim of this case report is to describe an uncommon presentation of Anti-N-methyl-D-aspartame receptor (anti-NMDAR) encephalitis with atypical radiological findings of Cytotoxic Lesions of Corpus Callosus (CLOCCs). Which, to our knowledge, has only been reported in few cases in Eastern countries [1,2].

Materials: A 17 years old male presented to our attention with a story of three months of loudness intolerance, preceded by three days flu. He made in an external structure audiometric tests and auditory brainstem response without anomalies and brain MRI that revealed a single midline rounded lesion in the splenium of the Corpus Callosum. Neurological examination was in the range of normality.

Methods: The patient made laboratory screening for systemic autoimmunity, infectious markers; oncological markers; resulted negative. A Lumbar puncture was performed, and Cerebrospinal Fluid did not show pathological findings at routine exams. In the suspicion of autoimmune encephalitis (AE), we made a panel for testing AE-autoantibodies, and he was positive for Anti-NMDAR on serum and CSF. He made also an electroencephalography that was normal. The symptomatology considerably improved after intravenous administration of steroids, with complete recovery after a month. A follow-up MRI revealed regression of the lesion. A whole-body PET-CT scan was planned to rule out malignancy.

Discussion: Anti-NMDAR encephalitis is the most common type of AE, accounting for 6% to 10% of all encephalitis3. It is characterized by the presence of an IgG1 antibody directed against the NR1 subunit of the NMDAR on the neuronal cell surface or synapses in the CSF. Cytotoxic lesions of the corpus callosum (CLOCCs) are secondary lesions associated with various entities4. In all of these conditions, cell-cytokine interactions lead to markedly increased levels of extracellular glutamate, with consequent excitotoxic damage. CLOCCs have been found in association with drug therapy, malignancy, infection, subarachnoid hemorrhage, metabolic disorders, trauma, and other entities – including AE. In our case, loudness intolerance, which we interpreted

as a cognitive/behavioral disorder, and anti-NMDAR antibody positivity allowed us to make a diagnosis of definite anti-NMDAR AE according to the latest diagnostic criteria [3].

Conclusions: In our case we made hypothesis that anti-NMDAR antibodies may have a more complex mode of operation and could even play a role in the pathogenesis of cytotoxic edema in CLOCCs, similar to the excitotoxic action of glutamate broadly reported in these lesions.

## IMMUNE PROFILING UNVEILS THE SYSTEMIC CYTOKINE MILIEU ASSOCIATED WITH ACUTE REVERSIBLE ENCEPHALOPATHY WITH CYTOTOXIC LESION OF THE CORPUS CALLOSUM (CLOCC) SECONDARY TO EBV INFECTION

S. Sperandei[1], L. Gaetani[1], G. Manni[2], M. Gargaro[2], E. Cresta[1], C. Gallina[3], A. Fiacca[3], C. Costa[1], L. Parnetti[1], F. Fallarino[2], M. Di Filippo[1]

[1]Section of Neurology, Department of Medicine and Surgery, University of Perugia (Perugia); [2]Section of Pharmacology, University of Perugia (Perugia); [3]Neuroradiology Unit, University Hospital S. Maria della Misericordia (Perugia)

Aim: We present the case of an 18-year-old male who experienced acute-onset reversible encephalopathy with a cytotoxic lesion of the corpus callosum (CLOCC) during the course of Epstein Barr virus (EBV) infection. The immune signature of this condition is still largely unknown [1,3].

Diagnostic work-up: The patient had no relevant medical history. He was admitted to our Section due to generalized tonic–clonic seizures and mental deterioration. In the 7 days before the admission, he experienced fever, cervical lymphadenopathy, sore throat and fatigue. On admission, his GCS was 11 (E4, V2, M5), he was confused and his body temperature was 38°C. High-field 3T brain MRI revealed hyperintense lesions within the splenium of the corpus callosum, subcortical white matter, and cortical regions. The lesions exhibited hyperintensity on DWI, FLAIR, and T2 sequences, along with hypointensity on ADC maps. Serial EEG recordings showed slow and paroxysmal abnormalities bilaterally. Serological analysis demonstrated positivity for EBV VCA-IgM and negativity for EBNA IgG, as well as a positive PCR for EBV, suggesting an acute systemic EBV infection. CSF analysis revealed mild lymphocytic pleocytosis and elevated protein levels. Microbiological tests on the CSF, including film array and PCR for neurotropic agents (including EBV), yielded negative results. These findings supported the hypothesis of a systemic inflammatory response leading to central nervous system manifestations secondary to EBV infection [2].

Follow-up data: Prompt administration of intravenous dexamethasone resulted in significant clinical improvement within 10 days. A follow-up brain MRI performed one week later demonstrated the disappearance of the callosal lesion, further confirming the diagnosis and emphasizing the reversible nature of the condition [1]. Immunological profiling: To gain further insight into the systemic immune response, plasma samples were subjected to detailed analysis using Luminex technology. Baseline profiling revealed low levels of interleukin 12-p70 (IL-12p70) and elevated levels of interferon gamma (IFN-γ), IL-6, IL-18, IL-10, IL-17A, IL-23, and IL-1α. Subsequent analyses demonstrated a dynamic pattern, with increasing levels of IL-12p70 and decreasing levels of the other cytokines over time, coupled with the clinical improvement.

Discussion: This case sheds light on the occurrence of CLOCC in the context of infectious disorders, with EBV infection serving as a compelling example [2]. It underscores the pivotal role of systemic inflammation in driving central nervous system manifestations and provide specific information on the associated cytokine milieu.

## MULTIPLE CRANIAL NEUROPATHY DUE TO VARICELLA ZOSTER VIRUS REACTIVATION WITHOUT VESICULAR RASH: A CHALLENGING DIAGNOSIS

A. Stornaiuolo, R. Iodice, R. De Simone, C. Russo, M. Rubino, S. Braca, A. Miele, S. Tozza, M. Nolano, F. Manganelli

Neurology, AOU "Federico II" (Napoli)

Objective: Ramsay Hunt syndrome, or zoster oticus, is a rare condition caused by reactivation of varicella-zoster virus (VZV) in the geniculate ganglion of facial nerve. Accounting for less than 1% of all herpes zoster cases, it is characterized by a clinical triad of ipsilateral facial paralysis, otalgia and vesicles in the auditory canal. However, up to 30% of cases may occur without skin vesicular eruption, and other cranial nerves, may be involved further complicating the diagnosis.

Case Discussion: A 77-year-old man presented to the emergency department with left facial palsy, speech difficulties with voice hoarseness, and mild gait abnormalities. He had experienced pharyngodinia, headache, and left otalgia a few days earlier. Initial tests including MRI with and without contrast were normal, while laboratory tests showed high levels of IgG and borderline levels of IgM antibodies against VZV, not diagnostic. Serum VZV-DNA was not detected. Because of voice hoarseness and swallowing difficulties, he underwent video-laryngoscopy documenting paralysis of the left palate and vocal cord, pointing to an involvement of glossopharyngeal and vagus nerves. Cerebrospinal fluid analysis confirmed the presence of VZV DNA, leading to a diagnosis of multiple cranial neuropathy due to VZV reactivation (Ramsay Hunt syndrome). The patient was treated with antiviral therapy and steroids, and showed gradual improvement over a couple of months, with complete recovery of speech and swallowing and partial recovery of facial nerve function.

Discussion: The case report highlights the diagnostic challenge of identifying Ramsay Hunt syndrome, when it presents in non canonical ways. Clinicians need to be aware of the possibility of multiple cranial nerve involvement in this syndrome. While peripheral facial nerve palsy is often idiopathic (Bell's palsy), a thorough evaluation is necessary to rule out secondary causes such as VZV reactivation. Antiviral therapy is effective in treating VZV reactivation, and steroids are also beneficial for improving nerve function in peripheral facial nerve palsy. The involvement of other cranial nerves in Ramsay Hunt

syndrome may occur due to the spread of VZV beyond the geniculate ganglion or through vascular pathways. The exact mechanism of cranial nerve dissemination is not yet fully understood.

Conclusion: This case report emphasizes the importance of considering Ramsay Hunt syndrome as a possible diagnosis in cases of atypical peripheral facial nerve palsy. Clinicians should be familiar with the diverse clinical presentation of the syndrome and the effectiveness of antiviral therapy in promoting nerve function recovery.

## SHOULD WE CONSIDER MYELIN OLIGODENDROCYTE GLYCOPROTEIN ANTIBODY-ASSOCIATED DISEASE (MOGAD) A PARANEOPLASTIC DISEASE?

M. Trentinaglia[1], A. Dinoto[1], S. Carta[1], V. Chiodega[1], S. Ferrari[1], V. Andreone[2], G. Maniscalco[2], S. Mariotto[1]

[1]Neurology Unit, Department of Neurosciences, Biomedicine, and Movement Sciences, University of Verona (Verona); [2]Neurological Clinic and Stroke Unit, "A. Cardarelli" Hospital (Napoli)

Objectives: To detect the incidence of neoplastic conditions in a cohort of patients with MOGAD and analyze their clinical and paraclinical features.

Materials: Retrospective cohort study and systematic literature review.

Methods: We retrospectively identified patients referred to our center from 1/1/2015 to 1/1/2023 with positive MOG antibodies tested with a live cell-based assay and associated with clinical features consistent with MOGAD. We then selected those with a diagnosis of tumor received within two years from disease onset and subsequently performed a systematic literature review to detect previous cases of co-occurrence between MOGAD and a neoplastic condition. Clinical and paraclinical data of all patients were collected and statistical analysis was performed.

Results: Among 150 patients, 2 (1%) received a diagnosis of tumor within two years. After literature review, 15 additional patients were collected. Median age was 39 years-old (range 16-73) and 12 patients were female. ADEM (n=4; 23.5%), encephalomyelitis (n=3; 17.6%), and monolateral optic neuritis (n=2; 11.8%) were the most frequent phenotypes. Median number of treatments was 1 (range 1-4) and improvement was reported in 14/17 cases (82.4%). Oncological findings were teratoma (n=4), CNS (n=3), melanoma (n=2), lung (n=2), hematological (n=2), ovary (n=1), breast (n=1), gastrointestinal (n=1), and thymic (n=1) neoplasms. Median time from tumor diagnosis to MOGAD onset was 0 months (range -60 to 20). MOG expression in neoplastic tissue was detected in 2/4 patients tested. Median Paraneoplastic Neurologic Syndrome (PNS)-Care score was 3 (range 0-7) being 11 patients classified as “non-PNS”, 5 as “possible-PNS”, and 1 as “probable-PNS”.

Discussion: Our study demonstrates that neoplastic conditions are rare in MOGAD. In addition, neurological manifestations and oncological accompaniments are extremely variable, MOG is usually not detected in neoplastic tissue, and most cases do not meet the criteria of paraneoplastic syndromes (PNS).

Conclusions: These findings suggest that MOGAD is not a paraneoplastic disease and that cancer screening should not be performed in patients with MOGAD on a routine basis.

## DEFINING THE ETIOLOGIC SPECTRUM AND CHARACTERISTICS OF NON-DEMYELINATING NMOSD MIMICS

P. Zara[1], A. Dinoto[2], S. Carta[2], V. Floris[3], D. Turilli[3], A. Budhram[4], S. Ferrrari[2], P. Solla[3], S. Mariotto[2], E. Flanagan[5], S. Chiriboga[6], E. Sechi[3]

[1]Department of Medical Sciences and Public Health, University of Cagliari (Cagliari); [2]Neurology Unit, Department of Neuroscience, Biomedicine and Movement Sciences, University of Verona (Verona); [3]Department of Medical, Surgical, and Experimental Science, University of Sassari (Sassari); [4]Department of Clinical Neurological Sciences, Western University (London-CDN); [5]Department of Neurology, Mayo Clinic (Rochester-USA); [6]Department of Neurology, Mayo Clinic (Jacksonville-USA)

Objective: Differentiating neuromyelitis optica spcectrum disorder (NMOSD) from its mimics is crucial to avoid misdiagnosis, especially in the absence of aquaporing-4-IgG. While multiple sclerosis (MS) and myelin oligodendrocyte glycoprotein-IgG associated disease (MOGAD) represent well established differential diagnoses, non-demyelinating NMOSD mimics remain poorly characterized. In this study we aimed to define the etiologic spectrum and characteristics of non-demyelinating NMOSD mimics.

Materials and Methods: A systematic search was conducted in Pubmed on January 2023 to identify reports of patients with non-demyelinating neurological disorders in whom NMOSD was suspected or misdiagnosed. Cases with uncertain or poorly defined final diagnoses, and articles predating the discovery of AQP4-IgG were excluded. Three novel cases seen at the authors' institutions were also included. Clinical-MRI characteristics of included cases were analysed and red flags for NMOSD misdiagnosis identified.

Results: After screening 2404 articles, 65 patients were included in the study in addition to 3 patients seen at the authors' institutions, for a total of 68 patients. Median age at symptoms onset was 44 years (range 1–78), 35 (52%) were females. Fifty-six (82%) patients did not meet the 2015 NMOSD diagnostic criteria at the time of misdiagnosis. The clinical syndromes misinterpreted for NMOSD were isolated myelopathy (43%), myelopathy and optic neuropathy (38%), isolated optic neuropathy (7%), or other (12%). Alternative etiologies included genetic/metabolic diseases (n=20), neoplasms (n=11), infections (n=11), vascular diseases (n=8), spondylotic myelopathy

(n=5), and other autoimmune disorders (n=13). The most common red flags for NMOSD misdiagnosis were lack of cerebrospinal fluid (CSF) pleocytosis (57%), lack of response to immunotherapy (55%), progressive disease course (54%), lack of gadolinium enhancement on MRI (31%), and presence of CSF-restricted oligoclonal bands (31%). AQP4-IgG positivity of no clinical significance (or false) was detected in 5 patients by enzyme-linked immunosorbent assay (n=2), cell-based assay (n=2: serum, 1; CSF, 1), and a non-specified assay (n=1).

Conclusions: The etiologic spectrum of NMOSD mimics is broad. Misdiagnosis frequently results from incorrect application of NMOSD diagnostic criteria, in patients with multiple identifiable red flags. False AQP4-IgG positivity, generally from nonspecific testing assays, may rarely contribute to misdiagnosis.

Background: Analysis of CSF and plasma biomarkers could be helpful to differentiate specific CNS condition and setting an appropriate therapy. A major advance in the field of neurology has been the development of blood-based biomarkers.

Materials and Methods: Patients presenting with signs and symptoms were enrolled if, before receiving a diagnostic lumbar puncture, signed a written informed consent. We retrospective analyzed CSF and plasma levels of several biomarkers of neuronal damage (NfL), astrocyte damage (GFAP), monocyte/macrophage activation (sCD163 and sCD14) and blood-brain barrier permeability (MMP-9 and TIMP-1).

Results: Eight-four subjects were included. Patients were affected by herpesvirus encephalitis (21/84), neuro-COVID (17/84), progressive multifocal leukoencephalopathy (PML, 14/84), HIV-associated neurocognitive disorders (13/84), bacterial meningitis (7/84), infection by unknown pathogens (6/84) and subjects without CNS involvement (control group, 6/84). Overall, positive correlation between CSF and plasma levels of NfL was found ($\rho$=0.8290, p<0.0001) as well as between CSF and plasma levels of GFAP ($\rho$=0.5752, p<0.0001). Both CSF NfL and GFAP levels were positive correlated with CSF levels of sCD163 ($\rho$=0.5730, p<0.0001 and $\rho$=0.4177, p=0.0007) as well as with CSF TIMP-1 levels ($\rho$=0.6286, p<0.0001 and $\rho$=0.5952, p<0.0001). In CSF, levels of monocyte/macrophage activation markers were positive correlated to plasma NfL levels (sCD163: $\rho$=0.5213, p=0.0026; sCD14: $\rho$=0.4992, p=0.0250). Finally, CSF TIMP-1 levels were positive correlated with plasma NfL levels ($\rho$=0.4075, p=0.0282) and plasma GFAP levels ($\rho$=0.4180, p=0.0300). Compared to control group, bacterial meningitis and PML groups showed higher CSF NfL levels (p=0.0091 and p=0.0003, respectively). Higher CSF GFAP levels in PML and HIV-associated neurocognitive disorder groups compared to control group were observed (p=0.0003 and p=0.0390, respectively). CSF GFAP levels were higher in herpesvirus encephalitis (p=0.0071), neuro-COVID (p=0.0155), HIV-associated neurocognitive disorder (p=0.0003) and bacterial meningitis (p=0.0005) compared to control group. Otherwise, CSF sCD14 levels were higher only in bacterial meningitis compared to control group (p=0.0172). CSF MMP-9 levels were higher in bacterial meningitis and PML groups (p=0.0145 and p=0.0321, respectively) compared to control group. Finally, in bacterial meningitis group higher levels of CSF TIMP-1 were found (p=0.0005).

Conclusion: Our data showed that CSF and plasma biomarkers of neuronal and astrocyte damage or inflammation may vary during CNS infections according to different causative agents. The observed correlations between CSF and plasma samples underscore the possibility of measuring CNS markers in an easily accessible source such as blood. The prognostic value of these biomarkers needs to be assessed in prospective studies.

## NEUROLOGICAL REHABILITATION AND NEUROTRAUMATOLOGY

## FEASIBILITY STUDY OF A NEW EXTENDED REALITY SYSTEM IN PARKINSON'S DISEASE

L. Baratto[1], E. Vallefuoco[2], A. Giglio[1], N. Cuomo[1], C. Russo[1], P. Arpaia[2], G. De Michele[1], E. De Benedetto[2], A. De Rosa[1]

[1]Department of Neuroscience, Reproductive and Odontostomatological Sciences, Federico II University (Napoli); [2]Department of Electrical Engineering and Information Technology, Federico II University (Napoli)

Objectives: Recent research has been indicating eXtended Reality (XR) as a promising tool for innovative and tailored therapeutic-rehabilitative intervention in Parkinson's Disease (PD). XR refers to the application of immersive technologies that allow users to submerge in a virtual world and/or interact with it. Our aim was to assess the feasibility of a new XR system in PD patients.

Materials: We enrolled 22 PD patients (17M/5F; mean age±SD 62.7±8.7 years) with MMSE>23 (mean±SD 28.8±1.8). All participants underwent neurological examination using UPDRS-III and Hoehn & Yahr scale (HY) for disease staging. They were administered for a game session using the Hololens2 XR viewer.

Methods: The experimenter started the game by the remote connection between the PC and the viewer applied to the subject's head. The patients performed the game session (which consists in popping virtual balloons) while sitting in a fixed position. The XR application was organized in two training sessions(one for each side) lasting one minute each, and eight experimental game sessions(four for side,

maximum of three minutes for each session) carried out respectively in "free" condition, during a simple cognitive task, during a contralateral motor task(finger tapping) and during complex cognitive task(mathematical calculation).At the end of the game session the System Usability Scale(SUS) to assess the level of perceived usability, and the User Experience Short Questionnaire(UEQ-S) to assess the immediate impressions, were administered.

Results: Overall, patients have not encountered any issues during the game session, showing a significant interest in the application proposed. The mean±SD of the SUS score was 77.9±18.1(SUS score>70 suggests good usability). At UEQ-S, the scores for both the pragmatic and the hedonic quality were high. We did not find any significant differences between the scores obtained by the more affected hand for all game levels except for a trend towards statistical significance in the difference between level 1 and level 2 performance(p=0.057). No significant differences were observed between the more affected and the less affected side in all game sessions. Furthermore, there was not any significant relationship between the questionnaire scores, the game results, and the demographic and clinical data, such as age, disease duration, motor subtype, UPDRS-III, and HY.

Discussion. The usability, acceptance and tolerability of our XR system have been good. The application was considered easy, clear, interesting, inventive and innovative by most of the patients. Although some subjects had complained fatigue during the third and fourth level of play, difficulty maintaining concentration did not significantly impact game performance.

Conclusions: Our XR system could be considered a tool for use in research settings and in clinical-rehabilitative practice.

## THE DIAGNOSTIC ACCURACY OF PLASMA GFAP AND UCHL1 LEVEL: AN ANALYTICAL SUPPORT TO CT IMAGING IN MILD HEAD INJURY

R. Brugnone[1], A. Esposito[2], R. Ascione[2], F. Daniele[2], D. Ruocco[2], C. Mazio[2], G. Semprebuono[2], M. Brunone[2], C. Carelli[3], C. S. Cimmino[4], M. Guarino[4], A. Senese[4], A. Fabbri[5], C. Esposito[2]

Head trauma is a common cause of admission in emergency departments (ED) and computerized tomography (CT) is the gold standard to diagnose trauma brain injury (TBI). Head trauma is classified in three degrees according to the obtained Glasgow Coma Scale (GCS) score: mild for patients with GCS 14-15, moderate for GCS 9-13 and severe for score of 8 or less. However, head CT reveals TBI in patients with mild head trauma in only 10% of cases, of which 1% needs neurosurgical treatment. Considering the risk of exposing patients to unnecessary radiation, the Canadian CT Head Rule was introduced in 2001 for identifying the pool of mild head trauma patients who needs a cranial CT. The possibility of matching these criteria with other brain injury markers (such as optic nerve echography and specific plasmatic biomarkers) is crucial for the early diagnosis of mild head trauma. The aim of this study is to assess if the combination of further different brain injury markers can predict a TBI. For our purpose, we verified the diagnostic accuracy of a new test for measurement of two specific proteins, glial fibrillary acidic protein and ubiquitin carboxy-terminal hydrolase L1 (GFAP and UCHL1 respectively). These proteins are released into plasma after brain damage. Further parameter of this study includes the evaluation of optic nerve dilation as a sign of intracranial hypertension for likely TBI. We enrolled 98 patients with mild head trauma who arrived in ED in the last 9 months. Each patient underwent a nerve optic echography and a head CT to verify a possible TBI, a blood sample to measure GFAP and UCHL1 levels via with chemiluminescent microparticle immunoassay (CMIA). Analysing the data, 76.53% of patients presented a normal value of GFAP and UCHL1 and a negative head CT (with a specificity and sensitivity equal to 72.21% and 40%). The remaining 23.47% had an increased of protein levels within 12 hours of the injury and a head CT confirmed a TBI in 8.8% of this patients' group. A possible correlation between proteins level and dilation of optic nerve is still under evaluation. These statistics showed that the GFAP and UHCL1 plasmatic levels have a high negative predictive value and it can be a valid support for excluding the need of CT scan, especially if it is matched with other parameters. Further studies are required to confirm the efficacy of these biomarkers.

## INSTRUMENTAL EVALUATION OF POSTURAL CONTROL IN PATIENTS WITH PARAPROTEINEMIC NEUROPATHIES

M. Corrado, D. Tornabene, L. Diamanti, R. De Icco, E. Vegezzi, M. Gastaldi, P. Bini, S. Masciocchi,

IRCCS Mondino Foundation, University of Pavia (Pavia)

Objectives: Peripheral neuropathies associated with paraproteinemia cause several neurological disturbances, ranging from sensory symptoms to gait ataxia. The objective of the present study is the prospective assessment of the posturographic features of this rare condition in a cohort of patients.

Materials and Methods: The postural analysis represents a secondary analysis of the main study, which is intended to assess clinically and instrumentally a cohort of 17 patients for 3 years, every 6 months. The experimental protocol consists of an instrumental postural evaluation using a force platform (BTS P-Walk, Milan, Italy) with the patient in an upright comfortable standing position. We will evaluate the parameters of the motion of the center of gravity (COG), namely the COG area, length, speed of oscillation and sway density (SD) in two conditions: eyes open (EO) and eyes closed (EC) (three 50-second and three 10-second recordings per condition). The instrumental evaluation will be conducted also in a group of healthy controls (HC).

Results: At the state of art, 17 patients (mean age 71.3±11.4 years, 6 females) and 5 HC (mean age 58.0±9.1 years, 4 females) completed the baseline evaluation. The parameters of the COG area were significantly different in the EC condition when compared to the EO session. More specifically: COG area (EC 133.5±245.7 mm2; EO 30.5±44.4 mm2; p=0.004), length (EC 113.8±145.6 mm; EO 49.1±20.8 mm; p=0.004), speed of oscillation (EC 11.4±14.6 mm/s; EO 4.9±2.0 mm/s; p=0.004) and sway density (EC 3.0±2.1 mm/s; EO 5.0±2.0 mm/s; p=0.004). By contrast, in the HC group we did not find significant differences in the two conditions: COG area (EC 10.3±12.6 mm2; EO 9.7±6.4 mm2; p=0.9), length (EC 35.2±9.6 mm; EO 34.5±6.9 mm; p=0.9), speed of oscillation (EC 3.5±0.9 mm/s; EO 3.4±0.7 mm/s; p=0.9) and sway density (EC 6.2±3.2 mm/s; EO 7.7±1.7 mm/s; p=0.72).

Discussion: The observed significant worsening of parameters in the EC condition indicates an impaired proprioceptive regulation of postural stability in patients.

Conclusion: Posturography represents an easy to use and reliable tool to assess postural stability of patients with polyneuropathy. Hopefully, we will be able to use posturographic indexes as an instrumental marker for sensory ataxia and monitor treatment response, although conclusive results will come from the complete longitudinal evaluation.

Sinai-USA); [9]Hospital Regional de Sorocaba, Hospital Dr Adib Domingues Jatene (Sao Paulo-BR); [10]Medical Affairs, AbbVie (Irvine-USA)

Objectives: Post-stroke spasticity (PSS) occurs in ≈58% of stroke survivors. The simple, 1-page PSS Referral Tool was developed to facilitate PSS early identification and referral by clinicians involved in stroke rehabilitation.

Materials: In PSS Referral Tool, red, yellow, and green colors indicate urgent referral to a spasticity specialist, routine referral with a recommendation for multidisciplinary team consult, or periodic monitoring, respectively. To validate the PSS Referral Tool use in clinical practice, an inter-rater reliability (IRR) study will be conducted.

Method: This 3-part observational, prospective study will use the PSS Referral Tool to assess and classify patients up to 1-year post-stroke with varying degrees and types of spasticity. Part A will consist of investigators at 2 sites recording 30 clinical assessment videos using a semi-structured script based on PSS Referral Tool categories. In Part B, 4 clinicians will select 15 videos (5 each for red, yellow, and green) for IRR assessment. In Part C, stroke rehabilitation clinicians recruited from 6 global regions will classify 5 randomly assigned videos into appropriate categories in 3 separate sessions.

Results: This study will report the intraclass correlation coefficient (ICC) for IRR of the PSS Referral Tool, using a 2-way random effect model ICC with 95% confidence intervals. Sample size calculation for 80% power (alpha=0.05) determined a need to recruit 270 clinicians stratified by 2 categories or 540 for 4 categories of PSS Referral Tool experience. ICC values range from 0.0 to 1.0, with higher scores indicating a more stable instrument.

Discussion: PSS Referral Tool will facilitate PSS early identification and referral by clinicians involved in stroke rehabilitation.

Conclusion: This study aims to ensure that the PSS Referral Tool possesses sufficient sensitivity and specificity for meaningful use by clinicians regardless of experience.

## PREDICTORS OF SHORT-TERM RECOVERY OF CONSCIOUSNESS IN PATIENTS WITH DISORDERS OF CONSCIOUSNESS

B. B. Hakiki[1], P. Liuzzi[1], A. Romoli[1], F. Draghi[1], D. Maccanti[1], A. De Nisco[1], R. Burali[1], M. Scarpino[1], A. Mannini[1], A. Magliacano[2], A. Estraneo[2], A. Comanducci[3], J. Navarro[3], C. Macchi[1], F. Cecchi[1], A. Grippo[1]

[1]Severe Acquired Brain Injuries, Don Gnocchi Foundation (Firenze); [2]Severe Acquired Brain Injuries, Don Gnocchi Foundation (Sant'Angelo dei Lombardi-AV); [3]Severe Acquired Brain Injuries, Don Gnocchi Foundation (Milano)

Aims: Disorders of Consciousness (DoC) include Unresponsive Wakefulness State (UWS), Minimally Conscious states minus (MCS-) and plus (MCS+) and often lead to permanent disability with huge ethical and economic consequences [1]. Reliable prognostic markers are critical in planning tailored care pathways and optimizing the use of resources in compliance with ethical and social issues. Our aim was to explore the prognostic value of demographic, anamnestic, clinical, and neurophysiologic findings on consciousness recovery at the discharge from an intensive rehabilitation unit (IRU).

Population: The present multicenter prospective, observational longitudinal study was conducted in the framework of the PRABI study [2]. All patients admitted to one of the three involved Fondazione Don Gnocchi units from January 2020 to January 2022 and fulfilling the following inclusion criteria were included: 1) age >18 years; 2) clinical diagnosis of DoC of any etiology; 3) time post-onset (TPO) < 3 months.

Methods: Within 1 week from enrollment, all patients underwent a clinical and neurophysiological assessments including: Coma Recovery Scale revised (CRS-R), Disability Rating Scale (DRS), a standard Electroencephalography (EEG) reported according to the terminology of the American Clinical Neurophysiology Society of Critical Care EEG [3] and Somatosensory evoked potential (SEPs). The independent variable included in the multivariate logistic regression analysis were: age, sex, TPO, etiology, CRS-R sub-scores (Auditory, Visual, Motor, Oro-verbal, Communication, and arousal), DRS total score, presence of SEP, and EEG patterns (Frequency, Antero-posterior Gradient, Cortical reactivity, Symmetry, Voltage). The dependent variable was the complete recovery of consciousness at discharge from the IRU.

Results: We included 104 patients: UWS:38 (36.5%), MCS- : 28 (26.9) and MCS-+: 38 (36.5); females: 46 (44.2%), Traumatic etiology: 35 (33.7%), median age: 67.5 years [IQR = 20] and median TPO: 40 days [IQR = 21]. After a median length of stay in the IRU of 90.5

days [IQR = 71], 102 patients were discharged from the IRU (2 deaths) including 61 (58.7%) emergent from DoC. Traumatic etiology (OR: 6.23, p=0.04), a higher CRS-R visual sub-score at admission (OR: 7.75, p<0.001) and presence of EEG cortical reactivity to eye opening (OR: 9.611, p<0.002) predicted the complete recovery of consciousness at discharge with R2 0.638.

Conclusions: The study suggests that the visual subscale of the CRS-R and cortical reactivity to eye opening on at admission are the best predictors of short-term consciousness recovery in patients with DoC. This data confirmed that the multimodal diagnosis of consciousness would allow a better neuroprognostication in patients with DoC.

## LONG-TERM EVOLUTION OF POST-ANOXIC PROLONGED DISORDERS OF CONSCIOUSNESS: AN INDIVIDUAL PATIENT META-ANALYSIS

A. Magliacano[1], F. De Bellis[2], F. Panico[3], L. Sagliano[3], L. Trojano[3], C. Sandroni[4], A. Estraneo[1]

[1]Severe Acquired Brain Injury Unit, IRCCS Fondazione Don Carlo Gnocchi ONLUS (Firenze); [2]Severe Acquired Brain Injury Unit, Fondazione Don Carlo Gnocchi ONLUS (Sant'Angelo dei Lombardi-AV); [3]Department of Psychology, University of Campania Luigi Vanvitelli (Caserta); [4]Department of Intensive Care, Emergency Medicine and Anaesthesiology, IRCCS Fondazione Policlinico Universitario "Agostino Gemelli", Università Cattolica del Sacro Cuore (Roma)

Prognosis of patients with severe anoxic brain injury and prolonged (28 days to 3 months post-onset) Disorders of Consciousness (pDoC) is usually considered poor, but solid prognostic indications for long-term clinical evolution are still lacking. In this study we performed a systematic review and meta-analysis of longitudinal studies on patients with post-anoxic pDoC addressing: 1) long-term clinical evolution (i.e., at least 6 months after the brain injury) in these patients, in terms of rates of mortality, any improvement in clinical diagnosis, and recovery of full consciousness; 2) demographic and clinical characteristics more likely associated with each of the above three outcomes. Following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA; PROSPERO ID: CRD42021264692), we performed a literature search on PubMed, Scopus and PsycINFO databases until 25th January 2023. The quality of evidence of included studies was evaluated using the Quality In Prognosis Studies (QUIPS) checklist. Then, meta-analyses of proportions were performed to estimate the rates of mortality, clinical improvement, and recovery of full consciousness. Furthermore, we used cross-sectional meta-analyses to investigate whether significant differences in demographic and clinical variables could be observed across outcomes. We identified 27 studies including a total sample of 357 (289 in Unresponsive Wakefulness Syndrome, UWS and 68 in Minimally Conscious State, MCS) individuals with pDoC due to anoxic brain injury with a follow-up diagnosis at least 6 months after injury. We found that 26% of included patients deceased, 26% showed any clinical improvement, and 17% recovered full consciousness. Higher likelihood of survival and of clinical improvement was associated with younger age, baseline diagnosis of MCS vs. UWS, higher baseline level of responsiveness as assessed by the CRS-R total score, and earlier admission to intensive rehabilitation units. These same variables, but time of admission to rehabilitation, were also associated with recovery of full consciousness. Our findings showed that anoxic pDoC is associated with a sizeable percentage of recovery and that clinical variables can help to predict clinical evolution. This study raises important ethical issues about the need for solid predictive factors, particularly in relation with decisions about withdrawal of life support or discontinuation of long-term management.

## STUDY OF NEUROPLASTICITY BY HIGH-DENSITY EEG IN POST-STROKE PATIENTS FOLLOWING ROBOT-ASSISTED UPPER-LIMB REHABILITATION

M. C. Mauro[1], A. Mazza[2], M. Germanotta[3], L. Cortellini[3], A. De Liso[4], A. Comanducci[2], I. Aprile[5], E. Guglielmelli[6]

[1]Don Carlo Gnocchi Foundation IRCCS (Firenze); [2]Multimodal Neurophysiology Laboratory for Rehabilitation (LuNaRe), Don Carlo Gnocchi Foundation IRCCS (Milano); [3]Department of Neurorehabilitation, Don Carlo Gnocchi Foundation IRCCS (Firenze); [4]Department of Neurology, Campus Bio-Medico University (Roma); [5]Department of Neurorehabilitation, Don Carlo Gnocchi Foundation IRCCS (Milano); [6]Department of Engineering, Campus Bio-Medico University (Roma)

Objective: Stroke is the second leading cause of death and the leading cause of disability in the world. In recent years, an increasing number of end-effector robots have been developed for the treatment of the upper limb [1], while only a bilateral exoskeleton is currently available. In addition to clinical assessment, monitoring of brain electrical activity, using Electroencephalography (EEG), has emerged for longitudinal assessment of patients with stroke outcomes. The proposed study is an RCT aimed at evaluating recovery in post-stroke patients after unilateral or bilateral robot-assisted upper limb rehabilitation using an EEG quantitative index.

Materials and Methods: Nineteen patients with ischemic stroke in the subacute phase underwent a 30-session upper limb neurorehabilitation program using the Arm Light Exoskeleton Rehab Station (ALEx RS). Each patient was randomly assigned to the experimental group (bilateral treatment) or the control group (unilateral treatment). In addition, neurophysiological evaluation was performed at the following time points: before the start of the first session (T0), immediately after the end of the first session (T1), at the end of the 30 treatment sessions (T2), and at 1-week follow-up (T3). From the acquired EEG data, the Brain Symmetry Index (BSI), one of the most used EEG parameters for the purpose of stroke prognosis, was calculated [2]. It is a metric that

quantifies the symmetry of Power Spectral Density between the two cerebral hemispheres. BSI index values obtained before (T0) and after (T2) the intervention were compared by a two-way repeated measures ANOVA, with time (2 levels: T0 vs T2) as the intragroup factor, and treatment group (2 levels: unilateral vs bilateral) as the intergroup factor, considering the eyes open and eyes closed conditions, separately.

Results: Statistical analysis showed an increase in the symmetry between the cerebral hemispheres (injured and healthy) following rehabilitation treatment in both the eyes open and eyes closed conditions (p=0.006 and p=0.01, respectively). This trend showed no difference in the two groups (unilateral vs bilateral), being the timeXgroup interaction factor statistically non-significant in both conditions (p=0.499 and p=0.997, respectively).

Discussion: The results show a progressive "normalization" of symmetry between the two cerebral hemispheres (injured and healthy) following robotic rehabilitation treatment, also accompanied by a clinical improvement in the upper extremity.

Conclusion: The results, therefore, show the change in the index following the intervention, suggesting its use as a means of investigating the mechanisms of neuronal plasticity involved in stroke rehabilitation.

## INFLUENCE OF CARDIORESPIRATORY FITNESS AND MRI MEASURES OF NEUROINFLAMMATION ON HIPPOCAMPAL VOLUME IN MULTIPLE SCLEROSIS PATIENTS

T. Morozumi[1], P. Preziosa[1], A. Meani[2], M. Albergoni[2], M. Margoni[3], E. Pagani[2], M. Filippi[4], M. Rocca[1]

[1]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [2]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [3]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute (Milano); [4]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: The hippocampus is a clinically relevant region characterized by neuroplasticity and neurogenesis that occur throughout the whole lifespan and contribute to functional preservation and restoration, making this structure an appealing potential target for treatment. Neuroinflammation and cardiorespiratory fitness (CRF) may influence hippocampal integrity by modulating the processes promoting neurogenesis and neuroprotection. This study aimed to investigate the effects of neuroinflammation and CRF on hippocampal volume in multiple sclerosis (MS) patients and to evaluate whether these differed according to MS clinical phenotypes (i.e., relapsing-remitting [RR] or progressive [P]). The influence of CRF and neuroinflammation on brain, grey matter (GM) and thalamic volumes was also evaluated to determine whether these effects were specific for the hippocampus.

Materials and Methods: 3D T1-weighted and fluid attenuation inversion recovery (FLAIR) MRI sequences were acquired from 81 MS patients (27 RR and 54 P) and 45 age- and sex-matched healthy controls (HC) using a 3.0 Tesla scanner. White matter T2-hyperintense lesion volume (T2-LV) and choroid plexus volume (CPV) were quantified as neuroinflammatory measures. Moreover, patients underwent cardiopulmonary exercise testing to assess maximum oxygen consumption (VO2max), a proxy of CRF. Associations of demographic, clinical, neuroinflammatory and CRF measures with normalized brain, GM, thalamic and hippocampal volumes in RRMS and PMS patients were assessed using Shapley and best subset selection regression.

Results: RRMS and PMS patients did not differ significantly in age (p=0.174) and sex (p=0.623). Compared to RRMS, PMS patients had higher Expanded Disability Status Scale (EDSS) score (p<0.001), longer disease duration (p=0.003), and a lower value of VO2max (p<0.001). For most volumetric outcomes, largest portions of variance were explained by T2-LV (variable importance [VI]=9.4-39.4) and CPV (VI=4.5-26.2). VO2max explained the largest portion of variance of normalized hippocampal volume in RRMS patients (VI=16.9) and was retained as a relevant predictor of this outcome (Std. β=0.374, p=0.023) together with T2-LV (Std. β=-0.330, p=0.016). However, it explained only a small amount of variance of normalized hippocampal volume in PMS subjects (VI=0.1) and of all the other volumetric outcomes in both groups (VI from 0.3 to 2.2).

Discussion: The positive association between hippocampal volume and VO2max is specific for this structure, and it is present only in patients with RRMS.

Conclusions: By exerting beneficial neurotrophic effects, a higher CRF may play a specific neuroprotective role on MS patients' hippocampal integrity, mainly in the RR phase of the disease.

## EXERGAMING INTEGRATED WITH AUTOMATED MOTOR ASSESSMENT IN PARKINSON'S DISEASE FOR REHABILITATION PURPOSES: A PILOT STUDY USING AZURE KINECT

L. Priano[1], C. Ferraris[2], G. Amprimo[2], F. Galli[3], C. Azzaro[3], R. Cremascoli[3], M. Bigoni[3], A. Mauro[1]

[1]Dept. Neuroscienses, University of Turin (Torino); [2]Institute of Electronics Information Engineering and Telecommunications (IEIIT), Consiglio Nazionale delle Ricerche (CNR) (Torino); [3]Div. of Neurology and Neurorehabilitation, Istituto Auxologico Italiano IRCCS, Osp. S. Giuseppe Piancavallo (Oggebbio - VB)

Objectives: Healthcare facilities traditionally employ targeted physiotherapy treatments to improve motor conditions in Parkinson's disease. Nevertheless, these treatments are underused because of the costs and resources involved in hospital settings. The paper presents an integrated solution suitable for home settings, targeted to stimulate physical activity through exergames in a virtual game environment, and integrated with the automated assessment of motor performance.

Patients and Methods: 12 patients with idiopathic Parkinson's disease were enrolled (Hohen & Yahr score: 2.5 ± 0.9; UPDRS part III: 29.5 ± 12.3; age: 69.5 ± 8.1 years; disease years: 7.3 ± 5.0; 7 males, 5 females. The new Azure Kinect DK camera (TM) and 3D non-contact body tracking libraries were used for real-time capture of body motion through a 3D skeletal model, both for motor assessment and avatar control during execution of exergames. Automated motor assessment was performed according to tasks derived from the UPDRS scale and included leg agility (LA), sit-to-stand (S2S), gait (G), posture and postural stability (PoS). Specific virtual exergames was developed and integrated: skiing, airplane, keyboard, bouncing ball (a gamified version of traditional leg agility). A two-week, exergaming-based experimental protocol was defined to evaluate its potential for future use in home environments, including the automated motor assessment before (T0) and at the end of the protocol (T1).

Results: The average clinical UPDRS score changed from 28.8 ± 4.7 (T0) to 27.1 ± 6.3 (T1). Similarly, the automated assessment of motor tasks (LA, S2S, PoS, and G), showed a slight improvement at T1 in 8 subjects, most parameters appearing stable in the other subjects. The improvement was evidenced for the exergames: the time to complete the level slightly decreased in T1, the number of points increased, and the errors decreased. Even if a significant proportion of participants was almost devoid of habits in using technologies (57%), all participants indicated medium to high overall system usability.

Discussion: This pilot study confirms the overall participants' significant engagement and enjoyment in the exergaming rehabilitation program, which demonstrated its feasibility and suitability for prolonged use, i.e., multiple daily sessions for several consecutive weeks. A more extended period is needed to quantify and evidence the benefits of exergaming through the assessment tasks.

Conclusion: These preliminary results are therefore encouraging and support the feasibility of the protocol, with proper adjustments, to deploy an automated motor assessment integrated, in real-time, with virtual exergames, in home settings, for rehabilitations purposes in Parkinson's disease.

## STRUCTURAL AND FUNCTIONAL CORRELATES OF DISABILITY AND GAIT IN MULTIPLE SCLEROSIS: FOCUS ON THE GLOBUS PALLIDUS

F. Romanò[1], M. Rocca[2], E. Pagani[3], P. Valsasina[3], A. De Simone[3], E. Parolin[3], M. Filippi[4]

[1]IRCCS San Raffaele Hospital, Vrije Universiteit Amsterdam (Amsterdam-NL); [2]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [3]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [4]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: The globus pallidus (GP) is divided into an internal (GPi) and an external (GPe) component. Previous works have reported associations between GP atrophy and gait impairment in people with multiple sclerosis (pwMS). In this work we explored the structural and functional alterations of the GP and its components in pwMS compared to healthy controls (HC). We also analyzed the relationship with clinical measures of disability and gait impairment.

Materials and Methods: Sixty pwMS and 30 age- and sex-matched healthy controls (HC) underwent 3T magnetic resonance imaging (MRI) including 3D-T1-weighted, dual-echo and resting state (RS) functional MRI. The timed 25-foot walk (T25FW) test and Expanded Disability Status Scale (EDSS) were administered. Two operators segmented left and right GP into GPi and GPe starting from FSL FIRST masks. Whole-GP, GPi and GPe normalized volumes and T1/T2 ratio were extracted, and seed-based RS functional connectivity (FC) was analyzed.

Results: PwMS had a higher T25FW than HC ($p<0.001$). The GP and its components were not significantly atrophic in pwMS ($p=0.08$-$0.73$). Compared to HC, pwMS had higher T1/T2 ratio in GP regions ($p=0.01$-$0.09$), which correlated with EDSS scores ($r=0.26$-$0.39$, $p=0.003$-$0.05$). Whole-GP RS FC analysis showed that pwMS had decreased connectivity between the left GP and right insula and between the right GP and frontal cortices. They also showed increased connectivity between the right GP and thalamus. When looking at RS FC of individual pallidal components, pwMS exhibited decreased connectivity between bilateral GPe and frontal cortices, as well as decreased intra-pallidal and increased thalamo-pallidal connectivity of the GPi. Lower RS FC between the GPe and frontal areas correlated with worse walking abilities and higher disability.

Discussion: Structural involvement of the GP in pwMS was similar across the two segmented portions. Our results confirm previous reports of increased iron accumulation in the GP of pwMS, which increases with disability. Regarding fMRI, the GPi and GPe showed component-specific RS FC alterations, which correlated with walking impairment and global disability.

Conclusion: Segmentation of the GP in its components might be useful in the study of functional correlates of walking impairment in pwMS.

## A DIGITAL PLATFORM FOR NEUROVISUAL REHABILITATION

A. Rufa[1], A. Bargagli[1], D. Landi[2], S. Sambati[2], A. Tozzo[2]

[1]Department of Neuroscience, University of Siena (Siena); [2]Brain Control, Liquid Web srl (Siena)

Objectives: Rehabilitation of visual deficits is crucial for improving cognitive and motor functions and quality of life, however, the influence of visual-sensory and oculomotor disorders on patient's outcome is often ignored in neurorehabilitation. The idea of creating a digital platform for neurovisual rehabilitation comes from our clinical experience with patients affected by neurovisual deficits. Our conventional home-based rehabilitation program for patients with these conditions lead to increased performance in various tasks; we needed an instrument that allowed us to constantly monitor the improvements of our patients, creating personalized rehabilitation programs with an increasing difficulty.

Materials: A digital rehabilitative platform was designed to include specific tasks for each deficit: saccadic tasks in patients with diplopia and alterations of extraocular muscles. Various levels of difficulties in visual search tasks, Benton's line and antisaccade task were designed for peripheral visual field deficits and Neglect rehabilitation. Visual search and visual sequential search tasks, visual recognition and identification of figures, 2-3D shapes, objects, facial expression recognition and colors (Stroop test) were designed for rehabilitation of visual perception, visual attention and visual agnosia.

Methods: The platform is accessible from both clinical and remotely; the clinician assigns the exercise to the patient from the platform, who receives an e-mail notification with a link that takes him to perform the exercise. A final report of each rehabilitation cycle is redacted and it allows a constant monitoring of patient's results but it is also used for obtain statistics data and for customizing rehabilitation on patient.

Results: We tested 46 patients: 21 patients with central visual deficits: 9 patients with diplopia, 2 patients with USN, 3 patients with hemianopia and 7 patients with visual perception deficits. The results

showed a significant improvement in subjective and objective visual functions.

Discussion: Our digital platform for neurovisual rehabilitation allows the clinician to personalize and monitor the treatment's progression and ensures an easily accessible instrument for patients and it showed an efficacy in improving neurovisual performance in neurological patients.

Conclusions: Neurovisual rehabilitation platform represents a valid instrument for rehabilitation of visual deficits in neurological patients.

## NEUROMOTOR REHABILITATION IN PARKINSONIAN SYNDROMES: OUTCOMES AND DISABILITY AFTER HIP FRAC TURE

P. G. Scamarcia, F. Ambrosi, A. Demontis, M. Guglielmi, E. M. Huci, L. Sanavia, L. Vulpio, G. Concardi

KOS Group, Department of Geriatric Specialist and General Rehabilitation, Polo Geriatrico Riabilitativo (Cinisello Balsamo-MI)

Objective: To investigate the clinical outcome of neuromotor rehabilitation after hip fracture in patients with clinically diagnosed parkinsonism.

Materials: 59 patients diagnosed with parkinsonism (45 patients with Parkinson's Disease and 14 patients with atypical parkinsonism) and 59 age and sex matched patients without parkinsonism underwent clinical assessment at neuromotor rehabilitation unit admission and at discharge (mean 40.77 days) after hip fracture surgery.

Methods: Demoghraphic, anamnestic, clinical and functional data were retrospectively collected. Modified Barthel Index (MBI) and modified Rankin Scale (mRS) were used as measures of disability. Demographic and clinical variables were compared between groups using Student's t-test, Mann-Whitney test and Pearson's chi-squared test when appropriate. Linear mixed-effects models were used to study the association between outcome, clinical and demographic variables. Statistical analyses were used to compare data between the two main groups (parkinsonism vs non-parkinsonism groups) and among parkinsonian patients (patients with Parkinson's Disease vs those with atypical parkinsonism).

Results: MBI was significantly lower and mRS was significantly higher in parkinsonism group at both admission and discharge, compared to non-PD group ($p<0.001$). MBI and mRS at discharge were significantly associated with group appartenence corrected for age and sex. Among parkinsonian patients MBI scores at admission ($p=0.02$) and at discharge ($p=0.04$) were lower in atypical parkinsonism (AP) group compared to Parkinson's Disease (PD) patients. Disability, defined by MIB and mRS scores, was significantly associated with the presence of AP ($p<0.001$), dementia ($p<0.001$), dysphagia ($p=0.01$) and postural instability ($p<0.001$), correcting for age, sex and disease duration.

Discussion: PD patients showed higher risk of hip fracture compared to non-parkinsonian patients [1], even though the outcome was controversial [2, 3]. In our knowledge, this is the first study that investigated the outcome of neuromotor rehabilitation in parkinsonian patients after hip fracture, showing higher disability in patients with parkinsonism, compared to those without. Among parkinsonian patients, those with AP, cognitive decline, dysphagia or postural instability showed the worst functional outcome.

Conclusions: According to our results parkinsonian patients, especially with AP, showed a worse outcome after rehabilitation for hip fracture compared to patients without parkinsonism. Cognitive decline, dyspagia and postural instability may represent relevant factors worsening the global outcome, with relevant prognostic implications.

## OXIDATIVE STRESS AND NUTRITIONAL STATUS IN POST STROKE PATIENTS UNDERGOING REHABILITATION TREATMENT: GENDER DIFFERENCES

M. Siotto[1], A. Guerrini[2], C. Cocco[2], M. Germanotta[1], L. Cortellini[1], A. Pavan[1], S. Insalaco[1], Y. Khazrai[2], I. Aprile[1]

[1]Department of Neuromotor, Don Carlo Gnocchi Foundation (Firenze); [2]Department of Science and Technology for Humans and the Environment, University Campus Bio-Medico of Rome (Roma)

After a stroke insult, even in the subacute phase [1], there is an overproduction of free radicals which overpower antioxidant defenses, causing oxidative stress (OS) and further tissue damage. Nutritional status is crucial for stroke-associated malnutrition [2] and for the metabolic antioxidant system. The aim of the study was to evaluate in men and women: i) the systemic OS marker and nutritional status parameters in patients at admission and after a rehabilitation treatment; ii) the correlation of these parameters with functional outcome. We enrolled 87 subacute stroke patients (42 women, 45 men; mean age $69 \pm 12$ years; NUTRISTROKE project: NCT04923165) admitted to our department and evaluated both at admission (T0) and after a six-weeks rehabilitation program (T1), which included a conventional and robotic physical therapy. Functional independence in activities of daily living was assessed by the modified Barthel Index (BI). The nutritional status was assessed by anthropometric measurements, the Geriatric Nutritional Risk (GNRI), and daily estimation of food consumption, together with a Mini Nutritional Assessment screening (MNA-SF®) at admission. Serum samples of patients were collected and analyzed for albumin, hydro-peroxides, total antioxidant defenses, and thiol content. Mann-Whitney U test, chi-squared test, or Paired Wilcoxon's signed-rank test were used to compare data. Correlation between variables was performed with Spearman rho correlation coefficients (JASP v.0.16.4). Women and men did not differ for parameters recorded, except for anthropometric measurements, as expected. Hydroperoxides levels were very high in men and women at T0 and T1, and antioxidants were apparently in the normal range, but the Oxidative Stress Index (BAP/d-ROMs ratio) was very low. Hydroperoxide levels decreased at T1, in parallel to an increase of OSI, in the whole group, and in men. Albumin and GNRI increased at T1 only in women. We found a correlation between MNA-SF®, GNRI (T0 and T1), food consumption, and recovery in terms of delta BI (BI T0-BI T1) in the whole group; women showed all these correlations, even stronger. Oxidative stress status is very high in subacute patients even three months after the stroke insult. The antioxidant defense is insufficient to counteract this condition and an inappropriate nutritional condition could contribute to exacerbating this scenario. Moreover, women are more impaired in terms of oxidative stress and seems that recovery is more related to nutritional status. This suggests that more efforts should be done

to assess the OS, so that to opportunely improve antioxidant intake, especially in women.

## NEUROMUSCULAR DISEASES - MYOPATHIES AND NEUROPATHIES

### A NOVEL MUTATION IN MYH14 IN A ITALIAN FAMILY WITH AUTOSOMAL DOMINANT DISTAL SPINAL MUSCULAR ATROPHY

P. Ajdinaj[1,2], M.G. Rispoli[1,2], L. Ferri[1,2], A. Tessa[3], F.M. Santorelli[3], A. Di Muzio[2]

[1]Neurology Unit, Department of Neuroscience Imaging and Clinical Sciences, University G. D'Annunzio of Chieti-Pescara (Chieti); [2]Centre for Neuromuscular Diseases, "SS Annunziata" Hospital (Chieti); [3]Molecular Medicine, IRCCS Fondazione Stella Maris (Pisa)

Introduction: Distal spinal muscular atrophy (dSMA) is a rare genetically and clinically heterogeneous group of disorders characterized by slowly progressive distal muscular weakness and atrophy without sensory abnormalities [1]. To date, at least 20 genes and 4 loci associated with dSMA have been reported [2,3].

Case Report: We report the case of an Italian family with autosomal-dominant dSMA with eight affected members. In all patients the first sign was abnormal ambulation, due to weakness and atrophy in distal lower limbs. Later in disease course the same pattern of distal weakness and atrophy involved upper limbs. Electromyography was neurogenic in distal muscles with reduced compound muscle action potential (CMAP) amplitudes. Sensory conduction was normal. Muscle MRI in III-(2) and III-(3) documented muscle atrophy of legs and forearms with fibrous-adipose replacement. Three patients (II-(3), III-(2), III-(3)) were also affected by sensorineural hearing loss confirmed by audiometry. We completed an exome sequencing of 136 genes in all affected members still alive, II-(3), III-(2), III-(3), III-(4), IV-(1) and IV-(2) to identify the causative variant in this family. Genetic analysis identified in all of them the heterozygous c.291G>T variant in gene MYH14, which was classified as likely pathogenic by genome aggregation database (gnomAD).

Conclusion: Although variants in MYH14 gene are yet known to be associated with progressive dSMA, the direct correlation between clinical phenotype and the c.291G>T variant confirms the pathogenicity of this mutation in dSMA. Our findings broaden the genetic spectrum of MYH14 associated dSMA and could improve molecular diagnostics of dSMA.

### OFTEN MISDIAGNOSED AND TREATABLE IMMUNE MEDIATED AUTONOMIC NEUROPATHY

C. Alberti[1], J. Spagliardi[1], F. Barbic[2,3], P. E. Doneddu[1,2], C. Cutellè[1], E. Nobile-Orazio[1,4]

[1]Neuromuscular Diseases and Neuroimmunology Service, IRCCS Humanitas Clinical and Research Institute (Rozzano-MI); [2]Department of Biomedical Sciences, Humanitas University (Milano); [3]Department of Internal Medicine, IRCCS Humanitas Research Hospital (Milano); [4]Department of Medical Biotechnology and Translational Medicine, Milan University (Milano)

Objectives: Autoimmune autonomic neuropathies (AAN) are a group of disorders characterized by an autonomic failure triggered by a dysimmune mechanism. Here we report two cases of AAN characterized by a diagnostic delay with negative consequences for patients and by a good response to intravenous immunoglobulin (IVIg) therapy.

Methods: A 24-year-old woman presented with a 10-year history of gastroparesis, urinary retention, sicca syndrome, paresthesia, and orthostatic hypotension following vaccination. The symptoms were interpreted as a spinal cord dysfunction, and she was implanted with a spinal cord stimulator. The patient was sent for a gastroenterological and then surgical evaluation, and she was offered a colostomy procedure. Autonomic tests showed the presence of autonomic failure. The laboratory and instrumental tests led to a diagnosis of Sjogren's for which IVIg therapy was performed with benefit. A 35-year-old man was evaluated for a history of altered sensitivity to heat and cold in the four limbs, gastroparesis, urinary retention, and orthostatic hypotension, which had occurred approximately 20 years earlier and resolved after plasmapheresis and steroids, and recurred following vaccination. The patient was prescribed laxatives and given the limited benefit he had to resort to numerous visits at the emergency department before being hospitalized. Autonomic tests showed the presence of autonomic failure and he was given IVIg with benefit.

Results and Conclusion: AAN are often misdiagnosed and that this can lead to important consequences for the patients. Several reports confirm a response to therapy with immunomodulatory drugs, in particular IVIg, in AAN.

### WHEN WEAKNESS IS NOT ALL: PORPHYRIA MIMICKING A CIDP

P. E. Alboini[1], L. Florio[1], A. Santoro[1], C. Guida[2], M. Nardella[2], A. Pagano[3], G. d'Orsi[1]

[1]Neurology Department, IRCCS Casa Sollievo della Sofferenza (San Giovanni Rotondo-FG); [2]Nephrology Department, IRCCS Casa Sollievo della Sofferenza (San Giovanni Rotondo-FG); [3]Intensive Care Unit II, IRCCS Casa Sollievo della Sofferenza (San Giovanni Rotondo-FG)

Introduction: Porphyria is a rare but treatable genetic disease caused by alteration of heme metabolism. Even if several types of porphyria had been described so far, porphyria may be dived into acute and chronic disease. Chronic syndromes include porphyria with skin manifestation and without acute attacks. Acute diseases include syndromes with acute manifestations such as pain, psychosis, neuropathy and coma. Porphyria may begin at any age, however only few cases with a late onset had been described.

Materials and Methods: We report a case of acute porphyria mimicking an inflammatory neuropathy. A 60 years old woman was referred to neurologist for a lower limb distal weakness. Her medical history was unremarkable except for a depression, treated with paroxetine. The patient underwent to nerve conduction studies, revealing a demyelinating sensory neuropathy. Hospitalization in our neurology department was suggested. At first the patient refused but after three months, in April 2023, the patient was referred to our department due to a worsening of symptoms. Another nerve conduction study showed a worsening of the demyelinating sensory neuropathy; motor nerve studies and needle EMG were normal. Brain and spinal MRI were unremarkable. Lumbar puncture showed an albumin-cytological dissociation. A CIDP was hypothesized and intravenous immunoglobulin was administered. During the treatment, the patient showed a worsening of neuropathy with an involvement of motor nerves. Moreover hyperCKemia and hypertransaminasemia were observed. A myopathy was hypothesized, however patient suddenly developed an hypercapnic coma and was transferred to the intensive care unit where she was intubated. In the intensive care unit a new intravenous immunoglobulin treatment was administered without benefit; a muscle MRI was performed and it was unremarkable. Patient underwent to steroid treatment: hyperCKemia was resolved where hypertransaminasemia was persistent. In few days the patient developed a severe pancytopenia. In the meanwhile her neuropathy further worsened. Even if patient never complained of abdominal pain, the association with neuropathy, pancytopenia and psychiatric disorders suggested porphyria. Urine porphobilinogen and elevated values of urinary porphyrins led to the diagnosis of acute intermittent porphyria. Patient was treated with heme arginate with a marked improvement of symptoms: actually the patient came out of coma and even neuropathy sowed a mild improvement.

Conclusions: Ancient physicians said: "if you don't know what it may be, think about porphyria". Actually, due to the broad spectrum of manifestation, porphyria may be underdiagnosed and it should be suspected in those kinds of inflammatory neuropathies unresponsive to treatment.

## FRIEDREICH ATAXIA IN A YOUNG WOMAN PRESENTING AS POLYNEUROPATHY

P. Alonge[1], V. Di Stefano[1], A. Torrente[1], A. Lupica[1], N. Rini[1], F. Calì[2], F. Brighina[1]

[1]Department of Biomedicine, Neuroscience and advanced Diagnostic (BIND), University of Palermo (Palermo); [2]Oasi Research Institute-IRCCS (Troina-EN)

Case Presentation: A 29-years-old woman came to our attention for the sudden onset of gait disturbance at 26. Personal history was unremarkable, besides spinal scoliosis treated with a corset. Family history was negative for neuromuscular diseases; parents were consanguineous (first-grade cousins). At 27 she had performed a brain and spine MRI that found no abnormalities (except for the known scoliosis). She also lamented tinnitus in the right ear; an audiometric examination evidenced sensorineural hearing loss in the right ear. Neurological examination evidenced bilateral pes cavus and bilateral dysmetria at the finger-nose and heel-to-shin tests. An ENG showed a sensitive polyneuropathy, with absence of SAPs from median, ulnar and sural nerve. Routine blood tests, cerebrospinal fluid analysis, autoimmunity serum panels and anti-neuronal antibodies were normal. Anti-ganglioside serum panel revealed a weak positivity of anti-GD 1b and anti-GT 1b IgM. Suspecting an inflammatory polyneuropathy, she was treated with prednisone 50 mg. Even if she reported a subjective improvement, neurological evaluation did not change. After two weeks, she presented serous retinal detachment at the right eye and the treatment was suspended, with rapid improvement of eyesight. However, gait and balance worsened. Suspecting a genetic syndrome, an NGS panel for spino-cerebellar ataxias was inconclusive, while a homozygous GAA triplets expansion was demonstrated in the FRDA gene. Her parents were found to be carriers for the expansion. To evaluate any subclinical cognitive impairment, neuropsychological tests were administered, with normal results.

Discussion: FRDA is the most common autosomal recessive spinocerebellar ataxia in Europe. It usually presents between 10 and 16 years with a multisystem involvement, affecting both the central and peripheral nervous systems, the musculoskeletal system, the myocardium and the endocrine pancreas. Late-onset forms (>20 y) occur rarely and often typical symptoms such as dysarthria, gait ataxia and cognitive impairment may be absent. [1] In our case, clinical presentation and family history pointed to an inflammatory etiology; clinical signs that could suggest a genetic etiology were subtle (namely, bilateral pes cavus and scoliosis).

Conclusion: Genetic testing should be considered even in mild suspicion of a genetic disorder to avoid misdiagnosis.

## MITOCHONDRIAL CARDIOMYOPATHIES: A CLINICO-PATHOLOGICAL STUDY

M. Ardito, G. Primiano, A. Sabino, C. Sancricca, S. Servidei

Neuroscience Department, Catholic University of the Sacred Heart, IRCCS, Fondazione Policlinico Universitario Agostino Gemelli IRCCS (Roma)

Objective: The aim of this study is to describe the clinical and pathological findings of three unrelated patients presenting with cardiomyopathy and different mitochondrial syndrome (PEO and MELAS associated with m.3243A>G mutation, MERRF and m.8344A>G).

Materials and Methods: In order to elucidate the etiology of the heart dysfunction, all patients underwent extended cardiac evaluations, including endomyocardial biopsy.

Results: Histologic analysis revealed different features in the three hearts' patients: in the m.3243A>G-PEO patient we observed classical focal accumulation of mitochondria with COX defect, while in the other two patients COX was slightly reduced. In the MELAS patient cardiomyocytes were hypertrophic and showed sarcoplasmic vacuoles filled with PAS-positive granules analogous to those

observed in storage disease and mitochondrial proliferation; in the patient affected by PEO and MERRF there was only mitochondrial abnormalities without cytoplasmic vacuolation.

Discussion: There was a good correlation between the histopathological finding and the severity of the clinical conditions. In fact, the 24-year old MELAS has been showing an acute heart failure that happened suddenly without warning and she passed away two weeks after the endomyocardial biopsy. On the contrary PEO and MERRF patients presented a long history of chronic cardiomyopathy diagnosed many years before histological investigations.

Conclusions: Our results show a histopathological variability of endomyocardial biopsy. The severity of histological findings reflects the clinical conditions of the patients and their prognosis.

## FATIGUE AND ASSOCIATED FACTORS IN PRIMARY MITOCHONDRIAL MYOPATHIES: A SINGLE-CENTRE COHORT SURVEY EXPERIENCE

I. G. Arena, I. Aricò, A. Toscano, C. Rodolico, R. Silvestri, O. Musumeci

Department of Clinical and Experimental Medicine, University of Messina (Messina)

Introduction and Objectives: Muscle pain and fatigue are commonly reported complaints in Primary Mitochondrial Myopathies (PMMs). We aim to investigate the prevalence of these disturbances and to stratify the different domains of fatigue in our cohort of patients affected by PMMs and tried to compare the possible relation between these conditions and others potentially influencing factors such as sleep disturbances or psychiatric comorbidities.

Materials and Methods: We administered self-reported or perceived fatigue and muscle pain routinely scales such as Modified Impact Fatigue Scale (MFIS), Fatigue Severity Scale (FSS), Back Pain Inventory scales in 50 patients affected by PMM and controls. PSQI (Pittsburgh Quality Index), ISI (Insomnia Severity Index), Hamilton Anxiety Rating Scale (HAM-A), BDI (Beck depression Inventory), NMDAS were also performed. Linear regression analysis was performed to evaluate the associations between the different variables.

Results: Fatigue resulted to be very common in our population (42/50; 84%). 11/50 (22%) reported muscle pain. Higher fatigue and pain scales rates relates with anxiety, depression and altered sleep quality ($p<0.05$). Higher age and NMDAS score were related with higher fatigue perceived and muscle pain.

Discussion: The burden of pain and fatigue in PMM seem to be associated to increased age and to overall clinical involvement. Pain and fatigue appear to influence sleep disturbances in this population and vice-versa. Anxiety and depression are likely contributing factors of fatigue and pain perceived.

Conclusion: Anxiety, depression and sleep quality questionnaire should be assessed routinely to PMM patients claiming fatigue and pain for a better assessment and management. Considering the different fatigue scales available, MFIS and MFI-20 appear to be more selective in the evaluation of these patients.

## MYASTHENIA GRAVIS, MULTIFOCAL MOTOR NEUROPATHY, AND ANTI-GBM NEPHRITIS: THREE AUTOIMMUNE DISORDERS IN ONE PATIENT

G. Atanasio, O. Pardeo, M. De Luca, S. Messina, C. Rodolico

Department of Clinical and Experimental Medicine, University of Messina (Messina)

Objectives: The coexistence of multiple autoimmune diseases in patients with a chronic autoimmune disease is common and known as "multiple autoimmune syndrome". The acute, simultaneous onset of multiple autoimmune disorders is rarer and has often been explained by the exposure of a genetically predisposed individual to a triggering factor. We present a case of three new-onset autoimmune disorders occurring simultaneously: anti-GBM nephritis, Myasthenia Gravis (MG), and Multifocal Motor Neuropathy (MMN).

Patient and Methods: We describe a 69-year-old man, affected by arterial hypertension and diabetes mellitus. He was hospitalized due to the subacute onset of tetra-hyposthenia, dysphagia, ptosis, and ophthalmoparesis rapidly evolved in few days. Two months before he had presented a lack of strength in the left upper limb. Early in the hospital stay, the patient presented progressive impairment of respiratory function and motor skills until he developed cardio-respiratory arrest. He was then admitted to the intensive care unit where after intravenous Ig therapy he progressively improved in motor skills. The patient underwent lumbar puncture which was negative for infectious and inflammatory diseases. He also underwent neurophysiological investigations (ENG, EMG, and SFEMG). Several autoimmunity laboratory tests were performed. An ultrasound study of the nerves has been carried out.

Results: At the beginning of the hospital stay, the patient's clinical and neurological picture rapidly deteriorated within a few days. He presented with a concomitant increase in gammaglobulin, serum IgG and IgA, and nonselective proteinuria. Therefore, high-dose Ig ev therapy was undertaken. Neurophysiological exams revealed peripheral motor trunks pathology with conduction blocks and altered neuromuscular junction. Screening tests for autoimmunity showed positivity of ARAB, anti-GBM, ABTG, ABTPO and ANA antibodies. CT scan of the chest excluded expansive masses or thymic hyperplasia. After the initial acute phase, the patient progressively improved with complete remission of the nephritic syndrome and progressive motor recovery. In all, two courses of Ig ev therapy were performed subsequently corticosteroid and azathioprine therapy was continued.

Discussion: To our knowledge, no other cases like this have been described. The concomitant occurrence of membranous glomerulonephritis and MG has been sporadically reported, especially associated with thymic pathology. In our case, we couldn't find a putative trigger cause explaining such abnormal immune response.

Conclusion: The present case of MMN, MG, and anti-GBM nephritis occurring in one patient indicates a common underlying immune mechanism, including the involvement of autoantibodies, complement activation and T cells.

## CO-OCCURRENCE OF OCULOPHARYNGEAL MUSCLE DYSTROPHY AND MYASTHENIA GRAVIS: AN ASSOCIATION OR AN INCIDENTAL FINDING?

A. R. Avallone[1], L. Bevilacqua[1], A. Renieri[2], S. Amabile[3], G. Piscosquito[1], P. Barone[1], C. Vinciguerra[1]

[1]Neurology Unit, Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", University Hospital San Giovanni di Dio e Ruggi D'Aragona (Salerno); [2]Department of Medical Biotechnology, Medical Genetics, University of Siena (Siena); [3]Department of Molecular Pathology and Medical Genomics, University Hospital San Giovanni di Dio e Ruggi D'Aragona (Salerno)

Introduction: Oculopharyngeal muscular dystrophy (OPMD) is an autosomal dominant late-onset myopathy, characterized by progressive ptosis, dysphagia and limb muscle weakness. Myasthenia gravis (MG) is an autoimmune neuromuscular junction disease, most commonly caused by antibodies against the acetylcholine receptor (AChR), leading to fatigable and fluctuating weakness that variably affect ocular, bulbar and limb muscles. Since both diseases may affect the same muscular groups, overlap and misdiagnosis can occur.

Case Description: A 80-year-old Italian man with a 30-years history of slowly progressive ptosis referred to our hospital for a recent onset of dysphagia and lower limbs weakness with difficulties in walking and climbing stairs. Seven of nine siblings shared similar symptoms since the age of 50 years. Neurological examination showed severe ptosis with upward gaze limitation, hypophonic speech, proximal muscle weakness involving pelvic and scapular girdle. Concentric needle EMG showed patchy myopathic abnormalities without spontaneous or insertional activity in proximal muscles but was normal in distal ones. Genetic testing for OPMD was significant for PABPN1 gene mutation with 14 GCN repeats. Given the fluctuating fatigability, expecially in the lower limbs associated to shortness of breath, a coexisting neuromuscular junction disease was suspected. High AchR antibodies titre was found in two different determinations. Repetitive nerve stimulation revealed a significant decrement from the accessory nerve. Pyridostigmine therapy was added to therapeutic regime, with immediate response and fast clinical improvement.

Discussion and Conclusions: Only few cases of genetic myopathies coexisting with AchR MG have been reported. This occurrence may be coincidental, but it could also indicate a disruption of immune tolerance to AChR due to autoinflammation (innate immunity) triggered by muscle fiber degeneration, rather than through adaptive immune processes in the thymus. Our case aims to suggest that even in patients with a confirmed genetical diagnosis, the presence of unusual clinical features forces to investigate additional overlapping condition, especially when a treatable disease like MG is suspected. Further case reports will be needed to better understand the mechanism underlying this association, in order to define the most effective and tailored therapeutic approach in these patients.

## A CASE OF TREATMENT-REFRACTORY ANTI-NUCLEAR-RIM NECROTIZING AUTOIMMUNE MYOSITIS

E. Baroncelli[1], L. Argenti[2], G. Pesce[3], C. Fiorillo[4], A. Murialdo[1], E. Pedemonte[1], G. Zocchi[1], M. Del Sette[1], G. Novi[1]

[1]Department of Neurology, IRCCS Ospedale Policlinico San Martino (Genova); [2]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa (Genova); [3]Laboratory of Autoimmunology, IRCCS Ospedale Policlinico San Martino (Genova); [4]Department of Neuroscience, Centre of Myology and Neurodegenerative Disorders, Istituto G. Gaslini (Genova)

Objectives: We report on a case of a 30-year-old patient affected by treatment-refractory necrotizing autoimmune myositis with predominantly bulbar symptoms and positivity for anti-nuclear-rim antibodies.

Methods: We report the case detailing medical and clinical history together with histological, genetic and autoimmune tests.

Results: A 30-year-old male was referred to our department due to onset of dysphagia and dysarthria. High CPK levels and electromyographic test were consistent with acute autoimmune myositis. Despite the presence of an anti-nuclear-rim pattern of antinuclear antibodies, myositis-specific autoantibodies panel tested negative. Muscular biopsy was then performed and showed a necrotizing autoimmune myositis. Patient was then treated with high-dose steroids, with a rapid, but incomplete, response. Due to persistent clinical and biochemical abnormalities, intra-venous immunoglobulins (2g/kg over 5 days) and cyclophosphamide (1 g/m^2) were administered. Due to a clinical and biochemical relapse patient was re-treated with high-dose steroids followed by rituximab (two 1 g infusions 15-day apart). A complete and long-lasting response was then achieved. Genetic analysis tested positive for HLA DPA1 (01:03), HLA DQA1 (02:01, 03:01) and DQB1 (02:01, 03:02) haplotypes that have been associated with cases of autoimmune myositis with antibodies anti-nuclear pore complex.

Discussion: The anti-nuclear-rim ANA pattern has only been described in four cases of myositis-overlap syndrome, each of them presenting a relapsing-remitting course with poor response to steroid therapy; moreover, it was described the association with HLA DPA1 (01:03), and DQA1 (05:01) haplotypes, the latter identified as the most probable risk allele for anti-nuclear-rim associated myositis [1]. However, our patient's genetic analysis showed only the presence of HLA DPA1 (01:03) haplotype, disproving such hypothesis. Additionally, we report that most first line treatments (i.e.: steroids, intravenous immunoglobulin, cyclophosphamide) resulted in transient disease remission, while rituximab administration resulted in a long-lasting disease remission with steroid discontinuation. Thus, the case we described highlights the possibility of achieving a complete and sustained therapeutic response in MSAs-negative necrotizing myositis, even after failure of conventional therapies, and underlines both the role of genetics, and the importance of recognizing an atypical ANA pattern as a guide to the correct therapeutic management.

Conclusion: In this report we show a case of anti-nuclear-rim autoimmune myositis showing that, albeit rare, this autoimmune pattern reflects the presence of a necrotizing myositis that could be refractory to conventional treatment and might need rituximab administration to induce a long-lasting remission.

## LONG-TERM OUTCOME IN GUILLAIN-BARRÉ SYNDROME WITH ANTI-PARANODE ANTIBODIES: A 5 YEAR FOLLOW-UP STUDY

E. Baroncelli[1], M. Bellucci[1], F. Germano[1], C. Castellano[1], E. Mobilia[2], G. Pesce[2], A. Lechiara[2], A. Assini[3], C. De Michelis[4], S. Grisanti[5], M. Gastaldi[6], A. Schenone[2], D. Franciotta[6], L. Benedetti[7]

Objectives: The aims of this study were to evaluate clinical and neurophysiological characteristics of patients affected by Guillain-Barré syndrome (GBS) that tested positive for antibodies directed against paranodal proteins neurofascin-155 (NF155), contactin-1 (CNTN1) and contactin-associated protein-1 (CASPR1), evaluating their long-term follow-up.

Materials: We retrospectively collected data of patients with diagnosis of GBS, hospitalized from 2013 to 2022, positive for paranodal antibodies. Patients with follow-up of $< 12$ months and diagnosed with acute onset chronic inflammatory demyelinating polyradiculoneuropathy (A-CIDP) were ruled out.

Methods: NF155, CNTN1, and CASPR1 antibodies were determined with in-house ELISAs. GBS variants were distinguished based on Wakerley classification [1]. Electrophysiological distinction between demyelinating and axonal forms was based on Hadden criteria [2]. Disability was assessed according to the GBS disability scale (GBS-DS).

Results: 21 patients (15 males, 6 females) with GBS confirmed at follow-up, tested positive for CNTN1, or CASPR1 antibodies (no seropositivity for NF155 antibodies). Mean age was 65.6 years (range 40-91). 18 patients had classic GBS: 12 acute inflammatory demyelinating polyneuropathy (AIDP), 3 acute motor sensory axonal neuropathy (AMSAN), and 3 acute motor axonal neuropathy (AMAN). Two patients were diagnosed with Miller-Fisher syndrome (MFS), and one with a GBS-MFS overlap. We excluded five patients with a follow-up of $\leq 6$ months. Of the remaining 16 patients, 5 had CNTN1 (classic GBS, 4; MFS, 1), 6 CASPR1 antibodies (classic GBS, 4; MFS, 1; overlap GBS-MFS, 1), and 5 had a double positivity (CNTN1/CASPR1, all classic GBS). Long-term follow-up data from onset was available in 76,2% of the patients (mean 4.68 years, range 1-9 years). At the disease nadir, 25% of the patients had a GBS-DS of $< 3$ and 75% $\geq 3$. At the last follow-up visit, 81.25% showed a GBS-DS of $< 3$.

Discussion: While the association of CIDP and paranodal antibodies is well described, cases of GBS seropositive are still scarcely known. Moreover, literature data regarding long-term follow-ups of these patients are lacking. Our cohort showed considerable follow-up period, phenotypic variability and good average recovery. Although our study presents some limitations, particularly the lack of a standardized laboratory assay for paranodal antibodies and confirmation with cell-based assays, the results highlight the importance of correlation between seropositivity, clinical phenotype and long-term follow-up data.

Conclusions: This is the first study evaluating the long-term follow-up of GBS with positivity for paranodal antibodies. More insights on the role of these antibodies in shaping GBS phenotypes require further studies on larger series.

## PHENOTYPIC SPECTRUM OF A SERIES OF TEMPORALLY CLOSE CASES OF GUILLAIN-BARRÉ SYNDROME

G. Baso[1], C. Ferrari Aggradi[1], G. Furciniti[1], S. Mambriani[1], D. Iacobucci[1], D. Saccomanno[1], D. Velardo[1], S. Corti[2], G. Comi[2]

[1]Department of Pathophysiology and Transplantation, University of Milan (Milano); [2]Department of Pathophysiology and Transplantation, University of Milan, Foundation IRCCS Ca' Granda, Department of Neuroscience and Mental Health (Milano)

Objectives: We report here some temporally close cases of Guillain-Barré-Syndrome (GBS) [1] with remarkable unexpected clinical characteristics, which were consecutively observed in our clinic over a period of nine weeks.

Materials: Patients with a diagnosis of GBS admitted to the Neurology ward of the Policlinic Hospital in Milan from January 12th to March 16th, 2023, were included.

Methods: Clinical features, diagnostic evaluations as well as treatment responses were collected.

Results: Among the five patients enrolled (four male, mean age 61,4 years), two presented as typical clinical variant, both with a likely antecedent viral febrile event; two as Miller Fisher syndrome although without seropositivity to antibodies against GQ1b; one as pharyngeal-cervical-brachial variant. All patients showed markedly sustained increase of arterial blood pressure and heart rate over the previous weeks, with three of them reporting recent starting of antihypertensive medication. Laboratory testing were normal. Cerebrospinal fluid analysis (CSF) (performed in 4/5) revealed elevated CSF protein with a normal white blood cell count in the two with typical forms, whereas normal values were found in the two with Miller Fisher variants. Serially performed electrodiagnostic studies showed demyelinating features in 4/5 of patients. Treatment response was overall sufficient. Of those patients, one received only intravenous immune globulin (IVIG) (0.4 g/kg per day for five days), whereas four received plasma exchange (PLEX) (four to six treatments over 8 to 10 days). Out of these four, two failed to improve and they subsequently received IVIG. These two were a woman with Miller Fisher variant who developed impending respiratory failure, while the other was a man with typical clinical variant with progressive severe weakness. Prognosis was poor (GBS-disability score, $\geq 3$) in 2/5 patients.

Discussion: We outlined the clinical features of 5 temporally close consecutive patients admitted in our clinic, which serves, alongside other centers, an area of about 1.352 million inhabitants. Notably three patients displayed GQ1b syndromes phenotypes. Interestingly, all patients suffered from subacute increase of arterial blood pressure and sustained increased heart rate starting two weeks before the onset of neurological symptoms, often requiring treatment modifications with good response.

Conclusions: This cluster of temporally close consecutive patients with GBS showed instead that cardiovascular autonomic dysfunction may represent a common early feature. Alongside supportive management, valuable immunomodulatory treatments are nowadays available [2], but outcome strictly depend from their use at an early stage. Therefore, this unusual clinical feature deserves prompt recognition.

## MYELIN PROTEIN ZERO MUTATIONS: CMT CLUSTERS ACROSS ITALY

A. Bertini[1], L. Gentile[2], T. Cavallaro[3], S. Tozza[4], M. Russo[2], S. Massucco[5,6], Y. Falzone[7], E. Bellone[5,6], F. Taioli[3], A. Geroldi[5], G. Occhipinti[2], S. Magri[1], M. Ferrarini[3], P. Saveri[1], F. Taroni[1], P. Mandich[5,6], S. Previtali[7], A. Schenone[5,6], M. Grandis[5,6], F. Manganelli[4], G. M. Fabrizi[3], A. Mazzeo[2], D. Pareyson[1], C. Pisciotta[1]

[1] Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [2]University of Messina (Messina); [3]University of Verona (Verona); [4]University Federico II of Naples (Napoli); [5]University of Genoa (Genova); [6]IRCCS Policlinico San Martino Hospital (Genova); [7]IRCCS San Raffaele Hospital (Milano)

Background: To investigate the clinical features of a large cohort of Charcot-Marie-Tooth patients with *MPZ* (myelin protein zero) mutation, focusing on the main clusters across Italy.

Materials and Methods: We retrospectively gathered a minimal dataset of clinical information, including type of mutation, disease onset, milestones timeline, disease severity (CMTES-CMT Examination Score), motor/sensory symptoms, cranial nerves involvement and use of orthotics. We performed Fisher's exact test/ANOVA/Spearman's Rank-Order Correlation, as appropriate, to compare patients with different mutations and analyze correlations between age and disease severity.

Results: We collected data from 180 patients: 58 had the p.Ser78Leu mutation (demyelinating CMT; from Sicily), 40 the p.Pro70Ser (axonal form; from Lombardy and Emilia Romagna), 38 the p.Thr124Met (axonal CMT; from Veneto), 24 the p.Ser44Phe (axonal type; from Sardinia), and 20 the p.Val102fs (intermediate form; from Campania and Puglia). Disease severity (CMTES) was highest in p.Thr124Met patients (9.4±6.6), followed by p.Pro70Ser (8.4±6.0), p.Ser44Phe (8.3±6.4), p.Ser78Leu (7.1±4.4), and p.Val102fs (1.6±1.7). Disease onset, determined by both the onset of walking difficulties and the age at first assessment, differed among the five clusters ($p<0.001$), namely earlier in the demyelinating p.Ser78Leu group (34.6±20.3; 49.0±21.3, respectively) and later in the axonal p.Pro70Ser cohort (56.4±5.8; 61.8±13.6, respectively). However, disease progression was faster for p.Pro70Ser patients ($rs=0.82$, $p<0.001$) as compared to those with p.Ser78Leu mutation ($rs=0.61$, $p<0.001$). In the p.Val102fs cohort, no patient reported walking difficulties ($p<0.001$), AFO use ($p<0.001$) or walking support need ($p<0.001$), and no correlation between age and disease severity was found. However, p.Val102fs patients more frequently experienced neuropathic pain as compared to other clusters (76%, $p<0.001$). In the other four groups, orthotic aid use ranged between 39-57% (17-33% for shoe inserts; 24-48% for AFOs), walking difficulties were reported by 70-74% of patients while walking supports were used by 16-25%. Sixteen percent of patients with the p.Ser78Leu mutation reported delayed autonomous walking (beyond 15 months), more than in the other four groups ($p<0.001$). Upper limb involvement, observed in the 12-42% of patients, did not differ across the five cluster. Hearing loss and pupillary abnormalities were almost exclusive of patients with p.Thr124Met (43% and 71%, respectively; $p<0.001$ for both) mutation.

Discussion and Conclusions: This is the largest Italian cohort of MPZ patients, reporting the five most frequent clusters and the comparison among them. The region of origin and some clinical peculiarities, reflecting different pathomechanisms, must help the clinician to guide the genetic analysis.

Funded by Telethon-Italy Foundation grant GUP13006 and GGP19099.

## USE, TOLERABILITY, BENEFIT AND SIDE EFFECTS OF ANKLE-FOOT ORTHOTICS IN CMT

Gemelli IRCCS (Roma); [10]Neuroscience Centre, Magna Graecia, University and Neuroimaging Research Unit, IBFM-CNR (Germaneto-CZ); [11]Department of Medical Sciences, Magna Graecia University, (Catanzaro); [12]Unit of Neurology and Neuromuscular Diseases, Department of Clinical and Experimental Medicine, University of Messina (Messina); [13]Department of Neuroscience, Presidio di Bozzolo ASST (Mantova)

Introduction: Shoe inserts, orthopaedic shoes and ankle-foot orthoses (AFOs) are important tools in the management of Charcot-Marie-Tooth disease (CMT) patients, but data about frequency of use, benefits and tolerance are scanty.

Materials and Methods: We administered to patients of the Italian CMT Registry an online *ad hoc* questionnaire investigating use, complications and (through VAS scale, 0-10) perceived benefit, tolerability and emotional distress of shoe inserts, orthopaedic shoes, AFOs. Mann–Whitney U test was performed to analyse the impact of different determinants on orthoses tolerability.

Results: We analysed answers from 266 CMT patients (136 females; mean age 47.5±12.9 years, range 20-77): 185 (70%) subjects were prescribed lower limb orthoses but 19% did not used them. Among the 150 users, only 69% reported current use. Overall, 39% subjects wore shoe inserts, 18% orthopaedic shoes, 23% AFOs. Among AFOs, Codivilla spring (41%), Toe-off (28%) and Peromed (24%) were the most frequently used. Complications were reported by 59% of patients. AFO users complained mostly of skin reddening (52%) and moderate-to-severe pain (41%) while calluses were a more frequent issue in both shoe inserts (36%) and orthopaedic shoes (36%) wearers. Complications accounted for the 37-42% of orthosis abandonment. AFO users showed greater emotional distress (5.5±3.5) and reduced tolerability (5.9±3.2) as compared to both shoe inserts (2.5±3.2, $p<0.001$; 7.1±3.1, $p=0.001$) and orthopaedic shoes (3.7±3.5, $p=0.003$; 6.8±3.1, $p=0.045$) users. Concerning AFOs, patients with moderate-to-severe CMT (CMTES>8 vs CMTES<=8) and moderate-to-severe (MRC<3 vs MRC≥3) weakness on foot dorsiflexion reported higher tolerability (6.6±2.9 vs 4.5±3.2, $p=0.002$; 6.3±3.1 vs 5.0±3.2, $p=0.038$, respectively) and perceived benefit (6.9±3.2 vs 5.1±3.3, $p=0.005$; 6.9±3.1 vs 5.0±3.4, $p=0.007$, respectively) to their device. Customization was

required for 60% of the orthotics and was related to higher compliance since those who personalized their orthotics were more prone to use it outdoor as compared to those who did not (75% vs 52%, p=0.001). Moreover, delayed customization was associated to lower tolerability (5.7±2.2 vs 7.3±2.0, p=0.006) and perceived benefit (6.2±1.9 vs 7.2±2.1, p=0.031), and to higher emotional distress (5.5±2.1 vs 3.2±1.7, p=0.004) with respect to quick personalization.

Conclusions: Orthoses are frequently used in CMT. However, 19% of subjects never used the prescribed device and abandonment was frequent. Although perceived benefits and tolerability are rather good, there is a high rate of complications and considerable emotional distress, which make their use problematic. A patient-based approach and employment of personalised/customised AFOs must be encouraged.

Funded by Telethon grant GUP13006.

## EVALUATING THE EFFECTIVENESS OF ECULIZUMAB IN THE MANAGEMENT OF REFRACTORY MYASTHENIC CRISIS

L. Bevilacqua[1], A. Toriello[1], G. Piscosquito[1], A. Iovino[1], U. De Marca[2], G. Calicchio[3], P. Barone[2], C. Vinciguerra[1]

[1]Neurology Unit, University Hospital of Salerno (Salerno); [2]Department of Medicine Surgery and Dentistry, University Hospital of Salerno (Salerno); [3]Anesthesia and Intensive Care Unit, University Hospital of Salerno (Salerno)

Introduction: Myasthenia gravis (MG) is a chronic autoimmune disorder caused by autoantibodies targeting different components of the neuromuscular junction (NMJ), which results in muscle fatigability up to respiratory failure in severe cases. Myasthenic crisis (MC), a life-threatening condition that requires hospitalization in ICU, with ventilatory support and treatments with intravenous immunoglobulins (IVIg) and plasma exchange (PLEX). We report the case of MC in a patient with Acetylcholine receptor antibodies (AchR-MG), refractory to standard treatments, responding to Eculizumab as rescue therapy with a rapid and complete recovery.

Case description: A 74 years-old Italian man previously diagnosed with MG, referred to our hospital for 10-days history of worsening eyelid and head drooping, double vision, feeding difficulties, limb weakness and dyspnea. Upon admission he promptly received IVIg infusion and high-dose prednisone, but his conditions worsened, requiring transfer to the Intensive Care Unit (ICU) and mechanical ventilation. Despite several attempts to wean him off the ventilator, his condition did not improve, and pneumonia was discovered. Given the high risk of sepsis despite adequate antimicrobial therapy, a second cycle of IVIg and PLEX were excluded. Hence, the disease was deemed refractory to conventional rescue therapies and, a month later, Eculizumab was initiated. The patient was successfully weaned-off ventilation and moved back to neurology department within 5 days from the first infusion. Over the next few weeks, he gradually regained independent breath and the ability to feed autonomously. Prednisone dosage was reduced, and he was discharged home after five weeks. Currently, he keeps receiving Eculizumab on outpatient basis, with excellent clinical condition and ongoing steroid tapering.

Discussion: Eculizumab is a humanized monoclonal antibody that selectively prevents the activation of the complement component C5, recently approved for refractory generalized AchR-MG. The observation of a complete terminal complement inhibition by the end of the first dose, and the significant reduction of the MG-ADL score during the first week of treatment in the REGAIN study support the evidence of its rapidity of effect. Our case aims to suggest that Eculizumab could also be considered as a fast-acting option in the emergency setting, when conventional treatments fail or are unfeasible. Of note, other reports suggest that delayed initiation of Eculizumab may reduce its effectiveness, leading to incomplete clinical recovery. Further clinical studies are needed to fully understand the role of Eculizumab in the management of refractory MC.

## LAMBERT-EATON MYASTHENIC SYNDROME IN A SINGLE CENTRE COHORT OF PATIENTS: CLINICAL, NEUROPHYSIOLOGICAL FEATURES AND THERAPEUTIC MANAGEMENT

F. Biasini, A. Pugliese, A. Barbaccia, S. Messina, O. Musumeci, A. Toscano, C. Rodolico

Clinical and Experimental Medicine Department, University of Messina (Messina)

Introduction: The Lambert-Eaton myasthenic syndrome (LEMS) is a rare neuromuscular junction disorder, mediated by paraneoplastic (P-LEMS) or primary auto-immune mechanisms (NT-LEMS). Patients typically present proximal muscle weakness, autonomic dysfunctions, and reduced tendon reflexes. High frequency repetitive nerve stimulation (RNS) shows an incremental response of compound muscle action potential (CMAP) amplitude. Furthermore, antibodies against presynaptic P/Q-type voltage-gated calcium channels (VGCC-Ab) are detected in 85–90% of patients.

Patients and Aim: We report herein a cohort of 12 patients affected by LEMS to describe clinical, neurophysiological, and therapeutic features along a median follow-up of 7,5 years (range 1-25 years).

Results: Our cohort includes 8 males and 4 females, with a mean age of 51,3 years old (SD ±17,5; range 10-80 years) at onset, characterized by difficulty in raising from a chair and in climbing stairs (12/12 patients), and dysautonomia (10/12 patients). Small cell lung carcinoma was diagnosed simultaneously with LEMS in one patient, who died for cerebral metastasis 2 years later. Interestingly, another patient developed xerostomia, bulbar symptoms, and lower legs muscle weakness three months after SARS-CoV-2 infection. All patients presented an increase of CMAP amplitude from a distal muscle after muscle maximum contraction. Six patients were tested positive for VGCC-Abs. All patients have been treated with 3,4-diaminopyridine, in addition with prednisone in eight cases and azathioprine in two of them. Moreover, two patients needed rescue therapy such as plasmapheresis and immunoglobulin at the onset or during the disease. After therapy, 58% of patients presented an improvement of at least 2 points in MG-ADL.

Conclusions: LEMS is a rare and insidious disorder, frequently misdiagnosed due to the non-specific clinical features. Neurophysiological studies and VGCC-Abs can allow a correct diagnosis to early detect a possible associated neoplasm and to start therapy, impacting positively on patients' quality of life and survival.

## EFFECT OF AGE ON METABOLOMIC CHANGES IN A MODEL OF PACLITAXEL-INDUCED PERIPHERAL NEUROTOXICITY

R. Bonomo[1], A. Canta[2], A. Chiorazzi[2], V. Carozzi[2], C. Meregalli[2], E. Pozzi[2], P. Alberti[2], C. Frampas[3], D. Van der Veen[3], P. Marmiroli[2], D. Skene[3], G. Cavaletti[2]

[1]University of Enna "Kore" (Enna); [2]Experimental Neurology Unit, School of Medicine and Surgery, University of Milano-Bicocca, (Monza); [3]Chronobiology, Faculty of Health and Medical Sciences, University of Surrey (Guildford-UK)

Introduction: Chemotherapy-induced peripheral neuropathy (CIPN) is one of the most common dose-limiting side-effects of paclitaxel (PTX) treatment. Many age-related changes have been hypothesized to underlie susceptibility to damage or impaired regeneration/repair after nerve injury. The results of these studies, however, are inconclusive and other targets, which might be used as potential biomarkers of nerve impairment, need to be investigated.

Methods: Twenty-four young (2 months of age) and 24 adult (9 months of age) Wistar male rats were randomized to either paclitaxel (PTX) treatment (10 mg/kg i.v. once/week for 4 weeks) or vehicle administration. Neurophysiological and behavioral tests were performed to investigate nerve damage at baseline, after 4 weeks and the 2-week follow-up period. Skin biopsies from sacrificed animals were examined for intraepidermal nerve fiber (IENF) density assessment. Blood and liver samples were collected for targeted metabolomics analysis using Ultra-Performance Liquid Chromatography-Mass Spectrometry (UPLC-MS/MS).

Results: At the end of treatment, the neurophysiological studies revealed a reduction in sensory nerve action potential amplitude ($p<0.05$ ) in the caudal nerve of young PTX-treated animals, and in both the digital and caudal nerve of adult treated animals ($p<0.05$). Behavioral tests revealed a significant decrease in the mechanical threshold in young PTX-treated animals ($p<0.001$), while adult treated rats showed no significant difference in mechanical threshold compared to controls. Concerning IENF assessment, both young and adult PTX-rats had reduced IENF density ($p<0.0001$), which persisted at the end of follow-up. Targeted metabolomics analysis showed significant differences in the plasma metabolite profiles between PTX-treated animals developing peripheral neuropathy and age-matched controls, with triglycerides, diglycerides, acylcarnitines, carnosine, long chain ceramides, sphingolipids, and bile acids playing a major role in the response to PTX administration.

Conclusions: Our study identifies for the first time multiple related metabolic axes involved in paclitaxel-induced peripheral neuropathy and suggests age-related differences in CIPN manifestations and in the metabolic profile.

## CONCOMITANT PERIPHERAL AND CENTRAL NERVOUS SYSTEM DEMYELINATION AFTER INFLIXIMAB THERAPY IN CROHN'S DISEASE: DOUBLY RARE, DOUBLY TROUBLE

C. Bravi, V. Montano, D. Viola, E. Schirinzi, G. Siciliano

Department of Clinical and Experimental Medicine, University of Pisa (Pisa)

Background: Infliximab is a monoclonal antibody belonging to Tumor necrosis factor-alpha (TNF-alpha) blockers, approved for treatment of several inflammatory diseases. However, side effects related to their use are described, including also uncommon cases of central or peripheral neuroinflammatory disorders.

Case Description: A 40-year-old female patient suffering from Crohn's disease since 2020 and treated with Infliximab since October 2022, came to our attention due to paresthesias in the four limbs. Hands paresthesias have been present since February, while feet paresthesias appeared after the third infusion of Infliximab in March 2023. At neurological evaluation, tactile hypoesthesia below knee level bilaterally and both proximal and distal weakness in the lower limbs were showed, in association with brisk deep tendon reflexes at four limbs. Electrophysiological study documented a diffuse sensitive-motor demyelinating pattern. CSF analysis revealed mild damage of the blood-CSF barrier, with pathologically increased albumin quotient and intrathecal IgM synthesis. Searching for peripheral antinerve and anti-onconeural antibodies showed low positive antibody titer for Anti GT1a and Anti GQ1b IgM gangliosides. A diagnosis of chronic inflammatory peripheral neuropathy was done. Due to the presence of unusual headache, in the suspicion of CSF hypotension, a brain MRI was performed with the unexpected finding of non-enhancing hypointense diffuse multiple areas in T1 sequences. No further lesion on cervical and upper dorsal spine were found. The patient was initially treated with high-dose corticosteroids, without significant benefit and subsequently with intravenous immunoglobulins at the standard dosage of 0.4 grams/kg/day for 5 days, with improvement of the clinical picture.

Discussion and Conclusions: Some cases of inflammatory demyelinating lesions of the peripheral or central nervous system are described in literature in patient treated with Infliximab. The mechanism of developing disymmune disorders is not clear, nevertheless some evidences support the hypothesis of a causal association. Co-incidence of peripheral and central demyelinating signs, as here reported, is more rare, underlying the importance of strict therapy surveillance and caution in use of TNF-alpha blockers.

## RAPIDLY PROGRESSIVE CRANIAL MULTIPLE NEUROPATHY: A TOUGH DIAGNOSIS, WHILE THE TIME IS RUNNING OUT

L. Bruno, D. Landi, M. Pierantozzi, T. Schirinzi, R. Cerroni, C. Lozi, G. Marfia, N. Mercuri, F. Izzi

Neurology Unit, University of Tor Vergata (Roma)

Getting to a diagnosis when a cranial multiple neuropathy occurs may not be easy, especially considering how frequent are overlap cases.

Case-report: A 42-year-old man was admitted to Neurology clinic of Policlinico Tor Vergata for subacute onset of saddle anesthesia

and cranial multiple neuropathy. The latter begun with unilateral left lower face paralysis, sensorineural hearing loss, vertigo, diplopia, and nystagmus. The patient had a 12-year clinical history of multiple sclerosis currently on Teriflunomide 14mg/d, primary intracerebral hemorrhage 8 years before, lung adenocarcinoma in remission treated with surgery, chemo- and radiotherapy the previous year. Two weeks before he had been vaccinated against SARS-CoV-2 and influenza. The symptomatology rapidly evolved within a month, causing dysphagia, dysarthria, facial diplegia, right hemifacial dysesthesia, and tongue, pharyngeal, and sternocleidomastoid unilateral weakness. In addition, he complained paresthesia with tingling-like sensation in hands and feet, tendon reflexes in the lower limbs were absent. The brain MRI showed enhancement of the optic nerves, optic chiasm, left oculomotor, trigeminal, statoacoustic and facial nerves, and the nerve roots of the cauda equina. Furthermore, there was evidence of tissue thickening in both ear canals and Meckel's cave. The demyelinating lesions were the same as those of previous MRIs, in absence of contrast-enhancement. Whole-body 18F-FDG-PET/CT was unremarkable. Serum ACE level was within normal range. The Cerebrospinal Fluid (CSF) analysis excluded infectious causes and showed hyperproteinorrachia (184.00 mg/dl), and mild pleocytosis (32.0 mmc), with CD4/ CD8 ratio equal to 4 and CD19+ cells. In the CSF were later identified isolated atypical epithelioid cells, suggestive of localization of lung adenocarcinoma. Eventually Anti-Glutamic Acid Decarboxylase (GAD) and Anti Glutamate Receptor 3 (GluR3) Antibodies were identified in both serum and CSF.

Discussion: Considering the subacute onset, the clinical and paraclinical picture, suspicion of Miller-Fisher or paraneoplastic syndrome were raised, and the patient was treated with methylprednisolone, intravenous immunoglobulins and eventually plasmapheresis, without benefits. The diagnostic workup was carried on, ultimately considering as the most reasonable the neoplastic or dysimmune etiopathogenesis [1]. Considering the results that came out later, the signs were attributed to meningeal carcinomatosis [2] and treatment with pemetrexed was set up [3].

Conclusion: The lack of standardized laboratory analysis for CSF, retrospective trials, and systematic nervous tissue biopsies made the diagnostic process so complicated. The presence of atypical epithelioid cells in CSF suggested a neoplastic etiology, nonetheless the detection of antiGluR3 and antiGAD antibodies, so far not associated with lung adenocarcinoma, should be considered as a culprit or a bystander?

## A NOVEL MISSENSE VARIANT IN THE ACADVL GENE IN A PATIENT WITH VLCAD DEFICIENCY: A CLINICAL AND GENETIC STUDY

F. Caria[1], S. Cotti Piccinelli[2], S. Damioli[3], B. Risi[3], E. Bertella[3], V. Bonito[3], B. Labella[4], L. Poli[4], A. Padovani[4], M. Filosto[2]

[1]NeMO-Brescia Clinical Center for Neuromuscular Diseases, University of Brescia (Brescia); [2]NeMO-Brescia Clinical Center for Neuromuscular Diseases, "Serena" Foundation, Department of Clinical and Experimental Sciences, University of Brescia (Brescia); [3]NeMO-Brescia Clinical Center for Neuromuscular Diseases, "Serena" Foundation (Brescia); [4]Department of Clinical and Experimental Sciences, University of Brescia (Brescia)

Objectives: Very long-chain acyl-CoA dehydrogenase (VLCAD) deficiency is a rare autosomal recessive long chain fatty acid oxidation disorder caused by mutations in the ACADVL gene. The myopathic form presents with exercise intolerance, exercise-related rhabdomyolysis and muscle pain usually starting during adolescence or adulthood. We report clinical and genetic findings of a VLCAD subject carrying a novel pathogenic mutation in ACADVL.

Patients and Methods: A 17-year-old boy presented with exercise-induced muscle pain and fatigue since his childhood. In the recent clinical history, episodes of exercise-related severe hyperCKemia and myoglobinuria were reported. A neurophysiological, myopathological and biochemical assessment was carried out. A 34 gene panel NGS analysis for metabolic myopathies and a familial segregation analysis were conducted.

Results: Electromyography and electroneurography were normal. Muscle biopsy showed "moth-eaten" fibers, and mild increase in lipid storage in muscle fibers. PAS staining was normal. NGS analysis displayed the already known heterozygote c.1769G>A (p.Arg590Gln) variant and the unreported heterozygote c.523C>T (p.Gly175Arg) change in ACADVL both having disease causing prediction. Healthy mother and father were heterozygous for c.523T>C and c.1769G>A respectively. Plasma acylcarnitine profile revealed high long chain acylcarnitine species levels, especially C14:1.

Discussion: The very long-chain acyl-CoA dehydrogenase is an enzyme that catalyzes most of the dehydrogenation of mitochondrial palmitoyl-CoA in liver, heart, and skeletal muscle. Clinical, histopathological, biochemical and genetic tests support the diagnosis of VLCAD deficiency in our patient. The report of a novel pathogenic missense variant in ACADVL expands the allelic heterogeneity of the disease.

Conclusions: VLCAD is a very rare metabolic myopathy; prompt diagnosis is essential for early starting a specific diet and avoiding prolonged fasting and strenuous exercise in order to minimize muscle damage and slow the disease progression.

## FOCAL NERVE ENLARGEMENT AND HYPERVASCULARIZATION IN COMPARTMENTAL SYNDROME: A SINGLE CENTER RETROSPECTIVE STUDY

S. Carta[1], M. Lauriola[2], S. Tamburin[1], G. Zanette[2]

[1]Neurology Unit, Department of Neuroscience, Biomedicine and Movement Science, University of Verona (Verona); [2]Neurology Unit, Pederzoli Hospital (Peschiera del Garda-VR)

Background: Compartmental syndrome (CS) is a potentially highly disabling but treatable disease defined by increased intramuscular pressure within a defined anatomic fascial compartment. In addition to muscular injury, elevated pressure around the nerve can inhibit local vascular flow resulting in nerve ischemia. The role of electrodiagnostic studies in differentiating nerve injury from muscle damage is limited. Data on nerve morphology by ultrasound techniques are still scarce.
Aim: To characterise the ultrasound features of peripheral nerve involvement in CS.

Methods: Retrospective study on patients with CS referred for nerve ultrasound from January 2016 to May 2023. Demographic, clinical and ultrasound parameters were collected.

Results: We identified 9 patients (median age 57.7, IQR 44.7-61.3; 7/9 men). Lower limbs were involved in 6/9 cases, 1 case presented a bilateral involvement. The following etiologies were identified: ischemic reperfusion injury (n=4), trauma (n=2), regional hematoma (n=1), complex regional pain syndrome (n=1), intensive care unit

(n=1). Ultrasound showed evidence of focal nerve injury (oedema, increased cross-sectional area) in all patients (peroneal nerve=7, tibial nerve=5, sciatic nerve=4, median nerve=3, ulnar nerve=2, posterior interosseous nerve=2). The median cross-sectional areas of the involved nerves were: peroneal nerve, 17 sqmm [IQR 14.5-18.5]; tibial nerve, 51 [IQR 50-52]; sciatic nerve, 72.5 [IQR 55-90]; median nerve, 12.5 [IQR 11.75-13.25]; ulnar nerve, 12 [IQR 12-12]; posterior interosseous nerve 6.5 [IQR 6.3-6.8]. All patients developing CS after an ischemic-reperfusion injury, and one patient who presented CS in intensive care unit during COVID infection, showed large tortuous vascularization located within the nerve and adjacent to the epineurium. In 4/5 patients, these abnormalities were proximal to the CS site. Hypervascularization was observed early after the CS (median time of first evaluation, 1.37 months [IQR 1.1–2.3]) and was persistent at follow-up in all patients (median, 12.5 moths [IQR 57.7-61.8]).

Conclusion: Nerve damage after CS appear as a focal increase in CSA. A subgroup of patients with ischemic-reperfusion injury shows vascular abnormalities in the affected nerve. This finding can possibly be related to the release of vascular growth mediators during the hypoxic phase and the increased downstream resistance in the distal vessels during CS. The impact of our findings on treatment and prognosis of CS needs further studies.

## ACUTE ONSET ANTI-MAG NEUROPATHY WITH PARADOXICAL RESPONSE TO RITUXIMAB: A CHALLENGING CASE

E. Cassano, R. Iodice, S. Tozza, F. Manganelli

Department of Neurosciences, Reproductive and Odonstomatological Sciences, University of Naples “Federico II” (Napoli)

Introduction: Anti-myelin-associated glycoprotein (anti-MAG) neuropathy is typically a chronic, progressive, predominantly sensory distal and demyelinating neuropathy, with ataxia and postural tremor. Herein we describe an atypical case of anti-MAG neuropathy.

Case Report: A 60-year-old man developed acute lower limb weakness and severe ataxia with difficulty in stance and walking. He was admitted to ER where received a diagnosis of Guillain-Barrè Syndrome (GBS) and was treated with intravenous immunoglobulin (IVIG) with mild improvement. Nerve conduction study (NCS) was consistent with a demyelinating GBS. After 6 months the patient worsened and was treated again with IVIG that were uneffective. Neurological examination showed severe sensory ataxia, marked lower limb distal muscle weakness, and gait was possible with unilateral aid. Deep tendon reflexes were reduced at upper limbs and absent at lower limbs. Distal postural tremor was observed at upper limbs. NCS confirmed demyelinating sensory-motor neuropathy and highlighted disproportionate distal nerve conduction slowing. Cerebrospinal fluid analysis showed mild protein increase (78 mg/dl) and laboratory testing revealed an IgM k monoclonal component. A diagnosis of paraproteinemic neuropathy with anti-MAG was advanced. Anti-MAG antibodies tested positive at high titer (88000 BTU; ELISA assay). The patient underwent intravenous methylprednisolone (500 mg/die for 5 days) unsuccessfully and after having received anti-MAG antibodies results, Rituximab treatment was started (1000-mg IV infusion at Day 1 and Day 15). Few days later the second infusion the patient experienced a dramatic clinical worsening and the patient became wheelchair-bound. Therefore, Plasma Exchange (PE) was started with neurological improvement that persisted at 6-month follow-up. Genetic analysis for MYD88 gene mutation was negative.

Conclusions: The present case shows some atypical features: the GBS-like onset that is uncommon (2%) in anti-MAG neuropathy and the paradoxical response to Rituximab that is the choice treatment for anti-MAG neuropathy. Such worsening is probably due to IgM flare related to B-lymphocyte lysis with resultant release of intracellular paraprotein and PE is typically the rescue therapy. Looking for MYD88 gene mutation (L265P) (60% of anti-MAG neuropathy) may be useful in case of unsatisfactory response to rituximab since alternative treatments are available (BTK inhibitors).

## MYOFIBRILLAR AND DISTAL MYOPATHY: NATURAL HISTORY OF AN ITALIAN COHORT OF PATIENTS

M. Cheli[1], S. Bortolani[2], E. Rolle[2], A. Vicino[1], S. Bonanno[1], T. Mongini[2], G. Tasca[3], L. Maggi[1]

[1]Neuroimmunology and Neuromuscular Diseases Unit, Foundation IRCCS Neurological Institute Carlo Besta (Milano); [2]Department of Neurosciences Rita Levi Montalcini, University of Turin (Torino); [3]John Walton Muscular Dystrophy Research Centre, Newcastle University and Newcastle Hospitals NHS Foundation Trusts (Newcastle Upon Tyne-UK)

Introduction: Myofibrillar myopathy (MFM) identifies a group of hereditary myopathies characterized by disorganized myofibrils with cytoplasmic inclusions. Distal myopathies (DM) are a genetically heterogeneous group of muscle disorders with prevalent weakness in the distal part of upper and lower limbs. Both diseases showed phenotypic heterogeneity and variable natural history. Aim of this study is to longitudinally assess the disease progression of MFM and DM in an Italian cohort of patients.

Methods: Patients diagnosed with MFM and DM were prospectively enrolled in three Italian neuromuscular centre, and they were evaluated on a yearly basis. The evaluation included full neurological examination with North Star Ambulatory Assessment and timed tests (get up from floor and chair) and IBM-FRS.

Results: We present here the data for the first year (T1) of follow-up of the included cohort. A total of 58 patients, 26 males and 32 females, were enrolled. Mean age at first evaluation was 49.3 years (range= 18-84) and we collected data at baseline, and T1 (1 years follow up) and T2 or T3 (2 and 3 years follow up respectively). The most common mutated genes were DES and GNE (n=8 pts), followed by DNAJB (n=7 pts) and DYSF and PLIN4 (n= 6 pts). Mean IBM-FRS and NSAA scores at baseline were 30,5 ±9,2 and 20 ±12,1, respectively. At baseline 44 patients (75,8%) were able to get up from the floor and the mean time was 7,19” (1,38”- 45,36”), 14 patients (24%) were unable to perform the test. At baseline only 8 patients (13,7%) can’t get up from the chair, mean time was 2,66“(0,58”- 27,51”) for the others 50 (86%). 31 patients reach T1 follow-up. We consider T1 follow up: IBM-FRS improved in 7 patients, 22,5% of the cases (+ 3,375, range of 1-8), remain stable in 9 patients, 29%, and had a reduction of -2,2

points (range 1-8) in 15 patients, 48,3%. NSAA score remain stable in 14 patients, 45%, has a reduction of 3pts (range 1-7) in 15 patients, 48,3%, and improve of 1 points in 2 patients, 6,4%. 3 patients at T1 visit lost capability to get up from the floor, mean time was 5,25" (1,24-16,96"), and 2 patients lost the ability to get up from the chair, the remain patients have a mean time of 3,11" (0,71"-8,47").

Conclusion: Our preliminary data suggest a disease stability or mild worsening according to NSAA and, to a lesser extent, IBM-FRS at one-year follow-up.

## ACUTE ONSET OF DYSESTHESIAS AND PARESTHESIAS

M. S. Cotelli[1], G. Cappelletti[1], A. Vaiano[1], D. Franzini[1], S. Giacomelli[1], F. Manelli[2], V. Palomba[3], R. Furloni[4], B. Borroni[5], V. Bertasi[1], M. Turla[1]

[1]Neurology Unit, Azienda Socio Sanitaria Territoriale Valcamonica (Esine-BS); [2]Emergency Unit, Azienda Socio Sanitaria Territoriale Bergamo Est (Seriate-BG); [3]Neurology Unit, Azienda Socio Sanitaria Territoriale del Garda (Desenzano Del Garda-BS); [4]Medicine Unit, Azienda Socio Sanitaria Territoriale Valcamonica (Esine-BS); [5]Neurology Unit, Azienda Socio Sanitaria Territoriale Spedali Civili (Brescia)

Introduction: Multiple cases of small fiber neuropathy following acute infection due to COronaVIrus Disease 2019 (COVID-19) have been reported in literature. Multiple case reports also described peripheral neuropathies after administration of the COVID 19 vaccine, including Guillain Barrè syndrome and small fiber neuropathy (SFN). The latter represents a peripheral neuropathy involving A-delta and C nerve fibers causing neuropathic pain and autonomic complaints. It can develop due to primary (genetic) or secondary causes. Main symptoms include sensory alterations, pain, dysautonomia. SFN patients can become disabled with relevant economic, familiar and psychological consequences. As the time of February 2023, 13 case reports of post-vaccination small fiber neuropathy had been reported.

Materials and Methods: Our patient, a 48 year old Caucasian man, was hospitalized due to acute tingling paresthesias and burning-stabbing dysesthesias involving four limbs distally and simmetrically, starting seven days after first dose administration anti COVID 19 vaccine (Cominraty). He also referred generalized weakness and hypotension. He performed routine blood tests, resulting all normal. His medical history was normal and he denied family history of neuromuscular disorders. Neurological examination showed mild thigh-to-pelvis flexion (3/5 according to the Medical Research Council-MRC scale) and leg-to-thigh extension (4-/5 bilateral MRC) weakness. He complained of dry mouth and reduced tearing. He performed brain and spinal cord magnetic resonance, screening tests for peripheral neuropathies, a thoraco-abdominal computed tomography, an esophagogastroduodenoscopy, electromyography, lumbar puncture, somato-sensory evoked potentials. which resulted all normal.

Results: Thigh small fiber biopsy showed a reduction in intraepidermal nerve fiber density (IENFD). Symptoms slightly improved to a combination therapy including gabapentin, amitriptylline and supplements.

Discussion: In our opinion temporal correlation between COVID 19 vaccine administration and the development of neuropathic symptoms seems to demonstrate its role in the pathogenesis of SFN, thus expanding existing literature. In previously reported cases SFN can be mild or severe and may or may not require treatment.

Conclusions: We suggest to consider small fiber neuropathy as a possible, even rare side effect of COVID 19 vaccinations in order to promptly recognize and treat it.

Background: The ACTN2 gene encodes the alpha-actinin-2 protein expressed in skeletal and cardiac muscle. Variants in ACTN2 have been first associated with cardiomyopathy and with an adult-onset form of distal myopathy named Adult-Onset Distal Myopathy 6 (MDP6; OMIM #618655) and a more severe condition named Congenital Myopathy with Structured Cores and Z-Line Abnormalities (Myocoz; MSCD; CMYP8; OMIM #618654).

Patient and Methods: A 48-year-old male presented with progressive distal lower limb and facial weakness since the age of 25. His mother has had scapulo-peroneal myopathy since the age of 40. They were diagnosed as having atypical FacioScapuloHumeral Muscular Dystrophy by a 32 kb D4Z4 fragment on chromosome 4. Proband's neurological examination showed limb muscle weakness and atrophy predominantly involving the distal segments associated with moderate upper and lower facial muscle weakness. A neurophysiological, myopathological, and imaging assessment was carried out. An NGS analysis for distal myopathies and a familial segregation analysis were conducted.

Results: Electromyography showed diffuse myogenic signs, more evident in the distal segments of the lower limbs. CK, LDH, and lactic acid were within normal limits. Cardiological examinations did not show signs of structural heart disease. Muscle MRI showed fat infiltration and atrophy of leg muscles. Multiple fibers with single central core-like abnormalities and rimmed vacuoles were observed on muscle biopsy. The NGS study highlighted the presence of the 2624_2625dup

(Pro876Cysfster26) mutation in the ACTN2 gene, resulting in a change in the reading frame and a prediction of pathogenicity.

Discussion: Myocoz is a congenital condition with facial weakness, a cleft palate, and diffuse muscle weakness. Muscle biopsy usually shows rimmed vacuoles and central cores. MDP6 usually presents in adulthood and is characterized by slowly progressive distal muscle weakness primarily affecting the lower limbs and resulting in gait difficulties, drooping foot, and muscle atrophy. Facial, respiratory, and cardiac muscles were usually unaffected. Some patients may develop proximal and upper-limb muscle weakness. Muscle biopsy may show increased numbers of internal nuclei, rimmed vacuoles, and fibrotic or fatty replacement. Our patient presents clinical and histopathological features of intermediate severity between Myocoz and MDP6, characterized by a predominantly distal involvement associated with facial weakness and central cores and rimmed vacuoles on muscle biopsy.

Conclusions: Our study helps to further expand the ACTN2-related disease spectrum of manifestation, suggesting that it is a complex and more heterogeneous condition than previously believed. Phenotypes intermediate between the severe congenital and adult distal forms may be observed and easily misdiagnosed as other myopathies.

## LAMOTRIGINE AS AN ANTI-MYOTONIC AGENT IN MYOTONIC DYSTROPHY TYPE 1: AN OPEN-LABEL SINGLE-CENTER PILOT STUDY

S. Cotti Piccinelli[1], B. Risi[1], F. Caria[1], S. Damioli[1], E. Bertella[1], F. Garofali[1], N. Ait Allali[1], C. Furlan[1], B. Labella[2], L. Poli[2], V. Bonito[1], A. Padovani[2], M. Filosto[3]

[1]Nemo-Brescia Clinical Center for Neuromuscular Diseases (Brescia); [2]Unit of Neurology, ASST "Spedali Civili", Department of Clinical and Experimental Sciences, University of Brescia (Brescia); [3]Nemo-Brescia Clinical Center for Neuromuscular Diseases, Department of Clinical and Experimental Sciences, University of Brescia (Brescia)

Objectives: The primary objective of our study was to evaluate the safety and efficacy of lamotrigine in treating myotonia in patients affected by Myotonic Dystrophy type 1. Secondary objectives were to assess the impact of treatment with lamotrigine on quality of life and the lowest effective dose for treating myotonia.

Patients: In this open-label pilot study, we included adult patients with clinical myotonia affecting daily living and genetically confirmed DM1. Myotonia was observed in eye orbicular muscles, hands, and/or leg muscles and affected daily living with a MBS score greater than or equal to 1. We excluded patients with concomitant treatment with mexiletine.

Methods: All patients received lamotrigine at an increasing dosage every 3 weeks, starting from 50 mg/daily up to 400 mg/daily. The primary outcome was a change in the severity score of myotonia (Myotonic Behavior Scale -MBS) as reported by the participants. The 9-Hole Peg Test (9HPT), the SF-36 questionnaire, and other tasks of daily living, such as disassembling a coffee maker and putting some coins in a wallet, were also assessed.

Results: We enrolled 14 DM1 patients. The medium age at enrollment was 43, and the latest follow-up available was after 12 months. The medium MBS score at baseline was 3.21, while at the last follow-up it was 2.43 ($p<0.05$). At baseline, medium 9HPT time was 38.7 seconds in the dominant hand and 49.6 seconds in the other hand, while at 200 mg daily, we found an improvement in both the dominant (32.1 seconds, $p<0.05$) and non-dominant hands (40,6 seconds, $p<0,05$). Clinical improvement in the other daily-living tasks tested was also observed. No further improvement was detected at 400 mg daily. The SF-36 questionnaire showed a statistically significant improvement in all domains. No significant adverse events were recorded; only a patient with a mild skin rash was reported.

Discussion: Our study showed that lamotrigine was safe in DM1 patients. Our data demonstrated a global improvement in both motor tasks and quality of life assessment that was evident already at the dosage of 200 mg daily. These improvements were not correlated to a further dose increase to 400 mg, suggesting a possible "ceiling effect".

Conclusions: Our pilot study shows very encouraging findings on using lamotrigine as an anti-myotonic agent in DM1 patients and should lead to the confirmation of these results on a large scale in controlled studies.

## BAD THINGS COME IN THREES: KEEP ALERT FOR GUILLAIN-BARRÉ SYNDROME

M. F. Creta[1], C. Gendarini[1], M. Pintus[2], L. Sacchi[1], M. Pozzato[1], T. Carandini[1], A. Arighi[1], [1] G. Comi[1]

[1]Neurology Unit, IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan (Milano); [2]Department of Biomedical Sciences, University of Cagliari (Monserrato-CA)

Objective: Guillain-Barré syndrome (GBS) is a rare neurological disorder characterized by progressive muscle weakness and paralysis, often triggered by an antecedent infection, but an increasing number of reports suggests that surgery could be a potential trigger event.

Materials and Methods: We describe the case of a 64-year-old woman with a history of multiple sclerosis (MS), who underwent a craniotomy for left middle cerebral artery aneurysm clipping. The surgery was further complicated by a subdural hematoma and a subsequent mild right hemiparesis with hyperreflexia. Five days after surgery, the patient developed subacute dysarthria, dysphagia, and gait difficulties. One week later, neurological examination was remarkable for progressive paraparesis, areflexia, and autonomic dysfunction characterized by tachycardia, poor blood pressure control, constipation, and bladder dysfunction.

Results: Diagnostic procedures included brain and spinal cord magnetic resonance imaging (MRI) with gadolinium, which showed new T2-lesions without enhancement, compatible with MS; the subdural hematoma remained stable, and lumbar rootlets enhancement was observed. Electrophysiological studies demonstrated acute axonal and demyelinating, motor and sensory polyradiculopathy. These radiological and neurophysiological findings support our clinical hypothesis of GBS. Lumbar puncture was not performed due to the presence of the subdural hematoma. Intravenous immunoglobulin treatment (2g/kg) was administered, and within two weeks significant clinical improvements were observed in terms of lower limb strength, dysphagia, and autonomic dysfunctions.

Discussion: This case underscores the potential association between surgery and the onset of GBS, emphasizing the need to consider GBS as a possible diagnosis, particularly in patients with pre-existing neurological conditions, even in the absence of recent infections.

Conclusion: Timely recognition and appropriate management of GBS can significantly improve patient outcomes and prevent potential complications associated with delayed diagnosis or misdiagnosis. Further research is warranted to better understand the underlying mechanisms and risk factors associated with the development of GBS following surgery.

## CYTOKINES IN CHRONIC INFLAMMATORY DEMYELINATING POLYRADICULONEUROPATHY AND MULTIFOCAL MOTOR NEUROPATHY: FROM PATHOGENESIS TO POTENTIAL BIOMARKERS AND TARGET OF IMMUNOMODULATORY THERAPIES. A SYSTEMATIC REVIEW

C. Cutelle'[1], A. De Lorenzo[1], P. Doneddu[2], M. Creta[1], G. Liberatore[2], E. Nobile-Orazio[1]

[1]Neuromuscular and Neuroimmunology Unit, IRCCS Humanitas Research Hospital, Milan University (Rozzano-MI); [2]Neuromuscular and Neuroimmunology Unit, IRCCS Humanitas Research Hospital (Rozzano-MI)

Objectives: Advances in cytokines understanding revolutionized treatment of rheumatoid arthritis and other autoimmune diseases. The aim of the study was to investigate the role of cytokines in Chronic Inflammatory Demyelinating Polyradiculoneuropathy (CIDP) and Multifocal Motor Neuropathy (MMN) through a systematic review of the literature.

Material and Methods: Ovid Medline, EMBASE and Web of Science were searched until August 31st 2022 for studies investigating cytokines levels in CIDP or MMN patients. Data were extracted according to a predefined protocol.

Results: Fifty-five articles on 1061 CIDP patients and 86 MMN patients were included (median of 18 patients per study, range 3-71). Studies differed in type of assay, manufacturer and control subjects. A minority of studies reported data on disease activity. Thirty studies tested cytokines in peripheral blood, 9 in cerebrospinal fluid, 10 in both, and 6 in nerve biopsy. IL6, IL17, CXCL10, and TNF-alfa, resulted increased in CIDP patients in most of the studies compared to controls. IL-6 and TNF-alfa levels also correlated with disability, TNF-alfa with therapeutic response and CXCL10 with clinical phenotypes in CIDP. In MMN patients, IL-1Ra resulted elevated in majority of studies.

Discussion and Conclusions: Our results suggest that IL6, IL17, CXCL10, and TNF-alfa might have a role in CIDP pathogenesis, and that more data are needed in MMN. The major limits or the review are the small sample size, particularly in MMN, and the wide heterogeneity of the studies. Further investigations on larger cohorts with a prospective design are needed to evaluate selected cytokines as pathogenic factors, biomarkers for disease monitoring and possible therapeutic targets.

## ATTENUATED TOTAL REFLECTION-FOURIER TRANSFORM INFRARED SPECTROSCOPY (ATR-FTIR) IN MUSCLE DISEASES

G. Dalla Zanna[1], C. Sancricca[1], A. Primiano[2], J. Gervasoni[2], A. Urbani[2], F. Marini[3], A. Sabino[1], R. Calvani[4], S. Servidei[1], G. Primiano[1]

[1]Department of Neurosciences, Sense Organs and Thorax, Agostino Gemelli IRCCS University Hospital Foundation (Roma); [2]Department of laboratory sciences and infectious diseases, Agostino Gemelli IRCCS University Hospital Foundation (Roma); [3]Department of Chemistry, Sapienza University of Rome (Roma); [4]Department of Aging, Orthopedic and Rheumatological Sciences, Agostino Gemelli IRCCS University Hospital Foundation (Roma)

Objectives: Inherited muscle diseases are a heterogeneous group of clinical conditions, characterized by histological and functional abnormalities of skeletal muscle. Attenuated Total Reflectance (ATR) is one of the sampling technologies used for infrared spectroscopy and, as a rapid and non-destructive technique, it is increasingly used in different biological applications. The aim of this study was to evaluate whether the biochemical profile determined by the ATR-Fourier transform infrared (FTIR) spectroscopic technique would allow to distinguish patients affected by late-onset Pompe disease (LOPD), Becker muscular dystrophy (BMD), limb-girdle muscular dystrophies (LGMD), and healthy subjects (HS).

Methods: A total of 40 participants were included: 11 LOPD, 10 BMD, 10 LGMD, 9 HS. For ATR-FTIR, muscle samples were cut at 10 μm in cross-section and placed onto diamond/ZnSe crystal for spectral analysis.

Results: The results obtained show that the spectroscopic fingerprint embeds sufficient information to allow a correct classification of the majority of participants in three groups: dystrophic (BMD and LGMD) and metabolic (LOPD) myopathies, healthy subjects (accuracy 88.4±7.1%). The ATR-FTIR analysis was also effective in classification rates using a two-class model: LOPD vs LGMD (accuracy 95.7±3.2%), LOPD vs BMD (accuracy 82.9±4.6%) and LOPD vs BMD+LGMD (accuracy 93.4±3.0%).

Discussion and Conclusion: In conclusion, our data suggest that ATR-FTIR profile is a reliable diagnostic biomarker for LOPD, BMD and LGMD. Future directions will include evaluating its role as a prognostic biomarker in these genetic diseases, also analyzing biofluids, and the ability of this technique to shed light on the underlying pathogenic mechanisms.

## DESCRIPTION OF A CASE OF WIEACKER-WOLFF SYNDROME IN A FEMALE PATIENT WITH A NEW MISSENSE MUTATION IN ZC4H2 GENE

F. D'Arma, M. De Luca, L. Gentile, G. Occhipinti, G. Iabichella, A. Graceffa, V. Rizzo, A. Toscano, A. Mazzeo, M. Russo

Department of Clinical and Experimental Medicine, University of Messina (Messina)

Objectives: Wieacker-Wolff syndrome is an X-linked neurodevelopmental disorder, caused by hemizygous or heterozygous mutation in the ZC4H2 gene. The clinical features are characterized by severe intellectual disability and symptoms of central and peripheral nervous system involvement, such as spasticity, hyperreflexia, muscle weakness and arthrogryposis in male. Female may be asymptomatic or often mildly affected. ZC4H2 is a gene subject to X-inactivation. The variable clinical manifestations of heterozygous carrier females with a "de novo" variant may be explained by the X-inactivation status within specific affected cells and tissues.

Materials and Methods: The patient was extensively investigated performing neurological examination, blood analysis including endocrinologic and profile as well as autoimmunity, Whole genome sequencing, neuropsychological evaluation using Weschler Intelligence Scale of Children (WISC-III), Electromyography with nerve conduction studies, acoustic, visual, motor and sensory Evoked Potentials, peripheral nerve ultrasound and muscle MRI.

Results: The patient has a phenotype characterized by mild axonal polyneuropathy with cranial nerves involvement and some CNS signs. She also has markedly curly hair and metabolic dysfunctions. Whole genome sequencing showed a missense mutation in ZC4H2 gene that results in the substitution Pro201His. Nerve ultrasonography highlighted reduced cross-sectional area of upper and lower limbs nerves.

Conclusions: We described the phenotype of a new mutation in ZC4H2 never reported before. The clinical phenotype of our patient extends the spectrum of this syndrome being different from the ones already present in literature. Considering the described phenotype, Wieacker-Wolff syndrome is a possible differential diagnosis with Charcot-Marie-Tooth and Congenital myasthenic syndrome.

## SEARCH PROGNOSTIC FACTORS IN GUILLAIN-BARRÉ SYNDROME

G. De Biasi[1], P. Della Valle[1], M. Serio[1], C. Noioso[1], A. Iovino[2], C. Vinciguerra[2], A. Toriello[2], P. Barone[1], G. Piscosquito[2]

[1]Neurology Unit, University of Salerno, Dept of Medicine Surgery and Dentistry "Scuola Medica Salernitana", Neuroscience Section (Baronissi-SA);[2]Neurology Unit, University Hospital "San Giovanni di Dio" (Salerno)

Objective: We retrospectively collected the data of 69 patients (49 M; 20 F) with definite Guillain Barré syndrome according to Brigthon Criteria, admitted in neurological unit of AOU San Giovanni di Dio e Ruggi D'Aragona (Salerno, Italy) between January 2009 and December 2022. This study aims to compare our cohort with those already reported in current literature and to research possible prognostic factors that may be useful to the clinician in managing the disease.

Methods: We collected: clinical findings, previous infectious disease history, routine laboratory examination, autoantibodies classically correlated to GBS and its variants, autoimmune screening. Furthermore we have evaluated the two neurophysiological studies (first within 7 days from onset and second after treatment or within 14 days from onset), CSF analysis, lumbosacral MRI and outcome at discharge.

Results: In 37 (54%) patients, clinical onset was preceded by infectious symptoms: diarrhea (11/37), upper respiratory tract infection (13/37), other infections (11/37), sars-cov2 vaccination (1/37), sars-cov2 infection (1/37). In 52/69 albumino-cytological dissociation was found (proteins > 45 mg/dl, cells < 5). Anti-ganglioside autoantibodies were found in 7/35 patients. Axonal pattern was found in 15/69 and the demyelinating in 47/69 patients. Typical phenotype was found in 59/69 patients (87%), atypical in 13/69 (13%). 68/69 received intravenous immunoglobulin (IVIG). Plasmapheresis was performed as first line treatment just in 1 case due to IgA deficiency; as second line, 3 out of 5 cases received IVIG, while the other two went through plasmapheresis. According to GBS Disability Scale, the prognosis was largely favorable at discharge (0-2 score in 71%), especially in patients with demyelinating pattern, severe disability was 19% (3-5 score), mortality was almost 10%. At 12 months follow up, about 70% of patients walked without any support.

Discussion and Conclusion: Our results are largely comparable with the Western series: male prevalence (70%), demyelinating pattern (71%), typical phenotype (87%), respiratory and gastrointestinal infections were the most common preceding the clinical onset, without any prognostic correlation with one of them or with the time from infection to clinical onset. We found no correlation between albumino-cytological dissociation, MRI roots enhancement or anti-ganglioside autoantibodies and prognosis. The IVIG remain a pillar of GBS treatment and the more-timely administration could correlate with a better prognosis. Long term outcome analysis confirmed that if GBS is rightly treated had a good prognosis.

## NFL AS A BIOMARKER FOR ATTRV AMYLOIDOSIS: A SINGLE CENTRE EXPERIENCE

M. De Luca, L. Gentile, G. Iabichella, G. Occhipinti, F. D'Arma, M. Aguennouz, A. Mazzeo, M. Russo

Clinical and Experimental Medicine, University of Messina (Messina)

Background: Hereditary transthyretin amyloidosis (ATTRv) is an autosomal dominant, adult-onset progressive systemic disease predominantly involving the peripheral nervous system and the heart [1]. Previously, biomarkers of peripheral nerve disease have focused on neurophysiological parameters. Even if these remain necessary for the diagnosis of peripheral neuropathies, due to the high expertise required, inter-operator variability and lack of sensitivity and responsiveness, its use as a biomarker of disease progression over time is limited [2]. Neurofilament light chain (NfL) are a neuronal protein that is released into the serum and cerebrospinal fluid when damage to the nervous system occurs. A few studies show NfL has been proved to be a promising biomarker to assess the state of the disease in ATTRv amyloidosis [3].

Aim of the work: Our work aimed to highlights any correlations between the serum concentration of neurofilaments and the severity of the disease in patients with ATTRv amyloidosis.

Materials: We selected 38 patients with ATTRv undergoing treatment with Patisiran, Inotersen, and Tafamidis, along with 10 carriers and 7 healthy controls. Patients and carriers were divided into 4 groups based on the main mutations present (Glu89Gln, Phe64Leu, Phe84Leu, and Thr49Ala). Serum NfL concentrations were determined using the ultrasensitive single-molecule array assay (Simoa) analysis.

Methods: For each subject, we collected two serum samples, on which neurofilament measurements were taken at 3 different time points: baseline, after 6 months, and after 12 months. At each collection, patients were evaluated using mNIS (Modified Neuropathy Impairment Score) CMTES, FAP stage and PND score (familial

amyloidotic polyneuropathy), CADT (compound autonomic dysfunction test) to assess the neuropathy status, and BNP and Troponin to assess cardiac function.

Results: We observed that the serum concentration of neurofilaments is well correlated with the severity of neuropathy manifested by the patients, regardless of the type of treatment they undergo or the expressed mutation.

Discussion: NfL has recently garnered interest as a reliable biomarker in neurodegenerative diseases, particularly in ATTRv V30M amyloidosis [3]. This study confirms previous reports and extends the utility of NFL as biomarkers even in non-Met30 patients.

## A RARE CASE REPORT OF TICK-BORNE ENCEPHALITIS (TBE) CAUSING PHARINGO-CERVICO-BRACHIAL BILATERAL PALSY, WITH NO CLINICAL INVOLVEMENT OF THE CENTRAL NERVOUS SYSTEM

D. Degan, T. Rosso, E. Turinese, A. Burlina

Department of Neurology and Stroke Unit, San Bassiano Hospital (Bassano Del Grappa-VI)

Objectives: We describe the case of a 74-year-old healthy man who met clinical and laboratory criteria of neuroinvasive tick-borne encephalitis (TBE) infection involving laryngeal recurrent, accessory, sovrascapular, axillary, muscolocutaneous, longus thoracicus, and phrenic nerves.

Materials and Methods: At the end of May, 2022, the patient started complaining of fatigue, drowsiness, and nausea. On 1st June he was admitted to our Neurology department, presenting with fever, headache, diffuse myalgia and polyarticular arthralgia. The IgM and IgG TBE antibodies were present in blood; anti-Borrelia Burgdorferi antibodies were negative. The patient lived in a rural area, anyhow he denied any tick borne. After 10 days from hospital admission, he presented severe weakness of the cervical paraspinal muscles with dropped head syndrome, hypophonia without dysphagia, bilateral upper cingulus palsy, and he was unable to walk autonomously. He had no alteration of consciousness, nor any meningeal sign. Brain and spinal magnetic resonance imaging (MRI) and EEG were unremarkable. Cerebrospinal fluid (CSF) analysis performed on 13th June revealed hyperproteinorrachia (144 mg/dL) without pleiocytosis and negative PCR test for TBE, confirmed also in blood and urine examinations. Repeat serological test for TBE was positive. Routine and standard electroneurographic (ENG) examination, including motor and sensory nerve conduction studies (Median, Ulnar, Radial, Tibial, Peroneal, and Sural nerves), F-waves, Blink reflex testing, and low-frequency repetitive stimulation, was normal. Unconventional nerves conduction studies from sovrascapular, axillary, muscolocutaneous, longus thoracicus, and phrenic nerves and ultrasound guided-electromyography (EMG) of sternocleidomastoid muscle and scaleni muscles revealed axonal damage and acute denervation. Patient was promptly treated with intravenous immunoglobulins (dosage of 2 g/kg), with a good clinical recovery. He underwent intensive rehabilitation treatment, obtaining further clinical improvement. After two months from hospital discharge, he was able to walk autonomously, to hold his head, and to raise his arms. He also had a complete recovery from hypophonia. The follow-up ENG examinations revealed progressively increased amplitudes of the compound motor action potentials (CMAPs) in the involved nerves.

Discussion and Conclusions: A 70 to 98% of TBE infections are asymptomatic. Meningitis or meningoencephalitis are most frequent clinical forms of TBE, whereas the cranial nerves involvement is rare and often asymmetrical [1,2]. When occurring with unusual clinical presentations and unremarkable routine diagnostic examinations, TBE diagnosis may be difficult, with increased risk of incomplete recovery and long-lasting morbidity.

## CHRONIC INFLAMMATORY DEMYELINATING POLYRADICULONEUROPATHY AND OPTIC NEUROPATHY: A CHANCE ASSOCIATION?

P. Della Valle[1], G. De Biasi[1], M. Serio[1], G. Acerra[1], A. Iovino[2], C. Vinciguerra[2], A. Toriello[2], P. Barone[1], G. Piscosquito[2]

[1]Neurology Unit, University of Salerno, dept of Medicine Surgery and Dentistry (Salerno); [2]Neurology Unit, University Hospital (Salerno)

Objective: Combined central and peripheral demyelination (CCPD) is a disease characterized by chronic inflammatory demyelination of peripheral nerves (CIDP) and central nervous system (CNS) involvement, mainly associated to N155 antibodies.

Methods: We report two CCPD patients presenting at the onset clinical and neuroradiological signs of monolateral optic neuritis (ON). In both patients it was performed brain and orbital MRI, neurophysiological study, visual acuity evaluation, tonometry, visual evoked potentials.

Case report: Case 1. A 59-year-old female reported acute onset of lower limb paresthesias and numbness, bilateral facial palsy. She also reported low visual acuity and pain during movements of left eye. The first dose of COVID-19 vaccine (ChAdOx1 nCov- 19) was administrated 15 days before. Cerebrospinal fluid examination (CSF) was consistent with albumino-cytologic dissociation (protein 74 mg/mL; 3 cells/1/4L). Repeated nerve conduction studies were consistent with CIDP (EAN criteria). Anti-gangliosides and nodal/paranodal autoantibody screening was negative. Brain MRI showed severe left ON (marked swelling with contrast enhancement). IVIG treatment slightly improved symptoms, high dosage of IV steroid did not improve visual acuity. Peripheral neuropathy was under control (25 mg of prednison), no visual function was recovered. Case 2. A 70-years-old male, with sars-cov2 infection about 2 months earlier, admitted to our department for progressive generalized hyposthenia, painful and tingling-type paresthesias at the lower limbs, low visual acuity in left eye. He progressively worsened becaming chairbound in 3 months. CSF examination revealed albuminocytologic dissociation (protein>50 mg/mL, cells<5/1/4L). Brain MRI demonstrated signs of left ON. Neurophysiological study was performed after six months from clinical onset and fullfied EAN criteria for CIDP. No anti-gangliosides or nodal/paranodal autoantibodies were found. IVIG and steroids treatment improved motor and sensory symptoms, but visual recovery remained poor. The patient required IVIG monthly.

Discussion: We report two CIDP patients (according EAN criteria) who developed also an ON. Few cases were reported in current literature of CCPD, usually associated with NF155 antibodies. We reported two CCPD patients not NF155 related. In both case, the peripheral phenotype improved regardless severity of onset, while the visual loss

did not respond to treatment (IVIG and prednison), and remained the major disability.
Conclusion: ON may be associated to CIDP, but the absence of NF-155 autoantibodies in our cases may suggest the possible involvement of new antigen that need to be studied.

## ACUTE MULTIPLE CRANIAL NEUROPATHY: AN UNEXPECTED CASE

C. Di Felice, S. Malatini, M. Angeletti, A. Riva, M. Cervigni, F. Cancellieri, N. Zannotti, G. Marini, M. Bartolini, M. Silvestrini, G. Viticchi

Neurological Clinic, Marche Polytechnic University (Ancona)

Objective: Botulism is a rare, neurotoxin-mediated, life-threatening disease caused by a neurotoxin elaborated by Clostridium botulinum. The most know typical clinical syndrome of botulism refers to the foodborne form caused by ingestion of food contaminated by preformed botulinum toxin. Foodborne botulism intoxication is often underdiagnosed; the initial symptoms are not pathognomonic and can be confused with more common clinical conditions (i.e., stroke, myasthenia gravis, Guillain–Barré syndrome in Miller–Fisher variant, Eaton–Lambert syndrome, tick paralysis and shellfish or tetrodotoxin poisoning). The diagnosis of botulism is based on clinical suspicion, as well as the decision to apply the specific antidote. It is important to recognize symptoms and formulate an early diagnosis to not delay treatment.

Case Report: A 60-year-old woman with no risk factors was admitted in the Emergency Department (ED) with a 1-day history of nausea, vomiting and dizziness followed by diplopia. In the ED the neurologist evaluating her asked for CT and CT angiography scan that showed no abnormalities. Blood tests showed only mild anaemia and hyponatremia. Toxicology screening resulted negative. Few time later the patient presented with bilateral ptosis, fixed bilateral mydriasis and dysphonia. Botulism intoxication suspicion was made despite the patient denied exposure to contaminated foods and no other family members reported symptoms. Serum and stool samples were collected, and the botulinum antitoxin administrated. The day after the patient developed dysarthria, dysphagia, and urinary retention. During hospitalization electroneuromyography and lumbar puncture were not performed due to the patient's opposition. Few days later the patient remembered eating vacuum-packed zucchini bought in a superstore. During the hospitalization, the patient presented a progressive improvement of the symptoms and was discharged home after 15 days in good general conditions. Botulinum toxin was found in stool sample only.

Discussion: Botulism should be suspected in a patient who develops acute symmetric cranial nerve palsy followed by flaccid paralysis. The diagnosis is based on clinical presentation and epidemiological context. The identification of toxin is not necessary to definitive diagnosis. Therefore, is important to avoid delay in treatment and even to ensure the detecting and the best clinical management of any subsequent cases.

We presented a case of food botulism with rapid evolution and total clinical response to antidote in which diagnosis was promptly made based only on clinical suspicious, despite the patient denied in a first moment a history of exposure to contaminated foods.

The 2021 EAN/PNS guidelines have refined the diagnostic criteria for typical CIDP and its variants, posing more stringent clinical definition [1]. The efficiency of these criteria to successfully classify each patient into a specific category remains however unclear. To assess the

ability of the 2021 European Academy of Neurology/Peripheral Nerve Society (EAN/PNS) clinical criteria for chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) to include within their classification the whole spectrum of clinical heterogeneity of the disease and to define the clinical characteristics of the unclassifiable clinical forms. The 2021 EAN/PNS clinical criteria for CIDP were applied to 329 patients fulfilling the electrodiagnostic (and in some cases also the supportive) criteria for the diagnosis of CIDP. Clinical characteristics were reviewed for each patient not strictly fulfilling the clinical criteria (unclassifiable). At study inclusion, 124 (37.5%) patients had an unclassifiable clinical presentation, including 110 (89%) with a typical CIDP-like clinical phenotype in whom some segments of the four limbs were unaffected by weakness (incomplete typical CIDP), 10 (8%) with a mild distal, symmetric, sensory or sensorimotor polyneuropathy confined to the lower limbs with cranial nerve involvement (cranial nerve predominant CIDP), and 4 (1%) with a symmetric sensorimotor polyneuropathy limited to the proximal and distal areas of the lower limbs (paraparetic CIDP). Eighty-one (65%) patients maintained an unclassifiable presentation during the entire disease follow-up while 13 patients progressed to typical CIDP. Patients with the unclassifiable clinical forms compared to patients with typical CIDP had a milder form of CIDP, while there was no difference in the distribution patterns of demyelination. A proportion of patients with CIDP do not strictly fulfill the 2021 EAN/PNS clinical criteria for diagnosis. These unclassifiable clinical phenotypes may pose diagnostic challenges and thus deserve more attention in clinical practice and research.

## BOTULINUM TOXIN TYPE A FOR NUMB CHIN SYNDROME

B. H. Ercole[1], Y. Tereshko[1], C. Lettieri[2], E. Belgrado[2], G. Merlino[1], G. Gigli[1], M. Valente[1]

[1]Clinical Neurology Unit, Department of Medicine (DAME), Azienda Sanitaria Universitaria Friuli Centrale (ASU FC), University of Udine (Udine); [2]Neurology Unit, Department of Neuroscience, Azienda Sanitaria Universitaria Friuli Centrale (ASU FC) (Udine)

Goal: Numb chin syndrome is a rare pain disorder characterized by decreased sensation and paresthesia in the territory of the mental nerve [1]. We describe a case of bilateral numb chin syndrome, secondary to Burkitt's lymphoma and characterized by the presence of persistent burning neuropathic pain, treated with Botulinum toxin type A (BoNT/A).

Materials: BoNT/A has proven to be effective in many neuropathic pain disorders [2]; however, there are no cases of neuropathic pain secondary associated with numb chin syndrome treated with BoNT/A.

Methods: The patient was treated with subcutaneous injections of BoNT/A (incobotulinumtoxinA, 100U/ml dilution), 10U on each side in the cutaneous territory of the mental nerve. The treatment was performed 12 times with a time interval between one injection and the other of 3-4 months.

Results: Each treatment was able to reduce basal pain significantly (8/10 vs 3/10 NRS) for 3-4 months. The procedure was well tolerated; the patient reported incomplete closure of the mouth of minimal entity that initiated 20 days after each treatment and lasted for 15 days.

Discussion: There are no cases of neuropathic pain associated with numb chin syndrome treated with BoNT/A. BoNT/A modulates neuropathic pain through the interference with the expression of TRPV1 on the plasma membrane of sensory fibers, dorsal root ganglia, and neurons in the central nervous system; moreover, it inhibits the release of CGRP and substance P in both the peripheral and central nervous system, interfering with the central and peripheral sensitization mechanism, and enhances the inhibitory opioid and GABA systems located in the dorsal horn and brainstem [3].

Conclusions: BoNT/A could be a safe and effective therapy for neuropathic pain associated with numb chin syndrome.

## CHANGING PERSPECTIVES: NEW INSIGHTS FROM NERVE ULTRASOUND IN FRIEDREICH'S ATAXIA

E. Evangelisti, P. Falco, E. Galosi, N. Esposito, G. Di Pietro, G. De Stefano, C. Leone, G. Di Stefano, A Truini

Department of Human Neuroscience, Sapienza University of Rome (Roma)

Background: Friedreich's ataxia (FRDA) is the most common cause of hereditary ataxia. It is a multisystem disease encompassing a wide spectrum of clinical manifestations. Frataxin mutation leads to a damage of the Peripheral Nervous System producing a sensory neuropathy, a key clinical feature in FRDA. Though Nerve Conduction Study (NCS) can easily detect a sensory neuropathy in FRDA, sensory nerve action potentials are usually severely reduced or absent thus implying a floor effect that hampers the utility of NCS in the diagnostic follow-up of FRDA patients (Creigh et al., 2019). In this clinical, neurophysiological and nerve ultrasound study we tested the usefulness of nerve ultrasound in the assessment of peripheral neuropathy in Friedreich's Ataxia.

Method: We prospectively enrolled 10 consecutive patients with a defined diagnosis of Friedreich's Ataxia. In the same day anamnestic data, neurological examination with functional and disability scales assessment (Scale for the Assessment and Rating of Ataxia (SARA), Inflammatory Neuropathy Cause and Treatment Disability Score (INCAT), Activities of Daily Living (ADL) and Instrumental Activities of Daily Living (IADL)), Nerve Conduction Study and peripheral nerves high-resolution ultrasound (HRUS) findings were collected. For each patient 24 nerve sites were quantitatively evaluated (Cross Sectional Area (CSA) assessment). CSA values were compared with 20 healthy volunteers.

Results: All the patients had a severe sensory axonal neuropathy (1 patient had a reduction of all sensory action potentials, the other 9 had absent sensory nerve action potentials). In FRDA, HRUS showed a significant nerve enlargement of the Median and Ulnar nerves at the axilla and at the arm ($p<0.001$). The total number of altered nerve sites directly correlated with clinical disability as assessed by SARA and INCAT score and inversely correlate with ADL and IADL.

Conclusions: Nerve ultrasound can highlight alterations along the nerves in Friedreich's Ataxia, mostly at the level of upper limbs. Nerve Ultrasound can provide information where NCS is no longer informative. Nerve ultrasound can be a valuable tool in the assessment of Friedreich's Ataxia.

## EXPANDING THE CLINICAL SPECTRUM OF MYOTONIC DYSTROPHY TYPE 2: A CASE SERIES

E. Faedo[1], S. Massucco[1], E. Scarsi[1], C. Gemelli[2], P. Mandich[1], F. Gotta[2], S. Patrone[2], A. Schenone[1], M. Grandis[1]

[1]Department of Neurosciences, Rehabilitation, Ophthalmology, Genetic and Maternal and Infantile Sciences (DINOGMI), University of Genoa (Genova); [2]Department of Neurosciences, Rehabilitation, Ophthalmology, Genetic and Maternal and Infantile Sciences (DINOGMI), IRCCS Ospedale Policlinico San Martino (Genova)

Introduction: Myotonic dystrophy (DM) type 2 (DM2) is an autosomal dominant condition caused by an expanded tetranucleotide repeat [cytosine-cytosine-thymine-guanine (CCTG)] within the first intron of the ZNF9 gene (CNBP gene). Usually, DM2 involves proximal muscles, therefore, it is also named Proximal Myotonic Myopathy (PROMM). The limb-girdle weakness is often the presenting feature of DM2 with progressive involvement of other muscles, including the facial district. Myotonia is also a frequent feature, affecting 75% of DM2 patients. Muscle pain, stiffness, and fatigue are variably associated with the main features. Furthermore DM2, like DM1, has a multisystemic involvement with ophthalmological, endocrinological, cardiac interest, while in DM2 cognitive impairment is absent.

Objective: We want to describe the clinical spectrum of DM2 in a case series of patients from the Neuromuscular outpatient clinic of the University of Genova.

Results: We evaluated 11 patients, 5 females and 6 males, with a mean age of 56.1 and an average disease duration of 15 years. 6 patients had already been diagnosed, while 5 have been tested in our laboratory. The presenting symptoms were muscle pain in three patients (27%), paroxysmal supraventricular tachycardia in one (9%), frontal balding in two subjects (18%), proximal weakness (18%) in two patients, and hearing loss around age 50 was in one case (9%). Myotonia was rarely reported as presenting feature. Interestingly, a 47-year-old man had an acute DM2 presentation with two episodes of severe hyperCKemia and muscle pain, with subsequent complete remission and unspecific mild signs of myogenic damage at electromyographic tests. We applied our diagnostic algorithm for hyperCKemia, which includes multiplex ligation-dependent probe amplification for Duchenne muscular dystrophy gene and DM1-DM2 genetic test, before next generation sequencing target gene panel for hyperCKemia, reaching an early diagnosis.

Discussion and Conclusions: In our outpatient clinic, DM2 is not uncommon (13% of patients with hyperCkemia or limb-girdle muscular dystrophy), likely because of our protocol which rules out myotonic dystrophies before further NGS tests. Moreover, we want to highlight uncommon presentations of DM2 such as recurrent rhabdomyolysis or early hearing loss, to expand the spectrum of clinical presentation.

## BLOOD TESTS MATTER: A RARE CASE OF MULTINEUROPATHY

C. Faini[1], G. Urbinati[2], O. Addimanda[3], I. Cani[2], F. Cianci[3], S. Ferrari[4], L. Gentile[5], M. Gentile[5], M. Magnani[3], F. Naldi[5], A. Zini[5]

[1]IRCSS Institute of Neurological Sciences of Bologna, Alma Mater Studiorum (Bologna); [2]Department of Biomedical and Neuromotor Sciences (DIBINEM), University of Bologna (Bologna); [3]UOC Rheumatology, Maggiore Hospital, AUSL Bologna (Bologna); [4]Department of Neuroscience, Biomedicine and Movement, University of Verona (Verona); [5]IRCCS Institute of Neurological Sciences of Bologna, Maggiore Hospital, AUSL Bologna (Bologna)

Background: Eosinophilic granulomatosis with polyangiitis (EGPA, formerly Churg-Strauss syndrome) is a systemic necrotizing vasculitis of small and medium-sized vessels characterized by the formation of extravascular granulomas, hypereosinophilia and eosinophilic infiltrates in various tissues. The neurological manifestations reported in the literature mainly concern the peripheral nervous system.

Case Presentation: A 21-year-old patient with history of chronic asthma, came to our observation for subacute onset of symmetric sensorimotor symptoms. We performed the following exams: lumbar puncture: protein 28 mg/dl (0.0-50); white blood cells 1/ml (0.0-5); MRI of the dorsal and lumbar spine with contrast medium: findings within normal limits; NCS: sensory-motor axonal multineuropathy; blood tests: eosinophilic leukocytosis (WB 28.20 10^09/L, of which 42% eosinophils), elevation of transaminases (AST 67 U/L, ALT 165 U/L) and troponin (54.6 ng/ml); chest-abdomen CT scan: pulmonary lesions of suspected granulomatous nature, groundglass bilateral thickenings and widespread thickening of the walls of the gallbladder. We suspected an axonal multineuropathy secondary to EGPA. We started a first line treatment with high-dose corticosteroids, followed by Rituximab. At the discharge, the patient was clinically stable and started a rehabilitation process.

Discussion: EGPA is one of the three anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis, among which is the one with the highest incidence of involvement of the nervous system, in most cases in form of multineuropathy. In our case, the clinical-laboratory features (such as axonal involvement, the absence of dissociation to the CSF, the subacute onset and the asymmetry at NCS) together with the anamnestic finding of organ damage and hypereosinophilia, directed our diagnostic suspicion towards an axonal multineuropathy secondary to systemic disease in the setting of hypereosinophilias. In this context, the main differential diagnoses to consider are secondary eosinophilias (such as EGPA and parasitosis), clonal hypereosinophilic syndromes and idiopathic hypereosinophilic syndromes. We've ruled out other causes of hyperesoinophilia, in particular we performed a genetic analysis for the research of the fusion gene FIP1L1/ PDGFR, with negative result. The diagnosis of EGPA allowed the prompt beginning of specific treatment, therefore we started a immunosuppressive therapy with rituximab. A biopsy of the anterior tibial nerve, which revealed a focal ischemic process of the nerve with evidence of lymphocytic inflammatory infiltrate, supported our hypothesis.

Conclusion: EGPA is a rare cause of peripheral axonal multineuropathy associated with hypereosinophilia important to diagnose since

a specific treatment is available and effective in the management of other systemic complications.

## A CASE OF AN ACQUIRED SENSORY GANGLIONOPATHY PRESENTED WITH A FIBROMYALGIA-LIKE PHENOTYPE

A. Fasolino, K. Longo, G. Alfieri, S. Salvatore, R. Renna, G. Maniscalco, V. Andreone

Neurological Clinic and Stroke Unit, "A. Cardarelli" Hospital (Napoli)

We describe a challenging case of possible inflammatory or paraneoplastic sensory ganglionopathy with severe small nerve fibre involvement presented as a fibromyalgia at onset, with a good response to immunomodulatory therapy. A 40-year-old woman with history of hypertension, unspecified dermatitis, endometriosis, irritable bowel syndrome, depression, recent thyroid cancer undergoing surgical and radiometabolic treatment. She reported widespread pain, itching, burning feet and mouth, dry skin and photophobia onset in October 2022. After 2 months, symptomatology evolved in paresthesias, fatigue, severe gait disturbance, initial motor weakness and the patient was brought out to our attention. Neurological examination revealed feet-slapping gait ataxia, positive Romberg sign, pinprick and tactile sensory loss without length-dependent pattern, hyporeflexia, mild distal hypopalesthesia and weakness in limbs. She also reported widespread burning pain, asymmetric numbness in upper and lower limbs, blurred vision, constipation. We found increased CSF protein without oligoclonal bands. Neurophysiological exams showed a severe axonal sensory neuropathy including foveal involvement and abnormal motor nerve conduction studies in 1 nerve in lower limbs. Brain and Spine MRI was normal. Extensive assessment for secondary causes was negative, including autoimmune and infectious serology, vitamin deficiency, Fabry disease genetic test, radiological and laboratory screening for occult cancer research and onconeural antibody. We exclusively found a mild ANA positivity (1:100) and bilateral sacroiliitis. During hospitalization the patient underwent a cycle of IVIG, rehabilitation and started steroid therapy with regression of small fibre damage symptoms and only slight improvement in others. The clinical picture of the patient is suggestive of a possible acquired inflammatory or paraneoplastic ganglionopathy. The non-length-dependent small nerve fibers sensory and vegetative symptomatology associated with mood disorder at the onset, resemble fibromyalgia syndrome. The axonal damage involving the foveal component in visual evoked potentials suggests a possible involvement of retinal ganglion cells, however other tests are needed. The history of dermatitis, the finding of bilateral sacroiliitis and the mild positivity of the ANA suggest an inflammatory genesis. However the history of cancer, the presence of motor alterations and poor response to immunomodulatory treatments suggest a paraneoplastic syndrome. Futher investigations to complete screening and research autoimmune and paraneoplastic causes, including HLAB27, FDG PET body, skin biopsy are scheduled. Autoimmune or paraneoplastic ganglionopathy is a clinical challenge which might present like a fibromyalgia syndrome due to initial small nerve involvement which may respond to immunomodulatory treatments. A close clinical and instrumental follow-up is mandatory in order to reach correct aetiological diagnosis and adequate therapy.

## COMPARISON OF EFFICACY OUTCOMES WITH VUTRISIRAN VS. PATISIRAN IN HATTR AMYLOIDOSIS WITH POLYNEUROPATHY: POST-HOC ANALYSIS OF THE HELIOS-A STUDY

S. Fenu[1], M. Polydefkis[2], F. Birklein[3], Y. Sekijima[4], D. Pareyson[1], M. Waddington Cruz[5], D. Danese[6], K. Capocelli[6], M. Merkel[6], C. Chen[6], J. Vest[6], D. Adams[7]

[1]Department of Clinical Neurosciences, IRCCS Foundation "Carlo Besta" Neurological Institute (Milano); [2]Department of Neurology, Johns Hopkins University School of Medicine (Baltimore-USA); [3]Clinic and Polyclinic for Neurology, Johannes Gutenberg University of Mainz (Mainz-D); [4]Department of Medicine (Neurology & Rheumatology), Shinshu University School of Medicine (Matsumoto-J); [5]Clementino Fraga Filho University Hospital, Federal University of Rio De Janeiro (Ufrj) (Rio De Janeiro-BR); [6]Alnylam Pharmaceuticals (Cambridge-USA); [7]Neurology Department, Aphp, Chu Bicêtre, Inserm U1195, Université Paris-Saclay (Le Kremlin Bicêtre -F)

Objective: Assess the relative efficacy of RNAi therapeutics for hereditary transthyretin-mediated (hATTR) amyloidosis with polyneuropathy. hATTR amyloidosis is a progressive, life-threatening disease caused by amyloid deposits derived from misfolded variant and wild-type TTR protein. Vutrisiran and patisiran are approved RNAi therapeutics that reduce TTR protein production to treat hATTR amyloidosis with polyneuropathy.

Materials: In the Phase 3 HELIOS-A study (NCT03759379), patients with hATTR amyloidosis with polyneuropathy were randomized (3:1) to vutrisiran (25 mg subcutaneously, Q3M) or patisiran (0.3 mg/kg intravenously, Q3W). Prespecified comparisons previously established the clinical efficacy of vutrisiran versus external placebo (from the Phase 3 APOLLO study of patisiran). The HELIOS-A patisiran arm served as a reference group, and comparison of TTR reduction between vutrisiran and within-study patisiran was included as a secondary endpoint.

Methods: Here, additional post-hoc analyses comparing the HELIOS-A vutrisiran and patisiran arms on clinical outcomes are reported: neuropathy impairment (modified Neuropathy Impairment Score+7 [mNIS+7]), quality of life (Norfolk-QOL-DN), gait speed (10-meter walk test [10-MWT]), nutritional status (modified body mass index [mBMI]), and disability (Rasch-built overall disability scale [R-ODS]).

Results: HELIOS-A enrolled 164 patients (vutrisiran, n=122; patisiran, n=42). TTR reduction with vutrisiran was non-inferior to that observed with patisiran (median difference [vutrisiran-patisiran] [95% CI], 5.28% [1.17, 9.25], 95% CI lower limit >–10%). In the current analysis, least-squares mean (±SE) changes from baseline to Month 18 for vutrisiran and patisiran, respectively, showed similar treatment effects: mNIS+7 (0.06±1.48 vs. 1.53±2.59; p=0.6248),

Norfolk-QOL-DN (−2.5±1.8 vs. −0.8±3.0; p=0.6472), 10-MWT (−0.019±0.025 vs. −0.053±0.043 m/s; p=0.4936), mBMI (21.8±9.2 vs. 7.6±15.8; p=0.4378), and R-ODS (−1.2±0.5 vs. −1.3±0.9; p=0.9266).

Discussion: At Month 18, vutrisiran and patisiran showed numerically and statistically similar efficacy for treating the polyneuropathy manifestations of hATTR amyloidosis.

Conclusions: These post-hoc findings demonstrate comparable efficacy between vutrisiran and patisiran, which both target the key pathogenic protein and have similar pharmacodynamic effects in terms of TTR lowering.

## CLINICAL AND PATHOLOGICAL FINDINGS IN A COUPLE OF ITALIAN GYPSY SIBLINGS WITH CHARCOT-MARIE-TOOTH TYPE 4D AND A REVIEW OF THE CURRENT LITERATURE

C. R. Ferrari Aggradi, E. Abati, F. Magri, D. Velardo, S. Corti, G. Comi

Neurology Department, Policlinico Hospital of Milan, Milan University of the Studies (Milano)

Objectives: Charcot-Marie-tooth disease type 4D (CMT4D) is an early onset autosomal recessive form of CMT characterized by severe demyelinating motor sensory neuropathy, muscle weakness and atrophy leading to gait impairment and foot deformities and hearing impairment. It is caused by mutations in the N-myc downstream-regulated gene 1 (NDRG1). Eight different mutations in NDRG1 have been identified so far. We report the case of two siblings of Romani ancestry, a 38-year-old man and a 40-year-old woman, with a NDRG1 mutation (p.R148) and concurrently provide a review of the current literature.

Materials: Two adult patients affected by CMT4D admitted to the Neurology Department of the Policlinico Hospital in Milan were evaluated clinically and instrumentally.

Methods: Disease staging was assessed through a battery of clinical and instrumental examinations as CMT neuropathy score, electromyography, visual evoked potentials, fiberoptic endoscopic evaluation of swallowing and pulmonary function tests. The review includes all articles focusing on CMT4D available online, published from 1998 to 2022.

Results: Both patients showed severe distal-proximal motor sensory neuropathy, severe muscle weakness and atrophy, mild dysphagia with the need of modified consistencies, mild pulmonary restrictive syndrome and sensorineural deafness. Neurophysiological tests showed markedly impaired motor and sensory conduction parameters. 15 articles, published from 1998 to 2022, were included in the review.

Discussion: The age at onset, in the first decade of life, and the clinical features are in line with the clinical course described in the literature about this pathogenic variant. p.R148 accounts for the majority of CMT4D cases, almost all of Romani ancestry. Because of the lack of data regarding other pathogenic variants, it is difficult to provide a comparison between potential differences in clinical phenotypes and age at onset, but it is interesting to notice that all the patients who had an onset with delayed motor milestones, meaning a very early onset, were p.R148 variant carriers.

Conclusions: Additional research into NDRG1 mutations and phenotypic characteristics may provide further information about potential genotype-phenotype correlations and prognosis.

## CEREBROSPINAL-FLUID TAU LEVELS AS A MARKER OF AXONAL DAMAGE IN GUILLAIN-BARRÉ SYNDROME

G. Filisetti[1], G. Tondo[2], M. Gianesella[3], S. Daffara[4], D. Francese[5], D. Michelone[4], M. Pelagi[4], C. Comi[2]

[1]Azienda Ospedaliero-Universitaria Maggiore della Carità, University of Piemonte Orientale (Novara); [2]Department of Translational Medicine, University of Piemonte Orientale (Vercelli); [3]Neurology Unit, S. Andrea Hospital (Vercelli); [4]Asl Vercelli (Vercelli);[5]Faculty of Biological Sciences, University of Piemonte Orientale (Alessandria)

Introduction: Inflammatory neuropathies (INs) are a group of acquired disorders of peripheral nerves, typically classified as acute or chronic. The most common INs, the Guillain-Barré syndrome (GBS) and the chronic inflammatory demyelinating polyneuropathy (CIDP) are predominantly demyelinating. Since these diseases affect peripheral nerves and the proximal nerve roots, the pathogenic process may lead to cerebrospinal fluid (CSF) biomarker alterations. High CSF levels of neurofilament light chain have been reported in GBS and CIDP, while the role of other biomarkers, including the CSF total-tau (t-tau), is still uncertain. Tau is a microtubule-associated protein involved in microtubule assembly and stability and is considered one of the most established biomarkers of axonal injury. Nonetheless, few studies explored its role in INs, and none reported correlations with neurophysiological data. Therefore, we aimed to investigate the value of CSF t-tau levels in revealing neuronal damage in INs and its correlation with clinical and neurophysiological data.

Methods: We included n=17 patients with INs diagnosed at the Neurology Unit of the S. Andrea Hospital, Vercelli, Italy. All patients had evidence of CSF albumin-cytologic dissociation and were classified according to the clinical presentation in GBS (n=12) and CIDP (n=5). Nerve conduction studies (NCS) were conducted in the upper and lower limbs. T-tau levels were measured in the CSF.

Results: GBS and CIDP groups were similar in age and sex. NCS studies showed a predominant demyelinating involvement in 67% of GBS patients. T-tau levels were significantly higher in the GBS than in the CIDP (218.4±90.9 vs. 125.3±59.6 pg/ml). Also, in the GBS, CSF t-tau levels were inversely correlated with the ulnar compound motor action potential (cMAP) amplitude and the sural sensory action potential (SAP) amplitude.

Discussion: In this study, we analyzed the role of CSF t-tau as a marker of axonal damage in INs. The higher CSF t-tau levels in GBS than in CIDP patients suggest greater neuronal damage in acute than in chronic INs. This might be related to a temporary higher permeability of the blood-brain barrier with higher release of t-tau from proximal nerve roots. NCS also showed correlations between t-tau levels and the ulnar cMAP and sural SAP amplitude, supporting the hypothesis

of acute axonal damage, even in predominantly demyelinating forms. As known, an axonal involvement in GBS may be related to a worse outcome. Therefore, we could assume that CSF t-tau levels may have a prognostic value, but further longitudinal confirmation is needed.

## LONG-TERM FOLLOW-UP STUDY OF MUSCLE MRI IN MYOTONIC DYSTROPHY TYPE 1: CORRELATIONS WITH DEMOGRAPHIC AND CLINICAL CHARACTERISTICS

L. Fionda, L. Tufano, A. Lauletta, S. Morino, M. Salvetti, E. Rossini, L. Leonardi, E. Bucci, G. Antonini, M. Garibaldi

NESMOS, Sapienza University (Roma)

Introduction: Muscle MRI is a useful biomarker of disease activity and severity in neuromuscular disorders. In the gene-therapy era, objective evaluation of natural history of progressive diseases and their correlations with clinical evolution are warranted. We recently reported data from 134 Myotonic Dystrophy type 1 (DM1) patients showing that Muscle MRI can detect muscle involvement also in the milder spectrum of disease (MIRS 1-2) and correlate with disease severity, and that STIR positivity and muscle atrophy could represent additional mechanisms for muscle wasting and weakness in DM11. Herein, we report on long-term follow-up data of muscle MRI study in 28 patients of this cohort.

Materials: Twenty-eight consecutive patients with genetically confirmed DM1 were included in this prospective, longitudinal study. Each patient underwent a complete neurologic examination including Muscular Impairment Rating Scale (MIRS) and a MRI study at baseline and at follow-up. Demographic and genetic characteristics of each patients were recorded.

Methods: We analyzed 32 couple of muscles of lower body (LB) and 16 couple of muscles of upper body (UB) by T1 and STIR sequences. T1-, STIR-, and atrophy-scores and their variations between MRIs were considered. Correlations between different MRI-sequences data and between MRI and demographic, clinical and genetic characteristics were analyzed.

Results: The median FU was 3 years (range 21-53 months). The average T1-score progression was +3.1% in LB (range 0-10.6%) and +0.8% in UB (range 0-4.2%). Patients with higher T1-score variation at FU showed an increase of MIRS rating at FU. 25% of patients did not show any progression in T1-score at FU regardless of disease severity and T1-score at baseline and time lapse between MRIs. Some patients with normal MRI study at baseline (T1 negative/STIR negative) showed STIR positivity in some muscles at FU (3.1-4.7%) and a minimal T1-score progression at FU (+0.3-0.6%) in certain of the STIR positive muscles. Muscle atrophy showed a progression regardless T1-score and STIR positivity or their progression at FU.

Discussion: Our results confirm that muscle MRI represents a useful tool to investigate disease severity and progression and can provide important information about muscle damage overtime. It can be able to detect alterations and progression also in clinically spared muscles. Moreover, MRI changes overtime have shown a good correlation with disease severity.

Conclusions: Muscle MRI is a sensitive biomarker to assess disease activity and progression in DM1.

A 21-year-old male farmer came to observation for fever, arthralgias, hyposthenia of lower limbs, right lumbosciatalgia, urinary urgency. The onset of neurological symptoms and signs was one year ago with myalgia after vaccination against coronavirus 19, which worsened at the third dose, accompanied by paresthesias and hyposthenia of right lower limb. Because of mild anti-Borrelia burgdorferi IgG positivity, the diagnosis was suspected Lyme disease (LD). However, bug bite was denied and anti-Borrelia positivity was not confirmed. Right lower limb hyposthenia, with Wasserman and Lasegue positivity, diffuse muscular hypotrophy, deep hypoesthesia at lower limb extremities, deep tendon hyperreflexia with achilleus clonus, Romberg positivity, antalgic gait were observed. The following examinations yielded negative results (MEP; -ENG-EMG; - cerebrospinal fluid analysis). CT showed hepatosplenomegaly. Lack of relaxation of internal sphincter was described at urodynamic test. Mild neutrophilia, monocytosis, positivity of Abs anti-Epstein-Barr (anti-EBV IgM 12,3, EBNA IgG > 600, EBV VCA IgG > 750) were detected. Cerebral and spinal cord MRI showed: right parietal gliotic area; mild C4-C5, C5-C6, minimal L4-L5 and L5-S1 disc protrusions. The patient was already under ceftriaxone and doxycycline. Corticosteroids and multivitamins were added. An area of migrant erythema appeared. Antibiotic therapy was stopped because of erythematous rash, followed by papules and vesicles, increased levels of bilirubin, transaminases and gamma-GT. At improvement of neurological signs, the patient was transferred to rehabilitation. Migrant erythema is considered a peculiar sigh of LD, although humoral response was negative. Usually, anti-borrelias IgGs persist for long time, even years [1]. Abs anti-VCA and anti-EBNA-1, presence of hepato-splenomegaly oriented toward a diagnosis of concomitant suspected EBV infection, which may account for LD relapse. Although Abs finding may be expression of past infection, the virus may be not eradicated,

yet. Autoimmune processes may be ongoing. Chronic inflammation may result in immunological exhaustion with increased susceptibility and vulnerability to other infections and oncogenic transformation. Moreover, it may exacerbate neurological condition related to other causes. The diagnosis might be confirmed by PCR. However, positivity may not be related to ongoing infection, the number of etiologic agents may be too low to be detected. There is controversy regarding the ideal type of sample, value of repeated assessment, especially if invasive, in paucisymptomatic, stable or improved patients. DNA may become undetectable after few months in immunocompetent patients [2,3]. The conundrum of suspected infective etiopathogenesis needs definition of guidelines. Clinical observation remains the pillar of clinical practice and follow-up schedule.

## ANTI-MAG NEUROPATHY WITH OVERLAPPING ANTI-CASPR2 RELATED PERIPHERAL HYPEREXCITABILITY SYNDROME

F. Forcina, M. Salvetti, S. Morino, L. Leonardi

Neurology, "La Sapienza" University of Rome (Roma)

Introduction: The myelin associated glycoprotein (MAG) is one of the main target antigen in autoimmune demyelinating neuropathy, which is mostly associated to IgM monoclonal gammopathies. Contactin-associated protein-like 2 (CASPR2) autoantibody disease is a very rare condition with a variable clinical phenotype. Most patients have autoimmune or limbic encephalitis, while peripheral hyperexcitability syndrome represents the third frequent presentation. An association of both conditions has never been described in literature, arising more considerations about pathogenesis and therapeutic options in this overlap syndrome.

Case Presentation: A 69-year-old man presented to medical attention for subacute onset of gait imbalance. A first neurological examination revealed sensory ataxia with absent tendon reflexes at lower limbs. A nerve conduction study (NCS) showed a demyelinating pattern with disproportionate involvement of the distal nerve segments, as revealed by diffusely prolonged motor distal latencies. EMG showed mild chronic neurogenic pattern in lower limb distal muscles. A distal acquired demyelinating symmetric (DADS) neuropathy was suspected, and high titer of anti-MAG antibodies (49671 BTU, n.v. <1000 BTU), as well as an IgM monoclonal gammopathy of undetermined significance (MGUS) were detected. The bone marrow aspirate examination resulted normal. A cycle of Rituximab (1 gr iv repeated after 2 weeks) therapy was administered to the patient without any significant improvement of symptoms and increased anti-MAG antibodies titer. After 6 months, the patients presented to our attention for new onset of proximal lower limb weakness, cramps and fasciculations. Neurological examination revealed severe symmetric bilateral ileo-psoas weakness, conspicuous bilateral quadriceps fasciculation with hypertrophy, and absent lower limb tendon reflexes. The gait was anserine with no signs of sensory ataxia. A new NCS showed diffuse reduction of motor and sensory responses with reduced conduction velocities at lower limb nerves. EMG revealed frequent fasciculations and myokymic discharges in lower limb muscles with neurogenic pattern, expecially in proximal lower limb muscles. High titer of anti-CASPR2 antibodies on cerebrospinalfluid and serum was detected, while anti-MAG antibodies were absent. An extensive screening for malignancies, including full-body CT-FDG-PET scan, was negative. Plasma Exchange was started with mild improvement of symptoms.

Conclusions: Anti-MAG titer slowly dropped after Rituximab administration, but several months later an anti-CASPR2 related peripheral hyperexcitability syndrome developed, with no obvious malignancies detected. This condition has never been linked to anti-MAG neuropathy, but the distribution of molecular components in the paranode and juxtaparanode of peripheral myelinated fibers may suggest a role of anti-MAG-induced structural changes, with CASPR2 antigen revealing for autoimmune response.

## CONCURRENT GUILLAIN-BARRÈ SYNDROME AND IMMUNE-MEDIATED NECROTIZING MYOPATHY: A CASE REPORT

R. Fratangelo[1], M. Lombardi[2], I. Di Donato[1], M. Bartolozzi[1], M. Baldini[1], S. Giannoni[1], S. Brotini[1], E. Bertini[1], L. Guidi[1]

[1]Department of Neurology, Usl Toscana Centro, Hospital of Empoli (Empoli); [2]SODc Neurophysiopathology, Department Neuromuscolo-Scheletrico e degli Organi di Senso, AOU Careggi University Hospital (Firenze)

Background: Guillain-Barrè syndrome (GBS) and inflammatory myositis (IM) may rarely occur together. This is the first report about coexistent GBS and Immune-mediated necrotizing myopathy (IMNM).

Case Report: An 84-year-old woman presented to the Empoli Hospital Emergency Room with progressive weakness, walking disability and limb numbness. She had a history of arterial hypertension and recent myocardial infarction treated with angioplasty and stenting. A neurological examination revealed symmetrical weakness in upper and lower limbs, absent deep tendon reflexes, distal hypopallestesia, dysarthria, dysphonia, diplopia, bilateral palpebral ptosis, isochoric pupils with normal light reflex, bilateral facial deficit, with intact consciousness. Her Erasmus GBS Respiratory Insufficiency Score (EGRIS) [1] was 5. A diagnosis of Guillain-Barré syndrome was made based on clinical presentation, albuminocytological dissociation in the cerebrospinal fluid, and electrodiagnostic studies (EDxs), that provided evidence of an acute inflammatory demyelinating polyneuropathy with signs of autonomic impairment. A cycle of intravenous immunoglobulin (IVIg) (0.4 g/kg for 5 days) was administered without improvement of neurological symptoms. She proceeded to have worsening respiratory function and lower level of consciousness, then developed tetraparesis and a progressive sinus bradycardia until sinus arrest. After cardiopulmonary resuscitation, she needed intubation and mechanical ventilation. Repetitive EDx confirmed GBS findings and showed features of diffuse muscle suffering. A diagnosis of co-occurrent myositis was made based on high serum creatine kinase level (2190 U/L) and positivity for specific PM-Scl75 antibodies. A muscle biopsy revealed features of an autoimmune necrotizing myopathy. Oral Prednisone (1 mg/kg/day) and an additional cycle of IVIg were started with neurological improvement. One month later, she received a further cycle of IVIg and prednisone was decreased. The outpatient evaluation at 3 months showed improved strength with mild dysphonia and palpebral ptosis. Few weeks later, the patient died of cardiological complications.

Conclusion: Just few case reports of coexistent GBS and IM have been published in the literature and this is the first one describing concurrent GBS and IMNM. After an initial diagnosis of GBS, the recognition of coexistent GBS and IMNM could be difficult since both can manifest with progressive motor weakness. Careful monitoring of response to therapy is essential in GBS, since worsening of symptoms despite an adequate therapy should raise the suspicion of a diagnostic error [2]. Nevertheless, GBS with severe presentation could be poorly responsive to an initial therapeutic approach [1] and these cases could represent a diagnostic challenge. In addiction, the use of serial EDxs, already recommended for diagnosis [3], may reveal useful additional elements for differential diagnosis.

## ZASP/LDB3-RELATED CARDIOMYOPATHY UNVEILED BY COVID19 INFECTION: A CASE REPORT

G. Gadaleta[1], L. Vercelli[1], G. Urbano[1], E. Rolle[1], S. Gallone[2], S. Pidello[3], C. Raineri[3], T. Mongini[1]

[1]Department of Neurosciences "Rita Levi Montalcini", University of Turin (Torino); [2]Department of Neurosciences "Rita Levi Montalcini", A.O.U. Città della Salute e della Scienza di Torino (Torino); [3]Department of Cardiovascular and Thoracic Medicine, A.O.U. Città della Salute e della Scienza di Torino (Torino)

Introduction and Objectives: Z-band alternatively spliced PDZ-motif (ZASP)/Lim domain-binding 3 (LDB3) mutations represent a rare cause of cardiomyopathy [1]. We present a case of distal-onset myopathy who developed a severe cardiopathy rapidly after COVID19 infection at 55 years.

Materials and Methods: A cross-sectional evaluation of past medical history, muscle biopsy, cardiac evaluations, magnetic resonance imaging (MRI) and next-generation sequencing (NGS) was performed after obtaining informed consent.

Results and Discussion: A 57-year-old man first presented at age 34 with post-exertional rhabdomyolysis requiring dialysis. Family history was unremarkable. The patient presented congenital club foot and reported multiple episodes of pigmenturia after physical activities from adolescence. The quadriceps biopsy at age 34 showed mild myopathic features, with granular/rod-like deposits and disorganized myofibrils at ultrastructural study, normal biochemistry. A generic diagnosis of 'congenital myopathy' was made at that time. Regular follow-up was unremarkable until the age of 55 when, one month after COVID19 infection, a cardiac MRI identified low ejection fraction (45%) even worsened after two months (39%), and diffuse hypokinesia. At neuromuscular re-evaluation at 57, CK was 10X UNL, muscle MRI displayed distal > proximal degeneration; mild heel walking, dorsal scoliosis and hypotrophic medial gastrocnemii and distal thighs were observed. An extended NGS panel was performed, identifying a likely damaging heterozygous missense variant in LDB3 gene (c.985G>A, p.Asp329Asn). Conclusion: COVID19 is known to induce severe myocarditis, especially in cardiopathic patients [2]. In our case, previously diagnosed as 'atypical congenital myopathy', COVID19 acted as a precipitating factor, allowing the identification of a ZASP/LDB3-related cardiomyopathy, broadening the phenotypic spectrum of this rare condition.

## A CASE OF TRANSTHYRETIN-RELATED FAMILIAL AMYLOID POLYNEUROPATHY WITH UNCOMMON BULBAR PRESENTATION AND CRANIAL NERVE INVOLVEMENT

F. G. Galbiati, C. Morotti Colleoni, G. Ferrero, E. Funelli, D. Montisano, V. Aprea, L. Stanzani

IRCCS San Gerardo Dei Tintori, University of Milano Bicocca (Monza)

Objective: Transthyretin (TTR)-related familial amyloid polyneuropathy (FAP) is an autosomal-dominant disorder caused by deposition of TTR amyloid in various organs [1]. Although systemic involvement, progressive sensorimotor and autonomic neuropathy are FAP hallmarks, diagnosis might be very challenging, due to a variable clinical presentation, depending on geographic areas and genetic heterogeneity [2]. Furthermore, variable penetrance makes family history poorly informative.

Materials: We describe the case of a 70-year-old male patient admitted to our Neurology ward.

Method: Electronic medical records, neuroimaging, neurophysiological reports and laboratory results were reviewed.

Results: The patient came to our attention with a 2-year history of ascending upper and lower limbs dysesthesia and hypoesthesia, associated with predominant bulbar symptoms including rhinolalia, dysarthria and paradoxical dysphagia. Moreover, he complained of chronic dry cough and he reported a weight loss of 20 kg in less than two years. At the admission, the patient had already been diagnosed with symmetric and length-dependent axonal sensorimotor polyneuropathy (PNP) but blood tests for PNP were unremarkable. Family history was negative; he had a past medical history of occupational asbestos exposure and bilateral carpal tunnel syndrome. The clinical examination showed generalized weakness, superficial hypoesthesia, steppage gait, hyporeflexia, orthostatic hypotension and severe tongue atrophy with fasciculations.

Discussion: We performed lumbar puncture and total body CT scan to rule out secondary PNP causes. The patient also underwent neurophysiological tests, as well as brain and whole spinal cord MRI, to exclude alternative diagnosis such as a motor neuron disease; electroneurography confirmed a severe axonal PNP, whereas electromyography showed chronic neurogenic changes in V, VI and XII cranial nerves territory. Transthoracic echocardiogram and cardiac MRI corroborated the suspicion of amyloidosis and genetic testing confirmed TTR-FAP diagnosis, revealing a heterozygous p.Phe64Le mutation. The patient also underwent sural nerve biopsy, which revealed severe loss of myelinated fibers as well as active axonal degeneration, without a Congo Red staining positivity.

Conclusion: Our case exemplifies the FAP diagnostic challenge and suggests taking this diagnosis into consideration in cases of unexplained axonal PNP, including atypical presentations with predominant bulbar symptoms.

Disclosure: the authors have no competing interests to declare.

## ASSESSING IMMUNOGLOBULIN TREATMENT DEPENDANCE IN CIDP AND MMN PATIENTS

L. Gentile, M. Russo, G. Iabichella, M. De Luca, G. Occhipinti, C. Rodolico, A. Toscano, A. Mazzeo

Department of Clinical and Experimental Medicine, University of Messina (Messina)

Introduction: Chronic inflammatory demyelinating polyneuropathy (CIDP) and multifocal motor neuropathy (MMN) are rare diseases, belonging to a spectrum of peripheral nerve disorders with complex dysimmune disease mechanisms. Several immune therapies have been reported to be variably effective in these neuropathies, including steroids, plasma exchange, and high-dose intravenous (IVIg) or subcutaneous (SCIg) immunoglobulins. Approximately two-thirds of patients remain treatment dependent in the long term, but remission can occur.

Methods: We present here clinical baseline data and 24 months follow-up of 20 CIDP or MMN patients, chronically treated with IVIg or SCIg, which underwent periodically attempts of treatment reduction/suspension. Neurological examination, with evaluation of MRC-SS, INCAT score, ONLS, ISS and R-ODS CIDP or MMN were performed at baseline and every six months, or in case of clinical deterioration.

Results: All patients periodically underwent 20% reduction of previously ongoing treatment. In about 25% of our cohort, IVIg or SCIg treatment was permanently reduced. Twenty-five% of patients experienced a relapse between 1 and 6 months after treatment reduction, but well recovered after treatment restabilization and periodically could afford temporary therapy decrease. The last 50% of patient were strictly IVIg or SCIg dependent. No adverse events due to IVIg or SCIg treatment were observed.

Conclusions: In conclusion, IVIg or SCIg treatment confirmed as a safe and effective long-term treatment for CIDP or MMN patients. However, it must be considered that a partial, or even complete, disease remission can occur in a quote of patient. So, periodically attempts of treatment reduction/suspension must be encouraged, with the aim of avoiding patient's overtreatment, with the relative consequences on health system costs, hospital care burden and patients' comfort and safety.

## ATYPICAL PRESENTATION OF MYOPATHY LINKED TO FILAMIN C MUTATION

F. Gruosso[1], D. Cassandrini[2], M. Goglia[1], G. Greco[1], E. Frezza[1], G. Vietri[1], G. Nardino[1], I. Petitta[1], L. Boffa[1], C. Rocchi[1], N. Mercuri[1], F. Santorelli[2], R. Massa[1]

[1]Neuromuscular Diseases Unit, Policlinico Tor Vergata and University of Rome Tor Vergata (Roma); [2]Unit of Molecular Medicine, Neurodegenerative and Neuromuscular Diseases, IRCCS Stella Maris Foundation (Pisa)

Case Presentation: A 62-year-old lady complained of profound weakness in lower limbs and diffuse muscle pain after repetitive strenuous exercise. Serum creatine kinase and myoglobin levels were elevated, 6732.00 UI/L and 1718.00 ng/ml, respectively, so she was hospitalized to carry out further investigations.

Methods and Results: Clinical evaluation proved a reduction of strength in thigh extensor and adductor muscles bilaterally, for left worse than right (respectively MRC 4/5 and 4.5/5), and in the extensors of the right leg (MRC 4/5). She reported a paternal family history of undefined myopathy and a personal, mild reduction of lower limb strength since a few years. During hospitalization, serum creatine kinase increased to a maximum value of 12234 UI/L; therefore, intravenous hydration therapy was adopted to reduce serum biomarkers of rhabdomyolysis and improve muscle symptoms. ECG was unremarkable. Needle EMG demonstrated an incomplete interference recruitment pattern and increased polyphasia in the tibialis anterior muscles and reduced amplitude of motor unit potentials with early recruitment pattern in vastus lateralis and triceps brachii muscles. Muscle MRI showed mild to moderate fat infiltration of right semimembranosus muscle and of semitendinosus, gracilis, sartorius, biceps femoris, adductor magnum, medial gastrocnemius, soleus, tibialis anterior muscles of both inferior limbs. According to a possible diagnosis of primary myopathy, using a targeted resequencing gene panel and studying the coding exons of 241 "muscle genes", we detected a heterozygous missense variant in the FLNC gene: c.2084G>C, (p. Arg695Pro) whose analysis aggregate of different tools is: "deleterious".

Discussion and Conclusion: Filamin C is a structural protein, whose main role is to maintain the integrity of sarcomeres, crosslinking the actin filaments and anchoring sarcolemmal proteins to the cytoskeleton [1]. FLNC gene mutations may be associated with different muscular and cardiac phenotypes, including myofibrillar myopathy and distal myopathy [2]. In particular, the Arg695Pro mutation has been described in a single case of limb-girdle myopathy [3], whereas a different aminoacid substitution in the same residue has been associated with hypertrophic cardiomyopathy [2]. This case adds further muscle phenotype variability of FLNC mutations, which could manifest with both proximal and distal myopathy and even as an exercise-related rhabdomyolysis at presentation.

## AN UNCOMMON OVERLAPPING PRESENTATION OF GUILLAIN-BARRÉ AND MILLER-FISCHER SYNDROME IN PEDIATRICS: CLINICAL PICTURE AND 6-MONTH FOLLOW-UP CASE REPORT AND LITERATURE REVIEW

G. Iabichella[1], L. Gentile[1], M. Russo[1], V. Rizzo[1], E. Gitto[2], M. De Luca[1], C. Rodolico[1], A. Toscano[1], A. Mazzeo[1]

[1]Department of Clinical and Experimental Medicine, University of Messina (Messina); [2]Department of Human Pathology in Adult and Developmental Age "Gaetano Barresi", University of Messina (Messina)

Background: Guillain-Barré Syndrome (GBS) is an immune-mediated, rapidly progressive polyneuropathy, with several clinical subtypes, such as Miller Fisher syndrome (MFS) and Bickerstaff brainstem encephalitis (BBE). These syndromes are usually diagnosed by means of clinical/neurophysiological evaluation, and cerebrospinal fluid examination. Brain-spine MRI and peripheral nerve ultrasound can be supportive. [1]

Case Report: Herein, we describe a case of a 11years old boy, who was admitted to Intensive Care Pediatric Unit of University Hospital of Messina for abrupt onset of respiratory failure, with the suspicion of a choking episode. Actually, clinical history and examination suggested an ascending paralysis with cranial nerves involvement. He underwent neurological examination, neurophysiological studies, cerebrospinal fluid analysis and brain/spine MRI, that revealed a GBS-MFS-BBE overlapping syndrome, with meningeal irritation. This little patient was treated with multiple intravenous immunoglobulin (IVIG) cycles with immediate benefit, substantial improvement of the respiratory failure and progressive remission of neurological deficits. At 6-month follow-up visit, the clinical picture nearly reached normality.

Discussion: Literature review showed that, while GBS incidence linearly increases with age, the disease is much rarer in children and adolescents, with the exception of some geographical area (East-Asia), with an incidence of 0.62 cases per 100,000 per years (PYs) in 0-9-year-olds, and 0.75 cases per 100,000 PYs in 10-19-year-olds. [2] As regards as therapeutic interventions, there are currently no specific differences between various GBS subtypes. Previous studies mainly suggest the use of IVIG to obtain relevant benefits. Plasma exchange is recommended in children IVIG therapy is contraindicated, or this turns out to be ineffective. [3]

Conclusion: We presented here a rare, especially in Western countries, GBS-MFS-BBE overlapping syndrome in pediatrics. Although clinical presentation suggested a respiratory failure due to a choking episode, neurological examination revealed areflexia that arose the suspicion of neuromuscular disorder. Prompt diagnosis and IVIG treatment resulted in rapid improvement of the clinical picture.

Introduction: The sensitivity of standard assessment of motor performance for evaluating progression and response to treatment in Late Onset Pompe Disease (LOPD) in clinical practice and clinical trials is still a controversial issue. Mobile health technologies (MHT) have been demonstrated to improve diagnostic accuracy in several conditions with motor impairment by enabling detection of subtle motor dysfunctions. Aim of our study was to test whether MHT could improve the evaluation of motor impairment in LOPD patients.

Patients and Methods: Eight LOPD patients which were able to walk without aids and treated with enzyme replacement therapy (ERT) were enrolled. Six-minute walking test (6MWT), "Timed Up and Go Test" (TUG) and speed in one time and repeated rising to chair were evaluated in all the patients by MHT-based gait analysis (Rehagait, Hasomed). Data were compared to healthy controls (HC, n=96) with ANOVA model age and sex-adjusted.

Results: LOPD patients showed greater angle in raise from chair task (p=0.03) compared to controls with reduced extension velocity (p=0.05), which may reflect trunk involvement of PD. Turning task revealed a reduced global and peak-force angular velocity in LOPD patients (p=0.01), which may reflect proximal lower limbs weakness and fragmentation of turning task. Overall, LOPD patients require longer step time (p=0.01) and perform shorter steps (p=0.05) with greater variability in length (p=0.04). Walking analysis of young LOPD patients (n=3) compared to controls aged $\leq$ 30 years old (n=21) did not differ in number of steps or distance performed in 6MWT, but young LOPD patients still showed greater step time variability (p=0.03) and shorter step lenght (p=0.01) with greater variability in length (p=0.02). Gait parameters analyzed by MHT consistently correlate with clinical motor impairment scales.

Conclusion: Our preliminary results suggest that wearable technologies can identify subtle walking abnormalities in paucisymptomatic patients not otherwise evident by usual clinical evaluation. These findings may have important implications for management, follow-up and treatment decisions in clinical practice. Importantly, our results suggest that MHT deserve to be evaluated as promising outcome measures for clinical trials. Further studies in a larger population are warranted to confirm our findings.

## LONG-TERM SAFETY AND EFFICACY OF ECULIZUMAB IN GENERALIZED MYASTHENIA GRAVIS: A 7 YEARS' EXPERIENCE

A. Lauletta, L. Tufano, E. Rossini, S. Morino, M. Salvetti, G. Antonini, M. Garibaldi, L. Fionda

Department of Neuroscience, Mental Health and Sensory Organs (NESMOS), Sapienza University of Rome, Sant'Andrea Hospital (Roma)

Objectives: Generalized myasthenia gravis (MG) is an autoimmune disorder that leads to disabling weakness via damage to the neuromuscular junction. In most patients, the disease is mediated by autoantibodies to the acetylcholine receptor, which activate the complement cascade. Eculizumab, a complement inhibitor, demonstrated its therapeutic efficacy in these patients, however, data regarding its long-term impact

is limited. Our aim was to describe safety, tolerability and efficacy of 7-year treatment of eculizumab in one patient with refractory anti-AChR-positive generalized MG.

Methods: We describe the case of one patient with refractory generalized MG who was finally treated with Eculizumab and subsequently followed at our institution over 7- year period.

Results: A 62-year-old man with refractory anti-AChR-positive generalized MG experienced several relapses although multiple therapies administration. Therefore, 7 years ago, Eculizumab was started leading to an optimal control of symptoms and sustained efficacy until now.

Discussion: Eculizumab has been recently approved in the United States, Europe and Japan for the treatment of anti-AChR-positive MG. In our 7 years' experience with one patient, Eculizumab has been shown to lead to a satisfactory control of the disease, in the absence of new exacerbations or adverse events. This case provides evidence for the long-term safety and sustained efficacy of Eculizumab for refractory gMG.

Objectives: Mitochondrial alterations represent a classic finding in sporadic inclusion body myositis (s-IBM) and in polymyositis with mitochondrial pathology (PM-Mito), although they have been occasionally reported in dermatomyositis (DM) and immune-mediated necrotizing myopathy (IMNM). However, while DM and IMNM usually show good treatment response, PM-Mito and s-IBM present a variable clinical course and poor response to treatments. The prevalence and significance of mitochondrial pathology in non-IBM myositis has not been deeply investigated, particularly if it could be a reliable marker of progression to IBM from PM-Mito and/or an index of treatment unresponsiveness and worse clinical outcome.

Methods: We reviewed clinical and histopathological data from 22 patients, followed in 4 Italian and 1 French institutions, with clinical and histological diagnosis of myositis and presence of COX-negative fibers at muscle biopsy.

Results: 16 patients [72,7%] were women; mean age was 65.7 years [range 39-78 years]. 4 patients had IMNM, 2 DM, 10 non-specific myositis (NSM), 6 Overlap myositis (OM). The mean number of COX-negative fibers was 3.5%. Mean age at muscle biopsy was 62,3 years. Only 5 patients [22,7 %] showed a complete recovery after treatment while the others had variable residual weakness. Treatment refractory and worst clinical outcome were observed in patients with higher percentage of COX-negative fibers.

Conclusions: These findings suggest that the presence of mitochondrial pathology could represent a marker of disease severity in non-IBM myositis patients, predicting a worse response to treatment.

## QUANTITATIVE SENSORY TESTING AND SKIN BIOPSY IN AN ITALIAN COHORT OF ATTRV PRESYMPTOMATIC CARRIERS: CROSS-SECTIONAL ANALYSIS AND PRELIMINARY LONGITUDINAL DATA

L. Leonardi[1], M. Salvetti[1], A. Truini[2], G. Antonini[1], M. Luigetti[3], S. Morino[1], M. Garibaldi[1], F. Forcina[1], L. Fionda[1], R. Costanzo[1], E. Galosi[2]

[1]NESMOS, Sapienza University (Roma); [2]Human Neuroscience, Sapienza University (Roma); [3]Neurology, Policlinico Universitario A. Gemelli, Cattolica (Roma)

Introduction: Hereditary transthyretin amyloidosis polyneuropathy (ATTRv-PN) pre-symptomatic carriers often show preclinical abnormalities at small fibre related diagnostic tests. However, no biomarker is still available to follow-up pre-symptomatic carriers, thus helping therapeutic decision making. Our study aimed at assessing nerve conduction study (NCS), quantitative sensory testing (QST), and skin biopsy parameters in a cohort of late-onset ATTRv pre-symptomatic carriers, and to evaluate whether they correlated with predicted age of disease onset (PADO).

Methods: consecutively enrolled late-onset ATTRv pre-symptomatic carriers underwent NCS, QST, and skin biopsy with intraepidermal nerve fibre density (IENFD) evaluation from a distal and a proximal site. Douleur Neuropathique-4 (DN4) and Small Fiber Neuropathy-Symptoms Inventory (SFN-SIQ) were used to assess painful and small fibre neuropathy related symptoms. PADO and time-to-PADO (delta-PADO) were estimated for each carrier, and correlations with diagnostic test measures were analysed. A subset of ATTRv carrier completed a lingitudinal evaluation of at least 1 years.

Results: Forty ATTRv pres-symptomatic subjects (M/F: 18/22; V30M/non-V30M: 26/14; age 49, IQR 42.5-59) were enrolled. Twenty carriers (50%) had distal IENFD reduction, with a non-length dependent distribution in 73% of cases. Eleven subjects (27.5%) had cold and/or warm detection threshold (CDT and/or WDT) abnormalities at QST. Delta-PADO positively correlated with sural sensory nerve action potential (SNAP) amplitude (r=0.416, p=0.004), and QST parameters like CDT (r=0.337, p=0.0017), WDT (r=-0.293, p=0.047), and mechanical detection threshold (MDT) (r=-0.462, p=0.003). Simple linear regression models showed a linear correlation between

delta-PADO and sural SNAP, CDT, and MDT. Six subjects completed a longitudinal anylisis at at least 1 year: 2/6 subjects showed a relevant modification at QST/Skin biopsy and were considered affected.

Conclusions: Our findings show that IENFD reduction and QST abnormalities may occur early in ATTRv pre-symptomatic carriers, often with a non-length dependent pattern. However, only sural SAP amplitude and QST parameters correlated with delta-PADO, suggesting that serial combined QST and NCS evaluation could be useful in ATTRv pre-symptomatic carriers' follow-up.

## RECURRENT MILLER-FISHER SYNDROME OR PHARYNGEAL-CERVICAL VARIANT OF GBS? A CASE REPORT AND A REVIEW OF THE LITERATURE ALONG A PATHOPHYSIOLOGICAL CONTINUUM

G. Libelli, R. Cancilla, E. Saccani, E. Chierici

Department of Medicine and Surgery, Neurology Unit, University of Parma (Parma)

Objectives: Miller Fisher Syndrome (MFS) is a variant of Guillain-Barré Syndrome (GBS), and its prevalence is 1/1,000,000. The aim of this case report is to describe a recurrent case of MFS, which is very rarely seen in clinical practice.

Materials: In February 2005 a 27-year-old male developed subacute onset of MFS, treated with intravenous immunoglobulin with complete recover. In January 2023 the same patient developed distal paresthesia, difficulty in walking and double vision, a week after an upper respiratory tract infection.

Methods: Neurological examination revealed bilateral external ophthalmoplegia and moderate ptosis, loss of vertical gaze, mild rhinolalia, ataxic gait exacerbated by eye closure, and generalized areflexia. Considering the clinical findings and the similarity to the previous episode, MFS was suspected, and treatment with intravenous immunoglobulin (IVIg) has been undertaken.

Results: CT and MRI of the brain were both normal. Viral serology tested negative. Neurophysiological examination showed a mild reduction in SNAPs amplitude and conduction velocity in the right median nerve, and absence of H wave bilaterally registered from soleus muscle. Assessing the blink reflex, a higher latency of direct and contralateral RII was documented. GT1a and GD1b antibodies tested positive. In both episodes, there was a gradual but quick recover after immunoglobulin treatment. One month later, neurophysiological findings returned to normal, and after two months there was complete clinical remission.

Discussion: MFS accounts for 1-5% of all GBS cases in Western countries, it is considered a post-infectious autoimmune disease. Recurrencies are seen in approximately 10% of cases, which is higher compared to GBS. Based on a literature review, over 90% of MFS patients have anti-GQ1b present, while other forms of antibodies are less common but possible. GT1a alone has been associated with the Pharyngeal-Cervical-Brachial-variant (PCB) characterized by cranial nerve paralysis, whereas MFS or Bickerstaff's brainstem encephalitis (BEE) are likely to present both GQ1b and GT1a antibodies. GD1b antibodies are correlated with peripheral neuropathy symptoms. IVIg or plasma exchange are used as treatment for MFS.

Conclusions: Our patient had two episodes of MFS with an eighteen-year symptom-free interval in between. This case report illustrates the stereotypical nature of the recurrent episodes in MFS, its relatively benign prognosis, and the detection of a unique and new combination of antibodies, GT1a and GD1b. Whatever the diagnosis, our description could help to find novel markers, both clinical and immunological, able to predict recurrencies in the vast field of nodo-paranodopathies, as both MFS and PCB are now considered.

## MULTIFOCAL MOTOR NEUROPATHY WITH CRANIAL NERVE INVOLVEMENT: A CASE REPORT

F. Lozza[1], N. Nasuelli[2], L. Godi[2], F. De Marchi[1], C. Comi[1]

[1]Department of Translational Medicine, University of Piemonte Orientale (Novara); [2]Neurology Unit, Ospedale SS. Trinità (Borgomanero-NO)

Introduction: Multifocal motor neuropathy (MMN) is a rare neuropathy characterized by progressive, asymmetric weakness and muscle atrophy without sensory abnormalities. It is mostly associated with the presence of high levels of anti-ganglioside GM1 antibodies (Abs anti-GM1) and positive response to immunomodulatory treatment. The onset is typically subacute, often starting from a distal upper limb, asymmetrically. The diagnosis is based on clinical and electrophysiological criteria, with the evidence of conduction block and focal demyelination. In addition, high levels of Abs anti-GM1, slight increase of proteins in cerebrospinal fluid (CSF), hyperintense T2 signal and fascicular enlargement in affected nerves on magnetic resonance (MRI) and clinical improvement with IVIg treatment can support the diagnosis.

Case Report: A 56-year-old patient presented with ptosis in the left eyelid and diplopia, tongue deviated to the right and weakness in the left hand. Also, the patient reported a similar symptomatology three years before, spontaneously resolved. Patient underwent: 1) a brain and cervical MRI, unremarkable; 2) lumbar puncture, which showed a slight protein increase (, no cells, glucose in range); 3) an electrodiagnostic study, which showed conduction block with a reduction in the amplitude and area of the compound muscle action potential (CMAP) after a proximal stimulation, without abnormal temporal dispersion in the four limbs, without sensory abnormalities. The symptoms spontaneously remitted. Further examinations executed to the CSF found the presence of high level of Abs anti-GM1, supporting the diagnosis of MMN. We followed the patient for five months after the diagnosis. He did not report any weakness or other symptoms. An electrodiagnostic study after two months confirmed the conduction block with slight improvement of the proximal amplitude in the median and radial nerve bilaterally.

Discussion: MMN is a rare neuropathy, with an estimated prevalence of 0.6-2/100000. Onset with cranial nerve is an even more rare condition, but other sporadic cases are reported in the literature. We suggest further studies to identify any pathological mechanisms or cofactors in the patients, like antibodies subtypes or differences in GM1 concentration level or composition, that can lead to a more severe cranial nerve involvement than limb involvement.

## MUSCLE PSEUDOHYPERTROPHY AS A PRESENTATION OF AMYLOID MYOPATHY

G. Lucioli[1], U. Costantino[1], D. Bernardo[2], A. Conte[2], G. Bisogni[2], K. Patanella[2], M. Sabatelli[3]

[1]Neurology, Catholic University of the Sacred Heart (Roma); [2]Neurology, Centro Clinico NEMO, Fondazione Serena Onlus (Roma); [3]Neurology, Centro Clinico NEMO, University of the Sacred Heart, Fondazione Serena Onlus, Fondazione Policlinico Universitario A. Gemelli IRCCS (Roma)

Objectives: We describe a case of amyloid myopathy, a rare clinical presentation of Light chain (AL) amyloidosis.

Case Description: A 62-year-old woman developed proximal weakness and fatigability in lower limbs. In few months jaw claudication, dysarthria and upper limbs impairment appeared. Myasthenia Gravis was suspected but the research of anti-acetylcholine receptor (AChR) and anti-muscle-specific kinase (MuSK) antibodies were negative and repetitive nerve stimulation (RNS) test was normal. Six months after the onset, we observed diffuse muscle hypertrophy and macroglossia. A new electromyography (EMG) was performed and a myopathic pattern with early type recruitment was detected. Laboratory tests showed no elevation of serum creatine phosphokinase (CPK) level; the presence of IgG lambda monoclonal gammopathy monoclonal with elevation of serum free lambda light chains suggested multiple myeloma, confirmed by bone marrow biopsy. The muscle MRI showed a remarkable and diffuse thickening of the subcutaneous fatty tissue that appeared hyperintensity on STIR sequences, without muscular flogosis or fibrosis. Lately deltoid muscle and abdominal fat pad biopsies showed the diffuse presence of amyloid deposits with Congo red staining.

Results: The patient was treated with corticosteroids, daratumumab and bortezomib and three months later we observed a slight reduction in muscle pseudohypertrophy, whereas a moderate hyposthenia in intrinsic hand muscles, iliopsoas, and tibialis anterior bilaterally was documented.

Discussion: AL amyloidosis is a systemic disease with a poor prognosis, the mean survival is about 22 months. The onset with muscle impairment or belated muscular involvement is rare so amyloid myopathy can be easily misdiagnosed. Commonly it is characterized by fast, progressive, proximal muscle weakness and fatigability, myalgia, muscle hypertrophy and macroglossia, dysphagia and jaw claudication. Therefore myositis, Myasthenia gravis or muscular dystrophies such as limb-girdle dystrophy must be excluded. Normal or slight elevation of serum CPK and characteristic MRI muscle findings in presence of hematological abnormalities lead to the diagnosis. Conventional MRI sequences are not sensitive to detect muscle amyloid deposition, but a thickening of the subcutaneous fatty tissue with hyperintensity on STIR sequences is peculiar; moreover, muscle flogosis or fibrosis are not typical. In any case, a muscle biopsy demonstrating amyloid deposit with Congo red staining is mandatory.

Conclusion: This report highlights the importance of early diagnosis of amyloid myopathy, to promptly start therapy. In presence of a rapid evolutive history of muscle weakness, macroglossia and muscle pseudohypertrophy associated with myopathic EMG pattern without hyperckemia, haematological screening must be performed and amyloid myopathy suspected.

## IMPACT OF BASELINE POLYNEUROPATHY SEVERITY ON VUTRISIRAN TREATMENT RESPONSE IN THE PHASE 3 HELIOS-A STUDY

M. Luigetti[1], D. Quan[2], J. Berk[3], I. Conceição[4], Y. Misumi[5], C. Chao[6], B. Bender[7], E. Aldnic[7], J. Vest[7], D. Adams[8]

[1]Department of Neurology, Cattolica del Sacro Cuore University (Roma); [2]Department of Neurology, University of Colorado Anschutz (Aurora-USA); [3]Boston Medical Center (Boston-USA); [4]Department of Neurology, Universidade de Lisboa (Lisbon-P); [5]Department of Neurology, Graduate School of Medical Sciences, Kumamoto University (Kumamoto-J); [6]Department of Neurology, National Taiwan University Hospital (Taipei-TW); [7]Alnylam Pharmaceuticals (Cambridge-USA); [8]Neurology Department, CHU Bicêtre, Université Paris-Saclay, Le Kremlin Bicêtre (APHPCedex-F)

Introduction: Hereditary transthyretin-mediated (hATTR) amyloidosis, also known as ATTRv amyloidosis, is a rapidly progressive, multisystem disease. Vutrisiran, an RNAi therapeutic, improved neuropathy and quality of life (QOL) versus external placebo in patients with hATTR amyloidosis with polyneuropathy in the Phase 3 HELIOS-A study (NCT037759379). This analysis evaluates the impact of baseline polyneuropathy severity on response to vutrisiran treatment.

Methods: Patients were randomized (3:1) to vutrisiran (25 mg subcutaneous injection q3m) or patisiran (0.3 mg/kg intravenous infusion q3w), a reference group. The primary endpoint was change from baseline in modified Neuropathy Impairment Score+7 (mNIS+7) at 9 months versus an external placebo group from the APOLLO study (n=77). This post-hoc analysis divided patients into approximately equal quartiles of increasing baseline Neuropathy Impairment Score (NIS): Q1 ≥5.0—≤20.5; Q2 >20.5—≤44.1; Q3 >44.1—≤73.1; Q4 >73.1—≤127. Mean change from baseline to Month 18 was summarized by quartile for efficacy endpoints.

Results: Across NIS quartiles, vutrisiran demonstrated benefit in mNIS+7 versus external placebo (mean change from baseline in mNIS+7 at Month 9/18: Q1, -3.3/-3.0 [vutrisiran] vs +13.8/+18.4 [external placebo]; Q2, -0.6/-3.1 vs +12.1/+24.5; Q3, -2.1/+6.2 vs +16.5/+33.1; Q4, +1.6/+3.2 vs +16.5/+30.7). Vutrisiran also demonstrated benefit versus external placebo across NIS quartiles for endpoints of QOL (Norfolk QOL-DN), disability (Rasch-built Overall Disability Scale), gait speed (10-meter walk test), and nutritional status (modified BMI). Overall, patients in lower NIS quartiles (less severe disease) at baseline maintained better scores at Month 18 compared with those in higher NIS quartiles. The external placebo group progressively worsened in all measures at Month 18.

Conclusions: Vutrisiran demonstrated benefit in neurologic function and other key measures, versus external placebo, across all baseline polyneuropathy severities. Patients who initiated vutrisiran earlier in their disease course retained the highest level of neurologic function after 18 months, highlighting the importance of early diagnosis and treatment.

## NFL LEVELS SIGNIFICANTLY DECREASE IN RESPONSE TO TREATMENT WITH PATISIRAN OR VUTRISIRAN IN HATTR AMYLOIDOSIS WITH POLYNEUROPATHY

M. Luigetti[1], E. Aldnic[2], S. Ticau[2], M. Polydefkis[3], H. Nienhuis[4], C. Karam[5], S. Ajroud-Driss[6], Y. Sekijima[7], M. Waddington-Cruz[8], J. Barnes[2], P. Nioi[2]

[1]Department of Neurology, Cattolica del Sacro Cuore University (Roma); [2]Alnylam Pharmaceuticals (Cambridge-USA); [3]Department of Neurology, Johns Hopkins University School of Medicine (Baltimore-USA); [4]Amyloidosis Centre of Expertise, University of Groningen, University Medical Center Groningen (Groningen-NL); [5]Department of Neurology, University of Pennsylvania (Philadelphia-USA); [6]Department of Neurology, Northwestern University Feinberg School of Medicine (Chicago-USA); [7]Department of Medicine (Neurology & Rheumatology), Shinshu University School of Medicine (Matsumoto-J); [8]CEPARM, National Amyloidosis Referral Center, University Hospital, Federal University of Rio de Janeiro (Rio de Janeiro-BR)

Background: Hereditary transthyretin-mediated (hATTR) amyloidosis, also known as ATTRv amyloidosis, is a rare, rapidly progressive, and fatal disease. Diagnosis is cumbersome and often delayed, and monitoring treatment response can be challenging. Neurofilament light chain (NfL) is a potential biomarker of disease progression and treatment response in patients with hATTR amyloidosis with polyneuropathy. NfL levels were analyzed in patients with hATTR amyloidosis with polyneuropathy from the Phase 3 APOLLO and HELIOS-A studies to further assess the potential utility of NfL in this disease.

Methods: NfL plasma levels were measured using the Quanterix® SimoaTM platform in healthy controls and in a subset of patients with hATTR amyloidosis with polyneuropathy who participated in the APOLLO or HELIOS-A studies, gave consent, and had sufficient volume of samples. Timepoints analyzed from APOLLO were baseline, 21 days, 4 months, and 18 months in placebo and patisiran groups, while samples from HELIOS-A were analyzed at baseline, 43 days, 4 months, 9 months, and 18 months in vutrisiran and patisiran groups.

Results: NfL levels measured at baseline were slightly higher in APOLLO than in HELIOS-A (69.4 pg/mL and 58.2 pg/mL, respectively) and did not differ significantly between treatment groups within each study. In the APOLLO placebo arm, NfL levels increased significantly relative to baseline at 4 months (+19.0 pg/mL, $p<0.001$), and there was a further increase at 18 months relative to baseline (+36.3 pg/mL, $p<0.001$). In the APOLLO patisiran arm, NfL levels decreased significantly at 4 months and 18 months relative to baseline (-20.0 pg/mL and -23.2 pg/mL respectively; $p<0.001$ for both). Similarly, in HELIOS-A, NfL levels in both patisiran and vutrisiran groups significantly decreased relative to baseline at 4 months (-9.7 pg/mL and -11.0 pg/mL, respectively; $p<0.05$ for both), and these decreases in NfL levels were maintained at 18 months post-treatment initiation (-16.4 pg/mL and -19.9 pg/mL, respectively; $p<0.001$ for both).

Conclusions: NfL may serve as a biomarker of treatment response as early as 4 months following initiation of treatment with patisiran or vutrisiran. The observed decreases in NfL levels from baseline are maintained through 18 months of treatment, in contrast to the significant increase in NfL levels observed in untreated patients, making it potentially useful for monitoring disease progression and treatment response over time in patients with hATTR amyloidosis with polyneuropathy.

## A CASE OF STATIN-ASSOCIATED ANTI-HMGCR IMMUNE-MEDIATED NECROTIZING MYOPATHY (IMNM) WITH A VERY COMPLICATED COURSE

S. Mambriani[1], G. Baso[1], C. Ferrari Aggradi[1], G. Furciniti[1], D. Iacobucci[1], D. Velardo[1], S. Corti[2], G. Comi[2]

[1]Department of Pathophysiology and Transplantation, University of Milan (Milano); [2]Department of Neuroscience and Mental Health, Neurology Unit, Foundation IRCCS Ca' Granda (Milano)

Objectives: The purpose of this case report is to demonstrate the importance of early diagnosis and to begin proper treatment as soon as possible in statin-associated anti-hydroxymethylglutaryl-coenzyme A reductase (HMGCR) immune-mediated necrotizing myopathy (IMNM).

Materials: We report the case of a patient diagnosed with IMNM hospitalized at the Neurology department of the Policlinic Hospital in Milan from February 17th to March 23rd 2023. A comparison was made with similar cases in the Literature available on PubMed [1-3]. Method: We considered the clinical onset, the evolution of symptoms and especially the response to treatment.

Results: A 64-year-old male under atorvastatin treatment (80mg/day) from 2021 due to myocardial infarction (modified Rankin Scale, mRS=1) started to complain two years later progressive proximal weakness, at first in the lower limbs and then in the upper limbs. Discopathy was initially hypothesized in absence of CK's dosage. About a month after the onset, he developed dysphagia, dyspnoea, rhinolalia and head drop and he came to our emergency room where lab work showed an elevated creatine phosphokinase (CK) level of 6082 IU/L and the electromyography showed proximal and bulbar myopathic suffering. Atorvastatin was discontinued in IMNM suspicion, which was then confirmed by muscle biopsy and high HMGCR antibodies. He was treated with intravenous steroids, oral prednisone, a cycle of immunoglobulins and methotrexate; rhinolalia, dyspnoea and head drop gradually improved except for compromised segmental strength, particularly the lower limbs, actually the patient is no longer able to walk (mRS=4). Dysphagia progressively worsened and a percutaneous endoscopic gastrostomy was placed. The course was also affected by the development of gallbladder stones, bacterial mumps, elevation of transaminases and hypokalemia.

Discussion: Side effects of statins include myopathy, myositis, or rhabdomyolysis; all of which usually resolve with statin cessation [1]. Alternatively, an uncommon condition is IMNM with positive

anti-HMGCR antibodies, that is often difficult to diagnose because symptoms may appear years after initiation of therapy, and it is complicated to treat due to the continued production of antibodies long after discontinuing the incriminating agent. The goal for treatment is to induce complete remission, defined as normal strength and normalization of CK. However, treatment response tends to be heterogeneous as evidenced by this case and the reason remains unknown [2,3].

Conclusions: Our case emphasizes the importance of timely IMNM recognition as early diagnosis may allow a prompt start of treatment to prevent debilitating complications and mortality.

## ACQUIRED TRANSTHYRETIN AMYLOIDOSIS IN DOMINO LIVER TRANSPLANTATION TREATED WITH PATISIRAN

M. Marasca[1], A. Salvalaggio[1], A. Cipriani[2], L. Frizziero[3], M. Cacciavillani[4], M. Corbetta[1], C. Briani[1]

[1]Neurology Unit, Department of Neuroscience, University of Padua (Padova); [2]Department of Cardiac Thoracic and Vascular Sciences and Public Health, University of Padua (Padova); [3]Ophthalmology Unit, Department of Neuroscience, University of Padua (Padova); [4]CEMES, Data Medica Group (Padova)

Hereditary transthyretin amyloidosis (ATTRv, v for variant) is an autosomal dominant disease, due to a mutation in the transthyretin (TTR) gene. The mutated TTR protein misfolds in amyloid deposits affecting multiples organs, mainly nerves, eyes, kidneys and heart. Hereditary ATTRv polyneuropathy is the most serious hereditary polyneuropathy of adult onset for which, until recently, the only therapeutic option was liver transplantation. We report on a 75-year-old man who, following a liver transplant, experienced a progressively worsening of neurological dysfunction impairing his quality of life. The patient had undergone underwent liver transplantation, after an incidental finding of HCV positivity with associated liver cirrhosis and hepatocarcinoma. Ten years later, the patient began to experience paresthesias distally in the upper limbs and in the right lower limb. The fine motility was affected, with difficulty in performing fine movements with hand fingers. Subsequently, dysautonomic symptoms occurred with orthostatic hypotension, erectile dysfunction, and an episode of urinary incontinence. Dysesthesias and weakness worsened over the months causing gait instability. Severe weight loss also occurred. Neurotoxicity of the immunosuppressants taken for the liver transplant was hypothesized, so tacrolimus was discontinued and cyclosporine started, with no benefit. A neurophysiologic study showed severe axonal sensory-motor polyneuropathy with signs of carpal tunnel syndrome bilaterally. On neurological examination, the patient had a wide base gait, with right foot drop; strength loss was present also at first interosseous muscles of the hand bilaterally; glove-shape hypoesthesia in the upper limbs and up to the knees in the lower limbs was present; vibration sense was absent at lower limbs, where there was also areflexia. An echocardiogram showed left ventricular hypertrophy with infiltrative cardiomyopathy. High-resolution ultrasound nerves examination showed no changes in nerves morphology or echogenicity. Molecular analysis of TTR gene mutations was negative. In view of the medical history and clinical picture, the possibility of an acquired TTR amyloidosis in domino liver transplantation was considered. Analysis of the medical records confirmed that the liver donor was a patient affected with ATTRv, carrying the Glu54Gln mutation, variant known to cause severe progression of neural and cardiac damage, which is further accelerated in iatrogenic forms. The patient immediately started treatment with a transthyretin gene silencing agent, patisiran, with benefit. In polyneuropathies, a thorough medical history is mandatory to foster a proper diagnostic workup. In the present case, it would have allowed early initiation of therapy, preventing disease progression and improving patient's quality of life.

## MULTIFOCAL RECURRENT NEURALGIC AMYOTROPHY AFTER SARS-COV-2 INFECTION IN AN IMMUNOCOMPROMISED PATIENT

M. Marasca[1], A. Salvalaggio[1], M. Cacciavillani[2], M. Anglani[1], S. Imbergamo[3], S. Pravato[3], R. Gasparotti[4], M. Corbetta[1], C. Briani[1]

[1]Department of Neuroscience, University of Padua (Padova); [2]CEMES, Data Medica Group (Padova); [3]Hematology and Immunological Unit, University of Padua (Padova); [4]Neuroradiology Unit, Department of Medical and Surgical Specialties, Radiological Sciences, and Public Health, University of Brescia and ASST Spedali Civili Hospital (Brescia)

We describe an immunocompromised patient who developed multifocal recurrent neuralgic amyotrophy after COVID infection. A 68-yr-old woman in September 2022 had successfully undergone allogeneic transplant for acute myeloid leukemia. No major infections occurred during aplasia, and complete response was obtained. After recovering from a mild SARS-CoV-2 infection during immunosuppressive therapy, she developed excruciating pain at left thigh with subsequent severe thigh weakness that forced the patient to stand and walk only with support. EMG revealed denervation in left rectus anterior and vastus medialis of the quadriceps femoris muscle, secondary to femoral nerve damage. Lumbosacral MRI was unremarkable. At neurological evaluation two months later the patient still had severe weakness (left iliopsoas and quadriceps femoris 2.5/5 MRC). Reduced tactile sensitivity at lateral aspect of left thigh was present. Lumbosacral plexus MRI with 3D neurographic sequences showed hypertrophy and hyperintensity of L3 and L4 roots and of left femoral nerve in its intrapelvic course up to the inguinal canal with slight contrast enhancement. Muscle MRI revealed muscular hypotrophy of left quadriceps femoris, related to denervation phenomena. Three months later, while immunosuppressive therapy was withdrawn, the patient complained of sudden acute pain at right arm and loss of strength at right hand that she was not capable of opening or stretching (right wrist extensor 2.5/5 MRC, fingers extensor 0/5, right interosseous and flexors fingers muscles 0/5, right thumb abductor 2/5). Sensation was preserved. Right winged scapula was present. EMG showed subacute denervation at triceps brachii, short abductor of the thumb, first interosseous and abductor of

the fifth finger, common flexor of the fingers muscles. At lower limbs, signs of subacute denervation at left ilio-psoas, vastus lateralis, vastus medialis and anterior rectus muscles of the quadriceps femoris were present. Nerve ultrasound and MRI neurographic of brachial plexus showed findings consistent with amyotrophic neuralgia. After pain subsided, the patient continued physical therapy with progressive strength improvement at left thigh, but still severe distal weakness at the right arm. Neuralgic amyotrophy after COVID infection has occasionally been reported. Generally, it is a monophasic episode although long-term functional deficits are common, and recurrence may occur. In our patient right brachial plexus involvement occurred 3 months after the onset at left lumbosacral plexus. It is possible that the immunological recovery secondary to the transplant might have delayed the healing or favored an early relapse.

## CYTOKINE FINDINGS IN CHECKPOINT INHIBITOR-RELATED POLYNEUROPATHY REVEAL A PATTERN DISTINCT FROM GUILLAIN-BARRÉ SYNDROME AND CIDP

A. Marziali[1], M. Fabris[2], F. Cortiula[3], D. Iacono[3], C. Lettieri[4], M. Valente[1], A. Vogrig[1]

[1]Clinical Neurology, Department of Medicine, University of Udine Medical School (Udine); [2]Department of Laboratory Medicine, Friuli Centrale University Sanitary Agency (ASUFC) (Udine); [3]Department of Oncology, Friuli Centrale University Sanitary Agency (ASUFC) (Udine); [4]Neurology Unit, Department of Neurosciences, Friuli Centrale University Sanitary Agency (ASUFC) (Udine)

Objectives: To compare clinical, immunological, and neurophysiological features of immune-related peripheral neuropathy following immune checkpoint inhibitors (ICI-PN) to those of patients with (i) Guillain-Barré syndrome (GBS) or (ii) chronic inflammatory demyelinating polyneuropathy (CIDP).

Materials: case report.

Methods: A patient with lung cancer was treated with two courses of iplimumab-nivolumab before developing a subacute peripheral neuropathy with distal limb weakness, paresthesia, and sensory ataxia. A large panel of cytokines was analyzed on serum and cerebrospinal fluid (CSF) samples using an ultrasensitive multiplex immunoenzymatic assays (Ella instrument, Bio-Techne, USA) and compared to those of a cohort of GBS (n=7) and CIDP (n=3).

Results: The patient showed complete oncological response according to RECIST v 1.1. The neurological symptoms did not improve after oral steroid therapy (1 mg/kg) but he regained the ability to walk without assistance after intravenous immunoglobulin (2 g/kg over 5 days). Compared to mean values of cytokines in GBS and CIDP patients, respectively, ICI-PN patient's serum showed a notable increase of IL10 (33.4 pg/mL vs 5.92 GBS; 2.69 CIDP), IFNgamma (7.9 pg/mL vs 1.3; 0.51), TNFalfa (40 pg/mL vs 17.91; 8.93) and CXCL10 (878 pg/mL vs 229.7; 127). Cerebrospinal fluid analysis showed a notable increase of TNFalfa (19,2 pg/mL vs 1.74; 0.87), CXCL10 (145959 pg/mL vs 373; 355.7), IL 10 (19.8 pg/mL vs 1.8; 1) and NfL (12686 pg/mL vs 950; 4645). Neurophysiology showed a mixed pattern with mainly axonal damage while a demyelinating pattern predominated in the other groups. The CSF and serum indirect immunofluorescence assay showed a patchy reaction of granular layer and diffuse reaction of molecular layer of primate cerebellum, absent in the other groups.

Discussion: Neurologic immune-related adverse events (irAEs) occur in 1-5% of patients receiving ICIs and their mechanisms have been poorly understood. [1,2] These neuropathies are commonly described as GBS (when they show an acute onset) or CIDP (when chronic and steroid-responsive) but their pathogenesis remain elusive and diagnostic labelling using know entities may be inaccurate. The ICI-PN patient here presented show some atypical findings, demonstrating mainly axonal damage and poor response to streroids. Cytokine and NfL pattern (in particular IL10, IFNgamma and CXCL10) are considerably higher than in GBS and CIDP patients [3], suggesting an involvement of T cells, in line with the proposed mechanisms of ICIs. [1]

Conclusions: PN-ICI demonstrates unique clinical and laboratory findings distinct from known dysimmune neuropathies such as GBS and CIDP, suggesting a different pathophysiology involving T cell-mediated mechanisms.

## EFGARTIGIMOD IN REFRACTORY GENERALIZED MYASTHENIA GRAVIS. REAL-LIFE EXPERIENCE FROM A SINGLE CENTER

M. Militello, P. Alonge, N. Rini, M. Trovato, A. Lupica, F. Brighina, V. Di Stefano

Department of Biomedicine, Neuroscience, and Advanced Diagnostic (Bind), University of Palermo (Palermo)

Background and Objectives: Myasthenia gravis is a rare chronic autoimmune disease affecting the post-synaptic membrane of the muscle junction characterised by debilitating, and potentially fatal, muscle weakness. [1, 2]. Treatment options available for the management of generalized myasthenia gravis (GMG) are undergoing rapid expansion in recent years with the introduction of new drugs, especially for the 10-30% of MG patients who are refractory to conventional treatments [1]. Among the most recent, neonatal fc receptor (FcRn) blockers and complement factor C5a inhibitors have showed promising results [3]. The aim of our study was to collect real-life experience data on the use of efgartigimod alfa, a human IgG1antibody Fc-fragment engineered directed against FcRn to reduce pathogenic IgG autoantibody levels in GMG patients.

Materials and Methods: Efgartigimod alfa was administered by intravenous infusion at a dose of 10 mg/kg, once a week for 4 weeks (one therapeutic cycle) [2]. The primary outcome used to assess the efficacy of the drug was the evaluation of the patient's reported symptoms by using the MG-ADL scale. The scales were administered before the start of the cycle and at the end of the treatment cycle. The patients' baseline therapy remained unchanged during the entire course of treatment.

Results: A reduction in MG-ADL scores was observed at the end of the first treatment cycle compared to baseline with a mean change of

– 6,75 points (ranging from -12 to -3). None of these patients required IVIG infusion at the end of the cycle for symptom control.
Discussion: The decline in scores obtained testifies to the efficacy of treatment with Efgartigimod and the rapidity of its action onset. All patients undergoing treatment are classifiable as responders if they experienced a reduction in MG-ADL ≥ 2 points during the first cycle [2].

Conclusions: The implementation of this anti-FcRn treatment showed to be particularly effective to treat patients with refractory GMG and certainly represent a therapeutic frontier. Considering his tolerability, efficacy, rapid onset of action and manageability, efgartigimod could in the future eventually replace the use of traditional and more challenging immunosuppressive therapies in terms of side effects [1]. Further data and longer observations are needed to confirm our data.

## ULTRASONOGRAPHIC AND ELECTRODIAGNOSTIC FOLLOW-UP IN COVID-19 VACCINE-INDUCED PARSONAGE-TURNER SYNDROME

E. Morena[1], G. Gentili[2], C. Romano[2], L. Leonardi[3], M. Salvetti[1], G. Antonini[1], S. Rinalduzzi[2], L. Fionda[1]

[1]Department of Neuroscience, Mental Health, and Sensory Organs (NESMOS), Sant'Andrea Hospital, Sapienza University (Roma); [2]Department of Neurology and Stroke Unit, San Camillo de Lellis General District Hospital (Rieti); [3]Department of Human Neuroscience, Sant'Andrea Hospital, Sapienza University of Rome (Roma)

We present a case of a 61-years-old Caucasian man who developed Neuralgic Amyotrophy (NA) after the first dose of Pfizer-BioNTech COVID-19 vaccine injection, in December 2021. Few days later, sharp left shoulder pain began, nearby the injection site, followed by ipsilateral severe deltoid, supraspinatus, bicep brachii, thenar and flexor pollicis longus muscles weakness, joint to first three fingers hypoesthesia. The patient come to our attention in February 2022. Through Peripheral nerve high-resolution ultrasound (HRUS), we revealed an hourglass-like fascicular constriction in left median nerve at arm, in correspondence of motor conduction block detected at nerve conduction study (NCS). Moreover, both axillary and musculocutaneous nerves cMAP (compound muscle action potential) amplitudes were reduced, joint to denervation activity of deltoid at electromyography (EMG). NA was diagnosed. The patient undertook steroid therapy with prednisone 0,7 mg/kg/die for 15 days, Pregabalin daily and intensive rehabilitation physiotherapy for months. In June 2022, a second NCS/EMG and ultrasonographic evaluation showed appearance of denervation of left bicep at EMG, but improvement of fascicular constriction at HRUS. To date, patient shows a significant but slow improvement of strength and paraesthesia over time. NA, also called Parsonage Turner Syndrome (PTS) or idiopathic brachial plexopathy, is a multifocal inflammatory neuropathy characterized by unilateral sudden-onset shoulder pain, followed by neurological motor weakness and dysesthesia. Although the exact aetiology and pathophysiology of NA are unknown, it has been reported to occur after infections, vaccinations, but also trauma and surgery [1]. HRUS of the peripheral nerve is a rapid, non-invasive and cost-effective technique that allow to gain imaging in the early stages of NA, revealing pathognomonic abnormalities of involved nerves [2]. Compared to other diagnostic technique, as MRI, HRUS the most sensitive tool to detect focal nerve lesion, especially in upper limb nerve studies [3].

## SUBACUTE SENSORY NEURONOPATHY OF DENNY BROWN ASSOCIATED WITH ANTI-HU/CV2 AUTOANTIBODIES: A CASE REPORT

M. Napolitano, M. Napolitano, A. Ranieri, S. Salvatore, G. Maniscalco, E. Di Battista, K. Longo, V. Andreone

Department of Neurology and Stroke Unit, Cardarelli Hospital (Napoli)

Introduction: Subacute Sensory Neuronopathy (SNN) was first described by Denny-Brown in 1948 [1]. This was associated with bronchial carcinoma and, in further studies, with autoantibodies specifically anti-HU. SSN usually presents a remarkable loss of proprioceptive sensibility resulting in pseudo-athetoid movements of the hands and severe instability on walking. Asymmetric pain and distal paresthesia are often observed. The most frequent neoplastic finding associated with SNN is small oat cell lung cancer, but recent studies have shown that it is also seen among patients with breast cancer, ovarian cancer and Hodgkin disease in 10-20% of cases [2-3].

Methods: Here we report a case of a 65 years old male patient hospitalized for subacute onset, in 15 days, of a severe alteration of the deep sensitivity of the limbs. His osteotendinous reflexes were ubiquitously abolished and a marked sensory ataxia, predominantly affecting the upper limbs at the distal level, was highlighted. The patient was no longer able to distinguish an object with his eyes closed in his hands. He did not complain of pain and cranial nerves were spared. A moderate diffuse atrophy and hypotonia were also revealed.
Results: He underwent an electroneurographic examination showing diffuse signs of sensory ganglionopathy. He also performed a CT scan of the body that did not revealed a lung cancer or other neoplasms typically correlated to sensory neuronopathies. As he had a history of intestinal polyposis he underwent also to a colonoscopy. The histological examination of an excised adenomatous polypoid lesion did not show a cancer. Onconeural autoantibodies research in serum and CSF was performed. Anti-HU and anti CV2 autoantibodies were found both in serum and CSF. The patient was treated with intravenous immunoglobulins and he obtained a partial recovery of his sensitivity disturbances over ten days.

Discussion: SNN is a very rare sensory neuronopathy almost always associated with the presence of a lung cancer discovered, in most cases, in the very early stage of the disease. Moreover, the detection of anti-HU autoantibodies in CSF and/or in serum strongly predicts the possibility of a lung cancer diagnosis over time. In our case we also detect in CSF anti CV2 autoantibodies which have been associated to small cell lung carcinoma as well. This evidence supports the need for a close

follow-up addressed primarily to a lung cancer detection. With this purpose a FDG-PET body scan can be of valid diagnostic aid.

## A PROSPECTIVE OPEN-LABEL TRIAL WITH RITUXIMAB IN CIDP PATIENTS NOT RESPONSIVE TO CONVENTIONAL IMMUNE THERAPIES

E. Nobile-Orazio[1], P. Doneddu[1], D. Cocito[2], R. Fazio[3], L. Benedetti[4], E. Peci[5], G. Liberatore[1], Y. Falzone[6], F. Germano[3], F. Gallia[1], E. Bianchi[7]

[1]Neuromuscular And Neuroimmunology Unit, IRCCS Humanitas Research Institute (Rozzano-MI); [2]AOU S. Luigi Gonzaga, University of Torino (Orbassano-TO);[3]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics and Maternal Infantile Science (DINOGMI), IRCCS San Raffaele Scientific Institute (Milano); [4]Division of Neuroscience, Department of Neurology, Institute of Experimental Neurology (Inspe), IRCCS Ospedale Policlinico San Martino (Genova); [5]Presidio Sanitario Major, Istituti Clinici Scientifici Maugeri (Torino); [6]Department of Neurology, Institute of Experimental Neurology, IRCCS San Raffaele Scientific Institute (Milano); [7]Neurological Diseases Laboratory, IRCCS Mario Negri Institute (Milano)

Aim of the Study: Chronic inflammatory demyelinating polyradiculoneuropathy is a chronic immune-mediated neuropathy often responding to steroids, intravenous immunoglobulins or plasma exchange. These therapies needs to be continued for a long period of time to avoid patient deterioration prompting the search for other immune therapies none of them proved to be effective in randomized trials. We evaluate the efficacy of rituximab in a prospective open-label study on patients with CIDP who had not improved to at least two conventional immune therapies.

Methods: We performed and open-label prospective study with intravenous rituximab (1 gram, day 1 and 15) on 20 patients with CIDP not responsive to at least two conventional immune therapies. The primary end-point was the proportion of patients improved by at least one point on the INCAT scale or two points on the MRC scale or four points on the RODs scale, 6 months after therapy with rituximab. Secondary endpoints included the proportion of patients who: improved 12 months after therapy; improved after 6 and 12 months in electrophysiological parameters; discontinued treatment with rituximab due to side effects or voluntary withdrew; improved the quality of life according to the SF-36 scale.

Results: Twenty patients were enrolled in the study including one who retired the consent before treatment and two screening failure. Thirteen of the 17 treated patients (76.5%) had improved at 6-month, 10 if we considered 4 MRC points improvement (58.8%). Of the 14 patients completing the 12-month follow-up (two lost to follow-up after being improved at month 8 and 10, and one deteriorated at 6 month), 13 had improved at 12 month (92.9%), 10 considering 4 MRC points (71.4%). When we included missing data, 15/17 had improved (88.2%; 12/17, 70.6% with 4 MRC). In 6/15 treated patients with available data (40.0%) nerve conduction parameters had improved by at least 20% in two nerves at 6-month and 7 of 13 (53.9%) at 12-month. Seven patients had moderate or mild adverse events including two that were possibly related to rituximab (cough and dysuria) but none of them retired from the study.

Discussion and Conclusion: Rituximab was a safe and effective therapy in patients with CIDP not responsive to conventional immune therapies.

## TO BBE OR NOT TO BBE: THIS IS THE QUESTION

G. Palumbo, R. Bencivenga, S. Tozza, R. Iodice, R. Dubbioso, L. Ruggiero, M. Nolano, F. Manganelli

Department of Neurosciences, Reproductive and Odontostomatological Sciences, University of Naples Federico II (Napoli)

Background: Bickerstaff brainstem encephalitis (BBE) is an immunologic disease characterized by the acute onset of external ophthalmoplegia, ataxia and consciousness disturbance. However, BBE may present with atypical phenotype overlapping with Guillain-Barré syndrome (GBS) variants. BBE is frequently (up to 70%) associated with IgG anti-GQ1b antibodies and more rarely with other anti-gangliosides antibodies. Herein we report a case of BBE overlapping with pharyngeal-cervical-brachial (PCB) variant of GBS.

Case-Report: A 75 years-old female was admitted with an acute onset of dysarthria. Moreover, relatives referred progressive 7-day history of agitation, irritability and unsteadiness. Her medical history was positive for rheumatoid arthritis and drug-treated hypothyroidism. Neurological examination revealed ataxic gait, bilateral dysmetria with intention tremor, slurred speech and absent deep tendon reflexes. Brain CT was unremarkable. Cerebrospinal fluid analysis (CSF) showed mild pleocytosis (10/mm3). CSF film-array PCR was negative. EEG revealed slow disorganized activity without paroxysmal features. The day after, she developed hypersomnolence, dysphagia and mild proximal weakness at the upper limbs, and psychiatric disturbances worsened with delirium. The patient underwent brain contrast-enhancement MRI and an extensive laboratory investigation including systemic inflammation, infection, tumor and metabolic markers that were normal. Electrophysiological study showed mild and asymmetric sensory neuropathy and H-reflex and of F-waves absent in lower limbs. Accordingly, BBE hypothesis was advanced and intravenous immunoglobulin (IVIG) was started with partial improvement. However, given the atypical clinical picture and unsatisfactory response to IVIG, intravenous methylprednisolone bolus was administered. Over few days, symptoms significantly improved. Serum anti-gangliosides analysis finally resulted positive for IgG anti-GD1a and anti-GT1b antibodies (IgG anti-GQ1b antibodies were negative).

Conclusions: Hypersomnolence and ataxia are consistent with the hypothesis of BBE. However, the atypical features of our case including the absence of ophthalmoplegia and the presence of oropharyngeal and brachial weakness, overlap with pharyngeal-cervical-brachial variant of GBS. This overlapping case provides further support that GBS variants and BBE are part of the same spectrum. The antibody profile influences the phenotype and IgG anti-GD1a and anti-GT1b antibodies may account for our atypical BBE phenotype overlapping with GBS variant. Corticosteroids are not recommended for the general management of GBS, however, their efficacy in GBS-variants might be useful.

## A NOVEL EMILIN-1 VARIANT ASSOCIATED WITH NEURODEVELOPMENTAL DISORDER AND CHILDHOOD-ONSET POLYNEUROPATHY

G. Pellegrino[1], F. Palumbo[1], S. Gallone[2], A. Canosa[1], C. Moglia[1], A. Chiò[1], A. Calvo[1]

[1]ALS Center, "Rita Levi Montalcini" Department of Neuroscience, University of Turin (Torino); [2]Neurology 1 U, AOU City of Health and Science (Torino)

Background: Elastin microfibril interface located protein-1 (Emilin-1) is an extracellular matrix glycoprotein implicated in elastogenesis and cell proliferation. Variants in the Emilin-1 gene have been related to autosomal dominant connective tissue disease and distal neuropathy.

Case Report: We report the case of a 33 y/o man with a history of neurodevelopmental disorder, childhood-onset polyneuropathy, recurrent spontaneous pneumothorax, and HLA-B27-related syndrome with Crohn's disease and uveitis. Neurologic examination identified sensory impairment with spastic ataxic gait, limb dysmetria and acral hypo-paresthesia. Amyotrophy and hypostenia were limited to the lower extremities, with pedes cavi and absence of patellar, Achilles and plantar reflexes. Spastic dysarthria and palmomental reflex further characterized the clinical picture. Neuropsychological assessment detected attentional lability, alogia, executive dysfunction, and behavior disorder with apathy, obsessive thoughts and isolation. MRI showed FLAIR hyperintense bulbar and mesencephalic lesions with coexisting enlargement of lateral ventricles occipital horns, convexity subarachnoid space and cerebellar cisterns. Electromyography confirmed diffuse severe predominantly axonal sensorimotor polyneuropathy with a length-dependent pattern. Blood and cerebrospinal fluid tested negative for the main causes of acquired neuropathy. After negative first-level genetic analyses (PMP22, MPZ, GJB1, MFN2, FXN), Next Generation Sequencing on a panel of genes implicated in neuropathies and the subsequent segregation study revealed the heterozygous variant c.544_546delinsAAC (p.Glu182Asn) in the Emilin-1 gene. This variant maps in a coiled-coil domain of the protein involved in the supramolecular assembly and was predicted to be highly deleterious (PolyPhen-2 score: 0.943, CADD score: 25.50). Even if carrying the same variant, the proband's mother had a forme fruste, with mild signs of neuropathy and central nervous system (CNS) sparing.

Discussion: This is the first reported case of full-blown neurodevelopmental disorder and polyneuropathy, associated with a novel variant in the Emilin-1 gene. Although further research is needed, current data support a correlation with the phenotype. Neuropathy is consistent with the Emilin-1 putative function in intramuscular nerve bundles and peripheral vascular resistance. The neurodevelopmental disorder is instead in line with former studies showing central-peripheral degeneration overlap in neuropathies and suggesting a role of Emilin-1 in CNS development. Unknown genetic or environmental factors may justify the observed and previously reported phenotypic heterogeneity among relatives carrying the same variant.

Conclusion: Our findings contribute to expanding the phenotypic spectrum of Emilin-1-related pathology, corroborating its role in both central and peripheral nervous systems.

## A NOVEL SPORADIC CASE OF MSTO1 GENE RELATED CONGENITAL MYOPATHY WITH SLOWLY PROGRESSIVE MUSCULAR INVOLVEMENT

A. Perna[1], V. Riso[1], M. Garibaldi[2], M. Savarese[3], B. Udd[3], A. Petrucci[1]

[1]Center for Neuromuscular and Neurological Rare Diseases, Neurosciences Department, San Camillo Forlanini Hospital (Roma); [2]Neuromuscular and Rare Disease Centre, Department of Neuroscience, Mental Health and Sensory Organs (NESMOS), Sapienza University of Rome, Sant'Andrea Hospital (Roma); [3]Folkhälsan Research Center (Helsinki-FIN)

Objectives: To describe a novel patient affected by infantile onset myopathy and cerebellar involvement, harboring compound heterozygous variants in MSTO1 gene.

Materials: A 48-year-old woman has been followed since she was 3 years aged at our Neuromuscular Center, for delayed motor milestones, language and learning difficulty, muscle weakness. Her parents were non-consanguineous. She started walking at 3 years of age, when scoliosis, arched palate, triangular face were first noted. Subsequently, she manifested a mild progressive muscle and cerebellar involvement, with dysarthria.

Methods: Diagnostic assessment included blood tests, muscular enzymes determination, neurophysiological studies, Holter ECG 24-hour monitoring, echocardiography, respiratory function tests, brain and muscle MRI muscle biopsy, Next-Generation Sequencing (NGS) based molecular testing on leukocytes DNA performed along with fourth-years follow up.

Results: Creatine kinase (CK) was constantly elevated (min 218 - max 1750 UI/L), EMG resulted myopathic, nerve conduction and repetitive stimulation studies were normal. Whole body muscle MRI documented diffuse fatty degeneration, mostly in latissumus dorsi, anterior serratus, maximus gluteus, semitendinosus and sartorius muscles while STIR positivity occurred in some muscles. Brain MRI showed cerebellar hypotrophy; Holter ECG 24-hour, echocardiogram and respiratory testing have been regularly performed during follow up and were normal; muscle biopsy displayed chronic myopathic changes. The disease slowly progressed over 40 years of follow-up and the patient's deambulation is actually still independent; she complains running loss, difficulty in postural changes and gait, mild proximal weakness, dysphagia, dysarthria. Targeted enriched NGS panel for myopathies and congenital myasthenic syndromes was negative, while whole-exome sequencing (Illumina, TruSightONE) documented two variants (NM_018116:exon1:c.3_6del:p.Gly4Profs*68 and p.R279H) in MSTO1 predicted to be pathogenic. Her mother and the first brother

were heterozygous for one MSTO1 variant (p.R279H), the second brother for the other variant; her father died before the genetic test.

Discussion: MSTO1 is a cytoplasmic protein that regulates mitochondrial morphology and distribution. MSTO1 related myopathy is characterized by congenital/infantile onset, cerebellar and cognitive involvement, and pigmentary retinopathy, mostly recessive inherited. In our patient, we identified two likely pathogenic variants in MSTO1, one of which novel the other one previously reported. Her clinical presentation would fit with the phenotypic spectrum: slowly progressive gait disturbances, cerebellar and cognitive impairment, except for ophthalmologic involvement.

Conclusions: Our case enriches the genetic and clinical information of MSTO1 related myopathies and emphasizes the role of reverse phenotyping for addressing diagnosis of rare neurogenetic diseases assessed by NGS.

## A CASE OF LATE-ONSET GENETIC LIPID STORAGE MYOPATHY IN A PATIENT WITH RHEUMATOID ARTHRITIS: A CASUAL ASSOCIATION?

S. Pierro[1], C. Casellato[1], G. Salvucci[1], S. Zanotti[2], M. Ripolone[2], L. Napoli[2], S. Lucchiari[3], S. Corti[4], M. Sciacco[2], A. Priori[1], C. Manfredi[1]

[1]Clinical Neurology Unit, San Paolo University Hospital, Department of Health Sciences, University of Milan, ASST Santi Paolo e Carlo (Milano); [2]Neuromuscular and Rare Disease Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico (Milano); [3]Department of Neurological Sciences, Dino Ferrari Centre, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico (Milano); [4]Neurology Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico (Milano)

Objectives: Lipid storage myopathies (LSMs) are a heterogeneous group of genetic disorders characterized by abnormal deposition of lipid droplets in multiple body organs' muscle fibres. Most of the causative genes are still unknown. Adult onset LSMs usually present either with progressive muscle weakness or recurrent rabdomyolisis [1]. Here we describe the case of a patient with late-onset LSM and rheumatoid arthritis (RA).

Materials and Methods: A 71-year-old man with recent history of subacute progressive muscle weakness, exercise intolerance and rabdomyolisis underwent neurological and instrumental investigation, muscle biopsy and genetic sequencing.

Results: The patient was admitted to our emergency department complaining of gait disorder, weight loss and cramping pains of the limbs over the last three months. He struggled with climbing stairs and shaving. His past history was relevant for acute lymphoblastic leukemia (into remission) and RA, with his rheumatologist recently interrupting methotrexate for good balance. His parents were related. Neurological examination showed moderate muscle weakness (grade 4/5 for the proximal limbs) with inability to stand up from squatting. Blood tests revealed elevated muscle enzymes with Creatine Kinase 5714 U/L, Alanine Aminotransferase (ALT) 289 U/L and Aspartate Aminotransferase (AST) 605 U/L; he also had increased rheumatoid factor (422 U/mL). The EMG revealed chronic myopathy of proximal muscles [2]. Considering his oncological history, we hypothesized a paraneoplastic myopathy, but total-body PET was normal. Therefore, we thought of RA flare-up after methotrexate discontinuation and overlap syndrome with RA and polymyositis (PM), previously misdiagnosed. However, he tested negative to myositis-associated autoantibodies. He finally underwent muscle biopsy, which did not show typical pathologic findings consistent with PM but revealed numerous lipid vacuoles inside muscular fibres, especially type 1, with normal MAD activity; many fibres showed necrotic phenomena; glycogen content was normal. We thus performed genetic testing with sequencing of CPT2 (negative) and the exome sequencing (ongoing).

Discussion: Considering the biopsy results and his family history, we can conclude for a late-onset genetic LSM in a patient with RA. LSMs are usually associated with visceral involvement, especially heart and liver, so patients should also be evaluated by other specialists. To date treatment of two out of four LSMs may improve or reverse clinical symptoms, thus it is important considering LSMs as a cause of progressive weakness in adults [3].

Conclusions: To date there are no reports of an association between RA and exacerbation of LSMs, so further studies are needed to establish whether there could be a pathogenetic link.

## PSYCHIATRIC SYMPTOMS IN MYASTHENIA GRAVIS

A. Pignolo, V. Di Stefano, S. Iacono, V. Virzi', V. Costa, A. Lupica, A. Torrente, P. Alonge, R. Monastero, F. Brighina

Biomedicine, Neuroscience and Advanced Diagnostics, University of Palermo (Palermo)

Background: Myasthenia gravis (MG) is a neuromuscular disease, clinically characterized by fluctuating muscular weakness. MG have autoimmune background involving the neuromuscular transmission by the presence of specific antibodies targeting different postsynaptic components of the neuromuscular junction. The most frequently detected pathogenic autoantibodies are against acetylcholine receptors (AChRs), that can also target nicotinic AChRs present throughout the central nervous system, leading to cognitive and psychiatric symptoms in MG patients. In this case-control study, were evaluated the frequency of psychiatric symptoms in MG, as well as the clinical, immunological, and cognitive aspects.

Materials and Methods: A total of 51 MG patients matched with 48 controls, underwent anamnestic and clinical evaluation, serological testing, and behavioral/neuropsychological tests. To assess the presence and severity of depression and insomnia the Beck Depression Inventory (BDI) and the Insomnia Severity Index (ISI) was performed. The self-assessment of general psychic symptomatology was obtained by the SCL-90 scale, exploring 10 dimensions: somatization, obsessive-compulsive dimension, interpersonal sensitivity, depression, anxiety, hostility, phobic anxiety, paranoid ideation, psychoticism, sleep disorders. The quality of life was evaluated by the Short Form 12 (SF-12)

scale, divided into Physical Component Summary (PCS) and Mental Component Summar (MCS). The frontal Assessment Battery (FAB) was used as a screening test for executive dysfunction.

Results: Somatization symptoms results significantly more represented in MG patient considering the SLC-90 subscores. Also, BDI-II score results significantly higher in MG patients respect controls. Confronting ocular and generalized MG we obtained a significant difference between the groups considering BDI-II and PCS scores. The univariate analysis showed an association between higher tilters of AChRs antibodies and higher BDI-II score. After multivariate analysis, MG patients with more generalized involvement have higher BDI-II score, while a trend toward a positive association between PCS, BDI-II and ISI score and arms/legs hyposthenia was found and a negative association between the Mestinon dosage and BDI-II score.

Discussion: The literature demonstrated an association between MG and psychiatric disorders, especially mood disorders. A cross-sectional study in Saudi Arabia reported that the odds of depression were twofold higher in MG patients. In two large meta-analyses long-term corticosteroid treatment in MG has also been linked to psychosis, depression and anxiety.

Conclusions: Depressive and anxiety symptoms usually develop as comorbidity during MG disease. This preliminary study showed the present of such psychiatric symptoms in MG. We need more studies to confirm these results with rather studies with larger number of patients.

## FACIOSCAPULOHUMERAL DYSTROPHY: AN EPIDEMIOLOGICAL INVESTIGATION IN ABRUZZO

G. Polito, C. Ciprietti, S. Melchiorre, P. Quintieri, P. Adjnaj, A. Di Muzio

Department of Neuroscience, Imaging and Clinical Science, "G. D'Annunzio" University of Chieti-Pescara (Chieti-Pescara)

Facioscapulohumeral muscular dystrophy (FSHD) is a skeletal muscle disorder characterized mainly by weakness in the facial muscles, scapula stabilizers and dorsiflexors of the foot caused by an autosomal dominant genetic defect consisting in a pathological decrease in the number of D4Z4 microsatellite repeats in the subtelomeric region of chromosome 4q35. FSHD is the third most common form of muscular dystrophy, after Duchenne dystrophy and myotonic dystrophy, with a prevalence between 1:15,000 and 1:20,000. In this survey we assessed the clinical, genetic, and epidemiological data of FSHD patients from Abruzzo followed in our Regional Centre for Neuromuscular Diseases in the last 20 years and compared with those currently available in literature in Italy and European countries (France and Netherlands). Our population consisted of 125 FSHD patients, from 68 families. Out of these, 93 patients from 48 families were from Abruzzo since almost one generation. Of these, 42.9% beginned with scapular involvement, 6.5% with facial weakness onset, 30.1% with lower limb involvement at onset, 1% experienced another onset, 19.5% were asymptomatic. Two had an allele size <15 Kb; 42 were in the 15-30 Kb subgroup and 49 had >30 Kb allele size. Regarding FSHD score 53.7% patients had 0-4 score, 27.0% a 5-9 score and 19.3% a 10-15 score. Comparing our population with the Italian data, the overall prevalence was higher (1,45/20000 vs 1,14/20000). We obtained the same result by comparing our results with those from the French FSHD registers (0.88/20'000) but a lower prevalence than in Netherlands (2.4/20'000). In addition, a further peculiar finding observed in our population was the high number of subjects with positive genetics with few or no symptoms. In conclusion we found a higher FSHD prevalence in the Abruzzo population compared with that in Italy and France but lower than Netherlands. We observed many cases of oligosymptomatic patients despite the presence of the genetic defect. These results can be attributed to the effort of the FSHD Italian network, and the deep and extensive genetic studies carried out both on patients with a suspected FSHD clinic and on their relatives, leading to a larger cohort of patients (symptomatic and asymptomatic) with a positive genetic result. Currently, more and more centre is collecting clinical and epidemiological data on these patients but further efforts are needed to better define the FSHD epidemiology and to identify patients to guarantee them early monitoring and treatment in a specialised neuromuscular diseases centre.

## MANAGEMENT OF PRESYMPTOMATIC JUVENILE PATIENTS WITH LATE-ONSET POMPE DISEASE (LOPD)

M. Porcino, O. Musumeci, I.G. Arena, C. Consulo, C. Usbergo, C. Rodolico, A. Toscano

Clinical and Experimental Medicine Department, University of Messina (Messina)

Objectives: To investigate the differences in disease progression and treatment response in juvenile patients with Late-Onset Pompe Disease (LOPD), compared to adult patients. To evaluate the proper timing to start Enzyme Replacement Therapy (ERT) in young presymptomatic patients.

Patients and Methods: We retrospectively collected clinical, morphological, biochemical, and molecular aspects in a cohort of 12 juvenile patients with LOPD. A longitudinal analysis of motor and respiratory functions assessed by MRC, 6MWT, GSGC, seated and supine FVC and muscle MRI findings was carried out.

Results: Mean actual age is 16.6 years. All patients were diagnosed for isolated hyperCKemia and mean age at diagnosis was 6.2 years (range 1-18). Median follow-up duration was 12 years (range 2-22). The commonest mutation was c.32-13T>G, found in compound heterozygosis in ten patients. Echocardiography was normal in all. Seven patients underwent muscle biopsy, which showed vacuolar myopathy with glycogen accumulation in four of them. Unspecific changes were detected in the other three cases. During the follow-up, five patients developed proximal muscle weakness, characterized by mild waddling gait and positive Gowers maneuver. One patient showed scapular winging. Symptoms onset occurred from 6 months to 6 years after the diagnosis. Muscle MRI revealed mild hypotrophy of the thighs before the development of symptoms in three cases. Four patients started alglucosidase alfa and one avalglucosidase alfa. Patients on ERT showed motor and respiratory stability over time.

Discussion: LOPD includes patients from 1 year of age to adulthood. The vast heterogeneity in clinical manifestations and disease progression is not fully explained, however a short disease duration and a young age seem predictors of good response to treatment. We have now sensitive diagnostic algorithms which allow an early diagnosis even in presymptomatic patients. In this subgroup, to intercept cellular pathological process, before organ damage and disease progression occur, and to choose the proper timing to start ERT is challenging. While a consistent biomarker of disease progression is still needed for LOPD, muscle MRI is a useful and sensitive tool to early detect muscle morphological alterations.

Conclusion: Juvenile patients represent an informative model for identifying prognostic factors and monitoring the disease progression under ERT. Early identification of clinical manifestations through a strict follow-up, including biannual clinical evaluation and annual muscle MRI is essential for a prompt treatment in young patients, which modifies the disease course.

## A CASE OF RECURRENT PALSY OF THE ABDUCENS NERVE IN AN HBV-POSITIVE PATIENT

P. Quintieri, M. Russo, C. Ciprietti, S. Melchiorre, G. Polito, R. Speranza, F. Dono, M. Onofrj, S. Sensi

Department of Neuroscience, Imaging and Clinical Sciences Gabriele D'Annunzio University (Chieti)

Background: The sixth cranial nerve is prone to multiple types of damage. Its convoluted course and proximity to bone structures frequently lead to nerve compression in case of orbital traumatism or intracranial hypertension. Furthermore, this nerve is susceptible to metabolic insults, particularly related to diabetic ischemia or vitamin B1 deficiency. Sixth nerve palsy frequently exhibits a monophasic course, but recurrent impairment can also be observed, primarily as a manifestation of ocular myasthenia. We here report a rare case of recurrent palsy affecting the sixth cranial nerve, associated with an uncommon etiology.

Case Presentation: A 72-year-old man was referred to the Emergency Department due to the acute onset of binocular diplopia. The neurological and ophthalmological evaluations documented impaired left eye abduction, as confirmed by the Hess screen test. The fundus oculi examination spotted no abnormality, and a brain MRI scan excluded any orbital or cerebral abnormality. A blood workup did not support a diagnosis of diabetes, vasculitis, or thyroid pathology. Serum tests for myasthenia-related antibodies (anti-AchR, anti-MuSK) were negative. The patient's medical history only included HBV chronic infection. In the past fifteen years, the patient had experienced two similar episodes, affecting the same nerve and side. In the past episodes, the patient had undergone the same diagnostic workup, which resulted negative and was treated with oral steroid therapy that resolved the symptoms within a month. A subsequently implemented oral prednisone regimen proved effective in reducing the severity of diplopia.

Conclusions: The patient was diagnosed with recurrent sixth nerve palsy, likely due to HBV. Peripheral neuropathy is not an uncommon manifestation in patients with chronic hepatitis virus infection. However, cranial nerves are usually spared by HBV or may be involved in complex or atypical presentations.

## CHECKPOINT INHIBITOR-INDUCED AUTOIMMUNE MYOSITIS WITH MYOCARDIAL INVOLVEMENT: THE IMPACT OF EARLY IDENTIFICATION AND SPECIFIC TREATMENT ON NEUROLOGICAL RECOVERY

D. Regina, G. Milella, F. Caputo, A. Introna, A. Fallacara, P. Iaffaldano, D. Paolicelli

Department of Basic Medical Sciences, Neurosciences and Sense Organs, University of Bari "Aldo Moro" (Bari)

Objectives: Immune Checkpoint Inhibitor (ICI)-related autoimmune myositis is an example of toxicity occurring in 0.38% of patients treated with ICIs [1]. This condition has shown to have a poor prognosis, especially for cases with myocardial involvement [1], which occurs in 41% of cases of (ICI)-related autoimmune myositis [1]. Therefore, prompt identification and specific treatment are critical key points to determine a better outcome.

Materials and Methods: We present the case of a 73 years-old man with a metastatic G3 urothelial bladder carcinoma who developed ptosis in left eye, mild anisocoria, horizontal diplopia in binocular vision due to bilateral abduction deficit, hypophonia and parahyposthenia two weeks after a first administration of Pembrolizumab.

Results: Diagnosis of immune-mediated myositis was made by clinical findings, electromyography, and the evidence of anti-titin antibody positivity. A bicameral pacemaker was implanted and a coronary angiography with PTCA was carried out with the placing of a DES on the IVA due to the development of a III-degree atrioventricular block and cardiac troponin elevation. An intravenous corticosteroid cycle of Solumedrol 4 g was administered without benefit. A subsequent cycle of plasmapheresis (a total of 6 sessions) was performed, with full regression of signs and symptoms. Intravenous immunoglobulins were not administered due to the prothrombotic risk. After 22 months the patient still presented with no residual neurological deficits.

Discussion: The features of our case are in line with the literature, which showed that bulbar signs resulted to be independently associated to the development of myocardial involvement [1]. This condition turned out to be resistant to standard corticosteroid treatment, making necessary more aggressive strategies such as plasmapheresis, performed in 47% of ICI-related myositis with myocardial involvement [1]. However, our case adds important considerations about the outcome. Referring to the literature, death occurred in 53% of subjects affected by ICI-related myositis with myocarditis, despite the treatment, with 83% of cases directly caused by myositis [1]; instead, our

patient had a full recovery after a plasmapheresis cycle and no residual neurological deficit at 22 months.

Conclusions: ICI-related myositis is a rare but potentially fatal condition that can occur in patient treated with checkpoint-inhibitors immunotherapy. Myocarditis is a serious complication of ICI-related myositis, which can hesitate in treatment refractoriness and poor prognosis [1]. On the other hand, an early recognition and subsequent specific relatively aggressive treatment such as plasmapheresis can determine a better prognosis and even full neurological recovery.

Introduction: Facioscapolohumeral muscular dystrophy (FSHD) represents a complex disease with high clinical variability and an intricate genetic landscape. Diagnostic criteria are based on the detection of the molecular signature (contraction of D4Z4 repeat units at 4q35 and/or hypomethylation in presence of 4qA permissive allele); however, this paradigm does not completely fulfill the understanding of phenotypes and disease natural history and often complicates familial genetic counseling.

Aims: Many molecules are at study both in pre-clinical and clinical trials, further prompting the need for prognostic indicators and biomarkers describing disease progression. A diagnostic flow-chart based only on genetic signature may not highlight the differences among patients and possibly bias the interpretation of response to a certain treatment. On the other hand, the clinical complexity hides further molecular mechanisms to be investigated.

Methods: Starting from these considerations, we aim at using FSHD as a disease model and develop a dedicated digital platform that can comprehensively collect all the variables involved, enabling a deep phenotyping towards a personalized plan of diagnosis and care. This will be achieved through an integrated and multiparametric approach, converging on a single support cloud-based, GDPR-compliant platform.

Study proposal: The study will involve a multicenter collaboration between neurologists and IT-professionals. The platform will be developed starting from the structure of the Clinical Comprehensive Evaluation Form, a tool shared by the Italian Clinical Network for FSHD, and will comprise modules for phenotype and pedigree, genetics and MRI. A machine-learning approach will inform automatic algorithms for recognition of clinical, genetic and imaging patterns and provide clinicians with correlation analysis among variables.

## HYPERKINETIC MOVEMENTS AND PARKINSONISM IN AXONAL SENSORY NEUROPATHY: ATYPICAL PATHS TO CANVAS

N. Rini[1], P. Alonge[1], L. Grillo[2], F. Calì[12], F. Brighina[1], V. Di Stefano[1]

[1]Department of Biomedicine, Neurosciences and Advanced Diagnostics (Bi.N.D.), University of Palermo (Palermo); [2]Research Unit of Rare Diseases and Neurodevelopmental Disorders, Oasi Research Institute-IRCCS (Troina-EN)

Introduction: Cerebellar ataxia neuropathy vestibular areflexia syndrome (CANVAS) is a rare, inherited, late-onset, and slowly progressive disease, characterized by cerebellar ataxia, bilateral vestibular areflexia, and peripheral sensory neuropathy caused by the pathogenic biallelic pentanucleotide intronic repeat expansion in replication factor complex subunit 1 (RFC1) gene. [1]

Case report: A 64-years-old Caucasian woman with cerebellar ataxia and sensory neuropathy associated with hyperkinetic extrapyramidal syndrome came to our clinic in 2021. Her symptoms had started about seven years earlier with postural imbalance and dizziness. In addition, her past medical history included bronchial asthma, discopathies, arthropathies and mood tone deflection. The family history was unremarkable. Initial neurological examination revealed nystagmus, decreased reflexes and absent ankle reflexes, reduced vibration and joint position sense throughout with ataxic gait and positive Romberg sign, bradykinesia in the tapping test on the left with signs of plastic rigidity in the activation tests on the left upper and lower limbs, bilaterally rising movements of the hands. Laboratory tests were normal. Brain MRI showed cerebellar atrophy, with diffuse white matter hyperintensity and bilateral pallidal microdeposits. Nerve conduction studies showed sensory axonal polyneuropathy with normal motor action potentials. DAT-SPECT imaging was normal. Testing for acanthocytosis was negative. In the suspicion of parkinsonism, a therapeutic test was started with levodopa, without any significant improvement. Subsequent neurological evaluations highlighted: progressive worsening of the ataxia with the need of support for walking, the appearance of mild orthostatic and postural tremor and reduced vestibulo-ocular reflexes. These finding lead to suspicion of CANVAS syndrome with associated parkinsonism. An NGS panel for parkinsonism and hereditary ataxias was performed, which excluded common genetic ataxic syndromes and showed biallelic intronic AAGGG repeat expansion in RFC1 gene, thus confirming CANVAS. In addition, due to prominent hyperkinetic distal movements, a genetic testing in the HTT gene was performed, showing a number of CAG triplets in the lower bounds (two distinct alleles of 16 and 25 CAG repeat units).

Discussion: This case illustrates the phenotypic variability in patients with biallelic expansions in RFC1. Since the identification of the AAGGG expansion, the association between RFC1 gene and parkinsonism have been rarely reported [2]. Indeed, we may hypothesize that deafferentation of sensory stimuli from distal part of the body could favor hyperkinetic phenomena such as the "alien limb" phenomenon [3]. Furthermore, the CAG triplets expansion of the HTT gene in this patient, although not pathogenic, might have a clinical role in the pathophysiology of extrapyramidal symptoms.

[1]Fondazione IRCCS, Istituto Neurologico Carlo Besta (Milano); [2]IRCCS Ospedale San Raffaele (Milano); [3]University of Genoa (Genova); [4]IRCCS Ospedale Policlinico San Martino (Genova); [5]University Hospital of Limoges (CHU Limoges - Dupuytren Hospital) (Limoges-F); [6]University of Milan (Milano); [7]Institute for Myelin and Glia Exploration, Jacobs School of Medicine and Biomedical Sciences, State University of New York at Buffalo (Buffalo-USA)

Background/Objectives: Neuropathies related to Myelin Protein Zero (MPZ, P0) mutations are very heterogenous and in Italy represent 10% of Charcot-Marie-Tooth disease (CMT) cases [1]. They are associated either with primary demyelinating CMT neuropathy with early onset (CMT1B) or with late onset predominantly axonal neuropathy (CMT2I/J) [2]. In this study we investigate two P0 mutations (P70S and T124M) associated with CMT2I and CMT2J, respectively.

Materials and Methods: By a translational approach, we have extensively characterized the clinical and neurophysiological phenotype of a large P70S-CMT2I population (n=29, with a likely founder effect in Northern Italy) and of eight T124M-CMT2J patients and studied axon-glial dysfunction mechanisms in cellular and animal models. We also evaluated a sural nerve and 12 skin biopsies from P70S-CMT2I patients by electron microscopy (EM) and immunohistochemistry (IHC), and three skin specimens from T124M-CMT2J subjects.

Results: P70S patients showed later onset and milder phenotype than T124M study participants (age of onset mean 52 vs 39 years, CMTES mean 9 vs 11/28). Upper limb motor nerve conduction velocities were in the CMT2 range in both patients' groups (42–60 m/s). Sensory impairment involved mainly vibration and pinprick sensation both in P70S and T124M subjects. 5/8 T124M patients had pupillary changes and 2/8 hearing loss. In vitro studies demonstrate that the P0-P70S mutant: reaches the cell membrane and does not co-localize with endoplasmic reticulum markers; maintains adhesion properties and is normally glycosylated whereas P0-T124M mutation prevents N-glycosylation and is likely responsible for extra modification not yet identified. Concerning the two authentic mouse models generated, T124M animals well recapitulate human disease [3]. P70S mice show only minimal evidence of axonal damage even at a late age but proteomic analysis will clarify the potential alteration of proteins involved in axonal transport. Finally, in EM the collected nerve and skin samples from P70S-CMTI patients reveal mostly normal nodes and very few abnormal paranodes. Preliminary results by IHC suggest a possible Schmidt-Lanterman incisures' involvement at least in T124M skin biopsies.

Discussion and Conclusions: How a mutation in a myelin protein causes an axonal neuropathy is still unclear but the role of P0 in Schwann cell/axon interactions appears crucial. With a translational approach we are starting to elucidate the role of the two variants in generating the CMT2I/J neuropathies.

## A NOVEL MUTATION IN THE LRSAM1 GENE IN A FAMILY WITH AUTOSOMAL DOMINANT CHARCOT-MARIE-TOOTH TYPE 2P

S. Scannicchio[1], G. Milella[1], M. Sozzo[1], P. Lasorella[1], B. Vitucci[1], S. Zoccolella[2], P. Lastella[3], V. Petruzzella[4]

[1]Neurology Unit, Department of Translational Biomedicine and Neurosciences (DiBraiN), University of Bari "Aldo Moro" (Bari); [2]Neurology Unit, Department of Translational Biomedicine and Neurosciences (DiBraiN), "San Paolo" Hospital (Bari); [3]Department of Biomedical Sciences and Human Oncology, University of Bari "Aldo Moro" (Bari); [4]Department of Basic Medical Sciences, Neuroscience, and Sense Organs, University of Bari "Aldo Moro" (Bari)

Objectives: Charcot-Marie-Tooth type 2P is a rare genetic axonal hereditary sensory-motor neuropathy disorder caused by mutations in the LRSAM1 gene.

Materials and Methods: We describe two siblings presenting with slowly progressive axonal sensory-motor polyneuropathy harboring a novel variant in LRSAM1 with autosomal dominant (AD) inheritance. Additionally, we conducted a review of the literature focusing on patients carrying a variant similar to the one reported herein.

Results: The proband, a 56-year-old woman, has been experiencing progressive distal lower-limb neuropathic pain and weakness since childhood. She started using foot-orthosis at the age of 25. Due to severe sensory ataxia and several accidental falls, she became wheelchair-bound at the age of 62. Neurological examination revealed moderate muscle weakness in ankle plantar/dorsal flexors, reduced pinprick and vibration sensations in the legs up to the knees, and absent deep tendon reflexes in lower limbs. Nerve conduction studies revealed sensory-motor axonal polyneuropathy in the lower limbs. Similarly, the proband's 48-year-old brother has been experiencing progressive symptoms since adulthood and began using unilateral assistance after a series of accidental falls. Clinical Exome Sequencing revealed a novel heterozygous variant, specifically c.2039_2043dup (p.Glu682AsnfsTer6), in the LRSAM1 gene. This variant resulted in a premature stop codon and loss of the RING motif, which is crucial for LRSAM1 activity.

Discussion: Our report presents clinical and genetic data from two patients belonging to the same family and carrying a novel heterozygous variant in the LRSAM1 gene. These patients exhibited phenotypes characterized by axonal polyneuropathy, with a predominant involvement of the sensory domain. This observation aligns with previous findings in Sardinian patients with AD CMT2P, who carried a closely related heterozygous mutation (p.Ala683ProfsX3). These findings confirm the variable age of onset, ranging from childhood to adulthood, and the slowly progressive disease course associated with CMT2P. Furthermore, we reported another closely related mutation (Glu680Asnfs*6) which has been reported in two patients with an early age of

onset (32 and 27) and initial sensory symptoms. Patients with a variant closely related to the one we reported, (p.Glu682_Ala683ins21), displayed impaired sensation of touch and disturbed proprioception.

Conclusions: This study expands the mutational spectrum of the LRSAM1 gene in CMT2P. Our data further validate the typical clinical hallmark of CMT2P as relatively mild and very slowly progressive axonal neuropathy, primarily affecting sensory domain. However, it is essential to recognize that, the sensory impairment associated with CMT2P can rarely impact functional independence, necessitating the use of unilateral assistance or wheelchair.

## COGNITIVE ESTIMATION BUT NOT EMPATHY IS IMPAIRED IN PATIENTS WITH MYOTONIC DYSTROPHY TYPE 1. A VOXEL-BASED MORPHOMETRY STUDY

L. Serra[1], V. De Sangro[1,2], G. Caruso[1], S. Bonarota[1], C. Di Domenico[1], A. Petrucci[3], C. Caltagirone[4], M. Bozzali[5]

[1]Neuroimaging Laboratory, Santa Lucia Foundation IRCCS (Roma); [2]Department of Human Sciences, LUMSA University of Rome (Roma); [3]Center for Neuromuscular and Neurological Rare Diseases, San Camillo Forlanini Hospital (Roma); [4]Behavioral and Clinical Neurology Laboratory, Santa Lucia Foundation IRCCS (Roma); [5]Neuroscience Department "Rita Levi Montalcini", University of Turin (Torino)

Objective: Myotonic dystrophy type 1 (DM1) is the most common muscular dystrophy in adults that affects several organs including the brain [1-2]. High level cognitive dysfunctions have been reported including social cognition deficits [3]. Aim of the present study was to deepen social cognition deficits and their neural correlates with a special interest on cognitive estimation abilities and empathy in DM1 patients.

Methods: 10 DM1 patients and 12 Healthy Controls (HC) underwent an extensive cognitive assessment including the Cognitive Estimation Task (CET) and the Empathy Quotient- EQ. They also underwent 3T-MRI scanning to collect T1-weighted volumes for voxel-based morphometry analyses. One-way ANOVAs were used for between-group comparisons in neuropsychological data. A two-sample T-test model was used to compare groups in grey and white matter volumetrics (GM and WM). Finally, one-sample T-test models were used to assess potential associations between neuropsychological variables and GM volumes in all individuals.

Results: Compared to HC, DM1 patients showed lower performances in several tests of the administered cognitive evaluation including the CET and in the filler items of the EQ. DM1 patients compared to HC showed the expected pattern of GM (parahippocampal gyrus, frontal pole, medial frontal gyrus, inferior temporal and fusiform cortex) and WM (fimbria, longitudinal inferior fasciculus, fronto-occipital fasciculus) volumetric decreases. Moreover, DM1 patients showed an inverse association between error scores on CET and GM volumes in the fronto-temporal cortex and angular gyrus, and an inverse association between the filler items of EQ and GM volumes in the anterior cingulate cortex. Finally, HC showed inverse associations between error scores on CET and GM volumes in the cerebellum.

Conclusion: This study confirms the presence of social cognition deficits in DM1 patients highlighting the role played by the cognitive rather than empathetic aspects, the latter resulting preserved. VBM suggests a neurobiological substrate for these higher-level abnormalities that impact on everyday-life activities and success of DM1 patients.

## A NOVEL DNM2 MUTATION IN A CASE OF A HEREDITARY PURE SENSORY AXONAL POLYNEUROPATHY

N. Setola[1], M. Oliva[1], L. Cipriano[1], E. Signoriello[1], S. Bonavita[1], S. Gambardella[2], C. Coppola[1]

[1]Department of Advanced Medical and Surgical Sciences, University of Campania "L. Vanvitelli" (Napoli); [2]IRCCS Istituto Neurologico Mediterraneo Neuromed (Pozzilli-IS)

Aims of the Study: Dynamin 2 (DNM2) belongs to a family of pleiotropic GTPases that mediate several cellular processes including endocytosis, actin assembly and centrosome cohesion. Mutations in DNM2 gene are associated with centronuclear myopathy, intermediate and axonal Charcot-Marie-Tooth (CMT) disease and lethal congenital contracture syndrome. The aim of this stydy is to report a new mutation in DNM2 gene associated to a hereditary pure sensory axonal polyneuropathy.

Material and Methods: We describe the case of a 59-year-old male who at the age of 30 presented an insidious onset of lower limbs numbness and burning pain that worsened in the last years leading to gait disturbances. His family history was positive for gait disorders. He, also, had been suffering for a long time from severe constipation and an abdominal X-ray revealed a giant faecaloma. Neurological and cognitive evaluation revealed bilateral pes cavus with hammer toes and visuo-spatial deficits associated to diffuse atrophy at Brain Magnetic Resonance Imaging scan. Nerve conduction study revealed a pure axonal sensory polyneuropathy. A genetic study was performed.

Results: The genetic and sequence analysis identified the heterozygous mutation NM_001005360.2:c.[383A>G]; NP_001005360.1:p.(His128Arg) in DNM2 gene (OMIM # 602378).

Discussion: We described clinical, instrumental and genetic aspects in a patient affected by pure sensory axonal polyneuropathy and carrying the novel p.Hys128Arg-DNM2 heterozygous mutation, which further expands the spectrum of DNM2 mutations and related phenotypes. Other interesting features are cognitive deficits and the stubborn constipation that we speculate is an expression of gastro-intestinal autonomic dysfunction, and we speculated that their association with DNM2 mutations could be not purely coincidental. However, additional series of DNM2 mutations carriers, adequately screened cognitive or for dysautonomic disorders, as well as further functional studies, will

be needed to verify this hypothesis and elucidate its possible underlying mechanisms.

Conclusions: This is the first description of a pure sensory axonal polyneuropathy associated with a novel p.Hys128Arg-DNM2 heterozygous mutation.

## DEMOGRAPHICS, CLINICAL CHARACTERISTICS, AND RISK FACTORS IN PATIENTS WITH ISOLATED ACUTE-ONSET DIPLOPIA AND PTOSIS: A RETROSPECTIVE STUDY

M. Sozzo, P. Lasorella, S. Scannicchio, B. Vitucci, G. Milella

Neurology Unit, Department of Translational Biomedicine and Neurosciences (DiBraiN), University of Bari "Aldo Moro" (Bari)

Objective: This retrospective study investigated demographics, clinical characteristics, and risk factors in patients admitted to the neurology unit with isolated acute-onset diplopia or ptosis.

Materials and Methods: A retrospective analysis of 5000+ medical records from 2016-2022 was conducted. Inclusion criteria: words "diplopia" or "ptosis" in medical history, presenting symptoms, or neurological examination, an extensive diagnostic work-up (brain magnetic resonance imaging, electromyography, lumbar puncture when required).

Exclusion criteria: Monocular diplopia, pre-existing ptosis, other neurological signs/symptoms beyond diplopia or ptosis, previous diagnosis of myasthenia gravis or multiple sclerosis, unclear discharge diagnosis. We assessed presence of diplopia/ptosis, cranial nerves involved, discharge diagnosis, and risk factors (hypertension, dyslipidemia, diabetes, stroke/myocardial infarction (MI) history). Differences in demographic and clinical characteristics between diagnosis groups were assessed through Kruskal-Wallis or Chi-squared as appropriates.

Results: Out of 126 selected patients (median age: 62; male-to-female ratio: 2.8:1), 85 (67%) had isolated diplopia, 4 (3%) had isolated ptosis, and 37 (30%) had both. Associated cranial nerve palsies included: abducens (36%), oculomotor (36%), trochlear (11%), two nerves involvement (6%), one patient had three nerves involved. Twelve cases lacked data about nerve involvement. Most common underlying mechanisms were: idiopathic mononeuropathy (IM) (50 patients), myasthenia gravis (MG) (28 patients), multiple sclerosis (MS) (19 patients) and ischemic strokes (IS) (15 patients). Younger age was associated with MS ($p<0.001$). Three out of 4 Isolated ptosis were diagnosed as MG. Among patients with Isolated diplopia: 15% was diagnosed as IS (13), 45% as IM (39), 18% as MS (16) while only 10% was diagnosed as MG. Almost half (16/37) of patients with diplopia-ptosis co-occurrence was diagnosed as MG ($\chi^2=29.7$, $p<0.001$). IV and VI cranial nerve palsy were associated with IM, while third nerve palsy was more common in MG. Co-occurrence of multiple cranial nerve palsies was similarly linked to MG and MS ($\chi^2=94.7$ $p<0.001$). Pre-existing stroke/MI and dyslipidemia were strongly associated with new-onset IS ($\chi^2=12.5$, $p<0.001$ and $\chi^2=22$, $p<0.001$ respectively). Hypertension was likewise associated with IS, MG, and IM ($\chi^2=24$, $p<0.001$). Diabetes prevalence was lower in MG than in IM, systemic polyneuropathy and IS groups ($\chi^2=15.8$, $p=0.001$).

Discussion and Conclusion: Our study provides insights into isolated acute-onset diplopia/ptosis based on a large sample and extensive time frame. Age, gender distribution, and cranial nerves involved align with previous research. Associations were found between risk factors and diagnoses: younger age with MS, III nerve palsy with MG, stroke/MI history and dyslipidemia with IS. Diabetes prevalence was lower in MG compared to other causes.

## HOMOZYGOUS R596G VARIANT IN TRIM32 GENE RELATED TO LGMD IN A NON-HUTTERITE PATIENT

P. Spadafora[1], L. Citrigno[1], S. De Benedittis[1], A. Qualtieri[1], F. Cavalcanti[1], G. Di Palma[1], O. Gallo[1], N. Romeo[2]

[1]Institute for Biomedical Research and Innovation, National Research Council (Mangone-CS); [2]Institute for Mediterranean Agricultural and Forestry Systems, National Research Council (Rende-CS)

Objectives: TRIM32 is a member of the Tripartite–Motif family of proteins characterized by a RING finger, a B-box motif, a coiled-coil region and six NHL-repeats [1]. TRIM32 has E3 ubiquitin ligase activity by participating in myofibrillar protein turnover. D487N mutation in the TRIM32 gene, has been associated with Limb Girdle Muscular Dystrophy Recessive type 8 (LGMDR8) in the inbred Hutterite population. We reported R596G homozygous missense variant in TRIM32 gene in a 54-year-old patient with LGMD from south Italy.

Material and Methods: Molecular analysis of the DYSF and FKRP genes was performed on the patient's DNA by direct sequencing. Subsequently the analysis was extended to 40 genes related with LGMD by NGS.

Results: We have identified in the patient a homozygous variant R596G in TRIM32 gene and the L276I heterozygous mutation in FKRP gene. The patient's parents were consanguineous.

Discussion and Conclusions: LGMDR8 was first described in Hutterites associated with the D487N mutation in the TRIM32 gene. To date, some missense, deletions, frameshifts variations in the same gene have been identified in European patients affected by LGMDR8. All variations fall into NLH domains of the TRIM32 gene. These domains are probably essential for the recognition of protein target that TRIM32 will have to ubiquinate [2]. We reported a patient with difficulty walking especially uphill already in the first decade of life. At about 22, he showed nocturnal calf cramps, hypotrophy and weakness of the shoulder girdle muscles, anterior tibialis and perineal deficits bilateral in the lower limbs, pes cavus, positive Gower, stepping gait, increased CPK and ventilatory failure. Immunohistological analysis of bioptic muscle tissue showed hypo/hyper atrophic fibers mainly rounded in shape, lipid accumulation, increase in

collagen and adipose tissue. Molecular analysis conducted by NGS for this patient showed the R596G homozygous missense variant in TRIM32 gene. This variant has been reported in the literature in a patient from southern Italy as probably pathological [3]. In silico analysis as Polyphen, MutPred2, Polyphen2, Panther, Sift, Mutation Taster also support a deleterious effect of the variant. Moreover, the patient showed the heterozygous Leu276Ile mutation in the FKRP gene which is the most frequent mutation responsible for LGMDR9. Both variants are likely responsible for the patient's phenotype with an additive effect. In fact, TRIM32 and FKRP proteins are part of the same pathway and they are essential for maintaining the integrity of the dystrophin glycoprotein complex.

## A CASE OF ANTI-HU PARANEOPLASTIC BRAINSTEM ENCEPHALITIS AND SUBACUTE SENSORY NEUROPATHY IN A PATIENT WITH ADVANCED PROSTATE ADENOCARCINOMA

J. Spagliardi[1], F. Terenghi[1], E. Nobile-Orazio[1,2]

[1]Neuromuscular and Neuroimmunology Unit, IRCCS Humanitas Clinical and Research Institute (Rozzano-MI); [2]Department of Medical Biotechnology and Translational Medicine, Milan University (Milano)

Paraneoplastic neurological syndromes (PNS) are rare immune-mediated neurological disorders that commonly occur with certain malignancies; the most common is small cell lung cancer but prostate cancer is also related in 2.5%-6.3% of cases. Anti-Hu antibody associated syndrome is the most common form of PNS. A 75-year-old man with a history of metastatic prostate adenocarcinoma mildly responsive to radiotherapy and androgen-deprivation therapy came to our observation with a six-month history of progressive distal paresthesia and postural and gait instability. He then developed difficulty articulating speech and dysphagia. The neurological examination showed distal lower limb hypoesthesia and paresthesias, diffuse hypotrophy with sensory ataxia prevalent in the lower limbs with areflexia. Inability to maintain a sitting position due to retropulsion and gait ataxia. Brain MRI showed a mild medullo-pontine atrophy and a T2 and FLAIR hyper intense-appearing images of the posterior portion of the left thalamus with increased diffusivity. EMG revealed a sensory axonal neuropathy with mild upper motor neuron signs and sensory evoked potentials showed peripheral involvement. Cerebrospinal fluid analysis showed only mildly elevated protein levels (81 mg/dl) and no cancer cells. A whole-body contrast-enhanced CT scan showed no disease progression. Then we tested a panel of cancer-associated auto-antibodies with positive anti-Hu antibodies results. A diagnosis of paraneoplastic neuropathy and brainstem encephalitis was made. The patient was treated with high doses of steroids but no significant improvement was observed and severe dysphagia necessitated the placement of a PEG. Anti-Hu antibodies has been reported in a large number of patients with various neurological disturbances including subacute sensory neuropathy, limbic encephalitis, brainstem encephalitis, chronic gastrointestinal pseudo-obstruction and paraneoplastic cerebellar degeneration. The clinical symptoms may be confined to one part of the nervous system or, more frequently, involve multiple areas overtime. Anti-Hu associated brainstem encephalitis usually presents subacutely with preferential involvement of the medulla and represents the predominant syndrome in 11% of anti-Hu positive patients. Paraneoplastic syndromes arise infrequently in prostate cancer and when they occur, it is usually in the setting of small-cell carcinoma of the prostate or advanced, hormone-resistant disease. We report a case of anti-Hu brainstem encephalitis presenting with dysarthria and dysphagia, with concomitant sensory neuropathy leading to a progressive disabling ataxia associated with a prostate tumor. To the best of our knowledge, this is the first case of association of a subacute sensory neuropathy and brainstem encephalitis in a patient with advanced prostate adenocarcinoma.

## CHARCOT MARIE TOOTH DISEASE ASSOCIATED WITH MME MUTATIONS: A CASE SERIES FROM FLORENCE, ITALY

M. Sperti[1], G. Rodolico[1], A. Bucur[1], D. Leccese[1], S. Torricelli[1], F. Santorelli[2], I. Carboni[3], M. Spalletti[4], S. Matà[5]

[1]Department of Neurology, University of Florence (Firenze); [2]Molecular Medicine, IRCCS Fondazione Stella Maris (Pisa); [3]Diagnostic Genetics Unit, Azienda Ospedaliero-Universitaria di Careggi (Firenze); [4]SODc Neurophysiopathology, Department of Neuromusculoskeletal and Sensory Organs, Azienda Ospedaliero-Universitaria di Careggi (Firenze); [5]Department of Neurological and Psychiatric Sciences, Azienda Ospedaliero-Universitaria di Careggi (Firenze)

Objectives: Charcot Marie Tooth disease (CMTD) type 2T is an axonal motor and sensory neuropathy characterized by adult onset of slowly progressive distal muscle weakness and sensory impairment. CMTD2T patient harbour mutations of the gene for the membrane metalloendopeptidase (MME), also called neprilysin or CD10, a transmembrane protein with a wide spectrum of substrates and physiological functions. CMT2T is a recessive disease; however dominant MME variants with incomplete penetrance have also been reported. Here we describe a small case series of patients with neuropathy associated with biallelic and monoallelic MME mutations.

Material and Methods: All the cases diagnosed at AOU Careggi affected by polyneuropathy with a MME mutation were reviewed. Demographic, EMG, laboratory, and clinical data were examined. All the patients alive gave informed consent to the study.

Results: We included 8 patients (6 females) in 6 families, 4 with biallelic and 4 with monoallelic MME mutation. Two patients were siblings and two were related (mother and daughter); altogether we found 6 different MME mutations. The mean age at disease onset was 56.5 years, younger among patients with homozygous mutations (51) as compared with those with heterozygous mutations (62). In all the cases the EMG examination disclosed a length-dependent prevalently axonal polyneuropathy, though the conduction velocities were also markedly reduced in all but 1 case. Mean CMT neuropathy score at last examination was 13, without differences among the two groups. Seven patients

were also affected by one or multiple autoimmune conditions (multiple sclerosis, celiac disease, Sjogren syndrome, anti-GAD associated epilepsy, Hashimoto thyroiditis, etc) and two had an IgG monoclonal gammopathy. Three patients had been previously diagnosed with other disorders (motor neuron disease, inflammatory polyneuropathy, compressive radiculopathy).

Discussion: Our data confirm the older age at onset of CMT2T with heterozygous mutations; however, contrary to what observed by others, the severity of the disease did not differ between patients with heterozygous and homozygous mutations. Interestingly, all the patients were affected by autoimmune diseases and/or monoclonal gammopathy, which could result from a dysfunction of the immune system as the result of the MME/CD10 gene mutation. Further studies are needed, however, to clarify this hypothesis.

Conclusion: Our data contribute to the knowledge of hereditary neuropathies with late and very late onset. We hope to encourage a collaborative multicenter Italian study on MME mutations.

## MELANOMA-ASSOCIATED CHRONIC INFLAMMATORY DEMYELINATING POLYRADICULONEUROPATHY: MORE THAN MEETS THE EYE

R. Tiberi[1], G. Carlini[2], E. M. Costantini[3], M. Coccia[3], M. Silvestrini[2], S. Luzzi[2]

[1]Neurological Clinic, NeMO-Ancona, Clinical Center for Neuromuscular Diseases, Marche Polytechnic University (Ancona); [2]Neurological Clinic, Marche Polytechnic University (Ancona); [3]NeMO-Ancona, Clinical Center for Neuromuscular Diseases, Ospedali Riuniti di Ancona (Ancona)

Introduction: Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) is a rare acquired immune-mediated peripheral neuropathy characterized by demyelination, generally responsive to immunosoppressive/immunomodulatory treatment. It can occur independently or in association with other diseases, including malignancies. We present an unusual case of a CIDP preceding a metastatic melanoma diagnosis.

Case report: A 54 years-old man presented with lower limbs paresthesias followed by bilateral weakness, to the point that he was unable to walk. Neurologic examination showed a moderate tetraparesis, diffuse paresthesias and unevokable deep tendon reflexes in the lower limbs. His medical history was unremarkable, except for a recent trip in the Philippines. A whole spine gadolinium-enhanced MRI showed cauda equina roots' hyperintensity, and EMG/ENG showed a sensorimotor demyelinating polyradicoloneuropathy; subsequently, a lumbar puncture was performed, with increased protein and normal glucose levels, 10 cells, a negative microbiological exam (including Borrelia, Flavivirus and Leptospira) and a damaged blood-brain barrier. Anti-MAG antibodies were positive, with a titer of 1:80, and so were anti-GD1A-IgG: anti-CASPR1, anti-contactin-1 and anti-neurofascin antibodies were negative. IVIG were administered for six days with unsatisfactory results. Methylprednisolone was then administered for five days, followed by five plasmapheresis procedures: a modest but temporary benefit was appreciated. Two chest-abdomen contrast-enhanced CT scans were performed in two months, the second of which showed an axillar lymphadenomegaly that revealed itself to be a melanoma metastasis. A dermatological examination found no lesion, while a global 18-FDG PET-scan showed a rectal and prostatic captation.

Discussion: When talking about paraneoplastic peripheral nervous system syndromes, there is a flourishing literature about hematological malignancies (mostly lymphomas), but fragmentary informations regarding solid tumors [1]. Melanoma-related CIDP has been described mainly in case reports, in contrast to the one associated with immunotherapy and immune-checkpoint inhibitors, the mainstay of this tumor treatment [2]. This case shows one of the possible diagnostic pitfalls in CIDP. The recent travel has initially led to speculations about a parainfectious etiopathogenesis, but a thorough investigation finally revealed the concomitant malignancy. Moreover, anti-MAG and anti-GD1A antibodies positivity, a potential confounding element, can be seen as a molecular mimicry phenomenon in an autoimmune arousal [3].

Conclusions: Although classically linked to other malignancies, melanoma must be considered in the CIDP diagnostic workup. Dermatological examination and stadiation with CT/PET scans are therefore required, especially when there is an unsatisfying response to IVIG and plasmapheresis. Unfortunately, there is insufficient evidence to determine whether this paraneoplastic syndrome correlates with a different prognosis or with peculiar electrophysiological and immunologic features.

## CLINICAL AND ELECTROPHYSIOLOGICAL CHARACTERIZATION OF IGM-ASSOCIATED POLYNEUROPATHY, WITH OR WITHOUT ANTI-MAG ANTIBODIES: A CROSS-SECTIONAL STUDY

D. Tornabene[1], G. Cosentino[1], M. Todisco[2], G. Tammam[1], E. Antoniazzi[2], M. Gastaldi[2], S. Scaranzin[2], C. Morandi[2], R. De Icco[1], M. Corrado[1], V. Grillo[2], M. Varettoni[3], C. Cavalloni[3], E. Vegezzi[2], E. Marchioni[2], L. Diamanti[2]

[1]Department of Brain and Behavioral Sciences, University of Pavia (Pavia); [2]IRCCS Mondino Foundation (Pavia); [3]Hematology Unit, IRCCS Policlinico San Matteo Foundation (Pavia)

Objectives: Clinical and instrumental assessment of a population with paraproteinemia-associated polyneuropathy, with or without serum reactivity to myelin-associated glycoprotein (MAG-Ab+/-).

Materials: We included 28 subjects (21 males, 7 females) with diverse haematologic diagnosis (MUGS: 18, Waldenstrom macroglobulinemia: 8, lymphoplasmacytic lymphoma: 1, non-Hodgkin B lymphoma: 1). Average age is 72.5 years (52-90). Average polyneuropathy duration is 9.3 years (1.2-22). Fifteen subjects received rituximab, one received cyclophosphamide, five received high-dose corticosteroids, one underwent periodic IvIg infusions for two years and two additional subjects were taking long-term oral corticosteroids because of concomitant rheumatological diseases.

Methods: Participants underwent MAG-Ab determination, clinical and disability evaluation (including mRS, ONLS, BERG, IRODS), extensive electrodiagnostic (EDX) testing including Terminal Latency Index (TLI) and modified F-ratio (mFR) determinations [1]. Additionaly, Quantitative Sensory Testing (QST) and, in a subset of 19 subjects, a force platform computerised balance assessment were performed.

Results: Twenty-eight subjects were MAG-Ab+. Clinically, polyneuropathy presented with distal symmetric reduced sensitivity (89%), paresthesia (61%), pain (21%), impaired gait/balance (57%), postural tremor (57%), muscle weakness (36%), cramps (57%). Eleven subjects (46%) reported some disability (mRS ≥2), 4 (14%) used walking aids and one (3,6%) was wheelchair-restricted. MAG-Ab+ subjects did not show significantly different disability than MAG-Ab- (mRS ≥2 in 50% vs. 40%; BERG score <45 in 33% vs. 30%; mean IRODS score 36,7 vs. 33,2, respectively). On EDX, eleven subjects had a predominantly axonal polyneuropathy (2 MAG-Ab+, 9 MAG-Ab-) and seventeen a predominantly demyelinating polyneuropathy (16 MAG-Ab+, 1 MAG-Ab-). All demyelinating polyneuropathies appeared symmetric, and nine showed a prominent distal involvement with at least one TLI <0.25 (including the MAG-Ab- case); TLI was not assessable due to severe impairment of different motor nerve responses (CMAP not elicitable) and/or median nerve entrapment at wrist in six patients. Two additional MAG-Ab+ cases showed an ulnar mFR >3.25, suggestive of proximal demyelination, together with TLI reduction. Spontaneous activity was recorded in distal muscles in eight cases (4 MAG-Ab+, 4 MAG-Ab-).

Discussion: Consistently with literature, MAG-Ab were associated with distal demyelinating and prominently sensory polyneuropathy. However, we found two MAG-Ab+ subjects with a primarily axonal neuropathy, and one IgM-associated distal symmetric demyelinating polyneuropathy without MAG-Ab. We also describe clinical and EDX evidence of relevant motor involvement. While half the patients showed some disability, only a few displayed severe mobility impairments.

Conclusions: The study outlines the heterogeneous peripheral nerve involvement in IgM paraproteinemia. QST, stabilometry and a twelve-months follow-up will provide additional insights.

## NOT JUST A LAZY TEEN: A CASE OF A REVERSIBLE NEUROMUSCULAR CONDITION

G. Urbano[1], G. Gadaleta[1], L. Chiadò-Piat[1], S. Boschi[1], L. Vercelli[2], T. Mongini[1]

[1]Neuromuscular Unit, Department of Neurosciences "Rita Levi Montalcini", University of Turin (Torino); [2]Neuromuscular Unit, Department of Neurosciences "Rita Levi Montalcini", AOU Città della Salute e della Scienza di Torino (Torino)

Objective: Highlight the importance of considering rare treatable neuromuscular conditions, such as lipid myopathies, among the differential diagnosis of weakness and fatigue.

Materials: Medical history, laboratory tests, imaging, muscle biopsy workout.

Methods: Review of the patient's history, clinical assessments, laboratory tests, and therapy.

Results: We report a case of a 17-year-old woman who accessed the ER for a 4-month progressive severe fatigability and myalgias, exacerbated by physical activity. Family and personal history were not relevant, apart from a long-standing refusal to practice sports, with a request for exemption from physical education at school and psychological support for depressive symptoms. No chronic medications were assumed. Previous cardiological assessments with echocardiography and ECG had resulted normal. All lab tests were normal, except for elevated CK (2769 UI/L). At neurological examination proximal girdle weakness, lumbar hyperlordosis, and waddling gait were observed. Thyroid tests, immune-rheumatological screening, neuromuscular junction antibodies, myositis-specific and myositis-associated antibodies tested negative; a lower limbs muscle MRI showed hyperintensities in STIR and T1 sequences in the thighs, significant for edematous areas and initial fibro-fatty substitution. After 21 days, a quadriceps muscle biopsy excluded an inflammatory myopathy, showing a diffuse, marked lipid accumulation in myofibers. The acylcarnitine profile on DBS confirmed an increase of the C8-C18 chains and the organic acid profile was altered (organic aciduria). Even though a genetic diagnosis was not available yet, the clinical signs and the laboratory findings suggested a diagnosis of Multiple Acyl-CoA Dehydrogenase Deficiency. The patient, therefore, started supplementary therapy with riboflavin, carnitine, and ubidecarenone with significant benefits to her condition. At neurological re-evaluation, after 3 months, neither myalgias nor fatigue were reported, and a clear improvement in proximal strength was observed.

Discussion: Lipid myopathies are characterized by a spectrum of clinical manifestations varying from severe infantile forms to paucisymptomatic adult-onset conditions, due to defects of mitochondrial fatty acid transport or metabolism [1]. In milder forms, hyperckemia and/or limitation in physical activity may be the only signs, whose timely detection may reduce the diagnostic delay and allow a prompt effective therapy.

Conclusions: Common non-specific symptoms such as fatigue and myalgias in teenagers might hide underestimated conditions. Although rare disorders, the presence of neuromuscular red flags should prompt further investigations. In this case, the patient recovered after a rapid laboratory and histological diagnosis and appropriate treatment [2,3]. Muscle biopsy may represent a faster tool for investigating neuromuscular treatable conditions than genetic assays, especially in differential diagnosis of seronegative inflammatory myopathies.

## DIAGNOSTIC COMPLEXITIES IN TWO FAMILIES WITH DESMINOPATHY

G. Vadi[1], F. Torri[1], M. Rende[1], G. Ali[2], A. Torella[3], F. Baldinotti[4], V. Nigro[3], G. Cenacchi[5], G. Ricci[1], G. Siciliano[1]

[1]Department of Clinical and Experimental Medicine, University of Pisa (Pisa);[2]Department of Surgical, Medical, Molecular Pathology and Critical Area, University of Pisa (Pisa); [3]Department of Precision Medicine, University of Campania "L. Vanvitelli" (Napoli); [4]Department of Laboratory Medicine, University of Pisa (Pisa); [5]Department of Biomedical and Neuromotor Sciences, University of Bologna (Bologna)

Introduction: Mutations in the desmin gene (DES) produce a variety of myopathic phenotypes including myofibrillar myopathy and limb-girdle muscular dystrophy, cardiomyopathy, ventricular arrhythmia and/or cardiac conduction disease including atrioventricular blocks. Desminopathies are often characterized by the presence of intracellular accumulation of desmin aggregates and their inheritance is typically autosomal dominant. We describe two families of desminopathy carriers presenting different clinical features. Family 1: A 54 y.o. man came to our attention for a history of myalgias and weakness in lower limbs. Notably, his brother and mother were followed by the Neurology Unit

of our hospital for a diagnosis of distal myopathy associated to the c.1280A>T variant in DES gene, predicted to be pathogenic through a splicing alteration. His muscle MRI showed slight oedema of right posterior leg. At muscle biopsy we observed several subsarcolemmal basophilic aggregates and the ultrastructural examination confirmed a pattern consistent with a myopathy likely to be classified as a myofibrillar myopathy. Surprisingly, a first genetic testing with NGS study of DES gene failed to identify any variant. Immunohistochemical analysis for desmin is currently underway to better characterize the pathological findings. We are planning to repeat the desmin genetic analysis in the patient and possibly proceed with an exome sequencing. Family 2: A 47 y.o. woman presented with a 3 years history of progressive limb-girdle weakness and hyperCKemia. Her 18 y.o. son was affected by a distal myopathy with dilatative cardiomyopathy (heart transplant at 11 years of age) and myofibrillary features at the muscle biopsy. He underwent genetic analysis by NGS panel that revealed a VUS in TTN gene, also detected in the asymptomatic father. Her muscle MRI showed fatty infiltration of legs bilaterally, vastii medialis and intermedius of left quadriceps, and fatty substitution of the glutei bilaterally. Myocardial MRI revealed diffused pattern of sub-epicardial and transmural fibrosis. She needed an ICD implant in January 2022. Reanalysis in trios in the SolveRD framework unraveled a mutation in DES gene.

Conclusions: These cases highlight the challenges faced in diagnosing myopathies with a particular variability of clinical and genetic features. A comprehensive approach combining clinical, histopathological, and genetic investigations is essential for accurate diagnosis, appropriate management, and genetic counseling in affected individuals and their families.

## A CASE OF DROPPED HEAD SYNDROME CAUSED BY TREATMENT WITH AN IMMUNE CHECKPOINT INHIBITOR

G. Verrini[1], E. Pronello[1], M. Burlone[2], G. Strigaro[1], L. Mazzini[1], M. Pirisi[2], D. Vecchio[3], R. Cantello[3]

[1]Neurology Unit, Department of Translational Medicine, Maggiore della Carità Hospital, University of Piemonte Orientale (Novara); [2]Medicine Unit, Department of Translational Medicine, Maggiore della Carità Hospital, University of Piemonte Orientale (Novara); [3]Neurology Unit, Department of Translational Medicine, Department of Health Sciences, Interdisciplinary Research Center of Autoimmune Diseases (IRCAD), University of Piemonte Orientale (Novara)

Introduction: Immune checkpoint inhibitors (ICI) are monoclonal antibodies increasingly used in cancer immunotherapy. By blocking down-regulators of the immune system, ICI could trigger neurological adverse events [1]. Only few cases of myositis and/or myasthenia gravis have been presented with Atezolizumab, an ICI targeting the protein programmed cell death-ligand 1 (PD-L1) [2].

Material and Methods: We present an 82-year-old Italian male with recurrence of multifocal hepatocarcinoma treated with hepatectomy and radiotherapy one year before, and then started on Atezolizumab plus Bevacizumab (inhibiting vascular endothelial growth factor A). After 3 cycles of the PD-L1 inhibitor, he suddenly developed shoulders and neck pain with mild proximal symmetrical limb weakness and, after few days, severe head-drop, cingular myalgia and mild dysphagia. Blood tests showed elevated serum creatine kinase levels without myositis, acetylcholine receptor and muscle-specific kinase antibodies. Electromyography and repetitive nerve stimulation test showed acute myopathic suffering of the cranial and cingular district. Myocardial involvement was excluded.

Results: We concluded for immune-related myositis involving neck and upper cinguli muscles. At first he was treated with high-dose intravenous steroids for 3 days with benefit limited to myalgia and, then, with intravenous immunoglobulins with almost complete resolution of the muscle deficits, at that time the CK level normalised. On follow-up, a month later, he reported a minimal weakness of the head extension in orthostatic position. Unfortunately, the abdominal follow-up showed disease progression and no further anticancer therapy was started. To prevent any muscle worsening, we restarted a low dose oral steroid, as maintenance therapy.

Discussion: Neurologic Toxicity of ICI includes weakness of proximal limbs, ptosis, dropping head and cervical extensor muscle weakness. Few cases of proximal weakness and dysphagia are described with Atezolizumab [2;3]. A systematic review of 18 RCTs showed an incidence of 0.38% for myositis in patients treated with ICI. Most patients received glucocorticoids, half of them IVIG and some received immunosuppressants with recovery of myositis in 68% of patients [2]. Our patient had ameliorated with IVIG, but low dose oral steroids were used as maintenance treatment. He recovered from his muscular condition that was severely affecting his quality of life.

Conclusions: We herein report a case of dropping head syndrome associated to Atezolizumab. This is an atypical presentation of an uncommon immune-related adverse event of PD-L1 inhibitors. Early recognition and proper treatment of muscle involvement could improve quality of life. Although there is no defined therapeutic protocol, our case mostly responded to IVIG.

## SERUM NEUROFILAMENT LIGHT CHAIN AS A BIOMARKER IN INFLAMMATORY DEMYELINATING POLYNEUROPATHIES: A SINGLE CENTER STUDY

F. Vitali[1], M. Sciarrone[2], A. Romano[1], V. Guglielmino[1], M. Luigetti[1]

[1]Neurology Institute, Agostino Gemelli IRCCS University Hospital Foundation (Roma); [2]Department of Neurosciences, Catholic University of the Sacred Heart (Roma)

Introduction: As axonal damage leads to the release of neurofilament light chain (NfL) into the cerebrospinal fluid (CSF) and plasma, NfL has recently been recognized as a diagnostic and prognostic biomarker of different central and peripheral neurodegenerative disease such as Alzheimer disease and amyotrophic lateral sclerosis. In the last years, different studies investigated the role of serum NfL (sNfL) as a biomarker of peripheral inflammatory neurological disease, such as chronic inflammatory demyelinating polyneuropathies (CIDP).

Methods: We collected the serum samples of adult patients with a probable or definite CIDP diagnosis and we measured the NfL concentration with ELLA system. Demographic, clinical and therapeutic data were available in electronic medical records. To evaluate the disability rate, we used modified Rankin Scale (mRS) and Overall Neuropathy Limitations Scale (ONLS) in its total, leg and arm sections.

Results: A total of 32 patients with CIDP were included in this study and most of them were on treatment at the time of sample collection. In our cohort, sNfL tended to be non-significative higher in patients with relapsing-remitting course (6/32) compared to chronic progressive course (26/32). Even if median sNfL levels resulted higher in patients with severe disability (mRS 4-5) than no, mild or moderate disability (mRS 0-3), no significant difference emerged. Similarly, no correlation was demonstrated between sNfL levels and ONLS score.

Conclusion: With this single-center retrospective study, we did not demonstrate any association between sNfL concentration and disability level or disease course in CIDP patients. Considering the limitations of this study (the small number of participants, the lack of treatment-naïve patients and the absence of subsequent sNfL dosage after the baseline), we can assume that these results are compatible with the efficacy of ongoing therapies and the lower entity of axonal damage characterizing inflammatory demyelinating diseases compared to neurodegenerative disorders.

## IMMUNE-MEDIATED SENSORY POLYRADICULONEUROPATHY AND ATYPICAL CORTICOSTEROID RESPONSE

M. Vitiello[1], A. Di Lionardo[2], R. Infante[2], F. Bianchi[2], L. Mancinelli[2], M. Longoni[2]

[1]Neurology Unit, "M. Bufalini" Hospital, AUSL Romagna, Alma Mater Studiorum (Cesena, Bologna); [2]Neurology Unit, "M. Bufalini" Hospital, AUSL Romagna (Cesena)

Objectives: Immune-mediated purely sensory polyradiculoneuropathy is recognized as a variant of CIDP. Caution should be exercised treating it with high doses of steroids as an adverse outcome is possible.

Materials and Methods: A 56-year-old female was admitted to our Department because of 18-month history of progressively worsening numbness and paresthesia in hands and feet and impaired balance. Neurological examination revealed decreased pin-prick and touch sensation in stocking-glove distribution, reduced vibration and joint position sense and areflexia. Muscle strength and cranial nerves were normal. The gait was wide-based and Romberg's sign positive.

Results: Electroneurography (ENoG) showed normal motor nerve parameters and reduced amplitude of all sensory nerve action potentials (SNAPs). Cerebrospinal fluid (CSF) examination showed an increased protein level (1,88 g/L) and a normal number of white blood cells supporting a albumino-cytologic dissociation. CSF polymerase chain reaction (PCR) for viruses and microscopic and coltural exams for bacteria, fungi and BK yielded a negative result. All blood exams (thyroid function tests, protein electrophoresis and immunofixation, vitamin B12, Treponema, Borrelia, HIV, autoimmune and paraneoplastic screening) were negative. No anti-ganglioside, anti neurofascin, anti contactin-1, anti caspr-1, anti sulfatide and anti MAG antibodies were detected. Chest and abdomen computed tomography scans showed a focal portal vein thrombosis. Magnetic resonance imaging (MRI) of the lumbar spine showed enlargement and enhancement of lumbar nerve roots.

Discussion: Considering the immune-mediate genesis, we primarily discarded plasmapheresis and intravenous immunoglobulins because of venous thrombosis; a bolus methylprednisolone (1 g/day for 5 days) was started. Since the fourth infusion, the patient began to present a drastic worsening of the pre-existing symptoms and a drammatic muscle weakness, including the cranial district. The EnoG now showed absence of all SAPs and of F-waves and diffuse reduction of motor conduction velocities nerve suggesting a demyelinating sensori-motor neuropathy. The patient was treated with plasmapheresis, which was not tolerated because of an abrupt hypotensive drop. We started intravenous immunoglobulins (IVIG – 0,4 g/kg/day for 5 days) with a gradual recovery. After discharge, she performed a nerve biopsy which confirmed CIDP diagnosis.

Conclusions: According to the criteria of the European Federation of Neurological Societies/Peripheral Nerve Society our case should be considered as atypical CIDP. In most cases, pure sensory neuropathy is a condition considered idiopathic. As the pure motor CIDP, an unfavorable response to steroid treatment in some cases of sensory CIDP is possible, suggesting to exercise caution when treating these cases with high dose steroids.

## ATYPICAL PRESENTATION OF HEREDITARY TRANSTHYRETIN AMYLOIDOSIS

D. Zoppi[1], S. Tozza[1], G. Palumbo[1], E. Cassano[1], F. Masciarelli[1], R. Iodice[1], L. Ruggiero[1], G. Palmiero[2], G. Limongelli[2], F. Manganelli[1]

[1]Department of Neurosciences, Reproductive Sciences, and Odontostomatology, University of Naples "Federico II" (Napoli); [2]Inherited and Rare Cardiovascular Diseases, Department of Translational Medical Sciences, University of Campania "Luigi Vanvitelli", Monaldi Hospital (Napoli)

Objectives: Hereditary Transthyretin Amyloidosis (hATTR) is a rare and progressive disease caused by a mutation in TTR gene. The peripheral nervous system involvement in late onset hATTR is characterized by disabling axonal sensory-motor length-dependent neuropathy, whereas cardiac involvement is characterized by hypertrophic cardiomyopathy with preserved ejection fraction. However, hATTR amyloidosis represents a diagnostic challenge for neurologists considering the great variability in clinical presentation. Here we report a hATTR case with atypical cardiological presentation.

Materials: A 68-year-old male patient suffering from dilatative cardiomyopathy (ejection fraction <28%, interventricular septum =9 mm) was referred to our Neurophysiology Unit for a one-year history of tingling at feet.

Method: Neurological examination revealed reduced tactile and pinprick at lower limbs and reduced distal deep tendon reflexes in the upper limbs and absent in the lower limbs. Nerve conduction study showed a sensory-motor multi-neuropathy and extensive laboratory workout was carried out to exclude more common acquired conditions of sensory-motor neuropathy. Meanwhile, he had undergone bone scintigraphy for a suspected foot stress fracture that unexpectedly demonstrated diffusely increased tracer uptake in the heart (Perugini score 3).

Results: Therefore, TTR genetic analysis was performed and Val-30Met mutation was detected. Therefore, he started treatment with Tafamidis 61 mg.

Discussion: Early diagnosis of hATTR is already challenging but becomes even more when hATTR presents with atypical phenotypes. In such case cardiac amyloidosis incidentally was detected by bone scintigraphy as dilated cardiomyopathy was certainly misleading. Also, he initially showed a multi-neuropathy pattern although it later evolved into a poly-neuropathic pattern, as emerged from the follow-ups.

Conclusions: However, though cardiac phenotype of hATTR usually presents as a restrictive or hypertrophic cardiomyopathy, rarely dilated cardiomyopathy has been described as well. In addition, a large variability of the electrophysiological tests is possible.

## NEURO-ONCOLOGY

### ELECTRO-CLINICAL, NEUROIMAGING FEATURES AND NEUROPATHOLOGICAL CHARACTERIZATION OF POLYMORPHOUS LOW-GRADE NEUROEPITHELIAL TUMOR OF THE YOUNG (PLNTY)

E. Anghileri, G. Didato, F. Deleo, F. Doniselli, M. Moscatelli, M. Rizzi, R. Paterra, M. De Curtis, M. Farinotti, E. Freri, S. Esposito, B. Pollo, A. Silvani, G. Marucci

Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano)

Introduction: Polymorphous low-grade neuroepithelial tumor of the young (PLNTY) as classified by 2021 WHO Central nervous system classification. It is an epileptogenic tumor, affecting young age, with peculiar radiological, and pathomolecular features [1, 2]. Only 52 cases of PLNTY have been described up to now. Besides typical morphological features, molecular profiling showed the evidence of BRAFV600E mutation and fusions involving FGFR2 and FGFR3 [2]. Herein, we describe 13 patients in an extensive approach.

Material and Methods: We selected patients affected by PLNTY based on data extraction from the FONDAZIONE IRCCS ISTITUTO NEUROLOGICO CARLO BESTA (FINCB) Cancer Registry (Apr 2017-Apr 2022) and on the histological review of 87 epileptic tumors (2017-2022). For the 13 identified PLNTY, we retrospectively collected history, electro-clinical (EEG and VEEG), neuroimaging and histo-molecular data. and high-resolution (1.5 or 3 T) IDH1/2, BRAF (V600E) sequencing, Kiaa1549::BRAF, FGFR3::TACC3, FGFR2::KIAA1598 and FGFR2::CTNNA3 fusion analyses was performed.

Results: We describe 13 patients, aged around 20.6 years (12.3-46.4). Most patients suffered from different degrees of epilepsy, mostly focal and some drug-resistant before surgery. Most of the patients showed any type of memory/executive impairment. The main feature of seizures was a difficult localization and even lateralization. Post-surgical seizure control was excellent. The tumors (n=11/13 temporal) presented as solid or solid-cystic cortical mass; calcifications were present in 4, and cyst in 6 cases. Microscopically the tumors showed infiltrative growth pattern, oligodendroglial-like cells. Malformation of cortical development was associated to the PLNTY in 2 cases. BRAF V600E mutation was detected in n=3 out of 7 cases, and FGFR3 fusion in n=5 out of 11 analyzed cases.

Conclusions: This study significantly extends the number of reported PLNTY. The electro-clinical data of our patients were characterized by bilateral interictal epileptiform discharges (IEDs) and difficult to lateralize seizures, both from the clinical and the electroencephalographic point of view. MRI features of the lesions were not homogeneous. PLNTY may present focal cortical dysplasia (n=2) and exhibit a tendency to develop extended epileptic networks. PLNTY, despite its name, occurs also in adult, and electro-clinical and radiological diagnosis can be challenging. As recently described, PLNTY can show the MAPK pathway activating alterations. The role of these mutations in the evolution of the disease need to clarify further.

Immune effector cell-associated neurotoxicity syndrome (ICANS) is a well-known complication after CAR-T therapy that may range from mild encephalopathy to coma or death due to fulminant diffuse cerebral edema (FCE). FCE is the most extreme neurological complication after CAR T-cell therapy: it occurs with a rapid neurological deterioration which typically lead to brain death within 24 hours. Hereby, we describe a case of CAR-T related FCE successfully treated with intensive neuro-intensive support in addition to immunosuppressive therapy. The patient is a 55-year-old woman suffering from follicular non-Hodgkin lymphoma infused with axicabtagene-ciloleucel. Prophylaxis with levetiracetam was administered. After CAR T-cells infusion, she developed a grade I Cytokine Release Syndrome (CRS) treated with tocilizumab (day+2) and steroids (methylprednisolone MPS, 1 mg/kg/q12h; day+4). Twenty hours later (day+5), she acutely developed headache and vomiting,

becoming comatose within few hours. Despite a normal brain-CT, FCE was suspected and high-dose-MPS (1000 mg/q12h), Anakinra (100 mg/q12h) and Siltuximab (11 mg/kg, single-dose) was promptly started. Intraparenchymal pressure monitor showed an initial ICP value of 45 mmHg. A stepwise management of ICP was started including hyperventilation, 30°elevation, hypertonic solution, and sedation with propofol and midazolam, and then thiopental because of refractoriness. Brain-CT performed the next day showed a diffuse brain edema. Anesthetic treatment was progressively tapered targeting on ICP. At anesthetic withdraw (day+9), the patient presented with non-convulsive status epilepticus treated with phenytoin and propofol. Based on cEEG, anesthetic was gradually withdrawn and stopped again (day+13). The patient presents a full recovery without neurological impairment at discharge (day+35). Fewer than ten FCEs related to CAR-T therapy have been reported: all but one has met an inauspicious end. Diagnosis of FCE needs to be initially based on clinical suspicion only, to avoid any delay of the neurointensive approach. Management of ICP elevation should begin at initial presentation and escalated based on ICP value, which represent an important biomarker of immunological therapy response in the early days too. Reaching rapidly normal ICP value is central in management of FCE to prevent secondary brain injury, allowing time for the immunosuppressive therapy to shut down the cytokine-storm. Since no prospective studies are available, an empiric immunosuppressive strategy toward multiple molecular targets (IL-6, IL-1, steroids) was justified by the severity of clinical features. In patients treated with CAR-T therapy, signs of cerebral hypertension should alert clinician to a prompt neurointensive management in addition to immunosuppressive therapy, because they may let the poor prognosis of FCE completely reversible.

## INSIDIOUS ONSET HEMIDYSTONIA DUE TO GLIONEURONAL TUMOR OF THE RIGHT PUTAMINAL-CAPSULAR REGION, IN A 9-YEARS-OLD-MALE: A CASE-REPORT

F. Bile[1], E. Vanore[1], D. Archetto[1], G. Cinalli[2], A. D'Amico[3], M. Melone[4]

[1]Department of Advanced Medical and Surgical Sciences, University of Campania Luigi Vanvitelli (Napoli);[2]Pediatric Neurosurgery Unit, Santobono-Pausilipon (AORN) Children's Hospital (Napoli); [3]Tortorella Private Hospital (Salerno); [4]Department of Advanced Medical and Surgical Sciences, 2nd Division of Neurology, Center for Rare Diseases and InterUniversity Center for Research in Neurosciences, University of Campania Luigi Vanvitelli (Napoli)

Background: Central nervous system (CNS) tumours are the most common pediatric solid cancers and a leading cause of cancer death in children aged 0 -14 years. Glioneuronal tumours represent over 30% of pediatric CNS neoplasms.

Methods: A 9-year-old boy presented for a 2 years clinical history characterized by prolonged and painful involuntary muscle contractions of the left lower limb, exacerbated by voluntary movement, resulting in unstable gait, and gradually extending to the ipsilateral upper limb with a slowly progressive evolution.

Results: Neurological examination showed left brachio-crural choreo-dystonic movements, worsened by motor tasks and relieved by antagonistic gestures. Routine blood tests, serum ceruloplasmin, 24-hour urinary copper excretion and cupremia were normal, as were genetic tests, and microscopic examination of the peripheral blood smear showed no acanthocytes. Brain MRI showed an ovoid lesion in the right putaminal-capsular region, surrounded by mild vasogenic oedema. Signal was isointense to grey matter on T1-weighted and markedly hypointense with a small central hyperintensity on T2-weighted images. DWI showed no signal restriction except for a thin peripheral border. Due to slight inhomogeneous hyperintensity on SWI, the patient underwent CT scan which excluded the occurrence of calcifications. Spectroscopy demonstrated a moderate increase in Cho/Naa ratio. After gadolinium injection, an intense and homogeneous enhancement was observed in absence of other similar formations in both brain and spine. DSC perfusion MRI showed a 2 relative cerebral blood volume (rCBV) value compared to unaffected contralateral side.

Discussion: On MRI evidence, the patient underwent frameless stereotactic neuronavigation biopsy using Stealth autoguide® robotic arm through right precoronal hole with trajectory avoiding left cortico-spinal tract on the basis of three-dimensional diffuse tensor imaging (DTI) tractography. Histology showed glial and neuronal cells. Immunohistochemistry showed GFAP+, Olig 2+/-, chromogranin -, NeuN-, Map2a +/-, synaptophysin -/+, CD34- , H3.3K27me (conserved), Ki-67 3%, plurifocally expressed P53, concluding for glioneuronal tumour diagnosis. Finally, the patient was transferred to the MRI suite, (Philips 1.5 Tesla) and under thermographic sequence three consecutive thermal ablation points with laser interstitial thermal therapy (LITT) were performed, which covered 90% of tumour volume.

Conclusion: Approaching diagnosis and treatment of childhood chorea-dystonia is a challenging condition. For timely therapeutic intervention, it is important to exclude potentially treatable causes. Advanced Brain Neuroimaging is crucial to guide the histological diagnosis of CNS lesions and to perform less invasive surgical procedure.

## INCRESED BRAIN TOXICITY AFTER RADIOTHERAPY IN MULTIPLE SCLEROSIS

P. Bini, L. Diamanti, E. Vegezzi, M. Gastaldi, S. Ravaglia, E. Marchioni

Unit of Neurooncology and Neuroinflammation, IRCCS Mondino Foundation (Pavia)

Radiotherapy could promote exacerbations of Multiple Sclerosis (MS) as described in literature, but it seems not to be responsible for its onset. MS lesions can look like metastases or radionecrosis, therefore differential diagnosis will be fundamental. Here we discuss how the presence of MS MRI pattern could represent a confounding factor for the correct diagnosis of post attinic brain damages and possibly induce its onset. We describe the case of a 26-year-old woman treated with proton therapy for

a great condrosarcoma of Petrous rock. Several lesions consistent with MS were occasionally discovered during MRI for the diagnosis of condrosarcoma. The diagnosis of MS was made according to McDonald's criteria and relation to the lesion load, preventive treatment with beta 1A Interferon was carried out. The condrosarcoma was inoperable and underwent diagnostic biopsy only. She received proton therapy 70 Gy in 35 daily fractions. The patient well tolerated the course of the radiation, without unexpected side effects and did not develop any neurological manifestations during the treatment. Only one month after proton radiation, she presented right facio-brachio-crural pyramidal hemisyndrome with ataxia, diplopia and dizziness. The MRI revealed lesions in the brainstem, posterior arm of the right external capsule, thalamus and hypothalamus suggestive for radionecrosis. She was treated with steroid ev without particular benefit. In the following weeks she was treated with bevacizumab 5 mg/kg/ev every 21 days for 6 cycles with clinical and radiological improvement. This case is atypical due to the early onset of radiotherapy complications and for the aggressiveness of the radionecrotic lesions. In fact, one month after the end of radiotherapy represents an extremely early onset time for brain radionecrosis. Pathophysiology of radiation-induced brain injury is well known. The radiation damage involves cellular elements in the inflammatory microclimate and leads to modifications such as increase permeability of blood-brain barrier (BBB), cellular swelling and vacuolization. Damage to these structures leads to hypoxia and increase of VEGF. Recent hypotheses indicate a damage of BBB in the pathogenesis of MS. Consequently we think that in our case MS and radiotherapy could have acted synergistically in anticipating and enhancing post-actinic complications. We advise that MS patients undergoing radiotherapy should be subjected to earlier post-radiotherapy radiological checks. We also believe that the site of any demyelinating lesions should be considered before planning treatment. Perhaps patients with MS could represent ideal models to understand what predisposing conditions for radiation toxicity.

## LIQUID BIOPSY OF MYD88L265P MUTATION FOR PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA (PCNSL): A PROSPECTIVE, OBSERVATIONAL STUDY

F. Bruno[1], L. Bertero[2], S. Ferrero[3], D. Drandi[3], M. Ferrante[3], E. Pronello[4], R. Palmiero[4], A. Pellerino[4], D. Garbossa[5], R. Soffietti[2], B. Bruno[3], R. Rudà[2]

[1]Division of Neuro-Oncology, Department of Neuroscience "Rita Levi Montalcini", University and City of Health and Science Hospital, University of Turin (Torino); [2]Pathology Unit, Dept. of Medical Sciences, University and City of Health and Science (Torino); [3]Dept. of Molecular Biotechnologies and Health Sciences, Division of Haematology, University and City of Health and Science Hospital (Torino); [4]Division of Neuro-Oncology, Dept. of Neuroscience, University and City of Health and Science Hospital (Torino); [5]Division of Neurosurgery, Dept. of Neuroscience, University and City of Health and Science Hospital (Torino)

Background: Primary Central Nervous System Lymphomas (PCNSLs) harbour MYD88L265P mutations in up to 60-70% of cases. Whether detection of MYD88L265P by liquid biopsy may be accurate for the diagnosis and disease monitoring of PCNSL patients is an emerging issue. In this study we aimed to assess the feasibility of MYD88L265P detection in the cerebrospinal fluid (CSF) and blood of patients with PCNSL and validate its use as a potential marker for diagnosis.

Patients and Methods: We prospectively collected data of patients who presented at our Institution with suspected PCNSL. CSF was obtained by lumbar puncture to analyse cytology, B cells immunophenotype, and MYD88L265P mutation status. MYD88L265P mutation was analysed by droplet digital PCR (ddPCR). Chi-square test and COX regression were used for statistics correlations.

Results: From May 2016 to March 2023, 29 patients were included. Median age was 71.0 years. 11 patients (37.9%) had multifocal lesions. 13 patients (44.8%) had a positive brain FDG-PET. All patients underwent lumbar puncture at diagnosis. CSF cytology was informative in 8 patients (27.6%), and CSF immunophenotype in 11 (37.9%). 18 patients (61.1%) underwent biopsy, whereas the remaining ones did not due to elevated surgical risks. Overall, MYD88L265P mutation was detected in the CSF and blood in 18 (62.1%) and 10 (34.5%) cases, respectively. In patients undergoing biopsy, MYD88L265 mutation was assessed on tumour tissue in 14/18 (77.8%) cases and found in 13/14 (92.8%). Among 13 patients with confirmed MYD88L265P mutation on tumour tissue, 8 (61.5%) and 6 (46.1%) harboured the mutation also in the CSF and blood MYD88, respectively. The only patient with no evidence of MYD88L265P mutation on tumour tissue had also CSF and blood negative results. Interestingly, in 4/11 patients (36.4%) who did not undergo biopsy and with negative CSF cytology and immunophenotype, the presence of the MYD88 L265P mutation on the CSF allowed to confirm the diagnosis of PCNSL. The presence of multifocal lesions, FDG-PET positivity and CSF positive cytology did not correlate with CSF/blood MYD88L265P positivity. Patients with CSF MYD88L265P mutation tended to have positive CSF immunophenotype as compared to MYD88L265P-intact (50.0% vs 18.0%, $p = 0.087$). The presence of MYD88L265P mutation did not correlate with progression-free survival or overall survival.

Conclusions: In our series, the presence of the MYD88L265P mutation was found in the majority of PCNSL patients who underwent biopsy (92.8%) and was confirmed in the CSF in most positive cases (61.5%). This suggests that liquid biopsy of CSF may be helpful for PCNSL at diagnosis and – potentially – for disease monitoring during treatments. Further correlations with clinical and radiological features, outcome, and potential therapeutic implications should be investigated in next prospective studies.

## SEIZURE OUTCOME ACROSS DISEASE TRAJECTORY IN IDH-MUTANT GRADE 2 GLIOMAS: WHICH IS THE IMPACT OF STANDARD ANTINEOPLASTIC TREATMENTS?

F. Bruno[1], A. Pellerino[2], M. Conti Nibali[3], E. Pronello[2], L. Bertero[4], D. Garbossa[5], L. Bello[3], R. Rudà[2]

[1]Division of Neuro-Oncology, Department of Neuroscience "Rita Levi Montalcini", University and City of Health and Science Hospital, University of Turin (Torino); [2]Division of Neuro-Oncology, Department of Neuroscience "Rita Levi Montalcini", University and City of Health and Science Hospital (Torino); [3]Neurosurgical Oncology Division, Department of Oncology and Hemato-Oncology, University of Milan (Milano); [4]Pathology Unit, Dept. of Medical Sciences, University and City of Health and Science Hospital (Torino); [5]Division of Neurosurgery, Dept. of Neuroscience "Rita Levi Montalcini", University and City of Health and Science Hospital (Torino)

Introduction: Most patients with IDH-mutant grade 2 gliomas suffer from seizures. Recently, the INDIGO trial showed that vorasidenib prolonged progression-free-survival (PFS) and time-to-next-intervention in IDH-mutant grade 2 glioma patients after surgery. We aimed to

identify which factors influence seizure-control in patients with similar characteristics of those of the INDIGO trial.

Patients and Methods: We retrospectively collected data of non-enhancing IDH-mutant grade 2 glioma patients (as per WHO-2021) who presented with seizures and evaluated seizure-freedom at 2 months after surgery, 6 months from starting either observation or adjuvant treatments, at recurrence, and 6 months after treatment of recurrence.

Results: Ninety-five patients were included. Oligodendrogliomas IDH-mutant/1p19q-codeleted grade 2 were 69 (72.6%), astrocytomas IDH-mutant grade 2 were 26 (27.4%). Thirty-five (36.8%) received gross-total resection (GTR). After surgery, 49 (51.6%) achieved seizure-freedom, more frequently after GTR vs non-GTR (57.9% vs 35.1%, p=0.048). Sixty-eight (71.6%) low-risk patients underwent observation, while 27 (28.4%) high-risk patients received adjuvant radiotherapy (RT) and/or chemotherapy (CT). Among the latter, 17/27 (63.0%) had persistent seizures before treatment initiation and, after 6 months, all of them displayed seizure-reduction, with 2/17 (7.4%) achieving seizure-freedom. In a multivariable analysis on PFS, ≥50% seizure-reduction (vs < 50%) after 6 months of adjuvant treatment reduced the risk of progression (HR 0.048, 0.004-0.585, p=0.017). Eighty-six (90.5%) patients recurred, and 51/86 (59.3%) displayed seizures. After 6 months of treatment of recurrence, 50/51 (98.0%) achieved seizure-reduction, with 10/51 (19.6%) reaching seizure-freedom. In a multivariable analysis, either CT or RT increased the probability of seizure-freedom at 6 months after recurrence (HR 5.316, 1.582-17.869, p=0.007).

Conclusion: We defined the entity of seizure-control after standard treatments throughout the disease course. Two findings are noteworthy: the prognostic importance of seizure-reduction after adjuvant treatments; the possibility to achieve seizure-control also with treatment of recurrence. This study could serve as a benchmark for a future evaluation of seizure-control after IDH inhibitors.

## USE OF VISMODEGIB IN ADULT PATIENTS WITH NEOPLASTIC MENINGITIS FROM SONIC HEDGEHOG (SHH)-ACTIVATED MEDULLOBLASTOMAS: A CASE REPORT

F. Bruno[1], A. Pellerino[1], E. Marchesani[1], B. Raschio[1], M. Borgognone[1], E. Pronello[2], L. Bertero[3], M. Levis[4], R. Rudà[1]

[1]Division of Neuro-Oncology, Department of Neuroscience "Rita Levi Montalcini", University and City of Health and Science Hospital, University of Turin (Torino); [2]Neurology Unit, Dept. of Translational Medicine, University of Eastern Piedmont (Novara); [3]Pathology Unit, Dept. of Medical Sciences, University and City of Health and Science Hospital (Torino); [4]Division of Radiotherapy, Dept. of Oncology, University and City of Health and Science Hospital (Torino)

Background: Vismodegib is a SHH-inhibitor that proved to be effective in locally-recurrent SHH-activated medulloblastoma. However, whether vismodegib is effective in case of neoplastic meningitis (NM) as well has not been assessed so far. Here, we present a case of a patient with NM from SHH-activated medulloblastoma who showed a dramatic response to vismodegib.

Case Report: A 34-year-old patient was diagnosed with a SHH-activated cerebellar medulloblastoma in 2015. He underwent gross-total resection, cranio-spinal radiotherapy (RT) and 5 cycles of lomustine, vincristine and cisplatin. Then, he remained disease-free until October 2021, when the MRI showed a new single contrast-enhanced nodule in the spine (T10), which was treated with stereotactic RT. However, the following MRI showed a diffuse leptomeningeal involvement, with new multiple linear and nodular lesions. The CSF cytology confirmed the presence of neoplastic cells. Therefore, in April 2022 vismodegib (150 mg daily) was started. The treatment was well tolerated, except for increased creatine phosphokinase (CTCAE v3.0 grade 1). After only 2 months of therapy, a reduction of the meningeal enhancement was seen on MRI, and after 4 months all nodular and linear lesions disappeared. Similarly, CSF cytology became negative after 4 months of treatment. However, after 8 months of treatment (December 2022), the MRI of the spine showed the new appearance of meningeal contrast-enhanced lesions, and CSF cytology confirmed the presence of neoplastic cells. Therefore, vismodegib was dismissed. In few days, the patient (who did not have any symptoms so far) developed severe meningeal symptoms, and palliative care was started, until his death in February 2023.

Conclusions: To our knowledge, this is the first report of an adult patient with NM from SHH-activated medulloblastoma achieving a complete response with vismodegib, even if temporary. Data from larger series are needed to confirm the effectiveness and safety of vismodegib in case of leptomeningeal spread.

Introduction: Esthesioneuroblastoma (or ENB), or olfactory neuroblastoma, is a rare malignant neoplasm of ectodermal origin originating from the olfactory neuroepithelium with neuroblastic differentiation and involving the sinonasal tract. It constitutes about 2% of all sinonasal neoplasm and presents and incidence of 0.4 per million population. A mild female predominance has been found in various studies. A bimodal age distribution has been described, with two peaks of age (30-50 years the first one, the seventh decade the second one). Three staging systems have been proposed: Hyams, Kadish, Dulguerov. The prognosis of EBN is both stage- and grade-dependent. 1700 cases in the world have been reported. We report the case of a 81 years –old Caucasian woman with mild neurological symptoms who was diagnosed with esthesioneuroblastoma.

Materials and Methods: She was evaluated due to persistent diplopia in primary position associated with stuffy nose and hyposmia gradually worsened in the previous sixth months. She denied recent viral infection, epistaxis, facial pain, excessive lacrimation or headache and her medical history was unremarkable. Neurological examination resulted normal (in particular ocular movements) despite diplopia in primary position. No cervical lymphadenopathy was seen.

Results: She performed brain computer tomography and brain magnetic resonance imaging showing a tumor of anterior cranial fossa hypointense to gray matter on T1-weighted images and hyperintense on T2-weighted sequences with diameter of 2.4 cm x1 cm x 1.8 cm, associated with fronto-orbital vasogenic edema, focal erosion of lamina papyracea and calcifications. Fronto-ethmoidal extracranial component involved presented diameters of 2 cm x 1.8 cm x 1.4 cm. Cervical magnetic resonance imaging resulted negative for metastases. She was sent to another center for surgical evaluation.

Discussion: We reported a case of esthesioneuroblastoma in an old Caucasian woman in good health, thus expanding existing literature.

Conclusions: In every patient, presenting with unilateral nasal obstruction with or without orbital and intracranial symptoms and signs, the diagnosis of esthesioneuroblastoma should be considered and prompt clinical and radiological evaluation should be performed.

## PARKINSONISM DUE TO MIDLINE GLIOMA: DIFFERENTIAL DIAGNOSIS AND ROLE OF DRUG THERAPY

A. Donniaquio[1], P. Gaviani[2], G. Simonetti[2], E. Aghileri[2], V. Redaelli[2], A. Botturi[2], M. Eoli[2], A. Silvani[2]

[1]IRCCS Polyclinic San Martino Hospital, Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DiNOGMI), University of Genoa (Genova); [2]Neuro-oncology Unit, Department of Clinical Neurosciences, IRCCS Neurological Institute Carlo Besta (Milano)

Objectives: Parkinsonism is an umbrella term that refers to brain conditions that cause slowed movements (bradykinesia), rigidity and tremors. The most common form of parkinsonism is Parkinson disease (PD), a chronic, progressive disorder caused by degenerative loss of dopaminergic neurons in the brain. Differential diagnoses of PD should always be considered. A wide variety of conditions can cause secondary parkinsonism. Structural causes include: normal pressure hydrocephalus, chronic subdural hematoma, tumors involving striatonigral circuits, head trauma. Movement disorders caused by brain tumors are rare. The purpose of this case report is to emphasize the importance of differential diagnosis in parkinsonism.

Materials and Methods: 58 y/o male patient presented ictal fine rest tremor in left hand and hyposthenia/rigidity of left hemisoma. Initially interpreted as an onset of PD he underwent a MRI that showed a diffuse T2/FLAIR alteration on right side of midbrain and pons with patchy and incomplete contrast enhancement. A stereotactic biopsy was performed and diagnosis of "diffuse midline high-grade glioma H3-wildtype and IDH-wildtype (P53 and GFAP negative)" was confirmed. Radiotherapy was started, and during follow-up the patient developed a worsening of clinic in term of tremor, bradykinesia and rigidity in the left limbs. Diagnosis of parkinsonism was made and Levodopa challenge test was performed.

Result: At the time point of parkinsonism's diagnosis, our patient had at MDS - Parkinson's Disease Rating Scale motor part three (MDS-UPDRS III) 30 points. He had no non motor symptoms related to PD. A initial dose of Levodopa was started without benefit. So he underwent a maintenance dose of Levodopa (400 mg daily) and antiedeman therapy (dexamethasone 6 mg daily), patient presented clinical improvement of tremor and bradykinesia with MDS-UPDRS III of 23.

Discussion: Diagnostic process for PD is complex and includes several features; presence of observable response to high-dose levodopa is an significant criteria. In this case report PD's clinical features are typical (asymmetrical parkinsonism) and he present a partial clinical improvement secondary to levodopa; but there are also two significant red flegs: ictal clinical onset and antiedema steroid therapy response. Our patient appears to have secondary parkinsonism due to diffuse midline high-grade glioma. Follow-up will be necessary to evaluate the clinical role of radiotherapy and the clinical response.

Conclusion: We emphasize the importance of neuroimaging in the onset of movement disorders, because in some cases it significantly improves prognosis and it allow to make differential diagnosis.

## ASSOCIATION BETWEEN BRAIN METABOLISM AND COGNITIVE IMPAIRMENT IN GLIOMA: A PRELIMINARY STUDY

S. Facchini[1], M. De Francisci[2], E. Silvestri[2], D. Cecchin[3], A. Bertoldo[2], M. Corbetta[1]

[1]Neurologic Clinic, Department of Neuroscience, University of Padua (Padova); [2]Department of Information Engineering, University of Padua (Padova); [3]Nuclear Medicine Unit; Department of Medicine, University of Padua (Padova)

Objectives: Brain gliomas show an altered cellular metabolism characterized by abnormally elevated glucose metabolism. The utilization of glucose can be examined in vivo through Positron Emission Tomography (PET) using fluorodeoxyglucose (18F-FDG). 18F-FDG PET imaging technique is used to characterize the tumor extent or tissue and detect the tumor recurrence/progression [1]. The link between metabolism and cognitive performance has been studied just in relation to radiotherapy [2]. The aim of this study was to investigate the relationship between regional glucose metabolism and cognitive functions in glioma.

Materials: 49 patients with glioma underwent a 60 min 18F-FDG PET imaging and, in the same session, a comprehensive neuropsychological assessment (verbal and visual memory, language, visual attention, working memory, executive functions).

Methods: Standardized glucose uptake value ratio (SUVR) was calculated, using the ipsilateral cerebellum white matter as reference, in 200 cortical parcels organized in 17 functional networks (Schaefer Atlas) and 12 subcortical and cerebellar parcels (HammersSmith Atlas). First, a Principal Component Analysis (PCA) was performed on the cognitive scores to reduce the dimensionality of the data. Then, we conducted a bivariate Spearman correlation analysis between the selected components and parcel-wise SUVR values.

Results: The PCA analysis revealed two main components explaining 57% of the total behavioral variance: PC1 loaded positively with scores reflecting overall 'cognitive performance'; PC2 loaded differentially on right (i.e., visuo-spatial attention, visuo-spatial span and working memory) vs. left hemisphere functions (i.e., verbal span and long-term memory, naming, verbal fluency). Metabolically, PC1 correlated significantly with SUVR with nearly all parcels of the left hemisphere

(r: 0.41±0,04 (mean±SD); p<0.05, FDR corrected). Specifically, PC1 correlated with parcels of the left temporo-parietal network (100% of the parcels), left central visual network (83%) and left dorsal attention network (83%). In contrast, PC2 showed a negative correlation with SUVR of right hemisphere networks (r: -0,44±0,06; p<0.05, FDR corrected), including somato-motor, control, default mode and temporo-parietal networks.

Discussion: These results reveal a well delineated pattern of correlation between cognitive performance and metabolism in glioma, which underlies a lateralization of function. Overall cognitive performance appears to positively correlate with metabolism of left-lateralized networks, while verbal memory and language functions are negatively linked to right-lateralized networks.

Conclusions: This study highlights, for the first time in literature, the role of alterations in metabolism in determining cognitive impairment in glioma patients.

## DIFFUSE MIDLINE GLIOMAS WITH H3K27M MUTATION: MONO INSTITUTIONAL EXPERIENCE

P. Gaviani, G. Simonetti, V. Redaelli, A. Botturi, M. Eoli, E. Anghileri, B. Pollo, F. Legnani, M. Marchetti, A. Silvani

IRCCS Carlo Besta (Milano)

Introduction: Diffuse midline gliomas (classified as a grade IV CNS tumor according to WHO) represent poor prognosis brain tumors that arise mainly in pediatric age, peaking between 5 and 10 years of age. However, although rarely they are also reported in adulthood, with a prognosis that remains severe even in this age group. These tumors are characterized for more than 90%, by mutations in the H3K27M protein. Due to the lack of adequate literature, the classification, epidemiologic, radiographic and clinical features still remain debated, especially in adults. Most cases are managed with surgery, radiotherapy and drugs. However, due to localization, the role of surgery is mainly for diagnosis.

Methods: We present a case report of adult diffuse midline gliomas (age >18 years at diagnosis) operated and treated at our institution since 2016 with description of tumor and radiologic, clinical characteristics and with description of treatments performed, together with PFS and OS of the group under review.

Results and Conclusions: From January 2016 to June 2023, 15 adult patients, 8 males and 7 females aged 20-68 years (median 42 years) were operated on at our institute with histological diagnosis of diffuse midline glioma. In 6/15 cases, the lesion was located at the thalamic level, in 5/15 cases at the midbrain bulb ponto level, in three/15 cases at the level of the basal nuclei, and in one case at the dorsal intra medullary level. Fourteen/15 patients underwent brain biopsy of the lesion, only one patient underwent partial exeresis of the lesion. The post diagnostic treatment of choice was radiation treatment with combination of temozolomide either concomitant or adjuvant. The prognosis of these tumors remains severe with median OS less than one year.

## PERAMPANEL IN BRAIN TUMOR-RELATED EPILEPSY: A SYSTEMATIC REVIEW

G. Mainini[1], P. Tabaee Damavandi[1], F. Pasini[1], G. Fanella[1], G. Cereda[1], J. Di Francesco[1], E. Trinka[2], S. Lattanzi[3]

[1]Department of Neurology, Fondazione IRCCS San Gerardo dei Tintori, University of Milano-Bicocca (Monza); [2]Department of Neurology, Christian Doppler Klinik, Paracelsus Medical University (Salzburg-A); [3]Neurological Clinic, Department of Experimental and Clinical Medicine, Marche Polytechnic University (Ancona)

Aims of the study: Brain tumor-related epilepsy (BTRE) is a common comorbidity in patients with brain neoplasms and it may be either the first symptom or develop after the tumor diagnosis. Increasing evidence suggests that brain tumors and BTRE share common pathophysiological mechanisms. Glutamatergic mechanisms can play a central role in promoting both primary brain tumor growth and epileptogenesis. Perampanel (PER), which acts as a selective antagonist of glutamate α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptors, may play a role both in the reduction in tumor growth and the control of epileptiform activity. This systematic review aimed to summarize the pre-clinical and clinical evidence about the antitumor properties, antiseizure effects and tolerability of PER in BTRE.

Materials and Method: We performed a systematic literature search using MEDLINE (accessed by Pubmed), Embase, the Cochrane Central Register of Controlled Trials (CENTRAL), and the US National Institutes of Health Clinical Trials Registry, from inception to week one of October 2022 (update on week one of February 2023). The search strategy included keywords in different combinations using Boolean operators. Duplicates, reviews, and articles in languages other than English were excluded. The risk of bias in any included clinical trial was assessed using the RoB 2 tool. This systematic review is reported according to the recommendations of the preferred reporting items for systematic reviews and meta-analyses (PRISMA) statement.

Results: Eight pre-clinical and eight clinical studies were identified. Discussion: The currently available evidence suggests that PER can be an effective and generally well-tolerated therapeutic option in patients with BTRE. In vitro studies demonstrated promising antitumor activity of PER, while no role in slowing tumor progression has been demonstrated in rat models; clinical data on the potential antitumor activity of PER are scarce.

Conclusions: Additional studies are needed to explore further the effects of PER on tumor progression and fully characterize its potentialities in patients with BTRE.

## PREDICTIVE SOCIAL FACTORS ASSOCIATED TO PLACE OF DEATH IN MALIGNANT GLIOMAS

A. Pace, D. Benincasa, V. Villani, S. Focarelli, A. Tanzilli, F. Cardone, A. Biscu, D. Alò, S. Di Felice

Neurooncology Unit, IRCCS Regina Elena Cancer Institute (Roma)

Background: Malignant gliomas (MG) are tumors affecting central nervous system (CNS) with a poor prognosis. Fast neurological decline (motor, cognitive and behavioural) causes high burden for patients and caregivers and requires specific setting of care (especially palliative care) helping patients to preserve their autonomy and assuring, in the end-of-life phase, the best care represented by dying at home with dignity that is considered in the literature an indicator of good quality of care in cancer patients.

Methods: The home care program for MG utilized in our Institution is aimed to offer palliative and supportive care during all the trajectory of disease and to facilitate death at home. To identify possible factors related with place of death, we've retrospectively investigated social and health data to discover possible factors associated with dying at home in MG patients. Every patient and caregiver/family were analyzed for many factors including sex, work, family relation, presence or absence of caregiver/family, presence of children.

Results: From January 2016 to December 2020, we've assisted at home 263 MG patients and collected complete data in 257 patients (6 patients was lost in follow-up). 174 (68%) of them were affected by Glioblastoma Multiforme (GBM) and 83 (32%) were affected by grade 3 anaplastic gliomas; 155 patients (61%) were male and 102 (39%) female. 137 patients (54%) died at home, 88 patients (34%) died in hospice and 32 patients (12%) died in hospital. Male caregivers assisted 178 MG patients of which 141 was male patients (79%); female caregivers assisted 79 MG patients of which 65 was female patients (82%) ($p<0.001$); presence of social network (family or other type) influenced positively place of death: MG patients who has social network died frequently at home respect on MG patients who didn't have social network that died frequently in hospital or hospice ($p<0.001$). No differences were found between age, sex (patient and caregiver), presence of minor children, education level, work, marital status and place of death.

Discussion: In this cohort of MG patients followed with a palliative home care service, place of death and dying with dignity is influenced by presence of social network and reliable caregiver. The evaluation social data in addition to clinical data is an important factor in order to plan timely the end-of-life phase and the decisions about possible place of death.

## RACTAC TRIAL: PHASE II MULTICENTRIC ITALIAN TRIAL ON REPOSITIONING OF THE ANTIPSYCHOTIC DRUG CHLORPROMAZINE AND ITS COMBINATION WITH TEMOZOLOMIDE IN MGMT UNMETHYLATED GLIOBLASTOMA PATIENTS

A. Pace[1], G. Lombardi[2], V. Villani[1], D. Benincasa[1], C. Abruzzese[3], I. Cestonaro[2], M. Corrà[2], G. Cerretti[2], A. Silvani[4], P. Gaviani[4], D. Giannarelli[5], M. Paggi[6]

Gemelli, IRCCS (Roma); [6]Proteomics Unit, IRCCS Regina Elena Cancer Institute (Roma)

The poor prognosis of patients affected by glioblastoma (GBM) prompts the search for new and more effective therapies, particularly for GBMs with unmethylated MGMT. In this regard, drug repurposing, can represent a safe and inexpensive way to bring novel pharmacological approaches from bench to bedside. Chlorpromazine, a medication in use since six decades for the therapy of psychiatric disorders, shows in vitro features that make it eligible for repositioning in GBM therapy. In our experimentation on six GBM cell lines, chlorpromazine inhibited cell viability in an apoptosis-independent way, induced polyploidy, reduced cloning efficiency as well as neurosphere formation and downregulated the expression of stemness genes. Notably, we found that chlorpromazine synergized with temozolomide, in reducing cell viability and strongly cooperated in reducing cloning efficiency and inducing cell death in vitro for all the GBM cell lines assayed. With these assumptions, we started a multicentric Phase II clinical trial on newly diagnosed GBM patients with unmethylated MGMT by adding chlorpromazine to temozolomide in the adjuvant phase of the standard first-line therapeutic protocol. The experimental procedure involves the combination of CPZ with standard treatment with TMZ in the adjuvant phase of the Stupp protocol. CPZ was administered orally at a dose of 50 mg/day – GG 1-28 – of every cycle of the adjuvant treatment with TMZ. Efficacy outcomes were evaluated using Kaplan–Meier methodology. OS was measured from diagnosis to death; PFS was determined from radiotherapy to the first sign of PD or death due to any cause. The trial was closed on December 2022. 53 patients have been enrolled, 39 male, 14 female. 21 patients completed 6 cycles of treatment, without relevant toxicity. The results shows a median PFS of 7 months (St. Dev. 5,7) and a median OS of 15 months (St.Dev. 6,9). 23 patients are still alive (43%). The addition of Chlorpromazine to the standard adjuvant chemotherapy with temozolomide was well tolerated in newly diagnosed Glioblastoma unmethylated patients, with promising impact on outcome measures. On the basis of the RACTAC trial results, a phase II multicentric trial evaluating Chlorpromazine added to standard treatment (RT+TMZ+adj TMZx 6 cycles plus CPZ) in newly diagnosed Glioblastoma patients is in preparation.

Aims: Neuro-oncology might be a promising field for the application of nanotechnologies, especially for malignant brain tumors with a low survival rate as glioblastoma. As a contribution to a broader perspective of the current state of research, we attempt to give an overview of healthcare practitioners' perceptions and intentions to use nanotechnology, with a focus on neuro-oncology.

Materials: A preliminary literature search did not identify any study focused on clinicians' perspectives towards nanotechnology in neuro-oncology. Therefore, we considered extending the search to nanomedicine to (i) spot any possible piece of knowledge within glioblastoma and (ii) evaluate whether potential useful information from other research fields could be transferred within glioblastoma research.

Methods: Studies had been identified by conducting a systematic search of electronic databases using keywords related to "nanotechnology", "perception" and "healthcare professionals". Studies were included if clinicians' knowledge (i.e. factual information) and/or opinions (i.e. judgment not necessarily based on facts) toward nanomedicine had been explored, regardless of the field of application.

Results: Seven studies published from 2011 to 2021 conducted in five countries were considered eligible. Cross-sectional study designs were used to assess students, medical residents, and clinicians' opinions toward nanomedicine. Participants' attitudes were positive, although accurate knowledge of nanotechnology was poor. Inadequate access to information on nanotechnology was reported, with education gaps in nanomedicine and the need to update university curricula claimed by students, medical residents, and clinicians equally.

Discussion: Current models of risk assessment suggest that time-saving cognitive and affective shortcuts support both laypeople and experts in the decision-making process under uncertainty, whereas they might be a source of error. Whether the knowledge is poor, heuristics are more likely to interfere with decision-making. Knowledge about current and future research in nanomedicine should be improved to (i) provide reliable sources of information, (ii) enable proper decision-making of upcoming healthcare workers, and (iii) minimize the influence of subjective variables.

Conclusions: Given the multi-professional nature of neuro-oncological care, internal shared knowledge and perspective are advisable, especially if international consensus on treatment strategy is unclear. A dedicated survey directed to all specialists involved in the diagnosis and treatment of gliomas exploring the possible impact of intention to use nanotechnology in glioblastoma is currently ongoing. Therefore, future search might be helpful to improve the knowledge of clinicians' perspectives in this field.

## TUMOR CELL LINES-RELEASED MICROVESICLES AND EXPRESSION OF ADHESION MOLECULES IN AN IN VITRO MODEL OF BLOOD BRAIN BARRIER FOR THE STUDY OF METASTATIC BRAIN DISEASE

A. Salmaggi[1], C. Vasco[2], A. Rizzo[3], C. Cordiglieri[4], E. Corsini[3], E. Maderna[5], E. Ciusani[3]

[1]Department of Neurosciences, ASST Lecco (Lecco); [2]Autoimmunity Laboratory, National Institute of Molecular Genetics, Policlinico of Milan (Milano); [3]Laboratory of Clinical Chemistry, Fondazione IRCCS Istituto Neurologico C. Besta (Milano); [4]Preclinical Immunology Lab, Fondazione IRCCS Istituto Neurologico C. Besta (Milano); [5]Neuropathology Unit, Fondazione IRCCS Istituto Neurologico C. Besta (Milano)

Aim: We aimed at assessing the effects of microvesicles released by different human cancer cell lines and of adhesion molecules expression on transmigration of cells through an in vitro model of blood-brain barrier and on endothelial cell apoptosis.

Materials and Methods: Human lung and breast cancer cell lines - A549, H460 (human lung cancer cells), MDAMB 231, MDAMB 453, SKBR3 and MCF7 (breast cancer cell lines) were all obtained from ATCC and were characterized for adhesion molecule expression and used to evaluate their migration ability in an in vitro model, consisting of rat astrocytes and either human umbilical cord endothelial cells or cerebral microvascular endothelial cells grown on the opposite sides of a porous polycarbonate, collagen-IV-coated membrane. Conditioned culture media and isolated EVs, characterized by super resolution and electron microscopy, were tested to evaluate their pro-apoptotic properties on human umbilical vein endothelial cells and human cerebral microvascular endothelial cells (HCMEC/D3) by annexin V binding assay.

Results: Our data showed a direct correlation between expression of ICAM1, ICAM2, β3-integrin and α2-integrin and the ability to firmly adhere to the blood–brain barrier (BBB) model, whereas the same molecules were down-regulated at a later step. Extracellular vesicles released by tumor cell lines were shown to be able to induce apoptosis in HUVEC while brain endothelial cells showed to be more resistant.

Conclusions: Down-regulation of adhesion molecules at a step immediately following transmigration might be one of the mechanisms implied in the temporary dormancy state of microscopic metastatic foci in the brain.

## QUANTITATIVE MGMT PROMOTER METHYLATION AND GLIOBLASTOMA LOCALIZATION: A VOXEL-WISE STUDY

G. Sansone[1], A. Salvalaggio[1,2], M. Maccari[3], M. Gaiola[1], L. Pini[2], G. Cerretti[3], F. Chioffi[4], D. D'Avella[5], G. Lombardi[3], M. Corbetta[1,6]

[1]Department of Neuroscience, Neurology Unit, University Hospital of Padua (Padova); [2]Padova Neuroscience Center (PNC), University Hospital of Padua (Padova); [3]Veneto Institute of Oncology IOV IRCCS, University of Padua (Padova); [4]Department of Neuroscience, Neurosurgery Unit, University Hospital of Padua (Padova); [5]Department of Neuroscience, Academic Neurosurgery, Neurosurgery Unit, University Hospital of Padua (Padova); [6]Venetian Institute of Molecular Medicine (VIMM), Fondazione Biomedica; Padova Neuroscience Center (PNC), University Hospital of Padua (Padova)

Objectives: The O-6-methylguanine-DNA methyltransferase (MGMT) promoter methylation status is one of the most important prognostic factors in glioblastoma (GBM) patients [1]. GBMs mainly arise in temporal, frontal and parietal lobes, however, tumour location does not directly impact patient prognosis, unless it influences the extent of surgical resection. Several studies assessed the relationships between MGMT methylation status and GBM location, yet no consistently significant association was reported [2,3]. Nonetheless, there is currently no published data regarding the association between GBM localization and the extent of quantitative MGMT methylation. The aim of the present study was to investigate the relationships between both qualitative and quantitative MGMT promoter methylation status and GBM topological characteristics.

Materials: Patient inclusion criteria were: histopathological diagnosis of GBM (WHO 2021); available presurgical routine MRI acquisitions including T2W, FLAIR, pre- and post-contrast T1W sequences; surgical operation in the departments of Neurosurgery of the "Azienda Ospedaliera Universitaria di Padova"; known MGMT methylation status.

Methods: Quantitative methylation assessment was obtained through pyrosequencing. GBM lesions were segmented into 4 tissues: necrosis, contrast-enhancing and non-contrast-enhancing tumor, that altogether were considered as "core", and "edema". The three resulting masks (core, edema and global) were normalized to a standard space (MNI). We investigated volume differences between MGMT-methylated and unmethylated GBMs through t-tests and performed Pearson's correlations between quantitative MGMT methylation status and mask volumes. Subsequently, two-sample t-tests assessing voxel-wise differences in mask location between MGMT-methylated and unmethylated tumors were performed with the FSL general linear model software and the "randomise" function (5000 random permutations). Furthermore, we both investigated linear relationships between quantitative MGMT methylation status and mask location and assessed location differences between highly- and lowly-methylated patients. The analyses were also repeated correcting for core, edema and global volumes, separately. Results underwent voxel-wise family-wise error correction; significance level was set to 0.05.

Results: 93 patients were included (66 males; mean age: 62.3±11.3 years), 41 were MGMT-methylated. The mean methylation level was 33.9±18.3%. GBMs were mainly located within frontal, temporal and, to a lesser extent, parietal lobes. No difference in GBM volume and location was found between MGMT-methylated and unmethylated patients. Moreover, we found no relationship between GBM topology and quantitative MGMT status.

Discussion and Conclusions: The present study not only confirms that MGMT methylation status is unrelated to specific anatomical localizations of GBMs, but also suggests that GBM topology, among MGMT-methylated tumors, does not depend on the level of MGMT promoter methylation.

## LONGITUDINAL NEUROCOGNITIVE AND NEURORADIOLOGICAL CHANGES IN MALIGNANT GLIOMA PATIENTS

A. Tanzilli, V. Villani, A. Pace

Neuro-oncology Unit, IRCCS Regina Elena National Cancer Institute (Roma)

Background and Aim: Current treatment options have increased overall survival in brain tumor patients, especially in low grade ones, reaching a 10-year rate of 60-80% according to tumor grade [1]. For this reason, cognitive and radiological long-term treatment effects have become relevant issues in clinical and research field. The few previous reports on this topic highlight progressive decline of attentional [2], mnesic and executive functions, associated with radiological abnormalities [3]. The aim of this study was a longitudinal evaluation of the correlation between radiological features and neurocognitive status malignant glioma patients with disease control.

Materials and Method: Malignant glioma patients were retrospectively selected from the database of the Regina Elena neuro-oncology unit. All of them underwent basal neuropsychological assessment and 3 follow-up evaluations (mean:21 months), tapping short and long-term memory, executive functions, attention and visuo-constructional abilities. They also underwent longitudinal neuroradiological examinations. Neurocognitive performances were corrected according to italian normative standard, while neuroradiological data (volumetry, cortical thickness and leucoencephalopathy) were compared with control subjects.

Results: 20 malignant glioma patients with neurocognitive and neuroradiological longitudinal data (12 male, mean age: 45 y; mean edu.: 12 y) were selected in a database of 1200 neurocognitive evaluations. All of them presented with stable disease and underwent longitudinal MRI scans. Histology was mostly oligodendroglioma (n.=7) and astrocytoma (n.= 8), while only 3 patients were diagnosed with glioblastoma. Patients underwent post-surgical and pre-radiotherapy cognitive assessment and 3 follow-ups. At baseline neurocognitive assessment 50% of patients presented with at least 1 cognitive

deficit, mainly affecting executive and mnesic functions. At follow-up 8 patients showed a stable and preserved cognitive status and in 5 patients a neuropsychological improvement was found. Among them, 2 patients presented with no deficit. 2 patients worsened neurocognitive performance and 7 showed longitudinal fluctuations. At the last follow-up, significant correlations emerged between cognitive deficits and leucoencephalopaty (p= 0,03), total grey-matter volume (p=0,03) and educational level (p=0,01). Patients with greater leucoencephalopaty and grey-matter reduction showed worse cognitive performances, while patients with higher education suffered less deficits.

Discussion: Although in a small sample size, our results confirm the role leucoencephalopaty and cortical volume play on neurocognitive status. Furthermore, data evidence the key importance of cognitive reserve to promote neurocognitive functioning in patients with disease stability. Overall, these results highlight the necessity of monitoring neurocognitive status in glioma patients even in case of stable disease.

## WHAT IS THE ROLE OF THE SECOND SURGERY TO RECURRENCE IN GLIOBLASTOMA: REAL LIFE EXPERIECE OF NEUROSURGERY

V. Villani[1], F. Rasile[2], A. Tanzilli[1], S. Telera[2], A. Pace[1], M. Lecce[2]

[1]Neuro-Oncology, IRCSS National Cancer Institute Regina Elena (Roma); [2]Neurosurgery, IRCCS National Cancer Institute Regina Elena (Roma)

Background: The majority of patients with Glioblastoma will experience disease progression. At recurrence, treatment options have limited efficacy. Many studies report a limited response rate and when present, it is of short duration. Surgery is an option for some patients, and surgical debulking can alleviate mass effect and symptoms. Some evidence showed that greater extent of resection at recurrence is associated with improved survival; however, other studies have not found an absolute benefit in terms of survival. The purpose of this study is to evaluate what is the impact of neurosurgery at recurrence in Glioblastoma patients.

Materials and Methods: We have included patients undergoing to surgery for recurrence of GBM with age >65 years. All patients were followed at the Neurosurgery Unit of National Cancer Institute Regina Elena and we considered patient not underwent to surgery.
Result: From neuroncology database of Regina Elena we extracted 138 patients underwent to second surgery (Sample 1) and 422 patients underwent to other treatments (sample 2). The median age in the sample 1 was 56 and 61 in the sample 2. The median number of cycle of temozolomide was 8 in the sample 1 and 6 in the sample 2. For the sample 1 the median time of second surgery was 13 months and in 49% previous 12 months, 51% after 12 months. At multivariate analysis we observed that on overall survival the second surgery have an impact after 12 months from first surgery, MGMT methylated, age at diagnosis. The factors that influence progression free survival was time to second surgery after 12 months and number of temozolomide.

Conclusions: This data is according with literature data. The role of second surgery may be at important role in selected patients in terms of progression and survival. The study has a large case study. The limitation of the study is that it is retrospective.

## VOLUMETRIC HIPPOCAMPAL CHANGES IN GLIOBLASTOMA: A BIOMARKER FOR NEUROPLASTICITY?

A. Zilioli[1], F. Misirocchi[1], C. Mutti[1], B. Pancaldi[1], E. Mannini[1], M. Spallazzi[1], M. Michiara[2], D. Cerasti[3], I. Florindo[1]

[1]Neurology Department, University-Hospital of Parma (Parma); [2]Oncology Department, University-Hospital of Parma (Parma); [3]Neuro-Radiology Department, University-Hospital of Parma (Parma)

Purpose: The pleiotropic effect of gliomas on the development of cognitive disorders and structural brain changes has garnered increasing interest in recent years [1] While it is widely accepted that multimodal therapies for brain cancer can foster cognitive impairment, the direct effect of gliomas on critical cognitive areas before anti-tumor therapies is still controversial [2]. In this study, we focused on the effect of IDH1 wild-type glioblastoma on the human hippocampus volume.

Methods: We carried out a case-control study using voxel-based morphometry assessment, analyzed with the Computational Anatomy Toolbox software. Glioblastoma diagnosis was performed according to the latest 2021 WHO classification [3]. Due to stringent inclusion criteria, 15 patients affected by IDH1 wild type glioblastoma were included and compared to 19 age-matched controls.
Results: We observed a statistically significant increase in the absolute mean hippocampal volume ($p = 0.017$), as well as in the ipsilateral (compared to the lesion, $p = 0.027$) and the contralateral hippocampal volumes ($p = 0.014$) in the group of patients. When the data were normalized per total intracranial volume, we confirmed a statistically significant increase only in the contralateral hippocampal volume ($p = 0.042$).

Discussion: We theorize that the presence of the GBM, with both its local and widespread detrimental effects, may induce a compensatory response within the hippocampus, one of the few sites having a neurogenesis capability in the adult brain. Brain tumors may thus represent an additional provocative factor for hippocampal plasticity. The higher proximity of the brain tumor may justify the volumetric differences observed between ipsi and contralateral mesial temporal areas, with ipsilateral limbic areas being more affected by the local cytotoxic effect exerted by the tumor, disrupting local brain networks. Moreover, the finding of substantial integrity and resilience in the mesial temporal areas before to the start of the multimodal therapies, suggests that the prominent memory deficits emerging during the course of the disease may be related to the radio- chemotherapy treatments, rather than being a direct consequence of the glioma.

Conclusions: To the best of our knowledge, this is the first study to explore hippocampal volumetric changes in a cohort of adult patients affected by IDH1 wild-type glioblastoma, according to the latest WHO classification. We demonstrated an adaptive volumetric response of the hippocampus, which was more pronounced on the side contralateral to the lesion, suggesting substantial integrity and resilience of the medial temporal structures before the initiation of multimodal treatments.

## PAIN

### NEUROIMAGING, NEUROPHYSIOLOGICAL AND PSYCHOPHYSIOLOGICAL ANALYSIS OF CONCOMITANT CONTINUOUS PAIN IN TRIGEMINAL NEURALGIA

G. De Stefano[1], D. Litewczuk[1], E. Galosi[1], G. Di Pietro[1], P. Falco[1], N. Esposito[1], J. Osman-Farah[2], F. O'Neill[3], B. Frank[3], A. Truini[1], G. Di Stefano[1]

[1]Department of Human Neuroscience, Sapienza University (Roma); [2]Neurosurgery Unit, The Walton Centre NHS Foundation Trust (Liverpool-UK); [3]The Pain Relief Foundation, University of Liverpool (Liverpool-UK)

Aim: A distinctive phenotype of Trigeminal Neuralgia (TN) is characterized by the presence of an additional type of pain, continuous and burning, besides the characteristic electric shock-like paroxysmal pain. Since this continuous pain tends to respond less to available treatments, it may be due to a different pathogenetic mechanism. The aim of the present study is to identify the neuroimaging, neurophysiological and psychophysiological characteristics that distinguish patients with concomitant continuous pain from patient with purely paroxysmal pain.

Materials and Methods: Patients with a definite diagnosis of Primary Trigeminal Neuralgia were subclassified according to the presence of concomitant continuous pain through a detailed clinical interview. Both groups underwent high-resolution 3T MRI with a volumetric study of the trigeminal nerve, laser-evoked potentials (LEP), and quantitative sensory testing (QST) according to the DFNS protocol.

Results: A total of 73 TN patients were enrolled, of which 28 reported concomitant continuous pain (38%). Patients with concomitant continuous pain showed a more severe trigeminal root atrophy ($p<0.001$), an attenuation of the LEP elicited by stimulation of C fibres ($p<0.005$) and of the Cold Detection Threshold as assessed by QST ($p<0.05$). The volume of the affected nerve showed a correlation with Wind-Up Ratio ($p<0.05$).

Discussion and Conclusions: Our multimodal findings converged in showing that concomitant continuous pain is characterized by axonal loss and impairment of the small trigeminal fibres. The correlation of the volume of affected nerve with Wind-Up Ratio suggests that the axonal loss may trigger hyperexcitability in the second order neuron. This abnormal activity could underlie the development of concomitant continuous pain.

### SMALL FIBER NEUROPATHY IN SYSTEMIC LUPUS ERYTHEMATOSUS. A CLINICAL, NEUROPHYSIOLOGICAL, AND HISTOPATHOLOGICAL STUDY

N. Esposito[1], E. Galosi[1], A. Truini[1], G. De Stefano[1], G. Di Stefano[1], P. Falco[1], C. Leone[1], G. Di Pietro[1], C. Pirone[2], V. Di Maio[2], M. Leopizzi[2], L. Tramontana[2]

[1]Department of Human Neuroscience, Sapienza University of Rome (Roma); [2]Department of Clinical Science, Internistic, Anaeshtesiological and Cardiovascular, Sapienza University of Rome (Roma)

Aim: Patients with Systemic Lupus Erythematosus (SLE) commonly complain of painful and autonomic disturbances. The impact of small fiber neuropathy (SFN) on these symptoms has been fragmentarily investigated, as well as its relationship with disease activity and immunologic variables. As a result of limited knowledge, SFN is still an underrecognized SLE complication. In this prospective study we aimed at assessing small fiber related diagnostic test findings in patients with SLE and painful disturbances, and at evaluating the association between SFN, immunologic disease variables, and clinical symptoms.

Materials and Methods: We enrolled 50 patients with SLE and painful disturbances and performed a comprehensive clinical and neurophysiological evaluation through Nerve Conduction Study (NCS) and Quantitative Sensory Testing (QST), a complete laboratory assessment of the main disease immunologic variables, and an extensive skin biopsy analysis, with somatic and autonomic innervation assessment and the detection of complement and inflammatory cells infiltrate.

Results: 38% of patients had diagnostic findings compatible with SFN, mostly with a non-length dependent distribution. 14% of patients had a mixed neuropathy (MFN) with both large and small fiber involvement. Patients with MFN were older respect to those with SFN ($p=0.0143$); large fibers mediated variables, i.e., sural nerve action potential amplitude and QST vibration detection threshold, showed a negative correlation with age ($p=0.0002$, $r=-0.502$; $p=0.0010$; $r=-0.471$) and disease duration ($p=0.0064$; $r=-0.392$; $p=0.0057$, $r=-0.420$), whereas small fibre related variables did not. Patients with SFN had more frequently presented hypocomplementemia in their clinical history ($p=0.0058$) and had more frequently been treated with cyclosporine A ($p= 0.0114$) respect to patients without neuropathy. No differences were found in painful and autonomic symptoms between patients with and without SFN.

Discussion and Conclusions: Our study shows that SFN with a non-length dependent distribution is a highly prevalent complication in patients with SLE and is an early manifestation of SLE related neuropathy. SFN is associated to hypocomplementemia, thus showing a relation with disease immunologic activity, and may also be related to disease modifying therapy. However, its role in conditioning painful and autonomic symptoms in SLE patients remains elusive.

## PREVALENCE OF HEADACHE IN A COHORT OF PATIENTS WITH PARKINSON'S DISEASE

A. Giglio, C. Russo, L. Baratto, S. Perillo, N. Cuomo, G. De Michele, A. De Rosa

Department of Neurosciences and Reproductive and Odontostomatological Sciences, Federico II University (Napoli)

Objective: Our aim was to assess the lifetime and last year prevalence and the phenomenology of the headache in a cohort of PD patients in comparison with control subjects (Ctrl).

Methods: We recruited 80 patients (36 F; 44 M) and 76 Ctrl (37 F; 39 M) selected among spouses and not consanguineous caregivers, comparable for age, sex and education. All participants underwent Beck Depression Inventory scale and a questionnaire assessing the presence of a history of headache and days with headache during the last year, describing characteristics of pain as well. Only patients were clinically evaluated by the motor section of Unified PD Rating Scale (UPDRS-III) and Hoehn and Yahr (HY) scale.

Results: Forty-seven patients (57%; 24 M/23 F) and 46 Ctrl (60%; 24 M/22 F; p=0.871) presented headache during the whole lifetime, whereas 28 patients (35%; 12 M/16 F) and 34 Ctrl (45%; 18 M/16 F; p=0.514) had suffered in the last year. No significant difference was observed in the overall prevalence of lifetime migraine among PD patients (30%; 5 M/9 F; p=0.387) compared to Ctrl (39%; 6 M/12 F; p=0.178), as well as the prevalence of tension-type headache (TTH) was comparable between the two groups (70% vs 61%; p=0.619). Migraine prevalence was significantly higher among women in both groups (11% M vs 25% F; p=0.067; 15% M vs 32% F; Ctrl: p=0.016). We found higher occurrence of headache family history (40% vs 13%; p=0.004), more common headache remission with age (p<0.001), particularly after the onset of motor symptoms (23%; p=0.037), among PD subjects rather than Ctrl. Furthermore, patients reported more common gradual onset of the pain (6% vs 16% p=0.068), less frequent visual aura (46% vs 64% p<0.001), and shorter attack duration than Ctrl (2% vs 13%; p=0.058).

Conclusions: The prevalence of migraine and TTH did not differ between PD subjects and controls. PD does not seem to act as a risk factor in the development of headache, but the dopaminergic pathway degeneration and progressive loss of DA activation on the trigeminal-vascular system might affect the severity and duration of the attacks and favor the improvement and remission of the headache in these patients.

## SEX DIFFERENCES IN TRIGEMINAL NEURALGIA

D. Litewczuk, G. Di Stefano, G. De Stefano, A. Truini

Department of Human Neuroscience, Sapienza University (Roma)

It is well established that trigeminal neuralgia is more prevalent in females that in males. Neurovascular compression with morphological changes of the trigeminal root represents the most recognized etiological factor. However, other factors may play a role in the framework of a multi-hit model. The primary aim of this study was to investigate sex differences in radiological and clinical characteristics of trigeminal neuralgia to better understand the multifactorial origin of this peculiar neuropathic pain condition. In this cross-sectional study patients with a definite diagnosis of primary trigeminal neuralgia were consecutively enrolled. Each patient underwent 3T MRI with sequences dedicated to the study of neurovascular compression. Major morphological changes of the trigeminal root were quantitatively assessed. Clinical characteristics were sistematically collected through a dedicated questionnaire. A logistic regression model was implemented to predict radiological and clinical characteristics based on sex. 114 patients with classical (87) or idiopathic trigeminal neuralgia (27) were enrolled. Female sex was predictive for Idiopathic trigeminal neuralgia. Male sex was predictive, among the comorbidities and clinical characteristics, for hypertension, the involvement of the left side and the second trigeminal division, alone or with the ophthalmic division. The preponderance of TN in the female sex and the association between idiopathic TN and the female sex suggest the role of additional etiological factors in the framework of a multi-hit model. The identification of clinical variables predicted by sex suggests the possibility that distinct phenotypes, with peculiar pathophysiological and therapeutic aspects, may occur females and males.

## AN OPEN STUDY OF BOTULINUM-A TOXIN TREATMENT FOR 1 YEAR OF CHRONIC NEUROPATHIC PAIN

D. Tedeschi[1], V. Laterza[2], G. Idone[2], G. Spano[2], A. Gambardella[1], F. Bono[2]

[1]Institute of Neurology, Magna Grecia University (Catanzaro); [2]Botulinum Toxin Therapy Center, Neurology Unit, AOU R. Dulbecco, Institute of Neurology, Magna Grecia University (Catanzaro)

Introduction: Neuropathic pain is one of the most difficult pain syndromes to manage. In fact, current medical therapy often remains unsatisfactory. Recent evidence suggests that botulinum toxin type A (BoNT/A) may also modulate the firing of afferent sensory fibers, thereby relieving chronic peripheral and central neuropathic pain [1].

Methods: An open-label pilot study of intradermal BoNT/A for neuropathic pain in patients with chronic peripheral or central neuropathic pain was conducted to evaluate its efficacy. We administered three targeted intradermal treatments with BoNT/A (50-300 Units), each performed every 4 months. The outcome measures were: reduction in visual analog scale (VAS) pain score and reduction in pain frequency compared with baseline values, and duration of benefit after each treatment.

Results: We recruited 31 patients with chronic neuropathic pain (18 females,13 males; mean age 58± 27). Divided as follows: trigeminal neuralgia group (32%), post-herpetic neuralgia group (10%), mixed peripheral neuropathic pain group (42%), central neuropathic pain group (16%). In trigeminal neuralgia group we find a significant reduction in VAS of pain of 56%( by 9.5 ± 1.5 at baseline to 4.2 ± 2.4 at 12 months) and 47% in the frequency of pain paroxysms, with an average duration of benefit of about 2.5 months; in post-herpetic neuralgia group we observed an average reduction of VAS pain of 44%( by 8.3 ± 0.5 at baseline to 4.6 ± 0.5 at 12 months), with an average duration of benefit of about 2 months; in peripheral neuropathic pain group we find a reduction of VAS pain of 47% ( by 8.3 ± 0.9 at baseline to 4.8 ± 1.3 at 12 months) and 58.33% reduction in pain frequency, with an average duration of benefit of 3 months; in central neuropathic pain group there was a reduction of VAS pain of 39%( by 8.6 ± 1.3 at baseline to 5.8 ± 2.2 at 12 months), with an average duration of benefit of 2.5 months. No serious adverse events were reported in all patients.

Conclusions: This open-label study demonstrates that targeted intradermal injections of BoNT/A for chronic neuropathic pain are safe and effective, suggesting that in patients with intractable neuropathic pain they could be a useful therapeutic strategy.

## SLEEP

### LONG-TERM MAINTENANCE OF EFFICACY AND SAFETY OF PITOLISANT IN THE TREATMENT OF RESIDUAL SLEEPINESS IN PATIENTS WITH OBSTRUCTIVE SLEEP APNEA

C. Caussé[1], J. Pepin[2], V. Attali[3], J. Verbraecken[4], J. Hedner[5], T. Sacco[6], I. Lecomte[7], R. Tamisier[2], P. Levy[2], P. Lehert[8], Y. Dauvilliers[9]

Objective: In people with obstructive sleep apnea (OSA) excessive daytime sleepiness (EDS) is a prominent symptom and it can persist, despite adherence to continuous positive airway pressure (CPAP). Pitolisant was effective in reducing EDS in two randomised controlled trials (RCTs), one in patients adherent to CPAP (HAROSA 1) and another in patients refusing or not tolerating CPAP (HAROSA 2). Being OSAS a chronic condition and since EDS might require prolonged treatment, we would verify whether the efficacy and safety profile which pitolisant showed in the short term is confirmed in the long-term.

Materials and Methods: Following the 12 weeks double-blind phase, to all adults included in the HAROSA RCTs, both the ones randomized in the pitolisant and in the placebo arms, an open label treatment, from week 13 to week 52 with pitolisant up to 20 mg/day, was proposed. The primary efficacy endpoint was the change in the Epworth Sleepiness Score (ESS) between baseline and week 52. Safety endpoints were: treatment-emergent adverse event(s) (TEAE), serious TEAE (TESAE) and special interest TEAE (TEAESI).

Results: 376 out of 512 adults included in the RCTs completed the 1-year follow-up. The mean baseline ESS were respectively 15.2±3.2 in the placebo group and 15.3±3.0 in the pitolisant arm. Any significant difference between studies were found for baseline ESS (p=0.538), age (p=0.06) and gender (p=0.09. The pooled mean difference in ESS from baseline to one year for the Intention to Treat sample was -8.0 [-8.3, -7.5]. Secondary endpoints, such as OSLER, EuroQol-5D, Clinical Global Impression, Patient's Global Opinion and PFS, showed significant improvements from baseline until the end of the year of follow up. The overall proportions of TEAE, TESAE and TEAESI were 35.1%, 2.0% and 11.1%, respectively, without any significant difference between the patients treated with pitolisant or placebo in the double blind phase. No cardiovascular safety issues were reported and systolic and diastolic blood pressure and heart rate didn't show clinically or statistically significant changes.

Discussion: Pitolisant was effective in reducing daytime sleepiness over one year in adults with OSA, with or without CPAP treatment and showed a good general and cardiovascular safety profile.

Conclusion: The outcomes of the present one year follow up open label study showed that pitolisant is suitable for the long term pharmacological management of OSAS's EDS.

### CIRCADIAN PHASE AND CLINICAL PHENOTYPE IN INSOMNIACS: PRELIMINARY RESULTS OF AN IN-HOME SALIVARY MELATONIN TEST IN 71 ADULT PATIENTS

R. Cremascoli[1], G. Giusti[2], D. Sparasci[2], C. Ghezzi[3], S. Cerri[3], M. Terzaghi[4], D. Soranna[5], A. Zambon[6], L. Bianchi[7], S. Cattaldo[8], E. Prina[8], L. Priano[1], A. Mauro[1], R. Manni[2]

Objective: Although insomnia and circadian rhythm disorders are distinctive diseases, extreme chronotypes and desynchronised circadian phase may contribute to insomnia pathophysiology. In particular extreme chronotypes and a desynchronised circadian phase may influence insomnia phenotype. The present study aimed to investigate the relationship between circadian phase and insomnia phenotype in both drug-free and treated patients affected by chronic insomnia disorder.

Materials: Seventy-one primary chronic insomniacs (M/F: 34/37; median age 51 years) and 20 healthy controls (HC; M/F: 13/7; median age 44 years) were enrolled. According to the timing of sleep

difficulties, patients were divided into subgroups: sleep-onset insomnia (SOI, 15 patients), early morning awakening insomnia (EMA, 27 patients), sleep-maintenance insomnia (SMI, 17 patients) and mixed insomnia (MI, 12 patients).

Methods: Patients were investigated for insomnia phenotype and subjective sleep quality by using clinical sleep scales and a sleep diary. Circadian phase was determined through Dim Light Melatonin Onset (DLMO) by means of a five-point in-home evening melatonin salivary test and phase angles were then calculated based on the sleep timing reported in the diary.

Results: The mean value of DLMO clocks did not differ between insomniacs and controls (p=0.54). However, the 26% of the insomniacs, 49% of whom were taking gaba receptor agonists as sleep aids, used to go to bed at a wrong circadian phase (BTWCP). This behaviour proved to be more frequent in patients with a late circadian phase. In fact, in insomnia group phase angles showed to correlate negatively with DLMO (Spearman's correlation index: -0.63 (95% CI -0.75 to -0.46). Furthermore, insomniacs show a significant lower percentage of long phase angles (longer than 2 h) than controls (p=0.02).

Discussion: Our data indicated that a late circadian phase was more frequent in SOL and SMI than in the EMA insomnia. These findings concur to indicate that circadian phase timing is likely to modulate clinical phenotypic insomnia subtype. In insomniacs' group phase angles showed to correlate negatively with DLMO, with patients having later circadian phases showing shorter phase angles. The distribution of this wrong behaviour was also different according to the clinical phenotypic insomnia subtype.

Conclusion: Our data confirm that circadian components of sleep regulation is likely to contribute to primary chronic insomnia phenotype in real life condition, in both untreated and treated patients. Investigating these components may help to expand our knowledge of the ultimate complex pathophysiology of chronic insomnia and to optimize the insomnia treatment.

## LONGITUDINAL ANALYSIS OF MUSCLE ACTIVITY IN SLEEP IN PATIENTS WITH ISOLATED REM SLEEP BEHAVIOUR DISORDER

F. Di Laudo[1], A. Silvani[2], L. Baldelli[1], L. Sambati[3], F. Mignani[1], G. Calandra Buonaura[1], P. Cortelli[1], F. Provini[1]

[1]Department of Biomedical and Neuromotor Sciences (DIBINEM) and IRCCS Istituto delle Scienze Neurologiche di Bologna, University of Bologna (Bologna); [2]Department of Biomedical and Neuromotor Sciences (DIBINEM), University of Bologna (Bologna);[3]IRCCS Istituto delle Scienze Neurologiche di Bologna (Bologna)

Objective: To analyze the motor activity in all sleep phases in patients with isolated REM sleep behaviour disorder (iRBD), a well-recognized prodromal state of an underlying α-synucleinopathy [1], and to compare this activity with healthy controls and longitudinally at a certain follow-up, using a recently validated automatic method together with the manual score of motor events.

Materials: Sleep was studied with video polysomnography (vPSG) and scored using American Academy of Sleep Medicine diagnostic criteria. A total of 30 vPSG were analyzed; the electromyographic activity (chin, upper and lower limbs) was analyzed both manually and automatically through the Distribution of Normalized EMG values (DNE) method [2].

Methods: We enrolled 10 patients referred to our centre with a diagnosis of iRBD and 10 healthy controls: firstly, we compared motor activity during sleep between these two groups; then, between patients' first vPSG (baseline) and a follow-up performed after 2,78 ± 2,41 years.

Results: Patients had 66,20 ± 7,29 years (80% males) with a disease duration of 8,19 ± 5,30 years at baseline; controls had 66,09 ± 7,31 years (90% males) and showed no significative differences in age (p=0,974) and sex (p=0,531) with patients. We found that patients presented more hypnic jerks compared with controls at baseline (p=0,029) and the number increased at follow-up (p=0,016). DNE method showed greater motor activity during REM sleep in patients than in controls, while there were no significative differences in sleep motor activity between baseline and follow-up groups analyzed with DNE.

Discussions: Our results showed that overall motor activity of patients with iRBD did not differ from controls during sleep period (except for REM phase) and did not change over time; however, we interstingly found an increased number of hypnic jerks as difference with both controls and baseline patients. Furthermore, DNE automatic method, already used for comparing motor activity in patients with synucleinopathies [3], was used for the first time in patients with iRBD and showed increased EMG activity in REM sleep in patients than in controls.

Conclusions: Although mostly stable over time, motor activity in sleep showed there are some motor phenomena (such as hypnic jerks) that should be considered in futher studies about pathophysiological aspects of iRBD and synucleinopathies and their role as possible disease biomarkers in iRBD patients. In addition, our pilot study suggested the automatic DNE method may have a role as a future diagnostic and monitoring method in these patients.

## WHY AND HOW OSA PATIENTS REFER TO CENTERS: THE OSAREDS STUDY DATA

L. Ferini Strambi[1], F. Placidi[2], A. Romigi[3], G. Plazzi[4], A. Lo Bue[5], T. Sacco[6], A. Braghiroli[7], F. Fanfulla[8], M. Bonsignore[9]

[1]Sleep Medicine Center, Vita-Salute University San Raffaele (Milano); [2]Sleep Medicine Center, Neurology Unit, University Hospital of Rome Tor Vergata, Tor Vergata University (Roma); [3]Sleep Medicine Center, Neuromed IRCCS (Pozzilli-IS); [4]Sleep Medicine Center, Neurological Science Institute IRCCS (Bologna); [5]Institute of Traslational Pharmacology, CNR (Palermo); [6]Medical Department, Bioprojet Italia (Milano); [7]Pulmonary Rehabilitation Division, Maugeri Clinical Scientific Institutes IRCCS (Veruno-NO); [8]Department of Pulmonary

Rehabilitation, Maugeri Clinical Scientific Institutes IRCCS (Pavia); [9]Pulmonology Department, Palermo University (Palermo)

Introduction: Several data suggest that obstructive sleep apnea (OSA) is underdiagnosed in many Countries, including Italy. Defining the journey of OSA patients may help in easing the referral, even educating the public on disease's symptoms. Objective: analysis on why and how patients included in the OSAREDS (OSA-related Residual EDS prevalence in Italian patients) study were referred to the Sleep Centers.

Methods: The reason for referring to Centers and the way the referral happened, besides characteristics, symptoms, comorbidities and CPAP variables, were retrospectively collected from medical records of OSA patients followed up by 7 Italian sleep Centers, and descriptively analyzed.

Results: The whole cohort included 2727 patients with a pre-CPAP visit (males: 77.3%, mean age±SD: 55.7±9.4 yrs, BMI: 31.2±4.7 kg/m2). For the majority of patients (69.9%), symptoms in general were the main reason for a first referral to Centers, more frequently requested by general practitioner (GP) (30.1%), than by specialist's prescription (26.2%) or spontaneous access (26.7%). In females, the GP's prescription prevailed (41.9%), while for males the spontaneous access was the more frequent way of refer to Centers (29.2%). The OSA symptoms that more often drove patients to Centers were: snoring (63.2%), EDS (20.2%) and breath pauses during sleep (10.0%). There were sex-related differences in symptoms driving the first referral: snoring was more frequent in males (M: 65.3% vs F: 56.1%) while EDS (Epworth Sleepiness Scale [ESS] score >10) was more frequent in females (M: 18.9% vs F: 24.8%). First referral to specialist was more often to neurologists (45.4%), pulmonologists (28.8%) and ear, nose an throat specialists (12.7%). Males more frequently referred to neurologists (M: 46.9% vs F: 39.9%) than to pulmonologists (M: 26.3% vs F: 38.1%). Occurrence of EDS seems related to the choice because, comparing patients that referred first to neurologists with the ones that consulted pulmonologists, both mean ESS score (10.1±5.4 vs 8.2±4.5) and frequency of EDS were higher (54.2% vs 23.8%).

Conclusions: In the OSAREDS study, symptoms, and in particular snoring more often than EDS, were the main reasons for referral to OSA Centers. Neurologists were more frequently the first specialist consulted in general, but gender and presence of EDS influenced the choice.

## CPAP THERAPY IMPROVED SLEEP AND EPILEPSY DISORDER IN A YOUNG, OBESE EPILEPTIC AND OSA WOMAN

F. Lamanna, A. Gardin, A. Messina, C. Vecchio, I. Aricò, A. Laganà, A. Labate, R. Silvestri

Clinical and Experimental Medicine, University of Messina (Messina)

Introduction: Sleep disorders and epilepsy are both common diseases in the general population. Comorbidity between Obstructive Sleep Apnea Syndrome (OSA) and epilepsy varies from 8% to 76% [1], with a recent meta-analysis reporting a 33.4% prevalence of mild-to-severe OSA in epileptic patients, which proved to be more susceptible to OSA than healthy controls [2].

Case report: We report a case of a 39 y.o. woman, non-smoker, suffering from temporal lobe epilepsy; she was diagnosed in 2018 upon experiencing her first nocturnal tonic-clonic seizure. She also suffers from hyperinsulinism, obesity (BMI: 36.3) and Von Willebrand Syndrome. In 2020, she came to our Sleep clinic because of excessive daytime sleepiness (EDS). She was taking Lacosamide (LAC) 150 mg twice daily with partial control of seizures, she had interictal bi-temporal epileptiform discharges (IEDs) during both wake and sleep more evident over the left hemisphere. She completed the following self-administered questionnaires: Epworth Sleepiness Scale (ESS; 13, n.v.<10); Pittsburgh Sleep Quality Index (PSQI; 14, n.v.≤5), Hamilton Anxiety Rating Scale (HAM-A; 23, n.v.≤17), Beck Depression Inventory (BDI; 22, n.v.≤10). An ambulatory cardiorespiratory monitoring showed AHI 28.9 (n.v. <5), with mean oxygen saturation of 93%. We suggested a CPAP treatment and she is currently sleeping with a CPAP device at 9 cmH2O with complete disappearance of EDS (ESS: 3). Very recently, the 2022 check-up showed withdraw of IEDs during sleep, and LAC has been reduced to 100 mg twice a day. At last check-up in May 2023, she reported improved sleep and life quality with no more EDS nor seizures. LAC has been also further reduced to 50 mg twice a day. Her CPAP compliance is excellent, with a median nocturnal use of 5 h 26 min and AHI of 0.5. The EEG background is within normal limits.

Conclusions: This is a case of a young, obese epileptic woman with persistent seizures despite antiseizure medication. Interestingly, the only CPAP treatment let to seizures and EEG abnormalities disappearance suggesting the potential role of CPAP in stabilizing sleep and epilepsy.

## IDENTIFICATION OF RISK FACTORS FOR OBSTRUCTIVE SLEEP APNEA IN PUBLIC TRANSPORT WORKERS

R. Lecca[1], E. Casaglia[2], F. Arippa[31], M. Bonzini[4], P. Bellaviti Buttoni[4], S. De Matteis[3], M. Figorilli[2], C. Patrizia[2], M. Lai[5], F. Meloni[5], P. Cocco[6], M. Puligheddu[2]

[1]Neurorehabilitation, S.S. Trinità Hospital, ASL Cagliari, University of Cagliari (Cagliari); [2]Interdepartmental Sleep Research Centre, University of Cagliari (Cagliari); [3]Department of Medical Sciences and Public Health, Department of Mechanical, Chemical engineering, University of Cagliari (Cagliari); [4]Dept Clinical Sciences and Community Health IRCCS Policlinico Foundation, University of Milan (Milano); [5]Department of Medical Sciences and Public Health, University of Cagliari (Cagliari); [6]Division of Population Health, University of Manchester (Manchester-UK)

Objective: Sleep Obstructive sleep Apnea (OSA) is more frequent in professional drivers than general population, leading to an increased risk daytime sleepiness and traffic accidents. Our multicenter study, conducted in collaboration between University of Cagliari and University of Milan aims to evaluate risk factors associated to OSA in a population of public transport companies workers.

Materials: We recruited 623 people (483 in Cagliari, 140 in Milan) who underwent yearly clinical evaluation with the occupational physician in the two centres. After signing informed consent, workers filled in different sleep questionnaires: Epworth sleepiness scale (ESS) for daytime sleepiness, Berlin Questionnaire (BQ) for risk of OSA, Morningness Eveningness Questionnaire (MEq) for chronotype, Pittsburgh Sleep Quality index (PSQI) for Sleep quality. Moreover we collected clinical and anthropometric data such as age, gender, BMI, smoke and alcohol consumption, blood pressure (BP), presence of comorbidities, neck circumference and Mallampati score.

Method: We considered as Suspected OSA patients those with a positive Berlin questionnaire, documented apnea episodes and at

least three of the following characteristics: history of hypertension or BP>140/90, BMI >35, persistent daily snoring for at least 6 months, Mallampati IV, neck circumference >41cm. To identify predictive risk factors for OSA we analyzed 20 clinically relevant characteristic for OSA association. We used a combination of univariate analysis therefore we used logistic regression in order to evaluate the combined effect of factors.

Results: We recruited 623 workers of public transport companies in Sardinia and Lombardy: 611 were man (98%) and 12 women (2%). Of those 623, 463 (68%) were drivers, others were maintenance workers. 112 (18%) workers were considered OSA patients. Univariate analysis showed a significant association between OSA and Mallampati IV, elevated diastolic BP, presence of metabolic comorbidities (metabolic syndrome, diabetes, hypothyroidism) elevated ESS score. Multiple regression confirmed all of the before mentioned as significant predictive factors for OSA except diastolic BP.

Discussion: Massive instrumental screening for sleep OSA in professional drivers would be the gold standard but is not feasible because of limited resources and reluctance from drivers to undergo polysomnography exam. Our study allowed the identification of predictive risk factors for OSA in a population of professional public transport workers. Identification of these factor is fundamental for the occupational physician in order to identify those patients at risk and refer them for further evaluation.

Conclusion: Screening for OSA in professional drivers is fundamental for the reduction of risk of traffic accidents and screening for risk factors helps the occupational physician to identify subjects to address to second level examinations.

## EXPLORING THE IMPACT OF OBSTRUCTIVE SLEEP APNEA IN NEUROLOGY INPATIENTS: INSIGHTS FROM STROKE AND TIA CASES

A. Matta[1], E. Idini[1], M. Sanna[1], A. Mazzoncini[1], A. Gaspardini[1], C. Perretti[1], E. Casaglia[1], M. Figorilli[1], M. Melis[2], S. Redolfi[1], M. Puligheddu[1]

[1]Institute of Neurology, University of Cagliari (Cagliari); [2]Institute of Neurology, University Hospital of Cagliari, University of Cagliari (Cagliari)

Objective: Obstructive sleep apnea syndrome (OSAS) is characterized by the presence of apneas and/or hypopneas, desaturations, frequent arousals, and sleep fragmentation. This study aimed to assess the prevalence of sleep breathing disorders among patients admitted to our neurology department and to examine their specific characteristics.

Material and Methods: The study enrolled 166 patients (95 males, M:F 1,33, mean age 68,56 ± 16,04 years, mean BMI 26,35 ± 4,66); 94 received a recent diagnosis of stroke or TIA, 72 were hospitalized for other neurological conditions. The patients with stroke or TIA underwent an immediate polysomnography (PSG), while among the remaining patients only those with ESS>8 and high risk BerlinQ performed the PSG. We investigated smoking, hypertension, hypercholesterolemia, diabetes, and atrial fibrillation (AF) as risk factors.

Results: A total of 65 patients underwent polysomnography: 38 had stroke/tia (77,55%), 32 hypertension (65,30%), 24 hypercholesterolemia (48,97%), 11 AF (22,4%), 8 diabetes (16,32%), 8 previous stroke/TIA (16,32%) and 10 were smokers (20,4%). A diagnosis of OSAS was made in 49 individuals (M:F = 1,72, mean age 73,28 ± 11,4, mean BMI 27,83 ± 3,51) in which we performed a stratification: mild OSAS (30,61%), moderate OSAS 20,40%, moderate-severe OSAS (4,08%) and severe OSAS (44,89%); among the patients with severe OSAS, 68,18% of them were admitted for stroke/TIA. In the patients where OSAS was excluded we found that 12 were admitted for stroke/TIA (75%), 3 individuals with a ESS > 8, and 9 individuals with a High Risk BerlinQ. Among those 9 patients, 7 (77,78%) were admitted for stroke/TIA.

Discussion and Conclusion: OSAS emerges as a significant and independent risk factor for cerebrovascular events. Therefore, it should receive comparable attention and investigation as other established cerebrovascular risk factors. Given that polysomnography can be conducted both in hospital settings and at patients' homes, it should be considered an essential examination for individuals with a history of stroke and TIA. Moreover, it is imperative to highlight the importance of systematically studying patients with neurological access through the use of questionnaires and polysomnography. In eligible patients, the implementation of continuous positive airway pressure (CPAP) therapy should be contemplated and actively promoted, in conjunction with addressing the primary risk factor.

## SLEEP DISORDERS IN ACROMEGALIC PATIENTS: THE EXPERIENCE OF OUR SLEEP CENTER

A. G. Messina[1], A. Gardin[1], F. Lamanna[1], C. Vecchio[1], I. Aricò[2], A. Labate[2], R. Silvestri[2]

[1]Neurology, AOU G. Martino (Messina); [2]Neurophysiopatology and Movement Disorders Clinic, AOU G. Martino (Messina)

Introduction: Sleep disorders are frequent in acromegaly, an endocrinologic disorder characterized by disproportionate skeletal, tissue, and organ growth due to GH and IGF-1 overproduction.

Objectives: To evaluate the prevalence of sleep disorders, comorbidities and their possible causes and consequences on quality of life in an acromegalic population.

Materials and Methods: Thirty-eight consecutive acromegalic patients (19 M) from Sicily and Calabria (ages 25-81 years) were evaluated through a structured sleep interview. The Epworth Sleepiness Scale (ESS n.v. <10) questionnaire was administered to those reporting excessive diurnal sleepiness (EDS), and the International Restless Leg Syndrome Rating Scale (IRLS-RS) to those suffering from RLS. The Pittsburgh Sleep Quality Index (PSQI), Hamilton Anxiety Rating Scale (HAM-A), and Beck Depression Inventory (BDI) were administered to all patients. Furthermore, they underwent ambulatory cardiorespiratory monitoring to evaluate the presence of sleep apnea (OSA).

Results: Our cohort presented the following comorbidities: cardiopathy (55%), diabetes (39%), hypertension (68%), steatosis (34%), thyroidopathy (23%), and psychiatric disorders (18%). EDS was reported in 94.9% (36 patients) of the sample. RLS was diagnosed in 38.5% (14) of acromegalic patients, insomnia in 73.7% (28), and snoring in 74.4% (28). OSA was diagnosed in 55.3% (21) of patients, with 41%

(15) employing CPAP or AutoBiPAP treatment. After six months of treatment, ESS and the other scores improved with the disappearance of diurnal somnolence and reduced anxiety and depression.
Discussion: RLS and OSA were frequent in our sample, as corroborated by the literature. A correlation between OSA and hypertension was observed, with a high risk of cerebrovascular outcomes. All thyroidectomized patients that were taking L-thyroxine suffered from RLS. Eight patients had both RLS and moderate-severe OSA. Insomnia was frequent in RLS patients, whereas EDS was prevalent in OSA patients.

Conclusions: OSA and RLS treatment could ameliorate sleep and improve the quality of life of these patients. Therefore, sleep studies should be considered in all patients diagnosed with acromegaly.

## SLEEP QUALITY IN MIGRAINE PATIENTS TREATED WITH ANTI-CGRP MONOCLONAL ANTIBODIES – A REAL-LIFE STUDY

A. Pascazio[1], G. Abbattista[2], L. Curto[1], E. Ferrari[1], M. Maestri Tassoni[3], D. Hoxhaj[1], G. Procopio[1], U. Faraguna[2], F. Baldacci[1], G. Siciliano[1], E. Bonanni[1], S. Gori[3]

[1]Neurology Unit, Department of Clinical and Experimental Medicine, University of Pisa (Pisa); [2]Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa (Pisa); [3]Neurology Unit, Department of Clinical and Experimental Medicine, Azienda Ospedaliero Universitaria Pisana (Pisa)

Aims: Our aims were to assess sleep quality in patients with high frequency or chronic migraine: i) before and after 3 months of treatment with anti-calcitonin gene related peptide (CGRP) (galcanezumab, fremanezumab) or anti-CGRP-receptor (R) (erenumab) monoclonal antibodies (mAbs); ii) comparing responders to non-responders, defining a response to anti-CGRP(R) mAbs as a reduction on monthly migraine days (MMD) of at least 50%.

Materials and Methods: In this monocentric observational study, 50 consecutive migraine patients resistant to conventional oral prophylaxis started treatment with anti-CGRP(R) mAbs. Patients were evaluated at baseline and after three months of therapy, considering changes in MMD, and in sleep quality by means of the Pittsburgh Sleep Quality Index (PSQI) questionnaire.

Results: Median age was 48 (41-59), with 35 (70%) female patients. At baseline patients had a median of 21 (14-30) MMD. Twenty patients started erenumab, 22 galcanezumab and 8 fremanezumab. At baseline, sleep quality was poor (PSQI median score 6 (5-10) in the whole group, and 20 patients (40%) were regularly taking hypnotic drugs. After 3 months of treatment, we observed a median significative reduction of 15 MMD (MMD at 3 months of 6 (2-14), p <0,001), and PSQI median scores to 5 (4,7), p 0,001. Thirty-three patients (66%) were at least 50% responders. Besides, number of patients taking hypnotic drugs did not change. Comparing responders (R) to non-responders (NR), we found no significant differences evaluating sleep quality, neither at baseline (PSQI R 6 (5-9) vs PSQI NR 8 (5-10), p 0,360) or after treatment (PSQI R 5 (4-8) vs PSQI NR 6 (5-7), p 0,481). Nevertheless, sleep quality significantly improved after treatment, both in responders (PSQI t0 6 (5-9) vs t1 5 (4-8) p 0,002) and in non-responders (PSQI t0 8 (5-10) vs t1 6 (5-7), p 0,013). The rate of poor sleepers among non-responders is the same after treatment (14 vs 14 patients), whereas they decrease among responders (28 vs 22patients, p 0,070).

Discussion and Conclusion: After three months of treatment with anti-CGRP(R) mAbs, a significant improvement in sleep quality occurred in migraine patients - who were overall poor sleepers-, although it was not enough to define a good sleep quality. Improvement seems to occur both in responders and non-responder patients, even if the rate of poor sleepers decreases only in responders. More longitudinal studies including objective sleep measures are needed to assess the impact of anti-CGRP(R) mAbs on sleep quality.

## TELEMEDICINE FOR INNOVATIVE MULTIDISCIPLINARY CARE OF PEOPLE WITH NARCOLEPSY, THE TELEMEDICINE FOR NARCOLEPSY (TENAR) RANDOMIZED CONTROLLED TRIAL

F. Pizza[1], L. Vignatelli[2], C. Oriolo[3], C. Zenesini[2], C. Bassi[3], S. Vandi[2], F. Ingravallo[3], G. Plazzi[4]

[1]IRCCS Istituto delle Scienze Neurologiche di Bologna, University of Bologna, Department of Biomedical and Neuromotor Sciences (DIBINEM) (Bologna); [2]IRCCS Istituto delle Scienze Neurologiche di Bologna (Bologna); [3]Department of Medical and Surgical Sciences (DIMEC), University of Bologna (Bologna); [4]IRCCS Istituto delle Scienze Neurologiche di Bologna, University of Modena and Reggio-Emilia (Bologna)

Objectives: Narcolepsy is a rare central disorder of hypersomnolence associated with metabolic, endocrine and psychosocial problems, requiring a multidisciplinary approach. Sleep centers with adequate skills and experience to manage disease complexity are sparse at a national level, thus forcing patients to undergo long and expensive journeys, further increasing the disease-related burden. We report the main results from a non-inferiority randomized controlled trial of televisit vs in-office management of people with narcolepsy, funded by the Italian Ministry of Health (RF-2016-02364742).

Materials: People with narcolepsy aged > 14 years were eligible for inclusion in a randomized controlled trial that compared multidisciplinary management (neurological, endocrinological, and psychosocial care) performed via televisit versus in-office visit for one year. Primary outcome was control of sleepiness (according to the Epworth Sleepiness Scale, ESS) at 12 months, with a non-inferiority margin of 1.5 points. Secondary outcomes were control of other symptoms, treatment compliance, metabolic control, quality of life, patient satisfaction with care, safety, and disease-related costs.

Results: 208 patients (106 female, 102 male; mean age 34 yrs; 13 teenagers) were randomized and 202 completed the study at 12 months (101 televisit arm; 101 in-office arm). At baseline, clinical and outcome variables were well balanced in the two groups. At 1 year follow-up, ESS score improved by 1.4 mean points in both groups; the adjusted

mean difference between groups was 0.44 (95% confidence interval -0.48 and 1.35). Cataplexy, Narcolepsy Severity Scale, Global Impression Scale, and Beck Depression Inventory did not differ at 12 months between groups. Among the metabolic outcomes, daily caloric intake, daily physical activity, body mass index, weight, and glucose improved in both groups, without difference between groups. Among psychosocial outcomes, patients that lost workdays due to narcolepsy were less in the telemedicine group (36% vs 64%).

Discussion: The multidisciplinary care of patients with narcolepsy through televisit was non-inferior to that provided with in-office visit, in terms of management of sleepiness and other symptoms. Overall, the multidisciplinary approach, including metabolic assessment, produced an improvement also in body mass index and adherence to physical activity, without differences between the two approaches. Instead, televisit allowed a lower impact on lost workdays compared with in-office visit.

Conclusions: Our data indicate the viability in terms of effectiveness and safety of multidisciplinary telemedicine care procedures for narcolepsy in adults and teenagers, paving the way to applying it in clinical practice and to other rare diseases.

## OVERLAPPING PHENOTYPE ASSOCIATED WITH A NOVEL DNMT1 VARIANT: THROUGH THE DEFINITION OF A COMPLEX DISORDER

M. Poli[1], A. Stefani[1], F. Izzi[1], E. Marchionni[2], M. D'Apice[2], G. Novelli[2], N. Mercuri[1], C. Liguori[1]

[1]Neurology Unit, Tor Vergata University Hospital (Roma); [2]Department of Genetics, Tor Vergata University Hospital (Roma)

Aim: To describe a patient carrying a rare heterozygous DNMT-1 (DNA methyltransferase 1) variant who developed an overlapping clinical phenotype between hereditary sensory neuropathy with dementia and hearing loss (HSN1E) and cerebellar ataxia with deafness and narcolepsy (ADCA-DN).

Patient and Methods: The proband is a 45 yo male who presented with anxiety and depressive symptoms since age 18, with later occurrence of postural and intention tremor, slurred speech, hypersomnia and involuntary limb movements during sleep. Over the years he was diagnosed with bilateral symmetrical sensorineural hearing loss and mild cognitive impairment, performed negative genetic analysis for MERRF, PTEN, ATX1, CGH array, NPC1-2 mutations. For further clinical worsening coupled with episodes of sudden loss of muscle tone, frequently causing falls, he was admitted to our Neurology department.

Results: Neurological examination at the admission showed ataxic gait, postural tremor, moderate dysarthria, severe hearing loss, hyperreflexia, positive bilateral Hoffman's sign, lower-limb hypopallesthesia, dysmetria and telekinetic tremor. A polysomnography was performed, which showed reduced sleep efficiency with a severe periodic limb movement disorder, and a Multiple-Sleep-Latency-Test recording a mean sleep latency of 3.4 minutes and two sleep onset rapid-eye-movement (SOREM) episodes. A diagnosis of narcolepsy type 1 was made and treatment with sodium oxybate 2.25 g BID was started, with referred clinical benefit on daytime sleepiness. The patient underwent an MRI that reported thinning of corpus callosum, ventricular dilation with reduced midbrain, cerebellar vermis and peduncles volume, and a fluorodeoxyglucose PET, not showing significant hypometabolism. A lumbar puncture was performed, with the evidence of normal CSF chemical analysis and biomarkers of neurodegeneration (total and phosphorylated tau, amyloid-β42). Electroneurography documented an axonal sensory-motor polyneuropathy. Under the hypothesis of DNMT1-related disorder, genetic studies were performed using next-generation sequencing: the heterozygous missense variants c.1619A>G, p.Tyr540Cys and c.2552T>C, p.lle851Thr were identified. Testing for HLA-DQB1 haplotype*06:02 was negative. The patient's parents and sibling underwent genetic counseling, with negative results.

Discussion and Conclusion: The mutation p.lle851Thr is described as a variant of unknown significance, while p.Tyr540Cys is reported as potentially pathogenic, with limited related literature. Our patient presented with clinical features outlining both phenotypes of DNMT-1 mutations. Overlapping symptoms and signs have already been described between the two entities, namely sensory neuropathy, cognitive decline, hearing loss [1] and narcolepsy [2], suggesting the definition of these diseases as a continuum. Further studies are needed to confirm the pathogenicity of the p.Tyr540Cys variant and to foresee different clinical presentations of DNMT1-complex disorder.

## PINEAL GLAND DYSFUNCTION: RELATIONSHIP WITH SEVERE SLEEP DISTURBANCE AND MULTIORGAN PATHOLOGIES

M. Turazzini, F. Coltro, R. Migliorini, C. Dal Lin, M. Girelli

[1]Dept of Neurology, Mater Salutis Hospital (Legnago-MI); [2]Psichiatry, Polyclinics Entolè (Padova); [3]Internal Medicine, Polyclinics Entolè (Padova);[4]Cardiology, Department of Cardiac, Thoracic and Vascular Sciences (Padova);[5]Radiology, Mater Salutis Hospital (Legnago-MI)

Introduction: The pineal gland is a small and unique organ which is localized in the geometric center on the brain. Description of this gland date back to antiquity but its functions are only partially known. We describe a case of a woman with severe sleep disturbance and a multiorgan and multi-functional pathologies caused by a voluminous cyst of the pineal gland with displacement to the left of its axis.

Material and Methods: In this study we describe the case of a woman who at the age of 41 yrs began to develop a series of multiorgan and multifunctional pathologies associated to a severe sleep disturbances. She was taken care of by numerous specialists for paroxysmal tachycardia and recurrent thrombophlebitis (cardiologist), environmental neurotoxic immune syndrome (psychiatrist), thyroiditis and adrenal adenoma and reduced function of CYP4502D6 (endocrinologist), endometriosis (gynecologist), deficit IgG3 e NK (immunologist) and lower eyelid basalioma (oncologist).

Result: Sleep disturbance (severe insomnia) was associated with stress due to a numerous and severe pathologies which on the other hand, had never been associated with a common cause. After three years she performed a neurological examination and a brain MRI which revealed a voluminous cyst of the pineal gland with displacement to the left of its axis.

Discussion: The pineal gland has a primary role in controlling sleep cycles by secreting melatonin and in neuroendocrine control. Anti-oxidant, anti-aging and anti-tumoral properties have also been attributed to it. Several cardiovascular effects are due to melatonin such as antihypertensive properties, regulation of heart race and vascular resistance. Melatonin is an important player in the regulation of immunogenecity, energy metabolism and glucose homeostasis. The pineal gland may influence the psychic function with a sophisticated immunoneuroendocrine network. The disrupted afferent and efferent pathways and the alteration / slowing of the secretion of neurohormones and neurotransmitters could be at the basis of pathological processes.

Conclusion: This case highlights "in vivo" the multiple but still partly unknown functions of the pineal gland. Unfortunately, the study of the pineal gland is currently very fragmented and sectoral by every specialist, which diagnoses and cures the effect but does not seek the cause. For this reason, this important organ and its complex functions should be investigated with new enthusiasm and interest in the future and a multispecialistic approach.

## TELEVISIT AS DIAGNOSTIC TRIAGE FOR PEOPLE WITH SUSPECTED NARCOLEPSY: THE TELEMEDICINE FOR NARCOLEPSY (TENAR) RELIABILITY AND DIAGNOSTIC ACCURACY STUDY

L. Vignatelli[1], F. Pizza[2], S. Vandi[2], F. Baccari[3], C. Zenesini[3], F. Ingravallo[4], G. Plazzi[5]

[1]IRCCS Istituto Scienze Neurologiche of Bologna (Bologna); [2]Department of Biomedical and Neuromotor Sciences (DIBINEM), University of Bologna (Bologna); [3]IRCCS Istituto delle Scienze Neurologiche of Bologna, Azienda USL (Bologna); [4]Department of Medical and Surgical Sciences (DIMEC), University of Bologna (Bologna); [5]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio-Emilia (Modena)

Objectives: Narcolepsy is a rare central disorder of hypersomnolence. Onset occurs at a young age, but patients experience an extended diagnostic delay. Sleep centers organized for narcolepsy work up are few and sparse at a national level, thus forcing patients to expensive journeys. Diagnostic reliability and accuracy of televisit compared with in-office visit was assessed in patients with suspected narcolepsy in the Telemedicine for NARcolepsy (TENAR) project, funded by the Italian Ministry of Health (RF-2016-02364742).

Materials: 220 patients (101 M, 119 F, mean age 35.3 years) were included. Forty-eight percent of the patients were from Emilia-Romagna, 25% from other region in the north of Italy, 17% from the center, and 10% from the south or islands.

Methods: We carried out a cross-sectional study with prospective recruitment of patients of any age with suspected narcolepsy referred to the Bologna outpatient Clinic for Narcolepsy. Reliability of the diagnostic judgment made after interview through televisit and after usual in-office visit was assessed with Kappa statistic. Diagnostic accuracy of the same judgment made after televisit was calculated compared with the final diagnosis (reference standard = ICSD3). The televisit was conducted via tablet for the patient, and via equipped pc in another room for the physician. The two visits (televisit or in-office) were conducted by two different physicians using a semi standardized clinical interview, and whenever a physician suspected narcolepsy the diagnostic work-up was offered to the patient.

Results: The raw agreement of diagnostic judgment between the two modalities (i.e., televisit and in-office) was 77%, corresponding to Kappa 0.65 ("substantial agreement"). At the end of the diagnostic process, 33% of patients were diagnosed with narcolepsy (51 type 1, 14 type 2). Televisit showed a sensitivity of 100% and a specificity of 45%. These results were comparable to those of the in-office visit (sensitivity 100%, specificity 41%).

Discussion: In people with suspected narcolepsy, diagnostic conclusions reached through televisit agree with those reached through the in-office visit. Diagnostic accuracy was almost identical between the two interview modalities.

Conclusions: Televisit with a semi standardized clinical interview could be considered as a diagnostic triage procedure, as it is accurate in excluding people without narcolepsy from advanced diagnostic procedures without losing any patients with actual narcolepsy. This approach should be implemented to reduce patients' mobility (e.g. people living far from sleep centers; health emergencies).

## HIV-ASSOCIATED NEUROCOGNITIVE DISORDER (HAND) MIMICKING NARCOLEPSY: A CASE REPORT

P. Zoleo[1], E. Ferlazzo[1], S. Gasparini[1], L. Manzo[1], O. Marsico[1], V. Bova[2], V. Cianci[2], G. Tripodi[2], U. Aguglia[2]

[1]Department of Medical and Surgical Sciences, Magna Graecia University (Catanzaro); [2]Regional Epilepsy Centre, Great Metropolitan "Bianchi Melacrino Morelli" Hospital (Reggio Calabria)

Introduction: Classical presentation of HIV-associated neurocognitive disorder (HAND) comprises difficulties in concentration, impairment in memory and executive functions and psychomotor slowing [1,2]. We describe a patient with HAND presenting with excessive daytime sleepiness mimicking narcolepsy.

Case: A 48-year-old previously healthy man presented with a five-month history of excessive daytime sleepiness and visual hallucinations. After a few months he developed cognitive decline and he experienced some falls without loss of consciousness. Neurological examination showed mild cerebellar ataxia. Epworth Sleepiness Scale (ESS) score was 22/24 (n.v. < 9). Neuropsychological tests revealed moderate multi-domain neurocognitive disorder. In the hypothesis of narcolepsy, we performed a multiple sleep latency test (MSLT) and brain MRI. MSLT evidenced hypersomnolence but was negative for sleep onset rapid eye movements periods (SOREMPs). Brain MRI revealed multiple lesions with T2-hyperintense signal in deep white matter and basal ganglia, in particular in hypothalamic-subthalamic region, without contrast enhancement. Hematologic examination revealed a borderline leucopenia (3.100 cells/ mm3) with lymphopenia (660 cells/ mm3). A HIV-1 antibody test was positive with a serum viral load of 500.000 copies/ml; CD4-cell count was 20 cell/ mm3. CSF analysis showed lymphocytic pleocytosis (52 cells/mm3), increased albumin count (3470 mg/dl) and normal glucose level. CSF orexin levels were not analyzed. We then performed a broad screening for infectious diseases, with syphilis and HBV test positivity. TPHA, VDRL, JCV-DNA test, Toxoplasma Gondii-DNA test, CMV-DNA test, HHV6 and HHV8-DNA test on CSF were negative; EBV-DNA test and HIV1-RNA test on CSF were positive. HAART and penicillin therapy was started. After two months there was a great improvement of daytime sleepiness (ESS score of 11), neurocognitive disorder and brain-MRI abnormalities.

Discussion: It is well known that narcolepsy is caused by hypothalamic dysfunction [3]. In our patient, the clinical picture was dominated by excessive daytime sleepiness and hallucinations, but criteria for narcolepsy were not met due to the absence of SOREMPs. These narcolepsy-like symptoms could be explained by brain lesions involving the hypothalamic-subthalamic region. Our report expands the phenotypic spectrum of HAND clinical manifestations.

## VEGETATIVE NERVOUS SYSTEM

### ACUTE UNILATERAL MYDRIASIS: ONLY BAD NEWS?

L. Becattini[1], E. Del Prete[2], F. Bianchi[1], G. Vadi[1], C. Meoni[1], B. Giovannini[1], G. Tognoni[2], G. Siciliano[1]

[1]Department of Clinical and Experimental Medicine, Neurology Unit, University of Pisa (Pisa); [2]Department of Medical Specialities, Neurology Unit, Azienda Ospedaliero Universitaria Pisana (Pisa)

Introduction: Acute unilateral mydriasis alerts neurologist, as it can potentially be related to serious neurological conditions, including cerebral aneurysm, stroke, intracranial haemorrhages, meningitis, and optic neuritis. However, this condition may sometimes be associated with less severe conditions, including migraine, trauma or drug exposure. Benign episodic mydriasis (BEM) has also been described.

Case Report: We present the case of a 28-year-old female with no significant medical history except for a personal and family history of migraine headaches. She came to emergency department for the sudden occurrence of an acute visual disturbance associated with unilateral pupil abnormalities. She reported prism-like vision, zigzag lines in the periphery of the left visual field, intense photophobia, and subsequent visual field deficit. At the evaluation, she exhibited impaired monocular visual acuity, blurry vision, and a dilated, sluggishly reactive left pupil. The patient did not report any other neurological symptoms, including headache. The neurologic evaluation did not reveal any significant findings, except for a persistent unilateral dilated sluggishly reactive pupil. A brain MRI with contrast and angiography resulted normal, as well as blood tests, including virological screening. An ophthalmic examination also resulted negative: she showed full visual fields on Computerized Visual Field testing, and normal intraocular pressures in both eyes. The patient was treated with FANS and the visual disturbance resolved completely in the following 14 hours, with two brief recurrences lasting less than an hour in the days after.

Discussion: Benign episodic mydriasis is a rare cause of acute anisocoria, predominantly affecting females with a history of migraine. It is a harmless condition that resolves spontaneously and does not cause permanent damage to the eye involved or to the visual system. The underlying pathophysiology of this condition remains poorly understood, however a hyperactivity of the sympathetic nervous system or a hypoactivity of the parasympathetic nervous system are likely involved. Patients with BEM may present with an isolated anisocoria or may experience additional symptoms like blurry vision, photophobia, orbital pain, nausea, eye redness, diplopia, or headache. Prompt and comprehensive evaluation is crucial to rule out the above-mentioned severe causes of visual disturbances and pupils abnomalities.

Conclusion: In our case, the patient was diagnosed with unilateral BEM. This diagnosis could be challenging for the Neurologist especially at the first presentation. BEM must be kept in mind in patients with episodic pupils abnormalities and normal imaging and laboratoristic findings, especially in female with a history of migraine.

### EVIDENCE OF CARDIOVASCULAR AUTONOMIC DYSFUNCTION IN A PATIENT WITH ACERULOPLASMINEMIA

V. De Franco[1], R. Cilia[2], R. Eleopra[2], A. Elia[2], N. Golfrè Andreasi[2], G. Devigili[2]

[1]University of Siena (Siena); [2]Foundation IRCCS Neurological Institute "C. Besta" (Milano)

Background: Aceruloplasminemia is a rare autosomal recessive disease classified among "neurodegeneration with brain iron accumulation" (NBIA), secondary to reduced activity of ceruloplasmin, a ferroxidase involved in the export of iron from cells. Clinical hallmarks include dementia, retinal degeneration and diabetes. The spectrum of neurological manifestations is remarkably broad including cerebellar symptoms, hyperkinetic movement disorders and, more rarely, hypokinetic movements. We describe here the main features of the autonomic nervous system involvement.

Clinical Case: A 62-year-old woman referred to our Institute with a history of about 13 years of progressive cognitive impairment, chorea, dysphagia and dysarthria. The non-motor signs and symptoms were microcytic anemia, constipation, urgent urinary incontinence and orthostatic hypotension. Before evaluation at our Institute was made early diagnosis for positive family history with evidence of microcytic anemia and elevated liver enzymes. The patient was treated, before the onset of neurological symptoms, first with deferiprone and later, due to the progression of the disease, with deferoxamine. Finally was proposed therapy with ferrochelant and fresh frozen plasma with high levels of ceruloplasmin, refused by the patient. Brain MRI showed iron deposition in basal ganglia nuclei, thalami, midbrain, dentate nuclei and white matter of the semioval centers associated with cerebral, cerebellar atrophy and diffuse cortical siderosis. DAT-scan assessed the integrity of presynaptic dopamine transporters in basal ganglia. Plasma epinephrine levels were reduced in both clinostatism 13 pg/ml (20 - 190) and orthostatism 11 pg/ml (20 - 190) while norepinephrine levels were normal both in clinostatism 249 pg/ml (70 - 480) and orthostatism 212 pg/ml (70 - 480), showing a slight reduction in orthostatism. 123I-mIBG scan showed a reduced density of the adrenergic cardiac sympathetic nerve endings. Cardiovascular autonomic reflexes showed presence of baroreflex failure, with delayed orthostatic hypotension at head up tilting test and impaired adrenergic sympathetic function at the Valsalva manouvre.

Discussion and Conclusion: Our patient showed reduced plasma levels of epinephrine, slight decrease in epinephrine and norepinephrine plasma levels in orthostatism. Myocardial scintigraphy proved impairment of post-ganglionic sympathetic cardiac innervation. Finally with cardiovascular autonomic test we found baroreflex failure and confirmed the dysfunction of the sympathetic system. Autonomic nervous system studies may provide interesting data to increase the awareness regard this rare condition and to extend the clinical spectrum of aceruloplasminemia.

## CARDIOVASCULAR AUTONOMIC FUNCTION IN GBA-ASSOCIATED PARKINSON'S DISEASE

T. De Santis[1], A. Cocco[1], E. Morenghi[2], A. Albanese[1], E. Valente[3]

[1]Department of Neurology, IRCCS Humanitas Research Hospital (Rozzano-MI); [2]Biostatistic Unit, IRCCS Humanitas Research Hospital (Rozzano-MI); [3]Neurogenetics Research Center, IRCCS Mondino Foundation (Pavia)

Objectives: Data retrieved from questionnaires suggested that patients with Parkinson's disease carrying GBA variants (GBA-PD) have an increased risk of dysautonomia, compared to patients with idiopathic Parkinson's disease (i-PD). Recent laboratory evidence also supported these findings, but a comprehensive electrodiagnostic assessment of the autonomic nervous system in GBA-PD is lacking. This case-control study provides a laboratory-based assessment of cardiovascular autonomic function in GBA-PD compared to i-PD with the aim to describe the prevalence, characteristics, and severity of cardiovascular dysautonomia in the two groups.

Materials and Methods: All patients underwent an autonomic battery including head-up tilt test, Valsalva maneuver, and deep breathing. The sympathetic noradrenergic system was assessed by measuring heart rate and blood pressure response to the head-up tilt and blood pressure response to the Valsalva maneuver. Parasympathetic function was assessed by measuring the Valsalva Ratio and the respiratory sinus arrhythmia. The severity of dysautonomia was graded with the Composite Autonomic Severity Score cardiovascular subscore (cv-CASS). The late heart-to-mediastinum ratio of 123I-MIBG uptake was calculated. Symptoms related to autonomic dysfunction were collected in each patient by means of the SCOPA-AUT questionnaire. The association of cv-CASS score and sympathetic and parasympathetic subscores with other clinical variables was explored using linear regression analysis. All calculations were performed with the Stata 15 program, considering significant a $p < 0.05$.

Results: A total of 34 GBA-PD and of 33 i-PD patients participated in the study. Age at disease onset was younger in the GBA-PD group. The main between-group differences were a greater supine and orthostatic heart rate in GBA-PD. This was coupled with evidence of higher parasympathetic cv-CASS subscores and higher SCOPA-AUT scores. There was no inter-group difference in the H/M ratio. Demographic and clinical features did not correlate with the severity of cardiovascular dysautonomia.

Discussion: We found a prominent dysfunction in parasympathetic parameters in the GBA-PD group, while sympathetic parameters were similar. It is arguable that cardiovagal dysfunction occurs earlier in the disease history than sympathetic dysfunction. The early parasympathetic dysfunction in GBA-PD may arise from an ascending pathology during the disease course, with a gut-to-brain spreading of alpha-synuclein aggregates through the vagus nerve, as proposed in the body-first subtype of PD.

Conclusions: We suggest a selective parasympathetic dysfunction in GBA-PD. This is the first study that performed a complete battery of cardiovascular autonomic tests in GBA-PD. Our data should be confirmed pathologically or with imaging studies to assess parasympathetic innervation.

## THE INVOLVEMENT OF THE SENSORY AND AUTONOMIC PERIPHERAL NERVOUS SYSTEM IN HYPERMOBILITY SPECTRUM DISORDER: MORPHOLOGICAL AND FUNCTIONAL STUDY

D. Dell'Aversana[1], A. Trinchillo[1], F. Masciarelli[1], R. Iodice[1], F. Vitale[1], R. Dubbioso[1], L. Ruggiero[1], V. Provitera[2], S. Tozza[1], L. Santoro[1], F. Manganelli[1], M. Nolano[1,2]

[1]Department of Neurosciences, Reproductive and Odontostomatological Sciences, University of Naples "Federico II" (Napoli); [2]Department of Neurology, Skin BiopsyLaboratory, IstitutiClinici Scientifici Maugeri IRCCS (Telese Terme-BN)

Objectives: Patients affected by Hypermobile Ehlers Danlos and Hypermobile Spectrum Disorder (HSD) often have a long history of sensory and autonomic symptoms complains. The aim of this study is to assess the peripheral involvement of sensory and autonomic nervous system in HSD.

Methods and Materials:14 patients with HSD (3 male, 11 female, 38±12 years) and 16 patients with idiopathic SFN (6 male, 10 female, 50±11 years) were recruited. Both patient groups underwent clinical evaluation and assessment of sensory and autonomic dysfunction trough the "Small Fiber Neuropathy Symptoms Inventory Questionnaire" (SFN-SIQ), the "Composite Autonomic Symptoms Score" (COMPASS-31), Quantitative Sensory Testing (QST), cardiovascular reflexes (Ewing's battery test), sympathetic skin response (SSR) and the Dynamic Sweat Test (DST). Cutaneous sensory and autonomic innervation was analyzed on punch skin biopsies from leg, thigh and fingertip applying indirect Immunofluerescence procedures.

Results: HSD patients were younger, with earlier onset of symptoms and longer disease duration then SFN patients ($p<0.05$). They also frequently suffered of migraine-type headache, dysimmune diseases, food and drug allergies and urticaria. They complained of pain with a generalized distribution and involvement of the perineal region in a third of the cases. Abnormal QST for each sensory modality was observed without significant differences in between patient groups. Autonomic symptoms involving the cardiovascular, gastrointestinal and sudomotor domains were significantly ($p<0.05$) more frequent in HSD than in SFN patients. Moreover, impairment of autonomic cardiovascular function with evidence of Postural Orthostatic Tachycardia Syndrome (PoTS) was observed in 7 HSD patients while it was absent in SFN

group (p<0.05). DST showed that in HSD compared with SFN patients a non-length-dependent reduction of sweat output per individual gland was present (3.56±2.73 nl/min vs. 8,97±7,49 nl/min). The morphological analysis of cutaneous nerves revealed a more severe loss of pilomotor and sudomotor nerve fibers, with a mild non-length dependent loss of epidermal nerve fibers (ENF) in HSD compared to SFN patients.

Conclusion: Small fiber involvement in HSD compared to SFN patients, presents with a distinctive pattern of generalized pain, often including perineal region and autonomic symptoms mostly involving cardiovascular and gastrointestinal domains. The morphological picture underlying this condition is a more severe loss of autonomic nerves and a mild non length-dependent loss of ENF.

## AUTONOMIC DYSFUNCTION IS ASSOCIATED WITH DISEASE PROGRESSION AND SURVIVAL IN AMYOTROPHIC LATERAL SCLEROSIS: A PROSPECTIVE LONGITUDINAL COHORT STUDY

V. Iuzzolino[1], M. Ferrara[1], F. Vitale[1], V. Provitera[2], G. Senerchia[1], L. Santoro[1], F. Manganelli[1], M. Nolano[2], R. Dubbioso[1]

[1]Department of Neurosciences, Reproductive Sciences and Odontostomatology, University of Naples "Federico II" (Napoli); [2]Istituti Clinici Scientifici Maugeri IRCCS, Neurological Rehabilitation Unit of Telese Terme Institute (Telese Terme-BN)

Background: Among non-motor symptoms, autonomic disturbances have been described in Amyotrophic Lateral Sclerosis (ALS) and reported as mild to moderate in up to 75% of patients [1, 2]. To date, no study has systematically investigated autonomic symptoms as prognostic factors in Amyotrophic Lateral Sclerosis (ALS). Main aim of this longitudinal study was to examine the association of autonomic dysfunction with disease progression and survival in ALS.

Methods: We enrolled newly diagnosed ALS patients and a healthy control group (HC). Time from disease onset to disease milestone (King's stage 4) and death were calculated to assess disease progression and survival. Autonomic symptoms were assessed by a dedicated questionnaire. Longitudinal evaluation of parasympathetic cardiovascular activity was performed by the heart rate variability (HRV). Multivariable Cox proportional hazards regression models on the risk of the disease milestone and death were used. A mixed-effect linear regression model was used to compare autonomic dysfunction with a HC group as well as its impairment over time.

Results: A total of 102 patients and 41 HC were studied. Autonomic symptoms occurred in 69 (68%) patients at diagnosis and progressed over time (post6: p= 0.015 and post12: p<0.001), especially in bulbar patients (p<0.001). A higher autonomic symptom burden was an independent marker of faster development of King's stage 4 (HR: 1.05; 95% CI 1.00 to 1.11; p= 0.022), whereas urinary complaints were independent factors of a shorter survival (HR: 3.12; 95% CI 1.22 to 7.97; p= 0.018). Lastly, ALS patients, compared with HC, complained more autonomic symptoms, and displayed a significant reduction of HRV (p=0.018); patients also showed a significant decrease of HRV at follow-up (p=0.009).

Conclusions: Autonomic symptoms at diagnosis were associated with a more rapid development of disease milestones and shorter survival in patients with ALS.

## ISOLATED CENTRAL DYSAUTONOMIA AS A LONG-STANDING PRODROME TO MULTISYSTEM ATROPHY: A CASE REPORT AND LITERATURE REVIEW

F. Luiso, R. Telese, F. Colucci, A. Braccia, N. Golfrè Andreasi, L. Romito, A. Elia, R. Cilia, R. Eleopra, G. Devigili

Parkinson and Movement Disorders, IRCCS Foundation "Carlo Besta" Neurological Institute (Milano)

Objectives: To describe the clinical features of a young-onset isolated central dysautonomia evolving into a clinically probable multisystem atrophy, and to review the relevant literature on the dysautonomic onset of this disease.

Case Report: A 38-year-old man presented with progressive dysautonomic symptoms. His past medical history included a previous hospitalization due to pulmonary embolism, linked to coagulation factors IX, XI, and XII deficiency, requiring chronic anticoagulant therapy. The patient exhibited a five-year history of hypotonic bladder dysfunction as the initial symptom, followed by constipation and erectile dysfunction after two years; he recently developed orthostatic hypotension. No other significant neurological symptoms were reported; the patient didn't complain of hyposmia or RBD symptoms. Upon admission, the neurological examination revealed only a mild left finger-to-nose dysmetria. Routine blood tests were normal. Cerebrospinal fluid analysis, including the search for oligoclonal bands, onconeural and neuronal cell surface antibodies (including anti-ganglionic acetylcholine receptor antibody), as well as neurodegeneration markers, were normal. Brain and spinal magnetic resonance imaging revealed small ischemic lesions in the bifrontal white matter and right cerebellar hemisphere, prompting a complete cerebrovascular screening that yielded negative results, except for the known coagulation factor deficits. SPECT with DaTSCAN and cardiac scintigraphy with MIBG showed normal results. Electromyography, electroencephalography, and motor and sensory evoked potentials were within normal limits. Autonomic nervous system testing revealed severe cardiovascular dysautonomia with cardiac and vascular sympathetic dysfunction, resulting in syncope at the fifth minute of the tilt test. Supine and orthostatic plasma norepinephrine levels were normal. Dynamic sweat test was normal, while sympathetic skin responses to endogenous stimuli were abnormal, indicating intact postganglionic sudomotor function. Ambulatory blood pressure monitoring documented a non-dipper blood pressure profile. Genetic testing for familial amyloidosis due to transthyretin gene mutation was negative. The patient was discharged with a diagnosis of central dysautonomia in the absence of prominent parkinsonian or cerebellar motor symptoms. At the two-month follow-up visit, the neurological examination revealed mild rigidity, bradykinesia and a rest tremor in

the left upper limb, ultimately meeting the 2022 criteria of clinically probable multisystem atrophy.

Conclusions: We presented a case of a young-onset, progressive, and long-standing isolated central dysautonomia, with the development of a mild parkinsonism 5 years after onset. The differential diagnosis between central or peripheral dysautonomic disorders (such as pure autonomic failure) is crucial in determining the clinical course and prognosis. The clinical follow-up of these patients, particularly from a motor perspective, is essential to better define the diagnosis.

## A CASE OF SEVERE MULTI-DOMAIN AUTONOMIC DYSFUNCTION

F. Masciarelli[1], M. Nolano[1], V. Provitera[2], S. Tozza[1], R. Iodice[1], R. Dubbioso[1], L. Ruggiero[1], F. Manganelli[1]

[1]Department of Neurosciences, Reproductive Sciences, and Odontostomatology, University of Naples Federico II (Napoli); [2]Neurology Department, Skin Biopsy Lab, IRCCS Istituti Clinici Scientifici Maugeri (Telese Terme-AV)

Objectives: Cases of multi-domain autonomic dysfunction may be challenging for clinicians for diagnosis and treatment.

Materials: We report a case of a 70 year-old male patient, with negative history, who started 10 years ago presenting loss of sweating in the right side. After 3-4 years symptomatology evolved in generalized loss of sweating, heat and exercise intolerance and frequent lipothymic episodes. Since 5 years he suffered from orthostatic intolerance, fatigue, dry skin, photophobia, weak urinary flow, urgent urination, absent ejaculation, erectile dysfunction, nocturnal dyspnea, constipation and burning pain. At physical examination anisocoria, tonic pupil in the left eye and weak light reflex in the left eye, absent in the right, were found. No motor function impairment was detected.

Methods: The patient underwent extensive neuroradiologic and neurophysiologic assessment. Moreover autonomic testing exploring cardiovascular and sudomotor function, quantitative sensory testing and cutaneous innervation analysis trough skin biopsy were performed.

Results: Brain and spine MRI and electroneurography were normal. Cardiac scintigraphy showed a global reduced 123 I-MIBG uptake. Cardiovascular reflexes revealed severe failure of parasympathetic and sympathetic function with evidence of orthostatic hypotension. Thermoregulatory sweat test showed generalized anhidrosis and a peripheral postganglionic damage was detected by the dynamic sweat test that showed a severe hypohidrosis after pilocarpine stimulation. Sympathetic skin response was absent and sensory thresholds were increased. Skin biopsy revealed a moderate loss of epidermal nerve fibers and Meissner corpuscles and a severe loss of autonomic cutaneous nerves. An extensive screening for causes including the search for TTR gene mutation and ganglionic AChR antibodies was negative. We performed a further analysis of cutaneous innervation observing intraneural deposits of phosphorylated a-synuclein.

Discussion: Based on symptoms, signs and functional and autonomic evaluation our patient had a picture of severe autonomic ganglionopathy. Since 50% of autoimmune autonomic ganglionopathy remain seronegative we could not exclude this diagnostic hypothesis, although the long course of the disease. Detection of deposits of phosphorylated a-synuclein orientated for the diagnosis of pure autonomic failure (PAF). A 3 year follow up demonstrated a lack of progression overtime with no appearance of motor involvement.

Conclusions: The search for cutaneous deposits of phosphorylated a-synuclein may help clinician in differentiating seronegative autoimmune autonomic ganglionopathy from PAF, avoiding unnecessary immunomodulatory treatment. Such patients may improve with symptomatic nonpharmacologic and pharmacologic strategies, but they need to be monitored overtime to early identify possible phenoconversion.

## SUCCESSFUL TREATMENT OF RETROGRADE CRICOPHARYNGEUS DYSFUNCTION WITH LOW DOSE BOTULINUM TOXIN. THE FIRST CASE REPORT FROM ITALY

C. Zaffina[1], L. Pavesi[2], C. Balzano[2], S. Mauramati[1], C. Giudice[1], M. Fresia[1], M. Todisco[1], E. Alfonsi[1], G. Cosentino[1]

[1]IRCCS Mondino Foundation, Department of Brain and Behavioural Sciences, University of Pavia (Pavia); [2]Independent researcher in Pharmaceutical Chemistry and Technology and in Nutritional Sciences (Novara)

Objective: The Retrograde Cricopharyngeus Dysfunction (R-CPD), identified for the first time in 2019, refers to a range of signs and symptoms such as gurgling noises from the chest and lower neck, excessive abdominal bloating, flatulence, painful hiccups, emetophobia and inability to belch. Since a systematic literature on this topic is still lacking, here we describe the first case report from Italy successfully treated with low dose botulinum toxin.

Materials and Methods (case description): A 28-year-old female patient suffered from abdominal swelling, gurgling noises, painful hiccups, nausea, flatulence and abelchia since she was a child. Over the years she underwent numerous specialists and was diagnosed with different kinds of diseases, including celiac disease and somatoform disorder, without any benefit from related therapies. When she was admitted to our department, she underwent a multidisciplinary assessment, which consisted of a Fiberoptic Endoscopic Evaluation of Swallowing, neurological and neurophysiologic examinations. An electrokinesigraphic and electromyographic evaluation of the laringo-pharyngeal district was performed, with normal findings. The patient was diagnosed with R-CPD based on clinical pictures and treated by the off-label injection of 10 units of onabotulinum toxin-A. In the subsequent days all her symptoms including pain and abdominal swelling began to improve.

At the time of this writing (3 months after treatment) the improvement persists and no significant adverse events has been reported.

Results: Since any other possible cause of the symptoms was ruled out, R-CPD was diagnosed based on patient's anamnesis, clinical symptoms, normal findings at instrumental investigation, and the clinical improvement following the low dose botulinum injection.

Discussion: The Retrograde Cricopharyngeus Dysfunction (R-CPD) is still largely unknown and often misdiagnosed as a gastrointestinal pathology. Since the injection with botulinum toxin served for both diagnosis and treatment, in this report we present the first case of R-CPD diagnosed in Italy, successfully treated with unilateral, anesthesia-free injection of 10 units of onabotulinum toxin-A into the cricopharyngeus muscle, representing the lowest dose reported to date.

Conclusions: Although pathophysiological mechanism are not clearly understood, the Retrograde Cricopharyngeus Dysfunction, once diagnosed, represents a treatable condition with a high rate of response, even at low doses of botulinum toxin injection treatment.

Objective: Our purpose is to provide reference values of thermal Quantitative Sensory Testing in the Italian population according to age, gender and different body sites using the new device Medoc 'Q-sense'.

Materials: 84 Italian healthy volunteers were recruited and divided into three age groups (18-39, 40-59 and 60-80 years). The test was performed by using an air-cooled heat probe connected to the Q-sense Conditioned Pain Modulation (CPM) device.

Methods: Temperature thresholds (Warm Detection Thresholds – WDT, and Cold Detection Thresholds – CDT) and Heat Pain Thresholds (HPT) were measured in all participants on the thenar eminence of the right hand, the right supraorbital frontal region and the dorsum of the right foot. To test the WDT and CDT, both the method of limits (MLI) and method of levels (MLE) were applied at each body site. The MLI was used to measure the HPT.

Results: Non-parametric reference limits (2.5th–97.5th) were calculated according to age, gender and tested site. WDT, CDT and HPT were affected by age, since subjects over 40 years old presented higher WDT and HTP values and lower CDT values. In the extra-trigeminal body sites, females showed lower WDT and higher CDT, while males had higher HPT. Worse sensory discriminative abilities and increased HPT values were found in people aged over 40 on the foot. Age-related differences were more evident with the reaction time-dependent MLI vs. MLE paradigm.

Discussion: This study is the first study to assess normative values of thermal QST in the Italian population, and the first study to report gender- and age-specific reference values in healthy subjects using the Q-sense device. Our study confirms that thermal QST values not only change with age, but body site- and gender-specific reference values are needed. Since we observed age related differences on the foot dorsum for both MLI and MLE paradigm, we assumed that a physiological reduction of small nerve fiber density with a length-dependent pattern might occur with age. About gender differences, our results showed that females have better sensory discriminative abilities than males.

Conclusions: Our findings show that demographic factors (e.g., age and gender) and the tested body site greatly affect thermal QST measures. These differences must be considered when QST is performed in patients with suspected small fibre neuropathy or different chronic pain syndromes.
