## CEREBROVASCULAR DISEASES

### THE PROGNOSTIC ROLE OF ACUTE STROKE LESION CHARACTERISTICS IN A SAMPLE OF MECHANICAL THROMBECTOMY ELIGIBLE PATIENT

G. Adamo, A. Bisogno, L. Pini, C. Baracchini, F. Causin, M. Corbetta

Department of Neuroscience, University of Padua (Padova)

Objective: Mechanical thrombectomy is an effective treatment for large vessel occlusion causing ischemic stroke. Several clinical and radiological factors guide outcome prediction and treatment eligibility. The Alberta Stroke Program Early CT score (ASPECTS), a 10-point quantitative score assessing early ischemic changes, and stroke volumetric variables (penumbra and lesion volumes) are the most common metrics that drive hyperacute stroke management [1]. We investigated the prognostic role of these outcomes, compared to clinical and stroke-induced brain dysconnectivity patterns, new metrics showing promising results in predicting post stroke impairment [2].

Methods: We retrospectively included patients who underwent acute mechanical thrombectomy (Clinica Neurologica, Hospital of Padova). The following metrics were collected: ASPECTS scores, (hyperacute) core and penumbra volumes, post mechanical thrombectomy lesion volumes. The latter were used to compute structural disconnection maps [2]. Functional outcome was represented by the modified rankin scale (mRS) at admission (pre-mRS), discharge (post-mRS) and after 90-days (mRS-90) [3]. National Institutes of Health Stroke Scale (NIHSS) at presentation was also evaluated. A multiple linear regression analysis compared four models including mRS-90 as the dependent variable. In the first model (M1) regressors included age, pre-mRS, and NIHSS; in the second model (M2) ASPECTS, core, and penumbra volume were added; in the third model (M3) structural disconnection information was included. The fourth model (M4) included age, pre-mRS, post-mRS, and NIHSS. Models were compared using a modified jackknife procedure. Finally, we investigated the voxel-wise relationship between mRS and structural disconnections.

Results: Fifty patients were included (thrombectomy performed from 2018 to 2021; mean mRS-90 = 2.2±1.8). M4 provided the highest adjusted r-squared in predicting mRS-90 (adjusted r2=0.614). The variance explained by the other models was: M1: r2=0.517; M2: r2=0.504; M3 r2=0.549. We then compared models r2 from the jackknife procedure, showing that M4 was significantly higher than the other models, while M3 (including structural disconnections) was higher compared to M2. Finally, a significant relationship ($p<0.05$) was observed between mRS-90 and damage to the corticospinal tract extending to the cingulum and the corpus callosum.

Discussion: We reported that clinical status is the most valuable prognostic factor after three months from the event. The ASPECTS and volumetric information showed the lowest prediction. On the contrary, structural disconnection was more informative for functional outcome. Conclusions: While clinical characteristics showed the highest prognostic prediction, brain dysconnectivity patterns may be helpful for post stroke prognosis.

### THE ROLE OF NOX-2 AND ET-1 IN PERIHEMATOMAL HYPOPERFUSION, ISCHEMIC LESIONS AND HEMATOMA EXPANSION IN PATIENTS WITH INTRAPARENCHYMAL CEREBRAL HEMORRHAGE

P. Amisano[1], S. Lorenzano[2], O. Schiavo[2], R. Carnevale[3], A. Ciacciarelli[1], I. Berto[1], M. Iacobucci[4], A. Melone[5], D. Toni[1], M. De Michele[1]

[1]Emergency Department, Stroke Unit, Sapienza University of Rome (Roma); [2]Department of Human Neurosciences, Sapienza University of Rome (Roma); [3]Department of Sciences and Medical-Surgical Biotechnology, Sapienza University of Rome (Roma); [4]Neuroradiology Unit, Department of Human Neurosciences, Sapienza University of Rome (Roma); [5]Division of Radiology, Emergency Department, Sapienza University of Rome (Roma)

Objectives: Perihematomal hypoperfusion may lead to the development of ischemic damage during intraparenchymal cerebral hemorrhage (ICH), resulting in worse prognosis. We aimed [1] to investigate the relationship between serum biomarkers related to vasoactive substances and the occurrence of hypoperfusion and ischemic perihematomal lesions in ICH [2] to evaluate their correlation with volumetric evolution of the hematoma and perihematomal edema.

Materials and methods: We included patients with ICH admitted to our Stroke Unit from January 2019 to July 2021. Blood samples were collected at three different timepoints (T0: admission to Emergency Room, T1: 12-24hs from symptoms onset, T2: 48-72hs from symptoms onset) to measure Endothelin-1 (ET-1), nitrites/nitrates (end products of nitric oxide, NO), NADPH oxidase-2 (NOX-2), metalloproteinase-12 (MMP12), asymmetric dimethylarginine (ADMA), and cortisol. Patients underwent brain MRI with perfusion study at T1 and MRI without perfusion at T2.

Results: Of 28 patients included in the study, 12 had ischemic perihematomal lesions at T1. We observed a borderline statistically significant difference in the NOX-2 concentration at T0 with higher levels in patients with ischemic perihematomal lesions compared to those without (34.9ppmv vs 22.4ppmv, p=0.051). NOX-2 values were significantly associated with hematoma-ipsilateral

hemispheric hypoperfusion at T1 (p=0.034) and the development of severe edema at T2 (p=0.011). ET-1 values at T1 inversely correlated with hemorrhage volume at T2 (ρ=-0.717, p=0.030). The development of ischemic perihematomal lesions was significantly associated with an increased volume of hematoma (p=0.005), perilesional edema (p=0.046), greater midline shift (p=0.036), and had a borderline statistically significant association with hemispheric hypoperfusion (p=0.055).

Discussion and conclusions: We found that oxidative stress-related biomarkers were associated with perihematomal hypoperfusion, severe edema and ischemic perihematomal lesions, although we cannot conclude on a causal relationship. The association between the lower ET-1 values with a larger hemorrhage volume is probably related to a decrease in the vasoconstriction of the ruptured vessel wall. Our study provides a starting point for the understanding of the physiopathological mechanisms of ICH.

## MULTIPLE CEREBRAL INFARCTS AND ENCEPHALOPATHY AS THE FIRST CLINICAL MANIFESTATIONS OF HYPEREOSINOPHILIC SYNDROME

G. Avola[1], S. Romano[1], M. Angeli[1], F. Brazzale[1], E. Giacopazzi[1], P. Castellini[2], A. Genovese[2]

[1]Operating Unit of Neurology and Stroke Care, Department of Medicine and Surgery, University Hospital of Parma (Parma); [2]Operating Unit of Neurology and Stroke Care, Department of Emergency-Urgency, University Hospital of Parma (Parma)

Background and aims: Hypereosinophilic syndrome (HES) is characterized by a peripheral blood eosinophil count >1.5 x 10^3/uL on two separate examinations at least one month apart and/or a bone marrow eosinophil percentage of 20% or higher, along with organ damage. Neurological involvement rarely occurs during the progression of this disease, particularly in its early stages. We present a case study of a 73-year-old patient with hypertension, dyslipidemia and mild obesity, who suddenly exhibited weakness in all limbs

Materials: Neurological examination revealed impaired consciousness and a deficit in the left lower cranial nerve VII. Additionally, the patient showed mild weakness in the right upper limb, severe weakness in the left upper limb, and moderate weakness in the lower limbs.

Methods: Brain CT-scan, brain-MRI, magnetic resonance angiography of the head, transthoracic echocardiography, cardiac magnetic resonance (CMR) EEG and osteomedullary biopsy were performed.

Results: Neuroimaging exams revealed multiple bilateral ischemic lesions. Laboratory tests indicated hypereosinophilia. Parasitological examination of the stool was negative, no allergies were reported, cytogenetic examination of the bone marrow aspirate and osteomedullary biopsy excluded a lymphoproliferative process. Echocardiography showed thickening of the mid-apical lateral wall of the left ventricle and subendocardial hyperdensity, confirmed by CMR, which also revealed hyperintensity due to late gadolinium enhancement and a thrombus within the mid-apical lateral wall of the left ventricle. These findings strongly suggested a diagnosis of Loeffler's endocarditis. During hospitalization, the patient experienced disorientation, aggression, and anosognosia, with EEG showing Generalized Rhythmic Delta Activity sequences preceded by point-wave-like graphoelements. Anticoagulant and steroid therapy were administered. The patient showed gradual clinical improvement, encephalopathy remitted and follow-up CMR indicated resolution of thrombus.

Discussion: A comprehensive diagnostic workup confirmed idiopathic HES. The increased blood viscosity induced by hypereosinophilia itself, along with cardioembolism related to intracardiac thrombus formation, are believed to be the primary mechanisms underlying ischemic strokes. Consequently, all lesions are typically found in watershed areas where the clearance of in situ-microthrombi or emboli from the heart is impaired. Finally, the encephalopathy results both from multiple cerebral infarctions and the neurotoxicity induced by hypereosinophilia.

Conclusions: According to the literature, most cases of HES, particularly those with Loeffler's endocarditis, show cardiorespiratory symptoms upon admission. Neurological findings as the first clinical manifestations make this case-report intriguing. Through this clinical case, we aim to raise awareness among clinicians about hypereosinophilia as a rare cause of stroke and encephalopathy, even in the absence of other symptoms.

## POSSIBLE MRI PREDICTORS OF HEMORRHAGIC TRANSFORMATION IN ACUTE STROKE PATIENTS UNDERGOING DAPT: A CLINICAL STUDY

M. R. Bagnato, L. Bruno, I. Maestrini, M. Diomedi

Stroke Unit, Tor Vergata University (Roma)

Aims: DAPT is a stroke secondary prevention therapy for different clinical scenarios. DAPT safety and hemorrhagic transformation (HT) predictors in acute ischemic stroke aren't well known. The aim of this study was to identify HT predictors to early detect patients at higher risk of bleeding on DAPT.

Material and Methods: We enrolled consecutive acute ischemic stroke patients, admitted to Stroke Unit between 2020-2022, undergoing DAPT (ASA + Clopidogrel) according to current guidelines, within 96 hours from onset. We collected clinical data. We evaluated the number of acute lesions, lesion volume using ABC/2 method and SVD markers on MRI performed when DAPT was started. The primary outcome was safety, defined as the absence of HT at control CT, 7 days after DAPT beginning.

Results: We enrolled 194 patients [median age 70, 66,5% men]. 28(14,4%) patients presented HT, among these, 4(2%) were PH. 87 patients (44,8%) underwent DAPT for acute carotid stent placement, 61(31,4%) for minor stroke and 46(23,7%) for symptomatic intracranial stenosis. Patients undergoing stenting procedures had higher HT rates (p<0,01). Treatment with Clopidogrel and dual antiplatelet loading dose had more HT (p=0,04, p=0,03). Higher NIHSS relate to HT. We defined a cut-off of 4, over which HT risk increases [AUC 0.799(95% CI 0.753-0.881), p<0.001]. No association between intravenous thrombolysis and HT was found. SVD radiological markers associated in CSVD and individually didn't rely with HT, except for lacunae, determining lower risk of HT (p=0,03). Larger lesion volume on MRI was the best predictor of HT risk (p<0.01). We identified a cut-off volume of 8.2 ml (AUC 0.82, 95% Sensibility 0,79, Specificity 0,8,

CI 0.745-0.9, p<0.001). Lesion volume>8.2 ml resulted in a 10-fold increased HT risk (95% CI 3.69-28.37, p<0.001).

Discussion: MRI volume cut-off is the best HT predictor in acute ischemic stroke patients undergoing DAPT. For patients with stroke volume >8.2 ml, at higher risk, a strict clinical-radiological monitoring could be warranted. Because of higher HT risk, management of Clopidogrel and dual antiplatelet loading dose should be evaluated, particularly, in moderate stroke and after stent positioning. Intravenous thrombolysis isn't associated with HT, so, in patients with minor stroke undergoing this treatment, DAPT for 21 days should be deepened and discussed.

Conclusions: Symptomatic HT during DAPT isn't very frequent, so DAPT may be considered safe in its various indications. However, minor HT events aren't negligible, because they may impair DAPT duration and expose to early ischemic risk, thus, it is useful to identify predictors.

## ROLE OF ENDOTHELIN-1 AND NITRIC OXIDE IN ACUTE ISCHEMIC STROKE LEPTOMENINGEAL COLLATERALS ACTIVATION

M. Beccia[1], A. Risitano[1], S. Lorenzano[2], I. Berto[1], O. Schiavo[1], R. Carnevale[3], V. Cammisotto[4], M. Iacobucci[5], M. Di Mascio[1], D. Toni[2], M. De Michele[1]

[1]Emergency Department, Stroke Unit, Sapienza University, Umberto I Hospital (Roma); [2]Department of Human Neurosciences, Umberto I Hospital (Roma); [3]Department of Medical and Surgical Sciences and Biotechnologies, Sapienza University (Latina); [4]Department of General Surgery and Surgical Speciality Paride Stefanini, Sapienza University (Roma); [5]Department of Human Neurosciences, Neuroradiology Unit, Sapienza University, Umberto I Hospital (Roma)

Background and aims: Good leptomeningeal collaterals (LMC) after large vessel occlusion (LVO) extend time window for endovascular therapy (EVT). Mechanisms regulating the LMC activation are not completely known. Aim of this study was to investigate the role of Endothelin-1 (ET1) and nitric oxide (NO) in post-stroke LMC regulation.

Methods: Ischemic stroke patients within 6 hours from LVO were included. Collateral status was evaluated on a Computed Tomography Angiography scan using the Menon scoring system. Patients were accordingly divided into three groups: poor, intermediate and good LMC. Recanalization was evaluated using Thrombolysis in cerebral infarction (TICI) score. Serum ET1 and NO were evaluated at three different time points from stroke onset: T0 (< 6h), T1 (24h), T2 (48h).

Results: We enrolled 102 patients (mean age was 76 ± 12.35): 45 with good (44.5%), 35 with intermediate (34.3%) and 22 with poor LMC (21.6%). Serum ET1 levels increased whereas NO levels decreased from T0 to T1 regardless of the collateral status. However, in patients with poor recanalization and poor LMC, serum ET1 values were higher at each time point (p 0.005). A significant association was also found between higher ET1 levels at T1 and poor outcome despite a good recanalization (p 0.030).

Conclusion: Although we found no significant association between the extent of LCM and ET1 and NO serum concentrations, present data show that the highest ET1 serum levels at 24 hours predict a poor outcome despite a good recanalization. A sustained ETA receptor mediated vasoconstriction could be hypothesized in these patients.

## THE OPACIFICATION TIME OF ASCENDING AORTA DURING CT ANGIOGRAPHY AS A PREDICTOR OF HEART FAILURE

S. Bellavia, I. Scala, P. Rizzo, J. di Giovanni, G. Frisullo

Department of Aging, Neurological, Orthopaedic and Head-Neck Sciences, University Hospital Foundation, Catholic University of Sacred Heart (Roma)

Objective: Heart failure (HF) represent the second most frequent cause of cardioembolic (CE) stroke. Brain CT angiography is routinely performed in the suspect of a large vessel occlusion. Placing a region of interest (ROI) at the level of the ascending aorta during the initiation of CT angiography, the opacification of the vessel is monitored until a threshold value of Hounsfield Unit (HU) is reached, automatically starting images acquisition. The opacification time of the ascending aorta (OTAA) may be affected by heart ejection fraction (EF) and inform on the occurrence of HF already during the emergency management of a stroke patient. We evaluated the existence of a correlation between the OTAA and the EF and tried to identify a cut-off value of this time, able to predict a diagnosis of heart failure and cardioembolic stroke.

Materials and Methods: We screened all patients discharged from the Policlinico Gemelli in Rome during an 18-month period, with a CT angiography of cerebral vessel and an echocardiographic evaluation of the EF performed during hospitalization. The opacification time of the ascending aorta was calculated as the time needed to reach a threshold of 40 Hounsfield Unit (T40HU) in the ROI. This threshold was chosen arbitrary as the one to which the machine (Meditech, GE-Optima TC 660) automatically starts arterial phase imaging acquisition. The Spearman correlation test was used to evaluate the existence of a correlation between the EF and the T40HU. We used a receiver operating characteristic (ROC) curve analysis to identify a cut-off value of the T40HU able to diagnose with good sensitivity and specificity the presence of HF and cardioembolic stroke.

Results: We enrolled 382 patients and found an inverse correlation between the EF and the T40HU, indicating longer time for aorta opalization as the EF decreases (Spearman Rho= -0.46, p<0.001). The ROC curve analysis identified a cut-off value of 16,8 seconds for the T40HU as able to predict with good sensitivity (90%) and specificity (63%) a diagnosis of heart failure with EF <40% (AUC = 0.84, CI=0.78-0.89) and acceptable sensitivity (67%) and a specificity of (66%) a diagnosis of cardioembolic stroke (AUC = 0.68, CI=0.61-0.74). Through the multivariate logistic regression, we confirmed this cut-off as an independent predictor of HF (EF<40%), and cardioembolic stroke.

Conclusions: The T40HU is a reliable indicator of HF with reduced EF, allowing to esteem heart function already in the emergency department even in the setting of an acute stroke.

## CAROTID WEB AND ISCHEMIC STROKE, AN UNEXPECTED CASE

L. Benedetti[1,2]; A. Falcou[2]; C. Cirelli[3]; F. Biraschi[3]; D. Toni[1,2]

[1]Dept. of Human Neurosciences, "La Sapienza" University of Rome (Roma); [2]Emergency Department Stroke Unit, Hospital Policlinico Umberto I (Roma); [3]Interventional Neuroradiology Unit, Hospital Policlinico Umberto I (Roma)
Dept. of Human Neurosciences, "La Sapienza" University of Rome (Roma)

Background: One third of all ischemic strokes is still defined as cryptogenic. The underlying mechanism upon most of them is considered to be the embolism from an undetermined source (ESUS). The Carotid Web is an intraluminal projection of hyperplastic intima arising from the carotid artery bulb which causes blood stagnation with the potential for distal embolization. Recent studies enlight the role of Carotid Web as an under diagnosed cause of stroke, especially in young healthy patients.

Case Presentation: A 66-year-old man came to Policlinico Umberto I ER because of appearance of pain and paresthesias, began in the right arm and extended in 20 days to the omolateral leg. A Cerebral MRI was performed, showing a thrombus inside the intra-cranial left Internal Carotid Artery and a left parietal-occipital and frontal acute ischaemic lesions. A Cerebral CT scan with angio sequences was performed next, detecting a plus image in the left Carotid Bulb, compatible with Carotid Web. The patient underwent a series of exams aimed to detect other plausible causes of the ischaemic stroke (auto-anticorpal screening, trans-toracic echocardiogram, long term ecg monitoring, cardiological examination, …), with negative outcome. Due to the absence of other causes of the stroke, after a brainstorming between Neurologists and Interventistic Neuroradiologists, it was decided to perform a left carotid stenting in order to exclude the Carotid Web, site of blood stasis.

Discussion: Our case underlines how Carotid Web has to be researched as a cause of stroke not only in young and healthy patients. Our patient is an over-sixtyfive but, due to the absence of other relevant causes of stroke, we assumed the carotid web as the responsible of the cerebral infarct. Literature data suggest endovascular treatment in symptomatic Carotid Webs as the best secondary prevention strategy, but there are not trial there to prove it. The rarity of CW hinders randomized clinical trials, so the creation of a unique database grouping all the observed and treated Carotid Webs from international stroke-units would be desirable in order to analyse and confront the results from various treatments (medical treatment vs endovascular treatment).

## MULTICENTRE TRANSLATIONAL TRIAL OF REMOTE ISCHAEMIC CONDITIONING IN ACUTE ISCHAEMIC STROKE (TRICS BASIC): A MULTICENTRE, RANDOMIZED, PRECLINICAL TRIAL IN FEMALE AND MALE RATS AND MICE. ON BEHALF OF THE TRICS BASIC STUDY GROUP

S. Beretta

IRCCS San Gerardo, University of Milano Bicocca (Monza)

Previous results from single laboratories support the efficacy and safety of remote ischemic conditioning (RIC), but phase 2-3 clinical trials have provided conflicting results. TRICS BASIC is a preclinical trial performed within a consortium of 7 Italian research laboratories. The TRICS BASIC trial investigated efficacy and safety of RIC in experimental acute ischemic stroke, using a robust, translationally oriented, randomized preclinical trial design, which included two animal species (rats and mice) of both sexes. The transient endovascular occlusion (60 min in mice; 100 min in rats) of the middle cerebral artery was chosen as the stroke model to be used for the trial. RIC treatment was applied by transient surgical clamping of the femoral artery after reperfusion (10 min in mice; 20 min in rats). Blinded outcomes assessment was performed for functional neuroscore (primary outcome) and infarct volume (secondary outcome) at 48 hours. A dedicated harmonization phase, which included all the participating laboratories, was performed before starting enrollment, to reduce the assessment bias for the neurobehavioral evaluation. The experimental cohort consisted in 206 animals (n=110 mice and n=96 rats). RIC treatment increased the proportion of good functional outcome (composite + 19%; OR 2.15; 95% CI 1.12 to 4.13; $p = 0.021$) and reduced the infarct volume (composite -38%; 95% CI -5% to -71%; $p = 0.013$) in both species, without safety concerns, compared to sham surgery. This study showed a moderate beneficial effect of surgically-delivered RIC treatment applied early after reperfusion in acute ischemic stroke models from multiple species and both sexes.

## LARGE-SCALE NETWORK TOPOLOGY OF ACUTE ISCHEMIC STROKE PREDICTS FUNCTIONAL OUTCOME AFTER ENDOVASCULAR TREATMENT

A. L. Bisogno[1], L. Pini[2], S. Raccanello[2], G. Adamo[1], C. Bertolotti[2], E. Fusaro[3], A. Salvalaggio[1], F. Causin[4], C. Baracchini[4], M. Corbetta[1]

[1]Department of Neuroscience, University of Padua (Padova); [2]Padova Neuroscience Center, University of Padua (Padova); [3]Padova Neuroscience Center, Azienda Ospedaliera Universita' di Padova (Padova); [4]Department of Neuroscience, Azienda Ospedaliera Universita' di Padova (Padova)

Objective: Mechanical thrombectomy restores blood flow after the acute occlusion of a brain vessel causing ischemic stroke. Volumetric data and vascular atlases guide acute stroke management entirely. [1] Recent literature recognizes the additional predictive value of remote disconnection data reflecting a large-scale network functional organization of the brain. [2] In this study, we test the prognostic ability of lesion topography embedded in different parcellations of

the brain. We compare a vascular atlas with a functional (i.e. grey matter) and structural (i.e. white matter) atlas to test which provides the best outcome prediction.

Materials and methods: We enrolled patients suffering from stroke who underwent EVT at the Stroke Unit of the Padua University Hospital from January 2018 to June 2022. On admission, we collected NIHSS scores, pre-event mRS and post EVT CT/MRI scans. At discharge and after three months we collected the NIHSS and mRS. [3] Lesions following EVT were manually segmented and embedded in a vascular atlas, a functional grey matter atlas and a structural white matter atlas. We performed a ridge regression model with a bagging procedure to assess outcome prediction. In addition, BCB toolkit indirectly estimated the structural disconnection caused by the lesion and whole-brain temporal correlation maps were calculated. We investigated the relationship between functional outcome and brain features at a voxel-wise level implementing a linear correlation including disconnectivity maps for each patient.

Results: A total of n=66 patients met inclusion criteria. The prediction of the mRS using lesion topography was the most robust for the functional and structural atlas (R2=0.382), followed by Figley's structural atlas (R2=0.338), while the vascular atlas provided the lowest prediction (R2=0.146). The voxel-wise functional dysconnectivity map showed areas significantly correlated with the mRS overlapped with the visual, sensorimotor and dorsal attention networks. The structural disconnection analysis showed the corticospinal tract, corpus callosum, corona radiata, thalamic radiation, left inferior and superior longitudinal fasciculus significantly correlated with the mRS ($p<0.05$).

Discussion: Considering lesion topography in a functional/structural atlas framework provided a better estimation of functional outcome in comparison to a vascular framework. In addition, we described post-stroke disconnectome patterns as applicable prognostic measures.

Conclusion: These results suggest these measures could be used in clinical practice, at present driven by neuroimaging features including solely volumetric and vascular scores.

## SUCCESSFUL DELAYED THROMBECTOMY IN A 12-YEAR-OLD PATIENT WITH ACUTE ISCHEMIC STROKE: A CASE REPORT

S. Boldrini, M. Meneri, G. Costamagna, S. Lanfranconi, I. Ghione, G. Comi, S. Bonato

Stroke Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Dino Ferrari Centre, Neuroscience Section, Department of Pathophysiology and Transplantation (DEPT), University of Milan (Milano)

Aims: To describe a case of pediatric acute ischemic stroke (AIS) due to middle cerebral artery dissection and treated with delayed endovascular treatment (EVT).

Materials and Methods: A patient with an ischemic stroke underwent a neurological examination, brain computerized tomography (CT) scan, brain magnetic resonance imaging (MRI) with angiography and perfusion studies, and EVT.

Results: A 12-year-old girl with no previous medical history was driven to the pediatric emergency department for sudden onset of aphasia associated with paresthesias and weakness in the right upper limb that occurred after minor facial trauma (dip in the pool). Upon arrival, the symptoms had already regressed. She was discharged after a normal brain CT scan. The following day, she returned to hospital after waking up with recurrence of symptoms. Her National Institutes of Health Stroke Scale (NIHSS) score at admission was 9. Brain CT scan showed a left lenticular hypodensity [Alberta Stroke Program Early CT Score (ASPECTS) of 8] and in supraortic CT angiography a left middle cerebral artery occlusion was found, with good collateral flow. MRI with perfusion imaging underlined a significant Diffusion Weighted Imaging – Perfusion Weighted Imaging mismatch in the left middle cerebral artery territory. She was treated with EVT with a final extended thrombolysis in cerebral infarction (eTICI) score of 2c. The patient experienced a full neurological recovery and was discharged home in excellent conditions one week after AIS.

Discussion: In the pediatric setting, EVT still remains an off-label procedure, especially for patients presenting outside the 6-hour time window. Emerging evidence suggests that patient selection should be more imaging-based than time-based and that the therapeutic window for EVT in children may extend beyond the established window for adult patients, with several reports of successful EVT even after 48h from AIS onset [1,2].

Conclusions: In pediatric strokes, advanced neuroimaging techniques could ameliorate the selection of patients who may benefit from reperfusion therapy. However, whether it is correct to apply the same criteria used in adults is still uncertain.

## A CASE OF EARLY CT-SCAN FALSE NEGATIVE TYPE-A AORTIC DISSECTION PRESENTING WITH SYNCOPE AND ISCHAEMIC MYELITIS: A CASE REPORT

L. Bonan[1], Y. Bartolini[2], A. Di Lionardo[2], L. Mancinelli[2], M. Longoni[2]

[1]IRCCS Istituto delle Scienze Neurologiche di Bologna, University of Bologna (Bologna); [2]Department of Neuroscience, Bufalini Hospital (Cesena)

Introduction: Aortic dissection is defined as disruption of the medial layer caused by intramural bleeding, followed by the separation of the aortic wall layers and formation of a false and a true lumen. Ischaemic spinal cord damage due to type A aortic dissection is rare, having an incidence of 1.0% [1]. Sensitivity and specificity of Computed Tomography Angiography (CTA) for aortic dissection are > 95%, with an accuracy reaching 99.5% [2]: CTA and Magnetic Resonance Imaging (MRI) are highly accurate, although false negatives and positives could occur.

Case Presentation: A 77-year-old man who had been suffering from hypertension, hypercolesterolemia and bradicinetic syndrome was admitted to the Emergency Department for a sudden loss of consciousness. Blood exams showed high levels of cardiac troponins. ECG revealed an episode of bradicardic atrial fibrillation associated with alteration of the ST segment in the inferior precordial derivations. Cardiac echography showed no pathologic changes of the aortic shape and normal kynesis of the left ventricule. CT scan was negative for acute aortic pathology. After a few hours, the patient appeared aware and collaborant, but he developed palsy and anesthesia of both legs, which did not improve during hospitalization. As MRI showed a case

of transverse myelitis, a chest CTA scan was performed, which was negative. After having ruled out other aetiologies, we prescribed an oral anticoagulant therapy to avoid cardioembolic events. However, since the strong clinical suspect, we performed a third CTA scan after a week, which revealed an aortic dissection of the sino-tubular junction associated with an intramural heamatoma expanding to the abdominal aorta. The patient underwent a surgical operation.

Discussion: This case is a rare example of a false negative result of a CT scan in the context of a type A aortic dissection. Aziz and others [3] described a case series in which four patients had a type-A aortic dissection which was not recognised by CT scan, pointing out the existence of the chance of failing of this technique, although the high accuracy.

Conclusion: We believe it is important to highlight false-negative cases of this acute and high mortality-related pathology in order to improve the diagnostic process and even to consider an ideal timing in which it could be useful to repeat the CT scan. This could avoid missing the chance to offer a correct surgical treatment and the possibility to recover from the ischaemic process.

## STURGE WEBER SYNDROME TYPE III IN ADULT PATIENT: A CASE REPORT

R. Bonetti[1], F. Terenghi[2], L. Politi[3], E. Nobile-Orazio[4]

[1]Neuromuscular and Neuroimmunology Unit, IRCCS Humanitas Clinical and Research Institute, University of Milan (Milano); [2]Neuromuscular and Neuroimmunology Unit, IRCCS Humanitas Clinical and Research Institute (Milano); [3]Department of Neuroradiology, Department of Biomedical Sciences, IRCCS Humanitas Clinical and Research Institute, University of Milan (Milano); [4]Neuromuscular and Neuroimmunology Unit, Department of Medical Biotechnology and Translational Medicine, IRCCS Humanitas Clinical and Research Institute, University of Milan (Milano)

Clinical presentation: A 50y old woman, without a previous relevant medical record, presented to emergency room (ER) reporting a first acute episode of left hemianopsia lasting 30 minutes followed shortly by the appearance of left hemisoma weakness and hypoesthesia with a marching course lasting 30 minutes. Neurological examination showed no focal signs. CT brain showed right cortical frontal-parietal-occipital hyperdensity similar to subarachnoid bleeding but with normal CT angiography. Brain RMN showed an enhancing right cortical fronto-parietal hyperintensity and thickening and a lesser extent also in the right occipital side and in left cingulate gyrus with possible post-critical significance but not excluding inflammatory disease like FLAMES or meningitic causes. We started anticonvulsant therapy and patient was admitted in the Neurological Unit Care. Laboratory test including autoimmunity, infectivological and thrombophilia screening were normal. Cervical spine MRI, EEG and full body CT were negative. CSF analysis showed 33 mg/dL protein, 9 white blood cells/mm3, intrathecal oligoclonal bands synthesis, virological and culture grew negative and malignant cells absent. In the hypothesis of inflammatory disease started Methylprednisolone ev therapy. The brain RMN check was found to be unchanged to previous one and anti MOG antibodies were negative. We decided to perform an angiographical study that showed a slightly prominent capillary-venous reticulum with early opacification of adjacent cortical outflow veins suggested the hypothesis of right hemisphere angiomatosis.

Discussion: Sturge-Weber syndrome (SWS) is a rare pediatric neurocutaneous syndrome defined, in the complete form, by the association of a facial capillary malformation with choroidal angioma, and/or leptomeningeal angiomatosis. Clinical presentation in late adulthood is possible but rarely reported and all the described cases are without facial port-wine stain but with specific typical characteristic neuroradiological findings (type III) [1]. Seizure is the most common neurological manifestation and stroke-like episodes, paroxysmal paralysis, transient hemiparesis and migraine are other neurological manifestations [1,2]. MRI features are in the form of T2W hyperintense signal in the subcortical white matter beneath the region of leptomeningeal angiomatosis. Cerebral angiography demonstrates aberrant pattern of both the arterial and venous cerebral circulation such as arterial thrombosis, abnormal venous drainage, paucity of superficial draining veins [2,3].

Conclusions: We report a rare case of adulthood variant of SWS in the fifth decade of life with no cutaneous and ophthalmological abnormalities. Diagnosing isolated leptomeningeal angiomatosis in late adulthood is challenging. Characteristics find of brain MRI different modalities and cerebral angiography can aid in establishing the diagnosis of SWS III after excluding infection, granulomatous inflammation and meningeal carcinomatosis.

## UNDERSTANDING THE PHYSIOPATHOLOGY OF CAROTID ARTERY DISSECTIONS AND PREDICTING THE EVOLUTION. A REAL CASE FLUID DYNAMIC AND MECHANICAL SIMULATION

A. Bonura[1], G. Musotto[2], G. Iaccarino[1], V. Di Lazzaro[1], F. Pilato[1]

[1]Unit of Neurology, Neurophysiology, Neurobiology and Psychiatry, University Campus Bio-Medico di Roma (Roma); [2]Bioengineering Unit, Ri.MED Foundation (Palermo)

Purpose: In this study, we performed a computer simulation to investigate the mechanical and rheological properties of symptomatic carotid artery dissection. The flow and vessel wall of a right internal carotid artery dissection in a patient with ischemic stroke were simulated. The aim was to evaluate the ability of the simulation to predict the clinical and physiopathological course of the dissection [1] in terms of the risk of thrombosis (by analyzing the shear strain rate, which evaluates the risk of thrombosis and its pathogenesis [2], cerebral hypoperfusion, deformation of the vessel wall, and extension of the dissection.

Methods: A two-way fluid-structure interaction (FSI) approach was adopted for simulation using Ansys multiphysics software [3]. The simulation considered three different arterial pressure conditions (hypotension, normotension, and hypertension) and two wall elasticity

conditions (normal and atherosclerotic) to analyse the factors influencing dissection evolution. The study results were analysed in terms of vascular wall shear strain rate, wall shear stress, flow velocity, intraluminal pressure, and wall deformation. Results were then compared with the clinical course and CT-angiography data obtained during the 6-month follow-up visit of the patients.

Results: Maximum shear rate was observed at the initial portion of the true lumen, while minimum shear rate was found at the terminal portion of the false lumen. The highest pressure occurred just prior to the dissection, coinciding with the greatest wall deformation. Maximum wall shear stress was identified at initial part of the true lumen.
Discussion: Analysis of shear rate demonstrated a low thrombotic risk, consistent with the absence of ischemic recurrence in the patient after 6 months. Wall shear stress analysis indicated a low risk of dissection extension, in line with the radiological stability observed during the same period. The simulation revealed high shear stress in the medial wall of the patient's C2 carotid segments, which correlated with aneurysmal dilation in those areas at the 6-month follow-up. Arterial pressure emerged as the primary determinant of thrombotic risk and wall deformation.

Conclusions: Computational simulation successfully predicted the clinical and pathophysiological evolution of a carotid artery dissection in a real case. The findings highlight the importance of studying rheomechanical parameters in determining the risk of complications and the course of dissection. This approach holds promise for personalized study and treatment of arterial dissections, leading to improved clinical management of patients.

## RISK FACTORS FOR POST-STROKE SEIZURES FOLLOWING REVASCULARIZATION THERAPIES: DATA FROM THE POPULATION OF MODENA, NORTHERN ITALY

G. Borzi[1], N. Orlandi[2], L. Picchetto[3], G. Giovannini[3], R. Ricceri[3], G. Bigliardi[3], S. Meletti[2]

[1]Stroke Unit, Neurology Unit, Department of Neuroscience, Ospedale Civile Baggiovara, Azienda Ospedaliera Universitaria di Modena (Modena); [2]Neurology Unit, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia (Modena); [3]Neurology Unit, OCB Hospital, AOU Modena (Modena)

Introduction: Cerebrovascular diseases represent the most frequent cause of acquired epilepsy in adult patients. However, the incidence and risk factors for post-stroke seizures in patients receiving reperfusion therapies have not yet been completely assessed.
Materials and Methods: Retrospective monocentric study of adult patients who received reperfusion therapies (e.g. intravenous thrombolysis [IVT] and endovascular thrombectomy [ET]) for a first ever acute ischemic stroke at the OCB Hospital in Baggiovara (Modena), Italy. Data collection occurred from January 2014 to December 2020. Early (ES) and late (LS) post-stroke seizures were classified according to the last ILAE definitions. The incidence of LS was assessed through a survival analysis, while a Cox regression model was used to identify outcome predictors.

Results: 974 patients were included, 607 (62%) and 139 (14%) of whom were treated with IVT or ET, respectively. In 228 cases, both treatments were performed. Overall, 25 patients (3%) developed ES, whereas LS occurred in 59 patients (6%). The highest incidence of LS was observed within 12 months from stroke (3.5%), whereas the cumulative rate of LS was 5.5% and 6.2% at 3 years and 5 years, respectively (mean follow-up: 48 months). Cortical involvement (HR 6.9 95% CI 2.3 – 20.4; $p = 0.04$) and stroke severity (e.g. NIHSS $\geq 11$) (HR 4.4, 95% CI 1.02 – 18.6; $p < 0.001$) were the main variables independently associated to the development of LS.

Conclusion: In our cohort the cumulative incidence of post-stroke seizure was low. Stroke severity and cortical involvement were independently associated to the risk of LS.

## UNILATERAL RELAPSING PRIMARY ANGIITIS OF THE CNS IN ISOLATED HEMIHYPERPLASIA: A RARE CASE REPORT

F. Boscain[1], C. Borsato[2], M. Volpe[2], P. Perini[1], E. Mampreso[2]

[1]Neurology, University Hospital of Padua (Padova); [2]Neurology, ULSS6 Euganea (Piove di Sacco-PD)

Introduction and Aims: Primary angiitis of the central nervous system is a well-known clinical entity, characterized by inflammation of the arteries of the brain, spinal cord and leptomeninges. Strictly unilateral findings, involving only one cerebral hemisphere, have been reported very rarely: in such cases, hemispheric differences in immune response mechanisms have been postulated [1].

Materials: We present the case of an 18-year-old man previously diagnosed with isolated hemihyperplasia (OMIM:235000), a rare congenital condition implying mild overgrowth of the right side of the body. The patient, whose medical history was negative for cerebrovascular risk factors, presented at the Emergency Department with right-sided hemiparesis starting abruptly one day prior.
Methods: An urgent contrast-enhanced brain MRI revealed an acute ischemic lesion in the left middle cerebral artery territory, just adjacent to the lateral ventricle, in the context of widespread unilateral white matter disease. Antiplatelet therapy was started as secondary prevention. The supra-aortic trunks and the circle of Willis were extensively examinated; however, the combination of Doppler ultrasound, CTA, black blood MRI, FDG PET-MRI and cerebral angiography displayed no sign of lumen or vessel wall alterations, with normal cerebral hemodynamics. A cardiac work-up, including both a transthoracic and a transesophageal echocardiography as well as a 24-hour Holter ECG monitoring gave negative results. Transcranial Doppler with bubble test found no evidence of intracardiac or intrapulmonary right to left shunts and toxicology, thrombophilia and immunological screenings were unremarkable except for positive serum anti-nuclear antibodies. Genetic testing for hereditary cerebral microangiopathies came back negative. The patient underwent a lumbar puncture and CSF analysis resulted within the normal range; however, oligoclonal bands were

detected. At this point, the hypothesis of small-vessel cerebral vasculitis was formulated and infectious causes were ruled out. As the diagnostic work-up was approaching its end, our patient experienced a recurrent acute ischemic stroke involving the left nucleocapsular region, as demonstrated by a control brain MRI.
Results: A diagnosis of primary angiitis of the CNS with strictly unilateral presentation was made and the patient was started on intravenous Cyclophosphamide. After a 6-month neurological follow-up, no signs of relapse were found.
Discussion and Conclusions: To the best of our knowledge this is the first literature report describing a case of unilateral relapsing primary angiitis of the CNS in the context of isolated hemihyperplasia. We believe this association supports the intriguing hypothesis of lateralized immune reactivity between the right and left brain.

## NEUROEMOTICONS: MOTOR APHASIA ASSOCIATED WITH AGRAPHIA AND ASYMBOLIA FOR NON-LINGUISTIC PICTURES REVEALED BY A WHATSAPP MESSAGE

F. Brigo

Department of Neurology, Hospital of Merano (SABES-ASDAA) (Merano-BZ)

Objective: To describe the case of a patient with sudden onset of motor aphasia associated with agraphia and asymbolia for non-linguistic pictures revealed by a WhatsApp message.
Methods: Case report.
Results: A 76-year-old woman affected by diabetes mellitus, Hashimoto thyroiditis and stomach neuroendocrine tumor underwent a thromboendarterectomy for a severe asymptomatic left-sided carotid artery stenosis. A few hours after the surgical procedure, she developed a motor aphasia with retained comprehension and mild right-sided facial-brachial paresis. She attempted to write a WhatsApp message to her daughter (later, she recalled that she aimed to inform the daughter about her status, asking if she was able to come to visit). The WhatsApp message that she sent revealed a severe impairment of written language, with incongruous use of emoticons that were inappropriate to the context and the intended meaning. The head CT and angio-CT did not reveal any acute cerebrovascular lesion or new vessel occlusion. Symptoms disappeared completely in a couple of hours. A subsequent brain MRI did not reveal any recent ischemic lesion.

Discussion: Patients with aphasia are generally able to represent objects, events and states using concrete and abstract graphic symbols [1]. Alexia and agraphia can be interpreted as manifestations of visual asymbolia (also called cortical visual aphasia) caused by a lesion or functional disruption of the left angular and supramarginal gyrus, involved in language processing. In 1870 Carl Finkelnburg (1832-1896) challenged the view that aphasia was a language disorder, by proposing that it should be regarded as a disruption in the correct understanding of the symbolic meaning (asymbolia) [2]. Our patient was affected by motor aphasia with agraphia; her neurological deficit entailed an impairment in the choice of emoticons used to graphically accompany the meaning of a written text providing emotional nuances to it. During the acute phase only motor aphasia and motor impairment were identified and adequately tested; it was not established whether she could accurately perceive and describe but not recognize the emoticons (visual agnosia).

Conclusions: This case is intriguing as it reproposes the ancient question of whether and to what extent aphasia and agraphia should be interpreted as the result of an impaired ability to understand and intentionally use concepts by means of acquired symbols (linguistic or graphic).

## PULSATILITY INDEX AS A PROGNOSTIC MARKER OF COGNITIVE AND CLINICAL OUTCOME IN A COHORT OF PATIENTS WITH ACUTE NON-DISABLING STROKE AND TIA WITH DIFFERENT ETIOPATHOGENESIS

N. Brunelli[1], C. Altamura[2], M. Marcosano[2], S. Rossi[2], C. Vico[3], C. Costa[4], A. Fallacara[5], M. Bach-Pages[6], F. Vernieri[2]

[1]Fondazione Policlinico Universitario Campus Bio-Medico, Campus Bio-medico University of Rome (Roma); [2]Department of Medicine and Surgery, Unit of Headache and Neurosonology, Unit of Neurology, University Campus Bio-Medico of Rome; Fondazione Policlinico Universitario Campus Bio-Medico, (Roma); [3]Neurology Unit, Azienda Sanitaria Territoriale 3 Marche (Macerata); [4]Neurology Unit, Sondrio Hospital, ASST Valtellina e Alto Lario (Sondrio); [5]Neurology Unit, Policlinico "Aldo Moro" (Bari); [6]Department of Biology, University of Oxford (Oxford-UK)

Background and aims: An impaired vasomotor reactivity (VMR) represents a negative prognostic factor for vascular and degenerative cognitive deterioration [1,2]. An elevated Pulsatility index (PI) might be related to impairment in several cognitive domains in patients with lacunar infarcts [3]. Currently, no prognostic markers are available in acute phase to assess the clinical/cognitive outcome of patients with acute non-disabling stroke or TIA. We aimed to assess if cerebral hemodynamics, evaluated by VMR and PI, represented a prognostic marker of clinical/cognitive outcome in acute Stroke/TIA patients.

Methods: Patients with TIA/non disabling stroke of anterior circulation were enrolled. Stroke etiopathogenesis was defined according to clinical guidelines. The observation period of 12 months included 4 assessments: T1 (48-72h from onset), T2 (1 month follow up [FU]), T3 (6 months FU) and T4 (12 months FU). Clinical scales and cognitive tests were performed every time (T1-T4), whereas VMR and PI of MCA and PCA were registered at T1 and T3.
Results: 124 patients with acute non disabling stroke/TIA and a median age of 66 (54.75-74.25) years were enrolled. 71% were men and 69,4% had a stroke. At T1, we found an inverse correlation between MCA PI and MMSE ($p<0.0001$) and MOCA ($p=0.001$) and between PCA PI and MMSE ($p=0.004$) and MOCA ($p=0.003$). A positive correlation was found between age and MCA PI ($p<0.0001$) and PCA PI ($p<0.0001$), while an inverse correlation was registered between age and MMSE ($p<0.0001$) and MOCA ($p<0.0001$). The same results were confirmed at T3. An inverse correlation was found between MCA PI at baseline and MOCA at T2 ($p=0.001$), MMSE ($p=0.014$) and MOCA ($p=0.001$) at T3, MMSE ($p=0.005$) and MOCA ($p=0.003$) at T4. An inverse correlation was registered between baseline PCA PI and MMSE ($p=0.003$) and MOCA ($p=0.004$) at T2, MMSE ($p=0.027$) and MOCA ($p=0.003$) at T3, MOCA at T4 ($p=0.020$). A positive correlation was observed between baseline MCA PI and mRS at T2 ($p=0.025$), T3 ($p=0.003$) and T4 ($p=0.001$). We also performed a multi-regression

analysis to explore the effect of all the vascular risk factors on PI at baseline. We found that age and diabetes were the main risk factors influencing MCA PI at T1 ($p<0.0001$) and that age was the only factor influencing PCA PI at T1 ($p<0.0001$).
Conclusion: A higher MCA/PCA PI in acute phase is a prognostic marker of worst cognitive/clinical outcome in patients with ischemic non disabling stroke/TIA.

## SPORADIC CEREBRAL AMYLOID ANGIOPATHY IN LATE-ONSET EPILEPSY: A CASE-CONTROL STUDY

A. Bulgari[1], O. Marsico[1], S. Gasparini[1], A. Mammì[1], J. DiFrancesco[2], P. Tabaee Damavandi[2], A. Pascarella[1], V. Cianci[3], V. Bova[1], M. Ascoli[4], R. Cutellè[1], M. Pasquale[1], C. Prestandrea[3], A. Prestandrea[3], C. Paleologo[3], E. Africa[5], P. Bruno[1], E. Ferlazzo[1], U. Aguglia[1]

[1]Department of Medical and Surgical Sciences, Magna Græcia University (Catanzaro); [2]Neurology Unit, S. Gerardo Hospital, University of Milano-Bicocca (Monza); [3]Regional Epilepsy Center, Great Metropolitan Hospital (Reggio Calabria); [4]Neurology Unit, Marche Nord Hospital (Pesaro); [5]Neuroradiology Unit, Great Metropolitan Hospital (Reggio Calabria)

Aim of the study: Sporadic cerebral amyloid angiopathy (CAA) is characterized by progressive amyloid deposition in the walls of leptomeningeal and small cortical arteries of the central nervous system [1]. Epilepsy is a common manifestation during the course of CAA [2]. Given the high frequency of CAA in elderly population and the epileptogenic role of cortical hemorrhagic lesions, it may be hypothesized that CAA can explain a proportion of late-onset epilepsies of unknown etiology. This study aims to assess the prevalence of CAA in patients with late-onset (>50 years) epilepsy of undetermined or vascular etiology and in age-matched non-epileptic controls.

Materials: We included subjects with late-onset epilepsy and controls affected by other neurological conditions.
Methods: All subjects underwent MRI (1.5 Tesla) including blood-sensitive sequences. In the epilepsy group, MRI had to be performed within 60 days from epilepsy onset. The diagnosis of probable CAA was posed according to Boston criteria 2.0 [3]. To evaluate differences between groups, a Chi-squared test was performed. We also calculated odds ratio (OR).

Results: We included 76 patients with late-onset epilepsy (39 males, mean age 71.01±8.93 years) and 134 age-matched controls (82 males, mean age 71.04±8.95 years). A diagnosis of probable CAA was done in 15.8% (12/76) of patients with late-onset epilepsy and in 2.9% (4/134) of the control group. This difference was statistically significant ($p=0.0008$). OR for seizures in CAA versus non-CAA was 6.09 (95% CI:1.89-19.64).
Discussion and Conclusion: In the present study, the prevalence of CAA was significatively higher in patients with late-onset epilepsy, suggesting a significant association between probable CAA and late-onset epilepsy. We suggest to perform MRI with blood-sensitive sequences in patients with late-onset epilepsy of undetermined or vascular etiology.

## WHICH CAME FIRST VERTIGO OR BASILAR ARTERY STROKE? [A CHICKEN AND EGG SITUATION]

G. Busi, E. Mannini

Neurology, University of Parma (Parma)

Introduction: Vertigo is considered one of the most insidious diagnoses in the emergency setting. A study evidenced that almost one-fourth of patients with acute vestibular syndrome had stroke [1]. Moreover, 19% of patients with basilary artery occlusion had a prodromal transient ischemic attack, with vertigo and headache being the most common prodromal symptoms (BASICS registry) [2,3].

Case Presentation: A 57-year-old woman with no relevant medical history except for occasional episodes of vertigo came to the emergency department (ED) because of objective dizziness and faintings. The neurological evaluation (NE) suggested a relapse of peripheral vestibular syndrome. As the brain CT showed no relevant features, the patient was discharged home with symptomatic therapy. Over the next three days, she experienced intense episodes of vomiting and remained bedridden. On the fourth day, after waking up healthy, new fluctuating symptoms occurred namely transient speech disturbances and weakness of the right hemisoma followed by contralateral weakness and headache. Therefore, she returned to the spoke center ED where she underwent a new NE which this time was consistent with an acute stroke (NIHSS = 9). A basilar artery occlusion was confirmed by CT angiogram. Because of the unclear onset of symptoms, she was centralized to the Hub Center in order to proceed to mechanical thrombectomy (MT). Upon arrival in Parma, the patient's clinical condition had worsened: she presented with decreased consciousness, speech absence, oculomotor abnormalities (right conjugate gaze deficit and nystagmus in leftward gaze), quadriparesis, more severe on the left side (NIHSS = 18). The endovascular procedure was effective and the patient had a gradual and complete recovery. As a brain MRI performed a few days later excluded recent ischemic lesions, it was unlikely to date the stroke onset back to the first episodes of dizziness. Further diagnostic investigations were performed and a patent foramen ovale with a large shunt and deep vein thrombosis were found out. Rheumatologic and thrombophilic screenings added no relevant elements. Thus, we postulated an etiology of paradoxical embolism, probably caused by episodes of vomiting (Valsalva maneuver) caused by peripheral dizziness. At this time has not yet undergone PFO closure surgery.

Conclusions: Dizziness remains one of the most insidious symptoms in neurology, making the differential diagnosis between posterior circulation stroke and otolaryngologic disorders complex. In this case, we assume that vertigo of peripheral origin was responsible (together with the patient's comorbidities) for a posterior circulation stroke.

## CONTROVERSIAL ENDOVASCULAR THERAPY IN CHILDHOOD ARTERIAL ISCHEMIC STROKE: A CASE REPORT

M. Caccamo, D. Galotto, S. Grimaldi, N. Marrone, G. Milella, G. Falcicchio, A. Manni, S. Lamberti, M. Savarese, D. Mezzapesa, M. Petruzzellis

Department of Basic Medical Sciences, Neurosciences and Sense Organs, University 'Aldo Moro' (Bari)

Introduction: Childhood arterial ischemic stroke (ch-AIS) poses a challenge in terms of treatment options due to limited data and different etiology from AIS in adults.
Materials and Methods: We report a case of a 15-year-old basketball player with AIS who underwent rescue therapy with intracranial stenting.

Results: He was admitted to the emergency department of pediatric hospital for acute onset, during a basketball game, of motor aphasia and right hemiplegia (NIHSS score 14) lasting two hours. Brain magnetic resonance imaging (MRI) showed left intracranial carotid apex (ICA) near-occlusion and globus pallidus ischemic lesion. The day after he experienced motor aphasia lasting 40 minutes so he was transferred to our Stroke Unit and cerebral angiography (CA) was done, confirming left ICA subocclusion involving the origin of the medial lenticulostriate vessels, probably due to dissection. Despite medical therapy with dual antiplatelet therapy (ASA plus clopidogrel then ASA plus ticagrelor) and appropriate hemodynamic control, neurological deterioration after 48 hours due to new ischemic lesions in left basal ganglia involving internal capsule occurred. The new CA revealed left ICA occlusion involving also the middle cerebral artery origin. Triple angioplasty with self-expandable stent was performed with ICA recanalization (mTICI 2c) and suspecting an inflammatory etiology, we did not proceed to ICA stenting (ICAS), but nimodipine and high-dose methylprednisolone were started. At 12-hours follow-up, the NIHSS score increased from 1 to 14, and transcranial doppler showed left ICA severe restenosis. ICAS was proposed but the parents declined, referring to another hospital. Meanwhile, a single bolus of cyclophosphamide was infused. In the other hospital, due to ongoing focal deficits, the patient underwent ICAS after 36 hours, but moderate right hemiplegia persisted.

Discussion: Identifying the cause of stroke can be challenging during the acute phase, making timely decisions about acute therapies difficult. Fluctuation of symptoms may provide clues but is not pathognomonic of different ch-AIS etiologies. The potential short and long-term sequelae of mechanical vessel manipulation, particularly in perforator-bearing segments and suspected diseased arterial walls, were additional concerns. The timing of ICAS in this case remains debatable, and we cannot exclude that earlier intervention may have yielded a better neurological outcome.

Conclusion: Endovascular therapies in childhood ischemic stroke remain a subject of controversy. This case report highlights challenges in managing ch-AIS and the potential role of ICAS as a rescue therapy. Future studies should aim to elucidate the safety and effectiveness of ICAS, also depending on stroke etiology.

Gemelli Foundation IRCCS (Roma)

Background and aims: Making a reliable prognosis when acute ischemic stroke patients are admitted to the emergency department is challenging. Our aim is to assess whether machine learning methods that collect and analyse clinical, demographic and radiological data of patients who are admitted to acute stroke care can predict the individualized clinical outcome at discharge.

Methods: We tested different artificial intelligence (AI) approaches (XGBoost, random forest, and support vector machine regressors) in 715 patients randomly divided into a training cohort (537) and a testing cohort (178). We tested the ability of AI to predict the variation of NIHSS at discharge compared to NIHSS at admission in each patient. We accepted a difference of $\leq$3 points between the predicted and the observed NIHSS variation when the initial NIHSS score was<5 and a difference of $\leq$4 points when the initial NIHSS was $\geq$ 5. For each model, we evaluated the prediction accuracy through the number of patients correctly predicted. Moreover, we calculated the median absolute error and mean absolute error of the regression.

Results: XGBoost emerged as the best machine learning model with an accuracy of 0.61, mean absolute error of 4.35 and a median absolute error of 3.0 in the testing cohort. The results show that NIHSS at admission, evident ischemic lesion at the first brain CT, age and M1 occlusion are the most significant predictors of the NIHSS variation.
Discussion: Our findings can potentially have important clinical implications if we consider that we have no predicting tool that can describe, in the very acute phase, the evolution of severity for each stroke patient. Moreover, we argue that integrating the model with variables acquired in different subsequent phases of the stroke pathway, we can improve the personalized prediction and further extend the prediction of outcome at 3 months or more.

Conclusions: In conclusion, the XGBoost regression model applied to the data available at admission shows promising results in predicting personalized NIHSS variation at discharge.

## REPERFUSION THERAPIES IN PATIENTS WITH ACUTE ISCHAEMIC STROKE AND ATRIAL FIBRILLATION: DATA ON SAFETY AND EFFICACY FROM A MULTI-CENTER COHORT STUDY

V. Cancelloni, M. Buratti, on behalf of RAF and RAF-NOACs study Investigators

Vascular and Emergency Medicine-Stroke Unit, Santa Maria Della Misericordia Hospital (Perugia)

Background and Aim: Intravenous thrombolysis (IVT) and/or mechanical thrombectomy (MT) are considered best practice in the acute management of ischaemic stroke, improving functional outcome and reducing both mortality, as well as long-term disability. Currently, data regarding the efficacy and safety of reperfusion therapies in patients with atrial fibrillation (AF) reports conflicting rates of hemorrhagic transformation, mortality, and functional outcome. [1] Our study aimed to evaluate the efficacy and safety of reperfusion therapies in patients with acute ischaemic stroke and AF.

Materials and Methods: We pooled individual data from two multicenter prospective cohort studies (RAF and RAF-NOACs) [2,3] which had enrolled consecutive patients with acute ischemic stroke and AF. Demographic, clinical, and treatment data were collected. We compared the baseline characteristics of patients treated and untreated with acute reperfusion therapies (IVT and/or MT) using the $\chi 2$ test for categorical variables or the Mann-Whitney U test for continuous variables. Multivariable logistic regression analysis was performed with the aim of identifying independent predictors for outcome events: 90-day favourable outcome (mRS 0-2) and mortality.

Results: Overall, 1,736 patients were included, 441 (25.4%) in the reperfusion-treated group and 1,295 (74.6%) in the untreated group. Treated and non-treated patients differed in age (mean 73.5±9.9 years versus 76.8±9.7, respectively), NIHSS score (mean 11.7±6.2 versus 7.2±6.7), presence of paroxysmal AF (48% versus 39.9%), and history of stroke or TIA (18.8% versus 28.7%). At 90 days, 120 patients were deceased (18 in the treated group and 102 in the untreated group) and 1,032 patients had favourable outcome (270 in the treated group and 762 in the untreated group). The results of the multivariable analysis evidenced that reperfusion therapies were significantly associated with a favourable outcome, but not with mortality (OR:2.28, 95% IC:1.65-3.17 versus OR:0.61, 95% IC:0.33-1.11, respectively). Regarding other risk factors, age and the NIHSS score were inversely correlated with favourable outcome (OR:0.97, 95% IC:0.96-0.99 and OR:0.84, 95% IC:0.81-0.86, respectively). These variables were also associated with a higher rate of mortality (OR:1.04, 95% IC:1.01-1.07 and OR:1.09, 95% IC 1.06-1.12 for age and NIHSS score, respectively).

Discussion and Conclusions: Patients with AF treated with reperfusion therapies had a significantly higher rate of favourable outcome compared to those patients with AF who had undergone conservative treatment. Mortality tended to be higher in patients with AF who had not been treated with reperfusion therapies.

## ISCHEMIC STROKE DESPITE ORAL ANTICOAGULANT: RETROSPECTIVE ANALYSIS OF INTRA-HOSPITAL COURSE

A. Canessa[1], P. Mortola[2], D. Sassos[1], L. Malfatto[1], M. Del Sette[1]

[1]Neurology, DINOGMI, IRCSS Policlinico San Martino, University of Genoa (Genova); [2]Neurological Clinic, DINOGMI, IRCSS Policlinico San Martino, University of Genoa (Genova)

Objectives: Oral anticoagulants (VKA and DOACs) are well-established therapies for the prevention of embolic stroke in patients with atrial fibrillation. Although anticoagulants are associated with a substantial reduction in risk, a limited group of patients (about 1.2% per year) suffer ischaemic stroke despite anticoagulation therapy. The objective of this study is to define the epidemiological characteristics, acute therapeutic management, and intra-hospital course of patients who suffer ischaemic stroke while undergoing anticoagulant therapy.
Materials: Medical records of all patients admitted to the Stroke Centre of the "Policlinico San Martino" Hospital in Genoa from 01/01/2021 to 31/12/2022.

Methods: Selection of all patients suffering ischaemic stroke while undergoing oral anticoagulant therapy. Detection of patients' weight, age, CHA2DS2-VASC, HAS-BLED, ongoing anticoagulant therapy, reason for said treatment, biohumoral parameters, ASPECT, NIHSS, mRS.

Results: Of the 1351 patients admitted to the Stroke Centre between 01/01/2021 and 31/12/2022, 149 (11%) had an ischaemic stroke during oral anticoagulant therapy. Of those, fifty-five patients (36%) were female, mean age 81 years. The mean CHA2DS2-VASC score was 4.6. One hundred and nine patients (71%) were taking DOAC, 40 patients (26%) were taking AVK. The mean value at NIHSS was 11 at admission, 8 at 24 hours and 7 at discharge from the Stroke Centre. The mRS at admission was 1, at discharge 3.7, with thirty-three patients passing away at the hospital. Eighty-five patients (55%) had LVO, fifty-nine (38%) underwent mechanical thrombectomy and twenty-one (13%) were treated with rTPA. In fifty-four (35%) patients the cause was due to inappropriate underdosing or poor compliance. In fifty (33%) patients no clear reason was identified, in twenty-one (14%) there was congruous stenosis of an intra/extracranial vessel. In the remaining cases, rarer aetiologies, multiple causes (including underdosing and malabsorption) or alternative diagnoses were identified.

Discussion: In the majority of the examined patients, the occurrence of stroke seems to be explained by inappropriate subtherapeutic dosing, by poor adherence to treatment or a non-cardioembolic aetiology. These observations are consistent with what is currently reported in the literature.

Conclusions: The problem under review is as topical and pressing as ever, and many related questions still lack an unanimous response. In particular, which is the best therapeutic strategy for secondary

prevention. For this reason, this analysis represents a starting point for the generation of subsequent prospective studies.

## HYPOGLOSSAL NERVE PALSY DUE TO CAROTID ARTERY DISSECTION: REPORT OF TWO CASES

M. Cantarella, C. Fiori, R. Baruffaldi, M. Silvestrini, S. Luzzi

Department of Experimental and Clinical Medicine, Polytechnic University of Marche (Ancona)

Introduction: Unilateral hypoglossal nerve palsy may result from several different pathologies. It is important to define the underlying pathology to manage the condition wisely. Among the vascular causes of isolated HN palsy ICA dissection is the most common. We present two cases of hypoglossal nerve palsy due to internal carotid artery dissection (ICAD) and discuss the potential mechanisms of acute hemi lingual atrophy.

Case Report: The first patient was admitted to the Department of Neurology due to swallowing difficulties, hypomobility of the tongue, ptosis and miosis of the left eye and neck pain. The tongue deviated to the left when protruded with left hemiatrophy. Magnetic resonance angiography (MRA) of the head and neck visualized a lack of opacification of the left internal carotid artery starting from the bulb, where it appeared markedly thinned, a finding compatible with occlusion due to dissection. The patient was discharged with antiplatelet therapy and extracranial vessel ultrasound (US) control, after one week, showed recanalization of the vessel. The second patient was referred to the Department of Neurology due to articulation disorders and swallowing difficulties associated to altered movements of the tongue. On admission, neurological examination revealed tongue deviation towards the left side with evidence of atrophy of the left half of the tongue. Computed tomography angiography (CTA) of the head and neck showed severe stenosis of both distal cervical and petrous part of left internal carotid artery. Epiaortic vessel US was normal. The patient was discharged with antiplatelet therapy. In both patients the atrophy of the tongue began acutely and resolved after a few weeks. Furthermore, the two patients didn't present cerebral ischemic events.

Discussion: Malignancy and surgery are the most common causes of isolated HN palsy. Vascular causes are rare, but they should be suspected when risk factors are present and symptom onset is acute. In our two patients the atrophy of the tongue had an acute onset and gradually improved during the hospitalization. Likely it was consequent to the local mass effect by which the dissection might acutely impair the function of the HN.

Conclusion: ICAD must be considered in differential diagnosis for young and middle-aged patients when an acute XII nerve palsy is found, isolated, or associated with other focal neurological symptoms. Vascular etiologies are rare and generally cause compressive HN neuropathy that could be identified with meticulous imaging.

## ADVANCED STROKE EVALUATION IN EMERGENCY DEPARTMENT

C. Carelli[1], F. Cesaro[1], C. Cimmino[1], G. Cristiano[1], V. de Simone[2], R. Esposito[1], A. Giunta[1], R. Candido[1], A. Senese[1], M. Ursi[1], M. Guarino[1]

[1]Emergency Department, C.T.O. Hospital (Napoli); [2]Cardiology Department, C.T.O. Hospital (Napoli)

Background: The ischemic stroke, one of the principle leading causes of death and disabling disease, can depend on various causes divided into 5-6 subtypes, including cryptogenic stroke (CIS). A common cardiac cause of CIS, especially in young patients, is the foetal persistence of the patent foramen ovale (PFO) which allows communication between the two atria and determines a right-to-left shunt with the consequent risk of passage of thrombi from the venous to arterial circulation system bypassing the pulmonary tree. The presence of PFO affects around a quarter of population, but it should be emphasized that it does not necessarily cause CIS.

Case Report: Man, 35 years old, arrived in emergency department (ED) for suspected CVA with symptoms that occurred few hours before. During the anamnesis, there were no noteworthy pathologies. Vital parameters, EKG and ABG were normal, while the neurological objective examination showed speech disorder, right facio-brachio-crural weakness with greater brachial involvement, for which it was performed a skull CT that was negative. Considering his young age and in the doubt of a possible malformation-aneurysmatic pathology of the intracranial arterial branches, an angio-CT was executed, which also was negative. Given the need to identify the cause of the ischemic event, a possible cardioembolic origin was investigated and a transthoracic echocardiogram (TTE) was performed which revealed a moderate tricuspid regurgitation with evidence of a jet directed towards the interatrial septum where there was an aneurysm without apparent shunt with color-Doppler. Therefore, the TTE was concluded by performing a Bubble test which highlighted a right-to-left shunt probably due to PFO and a transcranial Doppler (TCD) was executed to confirm the diagnostic suspect. The patient was directed in a cardiology department.

Conclusion: The increased diffusion of ultrasound practice in ED allows to diagnose easily the PFO-related stroke, recording a higher incidence than in the past. Nowadays, transesophageal echocardiography with contrast (c-TOE) is accepted as the gold standard for detecting right-to-left shunt through a PFO, but it is not a procedure to execute in ED. Moreover, other imaging modalities that use contrast agent such as TTE, TCD, CT and cardiac MRI have shown to have similar sensitivity and specificity in detecting a PFO, or making a differential diagnosis, when compared to TOE.

## THE ROLE OF ATRIAL CARDIOPATHY AS POTENTIAL CAUSE OF EMBOLIC STROKE OF UNDETERMINED SOURCE

A. Cascio Rizzo[1], G. Schwarz[1], A. Di Pietro[2], A. Bonelli[3], M. Di Pietro[4], F. Aruta[1], C. Motto[1], B. De Chiara[3], A. Moreo[3], E. Agostoni[1]

[1]Neurology & Stroke Unit, ASST Grande Ospedale Metropolitano Niguarda (Milano); [2]Neurology, AORN Sant'Anna e San Sebastiano (Caserta); [3]Cardiology, ASST Grande Ospedale Metropolitano Niguarda (Milano); [4]Neurology & Stroke Unit, Ospedale Renzetti (Lanciano-CH)

Background: Atrial cardiopathy (AC) is increasingly considered a potential mechanism of embolic stroke of undetermined source (ESUS). [1,2] Preliminary data from the ARCADIA trial have shown that anticoagulation would not be beneficial for preventing strokes in patients with AC. Etiological misclassification may have limited our understanding of the link between AC and ESUS due to the heterogeneous ESUS construct. After application of a recently proposed ESUS update[3], we investigated the pathogenic role of AC in ESUS.

Methods: We retrospectively included consecutive ESUS patients admitted to our Stroke Unit from-2018-to-2022. ESUS was defined according to standard criteria, then we applied the recently proposed construct and excluded patients with (1) high-risk PFO, (2) high-risk characteristics of supracardiac non-stenosing atherosclerosis, (2) cancer-related hypercoagulability. AC was defined as left atrial enlargement (LAE) based on standard criteria: LAVI>34mL/m2. The entire cohort was divided per LAE presence/absence: AC+ESUS if LAVI>34mL/m2 and AC-ESUS if LAVI≤34mL/m2. We assessed (1) clinical and radiological features of ESUS with AC, (2) the association between AC and stroke severity/outcome, (3) the risk of stroke recurrence, (4) the association between LAVI and stroke risk.

Results: Among 414 consecutive ESUS patients with LAVI measurement, 116 (28%) did not meet the recently proposed ESUS construct, 298 patients were included in the final analysis. The overall AC prevalence was 42%. AC+ESUS patients are older, have more hypertension, coronary artery disease and supracardiac atherosclerosis compared to AC-ESUS, suffers from more cortico-subcortical infarcts and fewer small isolated cortical lesions. We found no association between AC and stroke severity (aOR 0.99, 95%CI 0.95-1.03) and good outcome at 3-months (aOR 1.43, 95%CI 0.78-2.63). Over a median of 20 months, recurrent ischemic stroke occurred in 17 patients (5.9%). Kaplan-Meier analysis showed no difference in stroke recurrence among patients stratified according to AC (log-rank test, p=0.149), even after adjusting for baseline risk factors (HR 1.40, 95%CI 0.47-4.18). LAVI as a continuous variable was associated with stroke recurrence in AC-ESUS (aOR 1.44, 95%CI 1.08.1.93, p=0.013).

Conclusion: The prevalence of AC is higher in ESUS defined according to the proposed update, but despite this, it still unclear the role of AC as potential cause of ESUS and whether AC is an indicator of stroke recurrence. Other biomarkers other than LAE may better discriminate AC or we may have applied the wrong LAVI threshold to define LAE. Our results could be useful in the design of future trials attempting to demonstrate the benefit of anticoagulation in ESUS patients with AC.

## NEUROSONOLOGICAL VASCULAR EXAMINATION IN DIAGNOSIS AND FOLLOW-UP OF AN INTRACRANIAL ARTERIAL STENOSIS IN A PATIENT WITH DOUBLE-POSITIVE ANTIPHOSPHOLIPID SYNDROME: A CASE REPORT

F. Castellana[1], V. Inchingolo[2], L. Florio[2], G. Fratta[2], S. Socolov[3], E. Grandone[4], M. Pugliatti[1], G. D'Orsi[2]

[1]Department of Neuroscience and Rehabilitation, University of Ferrara (Ferrara); [2]Department of Neurology and Stroke Unit, I.R.C.C.S. Casa Sollievo della Sofferenza (San Giovanni Rotondo-FG); [3]Department of Neurology, "Grigore T. Popa" University of Pharmacy and Medicine (Iasi-RO); [4]Haemostasis and Thrombosis Center, I.R.C.C.S. Casa Sollievo della Sofferenza (San Giovanni Rotondo-FG)

Objectives: A case report on a young patient with antiphospholipid syndrome (APS) who experienced an ischemic stroke due to focal stenosis of the right middle cerebral artery (MCA). The study emphasizes the significance of ultrasonographic diagnostics in diagnosing and monitoring cerebral arterial stenosis.

Materials: A 42-year-old female admitted to our ward in 2022 due to clinical suspicion of a minor stroke.

Methods: A multidisciplinary team conducted comprehensive clinical assessments, laboratory tests, neurosonological vascular examination and radiological diagnostics to evaluate the patient.

Results: The patient had a medical history of essential hypertension, oral contraceptive use, and pregnancy-related complications, including an early miscarriage. In 2012, she tested positive for Lupus Anticoagulant (LAC) but she underwent no further checks or therapies. She presented in Emergency Room with dizziness, visual disturbance and left facial weakness lasting for approximately 12 hours. Brain CT-scan revealed a right parieto-occipital hypodense lesion. We immediately performed a thorough neurosonological study of carotid (extra- and intracranial) and vertebro-basilar circulation. The most significant finding was a severe stenosis of the proximal M1 segment of the right MCA (peak systolic velocity = 300 cm/sec), with microembolic signals (MES) in the downstream tract during continuous monitoring for 15 minutes. Angio-MRI confirmed the stenosis, and brain-MRI showed subacute multifocal right-sided ischemia. Blood tests indicated double positivity for aPL antibodies (LAC activity and aβ2GPI IgG). With the APS diagnosis, the patient's treatment was changed to acetylsalicylic acid and warfarin. Subsequent neurosonological examinations showed no changes in the stenosis and, after 6 days, disappearance of MES.

Discussion: Combination of laboratory findings with clinical history and previous LAC positivity led to the diagnosis of APS, according to the revised Sapporo Criteria [1,2]. In APS, stroke and transient ischemic attack (TIA) are the most common manifestation of vascular occlusion [1]. The neurosonological findings in this case pointed towards artery-to-artery embolism as the likely cause of the multifocal

ischemia. The disappearance of MES in neurosonological monitoring during the follow-up, indicated stenosis stabilization and reduced embolic risk after combined therapy with acetylsalicylic acid and warfarin.

Conclusion: A neurosonological vascular examination focused on the concept of Neuro-POCUS (Point of Care Ultrasound) offers a rapid and well-tolerated diagnostic tool. In this case it facilitated immediate identification of both morphological and hemodynamic characteristics of the stenosis through B-mode imaging and various flow-velocity assessment modalities (Color-Doppler, Power-Doppler and Micro-V technology). Furthermore, as we described, it allowed rapid and real-time monitoring of therapeutic response.

## PROPOSING A REPORTING METHOD FOR NEUROSONOLOGICAL ASSESSMENTS IN CASE OF CAROTID STENOSIS TO TRY TO CLEAR THE CLUTTER. THIS IS HOW WE DO… WHAT ABOUT YOU?

F. Castellana[1], V. Inchingolo[2], G. Malferrari[3], N. Merli[1], G. Fratta[2], L. Florio[2], G. D'Orsi[2], M. Pugliatti[1]

[1]Department of Neuroscience and Rehabilitation, University of Ferrara (Ferrara); [2]Department of Neurology and Stroke Unit, I.R.C.C.S. Casa Sollievo della Sofferenza (San Giovanni Rotondo-FG); [3]Neurology Unit, Arcispedale Santa Maria Nuova I.R.C.C.S. (Reggio Emilia)

Objective: Sharing research on establishing a standardized language for ultrasound (US) evaluation of carotid stenosis, based on examination reports, addressing the current heterogeneity in terminology and measurements.

Materials: Carotid US reports often mention stenosis percentages and severity adjectives. However, the variability in calculating stenosis range and lack of reproducibility with digital angiography pose challenges, resulting in ambiguous conclusions and interpretation-dependent outcomes.

Methods: We retrospectively collected carotid stenosis Doppler US reports from patients admitted to our Neurology department between January and December 2022. Definitions of stenosis degree, method used (NASCET or ECST), severity adjectives, and terms related to hemodynamic significance, near occlusion and collateral circulation were examined.

Results: A total of 104 carotid US reports were collected, with 54 also including transcranial color Doppler US for cerebral circulation evaluation. Neurologists conducted 48 examinations, while other specialists performed the rest. Precise percentage diagnoses were reported in 43 exams, while stenosis range was mentioned in 26 exams. NASCET and ECST methods were used in 41 and 23 exams, respectively. Severity adjectives like "moderate" and "critical" were present in 22 and 13 exams respectively. "Collateral circulation" and "near occlusion" were noted in 42 and 9 exams respectively.

Discussion: US has been used for detecting carotid plaques for decades, but discrepancies exist in how carotid stenosis is assessed and defined, not only because of the differences between angiography and US metrics but also because of the high heterogeneity of findings descriptions in the reports. In our opinion, in advanced settings with adequate expertise, it may be feasible to abandon the dichotomous description extracranial/intracranial findings and adopt a new definition: neurosonological study of carotid and vertebro-basilar circulation. Usage of NASCET stenosis range based on velocity criteria and consideration of "unstable plaque" characteristics would be beneficial. Also, different velocity cut-off in symptomatics and asymptomatics for < and > 50%, < and > 70% carotid stenosis should probably be considered.

Conclusions: Accurate carotid stenosis diagnosis with US requires integrating pathophysiological knowledge, clinical evaluation and multiparametric US measurements. Reports should not be limited to measurements but should represent a synthesis of information. In the case of stenosis, the report should encompass local findings as well as those from upstream and downstream circulation, following the pathophysiology of cerebral circulation rather than relying solely on topographical anatomy. Categorizing stenosis within a range helps establish treatment boundaries, although overall clinical and instrumental assessments remain crucial for decision-making both in symptomatics and asymptomatics.

## ACUTE ISCHAEMIC STROKE DESPITE ANTICOAGULANT THERAPY WITH DOAC: AN UPDATE

L. Ceccarelli[1], F. Kuris[2], S. Pez[3], F. Janes[4], S. Lorenzut[5], G. Merlino[4], G. Gigli[4], M. Valente[4]

[1]Clinical Neurology Unit, University of Udine (Udine); [2]Clinical Neurology Unit, Department of Medical Area, University of Udine (Udine); [3]Clinical Neurology Unit, Department of Head and Neck, University of Udine (Udine); [4]Clinical Neurology Unit, Department of Head and Neck, Azienda Sanitaria Universitaria Friuli Centrale, University of Udine (Udine)

Objective: To investigate patients who developed acute ischemic stroke (AIS) despite appropriate prevention therapy of cardio-embolism with DOACs (Direct Oral Anti-Coagulants).

Materials and Methods: We retrospectively collected data from our single-centre stroke registry of patients admitted from 1st Jan 2020 to 30th Apr 2023. Our sample included patients > 18 yo, treated with DOACs and admitted for AIS. We considered "true DOACs failure" patients reporting optimal adherence, treated with an appropriate DOACs dosage according to currently available guidelines and showed no other determined aetiology according to TOAST classification1.

Results: We collected 52 patients taking DOACs at the time of their AIS (age = 77,5 ± 9,6 yo; NIHSS = 7,3 ± 6,4). 9/52 (17%) had a recurrent event. Only 1 patient was treated with intravenous thrombolysis, 12 with mechanical thrombectomy. 5 patients were excluded because of other emerging determined aetiologies of stroke: 3 had Small Vessel Disease (SVD), 1 had Large Artery Atherosclerosis (LAA) and 1 had two concurrent mechanisms of stroke (LAA + other determined aetiology). Finally, 47 strokes fulfilled criteria for "true DOAC failure": 29 (61,7%) were cardioembolic (CE) and 18 (38,3%) were undetermined because at least one cause other than CE coexisted (UND-a). DOACs plasmatic levels (anti-Xa activity, ng/ml) were determined, at the time of admission, in 22/47 (mean = 103,5 ng/ml ± 81,6): 14 in the group

with CE as unique cause of stroke (92,1 ng/ml ± 67,2) and 8 in the group with competing mechanisms of stroke (118,0 ng/ml ± 98,5). Plasma levels were non significantly different in the two groups (p = 0,44). 3 patients treated with Rivaroxaban 20mg, 1 with Dabigatran 110 BID and 1 with Apixaban 5 BID, had very low DOAC levels (i.e.: <20 ng/ml); in all but one patient the very low levels corresponded to measurements at trough.

Discussion: A residual stroke risk in patients with Atrial Fibrillation despite anticoagulation ranges from 0.7% to 2.3% annually in primary and secondary prevention, respectively. AIS related to DOAC's failure requires a more extensive diagnostic work-up, revealing alternative causes (e.g.: paraneoplastic thrombophilia, mild unstable epi-aortic atherosclerosis, paradoxical embolism, etc.). However, the investigation of DOACs' plasmatic levels reveals low anti-Xa activity at the time of stroke in several patients, who consequently seem not to be protected from cardio-embolism itself. Further assessment of those patients will help to trace the boundaries between "true" and "apparent" failure, and to improve secondary stroke prevention strategies.

## PSEUDOTUMOR CEREBRI IN SYSTEMIC LUPUS ERYTHEMATOSUS: A CLINICAL CASE

R. C. Chavez, F. Arienti, G. Franco, E. Monfrini, I. Trezzi, G. Lazzeri, A. Di Fonzo

Neurology, Policlinico of Milan (Milano)

Introduction: Pseudotumor cerebri (PTC) is a clinical syndrome due to intracranial hypertension (IH), which can be idiopathic or secondary to specific conditions such as venous sinus thromboses, drugs and systemic illnesses. The underlying pathogenic mechanisms are uncertain, but proposed etiologies mainly include cerebral venous outflow abnormalities. In systemic lupus erythematosus (SLE), IH may be due to occult cerebral venous thrombosis (related to vessel inflammation or hypercoagulability) or to corticosteroid withdrawal. Here we describe a clinical case of PTC associated with SLE and cerebral venous thrombosis (CVT).

Materials: A 19-year-old woman presented to our ER with severe headache and vision loss. She has been diagnosed with SLE four years earlier and suffered from arthritis, butterfly rash, renal involvement (class VI nephritis), thrombocytopenia. Her blood exams were positive for ANA and anti-DNA antibodies, with low complement levels. Neurological examination showed bilateral lateral rectus muscle palsies and bilateral early papilledema. Brain CT scan and CT angiography were performed and resulted normal. A diagnosis of PTC was made and both prednisone and acetazolamide were started. After a week, ophthalmologic examination showed severe bilateral papilledema, therefore a lumbar puncture was performed showing an extremely high opening pressure (40 mmHg); subsequently the patient was referred for ventricular shunt surgery.

Results: Brain MRI revealed a right sigmoid sinus slowed down flow, suggestive for cerebral venous thrombosis, which was also confirmed on a repeated CT-angiography. After administration of anticoagulant therapy, the patient showed a progressive improvement of her symptoms.

Discussion: We described a clinical case of PTC presenting with headache, vision loss and bilateral nerve palsy in a patient with SLE. Several risk factors predispose SLE patients to develop PTC: anemia and hypertension, use of corticosteroids, and a hypercoagulable condition. In several reports dural sinus thrombosis was proposed to be the cause of PTC.

Conclusions: PTC should always be suspected in SLE patients presenting with headache, cranial nerve palsies and progressive visual loss, since it is a treatable condition, if rapidly recognized. We also suggest repeating brain imaging if the clinical suspicion remains high, even in presence of normal initial CT/MRI studies. Indeed, the sensitivity of angiography examinations may be limited in the early stages of CVT.

## ISCHEMIC STROKE FROM MULTIPLE LARGE VESSEL OCCLUSIONS IN SICKLE CELL ANEMIA, A THERAPEUTICAL CHALLENGE

C. Ciprietti, M. Russo, G. Polito, S. Melchiorre, F. Dono, M. Onofrj, S. L. Sensi

Department of Neuroscience, Imaging and Clinical Sciences, University G. D Annunzio of Chieti-Pescara (Chieti)

Background: Acute Ischemic stroke (AIS) is one of the leading causes of disability worldwide. We here report a case of severe steno-occlusive disease affecting both intracranial and extracranial large arteries with an uncommon etiology.

Case report: A 46-year-old man was admitted to the emergency room complaining of the onset, more than 10 hours before, of headache, right-sided sensory disturbances (paresthesias), and visual complaints. The neurological exam with visual field analysis revealed right hemianopia. The patient immediately underwent a brain CT scan and Angio-CT studies of the neck and intracranial vessels. Bilateral occlusion of the Internal Carotid Arteries, and bilateral occlusion of the P1 tract of the Posterior Cerebral Arteries, were discovered. The presence of remarkable compensatory hypertrophy of the right Ophthalmic Artery and Anterior Communicating Artery suggested underlying chronic processes. Despite symptoms compatible with acute stroke, IVT could not be administered as he was late for that line of intervention. Notably, the patient also had Sickle cell disease (SCD), a condition that could be responsible for the acute occlusion of cerebral arteries. The laboratory exams confirmed a current severe anemia (Hb 8,4 g/dL) with hemoglobin S (HbS) levels of 50%. The patient was also dehydrated. IV hydration was started along with erythrocyte apheresis and antiplatelet therapy. The therapeutical targets were HbS <30% and total Hb>10g/dL. The patient successfully underwent these treatments, and the acute neurological deficits significantly improved.

## LONG-TERM COGNITIVE OUTCOME IN PATIENTS UNDERGOING MECHANICAL THROMBECTOMY FOR MIDDLE CEREBRAL ARTERY OCCLUSION

S. Citro[1], D. Quaranta[2], G. Masone Iacobucci[2], C. De Caro[1], I. Scala[1], L. Rigon[1], V. Brunetti[2], C. Piano[2], C. Marra[1], P. Calabresi[1], G. Della Marca[1], V. Guglielmi[2]

[1]Department of Neuroscience, Catholic University of The Sacred Heart (Roma); [2]Neurology Unit, Agostino Gemelli University Policlinic (Roma)

Objectives: We had initially investigated the neuropsychological profile of previously cognitively intact patients one week after a successful mechanical thrombectomy for middle cerebral artery occlusion presenting with basal ganglia infarction. The rate of cognitively impaired patients was significantly high. There is limited knowledge regarding the long-term cognitive outcome of these patients. Indeed, the primary objective of this study was to evaluate potential modifications in the severity of cognitive impairment during a stabilized phase following the acute event, with an additional aim to potentially characterize the associated neuropsychological profile.

Materials & Methods: 8 months after thrombectomy (SD = + 2.5) for middle cerebral artery occlusion (M1 tract), 30 patients (M/F = 13/17) underwent a general cognitive assessment using MoCA and an extensive neuropsychological battery evaluating memory, visual praxis, attention, executive functions, and language. Patients were classified as cognitively impaired (CImp) or not (noCImp) according to a MoCA score $< 18$ or $\geq 18$, respectively.

Results: CImp amounted to 53.3%. CImp and noCImp did not differ in NIH-Stroke Scale (NIHSS) at admittance, NIHSS at discharge, ASPECT score, mRS at admittance and discharge, but they did in age ($p = 0.019$). Compared to noCImp, CImp showed worse performances in ratings of executive and attention functions and noun naming. Compared to MoCA performed one week after stroke (mean 15.3), mean follow-up-MoCA was more than 2 points higher (17.73). However, only two patients changed their status from CImp to noCImp, and two others worsened from noCImp to CImp. In the whole sample, the MoCA score was predicted by the age at stroke, NIHSS at admission, NIHSS at discharge, pre-stroke mRS and post-stroke mRS, and by the middle temporal atrophy scale ($p = 0.021$).

Discussion and Conclusions: Patients considered in this longitudinal study showed a relative long-term improvement in cognitive functions. However, the prevalence of CImp remained the same. Patients' long-term cognitive outcome strictly depended on age at stroke, clinical severity of the stroke, and degree of disability (especially residual post-stroke). Their cognitive profile was similar to other conditions involving basal ganglia damage, such as Parkinson's disease and vascular dementia.

## A RARE CAUSE OF CARDIOEMBOLIC STROKE: CASE REPORT

I. Ciullo, A. Stefani

Policlinico Tor Vergata, Tor Vergata University (Roma)

Case presentation: A 78-year-old man, who had a medical history of arterial hypertension and dyslipidemia, came to the Emergency Room due to a sudden onset of difficulty in speech and left hemiparesis. He was undergoing treatment using ACE inhibitors. On neurological examination he appeared conscious, oriented and dysarthric. Expressive aphasia and left hemiparesis were observed. The brain CT showed a subacute fronto-temporal ischaemia in the left hemisphere of the brain. The CT-angiography demonstrated a 45% stenosis of the left proximal internal carotid artery, while no stenosis was observed in intracranial vessels. There was no indication for immediate revascularization treatments. The patient was admitted to the Neurology Department. The Brain MRI confirmed the presence of the previously identified ischemic area, without any sign of haemorrhagic infarction. Dual antiplatelet therapy was administered. The transthoracic echocardiogram showed a large mobile mass in the left atrium of the heart (MD 4,2 cm). During diastole, the mass protruded into the left ventricular chamber. There was no apparent impact on systolic function (ejection fraction of 60%) caused by the mass. The patient was referred to the cardiothoracic surgery team. He underwent urgent surgical removal of the mass. The surgical intervention was successful, resulting in complete removal of the mass without any complications. The definite diagnosis of high-grade myxofibrosarcoma was established through histopathological analysis. The Total body PET did not reveal any hypermetabolic focality at the left atrium or at a distance. Two months later, the patient developed dyspnoea on exertion. The cardiac MRI showed a new growth in the left atrium that required additional investigation using cardiac CT which showed a large irregular polylobed growth with implant base in the left auricle, characterized by a significant contrast enhancement. The patient died 2 weeks later.

Discussion: Nearly one-fourth of ischemic strokes are caused by a cardioembolic event. While atrial fibrillation is the leading cause of cardioembolic strokes, cardiac tumours can also be a rare cause. Primary cardiac myxofibrosarcoma is an uncommon and highly malignant tumour that affects the heart. It is characterized by a set of three complications, namely constitutional, obstructive, and embolic complications. Stroke can occur as the initial presentation of this condition [1].

Conclusion: When evaluating a patient with stroke symptoms, it is crucial for healthcare providers to consider a comprehensive range of potential causes, including rare conditions like primary cardiac tumours [2].

Background: Patients with minor stroke and M2 occlusion undergoing best medical management (BMM) may face early neurological deterioration (END) that can lead to poor long-term outcome. In case of END, rescue mechanical thrombectomy (rMT) seems beneficial. Our study aimed to define factors relevant to clinical outcome in patients undergoing BMM with the possibility of rMT on END and find predictors of END.

Materials and Methods: Patients with M2 occlusion and a baseline National Institutes of Health Stroke Scale (NIHSS) score ≤5 that received either BMM only or rMT on END after BMM were extracted from the databases of 16 comprehensive stroke centers. Clinical outcome measures were a 90-day modified Rankin Scale (mRS) score of 0–1 or 0–2, and occurrence of END.

Results: Among 10169 consecutive patients with large vessel occlusion admitted between 2016 and 2021, 208 patients were available for analysis. END was reported in 87 patients that were therefore all subjected to rMT. In a logistic regression model, END (OR 3.386, 95% CI 1.428 to 8.032), baseline NIHSS score (OR 1.362, 95% CI 1.004 to 1.848) and a pre-event mRS score=1 (OR 3.226, 95% CI 1.229 to 8.465) were associated with unfavorable outcome. In patients with END, successful rMT was associated with favorable outcome (OR 4.549, 95% CI 1.098 to 18.851). Among baseline clinical and neuroradiological features, presence of atrial fibrillation was a predictor of END (OR 3.547, 95% CI 1.014 to 12.406).

Discussion: END is a frequent event in patients with a minor stroke due to involvement of the M2 segment of the middle cerebral artery and represents the most important predictor of long-term poor outcome in patients that are initially intended for medical therapy. Our study corroborates the evidence that rMT is indeed beneficial when END occurs. Clear-cut predictive factors of END are still missing. In our cohort, AF was associated with END, probably due to a series of mechanisms, including the cardiological comorbidities, the reduction of cerebral blood flow, in conjunction with less effective leptominengeal collaterals. Regardless of the underlying mechanism, the results of our study suggest that minor stroke patients with isolated M2 occlusion and concomitant AF should be closely monitored for possible worsening during BMM and promptly considered for rMT.

Conclusion: Patients with minor stroke due to M2 occlusion and atrial fibrillation should be closely monitored for possible worsening during BMM and, in this case, promptly considered for rMT.

Background: Seizures are a common complication of cerebral venous thrombosis. In this study, we intended to define clinical and neuroradiological factors associated with early and late seizures and predictors for seizure recurrence.

Materials and Methods: The database of our high-volume tertiary stroke center was screened for patients diagnosed with cerebral venous thrombosis between April 2006 and July 2021. Demographics, clinical, imaging, and instrumental data were collected. We described general characteristics of the population with summary statistics, furthermore, we tested univariate and multivariate associations for early/late seizures and relapses.

Results: Out of a total of 80 patients, 30 had seizures, either within the first week after onset (22 patients) or after (8 patients). Speech impairment and intracerebral bleeding were statistically associated with seizures in univariate analysis, but in a logistic regression model, only

brain damage with hemorrhagic infarct and/or presence of brain hematoma [OR 6.051; 95% CI 1.881−19.468] (p = 0.003) were predicting factors for seizures. Late seizures were significantly more frequent in younger age [OR 0.864; 95% CI 0.763−0.978] (p = 0.020). Early seizures resulted as protective factors for recurrence; an altered state of consciousness at baseline and late seizures resulted as predictive factors for relapses (0.0% vs. 81.0%, p = 0.005, and 100.0% vs. 19.0%, p < 0.005, respectively).

Discussion: Our study underlines that primarily hemorrhagic lesions are highly predictive of seizures during the acute phase. The need to identify patients with CVT at risk for seizure recurrence is relevant, as a definition of specific predictors may determine whether or not epilepsy can be diagnosed and thus treated. Our study points out that seizures occurring beyond 7 days from onset are highly predictive for relapses. Overall, we suggest that CVT patients with hemorrhagic supratentorial brain lesions should be strictly monitored in the acute phase to tackle possible epileptic complications. Besides, in case of late-onset seizures, long-term treatment seems reasonable due to an increased risk of recurrence. Indeed, although the presence of seizures appears to have no impact on the final outcome and long-term disability, the adoption of prophylactic measures according to specific predictors might improve the quality of life of patients.

Conclusions: Our study confirms brain bleeding as the strongest risk factor for seizures after cerebral venous thrombosis. Recurrence is unusual after early seizures, while the presence of late seizures seems to raise the risk of recurrence.

## GENDER DIFFERENCES IN TIME TRENDS OF INCIDENCE AND CASE-FATALITY OF INTRACEREBRAL HEMORRHAGE

F. Conversi[1], C. Gabriele[1], B. Orlandi[2], F. De Santis[2], S. Ricci[2], M. Foschi[1], S. Sacco[1], R. Ornello[1]

[1]Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila (L'Aquila); [2]Department of Neurology, SS. Filippo e Nicola Hospital (Avezzano-AQ)

Aims: Intracerebral hemorrhage (ICH) accounts for up to 20% of all strokes, but it is responsible for up to 70% of one-month stroke mortality. Sex-related differences in ischemic stroke have been widely investigated in several studies, nevertheless, there is still a lack of knowledge on this topic in spontaneous ICH. Thus, the purpose of this observational work is to provide information on ICH incidence during the study period and outcome in terms of case-fatality rate in spontaneous ICH in relation to gender.

Materials and Methods: We recruited patients from a prospective population-based stroke registry, admitted from 2011 to 2020 to the hospitals of the district of L'Aquila with first ever ICH. We evaluated the overall incidence of spontaneous ICH in men and women over the whole study period, the premorbid performance status according to the modified Rankin Scale (mRS). We also assessed case-fatality rates in both sex groups.

Results: The study included a total of 439 (58.7%) males and 309 (41.3%) females, with males having a mean age of 73.2 ±13.6 years and females having a mean age of 78.9 ±12.6 years (p<0.001). The overall incidence rate was 250.7 cases of ICH per 100.000 population per year (95% CI 243.4-257.7). The incidence rate was 30.2 cases per 100,000 person-years (95% CI 27.4-33.2) in men and 20.2. cases per 100,000 person-years (95% CI 18.0-22.6) in women. 51 (13.1%) of men and 48 (18.5%) of women had a premorbid-mRS ≥3 (p=0.026). The global 1-year case-fatality rate was 43.6% (95% CI 34.4-46.5); it was 40.1% (95% CI 43.2-50.0) in males and 48.5% (95% CI 41.1-57.0) in females (p=0.026).

Discussion: ICH seems to be a predominantly male pathology: according to our analysis, the overall ICH incidence rate was higher in men than in women. Females were, on average, 6 years older than males in the study population and, subsequently, more liable to develop comorbidities. Furthermore, men had slightly better outcome in terms of lower 1-year case-fatality rate compared to women, probably, because of their older age and worse premorbid condition.

Conclusions: Gender differences in primary spontaneous ICH is not explored enough field, in which there are still discordant results of studies. Understanding the burden of comorbidities and the underlying mechanisms of these differences on the incidence and outcome in ICH patients, may pave the way to more patient-tailored preventive and therapeutic strategies.

## SUCCESSFUL INTRAVENOUS THROMBOLYSIS IN CENTENARIANS: AN ITALIAN CASE REPORT

F. Cusmai, M. Caccamo, P. Lasorella, D. Regina, D. Mezzapesa, M. Petruzzellis

Department of Basic Medical Sciences, Neurosciences and Sense Organs, University of Bari "Aldo Moro" (Bari)

Introduction: Intravenous thrombolysis (IVT) for acute ischemic stroke (AIS) in oldest-old is never an easy decision. Lot of comorbidities and higher pre-stroke disability are the main reasons for IVT withholding in such patients. Sometimes the age itself is the only reason to rule out patients from the treatment, probably due to the lack of data about the safety of alteplase in these patients.

Methods: We report the case of a 101-year-old woman with acute partial anterior circulation syndrome, who received intravenous thrombolysis (rtPA), with complete regression of symptoms at discharge.

Results: The patient was admitted to our Emergency Department for acute blurred speech, left side hemiparesis, left lateral hemianopsia and gaze preference to right side (NIHSS 11) lasting for 1 hour. Her past medical history was remarkable for paroxysmal atrial fibrillation, arterial hypertension and chronic kidney disease. No significant disability was reported (mRS 1). On arrival, a basal CT scan was performed with no evidence of acute bleeding. The CT angiography highlighted right

M3 occlusion and perfusion CT (pCT) showed a wide parietal-temporal penumbra area with a limited ischemic core (Tmax >6s: 54.35 mL, CBF <20%: 3.4 mL, CBF <30%: 23.9 mL). Intravenous alteplase was started 2 hours from symptoms onset with early neurological improvement (NIHSS 4) and without complications. The 24-hs CT did not documented intracranial bleeding neither ischemic lesion. A complete remission occurred during the next 36 hours, and she was discharged asymptomatic after 4 days (NIHSS 0 and mRS 1). Apixaban 2,5 mg twice daily was given for secondary prevention.

Discussion: Searching in medical literature, we selected 28 cases of centenarians treated with rtPA in which outcome and pre-admission disability were available. Only 18 patients have low disability (mRS <3) before the event. Death within three months occurred in 11 patients but it was not related to the treatment. Risk-to-benefit ratio should always be evaluated for each oldest–old patient eligible for intravenous thrombolysis. Our case suggests that age should not itself be considered a reason to withheld IVT, in particular in patients with low pre-stroke disability.

Conclusion: To the best of our knowledge, this is the first case of centenarian's stoke treated with intravenous thrombolysis in Italy. As life expectancy will likely continue to increase, further studies about efficacy and safety of AIS therapy in oldest-old are needed.

## NEUROIMAGING IN MONOZYGOTIC TWINS WITH CADASIL DUE TO A NOVEL NOTCH3 VARIANT

R. Cutelle[1], E. De Santis[1], A. Bulgari[1], O. Marsico[1], L. Manzo[1], F. Vazzana[2], G. Tripodi[2], V. Cianci[2], S. Gasparini[1], A. Pascarella[1], U. Aguglia[1], E. Ferlazzo[1]

[1]Department of Medical and Surgical Sciences, Magna Graecia University (Catanzaro); [2]Regional Epilepsy Centre, Great Metropolitan Hospital (Reggio Calabria)

Background and Aims: Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) is an autosomal dominantly inherited cerebral small vessel diseases caused by mutations in NOTCH3 gene. The main clinical features include migraines with aura, recurrent ischemic strokes and dementia. In literature, reports of twins with CADASIL are scarce [1,2]. Herein we describe a pair of monozygotic twins with CADASIL carrying a new NOTCH3 variant.

Materials and Methods: Both twins underwent extensive clinical, laboratoristic and neuroradiological evaluation as well as genetic analysis of NOTCH3 gene.

Results: Twin A: he was a 45-year-old male, suffering from migraine, obesity, arterial hypertension and polycythemia; he referred to our Emergency Department because of a short-lasting (~ 5 minutes) episode of speech difficulties. Neurological examination was normal. Head CT showed extensive leukoencephalopathy. Brain MRI revealed diffuse, symmetrical, confluent periventricular white matter vascular lesions in the frontal, parietal and temporal lobes as well in external capsules, with sparing of anterior temporal poles. Clinical and neuroimaging data suggested the diagnosis of CADASIL. Genetic analysis of NOTCH3 gene demonstrated the presence of missense c.3329G>A, p.(Cys1110Tyr) variant. Genetic analysis for essential polycythemia (JAK2, BCR/ABL, MPL) was negative. Twin B: he suffered from migraine and polycythemia. He came for a 2-months history of trigeminal neuralgia (involving the 2nd branch of the left trigeminal nerve). Neurological examination was otherwise normal except for left facial hyperalgesia. Head CT showed diffuse leukoencephalopathy. Brain MRI demonstrated lesion distribution similar to his twin with an adjunctive T2-FLAIR hyperintense area in the left middle cerebellar peduncle along the intracisternal course of the fifth cranial nerve. Genetic analysis revealed the same NOTCH3 gene variant as his twin. He was given carbamazepine up to 600 mg/day with almost complete pain relief.

Discussion and Conclusions: We report clinical and neuroimaging features of a pair of twins with CADASIL due to a new missense NOTCH3 gene pathogenic variant, showing strikingly similar brain MRI findings. Sparing of anterior temporal poles represent an uncommon finding, mainly occurring in cysteine-sparing NOTCH3 mutations [3]. To date, only two pair of twins with CADASIL have been reported [1,2]; one family only showed similar neuroimaging pictures [2]. In our family, it remains to be elucidated if polycythemia is a casual comorbidity or represents a manifestation of this new NOTHC3 variant, expanding the spectrum of CADASIL phenotype.

## TRANSIENT ISCHEMIC ATTACKS IN A MIDDLE-AGED WOMAN WITH UNFUSED/TWIG-LIKE MIDDLE CEREBRAL ARTERY TREATED WITH ENCEPHALOMYOSYNANGIOSIS

V. D'Agostino[1], A. Formenti[2], M. Di Stefano[2], P. Melzi[2], M. Vaccaro[2], E. Tagliabue[2], L. Airoldi[2], A. Tetto[2], L. Mazzeo[2], L. Lorusso[2]

[1]Department of Neurology, IRCCS San Gerardo dei Tintori Foundation, School of Medicine and Surgery and Milan Center for Neuroscience, University of Milan-Bicocca (Monza); [2]Department of Neurology, San Leopoldo Mandic Hospital, ASST Lecco (Merate-LC)

Objective: Twig-like middle cerebral artery (MCA) is a rare unilateral vascular anomaly characterized by a replacement of the M1 segment of the MCA by a plexiform network of small vessels. Its prevalence rate ranges from 0.11% to 1.17%, especially in middle-aged females in East Asia [1]. It may be found incidentally or may present with headache or symptoms secondary to cerebral ischemia, transient ischemic attack, hemorrhage or aneurysm, usually not present before late adulthood.

Patient and Methods: A 49-years old woman was admitted to our Neurology Department for acute onset of recurrent right brachial-crural hyposthenia with gradual spontaneous resolution. No meaningful events in medical history or chronic pharmacological therapy were detected.

Results: The patient underwent to a brain computed tomography (CT) scan with no acute lesions demonstration; brain/neck CT angiography (CTA) showed unfused/twig-like feature of left MCA, no aneurysmal anomalies or intracranial stenosis were reported. Brain magnetic resonance imaging (MRI) scan detected micro-ischemic foci in the left frontal lobe cortex. Digital subtraction angiography (DSA) of brain found complete absence of left M1 branch, instead arterio-arterial

anastomoses which ensured distal opacification of orthograde ipsilateral M2 branches were marked. Furthermore leptomeningeal branches from the left anterior cerebral artery (ACA) and the posterior cerebral artery (PCA) supplied the distal left hemispheric territories and the left temporal lobe. In order to grade the possible hypoperfusion state of the brain, the patient was evaluated with a brain CT perfusion scan which demonstrated asymmetry of the cerebral blood flow (CBF) map in the left temporal area, an increase in the mean transit time (MTT) map diffused in the left hemisphere and in the right ACA area and similarly, time to peak (TTP) map had a lower value in the right hemisphere. According to our Neurosurgical department, patient was treated with an indirect revascularization technique like encephalomyosynangiosis (EMS) with a temporalis muscle flap placed directly over the cerebral cortex [2]. Then, indication to antiplatelet therapy was given.
Discussion and Conclusions: Currently, there is no consensus about the treatment of unfused/twig-like MCA, owing to its small prevalence and paucity of treatment data. Case reports in literature described successful extracranial-intracranial bypasses and combined direct/indirect revascularization. According to the low symptoms burden of our patient, the treatment was chosen to promote over time low-flow collateral neoangiogenesis in order to reduce hemodynamic insufficiency of the brain and to augment the vascular supply distal to the twig-like MCA.

## AN ATYPICAL CASE OF CAROTID ARTERY DISSECTION

G. M. D'Amico, C. Pachatz, N. Mercuri, F. Placidi

Department of Neurology, Tor Vergata University (Roma)

A 57-year-old man was admitted to our emergency department in September 2021 for persistent tightening headache with fluctuations throughout the day. He also noted mild articulatory clumsiness and mild swallowing difficulty for solid food over the past three days. There was no history of notable medical conditions and home therapies. On arrival in the emergency department, he had normal vital parameters except for mild increase of blood pressure (150/95 mmHg). He underwent brain CT scan from which no ongoing acuities were evident. He was transferred to the neurology department for further evaluation. On admission to the ward, the headache appeared attenuated and lateralized to the right parietal site. Clinical examination revealed mild speech articulation impairment and tongue deviation to the right during protrusion. No other neurological deficit was discernible. A lumbar puncture was performed during the hospital stay: CSF cells and proteins were normal and virological examination negative. Brain MRI with gadolinium excluded acute cerebral ischemia or pathological enhancement. However, the presence of altered endoluminal signal at the level of the distal extracranial third of the right internal carotid artery (ICA) with filiform opacification of the vessel lumen was reported. In the suspicion of carotid dissection, CT angiogram of the neck was urgently performed. The scan documented the presence of irregular and filiform vessel caliber of the right ICA in its distal extracranial tract with the extension up to the intracranial segment. In particular, there was evidence of an endoluminal hypodense image, in a circumferential arrangement, which wrapped the opacified vessel lumen "sleeve-like". The diagnosis of right ICA dissection was confirmed. According to the equal effectiveness between antiplatelet and anticoagulant therapy [1], the patient was treated with Cardioaspirin and Statin. Compression neuropathy of the ipsilateral hypoglossal nerve due to ICA enlargement was presumed. The patient underwent short-term corticosteroid therapy with gradual improvement of tongue weakness. Following ultrasound checks documenting normalization of carotid artery caliber and, in relation to the absence of absolute indication for continuing antiplatelet therapy, Cardioaspirin was discontinued after 9 months.
Discussion: This case documents that the clinical presentation of carotid dissection can be atypical [2]. Isolated hypoglossal nerve palsy associated with unilateral headache can be a warning sign for vascular disease even in the absence of specific risk factors [3].

## CEREBRAL FAT EMBOLISM: A CLINICAL AND PATHOPHYSIOLOGICAL CHALLENGE

A. de Falco[1], I. Cerillo[1], S. Montella[1], V. D'Agostino[2], N. Orabona[3], M. Mazzaferro[1]

[1]Neurology and Stroke Unit, Ospedale del Mare ASL Napoli 1 Centro (Napoli); [2]Neuroradiology Unit, Ospedale del Mare ASL Napoli 1 Centro (Napoli); [3]Orthopedic Unit, Ospedale del Mare ASL Napoli 1 Centro (Napoli)

Introduction: Cerebral fat embolism (CFE) is a rare incomplete type of fat embolism syndrome (FES) characterized by purely cerebral involvement. It usually occurs 12-72 hours after the initial trigger mainly represented by fractures of lower extremities. CFE pathophysiology is still not completely understood.

Case presentation: The patient was a 24-year-old male who was admitted to our ER for a right traumatic femoral bone multiple fracture. Twenty-four hours after he was admitted, he presented severe psychomotor agitation and confusion without focal neurological deficits. Brain CT and EEG were normal. Symptoms were diagnosed as a psychiatric disease triggered by pain. Afterwards, patient became anartric with severe drowsiness and consciousness impairment without meningeal or focal signs. A new brain CT was again normal. Symptoms at that point were considered collateral effects of sedation with neuroleptics. Because of neurologic worsening, he underwent to a brain MRI which showed a "starfield pattern" characterized by multiple, scattered, small and hyperintense lesions on DWI and T2 sequences localized in both white matter and deep grey matter in bilateral centrum semiovale, corona radiata and basal ganglia. This MRI pattern is typical of CFE. Pulmonary, abdomen and lower limbs CT angiography were irrelevant. Transoesophageal echocardiography with bubble study ruled out a PFO. Patient started desametaxone 8 mg BID, aspirin and enoxaparine. He underwent to surgery for fracture reduction and gradually improved along 2 weeks. Follow-up brain MRI after 2 weeks showed near disappearance of the previous pathological findings. He was dismissed at home with normal neurological examination.

Discussion: CFE symptoms, as in our patient, are non-specific leading to possible misdiagnosis. Brain CT and EEG are not relevant but MRI findings such as the "starfield pattern" if recognized is typical of CFE. The pathophysiological hypothesis is that fat droplets from the bone marrow are released in the venous system and through arteriovenous shunts (i.e. PFO) travel into the systemic circulation and reach the brain. In patients without PFO, as in our patient, the hypothesis is that very small fat droplets pass directly through the pulmonary capillary bed.

Conclusions: CFE diagnosis is challenging mainly in patients without systemic symptoms of FES. Brain MRI is needed for the typical

"starfield pattern". The way of travel of fat droplets to the brain circulation in patient without PFO and pulmonary vascular abnormalities is still debated.

## STARTING INTRAVENOUS THROMBOLYSIS IN IMAGING AREA IS ASSOCIATED TO EXCELLENT OUTCOME IN PATIENTS WITH ACUTE ISCHEMIC STROKE

A. De Mase, E. Spina, G. Servillo, S. Barbato, A. Ranieri, R. Renna, G. Alfieri, W. Di Iorio, K. Longo, P. Candelaresi, V. Andreone

UOC Neurology and Stroke Unit, AORN Antonio Cardarelli (Napoli)

Introduction: Door-to-needle time (DNT) is an established predictor of outcome in acute ischemic stroke (AIS), when intravenous thrombolysis (IVT) is indicated. Several strategies have been proposed to streamline in-hospital pathways, in order to achieve shorter DNT, and starting IVT directly in the CT/MRI suite appears to be among the most useful ones.

Aim: To explore the impact of starting IVT in the CT/MRI suite, here defined as imaging area (IA), on functional outcome in patients with AIS treated only with IVT.

Methods: All patients with AIS treated with IVT at our center in 2020, 2021 and 2022 were included. Patients undergoing endovascular treatment were excluded, to reduce heterogeneity. To assess the effect on outcome, we only included patients without any previous disability. The cohort was divided into two groups, depending on the IVT site. One group started IVT inside the IA, right after eligibility was confirmed, the other received the treatment outside the IA (emergency department or stroke unit). Regression analysis assessed the association between IVT site and 3-months outcome, defined by the modified Rankin Scale score.

Results: 301 patients who received only IVT were included in the analysis. 112 (37.2%) were in the IA group and 189 (62.8%) in the not-IA group. The groups had similar baseline characteristics. In the IA group DNT was 42 minutes shorter. Although a similar rate of functional independence at 3-months (mRS 0-2), the IA group showed a higher rate of excellent outcome (mRS 0-1) when compared to the not-IA group (54.8% vs 41.7%, p=0.03). The multivariate regression analysis demonstrated starting IVT in IA was independently associated to excellent outcome (OR 2.09 [1.05-4.18]).

Conclusions: Starting IVT in IA enables to noticeably cut down DNT, showing a significant impact on the outcome in AIS patients treated with IVT. Our study therefore emphasizes the importance of this treatment strategy and reinforces the idea it should be encouraged as standard-of-care.

## ISOLATED ACUTE ONSET AMNESIA DUE TO BILATERAL FORNIX INFARCTION. A CASE REPORT

L. De Rosa[1], N. Ravì[1], F. Giopato[2]

[1]Neurology Department, University Hospital of Padua (Padova); [2]Neurology Department, Hospital of Treviso (Treviso)

Introduction: Isolated acute-onset amnesia is a rare neurological syndrome and may represent a challenging diagnosis. Cerebrovascular etiology is uncommon, accounting for only about 1.2% overall. In these cases, the most frequent mechanism is represented by cardioembolism and the most commonly affected vascular territory is the posterior circulation. Acute amnestic syndrome due to bilateral fornix infarction is even rarer and only a few cases have been reported in the literature. Also known as "the amnestic syndrome of the subcallosal artery", this entity is the result of an acute infarction in the territory of the subcallosal arteries, which are perforating branches originating from the anterior communicating artery. However, in the few cases in which bilateral fornix infarction was reported, MRI abnormalities also involved the corpus callosum and anterior cingulate gyrus, while isolated bilateral infarction of the anterior fornix has rarely been described. Hereby, we present the case of a 61 year-old woman with acute onset of persistent anterograde amnesia due to bilateral anterior fornix infarction secondary to the occlusion of both anterior cerebral arteries.

Case presentation: About one hour after being involved in a minor car accident, a 61-year-old woman suddenly developed memory disturbances characterized by not being able to recollect recent events, including the collision itself. Her medical history included rheumatic mitral valve repair and pulmonary embolism due to venous thrombosis, but she was not taking any anticoagulant drugs. Except for amnesia, neurological evaluation on admission was normal and brain CT was unremarkable. At first, transient global amnesia was suspected and she was discharged from the E.R. However, due to persisting memory disturbances she was hospitalized four days later. Brain MRI showed T2-FLAIR hyperintensities with diffusion restriction in both columns of the fornix, anterior commissure and ventral hypothalamus, consistent with recent infarction. AngioMRI revealed a bilateral anterior cerebral artery occlusion (A1 segment), along with a persistent left trigeminal artery. CTA of cervical arteries, prolonged EKG monitoring and blood tests were within limits. Transoesophageal echocardiography showed moderate mitral regurgitation and left atrial enlargement, without signs of left atrial appendage thrombosis. Neuropsychological testing revealed an impaired episodic memory with encoding and recalling deficits, while remaining cognitive functions were preserved. Given the risk of thromboembolism due to structural atrial cardiopathy, anticoagulant therapy with warfarin was started.

Conclusions: Bilateral fornix infarction should always be taken into account in the differential diagnosis of a persistent acute onset amnestic syndrome, especially in patients with significant cerebrovascular risk factors.

Background and aims: According to international guidelines [1], based on the results of randomized controlled trials (RCTs), short-term (21-90 days) dual antiplatelet treatment (DAPT) is the gold standard for secondary prevention of minor ischemic stroke (NIHSS score ≤5) or high risk-TIA (ABCD2 score ≥4). We aim at evaluating DAPT benefits and risks in a real-world setting (RWS), even in patients not strictly following RCTs inclusion/exclusion criteria and procedures (timing and DAPT loading dose). [2]

Materials and Methods: The Real-life study on short-term dual antiplatelet treatment in patients with ischemic stroke or transient ischemic attack (READAPT) is a prospective, nationwide, multicentre, observational study, which has included patients with non-cardioembolic minor ischemic stroke or high-risk TIA receiving short-term DAPT in clinical practice since February 2021 with a follow-up of 90 days. Primary efficacy outcome is a new stroke event (ischemic or hemorrhagic) or death at 90 days. The primary safety outcome is a moderate-to-severe bleeding event.

Results: Up to 15th May 2023, 60 centers included 1554 patients who completed the follow-up period, 31 (2.0%) discontinued DAPT due to conditions requiring anticoagulation and were excluded, so 1523 (98.0%) patients were included in the follow-up analysis. Overall, most patients were male (1014, 65.25%) with a median age of 72 years (IQR 62-79). According to symptoms duration, 1077 (69.0%) patients had an ischemic stroke with a median NIHSS of 3 (IQR 2-4) and 477 (31.0%) a TIA with a median ABCD2 score of 4 (IQR 4-5); 296 (18.0%) received acute revascularization procedures. Only 118 (7.74%) followed both RCTs criteria and procedures. Median DAPT duration was 21 (IQR 21-68) days, 110 (7%) of patients early discontinued DAPT due to atrial fibrillation or need for anticoagulant (n=31, 2%), adverse event (n=20, 1.3%), lack of compliance/unknown cause (n=59, 3.8%). During the follow-up, 63 (4.0%) patients had a recurrent ischemic event, of which 37 (58.7%) were ischemic strokes and 26 (41.3%) were TIA. Eight (0.5%) patients died from any cause, 3 (0.2%) died due to vascular causes; 4 (0.3%) had intracerebral hemorrhages; and 46 (3.1) had bleedings. No significant differences, in terms of effectiveness or safety, were found between patients following and not following RCTs criteria/procedures.

Discussion and Conclusions: In RWS, patients with minor ischemic stroke or high-risk TIA treated with short-term DAPT, had similar proportion of ischemic recurrences and similar proportion of hemorrhagic events than in RCTs.

## THE USE OF ALTEPLASE, ALTHOUGH SAFE, DOES NOT OFFER CLEAR CLINICAL ADVANTAGES WHEN MILD STROKE IS NON-DISABLING

C. Del Regno[1,2], G. Merlino[1,2], L. Nesi[1,2], P. Vergobbi[1,2], M. D. Scanni[1,2], S. Pez[1,2], A. Marziali[1,2], Y. Tereshko[1,2], G. Sportelli[1,2], S. Lorenzut[3], F. Janes[1,2], G. L. Gigli[1,2], M. Valente[1,2]

[1]Clinic of Neurology, Azienda Sanitaria Universitaria Friuli Centrale (ASUFC) (Udine); [2]Department of Medical Area (DAME), University of Udine (Udine); [3]Neurology Unit, Department of Neurosciences, Santa Maria della Misericordia University Hospital, ASUFC (Udine)

Objectives: It is unknown if alteplase is effective and safe in patients with mild acute ischemic stroke (AIS). Determining whether symptoms are "disabling" or not is the crucial factor in the management of these patients. The aim of this study was to investigate the efficacy and safety of alteplase in subjects with mild, non-disabling AIS.

Materials: We included all consecutive patients admitted at our institution from January 2015 to May 2022 for AIS with a baseline NIHSS score of 0-5 and suitable for intravenous thrombolysis. In order to select only subjects with non-disabling AIS, we excluded patients who scored more than 1 point in the following NIHSS single item: vision, language, neglect and single limb. Patients who scored at least 1 point in

the NIHSS consciousness item were excluded as well. This study is a retrospective analysis of a prospectively collected database.
Methods: After application of the excluding criteria, we included 319 patients, stratified into patients receiving and not receiving alteplase just because of non-disabling symptoms.
Results: The two groups were comparable regarding demographic and clinical data. Rates of three-month favorable outcome, defined as three-month mRS score 0–1, were similar, being 82.3% and 86.1% in treated and untreated patients, respectively. Hemorrhagic complications and mortality occurred infrequently and were not affected by alteplase treatment.
Discussion and conclusions: This observational study demonstrates that the use of alteplase, although safe, is not associated with a better outcome in highly selected patients with non-disabling AIS.

## A CHALLENGING CASE OF VASCULAR MYELOPATHY DUE TO POSTERIOR SPINAL ARTERY INFARCTION

E. Della Sala[1], C. Gojani[1], G. Bosco[2], S. Leombruni[2], M. Caprioli[2], M. Romanelli[2], M. Bergui[3], G. Vaula[2], P. Cerrato[2]

Purpose: Diagnostic accuracy for myelopathies is challenging due to the multitude of possible pathophysiologic mechanisms, including inflammatory and vascular aetiologies amongst the most common. Spinal cord infarction is an important and underrecognized cause of acute spinal syndrome, although it is the most frequent non-inflammatory myelitis mimic. We present the case of a posterolateral bulbomedullary infarction due to focal stenosis of a vertebral artery [1,2].

Materials and Method: We reviewed the patient's medical history and performed Computed Tomography (CT) angiography and cerebral angiography, brain and cervical spine MRI, lumbar puncture and an immunological panel.

Results: A 46-year-old man was admitted to our division complaining dysesthesias which began in the left parieto-occipital region and subsequently spread to the left laterocervical area and to the left arm over the course of a few days. The neurological examination showed an impaired proprioception of the left upper limb, fine movement impairment of the left hand with dysdiadochokinesia and sensory loss of the left hemi-head, left arm and left hemithorax. CT angiography showed narrowing of the left vertebral artery in the intracranial tract (V4), distally to the emergence of the posterior inferior cerebellar artery (PICA). Brain MRI showed an area of altered signal at the left bulbomedullary junction, characterized by T2 and FLAIR hyperintensity, T1 hypointensity, DWI hyperintensity with unclear ADC restriction and minimal contrast enhancement. Lumbar puncture showed a slight increase in CSF proteins (53 mg/dL; normal values: 15-45 mg/dL). An immunological panel (including anti-MOG and anti-Aquaporin 4 antibodies) was performed which resulted negative. We then performed a cerebral angiography (DSA) which showed a focal stenosis at V4, at the usual origin of the posterior spinal artery. We decided to repeat a brain MRI, including vessel wall imaging, which showed enhancement at the site of the stenosis where a limited signal hyperintensity in FLAIR was evident [3].

Discussion: The case presents unusual aspects: although the gradual onset of symptoms and the site of the lesion in the posterolateral bulbomedullary junction would lean towards an inflammatory aetiology, the vascular alteration documented by the angiographic study and by MRI sequences leant towards an ischemic cause, in the territory of the posterior spinal artery.
Conclusion: We documented a rare case of posterior spinal artery infarction thanks to the neuroradiological study of vascular anatomy.

## A POTENTIALLY FATAL CAUSE OF VERTIGO: ROTATIONAL VERTEBRAL ARTERY SYNDROME

E. Della Sala[1], C. Gojani[1], G. Bosco[2], S. Leombruni[2], M. Caprioli[2], M. Romanelli[2], G. Vaula[2], P. Cerrato[2]

[1]Department of Neuroscience "Rita Levi Montalcini", University of Turin (Torino); [2]Department of Neurosciences "Rita Levi Montalcini", AOU Città della Scienza e della Salute di Torino (Torino)

Purpose: We present the case of a patient with recurrent strokes and a history of vertigo.

Materials and methods: We reviewed the patient's medical history and performed a diagnostic work-up for embolic sources and a digital subtraction angiography (DSA) of cerebral arteries.

Results: A 69-year-old woman with a history of hypertension, dyslipidemia, diabetes and episodes of unexplained vertigo, experienced acute onset of vertigo, paresthesias in the left hemi-face, dysarthria, and diplopia. She was admitted to the hospital where the neurological examination showed dysarthria, left lower facial droop, right inferior rectus muscle weakness with contralateral nystagmus (NIHSS 4). The brain computed tomography (CT) was unremarkable (ASPECTS 10) while neck and brain computed tomography angiography (CTA) revealed a basilar apex occlusion with patency of both posterior cerebral arteries (PCA). Endovenous thrombolysis with rt-PA was started and then a DSA study was performed which documented patency of basilar apex and occlusion of the left PCA at P3. The diagnostic work-up was negative for embolic sources (normal atrial volume, ECG monitoring during hospitalization was negative for emboligenic arrhythmias, Transcranial Doppler Ultrasound was negative for shunts). CTA of cerebral arteries showed narrowing of the right vertebral artery (VA) at V2, between vertebraes C3-C4, where vertebral canal appeared markedly deformed by degenerative spondyloarthrosis. Vertebral DSA was performed: angiograms after rotation of the patient's head to the right documented occlusion of the right VA at C3 level, which led to the hypothesis of rotational vertebral artery syndrome (Bow Hunter's syndrome). The patient was discharged and a double antiplatelet therapy

was started. Twenty days after discharge, the patient suffered from a transient ischemic attack in the territory of posterior cerebral circulation (right visual field impairment, motor impairment of right upper limb and dysarthria), with resolution of symptoms after 20 minutes. Given the failure of initial conservative management, the patient underwent decompressive surgery of the right VA at C3-C4 level and subsequent Anterior Cervical Discectomy and Fusion of C3-C4.

Discussion: Stenosis or occlusion of VA due to head rotation can lead to downstream hypoperfusion of brain or thromboembolism. Mechanical compression can occur anywhere along its course and aetiologies include osteophytes, herniated discs, spondylosis, tendinous bands or tumours. [1]

Conclusion: Bow hunter's syndrome is a rare but potentially treatable cause of strokes.

## EARLY NEUROLOGICAL DETERIORATION IN ISOLATED PONTINE STROKE: CLINICAL AND IMAGING FEATURES

B. Dell'Acqua, M. Vabanesi, R. Chieffo, A. Semerano, M. Bacigaluppi, G. Giacalone, L. Roveri, M. Filippi

Department of Neurology, San Raffaele Scientific Institute (Milano)

Objectives: Patients with isolated pontine ischemic stroke may face early neurological deterioration (END). We aimed to assess clinical and neuroimaging factors associated to END in pontine stroke.

Materials and Methods: We analysed 112 consecutive patients, admitted to our Stroke Center, with MRI/CT-defined isolated pontine infarction, without basilar artery occlusion. END was defined as persisting NIHSS increase ≥2 points, occurring <48h after admission. Lesion anatomy was classified by neuroimaging. Pontine warning syndrome (PWS) was defined as transient neurological symptoms, typical for posterior circulation, occurring 2-7 days before stroke onset.

Results: Among 112 patients with isolated pontine infarction, END was recorded in 36 (32.1%). Demographic data and stroke risk factors did not differ between END and clinically stable patients. While median baseline NIHSS was similar in both groups (3 vs. 4, p=0.25), median increase of 5 NIHSS points (range 1-12) was observed at discharge in END patients (p<0.001). PWS occurred in 14/36 (38.9%) subjects with END vs. 16/76 (21.1%) subjects without END (p=0.067). Significant chronic small vessel disease (MRI-based Fazekas score ≥2) occurred in 24/32 (75.0%) patients with END vs. 39/70 (55.7%) without END (p=0.08). Anteromedial lesion location was the most common (N=27 deep, N=38 superficial), followed by anterolateral (N=19), tegmental (N=16) and other (N=12). END was observed in 8/27 (29.6%) deep anteromedial, 18/38 (47.4%) superficial anteromedial, 4/19 (21.1%) anterolateral, 0/16 (0.0%) tegmental, 6/12 (50.0%) other (p=0.0061 overall).

Discussion and Conclusion: Early neurological deterioration is common in pontine stroke patients. We described possible association with significant chronic small vessel disease, ventral stroke location and occurrence of pontine warning syndrome.

## ISCHEMIC STROKE AS PRESENTING MANIFESTATION OF ESSENTIAL THROMBOCYTHEMIA DUE TO V617F MUTATION IN JAK2 GENE

I. Di Sarno, A. Miele, M. Nolano, R. Iodice, F. Manganelli

Department of Neuroscience, Reproductive and Odontostomatological Science, University of Naples Federico II (Napoli)

Introduction: Essential Thrombocythemia (ET) is a myeloproliferative syndrome characterized by increased number of blood platelets and most patients with ET harbor a V617F mutation in JAK2 gene. ET is a rare cause of cerebrovascular thrombotic event and hereby we describe a case of ischemic stroke as presenting manifestation of ET in a patient carrying a JAK2-V617F mutation.

Case Report: A 51-year-old female presented to our center with acute aphasia, right hemianopsia, hemiparesis and hypoesthesia (NIHSS:23), The CT angiography of neck and intracranial arteries showed a 90% occlusion at the origin of the left internal carotid artery (ICA). Neither thrombolysis was performed because the patient arrived at our center out of the ''window" time, nor acute carotid stenting surgery. The patient was scheduled for elective carotid stenting ten days later and in the meantime, she was treated with loading dose of aspirin 300 mg plus clopidogrel 75 mg followed by dual antiplatelet therapy (DAPT= aspirin 100 mg + clopidogrel 75 mg). Atorvastatin 80 mg once a day was also added in therapy. Blood tests revealed an increased platelet count (677 x 103/microL; normal values 150-450 x 103/microL) while no other common risk factor for stroke including hypertension, hyperlipidemia, diabetes mellitus, coronary heart disease, smoking, alcohol consumption, low physical activity, and obesity was recorded. Ten days later, CT angiography of the neck and intracranial arteries demonstrated a 60% reduction of carotid stenosis, with a residual atherosclerotic plaque of ICA (30% stenosis) and stenting procedure was not performed. The persistent increased platelet count led to hematological evaluation and the patient underwent genetic analysis revealing V617F mutation in JAK2 gene. Accordingly, she started additional treatment with hydroxyurea 1000 mg and allopurinol 300 mg daily.

Discussion: The present case suggests that ICA stenosis might have favored thrombus formation in a patient with ET due to V617F mutation in JAK2 gene. Patients with ET have reduced overall survival and increased risk of thrombotic events compared with the general population. The degree of elevation of the platelet count has not been shown to be predictive of developing a thrombotic event whereas patients with a history of thrombosis or those older than 60 with a JAK2-V617F mutation are considered at high risk.

## EARLY P-WAVE PREDICTORS OF AF IN PATIENTS WITH ACUTE ISCHEMIC STROKE: EVIDENCE FROM INSERTABLE CARDIAC MONITORS

A. Digiovanni[1], G. Fanti[1], M. D'Apolito[1], M. Onofrj[1], S. Sensi[1], M. De Angelis[2], M. Faustino[3]

[1]Department of Neuroscience, Imaging, and Clinical Sciences, "G. D'Annunzio" University of Chieti-Pescara (Chieti-Pescara); [2]Urgent Neurology Clinic and Stroke Unit, Department of Emergency, "Santo Spirito" Hospital (Pescara); [3]Department of Cardiology, "SS. Annunziata" University Hospital (Chieti)

Background and Aims: Asymptomatic atrial fibrillation (AF) is a risk factor for ischemic stroke. Active search of subclinical AF in cryptogenic stroke (CS) patients is crucial to define the optimal secondary prevention strategy since AF patients need anticoagulant therapy to significantly reduce their ischemic risk and, therefore, avoid new ischemic events [1]. Insertable cardiac monitors (ICM) are employed in clinical practice to reveal AF, and recent evidence indicates that they can detect AF in up to 40% of patients with CS [2]. Nevertheless, accurate analysis of some cardiological features, such as left atrial and ventricular strain, during the acute phase of ischemic stroke (i.e., during hospitalization) may help clinicians to suspect asymptomatic AF [3]. In this study, we investigated the role of p-wave predictors of AF in the acute phase of ischemic stroke, in patients followed with ICM.

Methods: This is a single-center retrospective study. An expert cardiologist blindly reanalyzed ECGs obtained at hospital admittance of forty-three patients discharged with a diagnosis of CS and then followed with ICM. The analysis was focused on p-wave features, such as enlargements, humps, and spikes.

Results: Continuous ECG monitoring revealed subclinical AF in 19 patients (44%). The analysis of p-wave features showed abnormalities in 19 patients. Among them, 12 received a diagnosis of AF at ICM follow-up. P-wave abnormalities were significantly associated with the occurrence of AF (OR = 4.16, CI 95% 1.15 - 15, p = 0.02). Interestingly, in the AF group the duration of hospitalization was significantly higher than in the nonAF group ($p<0.01$).

Conclusions: In patients with CS, p-wave analysis should be considered a useful step, to select patients at high risk of asymptomatic AF who need a careful follow-up and a prompt therapeutic switch to anticoagulation.

## A RARE COMPLICATION OF GIANT CELL ARTERITIS

S. Donzelli, M. Arenella, M. Angeletti, F. Cancellieri, M. Cervigni, S. Malatini, A. Riva, R. Tiberi, N. Zannotti, M. Bartolini, M. Silverstrini, G. Viticchi

Neurogical Clinic, Marche Politechnic University (Ancona)

Introduction: Giant cell arteritis (GCA) is a granulomatous medium and large-vessel vasculitis. It is the most common form of systemic vasculitis, affecting both extracranial and rarely intracranial vessels, with an incidence of 15-25 cases per 100,000 persons over 50 years of age. Stroke is a serious though uncommon complication of GCA: in a large series on 287 biopsy-proven patients with GCA, stroke was observed in 2.8% in a period from the symptom's onset to 4 weeks after the beginning of the treatment.

Case Report: We present a case of a 65-year-old man who developed suddenly nausea and vomiting with transient vertigo, without fever. The patient had no history of hypertension, headache or diabetes mellitus. Blood tests shows slightly elevated PCR levels of 3,7 mg/dl and VES of 62 mm/h. Brain CT revealed no abnormality. After 1 week he developed persistent imbalance, slurred speech and psychomotor slowing. MRI with gadolinium showed bilateral middle cerebellar peduncles infarction, angio-CT of the supra-aortic vessels showed irregular aspect of the vertebral arteries and an intracranial obstruction of the left vertebral artery, suggestive of vasculitis. Doppler of the supra-aortic trunks revealed a typical dark hypoechoic area around the vessel lumen, the so called "halo sign" in the left vertebral artery. Temporal artery doppler ultrasound revealed a diffused mild intima-media thickness; ophthalmological examination was normal. According to clinical symptoms and radiological signs we made a diagnosis of GCA The patient was submitted to intravenous corticosteroids at the dose of 1 g/d for 5 days, followed by an oral dose of 1 mg/Kg/ die. Subsequently he started therapy with Tocilizumab.

Discussion: Ischemic stroke is a relatively rare complication in GCA patients, especially in vertebrobasilar territory. Moreover, an early recognition of stroke is very important because cerebrovascular disease are one of the predominant causes of death in patients with GCA. The absence of clinical symptoms in the first phase of the disease is not a prognostic criterion of ischemic cerebral events. Our patient showed a good recover, with a complete improvement of the symptoms. Patient who developed vertebrobasilar stroke may have brainstem involvement and poor outcome despite steroid therapy.

Conclusion: In patients with ischemic stroke of the vertebrobasilar territory and a radiological assessment compatible with a vasculitis, a diagnosis of GCA should be considered, even in the absence of clinical symptoms, especially when multiple concentric stenosis of vertebral arteries are present. Delay of immunosuppressive treatment could worsen clinical outcome.

## POST-PARTUM HEADACHE AS PRESENTING SYMPTOM OF CAROTID ARTERY DISSECTION

S. Falletti, M. Bagnato, F. Placidi, C. Pachatz, N. Mercuri

Neurology Department, Policlinico Tor Vergata (Roma)

Introduction: Carotid artery dissection is an important cause of stroke or TIA, especially in young people. Bilateral dissection occurs less frequently. The classical presentation involves headache or neck pain, Horner's syndrome, TIA and stroke.

Case presentation: A 41-year-old woman came to our attention about 10 days after complicated vaginal delivery, for gradual onset of occipito-temporal headache, phono-photophobia, transient numbness in the left upper limb and production speech disorder. Vomiting, fever or neck stiffness were absent. Her anamnestic history revealed Hashimoto's thyroiditis in euthyroidism, pituitary adenoma in regular follow-up,

homozygous mutation of MTHFR gene. Neurological examination was normal. Brain MRI showed lesions involving the right parietal cortex, the left frontal lobe and the left head of the caudate, that were hyperintense with restricted diffusion, compatible with recent ischemic lesions. Ultrasonography of the internal carotid arteries (ICAs) documented double vascular lumen with intraparietal hematoma bilaterally, compatible with bilateral mid-distal level dissection, determining hemodynamically significant effects (PSV: 330 cm/sec, ICA/CCA ratio: 2.72). Computed tomography angiography confirmed multiple steno-dilatations and parietal thrombotic appositions at the mid-distal level of ICAs, suggested for dissection. In relation to bilateral localization of the pathology, no indication for endovascular treatment was placed. The patient underwent pharmacological interruption of lactation and was treated with double antiplatelet therapy and statin. After 2 weeks, a minimal progressive recanalization of the vessels lumen was highlighted by carotid ultrasonography. The patient began outpatient follow-up. Forty-five days after the event, carotid ultrasound test showed normalization of flow velocities at the mid-distal level of ICAs, so single antiplatelet and statin therapy was maintained.

Discussion: During puerperium the incidence of stroke increases. Postpartum dissection is a rare occurrence. Our patient's symptoms have several differential diagnosis, including intracerebral hemorrhage, cerebral venous thrombosis and reversible cerebral vasoconstriction syndrome. Although carotid dissection is not a frequent cause of headache during post-partum, it should be considered, assessed by imaging and promptly treated. As evidenced by the CADISS study, there is no difference in efficacy of antiplatelet and anticoagulant drugs at preventing stroke and death in patients with symptomatic carotid artery dissection.

Conclusions: Although bilateral carotid dissection is an extremely rare condition, it should be included among the differential diagnoses of headache in pregnancy and post-partum period, especially in the case of complicated deliveries, with the aim of a rapid radiological evaluation and individual targeted therapy.

## PEDIATRIC ARTERIAL ISCHEMIC STROKE: A SINGLE CENTER'S EXPERIENCE

M. A. N. Ferilli[1], G. Tiralongo[2], G. Monte[3], A. Carboni[4], L. Lucignani[4], C. Gandolfo[4], M. Valeriani[3]

[1]Neuroscience Department, Bambino Gesù Children's Hospital IRCCS (Roma); [2]Department of Pediatrics, Tor Vergata University Hospital of Rome, (Roma); [3]Developmental Neurology Unit, Bambino Gesù Children Hospital IRCCS (Roma); [4]Imaging Department, Bambino Gesù Children's Hospital IRCCS (Roma)

Objectives: Acute ischemic stroke in children (AISc) represents a rare condition with a great short- and long-term burden [1]. The aim of our study is to present our single-center case series data of patients with AISc.

Methods: We conducted a retrospective analysis from 2006 to 2023 of all AISc evaluated at our Pediatric Neurology Center. Children with age of onset between 28 days-of-life and 18 years were included and hemorrhagic strokes were excluded. Epidemiological, clinical, biochemical, neuroradiological and therapeutic data were collected by consulting our hospital database.

Results: Our case-series included 30 children: the onset mean age is 5.7 years (range: 6-months to 13-years), 15/30 have onset within the first 5 years of life (M/F:1). The cause was identified in 20/30 of patients: a predisposing genetic condition was found in 5 patients, cerebral vasculitis in 8, cardiogenic stroke in 5, 1 with arterial dissection and 1 intra-infective. The most frequent onset symptoms were hemiplegia or monoplegia (27/30), seizures (8/30) or amnesic-confusion state (7/30), while constitutional symptoms were present in 6 patients. None of our patients showed overt abnormalities of routine blood tests, except for one patient with sickle cell anemia. CSF analysis was conducted in 11/30 and only in 1 case was suggestive of HSV1 infection. On neuroradiological scans, the ACM territory was the most affected (28/30), while in 2 patients the lesions were present in the cerebellar-ponto-mesencephalic region. 22/30 were treated with acetylsalicylic acid, 13 with low-molecular-weight heparin and 7 with steroid. 12/30 received a combined treatment with at least 2 drugs. Only 2 patients presented with relapsing strokes.

Discussion and conclusions: We confirm that most AISc occur within the first 5 years of life. Our diagnostic-etiologic yield rate is high (66%), although not yet in line with international standards (80%), presenting, however, a high prevalence of vasculitis and low for cardiogenic and sickle-cell-related-stroke. The onset with focal neurological deficits is the most frequent, followed by seizures. Most AISc occur in the anterior circulation territory, whereas the posterior circulation failure is rarer (93% vs 7%). Treatments vary according to the individual patient's risk factors, although antiplatelet therapy or anticoagulant alone or add-on to steroid is the most common.

## CHARACTERIZATION OF A PANEL OF SERUM BIOMARKERS TO DEFINE FUNCTIONAL OUTCOME IN ISCHEMIC STROKE PATIENTS: FOCUS ON INFLAMMATION

F. Ferrari[1], F. Mazzacane[1], S. Moraru[1], B. Del Bello[1], S. Scaranzin[2], C. Morandi[2], M. Gastaldi[2], A. Persico[3], A. Cavallini[3]

[1]Department of Brain and Behavioral Sciences, University of Pavia (Pavia); [2]Neuroimmunology Research Unit, IRCCS Mondino Foundation (Pavia); [3]U.C. Cerebrovascular Diseases and Stroke Unit, IRCCS Mondino Foundation (Pavia)

Objectives: Inflammation is known to exacerbate ischemic injury leading to secondary delayed damage [1]. Although inflammation comprises several mediators, most of the studies have so far evaluated single molecules involvement in acute ischemic stroke patients' outcome [2], but the quest for biomarker panels is open [3]. The aim of this ongoing study is to determine the relationships between selected inflammatory serum biomarkers and functional outcome evaluated by mRS at discharge and at 3 months.

Materials and Methods: In this longitudinal prospective observational study, we included patients with acute ischemic stroke fulfilling these criteria: >18y, onset <24h, NIHSS >1, pre-stroke mRS=0-1, evidence of acute stroke at neuroimaging. Exclusion criteria: >80y, Transient Ischemic Attack, previous stroke/traumatic head injuries, other neurological disease, immunosuppression before stroke, eGFR<30mL/min, pregnancy. Patients were treated as standard of care. The following markers have been considered: Interleukin-6 (IL6) and receptor for advanced glycation end-products (RAGE) for inflammation,

neurofilament-light-chain (NfL) as a measure of neuronal damage. Biomarker serum concentrations were determined with ELLATM Automated Immunoassay System on samples collected within 24h (T0) and after 7±2 days from onset (T1).

Results: At present, we included 54 patients (31 males, mean age 61.48[±14.28]); 75.9% with minor, 16.7% moderate, 5.71% severe stroke. Biomarker median values were IL6=6.09pg/mL (IQR=5.79), RAGE=722pg/mL (IQR=532.00), NfL=26.30ug/mL (IQR=42.10) at T0; IL6=8.04pg/mL (IQR=15.85), RAGE=670.50pg/mL (IQR=386.50), NfL=92.95ug/mL (IQR=116.40) at T1. IL6 and NfL were higher at T1 vs T0 (p=0.012 and p<0.001, respectively). NfL positively correlated with both IL6 and RAGE serum concentrations at T0, and only with IL6 at T1. At discharge, RAGE-T0 and IL6-T1 correlated with mRS score while, at 3 months, no correlations were observed for either the inflammatory markers, being IL6-T0 at the limits of significance (p=0.058).

Discussion: Results confirmed the distinctive kinetics of RAGE and IL6 release in the blood after stroke, influenced by the extension of brain damage particularly at T0. Moreover, these inflammatory biomarkers differently correlated with functional outcome at discharge, reflecting their release kinetics and the intrinsic differences in the activation timing of inflammatory mediators. On the contrary, no correlations were observed at 3 months: this could be due to the small sample size and to the fact the majority of so-far enrolled patients had minor strokes.

Conclusions: These preliminary results are part of a larger Study to identify a biomarker panel to better characterize the physiopathological complexity and clinical evolution of ischemic stroke patients.

## PREDICTORS OF GOOD FUNCTIONAL OUTCOME IN PATIENTS WITH TANDEM OCCLUSION AFTER REVASCULARIZATION TREATMENT: SINGLE CENTER EXPERIENCE WITH 12-MONTH FOLLOW-UP

L. Ferrau[1], P. La Spina[1], A. Tessitore[2], D. Iati'[2], C. Casella[1], F. Giammello[1], A. Ciacciarelli[1], V. Tudisco[1], S. Vinci[2], R. Musolino[1], A. Toscano[1]

[1]Stroke Unit, Policlinico G. Martino (Messina); [2]Neuroradiology Unit, Policlinico G. Martino (Messina)

Objectives The primary aim of this study is to identify good clinical outcome predictors for patients presenting with tandem occlusion (TO), analyzing a series of demographics, clinical and radiological data, all compared to outcome measure at 3, 6 and 12-month follow-up. Secondly, we investigated what variables were able to influence mortality.

Background: TO is defined as a severe stenosis/occlusion of the cervical internal carotid artery ipsilateral to the intracranial occlusion. TO clinical features may be similar to other stroke subtypes due to isolated intracranial occlusion but with more severe neurological symptoms and worse outcome.

Patients and Methods: We collected data of 100 patients with TO that underwent revascularization treatments in our Stroke Unit Center. We studied different cohorts with good clinical outcomes, defined as a mild disability with mRS 0-2 at 3, 6 and 12-months versus those with poor clinical outcomes defined as mRS 3-6. Moreover, we analyzed what studied factors were able to influence mortality (mRS 6).

Results: Using univariate analysis, we noticed that at 3- and 6-month follow-up, smoker patients with younger age and low NIHSS at admission and at discharge showed better clinical outcomes than others. Besides, low burden of leukoaraiosis and combined use of mechanical thrombectomy (MT) with acute stent of extracranial lesion, were associated with good functional outcomes up to one year follow-up. About other variables related to death, higher age and high NIHSS, at 24h and at discharge, were associated with high percentage of mRS-6 at 90 days. At 6- and 12-month follow-up, patients with high rate of leukoaraiosis demonstrated higher risk of death. About treatment, patients who underwent MT alone, had a higher death rate than patients treated differently.

Conclusions: As a single Center experience, it has been demonstrated after one-year follow-up in patients with TO, what kind of variables might influence outcomes and mortality.

Agostino-Estense University Hospital (Modena); [4]Neuroradiology Unit, S. Agostino-Estense University Hospital (Modena); [5]Neuroradiology Unit, IRCCS Istituto Delle Scienze Neurologiche, Bellaria Hospital (Bologna); [6]Department of Neurology and Stroke Center, Maggiore Hospital (Bologna); [7]Stroke Unit, Careggi University Hospital (Firenze)

Background and Purpose: Carotid stenting in acute ischemic stroke is sometimes necessary to maintain the patency of the vessel during endovascular procedures in acute ischemic stroke. However, there are few data regarding antiplatelet management for carotid stenting placement in this setting and the optimal antithrombotic regimen in this setting is still unclear. This study aimed to investigate the difference between early single and dual antiplatelet therapy on short term outcomes in patients with acute ischemic stroke treated with carotid stenting.

Materials and Methods: A multicentre retrospective study was conducted in patients with acute ischemic stroke treated with emergent carotid artery stenting placement. Early antiplatelet treatment before 24 hours was made by neurointerventionalist and stroke neurologist according to local protocols and was single or dual antiplatelet therapy (SAPT and DAPT, respectively). Outcomes of interest were: any hemorrhagic transformation (HT) and at 24 and 48 hours after stroke and stent reocclusion. Independent associations were investigated with logistic regression assessing for confounders.

Results: We enrolled 181 patients, mean (+-SD) age 67.4 (+-12.1) years, 132 (73%) males, median (IQR) NIHSS 15 (10-20), 92 (51%) patients received rt-PA before endovascular treatment. Internal carotid artery was occluded in 148 (82%) and stenotic in 33 (18%) patients. Aspirin was the most frequent drug after stent placement (51%). After stent placement, 131 (72%) received DAPT and 50 (28%) received SAPT. HT at 24 hours was present in 51 (28%) patients (of whom 14 had HT soon after the endovascular procedure and were therefore administered with SAPT), 20 (40%) SAPT and 31 (24%) DAPT (p=0.029); HT within 48 hours occurred in 54 (30%) patients, 21 (42%) SAPT and in 33 (25%) DAPT patients (p=0.027). Considering patients without HT soon after endovascular treatment, HT at 24 hours was present in 6 (12%) SAPT and 31 (24%) DAPT patients (p=0.082), HT at 48 hours in 7 (14%) SAPT and 33 (25%) DAPT patients (p=0.105). Number of passes >3 increased risk of hemorrhagic transformation (ORmulti=4.78; 95%CI=1.33-17.11), length of endovascular treatment and treatment with rt-PA were not associated with HT. Stent reocclusion within 48 hours occurred in seven (5%) patients, two SAPT and five DAPT patients.

Conclusions: In patients with acute ischemic stroke, early single antiplatelet therapy was not associated with an increase of both hemorrhagic complications and stent reocclusion.

## ROLE OF TRANSCRANIAL DOPPLER ULTRASONOGRAPHY IN THE MANAGEMENT OF ACUTE POSTERIOR CIRCULATION ISCHEMIC STROKE RELATED TO BASILAR ARTERY STENOSIS

M. Filidei[1], F. Galletti[1], M. Principi[2], M. Allegritti[3], C. Conti[4], A. Riva[5], C. Di Schino[1], C. Colosimo[1], S. Caproni[1]

[1]Neurology and Stroke Unit, Neuroscience Department, "S. Maria" University Hospital (Terni); [2]Unit of Neuroradiology, "Santa Maria" University Hospital (Terni); [3]Division of Interventional Radiology, "Santa Maria" University Hospital (Terni); [4]Neurosurgery, Neuroscience Department, "Santa Maria" University Hospital (Terni); [5]Neurological Clinic, Marche Polytechnic University, (Ancona)

Objectives: To demonstrate the relevance of neurosonology in the management of acute ischemic stroke.

Materials and method: We present a case report of posterior circulation stroke related to basilar artery stenosis (BAS).

Results: A 79-year-old man awoke at 5 a.m. with right deviation of the head and right hemiparesis. His last known normal was 11 the previous night. His past medical history revealed arterial hypertension, diabetes mellitus and dislypidemia. The patient presented to the emergency department at 06 a.m. The neurological examination showed coniugate left gaze palsy, dysarthria and right hemiparesis. The National Institutes of Health Stroke Scale score was 16. Head Computed Tomography (CT) did not show acute lesions and the CT perfusion documented an area of ischemic core in the left pons and penumbra in pons, medulla and bilateral superior cerebellar hemispheres. CT angiography (CTA) documented distal BAS. An urgent brain MRI confirmed a right paramedian pontine diffusion-weighted imaging hyperintensity, in the context of which a moderate hyperintensity on fluid-attenuated inversion recovery (FLAIR) sequences was observed. Although BAS was associated with brainstem hypoperfusion, the FLAIR-positive lesion determined a significant risk for hemorrhagic transformation in case of revascularization. Hence, neurosonologic exam was performed and did not reveal hemodynamic demodulation in the proximal tract and in the top of basilar artery. Thus, digital subtraction angiography (DSA) and basilar artery stenting were avoided. Dual antiplatet therapy was administered. In the following days the patient showed a gradual progressive improvement.

Discussion: Posterior circulation stroke represents approximately 20% of all strokes, and It is associated with higher risk of recurrence (1), mortality and morbidity rates than anterior circulation ischemic stroke. BAS is one of the main causes of posterior circulation ischemic stroke, especially symptomatic stenosis greater than 50%, which is associated with multiple transient ischemic attacks (TIAs) and recurrent stroke (2). Currently, DSA is the gold standard for diagnosing BAS. However, DSA is invasive and expensive. Transcranial color-coded sonography (TCCS) can be employed to detect BAS. Moreover, TCCS allows dynamic real-time observation of the flow imaging of the BA, intracranial vertebral artery (IVA) and posterior cerebral artery, detecting the presence of collateral flow through the posterior communicating artery, assessing velocities and evaluating vascular stenosis using the Doppler spectrum (3).

Conclusion: The use of neurovascular ultrasound is a reliable and effective tool in acute posterior circulation stroke management as it can guide the choice of further investigation and treatment options.

## STROKE-LIKE SYMPTOMS IN A PATIENT WITH NEWLY DISCOVERED ATRIAL FIBRILLATION AND A HISTORY OF MULTIPLE SCLEROSIS

G. M. Fiore[1], I. Lombardo[2], V. Bessi[3], C. Sarti[1], E. Portaccio[4], F. Pescini[5]

[1]NEUROFARBA Department, Neuroscience Section, University of Florence (Firenze);[2]Department of Neuroradiology, Careggi University Hospital (Firenze);[3]Department of Neuroscience, Psychology, Drug Research and Child Health, Careggi University Hospital (Firenze);[4]Division Neurological Rehabilitation, Careggi University Hospital (Firenze);[5]Stroke Unit, Careggi University Hospital (Firenze)

Objectives: Male, 67-year-old. In 1995 he experienced an optic neuritis in the left eye, treated effectively with corticosteroids. In 2021 he had transient paresthesia and a Brain MRI revealed hyperintense lesions in the white matter on the T2/FLAIR sequences.

Materials and Methods: A lumbar puncture revealed only a slight increase in cerebrospinal fluid protein levels and no oligoclonal bands. Due to three new periventricular lesions at follow-up Brain MRI, the patient was diagnosed with multiple sclerosis and started on dimethylfumarate on 2020. On 2022, ha was admitted to hospital for the sudden onset of right homonymous hemianopsia (NIHSS 2). Brain MRI showed a lesion with restricted diffusivity and FLAIR hyperintensity in the left temporo-occipital cortico-subcortical region not involving a specific vascular territory, with cortical hemosiderin deposits and without blood-brain barrier alterations. No stenosis of the main intracranial vessels was found on MRI angiography and vessel-wall imaging (black blood sequences) showed no areas of abnormal wall enhancement. Extensive cardiovascular assessment was performed and a 24-hours ECG monitoring revealed a 4 hours episode of atrial fibrillation so DOAC therapy was initiated for primary prevention of embolism.

Results and Conclusions: Considering the patient's history and the radiological findings, the diagnosis of multiple sclerosis has been revised and Dimethyl-fumarate therapy was discontinued. A primary vasculitis of the central nervous system has been hypothesized. The patient is under consideration for cerebral biopsy to verify this hypothesis. At 3 months follow-up the patient had complete recovery from visual deficits (NIHSS 0) and did not experience any new neurological symptom.

Intermediate Thalassaemia (IT) is an autosomal inherited condition, characterized by decreased beta-chain synthesis, with clinical onset at childhood or adolescence. Altered beta globin loci may account for recessive or, less frequently, dominant genetic pattern [1,2]. Abortive erythropoiesis, haemolysis, increased intestinal iron absorption, extramedullary erythropoiesis and hypercoagulability are the hallmark of the disease. Thromboembolic events (TEE) are reported 0.9-4% in Major Thalassaemia (MT) and 3.9-29% in IT [3]. A 64 year old female came to our observation for transient right arm hypoesthesia in already diagnosed IT, with negative neurological, cardiological, radiological examinations, except arterial hypertension. She was dismissed on low dose antiplatelet therapy. At the age of 67 years, she was again admitted to neurological unit for recurrence. CT showed chronic, ischaemic encephalopathy and hypodense, left cerebellar area, unrelated to the acute event. Thrombocytosis and first-degree atrioventricular block with mild mitral prolapse were revealed. Moreover, episodes of atrial fibrillation with low ventricular rate were detected at Holter's ECG. Therefore, a pacemaker was implanted, and anticlotting therapy was prescribed. Nonetheless, after nine months, she presented left hypoesthesia and lower limb hyposthenia. There were moderate mitral, and tricuspid prolapse, mild aortic stenosis with insufficiency at echocardiography, pulmonary nodules at chest CT. Cerebral TC confirmed chronic, ischaemic encephalopathy and showed extramedullary intracranial and paravertebral erythropoiesis / hemosiderosis in already mesylate deferoxamine undergoing treatment, because of repeated, regular transfusions. At the age of 70, in the context of coronavirus 19 paucisymptomatic infection, a vertebrobasilar event recurred. Lastly, after seven months, she arrived at emergency department with right complete hemisyndrome, because of wide, left fronto-temporo-parietal ischaemia in the territory of middle cerebral artery with haemorrhagic infiltration. Hypercoagulability in IT is related to membrane changes in erythrocytes, haemolysis, hemosiderosis, chronic platelet aggregation, increased expression of adhesion molecules in endothelial cells, activation of clotting system, cardiac dysfunction, splenectomy, hormonal disorders, accounting for resistance to therapeutical strategy. The prevalence of overt strokes in IT patients with a history of thrombosis ranges between 5% and 9%. A rate of 37,5% ischemic lesions at MRI is reported in IT who were neurologically intact and had no conventional stroke-related risk factors. High incidence of silent brain infarction, large cerebral vessel disease, and impaired neuronal function are reported in splenectomized patients with TI. Accurate examination of neuroimaging is important to discern among extramedullary erythropoiesis, hemosiderosis and haemorrhagic infiltration.

Angelo dei Lombardi-AV); [11]Laboratory, S. Ottone Frangipane Hospital, ASL AV (Ariano Irpino-AV)

Background and Aims: Neuron-specific enolase (NSE) is a dimeric, intracellular, glycolytic enzyme, which is released after stroke, cardiac arrest, traumatic brain injury [1,2,3]. Its level may help in identification of patients at risk of poor outcomes, in decision making on intensive care, rehabilitation or palliative treatments. The aim of our study was to assess Neuron Specific Enolase (NSE) in Acute Strokes (AS) patients.

Methods: We recruited 210 patients affected with acute cerebrovascular syndromes (ACVS), subgrouped according to age (A: up to 29 years; B: 30-44 years; C: 45-64 years; D: 65-76 years; E: beyond 77 years) and volume of infarcted areas (1: small vessel occlusions, lacunes (SVO-L); 2: large-medium vessel occlusions (L-MVO). They underwent blood withdrawal within 24 hours, Computerized Tomography at Emergency Department and after 24 hours, Magnetic Resonance Imaging after 24 hours.

Results: NSE was not significantly higher in group D and E compared with A and B. Mild significance was detected in A1 vs B1 and C1 and between C2 vs D2, especially in patients with concomitant chronic ischaemic encephalopathy (CIE) (b) compared to those without CIE (a)

and in L-MVO. Pearson's test showed correlations of NSE with age, day1 GCS, day7 GCS, day7 MRS, PAP, LAD, BNP.

Conclusions: Altogether, our results highlight the importance of age consideration for a precise interpretation of haematological parameters. NSE release may increase by aging. It occurs in AS. As expected, its entity may decrease in CIE, when gliosis becomes predominant. It correlates with worst acute neurological and cardiological conditions, especially in elderly patients, as expression of acute sufferance and reduced clearance. Higher standard deviations and lower correlations related to concomitant multisystemic, chronic organ failure, especially in advanced age, may lessen statistical significance. Nonetheless, NSE may be a useful parameter of acute neuronal body death and blood brain barrier disruption, considering the brief half-life (24-72 hours in serum), while biomarkers with longer half-life, as tau protein (10 hours in plasma, 23+6,4 days in brain), Neurofilament light chain (several weeks to 2 months) may better indicate the burden of retrograde, anterograde and transneuronal neurodegeneration in CIE. Further biological and radiological data are needed to shed light on conflicting results of published studies on the issue. This would allow better prediction of brief and long-term prognosis and drawing up protocols of rehabilitation based on benefits/costs analysis.

## HYPERDENSE ARTERY SIGN (HAS) AS A MARKER OF ACUTE ISCHEMIC STROKE (AIS): ETIOPATHOGENETIC, HISTOLOGICAL AND NEUROSONOLOGICAL CORRELATES

P. Flace[1], F. Addabbo[2], F. Amati[3], G. Liaci[3], A. Marzullo[4], L. Pascazio[3]

[1]Medical School, University of Bari 'Aldo Moro', Hospital Structures of Universo Salute Opera Don Uva, Bisceglie (Bari, Bisceglie-BT); [2]Complex Unit of Statistics and Epidemiology, ASL-Taranto (Taranto); [3]Stroke Unit, Section of Neurology, Department of Translational Biomedicine and Neuroscience "DiBraiN", University of Bari 'Aldo Moro' (Bari); [4]Section of Pathology, Department of Emergency and Organ Transplantation, University of Bari 'Aldo Moro' (Bari)

Objectives: The focal hyperdensity of the middle cerebral artery (MCA) or of other large vessels, on non-enhanced cranial CT (NECCT), is the earliest radiological marker of AIS, being an indicator of occluding clot. The aim of this study is to evaluate the possibility to correlate thrombus features to stroke etiopathogenesis, thus suggesting effective therapies.

Materials and Methods: We extracted data from 20 subjects with AIS. All patients exhibited HAS on NECCT and Large Vessel Occlusion on CT-MR angiography. Sixteen patients underwent combined (bridging) or isolated treatment (IV-TL or TM), 4 subjects were excluded for intraprocedural complications (I° Group); the presence/absence of HAS was retrospectively evaluated in 19 patients with AIS and histological analysis of the extracted thrombi (II° group) was conducted. Ultrasounds and neuroimaging monitoring were given at Stroke Unit.

Results: The outcome was good in both groups, resulting in recanalization, except for 6 cases. Median thrombus length was 12-14 mm and MCA, M1 or M2 tract, was the principal occlusion site. The histological examination of the thrombi revealed, in the 16 subjects with HAS, an almost homogeneous distribution of fibrin, predominantly white thrombi in 9 patients and red thrombi in 7 patients, plus concomitant atrial fibrillation in 11 cases; in the 3 subjects without HAS a prevalence of white thrombi (2 vs 1) and absence of atrial fibrillation was observed; a slight prevalence of white, fibrin-rich thrombi, was also detected in longer procedures. An association trend between thrombi size and proximal occlusion, as well as extra-intracranial atheromatous load, highlighted by ultrasound, was observed; no association between the greater thrombus length and collaterals was detected, because longer thrombi occlude the vessels able to provide collateral compensations. The correlation between thrombus length and atrial fibrillation was almost significant (P=0,05).

Conclusions: The latest correlation suggests that cardiac thrombi are extended in length and their composition would give the hyperdensity to neuroimaging. Particularly, fibrin-rich thrombi are hyperdense and, if from cardio-embolic source, they have a solid component of red blood cells (RBCs), which is moreover responsible for the hyperdensity, unlike athero-thrombotics ones, less rich in RBCs; the cellular part decreases over time, leading to the organization of fibrin meshes: the fresher the thrombus is, the richer it is in RBCs. HAS is therefore an early marker of stroke and provide information both on the presence and on the features of the thrombus, suggesting to employ alternative thrombolytics and Thrombectomy with EA-TL.

## BILATERAL PTOSIS AND DIPLOPIA AS SYMPTOMS OF STROKE: A CASE REPORT

L. Florio[1], V. Inchingolo[1], F. Castellana[2], G. d'Orsi[1]

[1]Neurology Department, IRCCS Casa Sollievo della Sofferenza (San Giovanni Rotondo-FG); [2]Unit of Clinical Neurology, Department of Neurosciences and Rehabilitation, University of Ferrara (Ferrara)

Introduction: Bilateral ptosis and diplopia are unspecific symptoms of brain or cranial nerve injury. We hereinafter report a case of bilateral ptosis and diplopia as the only symptoms of stroke.

Materials and methods: A 59-year-old man was referred to our institution for a sub-acute presentation of bilateral ptosis and diplopia. His medical history was unremarkable except for a recent diagnosis of diabetes. On neurological examination a fixed bilateral ptosis was observed, associated with an abducent nerve palsy in the left eye. No other neurological signs nor signs of fatigable weakness were recorded. Blood exams were normal except for an increment of blood glucose and glycated hemoglobin, consistent with the history of diabetes. These signs are often found in neuromuscular transmission disorder and patient underwent to repetitive nerve stimulation and single fiber EMG: both of these exams were negative. AChR and MuSK antibody assays were negative. Myasthenia gravis was excluded and a brain MRI was performed, showing a minimal ischemic lesions in pons.

Then a transcranial doppler was done and it revealed a severe stenosis in the middle of the basilar artery associated with a moderate stenosis of the left posterior cerebral artery in the P2 segment. Finally, an angio-CT scan confirmed this datum. The patient was diagnosed with ischemic stroke and for the intracranial stenosis a treatment with dual antiplatelet therapy (acetylsalicylic acid and clopidogrel) and statin was administered.

Discussion: In a patient with only bilateral ptosis and diplopia often a neuromuscular transmission disorder is hypothesized. Actually, myasthenia gravis showed an increment of incidence in the last decades, especially in male patients with more than 60 years. Despite the incidence of increment, myasthenia gravis remains a rare disease and, in front of ptosis and diplopia, often other causes, such as tumors or neurodegenerative disorders, should be taken into account. Ischemic stroke has an highest incidence in male with more than 60 years, especially for those patients who have comorbidities such as hypertension, diabetes or hearth diseases. Posterior circulation infarction is more rare than anterior infarction and it is often associated with dysarthria, dysphagia and ataxia.

Conclusion: This case should be taken into account as it shows how posterior circulation infarction may be underhand and misdiagnosed.

## ASSOCIATIONS OF RISK SCORES WITH SVD BURDEN AND PROGRESSION IN ELDERLY PATIENTS ON ORAL ANTICOAGULANTS FOR ATRIAL FIBRILLATION: THE STRAT-AF STUDY

B. Formelli[1], E. Salvadori[1], C. Barbato[1], E. Barucci[1], C. Cardaci[1], F. Cesari[2], S. Chiti[3], S. Diciotti[4], B. Giusti[2], A. Gori[2], C. Marzi[5], F. Pescini[6], F. Arba[6], G. Pracucci[1], A. Ginestroni[7], E. Fainardi[7], R. Marcucci[2], A. Poggesi[1]

[1]NeuroFARBA, AOU Careggi (Firenze); [2]Atherothromobotic Disease Centre, AOU Careggi (Firenze); [3]Health Physics Unit, AOU Careggi (Firenze); [4]Department of Electrical, Electronic, and Information Engineering 'Guglielmo Marconi', University of Bologna (Bologna); [5]Institute of Applied Physics 'Nello Carrara' (IFAC), National Research Council of Italy (CNR) (Firenze); [6]Stroke Unit, AOU Careggi (Firenze); [7]Neuroradiology Unit, AOU Careggi (Firenze)

Objectives: Guidelines recommend CHA2DS2-VASc and HAS-BLED scores, based on clinical variables, for thromboembolic and hemorrhagic risk in atrial fibrillation (AF), however, their predictive value is limited. MICON-ICH and MICON-IS, including the imaging variable microbleeds (MBs), have been recently proposed in patients on antithrombotics.

Aims: In a cohort of elderly AF patients on oral anticoagulants we assessed the associations between MICON, CHA2DS2-VASc and HAS-BLED scores and small vessel disease (SVD) markers (baseline and progression), as anatomical substrate for both ischemic and hemorrhagic stroke.

Methods: Strat-AF study is an observational, prospective, single-center study that enrolled patients over 65 years, taking oral anticoagulants for AF. Brain MRI was performed at baseline and after 18 months. On MRI, SVD burden and progression were visually assessed with validated scales. Risk scores were calculated at baseline.

Results: 170 patients were enrolled (mean age:77.7+/-6.8 years, male:65%). At baseline, MICON-ICH was significantly associated with presence of all SVD markers (with severe White Matter Hyperintensities: 6.8±2.5 vs. 5.8±2.2, p=.001; with MicroBleeds: 9.4±2.0 vs. 5.3±1.7, p=.001; with lacunes: 6.6±2.4 vs. 5.9±2.3, p=.032; with Basal Ganglia-Enlarged PeriVascular Spaces: 6.5±2.4 vs. 5.4±2.0, p=.001; with Centrum SemiOvale-EPVS: 6.5±2.6 vs. 5.7±2.0, p=.015) and MICON-IS (with severe WMHs: 8.3±2.6 vs. 7.6±2.1, p=.034; with MBs: 9.6±2.2 vs. 7.4±2.0, p=.001; with lacunes: 8.8±3.0 vs. 7.4±1.9, p=.006; with BG-EPVS: 8.0±2.3 vs. 7.3±1.9, p=.012) with all but CSO-EPVS (p=.092), while CHA2DS2-VASc and HAS-BLED showed few significant associations (CHA2DS2-VASc with MBs: 4.2±1.2 vs. 3.6±1.5, p=.034; HAS-BLED with severe WMHs: 2.0±1.0 vs. 1.7±0.8, p=.034, and with lacunes: 2.0±1.0 vs. 1.7±0.8, p=.010). At follow-up, between neuroimaging SVD progression markers, only incident MBs (13%) were associated with MICON-ICH (7.3±3.0 vs. 5.7±2.3, p=.030) and MICON-IS (8.7±1.9 vs. 7.6±2.4, p=.046), while no significant associations were found for CHA2DS2-VASc and HAS-BLED.

Conclusions: Compared to CHA2DS2-VASc and HAS-BLED, MICON-scores were more consistently associated with the presence of microangiopathic neuroimaging markers, suggesting a potential stronger predictive ability for hemorrhagic and ischemic events in AF patients. Funded by Tuscany Region and Italian Ministry of Health.

## SUBARACHNOID HEMORRHAGE ASSOCIATED WITH ESSENTIAL THROMBOCYTHEMIA: A CASE REPORT OF A PATIENT WITH A CALRETICULIN MUTATION

E. Funelli, G. Ferrero, C. Morotti Colleoni, F. Galbiati, E. Schilke, C. Ferrarese

Department of Neurology, Fondazione IRCCS San Gerardo dei Tintori, School of Medicine and Surgery, University of Milano-Bicocca (Monza)

Objectives: Essential thrombocythemia (ET) is a myeloproliferative neoplasm characterised by thrombocytosis and dysfunctional platelets. A recent review identified 63 cases of ET and stroke, of which only 6 were haemorrhagic and 4 mixed (ischaemic and hemorrhagic) [1]. We describe a rare case of subarachnoid hemorrhage (SAH) in a patient affected by ET, in therapy with oncocarbide, aspirin and anagrelide, bearing a calreticulin (CALR) mutation, to enrich the literature on the subject.

Materials: We describe the case of a 54-year-old woman.

Method: Electronic medical records, neuroimaging and laboratory results were reviewed.

Results: The patient was admitted to the emergency department after developing a sudden severe frontal headache, associated with nausea and vomiting. A brain Computer Tomography (CT) scan revealed a left frontal SAH. The angio-CT study showed focal dilatation (3 mm) of the right middle cerebral artery, without vascular malformation. Aspirin and anagrelide were discontinued. On admission, platelets were raised (709.000/μL), as well as her International Normalized Ratio (1.22), and activated partial thromboplastin time was normal. Repeated CT scan showed no further intracranial bleeding during headache relapses and a regular evolution of the lesion. A cerebral Magnetic Resonance showed no venous intracranial abnormalities. The cerebral

angiography described slight calibre irregularities on atheromasic basis in the right anterior cerebral artery and both posterior cerebral arteries, but no intracranial high-flow vascular malformations. After 12 days, the patient was discharged on oncocarbide alone, with normal neurological examination except for a moderate headache. At haematological re-evaluation the indication to discontinue anagrelide and aspirin was maintained.

Discussion: To date, only one other case report of SAH has been described in association with a CALR mutation. Several mechanisms underlying hemorrhagic manifestations have been hypothesised, including a predisposition to aneurysm formation and rupture due to a weakened vessel wall or the induction of a condition mimicking a reversible cerebral vasoconstriction syndrome due to altered vessel tone (both attributed to a disturbance of the microcirculation within the vasa vasorum); an acquired Von Willebrand syndrome in the presence of severe thrombocytosis; furthermore, some studies have shown an increased incidence of bleeding in CALR-mutated patients undergoing antiplatelet therapy.

Conclusions: Management guidelines for ET mainly focus on thrombosis risk stratification and prevention [2]. However, haemorrhage (with an incidence ranging from 1.39 to 6.6 per 100 patient-years) is a rare but well-known complication that involves the central nervous system in 9.8% of cases [3] and that physicians must take into account.

## ANTICOAGULANT-RELATED INTRACEREBRAL HEMORRHAGE: NO SIGNALS OF IMPROVEMENTS OVER 10 YEARS IN ITALY

F. Gabriele[1], M. Foschi[1], E. De Matteis[1], F. De Santis[1], D. Ciuffini[1], F. Conversi[1], E. Colangeli[2], B. Orlandi[2], F. De Santis[2], S. Sacco[1], R. Ornello[1]

[1]Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila (L'Aquila); [2]Stroke Unit and Neurology Unit, S.S. Filippo and Nicola Hospital (Avezzano-AQ)

Background: Direct oral anticoagulants (DOACs) are increasingly adopted as alternatives to vitamin K antagonists (VKAs) [1]. This change in practice of anticoagulation might have impacted the incidence and characteristics of oral anticoagulant-related intracerebral hemorrhage (OAC-ICH) in recent years.

Aim: The aim was to provide an updated account on the epidemiology of OAC-ICH over a decade of increasing use of DOACs to assess whether the introduction of DOACs was associated with a change in time trends in incidence and case-fatality rates (CFRs) of ICH.

Methods: All patients with a first-ever spontaneous ICH residing in the district of L'Aquila (298,343 inhabitants) from 2011 to 2020 were prospectively included. We defined OAC-ICHs as an ICH occurring within 48 hours from intake of VKAs - regardless of the measured International Normalized Ratio (INR) value on hospital admission - or DOACs. Global and yearly incidence of OAC-ICH were calculated according to a Poisson model. To assess whether OAC intake was independently associated with 30-day and 1-year CFR, Cox regression analyses were performed with ICH score components [2] (age, NIHSS and Glasgow Coma Scale (GCS) scores, systolic blood pressure at ICH onset, ICH volume at onset, hemorrhage location, intraventricular extension) plus intake of OACs.

Results: We recorded 748 ICHs of whom 108 (14.4%) were OAC-related, 75 (69.4%) with VKA and 33 (30.6%) with DOAC intake, respectively. There was a non-significant trend toward an increase in OAC-ICHs from 2.35 (95% confidence interval [CI], 0.94-4.83) in 2011 to 4.02 cases per 100,000 person-years (95% CI, 2.08-7.03) in 2020 (p=0.482). Among OAC-ICHs, we observed a relative increase of DOAC-ICHs (0% in 2011; 83.3 % in 2020). 30-day and 1-year CFRs for OAC-ICHs were 48.1% and 51.9%, with a non-significant increase over time (p=0.847 and p=0.941). Univariate Cox regression revealed that OAC use was not a predictor of 30-day CFRs (HR 1.33, 95% CI, 0.98-1.80; p=0.064). GCS (HR 0.82, 95% CI, 0.68-0.97; p=0.025), non-lobar location (HR 0.45, 95% CI, 0.20-1.00; p=0.049), uncertain location (HR 3.28, 95% CI, 1.08-10.02; p=0.037) and intraventricular extension (HR 4.60, 95% CI, 1.94-10.86; p<0.001) were the only factors independently associated with 30-day CFRs for OAC-ICHs.

Discussion: During the study period, VKA-ICHs were gradually overcome by DOAC-ICHs. However, the incidence and case-fatality of OAC-ICH did not significantly change.

Conclusions: Despite the wider adoption of DOACs representing a safer alternative to VKAs, OAC-ICH remains a devastating complication of the use of oral anticoagulants with a huge impact on public health.

## PREDICTING ATRIAL FIBRILLATION AFTER CRYPTOGENIC STROKE WITH CLINICAL RISK SCORES: A RETROSPECTIVE ANALYSIS

D. Galotto[1], M. Caccamo[1], N. Marrone[1], S. Grimaldi[1], G. Milella[2], D. Mezzapesa[2], M. Petruzzellis[2]

[1]Department of Basic Medical Sciences, Neurosciences and Sense Organs, University "Aldo Moro" (Bari); [2]Stroke Unit, Policlinic Hospital (Bari)

Objectives: Atrial fibrillation (AF) is the most common cardiac arrhythmia and represents a frequent cause of acute ischemic stroke (AIS) but is often underdiagnosed in cryptogenic stroke (CS), mostly due to inadequate cardiac monitoring. The identification of a clinical risk score to predict AF among CS patients, could improve patient selection for prolonged monitoring.

Materials: We retrospectively collected the data of CS patients discharged from our Stroke Unit from February 2018 to March 2023.

Methods: A time-to-event analysis was performed to investigate variables associated to AF. Furthermore, we compare the predictive role of two published clinical risk scores: AF ESUS score (high sensitivity and negative predictive value with a relative risk of new incident AF 13 times higher in patients with score >0) and Graz AF risk score (high sensitivity and acceptable specificity, with cutoff level of 4 points). All statistical analyses were performed using IBM SPSS Statistics version 25.0.

Results: We collected demographic and clinical data of 156 patients with AIS and median age at time of event of 70,5 years old. Eighty-nine (57%) were male. Median follow-up from discharge was 16 months.

Thirty patients underwent to loop recorder implantation during hospitalization of whom 11 revealed AF after a mean time of 7 months. AF was discovered in 12 patients without implantable device after a mean time of 15 months. Overall, 23 patients (15%) experienced AF. Among all the demographic and clinical variables, univariate analysis identified hypertension (AH) (p=0.039), left atrial (LA) dilation expressed as diameter >40 mm (p<0.001), supraventricular premature beats (SPB) >125 on 24-hs electrocardiogram (EKG) (p=0.001) as significant predictors of developing AF. Comparing AF ESUS score and Graz score, the first showed an AUC of 0.565 (p=not significant), whereas the latter evidenced a sensitivity of 87% and a specificity of 62% with an AUC of 0.747 (p<0.0001).

Discussion: Our data confirmed previous studies reporting a significant association between AF and AH, LA dilation and SPB >125 on 24-hs EKG. The comparison between AF-ESUS score and Graz AF risk score showed an undoubtedly higher predictive ability of the latter one. Indeed, Graz AF score consist of an extended combination of EKG, neurological and cardiac imaging findings and blood biomarkers, strongly associated with occult AF.

Conclusion: Herein we demonstrated the utility of selecting CS patients for expensive cardiac long-term monitoring. Therefore, it is important to find a score that better identify CS patients at high suspicion of occult AF.

## CAROTID EAGLE SYNDROME: A CASE SERIES

A. Gardin[1], P. La Spina[1], F. Grillo[1], F. Giammello[2], C. Fazio[1], C. Casella[1], E. Nastro Siniscalchi[3], S. Cicchiello[3], K. Galletta[4], F. Granata[4], R. Musolino[1], A. Toscano[1]

[1]Stroke Unit, Clinical and Experimental Medicine Department, University of Messina (Messina); [2]International PhD Translational Molecular Medicine and Surgery, BIOMORF Department, University of Messina (Messina); [3]Maxillofacial Surgery Unit, BIOMORF Department, University of Messina (Messina); [4]Neuroradiology Unit, BIOMORF Department, University of Messina (Messina)

Background and Aims: Carotid Eagle Syndrome (CES) is a rare disease due to the conflict of the elongated Styloid Process (SP) with the Extracranial Internal Carotid Artery (EICA), causing vessel dissection or compression. Currently, the diagnosis is defined by an SP longer than 25-30 mm and by a suggestive clinical presentation, like syncope, stroke, Transient Ischemic Attack (TIA), or headache. [1] However, there has yet to be a widely approved consensus regarding the diagnostic criteria or the management of this pathology. [1] The aim of this single-centre study is to describe the clinical and radiological features of CES cases and the adopted therapeutic approach.

Methods and Materials: In this case series study, we reported patients with suspected CES, who have been admitted to the Stroke Unit of the University Hospital of Messina since February 2014. Symptoms at the onset, NIHSS at admission, and diagnosis at discharge were collected. Characteristics of the SPs (length) and the EICAs (presence of kinking, coiling, atherosclerotic plaques and dissection) were described using CT Angiography (CTA) images. We also reported the follow-up data and if the styloidectomy was performed.

Results: Among 14 CES patients, 9 (64%) were males (mean age: 54±11 years). The majority (79%) had an NIHSS < 5 at admission. At discharge, we reported 8 ischemic strokes, 4 TIAs, 1 syncope and 1 headache. Evaluating CTA images, the stylo-carotid conflict was evident in all cases, with an average styloid length of 30±6 mm. Furthermore, 7 patients (50%) showed carotid dissection and 8 patients (57%) had an abnormal course of the ICA, whereas in only one case were there relevant atherosclerotic plaques. Styloidectomy was performed in 4 patients and none of the 14 patients reported any recurrence at the follow-up.

Discussion and Conclusion: Even though most patients presented with mild symptoms, half of them developed an ischemic stroke and several carotid dissections were reported. Therefore, it is essential to suggest not underestimating the CES, which could lead to potentially life-threatening diseases (like stroke or carotid dissection) and whose incidence could be higher than expected. [1] In some cases, the abnormal course of the ICA may contribute to the genesis of the stylo-carotid conflict and it could predispose to vessel dissection. [2] The surgery approach seems safe, but the course of ICA should be taken into account pre-operatively because it may cause vascular accidents. [3]

## BRAIN IS NOT ONLY TIME: THE ROLE OF BRAIN CT PERFUSION IN ACUTE ISCHEMIC STROKE PATIENTS IN THE EARLY TIME WINDOW

L. Gentile[1], E. Sessagesimi[2], M. Paolucci[2], N. Caracciolo[3], A. Falcou[3], L. Migliaccio[1], G. Urbinati[4], S. Forlivesi[1], M. Gentile[1], C. Cirelli[5], A. Di Ruzza[5], M. De Michele[3], L. Simonetti[2], A. Zini[1], D. Toni[3]

[1]IRCCS Istituto delle Scienze Neurologiche di Bologna, Department of Neurology and Stroke Center, Maggiore Hospital (Bologna); [2]IRCCS Istituto delle Scienze Neurologiche di Bologna, Radiology Unit, Maggiore Hospital (Bologna); [3]Neurovascular Treatment Unit (UTN), Azienda Ospedaliera Universitaria Policlinico Umberto I (Roma); [4]Department of Biomedical and Neuromotor Sciences (DIBINEM), University of Bologna (Bologna); [5]Interventional Neuroradiology Unit, Azienda Ospedaliera Universitaria Policlinico Umberto I (Roma)

Aims: According to international guidelines, only non-contrast CT (NCCT) is required in acute ischemic stroke (AIS) patients who are eligible for intravenous thrombolysis (IVT) in the early time window. Aim of this study was to evaluate the possible role of advanced neuroimaging in predicting clinical and radiological outcome in AIS patients receiving IVT within 4.5 hours of stroke onset.

Materials: Patients presenting within 4.5 hours of AIS onset who underwent multimodal CT protocol (including NCCT, CT-perfusion (CTP) using RAPID software, CT-Angiography) and thrombolytic treatment between July 2021 and August 2022 were enrolled.

Methods: Demographic, clinical and neuroradiological data were recorded. CTP parameters as rCBF<30%, Tmax>6 seconds and volume mismatch were collected. We evaluated final infarct volume (FIV) at 24-36 hours follow-up neuroimaging (CT or MR), and 3-month clinical functional outcome using modified Rankin Score(mRS).

Results: 262 AIS patients were included. Compared to patients with 3-month good clinical outcome (mRS 0-2), patients with 3-month mRS 3-6 were older (p<0.0001), had higher baseline NIHSS score (median 10, IQR 5-17 vs 4, IQR 3-9; p<0.0001) and a longer onset-to-needle-time (p=0.03). Baseline ASPECTS was similar between the two groups (p=0.04), while all CT perfusion parameters were higher in patients with 3-month unfavourable outcome (rCBF<30% p=0.004; Tmax>6 seconds p=0.004; volume mismatch p=0.0001). Patients with 3-month mRS 3-6 had a larger FIV at follow-up (p<0.0001). In multivariable binomial logistic regression analysis rCBF<30% (OR 1.12, 95% CI 1.06-1.19, p<0.0001), baseline NIHSS score (OR 1.08, 95% CI 1.01-1.15, p=0.02) and TICI 0-2a (p =0.005) independently predicted FIV>10 ml; while age (OR 0.90, 95% CI 0.86-0.94, p<0.001), baseline NIHSS score (OR 0.93, 95% CI 0.87-0.99, p= 0.036), onset to needle time (OR 0.99, 95% CI 0.99-0.99, p=0.02) and rCBF<30% (OR 0.95, 95% CI 0.92-0.98, p=0.002) independently predicted 3-month mRS 0-2. In multivariable ordinal logistic regression analysis rCBF<30% was an independent predictor of 3-month mRS 3-6 (OR 1.04, 95% CI 1.01-1.06, p=0.001).

Discussion and Conclusion: In our study on early time window IVT, the extent of ischemic core predicted FIV and 3-month clinical outcome, performing better than the ASPECTS. The use of this latter to select patients to be submitted to revascularization treatments in the early time window should be reconsidered.

## CLINICAL AND LABORATORY PREDICTORS OF RESPONSE TO ANTIPLATELET THERAPY MEASURED BY ELECTRICAL IMPEDANCE AGGREGOMETRY IN SECONDARY STROKE PREVENTION

L. Giacobazzi[1], L. Ciolli[2], M. Ronzoni[1], A. Reia[3], F. Rosafio[4], L. Vandelli[4], M. Dell'Acqua[4], L. Picchetto[4], G. Borzì[4], R. Ricceri[4], S. Meletti[1], G. Bigliardi[4]

[1]Neuroscience, University of Modena and Reggio Emilia (Modena); [2]Neurology, San Giovanni Bosco Hospital (Torino); [3]Neurology, San Giuseppe Moscati Hospital (Aversa-CE); [4]Neurology - Stroke Unit, Modena University Hospital (Modena)

Background: Ischemic stroke is a neurological disease with an enormous social impact. The introduction and improvement of revascularization treatments in the acute phase, together with a more careful and specific secondary prevention therapy, of which antiplatelet therapies are the cornerstone, have revolutionated the prognosis of this neurological disease. Their use, guided by tools capable of measuring their effectiveness, such as aggregation tests, could allow to a more targeted therapy.

Goals: The aim of our study was to identify any clinical or laboratory test factors that could influence the response to the antiplatelet therapy, evaluated with the aggregometric tests (Multiplate®), therefore potentially predictive of better or worse response to antiplatelet agents.

Materials and Methods: This is a retrospective study on 2400 patients in secondary prevention therapy with antiplatelet drugs, evaluated with a electrical impedance aggregometric test (Multiplate®). Information was collected on various clinical and laboratory variables, for which the possible correlation with the aggregometry values (defined by the parameters ASPI, ADP, ASPI/TRAP and ADP/TRAP) was evaluated, identifying with multivariate potential independent predictors of antithrombotic response.

Results: For the ASPI test, the number of platelets resulted as an independent predictor of high residual platelet activity in response to ASA (OR 0.99, 95% CI 0.98–0.99, p < 0.001), and the same is for the RDW (OR 0.86, 95% CI 0.75-0.99, p < 0.001). For the ADP test, the platelets predict the high residual platelet reactivity to the inhibitor of P2Y12 receptor (OR 0.99, 95% CI 0.98-0.99, p < 0.001). The use of SSRI predicts a lower response to ASA in the ASPI/TRAP ratio (OR 0.63, 95% CI 0.41-0.97, p = 0.03), and the same is for the WBC (OR 0.89, 95% CI 0.85-0.94, p < 0.001). For the ADP/TRAP ratio, the SSRI use is related to a higher response to P2Y12 inhibitor (OR 3.80, 95% CI 1.59-9.07, p = 0.003) while alcohol use and PCR are related to a lower response (OR 0.94, 95% CI 0.88-0.99, p = 0.03).

Conclusions: Aggregometry is proposed as a potentially useful tool in identifying patients at increased risk of new cerebrovascular events. The evaluation of the predictive factors of residual platelet hyperreactivity could be a valid criterion for the selection of patients at greater risk of resistance to therapy and therefore candidates for monitoring with an aggregometric test. Our study needs confirmation, but it might be helpful to personalize treatment for patients with cerebrovascular diseases.

## NEURO-BEHÇET'S DISEASE: A RARE CAUSE OF STROKE IN YOUNG PATIENTS

L. Giacobazzi[1], R. Ricceri[1], L. Vandelli[1], M. Dell'Acqua[1], G. Borzì[1], L. Picchetto[1], F. Rosafio[1], S. Seri[2], S. Meletti[2], G. Bigliardi[1]

[1]Neurology, Stroke Unit, Modena University Hospital (Modena); [2]Neuroscience, University of Modena and Reggio Emilia (Modena)

Introduction: Behçet's disease (BD) is a recurrent, multisystemic, inflammatory disorder that frequently affects blood vessels; the involvement of central nervous system is reported in 10%-25% of patients, known as

neuro-Behçet disease (NBD). Although the pathogenesis of stroke in BD patients may be multifactorial, recurrent inflammation of cerebral blood vessels could play a crucial role in the development of ischemic stroke.

Case description: A 28-years-old male patient, with a history of recurrent oral aphthae and scrotal ulcerations, presented with acute diplopia, nausea/vomiting and postural instability. Evaluated several times in the past for papular lesions in the lower limbs and for alternate alvus, with finding of rectal and descending colon linear ulcers, associated lymphoplasmacytic infiltrate and increased IgG4 in the serum, the patient denies arthritis, Raynaud's phenomenon, inflammatory low back pain or uveitis. He only reported an episode of sudden memory loss for recent events, with gradual spontaneous recovery; since then he complained of increased memory difficulties. During hospitalization, a brain MRI documented a small ischemic lesion in the pontine tegmentum on the left side; MR Angiography and transcranial color-coded duplex (TCCD) excluded alterations of extra- and intracranial vessels. An extensive infectious, neoplastic and autoimmune screening, including screening for chronic inflammatory bowel disease, was inconclusive, except for IgG4 and IgE elevation. Due to hypovitaminosis B12 and B9 and the previous episode of confusion with transitory memory impairment, Wernicke's encephalitis was suspected, although the neuroimaging features were not quite typical, and supportive therapy with parenteral multivitaminic integration, including thiamine, was set ex juvantibus. Neuropsychological tests revealed marked attentional-executive deficits. In order to search for potential deficient neuropathies, electroneurography was performed. It showed a predominantly demyelinating sensorimotor asymmetric multineuropathy. Cerebro-spinal fluid examination was normal, including autoimmune encephalitis and onconeural antibodies research on CSF, as serum Anti-ganglioside. A cardiological screening excluded cardiac abnormalities or major arrhythmias, and the genetic investigation for Fabry disease was negative. HLA B51 and B08 were found, and, considering clinical presentations, diagnosis of Behçet's disease was made; according to rheumatologists, the patient started steroid therapy with progressive clinical improvement and regression of postural instability and diplopia reported on admission.

Conclusion: Behçet's disease may be an important cause of ischemic stroke, especially in young patients; therefore in patients who have no risk factors for ischemic stroke, but experienced cerebral small-vessel lesions, NBD should be considered.

## ISCHEMIC STROKE AND SUBARACHNOID HEMORRHAGE WITH REVERSIBLE VASOSPASM IN ACUTE BACTERIAL MENINGITIS: A CASE REPORT

A. Giordano[1], F. Scheveger[1], D. Mattavelli[2], M. Braga[2], S. Rosa[2], L. Pantoni[1,2]

[1]Stroke and Dementia Lab, Department of Biomedical and Clinical Sciences, University of Milan (Milano); [2]Neurology and Stroke Unit, Luigi Sacco Hospital (Milano)

Objectives: To report the clinical features and course of a patient with ischemic stroke and subarachnoid hemorrhage with reversible vasospasm during an acute bacterial meningitis.

Materials and Methods: A previously healthy 72-year-old woman presented to our hospital in January 2023. For a few days she had been experiencing headache and neck pain unresponsive to over-the-counter anti-inflammatory drugs. On admission, she had fever, high blood pressure and blood tests showed neutrophilic leukocytosis. Computed tomography (CT) scans of brain and chest were normal. Cerebral spinal fluid (CSF) analysis showed high cell count (8633 cells/microliter) and low glucose (24 milligrams/deciliter). Polymerase chain reaction test on CSF was positive for streptococcus pneumoniae. Antibiotic therapy with ceftriaxone and vancomycin was started. The patient was then admitted to the infectious diseases ward. Four days later, however, her consciousness worsened despite an improvement in lab tests.

Results: Brain CT showed a hypodense lesion in the left caudate nucleus and a subarachnoid hemorrhage near the anterior falx. CT angiography showed irregular appearance of both anterior cerebral arteries as effect of vasospasm. Cerebral angiography subsequently confirmed the presence of vasospasm in both anterior cerebral arteries. Intra-arterial infusion of nimodipine resulted in vasospasm regression. Nimodipine was orally continued for two weeks and imaging controls revealed no new vascular event. On discharge, although a complete motor recovery occurred, the patient lost her independence in activities of daily life, due to severe multi-sectorial cognitive deficit caused by strategic territory ischemic stroke [1].

Discussion: Cerebrovascular complications are commonly reported in patients with acute bacterial meningitis. The pathophysiological processes involved are vasculitis, vasospasm and arterial or venous thrombosis [2]. Streptococcus pneumoniae is the most common pathogen involved. Intracranial hemorrhage can be seen in up to 3% of patients with bacterial meningitis. The most frequently seen cerebral hemorrhage types are intraparenchymal and subarachnoid3. In this patient, ischemic stroke and subarachnoid hemorrhage were observed with delayed onset in respect of the acute infectious disease despite an improvement of systemic condition.

Conclusions: Neurological deterioration in a patient with acute bacterial meningitis should always lead to the suspicion of a cerebrovascular complication, of ischemic or hemorrhagic type. Diagnostic evaluation should include CT Angiography to exclude potentially treatable acute vasospasm.

## VARIANT ASCENDING PHARYNGEAL ARTERY MAINTAINING FLOW IN A SYMPTOMATIC OCCLUDED INTERNAL CAROTID ARTERY IN A PATIENT PRESENTING WITH SUBACUTE EMBOLIC STROKES. A CASE REPORT

C. Gojani[1], E. Della Sala[1], G. Bosco[2], S. Leombruni[2], M. Romanelli[2], G. Vaula[2], P. Cerrato[3]

[1]Department of Neurosciences "Rita Levi Montalcini", University of Turin (Torino); [2]Department of Neurosciences "Rita Levi Montalcini", AOU Città della Scienza e della Salute di Turin (Torino); [3]Department of Diagnostic Imaging and Interventional Radiology, AOU Città della Scienza e della Salute di Turin (Torino)

Purpose: We present a case of successfully treated internal carotid artery occlusion (ICAO) in the presence of a variant ascending pharyngeal artery (APA) providing flow to an internal carotid artery (ICA).

Materials and method: Review of patient's medical history, carotid ultrasound, head and neck Computed Tomography Angiography and endoarterectomy.

Results: A 55-year-old man with a history of diabetes, hypertension, hypercholesterolemia and smoking presented with mild right hemiparesis and impaired walking. A markedly increased differential blood pressure was observed between right and left arm. Neurological examination revealed motor aphasia, right lateral homonymous hemianopsia, mild right hemiparesis. Aortic dissection was ruled out by aortic CT-angiography. Brain CT showed an area of subacute stroke in the left temporo-occipital region and a chronic stroke in the left parietal region. Carotid ultrasound was performed showing patency of left common carotid artery with high resistance flow and occlusion of the left ICA in a short segment near its origin. Orthodromic flow was evident 1 cm distally to carotid artery bifurcation. Left ICA flow was secured by a collateral vessel with high peak velocity and prominent diastolic flow. A head and neck CT-angiography was performed which demonstrated mixed density atherosclerotic plaque at the carotid bulb extending longitudinally for 15 mm to the origin of the internal carotid artery, thereby causing a 3-4 mm occlusion of the left ICA. Flow to the left ICA was granted by a thin tortuous vessel corresponding to a variant left APA which was connected through anastomotic branches to the left thyro-cervical trunk. A subocclusive stenosis of the brachiocephalic artery was detected explaining the increased differential blood pressure. Because the left ICA was fed by APA and its occlusion was short and likely the embolic source of the strokes, patient underwent carotid endoarterectomy. After surgery, carotid ultrasound demonstrated patency of left ICA and inversion of flow of APA with increased resistance, reduced peak systolic velocity and absent diastolic flow.

Discussion: The presence of variant APA in a patient with ICAO (rarely reported in literature) granted flow to ICA probably preventing hemodynamic strokes and making the surgical approach safer. On the other hand, the presence of APA probably contributed making ICAO symptomatic by creating turbulent flow in proximal ICA in the presence of orthodromic flow. This prompted us to give indication to endoarterectomy.
Conclusion: We described a rare case of symptomatic ICAO in the presence of variant APA, successfully treated with endoarterectomy.

## BILATERAL CAROTID ARTERY DISSECTION IN HYPER-IGE SYNDROME: A CASE REPORT

M. Laudadio[1], G. Bosco[1], M. Caprioli[1], P. Cerrato[1], E. Della Sala[2], S. Leombruni[1], M. Romanelli[1], G. Vaula[1]

[1]Stroke Unit, Dept of Neuroscience, AOU Città della Salute e della Scienza Hospital of Turin (Torino); [2]Neurologia 2U, Department of Neurosciences, University of Turin (Torino)

Objective: To describe a case of hyper-IgE syndrome (HIES), with emphasis on vascular involvement as a possible manifestation of the disease in adulthood.

Materials: Review of the patient's medical history, clinical assessments and laboratory tests, neurologic and cardiologic evaluation, imaging tests.

Methods: We report the case of a 54-year-old patient who was admitted to the emergency department for rapid onset of sharp pain in the right neck and narrowing of the palpebral fissure in the right eye with ipsilateral headache. Some relevant comorbidities were present: previous left carotid dissection in 2018, permanent atrial fibrillation (AF), previous lung abscess and multiple episodes of sinusitis, recurring joint dislocations.

Results: The patient had previously worked as contortionist in a circus. At neurological examination a deficit of left IX cranial nerve and left Horner syndrome was present. Cranial-CT and angio-CT displayed findings indicative of right internal carotid (ICA) dissection. The patient was diagnosed with HIES through a gene segregation test following her daughter's HIES diagnosis. A dominant-negative (DN) IL6ST mutations (p.Cys733Leu fs Ter6) was documented. Blood examination showed high serum immunoglobulin E (IgE) concentrations 1584 kUI/L (nv <100). Xrays examination confirmed bone dysmorphism and retained deciduous teeth. Consensus was reached on conservative medical management with anticoagulation therapy. In the first few days, the patient had a favourable evolution with resolution of the pain in the right neck and headache and improvement of the signs and symptoms of Horner syndrome.

Result and Discussion: HIES are multi-system disorders and a rare primary immunodeficiency disease. It is characterized by staphylococcal abscesses, eczema, respiratory infections, chronic mucocutaneous candidiasis, elevated levels of serum IgE, eosinophilia and low levels of inflammatory markers during infection. Extrahematopoietic features, include various connective tissue, skeletal, and vascular abnormalities with mainly large vessel involvement that contributes to morbidity and mortality in HIES patients. Hypereosinophilia, defective angiogenesis or vasculitis are supposed to contribute to vascular damage. However the patient's job (contortionist due to joint hypermobility) could have had a role in facilitating carotid dissection at the neck, being responsible of microtraumas.
Conclusion: To our knowledge, this is the first report of bilateral ICA dissection in HIES in the medical literature. ICA dissection can be a manifestation of HIES in adult. We suggest to evaluate thoroughly patients with HIES for vascular involvement. The study of mechanisms involved in large vessels dissections in these patients may shade light on the disease pathogenesis also in non-genetic, sporadic cases.

## REVERSIBLE FOCAL CONTRAST-INDUCED NEUROTOXICITY FOLLOWING CORONAROGRAPHY MIMICKING ACUTE STROKE

S. M. Lazzarin, U. Pensato, S. Marcheselli

Stroke Unit, IRCCS Humanitas, Humanitas Research Hospital (Rozzano-MI)

Background: Transient contrast-induced neurotoxicity (TCN) is a rare but well-known complication of intra-arterial contrast administration (REF). The putative mechanisms are still partially unknown, yet iodinated contrast-driven endothelial damage and blood-brain barrier disruption arguably play a pivotal role. TCN may present with a wide

spectrum of neurological manifestations, including seizures, cortical blindness, altered mental status, and focal neurological deficits (REF). Therefore, accurate and prompt diagnosis is challenging.

Case report: We report the case of a 64-year-old man who underwent a coronary angioplasty with stent placement. At the end of the procedure, the patient exhibited acute-onset severe left hemiparesis and gaze palsy. A stroke multimodal study CT was unremarkable. Nonetheless, in the suspicion of an acute ischemic stroke, intravenous thrombolysis was administered. Following reperfusion therapy, the patient rapidly developed a cognitive-motor slowing. A follow-up brain CT revealed the disappearance of cerebral sulci and cortical blurring in the right frontoparietal cortical areas. Notably, a brain MRI did not reveal any restriction diffusion or other abnormalities. the clinical-radiological status resolved completely within 72 hours.

Conclusions: Contrast-induced neurotoxicity is an important clinical entity to consider in the differential diagnosis of stroke following coronarography. A temporal correlation between neurological dysfunction and the administration of iodinated contrast is required to diagnose this neurological condition. Even though it usually presents with encephalopathy and contrast stagnation in subarachnoid spaces, focal manifestations accompanied by atypical radiological features may occur.

## A LONGITUDINAL STUDY IN PATIENTS WITH CHRONIC DISORDERS OF CONSCIOUSNESS: COMPARISON BETWEEN PATIENTS WITH POSITIVE AND NEGATIVE OUTCOME

M. Leonardi[1], C. Ippoliti[1], A. Fornari[1], M. Cacciatore[1], F. Barbadoro[1], C. Stellato[2], F. Magnani[1]

[1]Neurology, Public Health, Disability Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [2]UOS Reti territoriali e continuità dell'assistenza, ATS Città metropolitana di Milano (Milano)

Objective: The evidence about outcomes in chronic Disorders of Consciousness (DOC) is poor, therefore we compared sociodemographic and clinical variables between patients who died (negative outcome) and the ones who did not (positive outcome).

Materials: We collected socio-demographic and clinical data of 129 DOC patients at the admission to long-term care structures in the geographic area of Milan (Italy) from the 2017 to 2021. Specifically, age, sex, time since injury (TSI), aetiology, number of infectious events and bedsores, Body Mass Index (BMI), Coma Recovery Scale-revised (CRS-r), Glasgow Coma Scale (GCS), and Disability Rating Scale (DRS) scores, were collected.

Method: Data were collected at the admission to the long term-care structure (T0) and twice a year until 2021 or at discharge (T1), occurred either because of death or other reasons (e.g. discharge). We divided the sample into two groups depending on the outcome (positive, negative). We compared the two groups considering each socio-demographic and clinical data, one at the time, as dependent variable. Mann-Whitney U test was used for continuous variables whilst Chi-squared test was used for categorical ones.

Results: Among the 129 patients (73 M; 60.8±14.4 years), the 83% was diagnosed with Unresponsive Wakefulness Syndrome whilst the 17% with Minimally Conscious State. At T1, 69 patients had a negative outcome (mean time from acute event to death: 2.57±2.92 years) and 60 a positive outcome. There were no significant differences between groups when considering the aetiology, TSI, number of bedsores, BMI, CRS-R, and the GCS (all p>.05). A trend was found for the patients' age (U=1685; p=0.07) and the total number of infectious events (U=1691; p=0.06). The two groups differed for the sex (X2= 6.13, p=.013), where the number of males was higher for negative outcome patients (n=46) than positive outcome patients (n=27), conversely the number of women was higher in positive outcome patients (n=33) than negative outcome patients (n=23). Significant difference was found also on the DRS score (U=1566; p=.015) where patients with a negative outcome had higher scores (25±2) than patients with positive outcomes (24±2).

Discussion: This is one of the few studies following a cohort of chronic DOC patients across the time.

Conclusions: Being a male and having a higher level of disability, at the time of the admission to the long term care structures, could increase the chance for an unfavourable outcome. However, future studies are needed to better explore the predictive values of such variables.

## ACUTE BILATERAL HORNER SYNDROME BY CERVICAL ARTERO-VENOUS MALFORMATION

C. Lovati, P. Bertora, L. Pantoni

Department of Biomedical and Clinical Sciences, University of Milan and Neurology Unit, Luigi Sacco University Hospital (Milano)

Background: Horner syndrome (HS) usually consists of unilateral ptosis, an ipsilateral miotic but quite normally reactive pupil (with delayed dilation), and ipsilateral facial anhidrosis. It is caused by a damage of the ipsilateral oculosympathetic pathway that is divided into three groups of neurons including first-order neurons (from hypothalamus through brainstem and extends into the upper portion of the spinal cord), second-order neurons (from spinal column, across the upper part of the chest and into the side of the neck) and third-order neurons (along the side of the neck to iris and eyelids). The first order may be disrupted by stroke, cerebral tumors, demyelination, syringomyelia or neck trauma (central HS); second order by lung cancers, schwannoma, aortic dissection, chest surgery (pre-ganglionic HS); the third order may be involved in carotid artery damage in the neck, migraine, and cluster headache (post-ganglionic HS). Very rarely it may be bilateral, due to bilateral interruption of the cervical sympathetic pathway or widespread autonomic neuropathy.

Case report: A 51-year-old man complained of a sudden onset sensitive and motor impairment in his left upper limb with difficulties in breathing when lying down. In about 30 minutes he reached the hospital. In the emergency room, he rapidly showed a progressive four limbs flaccid paralysis and breathing arrest with necessity of intubation. He remained vigilant, with face-mouth and tong grimaces, in the effort to inspire. Cranial nerves were functioning. Pupils were symmetrically pinpoint in room light. No drug was detected in the blood. Cerebral CT was normal. An angio-CT of brain, neck and chest showed normal

carotid and vertebral arteries and no aortic dissection. The patient, even intubated, was vigilant, collaborative, quadriplegic, bilaterally miotic, with a complete impairment of both spontaneous and voluntary breathing: the clinical presentation focused on a cervical spine acute disorder. CT scan did not show bleeding but spinal vessels seemed to be dilated and detectable with this method. An MRI scan showed a cord swelling from C3 level, with winding images T2-ypointense into the cord and around it at C3-C4 level. More caudally (D1-D3), a T2-hyperintense lesion without enhancement, resembling an ischemic lesion, was present. A type III artero-venous malformation was then diagnosed. The angiographic exam confirmed this suspect. No bleeding observed. An endovascular procedure was done. Autonomous breathing and walking were recovered in 4 months.

Discussion: No other cases of acute bilateral Horner syndrome induced by a spinal vascular malformation have been described before.

## PERSISTENT LEFT SUPERIOR VENA CAVA: AN UNUSUAL CAUSE OF RIGHT-TO-LEFT SHUNT AND EMBOLIC STROKE

A. Magi[1], L. Fusi[2], I. Zivi[2], L. Abate[2], R. Xhani[2], E. Raimondi[2], G. Remoli[1], G. Negro[1], G. Grampa[2]

[1]Department of Medicine and Surgery, University of Milano-Bicocca and San Gerardo Hospital (Monza); [2]Stroke Unit, Sant'Anna Hospital (Como)

Introduction: Juvenile ischaemic stroke in the young might be particularly challenging for definitive diagnosis and often requires a major diagnostic effort. Persistent left superior vena cava (PLSVC) is a congenital malformation caused by abnormal development of the left cardinal vein, resulting in a possible source of right-to-left shunt and embolic stroke.

Methods: We describe the case of a 23-year-old male patient admitted to our Neurology ward. Electronic medical records, neuroimaging and laboratory results were reviewed.

Results: Our patient presented to the emergency department with acute left hemiparesis (NIHSS 18). One week prior, he suffered a blunt trauma playing football, with consequent localized oedema in his left arm. CT angiography showed an occlusion of right MCA, which was submitted to intravenous thrombolysis with rTPA and mechanical thrombectomy. MRI identified a large infarct in the fronto-temporo-insular area, the deep nuclei and bilaterally in the occipital region. Screening for autoimmune/thrombophilic disorders was negative as well as genetic testing. Transthoracic (TTE) echocardiography was normal. A micro-bubble transcranial Doppler, conducted on his right arm, was negative for right-to-left shunt. A transoesophageal (TEE) echocardiography was performed: upon injection of the sonicated solution in the left antecubital vein, early opacification of the left atrium was noted. Computed tomography of the chest was performed, which objected the anatomical anomaly. Since the possible recurrence of strokes due to the congenital defect, the patient was then referred to a cardio-thoracic surgery center, where was submitted to PLSVC disconnection from the left atrium and connection with the right cava with interposition of a reinforced prosthesis. A presence of a thrombus inside the accessory vein was confirmed during the surgery process. The patient was transferred to a rehabilitation facility to provide tailored neuro-motor rehabilitation.

Conclusion: This case highlights the relevance of the correct choice of the venous side in performing a micro-bubble transcranial Doppler: echo contrast injection from the right antecubital vein may indeed give a false negative result and misunderstand a rare cause of paradoxical embolism. While the arm choice can be serendipitous, a possible misdiagnosis could also be achieved in the case of an inverted SVC injecting microbubbles from the left side: our advice is to perform the exam on both arms and, if a shunt is confirmed, to further investigate with investigations capable of optimally delineating the venous system and its anomalies.

## COMPARISON OF TROPONIN PEAK VALUES BETWEEN CEREBRAL HEMORRHAGES AND UNTREATED ISCHEMIC STROKES

L. Mancinelli, G. Prandin, I. Scali, F. Palacino, E. Vincis, G. Furlanis, P. Caruso, M. Naccarato, P. Manganotti

Clinical Unit of Neurology, Department of Medicine, Surgery and Health Sciences, University Hospital and Health Services of Trieste, ASUGI, University of Trieste (Trieste)

Purpose: Stroke-heart syndrome (SHS) is a documented complication of acute stroke. It consists in cardiac injury following an acute stroke, with consequent ECG changes, arrhythmia, myocardial injury, ACS heart failure, Takotsubo and sudden cardiac death. The interrelationship with acute myocardial injury also applies to cerebral hemorrhage, especially when extensive. The etiopathogenesis underlying this process is partly unknown, however inflammatory cytokines, the autonomic nervous system, the humoral system with catecholamines, cortisol and various cellular mediators appear to be involved [1-2]. Any or few studies have investigated the difference in this mechanism between ischemic and hemorrhagic stroke. The aim of this study is to compare the heart injury markers between cerebral hemorrhages and untreated ischemic strokes.

Materials: We included 152 patients hospitalized in 2022 in our Stroke Unit, 40 of whom with hemorrhagic stroke (HS) and 112 with untreated ischemic stroke (IS).
Methods: We compared demographic, clinical features (sex, age, cardiovascular risk factors) and markers of cardiac injury (maximum TnI level reached, NT-proBNP >3 times upper limit, maximum TnI > 3 times 99th percentile). Statistical analysis was performed with SPSS using $X^2$ test/Fisher-Yates test/Mann Whitney U test as needed.

Results: No statistical differences between the clinical/laboratory features were observed in the two cohorts (HS and IS untreated), except the NIHSS on admission (7.5; IQR 4-13 in HS and 4; IQR 2-85 in IS) with p=0.015 and discharge (4; IQR 1-7.25 in HS and 1; IQR 0-3 in IS) with p=0.004 and the mRS on discharge (4.5; IQR 1-5 in HS and 2; IQR 1-4 in IS) with p=0.011; the cardiac marker of injury were not statistically significant between the two groups, in particular NT-proBNP (33% in HS and 36% in IS; p=0.714), maximum TnI level reached (ng/l) in HS (15; IQR 8.75-35) and IS (12; IQR 7-30.75) with

p=0.278. The troponin elevation pattern up to 20% was 30% in HS and 28% in IS (p=0.779).

Discussion This study suggests there are no differences in TnI levels between HS and IS in the acute phase. The raise and fall pattern is superimposable. These data suggest that there could be a mechanism of cardiac damage independent of the nature that generated it.

Conclusions More studies are suggested to better investigate if there are substantial differences between HS and IS in the context of SHS, possibly by comparing the trend of the markers if single brain areas are specifically considered.

## PROXIMAL BASILAR ARTERY STENOSIS "SPONTANEOUS" RESOLUTION AFTER STA-MCA BYPASS IN A SUSPECTED MOYA MOYA DISEASE WITH POSTERIOR CIRCULATION INVOLVEMENT

N. Marrone[1], M. Caccamo[1], D. Galotto[1], S. Grimaldi[1], M. Petruzzellis[2]

[1]Hospital of Bari, University of Bari Aldo Moro (Bari); [2]Stroke Unit "Puca", AOUC Policlinico (Bari)

Introduction: Moya Moya angiopathy is still a challenging issue for vascular neurologist, despite recent literature updates on diagnosis and treatment. An extensive diagnostic work up is mandatory for an accurate diagnosis to choose best therapy option. Surgical revascularization procedures can improve cerebral perfusion and lower recurrency of ischemic attack and intracranial bleeding.

Methods: We report a case of suspected Moya Moya disease with posterior circulation involvement which underwent to direct revascularization with superficial temporal artery – middle cerebral artery (STA – MCA) anastomosis.

Results: A 46-years old male was admitted to the emergency department for recurrent transient episodes of expressive aphasia. Brain magnetic resonance (MRI) imaging showed multiple subacute subcortical ischemic lesions in the left middle cerebral artery territory. Brain MR angiography (MRA) and digital subtraction angiography (DSA) highlighted multiple intracranial stenoses involving bilaterally carotid siphon, middle (M1), anterior (A1-A2) and posterior (P1-P2) cerebral artery, and also proximal basilar artery. These findings were confirmed on transcranial doppler (TCCD). Extensive diagnostic work-up to rule out primary or secondary vasculitis was perfomed, unless the patient refused lumbar puncture. Aspirin and Clopidogrel was started at the admission and he was discharged asymptomatic as "suspected Moya Moya syndrome". TCCD follow up after 3 months showed worsening of the proximal left middle cerebral artery stenosis. MRA and TCCD at 4-months showed no new ischemic lesions neither progression of stenoses. DSA did not reveal pathologic findings on basilar artery. At 6-months from clinical presentation, direct revascularization with STA–MCA anastomosis was done. In the meanwhile, HLA B51 aplotipe positivity was discovered.

Discussion: Moya Moya differential diagnosis can sometimes be very challenging, particularly when there is both anterior and posterior circulation involvement. This stenotic pattern could be difficult to differentiate from primary cerebral vasculitis. Reliability and reproducibility of diagnostic procedures and a complete differential diagnostic work up are essential to avoid inappropriate therapeutic choice.

Conclusion: STA-MCA bypass was performed in a suspected case of Moya Moya disease (MMD). Changes in stenotic intracranial pattern with basilar stenosis resolution after the surgical procedure raised doubts about diagnosis, as MMD has a chronic progressive evolution. A careful follow-up to better assess the disease progression could be very useful also for correct diagnostic and therapeutic decisions.

## THERAPEUTIC STRATEGIES IN VASCULAR COGNITIVE IMPAIRMENT: A SYSTEMATIC REVIEW OF POPULATION, INTERVENTION COMPARATORS AND OUTCOMES

F. Masserini, C. Gendarini, G. Baso, L. Pantoni

Neuroscience Research Center, Department of Biomedical and Clinical Sciences, University of Milan (Milano)

Vascular cognitive impairment (VCI) is a common and heterogeneous condition, both from the clinical and pathophysiological viewpoint. Currently, no approved treatment exists for VCI or one of its subtypes. We performed a systematic review of randomized and non-randomized clinical trials in VCI with the aim of assessing flaws in previous studies and exploring whether any therapeutic option warrants further investigation. 1756 unique medical entries indexed by two widely employed search engines, PubMed® and Embase®, on clinical interventional studies and published from inception to December 31, 2021, were reviewed. We initially searched the two databases with a composite research string assessing the presence in title or abstract of the following keywords (and derivatives, truncations or synonyms thereof) alone or in combination: "vascular", "small vessel", "post-stroke", "subcortical vascular", "multi-infarct, "cognitive impairment", "dementia", "MCI", "therapy", "management". We then conducted a cooperative 3-person review of matching entries using Covidence systematic review software. Abstracts and then full texts were randomly screened for adherence to inclusion criteria by at least two reviewers. Any conflict was resolved by consensus and eventually by a fourth reviewer. Data from included studies were extracted, focusing on study characteristics, design, and population, employed interventions and any relevant outcome. Data were available from 118 trials including 19,223 participants with five different diagnostic VCI categories. Sixty-three different types of intervention were found (51 pharmacologic, 5 employing physical agent application, 7 rehabilitation approaches), the most frequently reported being acupuncture, donepezil, rivastigmine, and ginkgo-biloba extracts. Comparators were either placebo, best medical treatment, or other interventions. Treatment efficacy was assessed by means of 125 outcome measures (49 cognitive-behavioral, 29 instrumental, and 47 functional). A primary outcome measure was clearly pre-specified in only 50.8% of studies. Our review outlined that therapeutic trials in VCI have been heterogeneous in terms of populations, types of interventions, and outcomes. Overall, a lack of a clear pathophysiological rationale for the tested interventions emerges. To tackle more effectively this complex scenario, a change in the approach is needed. Future studies should focus on evaluating treatments with plausible clinical efficacy, employing reproducible outcomes, throughout an adequate timespan to observe possible effects.

## RISK OF RECURRENT STROKE IN PATIENTS WITH ATRIAL FIBRILLATION TREATED WITH ORAL ANTICOAGULANTS ALONE OR IN COMBINATION WITH ANTI-PLATELET THERAPY

M. Moci[1,2], P. Caliandro[3], V. Cancelloni[4], G. Reale[1], A. Zauli[2,3], M. Paciaroni[4] on behalf of RAF and RENO Investigators

[1]Intensive Neurorehabilitation Unit, Polyclinic University A. Gemelli Foundation IRCCS (Roma); [2]Department of Neuroscience, Sense Organs and Chest, Polyclinic University A. Gemelli Foundation IRCCS (Roma); [3]Neurology Unit, Polyclinic University A. Gemelli Foundation IRCCS (Roma); [4]Stroke Unit and Division of Cardiovascular Medicine, University of Perugia (Perugia)

Introduction: Ischaemic stroke patients with atrial fibrillation (AF) are at high risk of stroke recurrence despite oral anticoagulation therapy. Patients with cardiovascular comorbidities may take both antiplatelet and oral anticoagulation therapy (OAC/AP). Our study aims to evaluate the safety and efficacy of OAC/AP therapy as secondary prevention in people with AF and ischaemic stroke.

Patients and methods: We performed a post-hoc analysis of pooled individual data from multicenter prospective cohort studies and compared outcomes in the OAC/AP cohort and patients on DOAC/VKA anticoagulation alone (OAC cohort). Primary outcome was a composite of ischaemic stroke, systemic embolism, intracranial bleeding, and major extracranial bleeding, while secondary outcomes were ischaemic and haemorrhagic events considered separately. A multivariable logistic regression analysis was performed to identify independent predictors for outcome events. To compare the risk of outcome events between the two cohorts, the relation between the survival function and the set of explanatory variables were calculated by Cox proportional hazard models and the results were reported as adjusted hazard ratios (HR). Finally another analysis was performed to compare the overall risk of outcome events in both OAC/AP and OAC cohorts after propensity score matching (PSM).

Results: During a mean follow-up time of 7.5±9.1 months (median follow-up time 3.5 months, interquartile range ± 3), 2284 stroke patients were on oral anticoagulants and 215 were on combined therapy. The multivariable model demonstrated that the composite outcome is associated with age (OR: 1.03, 95% IC: 1.01-1.04 for each year increase) and concomitant antiplatelet therapy (OR:2.2, 5% IC:1.48-3.27), the ischaemic outcome with congestive heart failure (OR: 1.55, 95% IC: 1.02-2.36) and concomitant antiplatelet therapy (OR:1.93, 95% IC: 1.19-3.13), the haemorrhagic outcome with age (OR:1.03, 95% IC: 1.01-1.06 for each year increase), alcoholism (OR: 2.15, 95% IC: 1.06-4.39) and concomitant antiplatelet therapy (OR:2.22, 95% IC: 1.23-4.02). Cox regression demonstrated a higher rate of the composite outcome (hazard ratio of 1.93 [95% CI, 1.35–2.76]), ischaemic events (HR: 2.05 [95% CI, 1.45–2.87]) and bleeding outcomes (HR: 1.90 [95% CI, 1.06-3.40]) in OAC/AP cohort. After PSM analysis, the composite outcome remained more frequent in people treated with OAC + AP (RR: 1.70 [95% CI, 1.05-2.74]).

Discussion: Secondary prevention with combination of oral anticoagulant and antiplatelet therapy after ischaemic stroke was associated with worse outcomes in our cohort.

Conclusion: Further research is needed to improve secondary prevention by investigating the mechanisms of recurrent ischaemic stroke in patients with atrial fibrillation.

## IMPACT OF INFLAMMATORY INDEXES ON THE PROGNOSTIC PERFORMANCE OF ICH SCORE IN SPONTANEOUS INTRACEREBRAL HEMORRHAGE

S. Moraru[1], F. Mazzacane[1], F. Ferrari[1], A. Morotti[2], A. Persico[3], P. Profico[1], F. Bax[4], F. Kuris[4], L. Nesi[4], M. Valente[4], G. Merlino[4], A. Cavallini[3]

[1]Department of Brain and Behavioral Sciences, University of Pavia (Pavia); [2]Department of Neurological Sciences and Vision, ASST Spedali Civili (Brescia); [3]Department of Emergency Neurology and Stroke Unit, IRCCS Fondazione Mondino (Pavia); [4]Stroke Unit and Clinical Neurology, University of Udine (Udine)

Introduction: Systemic inflammation could lead to secondary cerebral damage after spontaneous intracerebral hemorrhage (sICH) with a potential detrimental effect on the functional outcome. Multiple parameters have been proposed to evaluate the systemic inflammatory response after sICH including Systemic Immune-Inflammation Index (SII), Systemic Inflammation Response Index (SIRI), and red-cell index (RCI). However, the impact of their inclusion on the performance of the existing clinical-radiological scores, as the ICH score, is still not known.

Methods: All patients admitted from January 2013 to December 2022 to the Stroke Unit of IRCCS Mondino and from January 2017 to September 2017 to the Stroke Unit of Udine University Hospital were retrospectively evaluated. Patients with secondary ICH, lacking neuroradiological, follow-up or laboratory data were excluded. Inflammatory indexes were calculated as follow: SII=platelets*(neutrophils/lymphocytes); SIRI=monocytes*(neutrophils/lymphocytes); RCI=(red blood cells*hemoglobin)/(lymphocytes*platelets). Area under the curve (AUC) of receiver operating characteristic curves (ROCs) were used to evaluate the performance of ICH score alone and in association with the inflammatory indexes and compared with DeLong test. A poor outcome was defined as a modified Rankin Scale 4-6 at 3-months.

Results: 206 patients were included in the final analysis, 88 (43%) were female and had a mean age of 75 (±11) years. 119 (58%) patients had an unfavorable 3-months outcome. Patients with a 3-months poor functional outcome had higher median SII (1367.6 vs 754.1, p<0.001) SIRI (4.0 vs 2.3, p<0.001), RCI (0.3 vs 0.2, p=0.01) and had more frequently ICH score >=2 (55% vs 9%, p<0.001). ICH score alone demonstrated a good prognostic performance (AUC 0.82 [95%CI: 0.77-0.87]). Among the inflammatory response markers, the addition to the model of SII (ICH score + SII: AUC 0.86 [95%CI: 0.80-0.91] ) and SIRI (ICH score + SIRI: AUC 0.85 [95%CI 0.80-0.90]) was able to improve its performance vs ICH score alone (p-values 0.004 and 0.01 respectively).
Discussion: Our data suggest that the addition of SII or SIRI to ICH score would allow to improve its performance in predicting the outcome of ICH patents at 3-months. The use of these biomarkers would be cost-free and very feasible in clinical practice, as they are calculated from routine blood tests. A better outcome prediction would be useful to tailor patients care and communications with relatives in the acute phase of ICH.

Conclusions: SII and SIRI could improve ICH score performance in predicting a poor 3-months outcome in sICH patients, without the need of additional diagnostic tests.

## THE ROLE OF THE OXFORD COGNITIVE SCREEN (OCS) IN ASSESSING COGNITIVE IMPAIRMENT IN STROKE UNIT - A PILOT STUDY

T. G. Morganti, R. Turano, D. Quaranta, G. Giuffre, C. Aiello, M. Gistro, C. Marra, G. Della Marca, A. Broccolini, V. Guglielmi

Neurology, Catholic University of the Sacred Heart (Roma)

Background: The Oxford Cognitive Screen (OCS) is a comprehensive battery of neuropsychological tests designed to evaluate cognitive deficits following a stroke. It covers five cognitive domains, including attention-executive function, language, memory, number processing, and praxis. Unlike widely used instruments such as the Mini-Mental State Examination (MMSE) or the Montreal Cognitive Assessment (MoCA), which were developed for neurodegenerative diseases, the OCS is specifically tailored to be inclusive and unaffected by aphasia and neglect. Thus, it holds significant potential for accurately assessing cognitive deficits in stroke patients.

Objective: This study aimed to compare the effectiveness of the OCS and MoCA in detecting cognitive impairments among stroke survivors. Additionally, we sought to examine differences in the cognitive profiles of patients with milder versus more severe outcomes three months after the acute phase.

Materials and Methods: Fifty patients consecutively admitted to our Stroke Unit for acute stroke with an average NIHSS score of 5 were enrolled. Patients were evaluated within five days of onset by means of the MoCA and OCS. Follow-up assessments were conducted three months later using the modified Ranking Scale (mRS) to stratify patients into good (n=39, mRS < 3) and worse (n=11, mRS > 2) outcome groups. Spearman's correlation coefficient was used to assess correlations between continuous variables, while the Mann-Whitney-U-test was employed to compare groups.

Results: Of the patients, 90% (n=45) exhibited abnormal scores on the MoCA (below 26/30), while all patients demonstrated impairment in at least one OCS subtest, indicating the higher sensitivity of the OCS in detecting even mild cognitive impairments. Significant correlations were observed between various MoCA and OCS subtest scores. NIHSS scores were correlated with OCS subtests involving sentence reading, number writing, and MoCA subtests assessing orientation. Patients with more severe outcomes at three months performed worse on OCS subtests related to sentence reading, number writing, and trails task, but no statistically significant difference was found in the MoCA global score.

Discussion and Conclusions: The OCS scale demonstrates greater sensitivity than the MoCA in identifying post-stroke cognitive disorders, particularly in cases of mild stroke, which may have significant implications for early intervention and tailored rehabilitation strategies. Additionally, the OCS appears to be a more valuable tool for predicting stroke outcomes. Further research with larger patient cohorts is warranted to validate and expand upon these findings and to explore this association more comprehensively. Moreover, incorporating longer longitudinal assessments may offer a better understanding of the predictive utility of this tool.

## ROLE OF TRANSESOPHAGEAL ECHOCARDIOGRAPHY IN EVALUATING ISCHEMIC STROKE DESPITE ADEQUATE ANTICOAGULATION THERAPY

M. Paolucci[1], L. Gentile[1], S. Forlivesi[1], L. Riva[2], A. Zini[1]

[1]Department of Neurology and Stroke Center, IRCCS Istituto delle Scienze Neurologiche di Bologna (Bologna); [2]Cardiology, Ospedale Maggiore, AUSL Bologna (Bologna)

Objective: This study aims to evaluate the role of transesophageal echocardiography (TEE) in the assessment of patients with ischemic stroke despite adequate anticoagulation therapy with direct oral anticoagulants (DOACs) or properly managed Coumadin therapy (within the therapeutic range). Methods: Sixteen patients (9 females and 7 males) who were on DOACs or Coumadin therapy (5 Apixaban, including 1 at reduced dosage; 3 Edoxaban, including 1 at reduced dosage; 3 Rivaroxaban; and 5 Coumadin) and were admitted to our department for ischemic stroke in 2022 with DOAC dosage or international normalized ratio (INR) within the therapeutic range underwent TEE. The average age of the patients was 72.8 years. TEE findings were analyzed and categorized.

Results: Among the 16 patients studied, 4 exhibited normal TEE findings. Six patients were diagnosed with endocarditis, one of whom also had an auricular thrombus. One patient had a ventricular thrombus, while 4 patients had an atrial thrombus. Three patients were found to have valvular pathology.

Discussion: TEE plays a crucial role in the evaluation of patients with ischemic stroke despite optimal anticoagulation therapy. It allows for detailed assessment of cardiac structures, identification of potential sources of embolism, and detection of coexisting pathologies such as endocarditis, thrombi, and valvular abnormalities. The presence of these conditions may contribute to the occurrence of embolic events despite therapeutic anticoagulation.

Conclusion: In this study, TEE revealed various cardiac abnormalities in patients with ischemic stroke despite adequate anticoagulation therapy. These findings emphasize the importance of TEE in the comprehensive evaluation of such patients, as it provides valuable information for guiding further management decisions. Early identification of endocarditis, thrombi, and valvular pathology through TEE can help optimize treatment strategies and potentially reduce the risk of recurrent embolic events. Considering the few available data [1, 2], larger studies are warranted.

## POSTERIOR REVERSIBLE ENCEPHALOPATHY SYNDROME DURING TREATMENT WITH LENVATINIB PLUS PEMBROLIZUMAB IN A PATIENT WITH METASTATIC ENDOMETRIOID ADENOCARCINOMA: A CASE REPORT OF AN UNCOMMON ADVERSE EVENT

F. Pasquin, R. Garbo, M. Rana

Neurology Unit of Gorizia-Monfalcone, ASUGI (Gorizia)

Aims: Posterior reversible encephalopathy syndrome (PRES) is a neurological disorder characterized by a subcortical white matter reversible vasogenic edema typically located bilaterally in the parieto-occipital region. Immunosuppressive and cytotoxic drugs can predispose for this uncommon condition. In a few case reports lenvatinib, an inhibitor of the tyrosine kinases of vascular endothelial growth factor receptor (VEGFR) used for the treatment of several cancers, has been shown to predispose to PRES. The mechanism is still unclear, but it seems to be linked to induced hypertension and endothelial dysfunction. Recently a combination therapy of lenvatinib plus pembrolizumab was approved for the treatment of advanced endometrioid adenocarcinoma. Pembrolizumab is an immune checkpoint inhibitor which is associated with the development of autoimmune diseases including encephalitis.

Materials: Here we report a case of PRES developed by a patient treated with lenvatinib plus pembrolizumab.
Method: A 63-year-old woman with a metastatic endometrioid adenocarcinoma presented with headache and a generalized epileptic seizure with consequent head trauma 6 months after initiation of lenvatinib plus pembrolizumab.

Results: The patient was referred to the emergency room where she underwent a CT scan of the brain with evidence of frontal and temporal cerebral contusions. Lenvatinib was immediately discontinued due to its association with increased bleeding risk. The electroencephalogram showed left fronto-temporal epileptic activity and the MRI revealed multiple bilateral areas of subcortical white matter edema. The patient rapidly recovered after lenvatinib discontinuation with a complete clinical and radiological recovery one week later. A diagnosis of lenvatinib induced PRES was then made.

Discussion: According to clinical presentation and neuroimaging the two main diagnostic hypotheses were PRES and autoimmune encephalitis. The rapid recovery of neurological symptoms after lenvatinib discontinuation led to encephalitis exclusion and PRES diagnosis without the need of a lumbar puncture. To the best of our knowledge this is the second case of PRES in a patient treated with lenvatinib plus pembrolizumab and the ninth linked to lenvatinib.

Conclusions: In the future there will certainly be a progressive increase in the use of these new targeted therapies for the treatment of a variety of malignancies. Linked to this, there will therefore also be a consequent increase in their life-threatening adverse effects, such as PRES, and their rapid recognition and treatment will be essential.

## FAST IS FINE, BUT ACCURACY IS FINAL

A. Pes, C. Baracchini, A. Pieroni, F. Viaro, S. Mozzetta, F. Favruzzo, L. De Rosa, A. Fattorello Salimbeni, P. Decet

Stroke Unit and Neurosonology Lab, Padua University Hospital (Padova)

Introduction: Arm and leg weakness is part of the FAST acronym used as a mnemonic to help detect and enhance responsiveness to the needs of a person having a stroke. However, a vascular neurologist should learn to be slow in a hurry, as good management is dependent on good assessment.

Case report: A 79-year-old woman with a history of hypertension, hypercholesterolemia, and remote right leg deep vein thrombosis was admitted to our emergency department due to an abrupt onset of intense cervical pain irradiated to her right shoulder, immediately followed by a marked weakness of the right extremities. The patient denied a recent trauma or infection. The neurological examination revealed a right hemiparesis: NIHSS 5 (2 points for arm weakness, 3 points for leg weakness). Cerebral CT and CT-Angio were unremarkable, therefore in the absence of clear contraindications, thrombolysis was promptly administered in the CT room. When the patient arrived at the Stroke Unit, an experienced vascular neurologist noted the absence of a right facial paresis, urging a spinal MRI which disclosed a spontaneous epidural hematoma extending from C1 to T3. A digital subtraction angiography did not document arteriovenous malformations or dural fistulas and a surgical approach was ruled out. On the following days, there was a progressive improvement of her right hemiparesis, although the patient still reported a persistent but slight cervical pain. On day 4, a spinal MRI showed a complete reabsorption of the hematoma. On day 5, the patient was completely asymptomatic and was discharged without any neurological deficits.

Discussion: Spontaneous spinal epidural hematoma (SSEH) is a rare condition defined as blood within the epidural space without known traumatic or iatrogenic cause compressing the spinal cord and leading to acute neurological deficits. Standard therapy is decompressive laminectomy, although spontaneous recoveries have been reported, as in our patient. Acute hemiparesis with cervical pain is a possible presentation of SSEH mimicking stroke secondary to a cervical dissection. Not recognizing SSEH can lead to a stroke misdiagnosis with an unjustified and potentially dangerous treatment.

Conclusions: An insufficient understanding of a patient's condition in a stroke-related emergency setting should slow down the process enough to gather the necessary information before choosing the optimal treatment, as an inaccurate assessment might be fatal.

## FRAILTY AS PREDICTOR OF IN-HOSPITAL COMPLICATIONS IN PATIENT WITH ACUTE ISCHEMIC STROKE

D. Pezzini[1], A. Pilotto[2], S. Gipponi[3], A. Morotti[3], A. Padovani[2]

[1]Neurology Unit, Department of Clinical and Experimental Sciences, University of Brescia (Brescia); [2]Neurology Unit, Department of Clinical and Experimental Sciences; Neurology Unit, Department of continuity of care and frailty; Laboratory of digital Neurology and biosensors, University of Brescia; ASST Spedali Civili Brescia Hospital (Brescia); [3]Neurology Unit, Department of continuity of care and frailty, ASST Spedali Civili Brescia Hospital (Brescia)

Background: Frailty is the most important short- and long-term predictor of disability in the elderly and thus might influence the clinical outcome of acute stroke [1,2].

Objective: To evaluate whether frailty predicts short-term complications during hospitalization in Neurology setting in elderly patients with stroke.

Methods: The study included consecutive patients older than 65 years admitted to a single Acute Neurology Unit. Predictors of stroke outcomes were assessed including demographics, baseline National Institute of Health Stroke Scale (NIHSS), comorbidities and treatment. Premorbid Frailty was assessed with a comprehensive geriatric assessment (CGA) including functional, nutritional, cognitive, social and comorbidities status [3]. Predictors of death, medical complications and duration of hospitalization were assessed in linear and logistic regression analyses.

Results: One-hundred and twenty patients with stroke entered the study (median age 73.5, 66.3-81.2 years). Frailty was diagnosed in 60 out of 120 patients and associated with older age ($p<0.001$), higher premorbid disability and stroke severity. Frailty status was associated with higher risk of complications (48.3% vs 11.7%, $p<0.001$) and longer median hospitalization (14 vs 9 days, $p<0.001$). Multidimensional frailty increased the risk of in-hospital complications (odds ratio (OR) 15.61, 95% confidence interval (CI) 1.43-170.47, $p=0.024$) independently of age and baseline NIHSS.

Discussion: Frailty is an important predictor of stroke short-term complications beyond age and severity. Larger on-going longitudinal studies are warranted to evaluate the clinical impact of multidimensional frailty evaluation on clinical management of patients in acute and chronic settings.

## FUNCTIONAL OUTCOME PREDICTION IN STROKE: LOCAL AND DISTAL LESION PROPERTIES

L. Pini[1], A. Bisogno[1], G. Adamo[1], C. Bertolotti[1], E. Fusaro[1], M. Corbetta[1]

[1]Padova Neuroscience Center, University of Padova (Padova); [2]Department of Neuroscience, University of Padova (Padova)

Objective: Predicting clinical recovery in stroke using neuroimaging features is an emerging field of research. Previous studies have attempted to predict clinical recovery based on lesion volume and topology with disappointing results. Here, we investigated whether a multivariate clinical approach incorporating advanced lesion properties could improve functional outcomes prediction in stroke.

Materials: We enrolled stroke patients who had undergone T1-weighted imaging or CT scan and completed the stroke impact scale (SIS) at 6/12 months post-stroke. For each lesion we computed local measures (lesion shape, tract density index - number of white matter fibers affected by the lesion - and within-lesion diffusion properties) and structural and functional network measures (percentage of networks disconnected by the lesion). Except for lesion shape, all other features were computed using a normative structural/functional connectome. A factorial analysis was performed on the SIS subitems. the resulting components were used as dependent variables in a ridge regression model with a bagging procedure. Three models were tested: one incorporating local measures as predictors, another including structural disconnected networks, and a third model using functional disconnected networks as predictors. The models were compared based on R-square values.

Results: Sixty patients were included (mean age 66). Three SIS components were identified, explaining over 70% of the variance. The first component was associated with motor items (renamed as physical), the second component with cognitive items (cognitive), and the third with emotional/social items (emotion/social). The first model (local measures) explained a small amount of variance (cognitive: 14%; physical: 11%; emotion/social: 6%). The structural disconnection network model explained a slightly higher, yet still low, amount of variance (cognitive: 17%; physical: 13%; emotion/social: 9%). The functional disconnection network model yielded higher variance prediction for the physical component (28%), increasing to 35% when sociodemographic variables were included. In contrast, both cognitive and emotion/social components were not well explained by functional disconnection (7% and 10%, respectively).

Discussion: The SIS scale comprises three components that can be predicted differently based on lesion properties. However, the prediction of cognitive and emotion/social outcome was low based on local lesion and network disconnection measures. In contrast, the physical component was more accurately predicted by functional network dysconnectivity.

Conclusions: These results emphasize the potential of network dysconnectivity as an important predictor of motor outcomes. Cognitive and emotional aspects may necessitate direct measures (e.g., diffusion-weighted imaging, resting-state fMRI) to better understand the complex alterations after a stroke.

## INTRALUMINAL NON-OCCLUSIVE THROMBUS AND EMBOLIC STROKE IN A PUERPERAL WOMAN

F. Poggetti[1], A. Cascio Rizzo[2], G. Schwarz[2], A. Gatti[2], R. Tortorella[2], E. Susani[2], M. Piano[3], E. Agostoni[2]

[1]San Gerardo Hospital, University of Milano-Bicocca (Monza); [2]Department of Neurology and Stroke Unit, ASST Grande Ospedale Metropolitano Niguarda (Milano); [3]Department of Neuroradiology, ASST Grande Ospedale Metropolitano Niguarda (Milano)

Introduction: Intraluminal non-occlusive thrombus (ILT) is a rare finding in patients with acute ischemic stroke, with a prevalence ranging

from 1.6%-to-3.2%. Although in most cases ILT is associated with atherosclerotic disease or arterial wall disorders, this finding has been also described in patients without any underlying vessel disease, but with a hypercoagulable state due to several etiologies. To the best of our knowledge there are no reports of ILT during pregnancy or puerperium.

Case report: We report a case of a 38-year-old puerperal woman with acute onset of mental confusion and left-sided weakness. She had no vascular risk factors and her medical history was unremarkable. After in-vitro fertilization pregnancy (IVF), she had a spontaneous vaginal delivery with post-partum hemorrhage (PPH, 900mL) treated with uterotonic agents and prophylactic anticoagulation (enoxaparin 4,000UI once-daily). Neurological examination confirmed mild dysarthria and mild left-sided hemiparesis, NIHSS score was 5. Brain CT and CT angiography showed sub-occlusion of the right distal MCA at the bifurcation and an intraluminal filling defect at the right carotid bulb, suspected to be a thrombus. Brain MRI was also performed and showed acute ischemia in the right caudate and lenticular nucleus. The patient underwent to urgent cerebral angiography and mechanical thrombectomy was performed with complete reperfusion. Intravenous thrombolysis was not administered due to the recent delivery and because the patient was out of therapeutic window. To better study the CTA finding, carotid ultrasound (CUS) was performed which revealed a homogeneous intraluminal isoechoic formation, adhering to the carotid wall, suggestive of a thrombus. She was treated with acetylsalicylic acid 100mg and enoxaparin 6,000UI. All other tests excluded other potential sources of embolism. Complete blood tests were normal, excluding any hereditary or acquired thrombophilia. In follow-up imaging the intraluminal thrombus gradually decreased in size and then disappeared without revealing any underlying carotid defect. At discharge the neurological examination was normal.

Conclusion: In pregnant or puerperal women the hypothesis of an ILT as cause of an embolic stroke should be considered. In our case the pregnancy-induced changes (hypercoagulability and endothelial dysfunction), further enhanced by IVF and PPH, may have led to thrombus formation in a vascular region, such as the carotid bulb, usually characterized by wall shear stress due to a non-laminar and turbulent blood flow. Little is known about the best therapy, both antiplatelets and anticoagulants are used in clinical practice and outcome is generally good with complete thrombus resolution at follow-up.

## CARDIAC INJURY AFTER STROKE, A COMPARISON BETWEEN TRANSIENT ISCHEMIC ATTACKS AND ISCHEMIC STROKE

G. Prandin, I. Scali, F. Palacino, L. Mancinelli, E. Vincis, G. Furlanis, P. Caruso, M. Naccarato, P. Manganotti

Clinical Unit of Neurology, School of Neurology, Department of Medicine, Surgery and Health Sciences, ASUGI, University of Trieste (Trieste)

Purpose: Transient ischemic attack (TIA) is defined as transient episode of neurological dysfunction caused by focal brain, spinal cord, or retinal ischemia, with clinical symptoms typically lasting less than one hour, and without evidence of acute infarction [1]. In this type of ischemic event, there are no data about a possible cardiac injury tested with troponin. After a stroke the cardiac involvement due to a neuroinflammatory response (recently defined as Stroke Heart Syndrome) is well established [2]. The aim of this study is to compare troponin levels after a stroke or TIA.

Materials and methods: This is a retrospective, single center study on 565 patients (73 TIAs, 492 stroke). We collected demographic characteristics, cardiovascular risk factors, cardiac data such as troponin, NT-proBNP, left atrial dilatation, etiology of the ischemic event (TOAST classification).

Results: We compared IS to TIA for each TOAST subtype. In all groups no substantial differences were found in demographic and past medical history ($p>0.05$). Maximum troponin levels were significantly lower in TIAs than in IS ($p<0.05$), except in lacunar etiology strokes were troponin levels were similar in both groups. In multivariate analysis troponin levels over the 99 th percentile (18 ng/l) were inversely associated with TIAs (OR 0.118; 95%IC 0.050-0.277 and lacunar strokes (OR 0.180, 95%IC 0.085-0.379)), and directly correlated to NT-proBNP (OR 4.071, 95%IC 2.521-6.573) and age (OR 1.057; 95%IC 1.035-1.080).

Discussion and Conclusions: Troponin level after TIAs is significantly lower than IS. Troponin levels after an ischemic event are also independently correlated to NT-proBNP, age and lacunar strokes subtype.

## TAKOTSUBO AFTER LEFT BULBAR ISCHEMIC STROKE (WALLENBERG SYNDROME): A CASE REPORT

G. Prandin, L. Mancinelli, F. Palacino, I. Scali, E. Vincis, G. Furlanis, P. Caruso, M. Naccarato, P. Manganotti

Clinical Unit of Neurology, Department of Medicine, Surgery and Health Sciences, ASUGI, University of Trieste (Trieste)

Purpose: Takotsubo syndrome (TTS) is a well known cardiac complication after stroke. It is more commonly reported after subarachnoid hemorrhage (SAH) or ischemic stroke involving insular areas. Rare case reports of TTS after massive involvement of posterior circulation strokes are described (basilar artery occlusion). However there are no data about TTS after Wallenberg Syndrome (WS).

Materials: We describe one case of TTS after a left bulbar ischemic stroke (WS).

Methods: We performed a PubMed search using the following MeSH terms “(Takotsubo) AND (ischemic stroke)” or “(takotsubo) AND (brainstem stroke)”, looking in particular for articles that explain any relationship between small brainstem infarction and TTS.

Results: A 91 years old woman, affected by arterial hypertension, dyslipidemia, previous PTCA-treated myocardial infarction (2014), was admitted to our Stroke Unit for sudden onset of mild left ataxic hemiparesis and dysmetria, vertigo and nystagmus. Brain CT scan did not show ischemic lesions while CT angiography demonstrated a distal left vertebral occlusion. The patient was treated with rtPA with mild improvement. During the standard blood tests, a troponin (up to 2364 ng/l) and NT-proBNP increase (4703 pg/ml) were correlated to a cardiac dysfunction at transthoracic echocardiography (left apical akinesia), with clear disproportion between the diffuse left wall dysfunction and the moderate troponin rise. Moreover new ECG alteration

appeared (as QT prolongation and negative T waves), without ECGrafic signs of acute AMI.

Discussion: In literature TTS is commonly described after an involvement of the autonomic network (insulae, diffuse lesions of the brainstem) [1-2]. The role of small medullary infarction as in Wallenberg syndrome in inducing TTS may be linked to a general stress response following a stroke wherever it is located, not only insular or massive posterior circulation strokes.

Conclusions: TTS is a rare complication after stroke. More studies are needed to better evaluate the role of small infarctions as possible triggers of autonomic stress response leading to TTS.

## THE EFFECT OF CITICOLINE IN MODULATING BRAIN CORTICAL PLASTICITY IN SUBACUTE/CHRONIC ISCHEMIC STROKE PATIENTS

E. Premi[1], V. Cantoni[2], J. Rivolta[2], A. Costa[3], I. Delrio[3], M. Gamba[3], N. Gilberti[3], M. Locatelli[3], R. Spezi[3], V. Vergani[3], A. Benussi[2], S. Paolucci[4], G. Koch[4], B. Borroni[2], M. Magoni[3]

Objectives: Ischemic stroke is the first cause of persistent disability and it frequently affects cognitive abilities, with a series of syndromes ranging from mild cognitive impairment to dementia. Research on animal models of ischemic stroke supports the idea that pharmacological treatments potentially enhancing intrinsic brain repair and plasticity could reduce acute brain damage, improving functional recovery. Citicoline (an exogenous form of cytidine-5'-diphospho-choline) is a molecule potentially able to enhance brain plasticity, and it has been extensively studied in several neurological disorders [1, 2]. A previous experimental study showed that patients who had experienced an ischemic stroke and started citicoline for 8 weeks within 36 hours from the event had an improvement in intracortical excitability measures, assessed through transcranial magnetic stimulation (TMS) protocol [3]. Taking into account these findings, the present experimental study will evaluate the effect of a longer treatment with citicoline on cholinergic neurotransmission using TMS protocols, in ischemic stroke patients within three months from the event.

Methods/Design: This single-blind, multicentric, randomized clinical study will include 100 patients, aged 60 to 80 years, who experienced a stroke in the past three months and have a National Institutes of Health Stroke Scales (NIHSS) < 14. Patients will be randomly assigned to two different groups with a ratio 1:1. Patients randomized to the first group, will receive conventional treatment and oral citicoline 1000 mg once daily for 16 weeks. Patients in the second group, will receive conventional therapy for 8 weeks, then oral citicoline 1000 mg once daily will be added for 8 additional weeks. Patients will be evaluated at baseline (T0), after 8 weeks (T1), after 16 weeks (T2) and after a 8-week follow-up (T3). At all timepoints (T0, T1, T2 and T3) enrolled patients will be evaluated with TMS and clinical scales (MMSE-Mini Mental State Examination, NIHSS, RAVLT- Rey's auditory verbal learning task, Trail Making Test A and B and Test of everyday attention).

Discussion: TMS techniques have been widely used to assess vascular pathology and can be useful to detect brain changes in patients with ischemic stroke. As citicoline has been shown to have effects on animal models of ischemic stroke as well as enhancing brain plasticity in ischemic stroke patients, this randomized experimental study will shed lights on the effect of citicoline on neurotransmission pathways and specifically will confirm the effect on citicoline on the cholinergic pathway using an objective measure, such as TMS.

## ATRIAL FIBRILLATION DETECTION WITH LOOP RECORDER IN ESUS (EMBOLIC STROKE OF UNDETERMINED SOURCE): A PROSPECTIVE MONINSTITUTIONAL SERIES

E. Pronello[1], T. Fleetwood[1], R. Tarletti[1], A. Parodi[2], G. Rondinara[2], R. Cantello[1], G. Patti[2], C. Comi[3]

[1]Neurology Unit, Department of Translational Medicine, University of Eastern Piedmont (Novara); [2]Department of Translational Medicine, University of Eastern Piedmont, Azienda Ospedaliero-Universitaria Maggiore della Carità (Novara); [3]Neurology Unit, S. Andrea Hospital, Department of Translational Medicine, University of Eastern Piedmont (Vercelli)

Objectives: We aim to determine the prevalence of occult atrial fibrillation (AF) in patients with diagnosis of ESUS through continuous cardiac monitoring using ILR.

Materials and methods: We prospectively collected data from 2019 to 2023 of 48 patients with ESUS implanted with ILR including risk factors and home therapy before the event, clinico-radiological elements and the complete diagnostic work-up data. We also evaluate any correlations between risk factors and AF.

Results: The median age was of 66,5 (37-82) years. The majority of patients were men (60%) and the median time of cardiac monitoring was of 14,5 months (1-45). The main cerebrovascular risk factors were collected (hypertension, diabetes, dyslipidemia, previous stroke, cardiopathy, vasculopathy, smoking) and 71% of patients had at least 1 of them, while the 52%, 27%, 12,5% had at least two, three or four of them respectively. 29,2% of patients were on antiplatelet or anticoagulant treatment before stroke. The median NIHSS was 4 (1-24) at onset and 0 (0-4) at discharge, with a mRS ≤2 in 87,5% of patients. In 50% of patients multiple ischemic lesions, suggestive of embolic events, were found on CT or MRI scans. Atrial fibrillation was detected in 16 patients (33,33%) with a median time from the implantation of the ILR and from the ischemic stroke to the AF registration of 29 days (2-267) and of 89 days (7-622) respectively. To univariate analysis age was the only significant predictor, with an OR of 15,0 (95% CI 1,7 - 127,4) for patients older than 60 years.

Discussion: Prolonged monitoring with ILR can give a high percentage of occult AF detection and our data regarding overall prevalence is in line with those from literature. The majority of the events were recorded in the first 2 months after implantation and data analysis on possible predictive factors is still ongoing. Our detection rate (20,83% at 2 months, 33,33% at 9 months) is much higher than in

CRYSTAL AF study and other studies and series from literature. Age was the only significant predictor found in our study, as in literature; no other risk factors were found to be statistically significant.

Conclusion: We confirmed the data available in literature about AF detection in ESUS with ILR. An accurate selection of the patient, after a complete work-up analysis, and definition of ESUS is mandatory to increase the sensitivity of the continuous cardiac monitoring. Further research is needed to determine more risk factors of AF other than age.

## EPIDEMIOLOGY AND OF ANEURYSMAL AND NON-ANEURYSMAL SUBARACHNOID HEMORRHAGE AND ITS SUBTYPES OVER 10 YEARS IN A POPULATION-BASED STUDY

C. Ragaglini[1], M. Foschi[1], F. De Santis[1], A. L. Molliconi[2], R. Ornello[1], S. Sacco[1]

[1]Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila (L'Aquila); [2]Department of Internal Medicine, Public Health, Life and Environmental Sciences, University of L'Aquila (L'Aquila)

Objectives: We aimed at giving an updated report of either aneurysmal (a-) or non-aneurysmal (na-) SAH epidemiology over the last 10 years. Materials and Methods: Our prospective population-based registry included patients with first-ever SAH occurring from January 2011 to December 2020. Clinical and neuroimaging records were screened to evaluate the presence of intracranial aneurysms in order to differentiate aneurysmal (aSAH) from non-aneurysmal SAH naSAH) and to retrieve information on surgical treatments. Incidence rates were standardized to the 2011 Italian and European population. We also estimated 30-days and 1-year case-fatality rates (CFRs).

Results: 194 patients (60.8% women; mean age 62.5±16.0 years) were included (76.8% aSAH and 23.2% naSAH). The crude incidence rates per 100,000 person-years of SAH, aSAH, and naSAH were 6.5 (95% CI 5.6-7.5; p for trend=0.764), 5.0 (95% CI, 4.2-5.9; p for trend=0.831) and 1.5 (95% CI, 1.1-2.0; p for trend=0.815), respectively. SAHs 30-day and 1-year CFRs were 28.4% (95% CI 21.4-36.9%) and 37.1% (95% CI 29.0-46.7%) respectively. Compared to aSAH, naSAH patients had older age (68.8±19.7 vs 60.6±14.2 years; P=0.012), lower prevalence of cigarette smoking (17.9% vs 36.4%; p<0.001), and higher prevalence of atrial fibrillation (15.7% vs 2.8%; p=0.005). Considering the two types of naSAH, the perimesencephalic form affected younger patients compared to non-perimesencephalic naSAH (57.8±16.2 vs 75.5±18.7 years; P=0.002) and 30-day and 1-year CFRs were higher for non-perimesencephalic naSAH (p=0.022). Discussion: Although literature reported a globally decline in SAH incidence, in our cohort remained almost stable and was highest in patients aged >75 years. Those last data are in line with worldwide trends pointing toward an increasing age at SAH onset probably due to prevalence of vascular risk factors, mainly arterial hypertension and cigarette smoking. Our 30-day case-fatality rate was slightly higher and may be explained by the relatively high mean age of our sample. In line with literature, most patients had aSAH, despite naSAHs cases were a higher proportion compared with similar population-based studies. In naSAHs subtypes we found difference in CFRs, in particular non-perimesencephalic naSAH is associated with worse prognosis compared with perimesencephalic one.

Conclusion: We found a low and stable incidence of SAH and a shift towards older age at SAH presentation compared with previous data. naSAH is an emerging and heterogeneous entity and the distinction between its two subtypes is of prognostic relevance; considering the lower frequency, larger epidemiological studies are warranted.

Background: Vascular Ehlers-Danlos syndrome (EDS) is a collagen genetic disorder caused by COL3A1 gene mutations. It is a rare cause of stroke by ruptured aneurysms, cervical artery dissections and carotid-cavernous fistula (CCF).

Case report: A 42-year-old woman with a genetic diagnosis of EDS, was admitted for sudden onset of headache and paralysis of 3rd and 6th cranial nerves. She had a history of hypertension, bowel perforations, and splenic artery aneurysm. CT-angiography showed left fronttemporal subarachnoid hemorrhage (SAH) and a CCF. After seven days she presented recurrent episodes of motor aphasia that became persistent two days later. Aphasia furtherly worsened, CT-angiography with CT-perfusion was repeated showing severe left internal carotid artery (ICA) stenosis due to dissection in C1 segment and hypoperfusion in the left MCA territory (ischemic core 31 ml, penumbra/core 1.8). Urgent endovascular stenting of ICA was performed and in the same intervention CCF was transarterially embolized. Post-intervention

time was complicated by left temporal hematoma with initial transuncal herniation and acute respiratory insufficiency requiring invasive intracranial pressure (ICP) monitoring and tracheostomy. Progressively, patient improved with suspension of air support and ICP monitoring. At demission (40 days after the intervention) she presented sporadic anomies, left ptosis and slight sixth cranial nerve palsy.

Conclusions: Our patient presented two types of vascular complications due to EDS: CCF with SAH and spontaneous homolateral ICA dissection, partly consequent to high flow compensating arteriovenous steal. Endovascular procedure was technically difficult for high risk of hemorrhage in vessels fragility; carotid stent was implanted to treat acute ischemic stroke.

## MOVING FROM CT TO MRI IN ACUTE ISCHEMIC STROKE: EFFECTS ON DIAGNOSIS, REVASCULARIZATION METRICS AND MEDIUM TERM OUTCOMES

C. Rapillo[1], V. Dunet[2], S. Pistocchi[2], A. Salerno[3], V. Darioli[4], B. Bartolini[5], S. Hadju[5], P. Michel[3], D. Strambo[3]

[1]Stroke Unit, Careggi University Hospital (Firenze); [2]Neuroradiological Unit, Lausanne University Hospital (Lausanne-CH); [3]Stroke Unit, Lausanne University Hospital (Lausanne-CH); [4]Emergency Department, Lausanne University Hospital (Lausanne-CH); [5]Service of Diagnostic and Interventional Radiology, Lausanne University Hospital (Lausanne-CH)

Background and Aims: The relative value of CT and MRI in acute ischemic stroke (AIS) is debated. In May 2018, in Lausanne University Hospital (CHUV) we switched from CT to MRI as first line imaging for all suspected AIS. Here, we aimed to retrospectively assess the effects of this paradigm change on diagnosis, revascularization metrics and safety and disability outcomes.

Methods: From the Acute STroke Registry and Analysis (ASTRAL) we selected an identical number of patients during the MRI-first-period (05/2018-08/2022) and the preceding CT-first-period (until 2012). We compared outcome measures in the two periods by univariate and multivariate analysis and we performed time-trend analyses for the main outcomes.

Results: The median age of the 2972 included consecutive AIS patients was 76 (IQR=65-84) years, and 1361 (46%) were female. In the MRI-period, 80% underwent MRI as first acute imaging. The proportion of patients requiring a second acute imaging modality for diagnostic ± revascularization reasons increased from 2.1% in the CT-period to 5% in the MRI-period (puniv<0.05) while the rates of subacute imaging (until the end of hospitalization) decreased from 79% to 60% (padj <0.05). The rates of initially missed AIS diagnosis (chameleons) was similar (3.8% vs 4.4%, padj=0.32). Stroke mimics treated by intravenous thrombolysis (IVT) decreased by half (8.6% vs 4.3%, padj<0.05). The MRI-paradigm was not associated to the rates of undetermined stroke mechanism at the end of hospitalization. We assessed 1131 consecutive IVT and 662 endovascular (EVT) treated patients. Median door-to-needle-time was 31min (IQR=24-48) in the CT-period vs. 43min (IQR=33-58) in the MRI-period (+12 min, puniv<0.01), while median door-to-groin-time was unchanged. In the CT vs. MRI periods, rates of missed IVT opportunities were respectively 3.1% vs. 0.8% (puniv<0.01); rates of symptomatic intracranial haemorrhage (SICH) after IVT were numerically, but non-significantly, lower (5.6% vs 3.2%, padj=0.07) and SICH after EVT (±IVT) were similar (6.5% vs 4.2%, padj=0.21). Disability at 3 months was unaffected for both IVT and EVT-treated patients (common adjusted odds ratio for favourable Rankin shift 1.23,95%CI=0.96-1.58; p=0.1 and 0.93,95%CI=0.67-1.29, p=0.674 respectively) and in the overall cohort.

Conclusion: The paradigm shift from CT to MRI as first-line imaging for AIS in a comprehensive stroke centre seems feasible. MRI was associated with reduced IVT for stroke mimics, but not with rates of missed AIS diagnosis and undetermined stroke mechanism at discharge. The MRI paradigm was associated to reduced rates of missed IVT opportunities. We observed longer door-to-needle and stable door-to-groin times during the MRI-period. Safety (SICH) and 90-day disability were not affected.

## INVESTIGATING TEMPORAL MUSCLE THICKNESS (TMT) AS A PREDICTOR OF FUNCTIONAL OUTCOME AFTER REVASCULARIZATION TREATMENTS FOR ACUTE ISCHEMIC STROKE

B. Ravera[1], C. Lombardi[1], I. Scala[1], P. Rizzo[1], G. Frisullo[2], A. Broccolini[2], G. Della Marca[2], M. Monforte[2]

[1]UOC Neurology, Catholic University of Sacred Heart, (Roma); [2]Multispecialty Department of Neurology, Policlinico A Gemelli University Foundation (Roma)

Objectives: The study aims at investigating temporal muscle thickness (TMT) as a predictor of functional outcome in patients with acute ischaemic stroke who received revascularization procedures.

Materials and Methods: Consecutive patients affected by ischemic stroke who underwent thrombectomy and/or thrombolysis at our center were included in this observational retrospective study. Demographic, clinical and radiological data were extracted from electronic reports. TMT was measured on emergent brain Computed Tomography (CT) images acquired at arrival in the emergency room, according to published protocols. Modified Rankin Scale (mRS) scores at 3 months represented the main endpoint of functional outcome. Patients were further divided into two groups: at-risk vs not-at-risk of sarcopenia, based on a literature cut-off of mean TMT. Univariate and multivariate analyses were performed to assess the significance of mean TMT as a predictor of functional outcome.

Results: 126 patients (53 f and 73 m) were included in the study. Mean age was 72 ± 14 SD (range 24 - 95), baseline NIHSS was 11.7 ± 6.9. 34 patients underwent thrombolysis, 50 patients thrombectomy and 42 both. Mean TMT was 5.4 mm ± 1.9 (range 1.2 - 11.7); male patients had higher TMT values compared to female (mean value 5.9 vs 4.6, p<0.0001). We found a correlation between mean TMT and age (r -0.32, p<0.001) and with mean TMT and pre-existing mRS (r -0.34, p<0.001) but not with BMI. In the univariate analysis patients with unfavorable outcomes at 90 days (mRS > 3) had lower values of mean TMT (4.9 vs 5.6 mm, p=0.02), as well as the subgroup of patients who passed away (n = 17, 13.5%; 4.1 vs 5.6 mm, <0.001). We found that patients at-risk of sarcopenia were more likely to die (OR 6.8, 95% IC 2-20, Fischer's exact test p<0.001). In the multivariate analysis, after adjustment, neither mean TMT nor belonging to the at-risk of

sarcopenia group were confirmed as independently associated with worse outcomes.

Discussion: Despite proper care and treatment, functional outcome in patients with acute ischemic stroke isn't always as favorable as expected. There are many known factors that influence patient's recovery (age, gender, initial severity of stroke, functional status at admission, etc.) but many more are under investigation to improve treatment personalization and prognostication. The measurement of temporal muscle thickness (TMT) has been introduced as an easily obtainable new surrogate marker to identify patients at risk of sarcopenia, which is known to be a major cause of disability and frailty, especially among the elderly population, due to its high correlation with skeletal muscle mass, muscle function and nutritional status. It has already been studied as a prognostic factor in other neurological disease (cerebral aneurisms and glioblastoma multiforme). Reliability of TMT evaluation as a tool to identify sarcopenic patients has been confirmed in a mixed stroke population (ischemic and hemorrhagic) but there are no data available regarding its relationship with ischemic stroke outcome after acute phase treatment. In this study a correlations was found between unfavourable outcomes at 90 days (mRS > 3) and lower values of TMT whereas, in the multivariate analysis, neither mean TMT nor belonging to the at-risk of sarcopenia group were confirmed as independently associated with worse outcomes.

Conclusion: A trend in higher frequencies of very severe outcomes for patients at-risk of sarcopenia undergoing revascularization treatments for acute ischemic stroke was identified. Actual evidence fully supports treatment of this frail population according to established guidelines. Further investigations are needed to verify if sarcopenia may be an independent prognostic factor.

## REFRACTORY AND FATAL STATUS EPILEPTICUS AS PRESENTATION OF CEREBRAL AMYLOID ANGIOPATHY RELATED INFLAMMATION: CLINICAL AND AUTOPTIC FINDINGS

N. Ravì[1], F. Rossato[1], A. Petullà[1], M. Gardiman[2], S. Mozzetta[1], A. Cagnin[1]

[1]Department of Neurology, University of Padova (Padova); [2]Department of Pathological Anatomy, University of Padova (Padova)

Introduction: Cerebral amyloid angiopathy related inflammation (CAAri) is a rare yet aggressively relapsing disease. The diagnosis is often based on clinical and radiological data, but the gold standard remains brain biopsy or autopsy. Early diagnosis is important to start immunomodulant therapy that has been proved to be effective. Herein we present a case of an 80 years-old woman who was diagnosed with CAA-ri and died because of super-refractory status epilepticus with no response to high dose steroid therapy. Her diagnosis was confirmed by histopathological examination of the brain tissue.

Aim: To report atypical clinical and radiological findings of CAAri and to describe pathological findings.

Case presentation: An 80-years-old woman with no history of chronic disease complained of sudden intense headache, followed by gaze deviation and clonic movements in the left limbs. At emergency department, a CT scan showed right temporal subarachnoid haemorrhage. Deep sedation was started along with administration of levetiracetam and the patient was admitted to intensive care unit. Cerebrospinal fluid examination was normal. Biomarkers for biological Alzheimer's disease were positive (increased phosphorylated tau and decreased level of β-amyloid protein 1-42 and decreased β-amyloid 1-42/1-40 ratio). APO-E genotype was ε3/ε3. The first EEG showed occasional fronto-central epileptiform features. Follow-up EEG showed non-convulsive epilepticus status not responsive to polytherapy with brivaracetam, perampanel and lacosamide. MRI revealed multiple microbleeds with lobar distribution and bilateral disseminated sulcal superficial haemosiderosis, right parietal subcortical confluent white matter hyperintensities. No post-contrastographic enhancement was noted. High dose steroid therapy was started with methylprednisolone 1000 mg for five days with tapering in the following five days. There was no response to immunomodulatory therapy with persistent super-refractory epilepticus status with more evident epileptiform frontal-temporo-parietal activity (ictal-interictal continuum) without any change after continuous infusion of add-on valproic acid. The patient died 19 days after admission. Brain autopsy confirmed a thioflavin, Congo-red positivity of brain specimens from the right parietal lobe with marked parenchymal oedema.

Conclusion: Refractory status epilepticus has been reported in CAAri but seldom as first manifestation of the disease. Lack of response to high dose steroids in these cases should be immediately followed by second-line immunosuppressive treatment. Histologic characterization of the inflammatory response may prompt deeper understanding of the physiopathology of this malignant form of the disease.

Background and aims: Following a stroke, EEG-based brain networks' overall balance between local specialization and global integration, known as "Small-worldness" (Sw), experiences complex changes. Sw is characterized both by high segregation (high clustering coefficient, Cw) and high integration (low shortest path length, Lw). We found that acute stroke causes a reduction of delta network Sw and an increase of alpha network Sw. In this multicentric observational study, we aimed to evaluate whether specific networks characteristics at admission and at discharge are associated with different neurological severity and, thus, different clinical evolution.

Materials and methods: We recruited patients admitted for acute anterior circulation stroke; we recorded a first 64-channel EEG within 24 hours and a second EEG within 5 days from stroke onset. We obtained NIHSS at admission and at discharge. Connectivity analysis was performed with eLORETA for each EEG frequency band. We compared connectivity parameters of first vs second acquisition and then we performed a regression analysis using stroke severity as dependent variable.

Results: We enrolled 80 consecutive patients (57% female, median age 75, 53% right hemispheric stroke). Median NIHSS at admission was 11 (IQR:6-15), 5.5 (IQR:2-12) at discharge. We found no difference in terms of clustering between first and second acquisition, while we found a reduced global integration (higher Lw) for alpha 1 and alpha 2 networks at first acquisition ($p=0.041$, $p=0.024$). Concerning overall network balance, we found that alpha 1 network Sw was higher in the second acquisition than in the first ($p=0.014$). The regression model found an indirect association between alpha 1 Sw at first acquisition and NIHSS at admission ($p=0.043$) and a direct association between delta Sw at second acquisition and NIHSS at discharge ($p<0.0001$). Finally, the regression model found a direct association between delta Sw at first acquisition and NIHSS at discharge ($p=0.024$) and delta Cw at first acquisition and NIHSS at discharge ($p=0.029$).

Discussion: While brain connectivity dynamically changes in stroke acute phase, delta network rearrangements have a potential prognostic role. In fact, a higher delta Sw at admission predicts greater stroke severity at discharge. Such rearrangement seems to depend more strongly on modifications of local segregation induced by the lesion itself. The indirect association between alpha 1 Sw and stroke severity probably depends on the perturbation of physiological brain rhythms induced by brain damage.

Conclusions: Delta network rearrangements induced by acute stroke can predict stroke severity at discharge, being a potential prognostic factor.

## SEX-DIFFERENCES IN SHORT-TERM OUTCOME IN YOUNG ADULT PATIENTS WITH ACUTE ISCHEMIC STROKE WHO UNDERWENT REVASCULARIZATION TREATMENT: A SINGLE CENTER CASE SERIES

R. Renna[1], G. Spagnoletti[2], M. Rippa[1], G. Alfieri[1], S. Barbato[1], P. Candelaresi[1], A. De Mase[1], G. Della Rocca[1], M. Di Battista[1], M. Di Giovanni[1], W. Di Iorio[1], A. Fasolino[1], K. Longo[1], M. Napolitano[1], E. Prestipino[1], A. Ranieri[1], S. Salvatore[1], G. Servillo[1], E. Spina[1], V. Andreone[1]

[1]UOSC Neurology, Stroke Unit, AORN Cardarelli (Napoli); [2]Division of Hepatobiliopancretic Surgery, Liver and Kidney Transplantation, Pediatric Hospital Bambino Gesù (Roma)

Introduction: There are few data in the literature about short term clinical outcome in young adults with acute stroke after revascularization with thrombolysis (IVT) and/or endovascular treatment (ET) and gender differences in treatment response. [1-3]

Objectives: To assess gender differences in short-term clinical outcome in young adults with ischemic stroke after IVT and/or ET.

Materials and Methods: Clinical and radiological data from 127 consecutive patients aged < 50 years with ischemic stroke were collected. They were admitted in the Stroke Unit of "Cardarelli" Hospital between August 2017 and September 2022 for revascularization with IVT and/or ET. NIHSS and TOAST classification were used to define stroke severity and aetiology. Patients' clinical short-term outcome was assessed by NIHSS.

Results: In the study period 1494 patients with ischemic stroke who underwent revascularization treatment were admitted in our Stroke Unit. 127 patients (8.5%) were aged ≤50 years and were defined young adults. They were 54 females and 73 males. Mean age was 42.2+8.8 years for women and 42.9+7.1 years for men. The most frequent risk factors in the entire population were smoking, hypertension, and dyslipidemia. The only statistically significant difference in risk factors distribution between men and women was the history of stroke (14.8% of females and 4.1% of males). Patent foramen ovale was more frequent in the female population, but gender difference did not gain the statistical significance. All the patients considered in the present study underwent revascularization treatment: 69 patients (26 females, 43 males) underwent IVT, 40 patients underwent IVT plus ET (20 females, 20 males), and 18 patients (5 females, 13 males) underwent primary ET. Mean NIHSS score at admission was 10.55 for women and 10.77 for men. Mean NIHSS score 2 hours after treatment was 6.55 for women and 8.41 for men. Mean NIHSS score 24 hours after treatment was 5.04 for women and 6.78 for men. Mean NIHSS score 7-days after treatment was 2.23 for women and 4.75 for men and this difference in 7-days mean NIHSS score between female and male groups was statistically significant (p 0.013). There was no statistically significant interaction between sex and type of treatment on NIHSS at admission, at 2 and 24 hours, and 7-days after revascularization treatment.

Conclusions: Young female patients with ischemic stroke treated with revascularization (IVT, IVT and ET or ET) had a better short-term outcome in comparison with young male patients, as documented by a lower mean NIHSS score 7-days after treatment, independently from treatment type.

## BOWHUNTER SYNDROME AND CEREBELLAR STROKE, A CASE REPORT

G. Rinaldi[1], A. Picchioni[2], A. Bellotti[3], M. Alabiso[3], E. Cresta[3], I. Corbelli[3], S. Cenciarelli[2], L. Parnetti[3], P. Sarchielli[3]

[1]Medicine Department, University of Perugia (Perugia); [2]Neurological Clinic, Hospital of Città di Castello (Città di Castello-PG);[3]Neurological Clinic, Hospital of Perugia (Perugia)

Background: Bowhunter syndrome (BHS) is an uncommon cause of vertebro-basilar insufficiency that results from occlusion or injury to the vertebral artery (VA) during neck rotation. The cause is often a bony abnormality that may compress the VA, compromising distal flow. Posterior circulation strokes in young individuals should alert the neurologist to suspect BHS, especially if rostral cervical spine abnormalities are detected on initial head imaging.

Case presentation: A 18 year-old patient came to the Emergency Room for subjective acute vertigo, nausea and vomiting, that lasted about five hours. The initial neurological evaluation (after symptom cessation) revealed no focal deficits, brain Comuted Tomography (CT) revealed no recent lesions and Doppler ultrasound showed a demodulated flow in the left extra- and intracranial vertebral artery, in the absence of other pathological findings. The patient refused hospitalization; antiplatelet therapy was introduced and the patient underwent a brain MRI six days later, which showed a recent left cerebellar ischemic lesion. To investigate the etiopathogenesis of the ischemic stroke, in the absence of any cardiovascular risk factors, the patient underwent a CT angiography with the evidence of left vertebral artery stenosis (especially in V4) and an altered structural morphology of the C1 vertebra which determined a reduction in the diameter of the artery at the vertebral crossing point. Suspecting BHS, he subsequently underwent dynamic cerebral angiography which showed dysmorphic appearance of the atlanto-occipital junction and anterior subluxation of C1 with respect to the occipital condyles bilaterally associated with small bone outgrowth of the posterior arch of C1, with consequent anomalous course of the vertebral artery in V3-V4 especially on the left. When asked, the patient confessed frequent neck rotation maneuvers, which he performed daily to release neck muscle tension. In relation to the risk-benefit ratio, surgical treatment was not recommended, in favor of a conservative medical approach.

Conclusion: Although BHS is among the rarest causes of ischemic stroke, it should be suspected in young patients with no clear cardiovascular risk factors, presenting with symptoms suggestive of posterior circulation stroke.

## THE PROGNOSTIC ROLE OF C-REACTIVE PROTEIN AND OTHER INFLAMMATION SERUM MARKERS IN STROKE: AN OBSERVATIONAL, RETROSPECTIVE STUDY

P. A. Rizzo[1], I. Scala[1], S. Bellavia[1], J. Di Giovanni[1], G. Frisullo[2]

[1]Neurology Department, Catholic University of the Sacred Heart (Roma); [2]Neurology Department, Fondazione Policlinico Universitario "A Gemelli IRCCS (Roma)

Background: Inflammation plays a significant role in the pathophysiology of ischemic stroke that triggers an inflammatory response [1], including the release of pro-inflammatory cytokines and activation of immune cells. C-reactive protein (CRP) is an acute-phase reactant, commonly used as a nonspecific marker of systemic inflammation.

Aim: The aim of the study was to evaluate the predictive role of CRP for the outcome in patients with ischemic stroke, in comparison with other markers or indices of inflammation. We also tried to identify a useful cut-off in clinical practice to stratify the risk of patients admitted to the emergency department with acute cerebrovascular disease.

Material and methods: We included in the study all consecutive patients affected by ischemic stroke or transitory ischemic attack, referred to the Stroke Unit of Policlinico Agostino Gemelli between December 2019 and June 2021 which performed C-reactive protein (CRP), leukocyte formula, fibrinogen and erythrosedimentation rate (ESR) within the first 24 hours after the stroke. Demographic, clinical features, admission and discharge NIHSS score, risk factors and outcome a 3-month follow-up through mRS score were collected.

Results: Starting from 1058 subjects, we enrolled in the final analysis 339 acute ischemic stroke patients, 215 with a good outcome (mRS=0-2) and 124 with poor outcome (mRS=3-6) after 3-month follow-up. We found significantly higher CRP, ESR, Fibrinogen serum levels and SIRI (systemic inflammation response index) in patients with a 3-months poor outcome. The multivariate analysis confirmed CRP and Fibrinogen values as independent poor outcome predictors. Evaluating death predictors, high serum levels of CRP, ESR and high SII (systemic inflammation index) and SIRI were significantly associated with an increased mortality, and, after multivariate analysis, CRP was confirmed as an independent predictor. Moreover, through a receiver operating characteristic (ROC) curve analysis, we identified a CRP cut-off value of 11,5 mg/L (milligrams/liters) as a good predictor of both 3 months outcome (sensitivity: 58%, specificity: 62%, AUC= 0,642) and mortality (sensitivity: 83%, specificity: 60%, AUC= 0,755).

Conclusion: Elevated CRP appears to be a reliable predictor of poor outcome and mortality in ischemic stroke. The PCR cut-off could be an useful tool in the risk stratification of acute stroke patients already in the emergency department to optimize a more suitable diagnostic-therapeutic path or a more appropriate patient monitoring setting.

## STROKE-RELATED DELIRIUM IN PATIENTS UNDERGOING REVASCULARIZATION TREATMENTS: A RETROSPECTIVE, OBSERVATIONAL STUDY

E. Rollo[1], M. Monforte[2], V. Brunetti[1], M. De Scisciolo[1], L. Fulignati[1], R. Di Iorio[2], S. Silva[3], A. Scavone[3], A. Caricato[3], P. Calabresi[1], G. Della Marca[1]

[1]Department of Neurosciences, University Cattolica del Sacro Cuore (Roma); [2]Neurology Unit, Fondazione Policlinico Universitario A. Gemelli IRCCS (Roma); [3]Department of Anesthesiology and Intensive Care Medicine, Fondazione Policlinico Universitario A. Gemelli IRCCS (Roma)

Background: Delirium is a complex neuropsychiatric disorder, which often complicates acute illnesses, including acute stroke [1]. In literature the prevalence of delirium in patients undergoing revascularization treatments for acute stroke is not clearly established, since the available epidemiological data mainly refer to the pre-thrombectomy era [2]. The primary aim of the present study was to evaluate the prevalence of delirium in patients undergoing revascularization treatments for acute stroke. Secondary aims were: 1) risk factors for stroke-related delirium; 2) impact of delirium on stroke outcome.

Materials and methods: We retrospectively reviewed the clinical charts of patients admitted to the Stroke Unit of Policlinico Gemelli from 2018 to 2021. Inclusion criteria were: ischemic stroke; treatment with thrombolysis and/or mechanical thrombectomy. Exclusion criteria were: impossibility to retrieve medical records; coma; mutacic patients. Delirium was diagnosed based on the DSM-V criteria [3] by reviewing nurse and medical records.

Results: The study cohort consisted of 445 patients. Mean age was 73.8±13.1, mean NIHSS was 11.9±7.3. Endovascular treatment (EVT) was performed in 226 (50.8%) patients, thrombolysis in 343

(77.1%) both in 124(27.9%). Delirium prevalence was 165/445(37.1%). Among the subgroup treated with mechanical thrombectomy, 92% of patients underwent general anesthesia during the procedure, and 80% were subsequently hospitalized in Neuro-ICU. In the univariate analysis, delirium was associated with EVT (p=0.01), atrial fibrillation (p=0.024), aphasia (p=0.003), hyperglycemia at stroke onset (p<0.001), use of central nervous system acting drugs (p=0.002), cognitive impairment (p<0.001), pneumonia (p<0.001), oxygen-therapy (p<0.001), antibiotic therapy (p<0.001). Patients with delirium were older (p<0.001), had higher NIHSS at stroke onset (p<0.001), and after treatment (p<0.001), and higher disability pre-stroke (p<0.001). In the multivariate analysis, risk factors for delirium were age (OR=1.04; 95% C.I.=1.02-1.07; p=0.001), NIHSS after treatment (OR=1.18; 95% C.I.=1.12-1.25; p<0.001), oxygen-therapy (OR=1.86; 95% C.I.=1.06-3.26; p=0.032), antibiotic therapy (OR=2.46; 95% C.I.=1.27-4.76; p=0.007), cognitive impairment (OR=3.17; 95% C.I.=1.24-8.14; p=0.016). Patients with delirium were less often discharged home (p<0.001), had prolonged hospitalization (p<0.001) and increased 90-days disability (p<0.001).

Discussion and conclusion: In the last years, stroke management has radically changed, due to the introduction of effective treatments and with the extension of the therapeutic window up to 24 hours. This study adds knowledge to the prevalence and risk factors of delirium in the new clinical scenario of acute stroke care. In our cohort, delirium was not associated with general anesthesia for EVT nor to Neuro-ICU hospitalization after EVT. Delirium is a frequent complication in acute stroke patients undergoing revascularization treatments and negatively affects stroke outcome.

## INTRAVASCULAR STENTING IS SAFE AND EFFECTIVE IN SECONDARY PREVENTION OF CEREBRAL ISCHEMIC EVENTS IN PATIENTS WITH CAROTID WEB

R. Ronco[1], G. Nuzzaco[1], F. Frediani[1], L. Valvassori[1], A. Priori[2], S. Tonietti[1]

[1]Department of Neuroscience, ASST Santi Paolo e Carlo (Milano); [2]Department of Health Sciences, University of Milan (Milano)

Background and aims: A carotid web (CaW) is a thin intraluminal shelf-like lesion along the wall of the internal carotid artery. Although it has been recognised as a common cause of cryptogenic stroke in young adults (9.8-37%), optimal management strategies of CaW cases in primary and secondary cerebral ischemic events (CIE) prevention appear unclear.

Clinical case: We report the case of a 44-year-old woman experiencing transient 10 minutes-long acute left upper limb paresis followed by confusion and multiple short-lasting episodes of aphasia. The week before, she had complained of objective vertigo, nausea and vomiting lasting about 30 minutes. This patient had no medical history of cerebrovascular events and no known risk vascular risk factors. Symptoms had already regressed when she sought medical attention a few hours after the first episode (NIHSS = 0) and she remained asymptomatic throughout hospital stay. CTA and cerebral angiography showed the presence of CaW along the left carotid bifurcation. Diffusion-weighted brain MRI revealed multiple small recent ischemic lesions in left frontal and insular cortex. Appropriate testing allowed to exclude other causes of ischemic events in young individuals (trombophilic, vasculitic and genetic disorders, PFO and drug abuse).

Methods: We conducted a search across Medline via PubMed using the terms [Carotid Web] AND [stroke], which yielded 256 results. After selection of studies describing the recurrence rate of CIE in cohorts of patients with CaW treated with either medical therapy or intravascular stenting, we included 3 studies [1,2,3].

Results: Symptomatic patients with CaW treated with medical therapy have a higher risk of experiencing a new CIE compared to patients who underwent carotid stenting (17-29% vs 0%). Based on these findings, we proceeded with CaW stenting (N days after hospital admission = 12). The procedure was carried out without complications and the patient was then dismissed. By telephone follow-up at 4 months our patient proved to be CIE-free with no complications from intravascular stenting.

Conclusions: Patients with CaW have a high recurrence rate of CIE. Our case confirms safety and efficacy of carotid stenting in a young individual with symptomatic CaW. Despite mounting evidence proving intravascular stenting to be safe and superior to medical therapy in secondary prevention of CIE in CaW cases, latest guidelines are currently lacking definite management indications in such patients. Therefore, strong randomised studies with longer follow-up windows are warranted.

## CASE REPORT OF MULTIEMBOLIC CEREBROVASCULAR STROKE ASSOCIATED WITH LUNG ADENOCARCINOMA

M. Rotolo, A. Pecoraro, R. Napoletano, P. Barone

Department of Medicine, Neuroscience section, Hospital of Salerno (Salerno)

Background: Thromboembolic events such as deep vein thrombosis (DVT), pulmonary embolism (PE), arterial thrombosis, non-bacterial thrombotic endocarditis, and ischemic strokes can be the initial event leading to the diagnosis of an underlying malignancy; this is due to abnormalities in the coagulation cascade that often accompanies many oncologic diseases.

Case Report: A 54-year-old Caucasian female, with a medical history of atrial tachycardias and thyroidectomy, was admitted to our emergency department due to an acute onset of slurred speech and right hemiparesis (NIHSS score 8). CT and CTA showed an hypodensity of the middle frontal gyrus and M1 segment occlusion of the left MCA. Mechanical thrombectomy was performed with a complete recanalization (the patient was outside tPA time window). During hospitalization her neurological symptoms progressively improved until they disappeared. An extensive work-up was undertaken to determine the cause of the stroke: supra-aortic trunks ultrasound, transcranial doppler bubble-test, cardiologic evaluation with Holter-ECG and trans-thoracic

echocardiogram were unremarkable. Blood tests including for systemic autoimmunity, infectious screening, hereditary thrombophilia and oncomarkers testing just revealed increasing levels of CA 15-3 and CEA). The patient also reported the presence of dry and persistent cough started four weeks before her hospitalization, so a complete pneumological screening was performed: a non-tuberculous mycobacteria pneumonia and lung adenocarcinoma (ROS-1 mutation positive) were diagnosed and an appropriate antibiotic therapy and treatment with Entrectinib monoclonal antibody were started. In the following days, the patient presented acute onset of dyspnea followed by chest pain and CT angiography scans showed pulmonary embolism so anticoagulant therapy was promptly started (later discontinued because of hemorrhagic pleural effusion). After a few weeks, our patient complained sudden onset of visual disturbance and a brain MRI revealed an ischemic stroke at right occipital lobe. Subsequently a transesophageal echocardiography was performed and it revealed a round 4 mm neoformation adhering to the aortic valve wall that was compatible with a likely embolic source causing stroke.

Discussion: Approximately 30% of patients with ischemic stroke have an embolic stroke of undetermined source (ESUS). An estimated 5% to 10% of patients with ESUS have an active cancer diagnosis and our observation supports that it is required to perform an accurate and complete screening to rule out a possible organic emboligenic source, mainly when malignancy diagnosis coexists, because most cases are discovered incidentally post-mortem. Transesophageal echocardiography allowed us to find the likely emboligenic source causing recurrent cerebrovascular strokes in this patient.

## STENT PLACEMENT IN ACUTE ISCHEMIC STROKE DUE TO BASILAR ARTERY OCCLUSION: A SINGLE-CENTRE PRELIMINARY EXPERIENCE

S. Sammali, P. Nencini, C. Sarti, M. Lamassa, A. Poggesi, B. Piccardi, F. Pescini, V. Palumbo, M. Nesi, L. Renieri, N. Limbucci, F. Capasso, E. Fainardi, F. Arba

Stroke Unit, Careggi Hospital, University of Florence (Firenze)

Introduction and Objectives: Ischemic stroke due to basilar artery (BA) occlusion is a rare but highly disabling and deadly pathology. In clinical trials, around two-thirds of patients enrolled were treated with endovascular therapy and stenting placement. Although BA stenting may represent a rescue therapy in selected patients, benefits in clinical settings have not been fully elucidated. We aim to investigate the outcomes of patients with acute ischemic stroke due to BA occlusion treated with stenting compared with thrombectomy/thrombus aspiration.

Materials and Methods: We performed a single-center retrospective study in consecutive patients with acute ischemic stroke due to BA occlusion treated with endovascular procedures from November 2018 until December 2022. Neurointerventionalists and neurologists made the decision to perform thrombectomy/thrombus aspiration or stenting placement. Outcomes of interest were: early neurological deterioration (NIHSS at 24 >=4 points compared to baseline NIHSS), any intracranial hemorrhage at 24 hours, good recanalization of the BA, discharge destination, and death at three months.

Results: We included 38 patients in the analysis. Mean (+-SD) age was 72 (+-12), 24 (63%) were males, median (IQR) NIHSS at onset was 12 (3-18), 12 (32%) patients were treated with stenting, and 26 (68%) underwent mechanical thrombectomy. Sixteen patients received treatment with rt-PA (42%) as bridging therapy, and median (IQR) timing between symptoms onset and endovascular treatment was 405 minutes (295-610). Patients in the stent group were more likely to present early neurological deterioration after the procedure (50% vs. 17%, $p<0.05$); there were no differences regarding intracranial hemorrhage (17% vs. 12%, $p=0.67$) and good recanalization between the two groups (90% in the stenting group and 86% in the control group, $p=0.89$). In the stenting group, 40% of patients were discharged at home compared with 24% of the thrombectomy/thrombus aspiration group ($p=0.34$). Death at three months occurred in 4 patients out of 9 in the control group (44%) and in 3 patients out of 6 in the stent group (50%) ($p=0.4$).

Discussion: In patients with acute ischemic stroke due to BA occlusion treated with endovascular procedures, stenting placement was associated with early neurological deterioration despite similar recanalization and intracerebral hemorrhage occurrence.

Conclusion: Our results suggest that basilar artery stenting should only be adopted as a rescue therapy as it is associated with periprocedural neurological deterioration.

## AUTOMATED PUPILLOMETRY PREDICTS THREE-MONTH STROKE OUTCOME: AN OBSERVATIONAL, PROSPECTIVE, COHORT STUDY

I. Scala[1], M. Miccoli[1], P. Pafundi[2], P. Rizzo[1], S. Bellavia[1], J. Di Giovanni[1], A. Broccolini[2], G. Frisullo[2]

[1]Department of Neuroscience, Catholic University of the Sacred Heart (Roma); [2]Facility of Epidemiology and Biostatistics, Gemelli Generator, Fondazione Policlinico Universitario A. Gemelli IRCCS (Roma); [3]Department of Neuroscience, Sensory Organs and Chest, Fondazione Policlinico Universitario Agostino Gemelli IRCCS (Roma)

Study Objectives: The aim of the study was to analyze the prognostic role of Automated Pupillometry (AP) in patients with acute ischemic stroke, defined through the score of the modified Rankin Scale (mRS) after three months from the Acute Stroke (AS) onset.

Materials and Methods: In this observational, cohort study, we included consecutive adult patients admitted to a comprehensive stroke center with a diagnosis of ischemic stroke from March 2021 to July 2022.

Exclusion criteria included: Clinical history of previous eye surgery, eye trauma, or major eye disease, bilateral strokes, and previous neurological disorders. Automated pupillometry assessment was performed within 72 hours of stroke onset, and parameters of the eye ipsilateral and contralateral to the brain lesion were considered. Stroke outcome was assessed by the 3-month modified Rankin Scale (mRS), obtained from an outpatient follow-up visit or telephone call. The following dichotomizations of the 3-month mRS were used for the statistical analysis: $mRS \leq 1$ vs $mRS > 1$; $mRS \leq 2$ vs $mRS > 2$; $mRS \leq 3$ vs $mRS > 3$. Statistical analyses were performed through univariate and multivariate logistic regression. Optimal thresholds for AP parameters were obtained via Receiver Operating Characteristic (ROC) curves.

Results: 157 patients were included in the study [median age 74.00 (63.00 – 82.00) years, 91 (57.96%) men]. Several AP parameters were

found to be prognostic predictors in the unadjusted analysis, such as dilatation velocity in the eye ipsilateral to the ischemic lesion (DVi), contralateral DV, and contralateral constriction index. In particular, a reduction of DVi was a predictor of poor prognosis for all the outcome models analyzed in the unadjusted analysis (mRS≤1 vs mRS>1: p=0.007; mRS≤2 vs mRS>2: p=0.007; mRS≤3 vs mRS>3: p=0.001) and an independent predictor in the model mRS≤3 vs mRS>3 in the multivariate logistic regression (p=0.022). A DVi<0.875 mm/s predicted an unfavorable outcome with 65% specificity and 56% sensibility.

Discussion and Conclusion: We found that several AP parameters are predictors of ischemic stroke prognosis and that a low DVi is an independent predictor of poor stroke outcome, defined as a three-month mRS>3. Several studies concord on the critical role of AP a in predicting the prognosis of patients with head trauma [1] and after cardiac arrest [2], but only few pieces of evidence are available for patients with stroke [3]. The results of our study suggest that AP may be a useful tool to predict the prognosis of stroke patients and that the automated assessment of pupillary light reflex should be performed routinely in such individuals.

## NEXT GENERATION SEQUENCING AND WHOLE-EXOME SEQUENCING OF PATIENTS WITH SPONTANEOUS CERVICAL ARTERY DISSECTIONS: A PROSPECTIVE, OBSERVATIONAL STUDY

I. Scala[1], V. Trevisan[2], P. Rizzo[1], S. Bellavia[1], J. Di Giovanni[1], F. Colò[1], P. Concolino[3], A. Minucci[4], A. Broccolini[5], C. Leoni[2], G. Frisullo[6]

Study objectives: This study aims to find the pathogenic genetic variants prevalence in an adult cohort of patients with spontaneous Dissection of the Cervical Arteries (CeAD).

Materials and methods: We enrolled consecutive adult patients admitted to a comprehensive Stroke Unit for non-traumatic CeAD with or without stroke. Patients with CeAD who met at least one of the following criteria were included in the study: 1) multiple structural vessel wall abnormalities; 2) family history of arterial dissections/cerebrovascular diseases in youth; 3) clinical/radiological/dysmorphic findings suggestive of genetic diseases.

Exclusion criteria were: 1) Trauma within 3 months from CeAD diagnosis; 2) previous diagnosis of connective tissue diseases; 3) CeAD risk factors (low alpha-1 antitrypsin levels, uncontrolled hypertension). All patients underwent total-body CT and a dysmorphological examination. For eligible patients, a Next Generation Sequencing (NGS) of the clinical exome using the Clinical Exome Solution® kit was performed, followed by the design of 38 genes virtual panel related to genetic conditions associated with vascular fragility. In patients whose NGS was inconclusive, but who met at least two out of three inclusion criteria, a Whole Exome Sequencing (WES) was performed. Bioinformatics analysis was performed using the SOPHiA DDM platform.

Results: NGS was performed in ten patients [40% female, median age:41]; genetic variants were identified in three patients (30%). One female patient showed a heterozygous c.4565T>C variant of uncertain significance of MYLK gene; another woman was found to be affected by Marfan syndrome (heterozygous pathogenic variant c.67392 T>G of FBN1 gene), and a de novo heterozygous pathogenic variant c.1862G>A of COL3A1 gene was found in a male patient affected by vascular Ehlers-Danlos disease. WES was performed in five out of seven subjects (71.4%) with normal NGS and found a heterozygous pathogenic variant c.2371C>T of COL4A3 gene in a woman. The overall prevalence of genetic mutations was 40%. Among the four patients with genetic variants, positive family history was the most represented risk factor (100%), followed by the evidence of multiple vessel wall alterations (75%), and of suggestive clinical/radiological/dysmorphic findings (50%). 50% of patients had all three risk factors.

Discussion and conclusion: We found a genetic variant in 40% of our selected population with spontaneous CeAD suggesting that, in these patients, family history and whole-body vascular anatomy should always be investigated. In accordance with previous literature [1,2], our results suggest that heritability in spontaneous CeAD plays a major role, and that genetic analyses should be performed in patients with at least one suggestive criterion.

## FIBRINOGEN DEGRADATION COAGULOPATHY: A MIRROR OF THROMBOLYSIS EFFECTIVENESS IN STROKE PATHOLOGY?

I. Scali, M. Naccarato, G. Furlanis, G. Prandin, F. Palacino, E. Vincis, L. Mancinelli, P. Caruso, P. Manganotti

Clinical Unit of Neurology, Department of Medicine, Surgery and Health Sciences, Clinical University Hospital and Health Services, University of Trieste (Trieste)

Background and aims: Thrombolysis during ischaemic stroke degradates fibrin matrix of occluding vascular thrombus, reperfunding cerebral tissue; its effect is extended to circulating fibrinogen because of its incomplete specificity, resulting in fibrinogen depletion. Recently several studies demonstrated importance of monitoring fibrinogen levels after thrombolysis to reduce intracerebral haemorrhage risk. Beyond this, our aim was to investigate if there was a different fibrinogen dynamic profile between patients who underwent high successful thrombolysis and patients who experimented low response to endovenous treatment.

Materials: We retrospectively collected ischemic stroke patients admitted to Trieste Stroke Unit and acutely treated with thrombolysis or bridge thrombectomy between January 1st, 2019 and December 31st, 2021 who underwent to a complete fibrinogen monitoring: peripheral blood samples were drawn at baseline and at predefined time-points of 2, 6, 12 and 24 hours after thrombolysis.
Methods: We divided patients into two groups. Group H ("High" successful thrombolysis) included patients with absolute 3 points-difference or relative 50%-difference between admission- and 24 hours-NIHSS score; remaining patients filled Group L ("Low" successful thrombolysis). We evaluated differences using Mann-Whitney U test for numeric or Chi-square test for nominal variables (statistically significance when $p < 0.05$).

Results: 260 patients were included: 140 in Group H, 120 in Group D, without significant differences in age, gender, cardiovascular risk factors, Bamford Classification, TOAST aetiology, onset-to-needle time. Starting from similar baseline values, we found a trend of lower absolute fibrinogen levels in Group H at 6 (median 210 vs 226 mg/dL, p=0.09), 12 (218 vs 236, p=0.06) and 24 hours (240 vs 246, p=0.08). A sub-analysis including patients who underwent to thrombolysis alone (109 in Group H and 93 in Group L) showed significant high fibrinogen drop from baseline in Group H at 2 (77 vs 47 mg/dL, p=0.01) and 6 hours (92 vs 58, p=0.04).

Discussion: Our study suggest a different fibrinogen profile between ischaemic patients who underwent high or low successful treatment: monitoring step-by-step fibrinogen levels in the first 24 hours after thrombolysis, we noted steady lower values in patients with higher improvement from stroke symptoms. Focusing on thrombolysis alone, fibrinogen drop occurs especially in the first 2-6 hours. In this way, rTPA-related fibrinogen degradation coagulopathy could be a mirror of thrombolysis strength in dissolving local cerebral thrombus.

Conclusions: In addition to preventing intracerebral haemorrhage risk, monitoring the curve of fibrinogen levels in the first 24 hours could be useful to follow thrombolysis efficacy in stroke patients.

## HISTOLOGIC ASSESSMENT OF CEREBRAL VENOUS THROMBUS RETRIEVED FROM ENDOVASCULAR THROMBECTOMY: FIRST CASE REPORT

G. Schwarz[1], A. Cascio Rizzo[1], M. C Aquilano[1], M. Di Como[1], M. Bacigaluppi[2], A. Cervo[1], A. Macera[1], G. Pero[1], F. De Angeli[1], C. Ceresa[1], C. Motto[1], R. Tortorella[1], A. Guccione[1], A. Gatti[1], E. Bonoldi[1], M. Piano[1], E. C Agostoni[1]

[1]ASST Grande Ospedale Metropolitano Niguarda (Milano); [2]IRCCS San Raffaele Scientific Institute (Milano)

Background: Endovascular thrombectomy (EVT) is a treatment option in patients with cerebral venous thrombosis (CVT) who deteriorate despite anticoagulant treatment. Histologic assessment of the thrombi removed in CVT may provide insights into the pathophysiology of the disease and allow advancements in treatment.

Case report: A 47-year-old woman (smoking habit and estradiol/progesterone-releasing intra-uterine device) diagnosed with massive CVT, underwent EVT (complete recanalization via aspiration catheter and stentriever) due to acute-onset left-sided weakness and dysarthria despite 72h of full-dose subcutaneous low-molecular heparin. Two main reddish clots (maximum diameter 15 mm) were retrieved. Microscopic assessment showed an erythrocyte-rich thrombus (83.9% of entire thrombus surface) with layers of platelets/fibrin: lines of Zahn (13.9% of entire thrombus surface). The scarce inflammatory cells were predominantly (90%) intact neutrophilic granulocytes (MPO+), mixed with scant T-lymphocytes (CD3+) and macrophages (CD68+). We found no evidence of hemosiderin (Iron Stain with Prussian Blue Stain/Pearl's stain), endothelial cells (CD34+), plasma cells (CD138+) or B-lymphocytes (CD20+). Other etiological evaluations were unremarkable, with complete clinical recovery.

Conclusion: This is the first case report of CVT with complete histologic assessment of thrombus retrieved via EVT. Similar to ischemic stroke, thrombus assessment in CVT may provide insights into the pathophysiology of the disease and guide treatment advancements.

## MULTIMODAL OUTCOME PREDICTION IN LARGE-VESSEL-OCCLUSION ISCHEMIC STROKE, COMBINING PERFUSION-BASED PARAMETERS AND TIME-TO-IMAGING

G. Schwarz[1], E. C Agostoni[1], G. Saliou[2], S. Hajdu[2], A. Salerno[2], V. Dunet[2], P. Michel[2], D. Strambo[2]

[1]Department of Neurology and Stroke Unit, ASST Grande Ospedale Metropolitano Niguarda (Milano); [2]CHUV (Lausanne-CH)

Background: Early infarct growth rate ([EIGR] ischemic core / time to imaging [TTI]) is a promising parameter to predict outcome in patients with ischemic stroke (AIS) due to large vessel occlusion (LVO). The prognostic value of other parameters such as the rate of regression of the ischemic penumbra (Early-Penumbra-Reduction Rate [EPRR]: penumbra/TTI) and the Penumbra-to-Core-Rate ([PtCR] (ischemic penumbra/ischemic core)/TTI) has never been studied.

Methods: From ASTRAL registry we included LVO patients with available baseline perfusion metrics. EIGR, EPRR and PtCR were calculated for each patient. The association with outcome (90-day mRS 0-2 and (un)favorable point shift in 90-day mRS) of perfusion-based parameters (considered both as continuous variable and as dichotomized variable [fast versus slow progressors]) was assessed via multivariate regression analysis and comparing area under the receiver operating characteristic curve (AUROC) (via likelihood ratio [LR] tests). Cutoff to define fast/slow progressors, for each perfusion parameter, were defined by maximizing the Youden Index.

Results: Two hundred forty-eight patients were included. All dichotomized perfusion-based parameters were independently associated with

90-day mRS 0-2 (EIGR aOR 3.04 [95%CI 1.48-6.2] p=0.002; EPRR aOR 0.38 [95%CI 0.17-0.81] p=0.012; PtCR aOR 0.38 [95%CI 0.19-0.80] p=0.010). When considered as continuous variable, EPRR (aOR 0.63 [95%CI 0.40-0.99] p=0.046) and PtCR (aOR 0.77 [95%CI0.62-0.96] p=0.022) (but not EIGR) were independently associated with 90-day mRS 0-2. Compared to EIGR and EPRR, PtCR had the best predicting AUROC, both as dichotomized variable (0.62 versus 0.63 versus 0.68 [9%%CI 0.63-0.74] LR test p value < 0.001) and as continuous variable (0.60 versus 0.67 versus 0.73 [95%CI 0.66-0.80; LR test p value < 0.001).

Conclusion: Perfusion-based parameters combined with time-based parameters are promising predicting metrics. The ratio combining (1) ischemic core, (2) penumbra and (3) time-to-imaging (Penumbra-to-Core Ratio) has the highest prognostic predicting value.

## REPERFUSION TREATMENT IN BASILAR ARTERY OCCLUSION WITH MILD SYMPTOMS

G. Schwarz[1], A. Cascio Rizzo[1], M. Matusevicius[2], C. Roffe[3], D. Toni[4], E. C Agostoni[1], N. Ahmed[2]

[1]ASST Grande Ospedale Metropolitano Niguarda (Milano); [2]Karolinska Institute (Stockholm-S); [3]Keele University (Stoke-on-Trent-UK); [4]Sapienza University (Roma)

Background: Endovascular treatment (EVT) improves outcome after basilar artery occlusion (BAO) in patients with moderate to severe neurological deficits. However, optimal treatment for BAO with mild symptoms (NIHSS score 0-5) is unknown, both in the early (0-6 h from onset) and the late (>6 to 24 h) time windows. To determine whether EVT improves outcomes after BAO with mild symptoms we (1) compared EVT+/-IVT versus IVT alone in the early-time-window and (2) mild versus non-mild symptom BAO for EVT+/-IVT in the late-time-window.

Methods: From SITS-International Stroke Thrombolysis and Thrombectomy Register we included consecutive BAO patients between 2015 and 2022 treated by EVT, IVT or both within 24h from symptoms onset. Via Doubly Robust approach (propensity score matching [PSM] plus multivariate logistic regression), we compared efficacy (3-month modified Rankin Scale [mRS]) and safety (symptomatic ICH [SICH] and death at 3-month) outcomes in the early-time-window (onset-to-treatment ≤6h) in mild BAO (EVT+/-IVT versus IVT-alone) and in the late-time-window (onset-to- EVT+/-IVT treatment > 6h): mild-BAO versus non-mild-BAO.

Results: 1862 patients were included (median NIHSS score 13 [IQR 7-23]; 1361 (74.9%) treated in early-time-window). For patients with mild symptoms in the early-time-window (178 matched patients, with 1:1 ratio) functional outcome was significantly worse with EVT+/-IVT than with IVT alone (aOR for mRS 0-2 0.27 [95%CI 08 - 89] p=0.016; aOR for mRS 0-3 0.20 [95%CI 0.06-0.61]; p = 0.05). In the late-time-window (150 matched patients, with 1:2 ratio) mRS 0-2 (aOR 7.89 [95%CI 2.18-28.52];p=0.002), mRS 0-3 (aOR 7.57 [95%CI 2.09-27.42];p=0.002 and mortality (aOR 0.88 [95%CI0.02-0.37];p=0.001) with EVT+/-IVT were significantly better for mild BAO than for non-mild BAO. This difference disappeared after including baseline NIHSS score in adjusted analysis. There were only 2 SICH in both PSM-based analyses.

Conclusion: Our study on BAO patients presenting with mild symptoms suggest that (1) IVT alone may be the preferred choice in the early-time-window, while (2) EVT+/-IVT can be a treatment option even in the late-time-window for these patients. Randomized trials are needed to identify the optimal reperfusion therapy for patients with BAO and mild symptoms.

## ISCHAEMIC STROKE IN PATIENTS WITH KNOWN ATRIAL FIBRILLATION: THERAPEUTIC DECISIONS IN CLINICAL PRACTICE AND POSSIBLE FUTURE PERSPECTIVES

G. D. Scrima[1], F. Meucci[2], G. Pracucci[1], C. Rapillo[1], B. Piccardi[3], M. Stolcova[2], F. Ristalli[2], A. Mattesini[2], C. Nozzoli[4], A. Morettini[5], A. Moggi Pignone[6], P. Nencini[3], C. Di Mario[2], C. Sarti[1]

[1]NEUROFARBA Department, University of Florence (Firenze); [2]Structural Interventional Cardiology, Careggi University Hospital (AOUC) (Firenze); [3]Stroke Unit, Careggi University Hospital (AOUC) (Firenze); [4]Internal Medicine 1, Careggi University Hospital (AOUC) (Firenze); [5]Internal Medicine 2, Careggi University Hospital (AOUC) (Firenze); [6]Internal Medicine 4, Careggi University Hospital (AOUC) (Firenze)

Introduction: The best prevention for ischemic stroke due to atrial fibrillation (AF) is oral anticoagulant therapy (OACT) either VKA or DOAC. [1] Left atrial appendage occlusion (LAAO) represents an alternative if OACT is contraindicated. [1] Ischemic stroke despite OACT can occur in patients with AF due to: -stroke unrelated to AF; -cardioembolic stroke due to AF in case of a) poor INR control on VKA; b) poor compliance to or sub-optimal dosage of DOAC, c) despite adequate OACT, i.e Resistant Stroke (RS) [2].

Aims: To describe the secondary prevention strategies undertaken in patients with known AF and ischemic stroke. To estimate the percentage of RS.

Materials and Methods: Retrospective analysis of patients hospitalized for ischemic stroke and known AF. Pathogenesis defined according to TOAST criteria. Prevention therapy on admission, recommended therapy at discharge, therapy at follow-up, outcome were recorded. Definition of adequate OACT: -VKA if INR≥1,7; -DOAC if indications/dosage followed European guidelines, and if good compliance was declared or plasmatic levels were in range.

Results: We identified 226 patients, 61% female, median age 84.04 years, IQR 77.9-88.6. Admission therapy: 53% OACT (32% VKA, 21%

DOAC), 1% LAAO, 32% antiplatelet or low molecular weight heparin (LMWH), 14% no therapy. Seventy% of stroke were classified as cardioembolic. At discharge, OACT was recommended to 85% of patients that on admission were on antiplatelets or did not take any therapy. Survival at follow-up resulted significantly higher in patients on DOAC compared to those on antiplatelets or LMWH ($p<0.001$) after adjustment for age by Cox regression. OACT resulted adequate in 52.1% (44 VKA, 18 DOAC), non-adequate in 37.8% (28 VKA, 17 DOAC), uncertain in 10.1% (12 DOAC). Fifty-seven% of patients on adequate OACT presented a RS(70%VKA, 30%DOAC). Recommended therapy at discharge in RS group: -DOAC: 2 maintained with their therapy, 2 were shifted to VKA, 5 to another DOAC and 3 to non-specified OACT. -VKA: 7 maintained with VKA, 5 were shifted to DOAC, 7 to non-specified OACT and 2 unknown.

Discussion: Fourty-six% did not take OACT on admission despite lack of contraindications. OACT was not adequately assumed in 37,8%. More than 50% of patients on adequate OACT presented a RS.

Conclusions: Adequate OACT may be insufficient to prevent AF-related embolism and subsequent therapeutic decisions are empirical. Specific LAA morphologies are associated with higher thrombosis risk [3] potentially resistant to OACT. LAAO as add-on therapy to OACT could be an option worthy to be explored.

## PRIMITIVE ANGIITIS OF THE CENTRAL NERVOUS SYSTEM: KALEIDOSCOPIC PRESENTATION, DIAGNOSIS AND TREATMENT

G. D. Scrima[1], A. Picchioni[2], A. Matucci[3], M. Nesi[2], A. Buccoliero[4], L. Bordi[5], F. Meucci[6], C. Sarti[1]

[1]NEUROFARBA Department, University of Florence (Firenze); [2]Stroke Unit, Città di Castello Hospital USL Umbria 1 (Città di Castello-PG); [3]Immunoallergology, Careggi University Hospital (AOUC) (Firenze); [4]Pathological Anatomy, Careggi University Hospital (AOUC) (Firenze); [5]Neurosurgery, Careggi University Hospital (AOUC) (Firenze); [6]Structural Interventional Cardiology, Careggi University Hospital (AOUC) (Firenze)

Background: Primitive angiitis of the central nervous system (PACNS) represents a diagnostic challenge for its rarity and presentation [1].

Materials and Methods: On November 2020, a 50-year-old man arrived at the emergency room for loss of consciousness and generalized tonic-clonic movements preceded by paresthesia of the left upper limb. Neurological examination was unremarkable. A brain-CT revealed a lesion in the right upper parietal cortico-subcortical area without mass effect. At contrast MRI: showed a moderately increased diffusion, with an irregular graphic impregnation with a gyriform morphology following the cortical pattern with hypoperfusion at the subcortical level and an inconstant increase in microvascular permeability in cortical area. The lesion was classified as ischemia in subacute evolutionary phase. Patient's cardiovascular risk factors: hypertension, grade II obesity, past smoking habits, and alcohol abuse. After a thoroughly research of ischemic stroke cause only a permanent patent foramen ovale(PFO), severe after Valsalva maneuver, was found. He had no deep vein thrombosis in legs and in pelvis, nor pro-thrombotic diathesis. Percutaneous PFO closure was proposed by Heart&Brain Team; the intervention was postponed for patient's choice.

Results: On February 2021 he developed left lateral hemianopsia, difficulty in left-hand coordination, and left leg hypoesthesia. MRI showed an increased lesion volume and metabolic disease/vasculitis/neoplasm were hypothesised. Perfusione and spectroscopy brain MRI revealed deep hypoperfusion of the lesion, with irregular increase in cortical microvascular permeability, elevation of Choline peak, lowering of N-Acetyl-Aspartate and a double inverted peak in Lactate indicative of hypoxia Total body PET ruled out neoplasm and systemic signs of inflammation. Serological and urinary screening excluded metabolic disease. He further deteriorated on walking and balance, so invasive investigations were carried out: -lumbar puncture: no cellular or protein increase; -brain biopsy: inflammatory infiltrate mainly mononuclear, with immunophenotype T (CD3 ++; CD20, CD79a +/-, CD30 +/-) which thickened in the perivascular and vascular walls; a histiocyte-macrophage infiltrate (CD68 +) was also documented.

Conclusions: PACNS was diagnosed. The whole diagnostic process took about 1 year. The patient was treated with high-dose intravenous steroids and cyclophosphamide without benefit. Anti CD20 therapy was then begun.

Discussion: Onset with seizure without neurological signs in the presence of cerebral lesion should rise the suspect of "atypical" ischemia or something else. When suspecting a small vessel PACNS a cerebral biopsy and consecutively appropriate therapy should not be delayed. The attributable role of PFO is still challenging in clinical practice.

## MYLK GENE MUTATION IN FUSIFORM BASILAR ARTERY ANEURYSM: TWO CASE REPORTS

S. Seri[1], M. Dell'Acqua[2], B. Riboli[3], M. Gatti[3], L. Paganini[3], L. Vandelli[2], F. Rosafio[2], G. Borzì[2], R. Ricceri[2], L. Picchetto[2], S. Meletti[1], G. Bigliardi[2]

[1]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia (Modena); [2]Stroke Unit, Neurology Unit, Department of Neuroscience, Ospedale Civile Baggiovara, Azienda Ospedaliera Universitaria di Modena (Modena); [3]Medical Genetics, Azienda Socio-Sanitaria Territoriale (ASST) di Cremona (Cremona)

Introduction: Vertebrobasilar fusiform aneurysms have low incidence and male predominance [1], but only few studies focus on the genetic pathogenesis. MYLK gene mutation is already known in patients with aortic aneurysm, but we have no evidence about its role in vertebrobasilar fusiform aneurysm. We present two patients with fusiform basilar artery aneurysm and two different MYLK gene variants. Patients showed a prevalent compressive effect on brainstem and ischemic complications due to the perforating arteries occlusion by an intra-aneurysmatic thrombosis; none of them had the rupture of the aneurysm.

Cases 1: A 50 years-old man, with hypertension and dyslipidemia, was admitted with a posterior circulation TIA, and MRI imaging showed

a partially thrombosed fusiform basilar aneurysm. During the seven years of follow-up, he showed progressive worsening of neurological symptoms mainly due to the aneurysm growth with a brainstem compressive effect. Thus, antiplatelet therapy was started, together with cycles of steroid therapy, with only partial clinical benefits. Genetic exam revealed heterozygous MYLK variant (c.1348_1356delinsTCT,p.(Glu450_Thr452delinsSer)). Further studies showed thoracic aortic dilatation, without any other aneurysm. No other family member had vascular diseases.

Case 2: A 52 years-old man with hypertension, dyslipidemia, and obesity, was admitted for a partially thrombosed fusiform, basilar aneurysm discovered after a brainstem ischemic stroke. After multiple ischemic relapses during antiplatelet therapy, an anticoagulant therapy was started. The patient showed a clinical stability for over three years of follow-up, but neuroimaging showed a progressive growth of the intra-aneurysmatic thrombosis. Genetic study showed two rare heterozygous mutations: MYLK gene (c.4336G>A,p.(Glu1446Lys)), and LOX one (c.840C>A,p.(Ser280Arg)). Abdominal Angio-MR showed an aortic sub-renal ectasia, but no other systemic aneurysm. About his family, the mother died after hemorrhagic stroke due to an intracranial aneurysm rupture, and a sister, who refused genetic tests, had an aortic ectasia.

Discussion: MYLK gene mutation has never been described in patients with intracranial aneurysm. These two patients have basilar artery aneurysm and two different MYLK gene variants of uncertain significance (Class 3 ACMG). Both aneurysms are fusiform, like what is described for aortic ones. Furthermore, the second patient presents a probably pathogenic LOX gene mutation (Class 4 ACMG), but the interaction between these two gene variants is unknown. As for the treatment, we decided to apply two different conservative medical treatments based on the different clinical presentation.

Conclusion: The aim of these two case reports is underlying the possible association between MYLK gene mutation and basilar artery fusiform aneurysm.

## EARLY LOADING DOSE OF DUAL ANTIPLATELET TREATMENT IN ACUTE ISCHEMIC STROKE ASSOCIATED WITH TANDEM LESIONS

E. Spina[1], P. Candelaresi[1], A. de Mase[1], G. Servillo[1], S. Barbato[1], G. Leone[2], G. Guarnieri[2], A. di Donna[3], V. Opancina[4], S. Jankovic[5], F. Giordano[2], M. Muto[2], M. Muto[2], V. Andreone[1]

[1]Neurology and Stroke Unit, AORN A. Cardarelli (Napoli); [2]Diagnostic and Interventional Neuroradiology, AORN A. Cardarelli (Napoli); [3]Unit of interventional neuroradiology, University of Campobasso (Campobasso); [4]Department of Radiology, University of Kragujevac (Kragujevac-SRB); [5]Department of Pharmacology and Toxicology, University of Kragujevac (Kragujevac-SRB)

Introduction: Acute antiplatelet treatment in tandem lesions treated with intravenous thrombolysis (IVT) and endovascular thrombectomy (EVT) including acute carotid stenting (CAS) is challenging as a careful balance between the risk for parenchymal hematoma (PH) and stent thrombosis is needed.

Aim: To investigate the effects of early (within 12 hours) loading dose of Aspirin and Clopidogrel (A+C) after IVT and EVT plus CAS.

Methods: A retrospective analysis from a single center was performed. The main outcome was occurrence of PH. Secondary outcomes included rate of stent thrombosis, mortality, and independence at 90 days.

Results: The study included 71 patients. All patients received IVT and EVT plus CAS and 500 mg Aspirin. 7 patients did not receive any Clopidogrel treatment: 2 because of early stent thrombosis and 5 due to early PH. In the 64 patients receiving adjunctive Clopidogrel, both timing of treatment (early versus late) and dosing (300 mg versus 75 mg) did not affect the rate of PH (4.4% versus 8.3% versus 13.8% respectively [p NS]). Lower pre-Clopidogrel ASPECTS was the only significant predictor of PH (OR 0.333, 95% CI 0.148 – 0.753), and ASPECTS <8 predicted the development of PH (sensitivity 78%, specificity 73%). Stent occlusion occurred less frequently in patients treated with early loading dose (0% versus 8.5%). Rate of mortality and independence did not differ.

Conclusions: Administration of a loading dose of A+C within 12 hours after IVT and EVT plus CAS in tandem lesions resulted safe in terms of hemorrhagic transformation and effective in preventing stent thrombosis.

## SELECTIVE USE OF BRAIN MRI IN SYMPTOMATIC PATIENTS CANDIDATES FOR CAROTID ENDARTERECTOMY: INSIGHTS FROM SAN GIOVANNI DI DIO HOSPITAL, FLORENCE

M. Squitieri[1], C. Biagini[2], L. Tramacere[2], A. Borgheresi[2], B. Chiocchetti[2], I. Donnini[2], G. Lucidi[2], M. Piccininni[2], L. Raglione[2], V. Rinnoci[2], D. Caimano[2], S. Dallagiacoma[2], M. Baruffi[3], C. Alessi[3], A. Faraone[3], E. Chisci[4], A. Guidotti[4], C. Pigozzi[4], C. Cardinali[2], C. Alaimo[2], M. Calistri[2], E. Del Sordo[2], A. Gallerini[2], M. Hezayen[2], T. Furlan[2], C. Sarti[2], R. Sterpu[2], D. Battista[2], A. Fortini[3], M. Michelagnoli[4], A. Poggesi[1], M. Cincotta[2]

[1]Department of Neurosciences, Psychology, Drug Research and Child Health NEUROFARBA - University of Florence (Firenze); [2]Department of Medicine, Neurological Unit, San Giovanni di Dio Hospital (Firenze); [3]Internal Medicine, San Giovanni di Dio Hospital (Firenze); [4]Department of Surgery, Vascular and Endovascular Surgery Unit, San Giovanni di Dio Hospital (Firenze)

Objectives: Symptomatic patients with carotid stenosis >50% require accurate clinical and instrumental assessments to evaluate the indication for early revascularization. Since, there is an increasing demand for emergency MRI due to new thrombolysis guidelines, it is crucial to define an appropriate use of brain MRI to ensure patients receive the most effective treatment while optimizing the allocation of economic resources. We analysed the application of brain MRI in a series of patients eligible for early carotid endarterectomy (CEA) in order to investigate the impact of brain MRI on the treatment decision and its effect on the timing of the intervention.

Methods: We conducted a retrospective observational study on consecutive symptomatic patients presenting carotid stenosis >50%. They were admitted to the Stroke Unit of San Giovanni di Dio Hospital between January 2016 and April 2021. The patients were divided in two groups: one group underwent early CEA following a multidisciplinary assessment, while the other group did not undergo the procedure. Furthermore, within each group, we further distinguished between patients who underwent brain MRI and those who did not.

Results: Out of the 218 patients included in the study, 179 patients underwent early CEA, while 39 patients did not undergo the procedure.

Among the patients treated, MRI was performed in 26 (14.5%). The time from symptom onset to CEA was measured to be 6.56 ± 4.51 days in the group that underwent MRI, while in the group that did not undergo MRI, it was 4.79 ± 3.64 days (p = 0.07). Likewise, in the MRI group, the interval from hospital admission to CEA was found to be 4.19 ± 2.88 days, whereas in the group that did not undergo MRI, it was 2.62 ± 2.02 days (p = 0.01). Among the patients who did not undergo early CEA, MRI was performed in 43.6% of cases. In 94.1% of those cases, the MRI results influenced the treatment decision.

Conclusions: The data indicate that the selective use of brain MRI in patients eligible for early CEA has a significant impact on the therapeutic decision in the majority of cases. This highlights the usefulness of MRI in the preoperative diagnostic workup. Although MRI slightly extended the average duration of hospitalization, it did not lead to a significant increase in the interval between symptom onset and CEA beyond the optimal threshold.

## A NOVEL NOTCH3 MUTATION CAUSING A NON-CYSTEINE CHANGE ASSOCIATED WITH CEREBRAL ARTERIOPATHY WITH SUBCORTICAL INFARCT AND LEUKOENCEPHALOPATHY (CADASIL)

G. Stufano[1], V. Arnao[2], G. Schirò[1], G. Sorbello[1], G. Salemi[1], P. Ragonese[1], M. D'Amelio[1], P. Aridon[1]

[1]Department of Biomedicine, Neuroscience and Advanced Diagnostics (BiND), University of Palermo (Palermo); [2]Neurology - Stroke Unit, A.R.N.A.S. Civico (Palermo)

Objective: To report a rare cause of CADASIL with a transversion in exon 18 of NOTCH 3 gene causing a non-cysteine change and its implication.

Design/Methods: We screened a patient with headache, vascular leukoencephalopathy and history of stroke for NOTCH3 mutations. Following informed consent, total genomic DNA was extracted from peripheral blood leukocytes using standard procedures, polymerase chain reaction (PCR) was performed with primers (comprising intron–exon boundaries) specific for exons 2–24 of the NOTCH3 gene and sequencing of these purified PCR products was performed.

Results: A 39-year old female patient with a history of stroke, three years before, hypertension, hypercholesterolemia, migraine, atonic seizures and ischemic cardiomyopathy, was admitted to hospital for the onset of asthenia, postural instability, dizziness, nausea and headache. CT scan revealed a colloid cyst of the third ventricle and the two previous ischemic lesions in left fontal and right parietal lobe. Neurological examination revealed only left-side hemiparesis, result of previous stroke, and a movement disorder characterized by dystonic features of the hands. Her emotions were noticeably unstable and neuropsychological assessment revealed no cognitive impairment. The results of ultrasound of carotid artery, electrocardiography and echocardiography, electroencephalography and Transcranial Doppler sonography (TCD) and were normal. Brain MRI showed in correspondence of the III ventricle, in the median area a 7 mm colloid cyst and multiple symmetric white matter hyperintensities in correspondence of the deep white matter and the two lesion in left frontal and right parietal lobe to be referred to gliotic outcomes. Brain magnetic resonance angiography was normal. A skin biopsy was refused by the patient. Considering the clinical symptoms, the MRI features and the CADASIL Scale Score the diagnosis of CADASIL was suspected. Genetic sequencing revealed a novel mutation, c.2918C>A. This transversion in exon 18 cause a probably pathogenetic (class 4) aminoacid change in position 973 (p.His973Pro). Genetic analysis was declined by the sister of the proband. The 973 Histidine is highly conserved during evolution as demonstrated by a phylogenetic analysis of NOTCH3 performed on BLASTP. Multiple sequence alignment with this conserved 973 Histidine were reported in in different species out of 100 orthologs vertebrate sequences analysed.

Conclusions: CADASIL with a point mutation in exon 18 of NOTCH 3 gene causing a non-cysteine change may present with milder disease and MRI phenotypes.

## ISOLATED INSULAR STROKE: TOPOGRAPHY IS THE ANSWER FOR GOOD OUTCOME AND CARDIAC INVOLVEMENT

S. Tartaglia[1], F. Kuris[1], R. Sperotto[1], L. Ceccarelli[1], D. Bagatto[2], S. Lorenzut[3], G. Merlino[4], M. Valente[1], G. Pauletto[3]

[1]Clinical Neurology Unit, University of Udine Medical School (Udine); [2]Division of Neuroradiology, Udine University Hospital (Udine); [3]Neurology Unit, Udine University Hospital (Udine); [4]Clinical Neurology Unit, Udine University Hospital (Udine)

Objective: To describe relevant features of pure insular stroke, focusing on cardiovascular factors.

Materials: Data were retrospectively collected from medical charts and consisted of demographic and baseline clinical characteristics, comorbidities, electrocardiograms, echocardiograms, stroke topography and etiology, reperfusive treatments, and outcome measures.

Methods: We identified 15 isolated insular ischemic strokes, visually assessed by a board-certified Neuroradiologist, occurred between January 1 st 2020, and December 31st 2021. Stroke etiology was defined according to TOAST classification. Outcome measures included NIHSS and mRS at discharge, in-hospital mortality, major neurological improvement at discharge and 3-months mRS.

Results: Five patients had history of atrial fibrillation (AF), while, in four cases, AF was newly detected. Other kinds of newly detected arrhythmias were found in eight patients. Three patients showed severe left atrial dilatation, while three other patients showed mildly reduced left ventricular ejection fraction. 80% of patients showed left insular involvement with middle cerebral artery (MCA) occlusion. Cardioembolism was the most frequent etiology. Regarding onset symptoms and signs, language disorders were most frequently

observed, followed by motor and somatosensory deficits. Newly detected cardiovascular alterations were found in 66,7% of cases, being the prevalent atypical presentation. Bridging therapy (rtPA + MT) was performed in most cases. Median NIHSS at discharge was 0 (baseline 11) and median mRS was 2 (baseline 0), while 3-months mRS was 0. Most of patients had major neurological improvement at discharge and good outcome at 3-months follow-up.

Discussion: Our findings showes that cardioembolism is the main pathological mechanism for insular stroke, in contrast to a recent review where cryptogenetic etiology appears to be the main one [1]. Cardiac alterations were frequently discovered during the acute phase, as the insula is known to play a key role in autonomic control [2]. The majority of our patients were discharged with slight disability and no disability was found at 3-months follow-up: thus, in line with previous studies, pure insular strokes seem to have a favorable outcome [3].

Conclusions: Our data suggest the possibility for isolated insular strokes patients to completely recover after acute ischemic stroke, notwithstanding the pivotal role of the insula in cerebral connections and the frequent association with MCA occlusion. Cardioembolism and cardiac arrhythmias must be taken into considerations. To our knowledge, this is the largest case series of pure insular stroke and might be useful for future systematic reviews.

Anna Hospital (Ferrara); [6]Department of Neurology and Stroke Center, IRCCS Institute of Neurological Sciences, Maggiore Hospital (Bologna); [7]Department of Neuroradiology - Charité - Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin (Berlin-D); [8]Cardiovascular and Emergency Medicine, Stroke Unit, University of Perugia/Azienda Ospedaliera Santa Maria Della Misericordia (Perugia); [9]Department of Continuity of Care and Frailty, Neurology Unit, ASST-Spedali Civili (Brescia)

Objective: To describe the recovery trajectories of patients with primary spontaneous intracerebral hemorrhage (ICH) patients from 90 days to 1 year after the index event and to investigate predictors of functional outcome improvement.

Materials & methods: Retrospective analysis of patients admitted to six European Stroke Centers for supratentorial ICH. Functional outcome was measured with the modified Ranking Scale (mRS) at 90 days and 1 year. Predictors of functional outcome improvement were explored with binary logistic regression, adjusted for known prognostic factors and variables with $p<0.1$ in univariate analysis.

Results: A total of 703 patients were included (median age 77, 56% males) of whom 245 (34,9%) died within three months. Among survivors, 28,6% had an improvement of mRS from 90 days to 1 year, 17% had a worsening of mRS and 54,4% had a stable functional status. Age (Odds Ratio (OR) per 1 year increase, 0,980; 95% Confidence Interval (CI), 0,963-0,996, p=0,016) and pre-stroke disability (OR per 1 point mRS increase at baseline, 0,764; 95% CI, 0,625-0,934, p=0,009) were associated with lower odds of functional improvement. Conversely, patients with deep hemorrhages were more likely to experience long-term mRS improvement (OR, 1,725; 95% CI, 1,100-2,705, p=0,018). Of note, traditional acute phase predictors like ICH volume, Glasgow Coma Scale score and ventricular hemorrhage presence were not associated with long-term changes in functional outcome.

Discussion: ICH is a disabling condition and most survivors have great morbidity and mortality during the acute phase. Most ICH trials assessed outcomes at 3 months, but recent evidence has shown that recovery trajectories may continue up to 1 year after ICH [1]. Our findings support this evidence and indirectly confirms the need for full medical support in the acute phase. [2]

Conclusions: Functional outcome recovery is common beyond 90 days from acute ICH. Our findings might inform future trials and improve prognostication in clinical practice.

## MULTIPLE STROKES IN A PATIENT WITH EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS: A CASE REPORT

A. Troisi[1], D. Cerone[2], R. Ornello[1], S. Sacco[1]

[1]Department of Applied Clinical Sciences and Biotechnology, University of L'Aquila (L'Aquila); [2]Neurology and Stroke Unit, Hospital S. Salvatore (L'Aquila)

Eosinophilic granulomatosis with polyangiitis (EGPA) is a small and medium-vessels vasculitis with systemic involvement, such as the respiratory tracts, skin, heart and kidney. Although neurologic manifestations of EGPA are reported, they are limited to peripheral neuropathy, and central nervous system (CNS) manifestations are poorly described. This case report aims to describe CNS involvement in EGPA in a patient with several confounders in her medical history. A 65-years-old woman with history of asthma, atrial fibrillation (AF), chronic ischemic heart disease, polycythemia vera, dyslipidemia, and hypertension was admitted due to sudden onset of chest pain accompanied by nausea. Blood tests revealed elevated cardiac enzymes and an ECG indicated ST-segment depression. Transthoracic echocardiography appeared normal. Coronary angiography didn't reveal occlusions. Systemic revascularization was not recommended due to recent anticoagulant use. Approximately 36 hours after symptom onset, the patient suddenly appeared drowsy and exhibited confabulations. A brain MRI performed 3 hours after neurological onset revealed multiple areas of microvascular tissue distress with hyperintensity in

diffusion weight imagine (DWI): subcortically in bilateral thalamus, corpus callosum, perirolandic, occipital and cortically in cerebral and cerebellar hemispheres. Neurological examination showed right limb plegia and Bouchard nodules on both hands. The routine blood tests showed hypereosinophilia (4.000/µl), elevated C-reactive protein (50.4 mg/dl) and high hemoglobin levels. Thrombophilia screening yielded negative results. Serum tests were negative for p-ANCA. Electroencephalogram (EEG) showed diffuse slowing consistent with multiple brain lesions. Electroneuromyography did not reveal peripheral neuropathy. Doppler imaging ruled out significant stenosis in the epiaortic vessels. The diagnosis of EGPA was considered given the history of asthma, extravascular eosinophilia and clinical and laboratory features. Immunosuppressive therapy was started with prednisolone for 5 days, but the patient's general conditions didn't improve. A follow-up brain MRI showed a reduction in lesion load in DWI, but with some persisting areas, indicating ischemic lesions. In response to the incomplete response to treatment, mycophenolate and rituximab were added. Two weeks later, the patient significantly improved her consciousness and muscular strength. She started rehabilitation. This clinical case highlights the possible differential diagnosis of multifocal brain lesions due to an inflammatory (vasculitis) or ischemic etiology. The presence of AF initially led to misleading suspicions, but the combination of clinical and laboratory features attributable to EGPA, allowed for a correct diagnosis and treatment. Moreover, compared to the literature, the widespread and multiple spread of the disease in CNS involvement of EGPA necessitated the use of a combined second-line therapy.

## ACUTE ISCHEMIC STROKE ASSOCIATED WITH LEFT VENTRICULAR THROMBUS: A SINGLE CENTER EXPERIENCE

V. Tudisco[1], P. La Spina[1], F. Giammello[1], L. Ferraù[1], C. Vecchio[1], P. Crea[2], G. Di Bella[2], R. Donato[3], M. Fazio[1], A. Naro[1], T. Brizzi[1], R. Musolino[1], A. Toscano[1]

[1]Stroke Unit, Department of Clinical and Experimental Medicine, University of Messina (Messina); [2]Cardiology Unit, Department of Clinical and Experimental Medicine, University of Messina (Messina); [3]Department of Biomedical Sciences and of Morphologic and Functional Images, University of Messina, Azienda Ospedaliera Universitaria 'Policlinico G. Martino' (Messina)

Background: Left ventricular thrombus (LVT) is a known complication in patients with myocardial infarction (MI), primarily in anterior MI [1]. LVT is a rare cause of cardioembolic ischemic stroke (IS) and may remain unrecognized, as "embolic stroke of undetermined source (ESUS)"[2]. Transthoracic echocardiography (TTE) is the first investigation for the detection of LVT, and adding intravenous contrast increases its sensitivity. Cardiac magnetic resonance imaging (MRI) has a high sensitivity and specificity for thrombus delineation. Guidelines recommend treatment with vitamin K antagonists (AVK) for a period of a minimum of 3 to 6 months up to one year [3].

Patients and Methods: At the Stroke Unit of the 'G. Martino' University Hospital of Messina, from 2014 to 2022, out of 2792 patients with acute IS, LVT was reported in 15 patients (mean age = 65.8). 12 patients were discharged with a diagnosis of "cardioembolic IS", with transthoracic echocardiograph LVT detection. 3 patients were discharged with a diagnosis of ESUS and underwent cardio-MRI.

Results: The cardiological assessment with TTE showed diffuse hypo-akinesias and reduced left ventricular ejection fraction (LVEF<50%) in all patients. 13 patients (86%) had an ischemic stroke due to occlusion of a large vessel of the anterior circle, the remaining had bilateral ischemic lesions of the anterior circulation. 8 underwent mechanical thrombectomy, 3 thrombolysis and 4 bridging. 8 patients had hemorrhagic transformation of infarcted brain tissue, 2 of whom did not undergo reperfusion procedures. In 9 patients the TTE found LVT; in 3 patients the TTE showed LVT risk factors, so they performed cardio-MRI with finding of mural thrombosis.

Discussion: In patients untreated with AVK, the rate of stroke or systemic embolization due to LVT is about 15% (2). In particular, while the newly formed thrombus may be highly mobile and protruding into the ventricular cavity, the older thrombus tends to have smooth cavitary surface and typically more static and can be hardly seen at the TTE [2]. Whether there is a high clinical suspect of LVT thrombosis, due to a history of anterior MI or TTE findings (diffuse hypo-akinesia and LVEF<50%), cardio-MRI remains the gold standard examination for LVT detection. This examination should be performed when other methods, such as TTE, are not adequate for diagnostic outcomes.

Conclusions: LVT is a rare cause of cardioembolic IS. In patients with history of MI or presence of TTE risk factors LVT should be suspected in order to follow correct diagnostic/therapeutic procedures.

## A CASE OF A PATIENT WITH ACUTE BULBO-MEDULLARY ISCHEMIC STROKE AND SUDDEN QUADRIPLEGIA IMPROVED AFTER INTRAVENOUS THROMBOLYSIS

C. F. Vecchio, F. Grillo, M. Cotroneo, C. Dell'Aera, G. Fiume, R. Musolino, P. La Spina, A. Toscano

Department of Clinical and Experimental Medicine, University of Messina (Messina)

Introduction: Acute quadriplegia may be the clinical manifestation of potentially life-threatening disorders [1]. If it is caused by a vascular pathology, its early identification became crucial for treatment and prognosis.

Case Presentation: A 64-year-old patient, with a history of heavy smoking, arterial hypertension, dyslipidemia, and cervical spine stenosis (surgically treated five years earlier), was admitted for a sudden onset of anarthria and quadriplegia. In addition, he showed drowsiness, hypoesthesia and right Babinski sign with NIHSS score of 24. Brain CT scan was inconclusive while cervical and brain MRI showed on Diffusion Weighted Imaging (DWI), a hyperintense lesion in the left median-paramedian bulbo- medullary junction at the level of the pyramid decussation. Intravenous thrombolysis was rapidly administered according to ESO criteria [2]. During hospitalization, other causes of sudden quadriplegia were excluded by laboratory examinations. Electrophysiology and electroencephalography were also performed. Because of a lung cancer incidentally found, paraneoplastic encephalitis was excluded because of absence of cytoplasmic and surface

onconeural markers. The neurological pattern progressively improved; the patient was discharged with an NIHSS score of 3 after two weeks.

Conclusions: Acute quadriplegia can be caused by a large variety of central or peripheral nervous system diseases. In case of vascular accidents, a timely intervention is crucial. In this anecdotal case of bulbo- medullary ischemia, a thrombolytic treatment was effective and safe, improving patient clinical condition.

## EFFICACY AND SAFETY OF THROMBOLYSIS FOR ACUTE ISCHEMIC STROKE PERI-PROCEDURAL TO CORONARY ANGIOGRAPHY IN PATIENTS UNDERGOING ANTICOAGULATION WITH UNFRACTIONATED HEPARIN AFTER ANTAGONIZATION WITH PROTAMINE SULPHATE: A CASE REPORT AND REVIEW OF THE LITERATURE

E. Vincis, G. Furlanis, P. Caruso, M. Naccarato, P. Manganotti

Clinical Unit of Neurology, ASUGI (Trieste)

Objectives: Acute cerebrovascular events could be serious, although rare, complications of diagnostic and interventional angiographic procedures, especially coronary angiographies [1]. Usually, these procedures are performed while the patient is undergoing anticoagulation with UFH, which, with the consequent elongation of aPTT, would exclude this subgroup of patients from thrombolytic treatment. We aim to reinforce the idea that intravenous thrombolysis can be safe and effective in treating patients with acute cerebrovascular events following coronary angiographies while on anticoagulation with Unfractionated Heparin (UFH), after adequate antagonization of UFH action with Protamine sulphate.

Materials: We reported the case of a patient who developed acute focal neurological deficits after a coronary angiography performed due to an unstable angina that was treated effectively and safely with intravenous thrombolysis after antagonization of UFH action with Protamine sulphate administration.

Methods: We performed a Pubmed search using the following MeSH terms "(Thrombolysis), (Unfractionated Heparin), (Coronary Angiography) AND (Protamine)", looking for articles reporting cases of patients who developed acute cerebrovascular deficits periprocedural to coronary angiography while on anticoagulation with UFH who underwent intravenous thrombolysis after Protamine sulphate administration.

Results: We reported the case of a patient undergoing coronary angiography for unstable angina on anticoagulation with UFH who, at the end of the procedure, developed left upper limb drift, dysarthria and drowsiness. NCCT was negative (ASPECT score 10) but CTA demonstrated superior cerebellar artery occlusion, thus the patient was not eligible for mechanical thrombectomy. The aPTT on admission to the Stroke Unit was 100.7 s. 50 mg of i.v. Protamine sulphate was administered, with rapid normalization of aPTT (24.5 s) and subsequent prompt initiation of thrombolytic treatment within 4.5 h since symptoms onset. There was an improvement in neurological symptoms, with no evidence of haemorrhagic transformation of the left cerebellar ischemic lesion pointed out by the follow-up NCCT.

Discussion: The case we presented, taken together with the preliminary body of evidence found in the literature [2,3], supports the efficacy and safety of intravenous thrombolysis in patients anticoagulated with UFH after adequate antagonization with Protamine sulphate, especially in the setting of periprocedural acute cerebrovascular events secondary to coronary angiography.

Conclusions: Intravenous thrombolysis after reversal of UFH anticoagulation therapy with Protamine sulphate may be safe and effective in treating ischemic stroke patients and it can increase the number of patients eligible for intravenous thrombolysis.

## THE ROLE OF IPSILATERAL AND CONTROLATERAL CAROTID STENOSIS ON THE OUTCOME OF REPERFUSION TREATMENT FOR ISCHEMIC STROKE

G. Viticchi[1], L. Falsetti[2], A. Riva[1], S. Paolucci[1], S. Malatini[1], M. Cervigni[1], E. Guerrieri[3], M. Bartolini[1], M. Silvestrini[1]

[1]Neurological Clinic, Marche Polytechnic University (Ancona);[2]Internal and Subintensive Medicine, Azienda Ospedaliero-Universitaria delle Marche (Ancona);[3]Emergency Medicine Residency Program, Marche Polytechnic University (Ancona)

Objectives: Carotid stenosis is considered a major risk factor for acute ischemic stroke (AIS). Ipsilateral carotid stenosis (ICS) and contralateral carotid stenosis (CCS) play a different role on AIS severity and prognosis, but few data are available about their impact on interventional therapies efficacy. Aim of this study was to evaluate the impact of ICS and CCS on the efficacy of intravenous thrombolysis (IT), mechanical thrombectomy (MT) or both and of antiplatelet therapy (AT). Moreover, we evaluated the different incidence of major complications (deaths and hemorrhagic infarction) among patients treated by different approaches.

Methods: We enrolled all the consecutive patients admitted for AIS to the Stroke Unit of Azienda Ospedaliero-Universitaria delle Marche and submitted to IT, MT, IT+MT or AT. We established the presence of a significant ICS or CCS ($\geq$ 70%) by ultrasound examination or brain angio-CT or MRI. We collected clinical and instrumental information about our patients and employed as the main outcome measure the delta National Institutes of Health (NIH) Stroke Scale from the symptoms 'onset to the discharge.

Results: We finally enrolled 460 subjects, of which 86 with significant ICS and 38 with CCS. We observed a significant linear trend of delta(NIH) between carotid stenosis categories for patients undergoing IT (p=0,011), MT (p=0,046) and MT+IT, but we did not observe any significant trend among untreated subjects. Delta(NIH) was significantly higher among patients undergoing to any procedure (any procedure: 6[3] versus no procedure: 1[2]; p<0,0001). Actively treated patients showed a more frequent incidence of hemorrhagic infarction during hospitalization (any procedure: 28,5% versus no procedure: 6,9%; p<0,0001), while no significant differences were found in in-hospital death (any procedure: 6,90% versus no procedure: 3,40%; p=0,098).

Discussion: ICS and CCS act in different ways on cerebral hemodynamic, both by microembolization and by collateral circles effectiveness. Their presence influence in a significant way the outcome of AIS patients treated by interventional therapies. The importance of an early diagnosis to start the best medical therapy seems to be central in the prevention of AIS and should be suggested especially in individuals at higher vascular risk.

Gemelli University Hospital (Roma); [12]Department of Neuroradiology, Karolinska University Hospital (Stockholm-S)

Objectives: Hemorrhagic transformation of infarcted tissue (HT) is commonly observed after intravenous thrombolysis (IVT) and endovascular thrombectomy (EVT) in ischemic stroke patients. HT may delay the start of secondary stroke prevention and be associated with increased early stroke recurrence. We aimed to assess whether the presence and severity of intracranial hemorrhage after reperfusion treatment are associated with a delayed start of secondary stroke prevention therapy and to evaluate differences in stroke recurrence within three months.

Materials: We conducted a retrospective matched-control dual-center study collecting data of consecutive patients with ischemic stroke receiving IVT and/or EVT at Fondazione Policlinico Universitario A. Gemelli IRCCS in Rome and at Karolinska University Hospital in Stockholm in Sweden. We classified post-treatment ICH on CT within 36 hours as petechial hemorrhagic infarction (HI), parenchymal hematoma (PH), remote parenchymal hematoma (rPH), subarachnoid hemorrhage (SAH) and intraventricular hemorrhage (IVH) and grouped HI and minor SAH as "minor HT" and PH, rPH, major SAH, and IVH as "major HT".

Methods: Primary outcome was the time between revascularization and the start of any secondary prevention therapy; secondary outcomes were recurrent ischemic and hemorrhagic stroke and death within three months. A logistic regression model was fitted for the patient status (hemorrhagic vs. non-hemorrhagic). Additional analysis was performed using propensity score matching (PSM) to control for selection bias and baseline differences.

Results: The logistic regression model showed a statistically significant delay (median 28 vs 24 hours) in the start of antithrombotics in HT patients. Similar results were observed after PSM. We compared no-, minor- and major-HT patients after PSM and found that both no- and minor-HT patients had similar secondary prevention timings (26 vs 24 hours) and rates of stroke recurrence. In contrast, patients with major HT started antithrombotics later (median time 39 hours) or not at all (21.6%), but stroke recurrence was similar.

Discussion: Minor HT did not delay the start of antithrombotics or anticoagulants compared to no HT, with no significant difference in safety outcomes. Major HT patients remain a clinical challenge with a delayed or lacking start of treatment. In this group we did not see a higher rate of ischemic recurrence, although maybe masked by the elevated early mortality.

Conclusions: In conclusion, HT influences the timing of secondary prevention in ischemic stroke patients undergoing reperfusion treatments. Patients with only petechial or minor subarachnoid hemorrhage may start antithrombotic therapy equally early as those with no hemorrhage with similar safety.

# CLINICAL NEUROPHYSIOLOGY AND BASIC NEUROSCIENCE

## NEUROMODULATION OF CHRONIC PAIN IN FIBROMYALGIC PATIENTS: A NEUROPHYSIOLOGICAL STUDY

G. Aglieco[1], M. Vergari[1], R. Ferrucci[2], A. Naci[1], F. Mameli[1], M. Takeko-Molisso[1], S. Barbieri[1]

[1]S.C. Neurophysiopathology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico (Milano); [2]Department of Oncology and Hemato-Oncology, University of study of Milan (Milano)

Objective: Fibromyalgia is a pathology characterized by widespread chronic pain, fatigue, and psychological symptoms, which affects patients' quality of life. Non-pharmacological treatments, such us non-invasive neuromodulation technique [1] and exercise therapy [2], seem to reduce perceived pain and therefore improve patients' quality of life.

Our study aims at verifying the effect of direct current stimulation, with or without concomitant exercise therapy, on chronic pain in fibromyalgic patients and assess its neurophysiological effects.

Materials: Outcome variables, such us questionnaires on pain (BPI, VAS) and quality of life (SF12, HADS), electroencephalography (EEG) and Laser Evoked Potentials (LEP), will be evaluated before the beginning of each treatment (T0), at one week (T1), at the end of the treatment (three weeks, T2), and again after three months from the start (T3).

Methods: Patients were randomised into three groups: (A) treatment with direct current administered three times a week for three weeks, in sessions of 20 minutes at an intensity of 2 mA; (B) treatment with computer-based training, three times a week for three weeks; and (C) combination of direct current stimulation and computer-based training, alternated during the week, for three weeks. Direct current stimulation was applied on the scalp over somatosensory area (cathode) and on the spinal cord over the 10th vertebra (anode).

Results: Reduction in the scores of the pain assessment scales emerged in all groups. By analyzing the LEP data, we found an increase in the nociceptive threshold and a decrease in the amplitude of N2/P2 responses in T1, T2 and T3 in groups C and A. By analyzing the electrical cortical activity, an increase in the absolute power of the alpha-band rhythm was recorded (8-13 Hz) in both T1 and T2 in group C.
Discussion: Data obtained show a decrease of pain after non-invasive treatment applied, related to significant modification of neurophysiologic parameters studied. This information suggests an involvement of nervous system on genesis and maintenance of chronic pain in fibromyalgic patients.

Conclusions: Non-invasive neuromodulation techniques and exercise therapy are demonstrated as promising therapeutic tools in the management of chronic pain in patients with fibromyalgia.

## HAPPINESS: THE INGREDIENT FOR A HEALTHY LIFE. A PIONEERING AP-PROACH BY DR HUNTER "PATCH" ADAMS

G. Alagona[1], A. Pennisi[2], G. Naso[1], N. Russo[1], G. Rapisarda[1], M. Coco[2]

[1]Neurology, Cannizzaro Hospital (Catania); [2]Disfor, University of Catania (Catania)

When talking about the power of happiness, a name comes readily to mind: Hunter "Patch" Adams, the American physician who has devoted his life to making people happy and who has made humor and happiness his reason for living. "Patch" Adams became famous worldwide thanks to a comedy-drama based on his life. As he himself states in his famous book titled "Gesundheit! Bringing Good Health to You, the Medical System, and Society through Physician Service, Complementary Therapies, Humor, and Happiness": "Humor is an solution to all ills. I consider the fun as essential as love. The principal thing, when you question individuals what they appreciate regarding life, is the fun they have, whether it is dancing, gardening, golf, or writing books. Life is a miracle and it is so wonderful to be alive that I ask why anyone wastes a minute! Laughter is the greatest medicine!".

## NOVEL PLEKHG5 MUTATION AS A MODEL OF NON-INTERDEPENDENT COEXISTENCE OF AXONAL AND DEMYELINATING FEATURES IN HEREDITARY POLYNEUROPATHY: BEYOND THE ELECTROPHYSIOLOGICAL DICHOTOMY

M. Brienza, F. Cortese, L. De Giglio, M. Altavista, E. Pennisi

UOC Neurology, San Filippo Neri Hospital, ASL RM1 (Roma)

Aim: To describe the clinical and electrophysiological pattern of novel PLEKHG5 neuropathy as an example of pure mixed neuropathy.

Introduction: The characterization of neuropathies as "axonal" or "demyelinating" could be reductive in many cases. Among acquired neuropathies, this concept was overcame by the electrophysiological and pathophysiological characterization of node and paranodopathy. Genetic neuropathies also offer a valid contribution, demonstrating how axonal vs demyelinating dichotomy could be sometimes too reductive. We describe the case of an hereditary sensory-motor neuropathy due to a mutation of PLEKHG5 gene, in which dysmyelinating and axonal damage recognize different, not primitively interdependent, pathophysiological mechanisms.

Case Report: Our 38y.o. patient, of Afghan nationality, born from a consanguineous couple, harbored biallelic mutation c2293C>T(Gln 765)in exon 20 of PLEKHG5 showed ,at neurological examination, hypotrophy of shoulder and pelvic girdle muscles, both distal and proximal hyposthenia, bilateral drop foot without sensory involvement. ENG showed marked reduction of cMAPs from peroneal and axillary nerves and amplitude at lower limits of the normative values from median and ulnar nerves. Conduction velocities (CV) were widely reduced, even in nerves with preserved cMAP amplitude; F waves latencies were prolonged and no conduction blocks were detected. A mild, subclinical and widespread reduction in SAPs was detected. Needle EMG showed spontaneous denervating potentials and giant, polyphasic MUAPs polyphasic, with decreased recruitment in proximal and tibial muscles.

Discussion: PLEKHG5 mutations are associated with different clinical phenotypes including distal hereditary motor neuropathies (dHMN) and intermediate Charcot-Marie-Tooth disease (CMT). The product of this gene regulates autophagy of synaptic vesicles in axon terminal of motoneurons. Our electrophysiological data could have suggested a predominant axonal involvement, relegating this form among axonal neuropathies, according to the classical definition. However, this could not have explained the widespread slowing of CV and the prolonged F wave latency even in not severely involved nerves and

therefore not explainable by the loss of large diameter fibres as in intermediate CMT. Moreover, the clinical and electrophysiological pattern would not be typical of a length-dependent hereditary axonal polyneuropathy and not even suggestive of motor neuron disease because of the sensory involvement. These data are, instead, consistent with a further, different pathomechanisms according to which PLEKHG5 inactivation leads to a axon/Schwann cell units disease characterized by myelin infoldings in peripheral nerves.

Conclusion: PLEKHG5 mutation causes a polyneuropathy with phenotype ranging from MND and intermediate CMT. The uniqueness of this case is the coexistence of both phenotypes in the same patient due to a novel mutation not previously described in literature. Only an accurate electrophysiological examination, aimed to a precise description and not to a mere attempt of classification, can guide the clinician and the geneticist to the most targeted and coherent etiopathogenetic research.

## KINEMATIC ANALYSIS OF HAND DEXTERITY IN HEALTHY SUBJECTS

A. Cannavacciuolo[1], G. Paparella[1], L. Angelini[2], D. Colella[2], D. Costa[2], D. Birreci[2], S. Grandolfo[2], M. De Riggi[2], A. Berardelli[1,2], M. Bologna[1,2]

[1]IRCCS Neuromed (Pozzilli-IS);[2]Department of Human Neurosciences, Sapienza, University of Rome (Roma)

Objectives: Manual dexterity, a crucial motor function evaluated through the coin rotation task [1-3], has not been quantitatively studied using objective kinematic analysis. Here we aimed to conduct a kinematic analysis of hand dexterity in a sample of healthy human subjects.

Materials: Fifteen healthy young right-handed participants (6 females, mean age±standard deviation - SD 30.4±4.1) were enrolled. Handedness was assessed using the Edinburgh Handedness Inventory, and all participants had a score > 70. Kinematic analysis of a coin rotation task was performed using an optoelectronic system (SMART motion system, BTS, Milan, Italy). Reflective markers were placed on the coin to track its position during the task.

Methods: Participants performed the coin rotation task for 15 seconds under four separate conditions: using the dominant and non-dominant hands and rotating in both clockwise and counterclockwise directions. Motion analysis was conducted using specialized software (SMART Analyzer, BTS Engineering, Italy). we measured the total number of rotations executed, movement rhythm, as assessed by the coefficient of variation (CV) of the inter-cycle intervals, and the peak velocity achieved. Data were analyzed using two-way analysis of variance (ANOVA) with the factors of 'hand dominance' (dominant and non-dominant) and 'rotation direction' (clockwise and counterclockwise). Statistical significance was determined at $P < 0.05$.

Results: Although no significant differences were found for the total number of movements performed (mean ± SD: 6.4 ± 0.9), significant effects were observed for the 'hand dominance' factor in terms of both the CV [F(1, 14)=13.859, P=0.002] and movement velocity [F(1, 14)=7.076, P=0.018]. Notably, the non-dominant hand consistently exhibited higher CV values and lower movement velocities, indicative of poorer motor performance. Moreover, neither the rotation direction factor nor the interaction between factors showed significance for both CV and movement velocity, indicating that the direction in which the movement was performed did not differentiate between the dominant and non-dominant sides.

Discussions: This study represents the first attempt to provide objective quantification of a commonly used movement for assessing manual dexterity. The objective data obtained from this study could potentially provide indirect insights into the cerebral areas involved in the execution of manual dexterity movements and praxis functions.

Conclusions: The proposed methodology holds promising implications for research studies in healthy subjects and in neurological conditions, e.g., it can aid in the assessment, monitoring, and treatment evaluation of manual dexterity impairments in Parkinson's disease and other movement disorders, as well as in pyramidal and cerebellar diseases.

## TRANCRANIAL MAGNETIC STIMULATION IN MITOCHONDRIAL NEUROGASTROINTESTINAL ENCEPHALOPATHY (MNGIE)

C. Civardi, C. Collini, C. Tirassa, E. Negri, C. Geda

Department of Neurology, ASL TO4 (Ivrea-TO)

Background: Mitochondrial neurogastrointestinal encephalopathy [1] (MNGIE) is an extremly rare disorder due to recessive mutations in the thymidine phosphorylase gene. Clinical manifestations include gastrointestinal dysmotility, diffuse asymptomatic leukoencephalopathy, severe demyelinating polyneuropathy. This study aimed to explore, for the first time in a patient with MNGIE, cortical spinal involvement/conduction time and excitability with single pulse transcranial magnetic stimulation (TMS).

Methods: A 40 year old man with molecular diagnosis of MNGIE underwent to neurophysiological investigation a with single pulse TMS [2]. We studied motor evoked potentials in the first dorsal interosseous muscle bilaterally. Motor evoked potential variables were assessed following the guidelines of the IFCN. We measured the following variables: relaxed motor threshold (rT); central motor conduction time (CMCT) during maximum efforts of the target muscle was calculated as cortical MEP latency (CTX) − radicular MEP latency -1ms and length of the central silent period. A round coil at the vertex was used. We repeated TMS Study after ten months. The control group consisted of 38 participants (age range, 22–65 years)

Results: Motor threshold was bilaterally higher as compared with controls (right FDI rT 65; left FDI rT 66 left; mean control group 51+8.6). CMCT was bilaterally prolonged (right FDI 11 ms, left FDI 10 ms; mean control group 6.5 + 0.8 ms) while central silent period was normal (right FDI 175,8 + 11,3; left FDI 201,3 + 10,6; mean control group 185 + 20). After 10 months CMCT did not changed

while CSP length slightly increased (right FDI 183,6 + 11,3; left FDI 221,1 + 11,6).

Conclusions: Transcranial magnetic stimulation disclosed in this patient with MNGIE for the first time a significant involvement of the central motor conduction time while intra-cortical inhibitory phenomenon at least for the GABA-B mechanisms were preserved [3]. TMS could be a useful tool for understand this rare disorder.

## THE ROLE OF MUNIX AS A NOVEL ELECTROPHYSIOLOGICAL BIOMARKER FOR EVALUATING SEVERITY, MONITORING PROGRESSION AND PREDICTING PROGNOSIS IN ICU-ACQUIRED WEAKNESS

A. Comanducci, P. Arcuri, T. Atzori, M. Bianco, A. Fogo, T. Lencioni, A. Lax, N. Morici, P. Banfi, J. Navarro

IRCSS Fondazione Don Gnocchi (Milano)

Objectives: Intensive Care Unit Acquired Weakness (ICUAW) is a debilitating condition that significantly impacts patients' survival and quality of life [1], with long-term effects on morbidity and mortality rates [2]. However, the lack of substantial prognostic biomarkers hinders our understanding and management of ICUAW, particularly in the Intensive Rehabilitation Unit (IRU). The objective of this study was to investigate the potential of the Motor Unit Number Index (MUNIX), a non-invasive neurophysiological technique that efficiently estimates the number of functional motor units by recording surface electromyography (EMG) signals during voluntary muscle contractions at varying force levels [3], as a valuable biomarker for ICUAW management and predicting patient outcomes.

Material and Methods: In this longitudinal prospective study, 88 ICUAW patients, diagnosed using a combination of EMG and electroneurography criteria, underwent MUNIX measurements at admission in IRU (T0). We correlated MUNIX values with ICUAW severity, quantified using the MRC sum-score. At discharge (T1), a subset of 20 patients underwent a repeated neurophysiological examination and an assessment of gait and balance residual abilities (Performance Oriented Mobility Assessment, POMA). Multivariate logistic regression was used to evaluate the association of clinical and neurophysiological variables at T0 with functional recovery (modified Barthel Index) at T1.

Results: Statistical analysis revealed a significant negative correlation between MUNIX and MRC sum-scores ($r = -0.68$, $p < 0.001$) at T0. Logistic regression analysis showed that that MUNIX was one of the most indicative of good functional recovery among all the parameters collected at T0 (each one-unit increase in MUNIX was associated with 2.4 times higher odds of good functional recovery at T1 95% CI: 2.2 - 2.8, $p < 0.01$). Finally, for the subset of patients with follow-up neurophysiological measurements, Pearson's analysis demonstrated a significant correlation ($r = 0.72$, $p < 0.01$) between the change in MUNIX from T0 to T1 and the balance abilities as measured by POMA at T1.

Discussion: The findings suggest that MUNIX could serve as a supplementary biomarker for ICUAW severity in conjunction with EMG techniques at T0. Furthermore, MUNIX measurements and their changes over time could be used to monitor disease progression and predict successful rehabilitation outcomes at T1.

Conclusions: In conclusion, our findings propose MUNIX as a promising, reliable, and non-invasive tool for assessing ICUAW severity and tracking disease progression in IRU. The integration of MUNIX in clinical practice could substantially contribute to optimizing prognosis and improving patients' quality-of-life following ICU discharge.

## PERIODIC DISCHARGES (PDS) IN PATIENTS WITH BRAIN TUMOR PATHOLOGY: CLINICAL AND ELECTROPHYSIOLOGICAL FEATURES

S. Consoli[1], F. Dono[1], G. Evangelista[1], C. Corniello[1], S. De Angelis[1], S. Cipollone[1], D. Liviello[1], M. Onofrj[1], F. Anzellotti[1], S. Sensi[2]

[1]Department of Neuroscience, Imaging and Clinical Science, University G. D'Annunzio of Chieti-Pescara (Chieti);[2]Behavioral Neurology and Molecular Neurology Units, Center for Advanced Studies and Technology, CAST, University G. D'Annunzio of Chieti-Pescara (Chieti)

Objectives: Periodic discharges (PDs) represent an EEG pattern commonly found in association with focal cerebral lesions, particularly brain tumors (BT). The clinical interpretation of PDs is controversial as well as their pathophysiological origin. The aim of this study is to describe the prevalence and characteristics of PDs in patients with BT, focusing on their association with epilepsy diagnosis and status epilepticus (SE).

Materials and methods: Adult patients suffering from BT who underwent a video-EEG recording were retrospectively selected from the Neurology Clinic of "G. d'Annunzio" University of Chieti-Pescara from January 2016 to January 2023. Demographics, clinical features, as well as tumor characteristics, and radiological findings, were collected. Video-EEG data were reviewed to identify patients with PDs. Diagnosis of epilepsy and SE were made according to ILAE criteria.

Results: 175 patients (115 primitive BT, mean age 61.3; 60 metastatic BT, mean age 70.1) were enrolled. Thirteen patients (7.4%) showed PDs at video-EEG, of whom 12 with primitive BT. Patients with PDs presented lateralized PDs (LPDs) in most cases (84.6%), with a mean frequency of 1.25 Hz and temporal lobe localization in 76.9%, concordant with the tumor lesion side in 66.7% of the cases. Nine patients suffered from epilepsy, whereas SE was described only in three patients. Comparing primary BT with and without PDs, patients with PDs presented more often a parieto-occipital lesion localization (p=0.01) and high-grade histology (p=0.01). No differences were observed according to sex, age, lesion dimension, and lateralization.

Conclusions: PDs can be more frequently observed in high-grade primary BT with parieto-occipital localization instead of metastatic BT. In addition, PDs are highly associated with epilepsy diagnosis but hardly ever can represent an ictal pattern.

## SINGLE-FIBER ELECTROMYOGRAPHY (SFEMG) IN PATIENTS WITH SUSPECTED OCULAR MYASTHENIA: A COMPARISON STUDY BETWEEN VOLUNTARY VS. STIMULATED TECHNIQUE

G. Cosentino, G. Tammam, M. Todisco, P. Prunetti, M. Fresia, L. Marchetta, A. Montini, C. Zaffina, E. Alfonsi, C. Tassorelli

IRCCS Mondino Foundation, University of Pavia (Pavia)

Objective: Single-fiber electromyography with voluntary activation (SFEMG-v) is one of the main electrophysiologic techniques used for the diagnosis of neuromuscular junction disorders. However SFEMG-v may be poorly tolerated for its extensive duration or for the difficulty of maintaining constant voluntary contraction. The SFEMG with near-nerve stimulation (SFEMG-s) may have some advantages, though there is lack of evidence regarding its diagnostic accuracy. In particular, no studies are available comparing the two methods in a population of patients with and without myasthenia. The aim of this study was to compare the results of these two techniques in a cohort of patients with suspected ocular myasthenia using reference values obtained in a population of age- and sex-matched healthy subjects.

Material and Methods: This study involved 33 patients with suspected ocular myasthenia (mean age 63 years, 9F) and 14 healthy subjects (mean age 52 years, 5F). All patients underwent an electrophysiological assessment consisting of repetitive nerve stimulation, SFEMG-v and SFEMG-s by using a concentric needle electrode. We tested the right orbicularis oculis in all subjects. Diagnosis of ocular myasthenia or ptosis and/or diplopia of other etiology was made based on extensive clinical, laboratory and instrumental investigations including assessment of treatment response to steroid and/or pyridostigmine and search for AchR-Ab.

Results: Ocular myasthenia was diagnosed in 18 of 33 patients without considering the results of SFEMG investigation. In most patients the results matched between SFEMG-v and SFEMG-s; however, in 3 of 33 patients (all with ocular myasthenia) the tests results were inconsistent since only SFEMG-s resulted positive. Sensitivity was 66,7% and 83,3% for SFEMG-v and SFEMG-s respectively, while both techniques had a specificity of 80%. No statistical differences were observed at the chi-square test between the two techniques. Area under the curve (AUC) was 0.73 for SFEMG-v and 0.82 for SFEMG-s.

Discussion and Conclusions: This is the first study to assess diagnostic accuracy of vSFEMG vs stSFEMG for diagnosis of ocular myasthenia. Both SFEMG-v and SFEMG-s had good accuracy and no statistical differences were observed in sensitivity and specificity values between the two methods. It is noteworthy that sensitivity and specificity values of both tests were suboptimal for diagnosing ocular myasthenia. Test repetition over time could be helpful in doubtful cases.

## ECULIZUMAB AS FAST-ACTING RESCUE THERAPY IN A MYASTHENIA GRAVIS PATIENT WITH WORSENING SYMPTOMS WHILE ON TREATMENT WITH EFGARTIGIMOD: A CASE REPORT

N. Cuomo, A. Sarnataro, A. Marsili, G. Puorro, M. Campanile, C. Pane, F. Saccà

Department of Neurosciences, Reproductive and Odontostomatological Sciences, Federico II University (Napoli)

Objectives: Two novel FDA and EMA approved agents are available for treatment of refractory generalized Myasthenia Gravis (gMG): Eculizumab, an anti-C5 monoclonal antibody, and Efgartigimod, an antibody fragment targeting the FcRn. We describe a case of a patient who suffered a gMG relapse while on treatment with Efgartigimod, that was promptly rescued with Eculizumab treatment.

Materials and Methods: A 46 years old woman was diagnosed with anti-AChR positive gMG in 2012. She underwent thymectomy for thymic hyperplasia and started symptomatic treatment with pyridostigmine. She then started prednisone and azathioprine. IVIg was used with little benefit. She developed many side effects from chronic prednisone use: osteopenia, hypercortisolism, overweight. In December 2022 she started intravenous treatment with Efgartigimod (10 mg/kg weekly for four consecutive weeks for each cycle). At the time she took 75 mg/die azathioprine, 10 mg/die prednisone and 300mg/die pyridostigmine. Her MG-ADL and qMG score at baseline were 5 and 16, respectively. She started Efgartigimod infusions and clinical evaluations on a weekly basis.

Results and Discussion: Soon after the first week, her MG-ADL score dropped to 1, while her qMG was 11 after the first treatment cycle (4 administrations). This suggested a small reduction of prednisone to 5 mg/die and pyridostigmine to 240 mg/die. Her scores remained stable during the next months, during which she practiced two cycles (each consisting of 4 weeks of treatment followed by 4 weeks of clinical monitoring without drug administration). During the third cycle (18 weeks after starting treatment) her symptoms began to worsen, she reported an MG-ADL score of 9, and a measured QMG score of 20. For these symptoms she had to stop working. We immediately discontinued treatment with Efgartigimod and started Eculizumab as a rescue and long-term therapy (900 mg iv weekly for the first 4 weeks, followed by 1200 mg from the fifth week and every two weeks). After the first week, her MG-ADL dropped to 5 and at the beginning of the maintenance phase (fifth week) her MG-ADL and QMG score were 1 and 14, with great symptom relief and improvement in quality of life.

Conclusions: As far as we know, this is one of the first case reports of Eculizumab as a rescue therapy in a patient not responding to Efgartigimod. Eculizumab showed a fast and sustained action improving clinical measures of gMG.

## DISCLOSING CENTRAL AND PERIPHERAL EXCITABILITY IN RESTLESS LEGS SYNDROME

A. De Grado[1], A. Bystrup Jacobsen[2], G. Fanella[3], M. Otto[2], P. Lanteri[4], H. Tankisi[2]

[1]Fondazione IRCCS Istituto Neurologico Carlo Besta, University of Milan (Milano); [2]Department of Clinical Neurophysiology, Aarhus University Hospital (Aarhus-DK); [3]Department of Neurology, Fondazione IRCCS San Gerardo dei Tintori, University of Milano-Bicocca (Monza); [4]Neurophysiology Unit, IRCCS Fondazione Istituto Neurologico, University of Milan (Milano)

Background and Aims: Restless legs syndrome (RLS) is a neurological sensory-motor disorder causing an urge to move the legs due to an uncomfortable sensation occurring at rest. The underlying pathophysiology of RLS has not been elucidated yet. Previous studies showed decreased intracortical inhibition, enhanced spinal excitability and peripheral Ih channel dysfunction using heterogeneous methods, therefore leading to conflicting results [1]. In this study we investigated cortical, spinal and nerve excitability parameters simultaneously for the first time.

Material and Methods: We recruited 40 patients (PT-TOT) and 20 age-matched controls (HCs), subdividing the patients' group in patients on medication (PT-ON) and patients off medication (PT-OFF). We studied cortical excitability using threshold-tracking transcranial magnetic stimulation (TT-TMS) [2], recording the following parameters from the abductor pollicis brevis (APB): rMT, Short-Interval Intracortical Inhibition (SICI), Short-Interval Intracortical Facilitation (SICF), Long-Interval Intracortical Inhibition (LICI) and Intracortical Facilitation (ICF). Spinal cord excitability was assessed by recording F-waves, H-reflexes and long latency reflexes (LLRs) from APB and flexor carpi radialis (FCR). Nerve excitability testing (NET) was performed using the extended TRONDNF protocol, recording from the APB.

Results: TT-TMS showed a statistically significant decreased SICI in PT-TOT compared to HCs at numerous inter-stimulus intervals (ISIs), with 2.5 ms (12.99±2.06 vs 21.4±2.25%, $p<0.05$) and 3.5 ms (2.23±1.84% vs 7.92±1.58%, $p<0.05$) being the most affected ISIs; this difference was even more marked between PT-ON and HCs, with SICI reduction spanning throughout the whole 1-7 ms ISIs interval range (average: 2.82±2.03% vs 8.2±1.07%, $p<0.05$). We furthermore observed an increased SICF at 1.9 ms between PT-ON and HCs (-5.15% vs -0.4%, $p<0.05$) and a statistically significant increase in APB-LLRII (92 μV vs 58.5 μV, $p<0.05$) and FCR-LLRIII amplitude (14 μV vs 7 μV, $p<0.05$) between the same two groups. We found no changes in NET parameters. The cohorts displayed no age or sex differences.

Discussion: Decreased SICI is a widespread phenomenon, not confined only to the motor cortex of the leg; consistent with previous findings, this reflects reduced intracortical inhibition possibly due to dysfunctional subcortical projections. Increase in SICF is a novel finding, furtherly reinforcing the concept of augmented intracortical facilitation. The increase in LLRs amplitude points towards spinal hyperexcitability, possibly due to weakened supra-spinal descending inhibitory projections, thus providing a possible explanation to the uncomfortable sensation experienced by the patients [3].

Conclusions: Our findings aim towards decreased cortical inhibition coupled with increased cortical facilitation and enhanced spinal excitability in RLS pathophysiology, with no clear PNS alterations.

## FOOD-BORNE BOTULISM. WHEN NEUROPHYSIOLOGY CAN ADD A TIP: A CASE REPORT

D. Degan, T. Rosso, E. Turinese, A. Burlina

Department of Neurology and Stroke Unit, San Bassiano Hospital (Bassano Del Grappa-VI)

Objectives: We describe the case of a man with early diagnosed food-borne botulism, treated with antitoxin serum, with normal magnetic brain imaging (MRI), unremarkable blood examinations, and normal electrodiagnostic conduction studies, except for the absence of the sympathetic skin response (SSR).

Materials and Methods: A 64-year old man accessed our Emergency Department (ED) on 11th January, 2023. He had unremarkable history, except for eating a precooked canned vegetable soup of industrial origin, on 07th January. After 2 days, he had gastrointestinal discomfort and diarrhea, vomiting, mild headache, asthenia, but he did not seek medical attention. On 11th January, he accessed the ED complaining of blurred vision and photofobia. On 12th January, he had diplopia and dysphonia, followed by internal and external ophthalmoplegia, dysarthria, dysphagia, and dry mouth. An urgent brain MRI excluded any inflammatory, vascular or neoplastic brainstem lesion. Urgent cerebrospinal fluid analysis was performed, and antiganglioside and antineuron antibodies were normal. Food-borne botulism was suspected, and during the night the patient received antitoxin serum (BAT Botulism Antitoxin Heptavalent-A, B, C, D, E, F, G; equine) after approval of Pavia CAV (Centro Anti Veleni), arrived from Bologna National Storage Center. Laboratory diagnostic confirmation was obtained after five days, by testing clinical specimens (toxin B-producing Clostridium was found in the stool sample by the PCR test) and leftover food (toxin B-producing Clostridium was found in a soup sample by microbiological examination, PCR and mouse bioassay) by Istituto Zooprofilattico Sperimentale delle Venezie activated by the Local Department of Hygiene and Public Health. Electrophysiological study performed the day after hospital admission revealed normal sensory and motor conduction, with reduced amplitude of the compound muscle action potentials (CMAPs), and no decremental response at electrical repetitive stimulation at 3 Hz, neither facilitation at 20Hz. The SSR study was pathological, and it remained absent for two months, until the complete clinical recovery.

Discussion and Conclusions: Differential diagnosis of food-borne botulism include Miller-Fischer variant of Guillaine–Barré syndrome, myasthenia gravis, Eaton–Lambert syndrome, brainstem lesions, tick paralysis, and shellfish or tetrodotoxin poisoning [1]. Clinical suspicion of foodborne botulism must be considered early, because of the urgency of rapid treatment with antitoxin to reduce neuro-denervation. Considering the latency of laboratory results, an accurate clinical history, together with neurophysiological studies, may be crucial for early diagnosis.

## BELL'S PALSY: NEW PERSPECTIVES FROM NEUROPHYSIOLOGY AND NERVE ULTRASOUND

G. Di Pietro[1], P. Falco[1], C. D'Elia[2], G. De Stefano[1], E. Galosi[1], G. Di Stefano[1], C. Leone[1], P. Mancini[2], A. Truini[1]

[1]Department of Human Neuroscience, Sapienza University (Roma); [2]Department of Sense Organs, Sapienza University (Roma)

Background and Aims: Bell's palsy is the most common cause of acute peripheral facial palsy. Although the etiology of the disorder is unknown, inflammation and oedema of the facial nerve probably play a key role in the pathogenetic process. Most patients recover within a few months, while up to a third have a residual functional deficit with the presence of facial muscle weakness or synkinesis [1]. Despite the fact that electrodiagnostic tests are widely used for the evaluation of facial nerve paralysis, data on the predictive value of these tests are conflicting. In recent years, nerve ultrasound has gained attention as a valuable tool for the diagnosis of peripheral nervous system diseases [2]. This clinical, neurophysiological and nerve ultrasound longitudinal study is aimed at assessing the utility of facial nerve ultrasound as a supportive tool for the diagnosis and assessment of Bell's palsy.

Methods: We prospectively enrolled 34 consecutive patients with Bell's palsy. All patients underwent clinical examination, neurophysiological testing (including facial nerve conduction study) and HRUS evaluations after 10-15 days (T0), one month (T1) and three months (T2) the onset of Bell's palsy. Patients who did not experience a complete recovery within three months were also evaluated after six months (T3). We have then compared the accuracy of HRUS with that of facial nerve conduction study in predicting the incomplete clinical recovery at three and six months.

Results: At T0 the facial nerve diameter, as assessed with HRUS, was larger on the affected side than on the normal side, particularly in patients with incomplete recovery at T1, T2 and T3. Nevertheless, ROC curve analysis showed that the facial nerve diameter at T0 had a lower predicting value than the facial nerve conduction study for an incomplete clinical recovery at three (T2) and six (T3) months.

Discussion and Conclusion: In the acute phase of Bell's palsy HRUS shows abnormally increased facial nerve diameter. The observed nerve enlargement may be due to inflammation-induced swelling of the nerve probably spreading from the geniculate ganglion [3]. Neverthless, the predicting value of this technique for incomplete clinical recovery at three and six months is lower than that of the nerve conduction study.

Anna University Hospital (Ferrara); [4]Neurology, Public Health, Disability Unit IRCCS Carlo Besta Institute (Milano); [5]Department of Human Neurosciences, Sapienza University (Roma); [6]Rehabilitation Unit, Foligno Hospital (Foligno-PG); [7]Neuroradiology Dept, Vita-Salute San Raffaele University (Milano); [8]Psycology Dept, Bicocca University (Milano); [9]Neurorehabilitation Unit, Quarenghi Clinical Institute (San Pellegrino Terme-BG); [10]National Federation of Traumatic Brain Injury, FNATC (Pordenone);[11]Neurophysiology Unit, Careggi Hospital (Firenze)

Introduction and aims: After a severe anoxic brain injury, comatose patients can evolve toward prolonged Disorders of Consciousness (pDoC; 1). Anoxic aetiology is considered to have worse outcome than traumatic brain injury, and based on solid predictors of poor outcome, this often leads to withdrawn of life-sustaining therapy in the acute phase. In this perspective, few data are available about care pathways for survivors with post-anoxic coma and pDoC. [1] To address these issues, 9 Italian Scientific Societies shared their expertise for providing a Consensus on diagnostic and prognostic procedures, still debated in literature.

Methods: Twelve working groups, involving 22 multidisciplinary professionals from the 9 scientific societies, implemented a systematic literature review focused on 12 PICO questions addressing the acute (n=6) and the post-acute (n=6) phases. The quality of evidence of the included studies was evaluated using the Oxford Centre for Evidence-Based Medicine Levels of Evidence. In March 2023, a Jury involving representative members of the Italian scientific societies and 2 patients' family associations weigh up working groups' reports for elaborating conclusive recommendations.

Results: A total of 47 out of 1,217 screened papers have been included. Each working group produced a report on the literature review, strengths, and limits of evidence for each PICO. For each PICO, 2-4 Jury recommendations were provided based on the evidence levels of eligible articles and expert opinion.

Discussion: The general and common suggestion was for multimodal patient assessment combining validated clinical scales, targeted neurophysiological assessment, and, when available, neuroimaging to improve diagnosis and prognosis and guide individualized treatment [2]. A strong recommendation was to use standardized and validated diagnostic criteria (e.g., Salzburg criteria for non-convulsive status epilepticus) and standardized terminology for neurophysiological analysis (e.g., ACNS 2021 terminology for EEG) [3]. Because of the limited evidence available on patients with anoxic aetiology, the Jury suggested developing multicentre longitudinal studies to ascertain the diagnostic and prognostic value of advanced tools (e.g., functional neuroimaging) to identify patients with "covert awareness".

Conclusions: Recommendations from this Consensus Conference will guide clinicians in the management of post-anoxic coma and pDoC from the acute to chronic phase, and hopefully could serve as a starting point for an international consensus on diagnostic and prognostic procedures for such complex patients.

## INHIBITORY CORTICAL CONTROL IN HEALTHY SUBJECTS: MODULATION OF BETA AND GAMMA OSCILLATIONS IN FRONTAL CORTICAL AREAS

M. Falletti[1], I. Marc[2], V. D'Onofrio[3], F. Asci[1], S. Ferraina[2], A. Suppa[3]

[1]Department of Human Neuroscience, Sapienza University of Roma (Roma); [2]Department of Physiology and Pharmacology, Sapienza University of Rome (Roma); [3]Padova Neuroscience Center, University of Padua (Padova)

Objectives: The inhibition of an ongoing response is a key component of executive control implying the voluntary suppression of inappropriate behaviours [1]. Physiological mechanisms underlying this response are based on an integrated cortical network, including the inferior frontal gyrus (IFG) and the dorsal premotor cortex (PMd) [2]. Inhibition of unwilling actions can be experimentally probed through a standardised paradigm, the Stop Signal Task (SST), that requires subjects to start a movement as quickly as possible when a Go Signal is presented and to refrain from it if suddenly a Stop Signal appears during the reaction time (RT). This protocol allows for the assessment of the inhibitory ongoing response, reflected by the Stop Signal Reaction Times (SSRT). Recently, it has been demonstrated in healthy subjects (HS) that the activation of these cortical areas during specific behaviours is reflected by modulations of beta-/gamma- oscillations [3]. These oscillations can be experimentally and noninvasively modulated by transcranial alternating current stimulation (tACS) protocols. The aim of this study is to explore the role of cortical beta-/gamma- oscillations in the physiology of inhibitory human behaviours through SST protocol performed during specific tACS paradigms, in HS.

Materials and Methods: Six HS performed the SST during three different tACS protocols (β-, γ- and sham-tACS) randomly delivered over the IFG and PMd, bilaterally, over two different days. The coordinates of right and left IFG and PMd were assessed through neuronavigation. During the SST paradigm we quantified RT and SSRT.

Results: Preliminary results suggest that beta- and gamma- tACS differently modulate action inhibition in HS. A two-way repeated measures Anova revealed a significant interaction among the factors Area (IFG; PMd) and tACS(β; γ). Post-hoc comparisons pointed out a significant difference in γ-tACS modulation among the two areas (p=.03); gamma-tACS applied over the IFG decreased RTs, while the stimulation of the PMd increased RTs. Furthermore, gamma-tACS increased SSRTs when applied over both IFG and PMd.

Discussion and conclusion: We demonstrated that beta- and gamma-tACS can modulate cortical oscillations underlying physiological mechanisms of inhibitory control behaviours, in frontal cortical areas, in HS. These preliminary results provide the background for future applications in neurological disorders characterised by deficit of inhibitory control, such as Parkinson's Disease.

## EEG AND BRAIN MRI ALTERATIONS IN TRANSIENT GLOBAL AMNESIA: DO TIME AND GENDER MATTER?

C. Ferrazzoli[1], A. Castelli[1], V. Ferrazzoli[2], A. Pagano[1], G. Di Mauro[1], C. Liguori[1], N. Mercuri[1], F. Placidi[1], F. Izzi[1]

[1]Department of Systems Medicine, Tor Vergata Hospital (Roma);[2]Department of Neuroradiology, Tor Vergata Hospital (Roma)

Objectives: The aim of the study is to evaluate the prevalence and characteristics of EEG and Brain MRI findings in patients with transient global amnesia (TGA).

Materials and Methods: In this single-center observational retrospective study, we examined adult inpatients consecutively admitted to the Neurological Clinic of Policlinico Tor Vergata from 2013 to 2023 with TGA diagnosed according to Hodges and Warlow criteria [1]. Only patients who underwent both EEG recording and brain MRI were included. Data were collected on demographics, past medical history, results of diagnostic investigations, and TGA recurrence.

Results: 69 patients (41 females, 28 males, mean age 62.38±9.20 years) fulfilled the inclusion criteria. Mean duration of TGA symptoms was 5.46±6.14 hours. Medical history of hypertension was detected in 36%. Ten out of 69 patients (14.49%) experienced a recurrence of TGA [2]. EEG abnormalities were found in 47/69(68.1%) patients, mainly bilateral (left 38.3%, 51% bilateral, 10% right, p =0.002). Focal slowing was observed in 23/69 (33.3%) and interictal epileptiform abnormalities (spikes, sharp waves) in 24/69 (34.8%). Mean latency of EEG recordings from TGA was significantly shorter in recordings with epileptiform abnormalities than the normal EEG group (47±22.63 vs 61.86±36.6 hours, p=0.013). Brain MRI showed DWI positive lesions in hippocampal/parahippocampal region in 16/69 patients (23.2%), with a statistically significant left prevalence (left 11/16, bilateral 4/16, right 1/16, p=0.007). The time interval between the attack and brain MRI was significantly shorter in the DWI positive group than normal MRI (82±27.66 vs 101.43±45.54 hours, p<0.05). We did not observe significant differences between patients with normal EEG and epileptiform abnormalities and between MRI-DWI positive and negative groups, regarding age, past medical history of hypertension, event duration and recurrence of TGA, except gender since epileptiform alterations were significantly more frequent in females than males (19/41, 46.3%, vs 5/28, 17.86%, p<0.05). No significant correlation was found between DWI positivity and EEG alteration [3], nor a significant association between lateralization of abnormalities.

Conclusions: The present study confirms the importance of timing as the time interval between TGA attack and diagnostic investigations correlates with the rate of EEG and MR-DWI findings. A left dominance of DWI lesions was found, as reported in previous studies, but no lateralization of EEG abnormalities, with no significant association between MRI and EEG findings. Furthermore, our data demonstrated a significant correlation between gender and paroxysmal EEG abnormalities, suggesting that women may have a different underlying etiology for TGA, which has so far not been clarified.

## NEUROCHEMICAL DATA ON THE PERIVASCULAR NEURON: A NEGLECTED NEURON TYPE OF THE BLOOD BRAIN BARRIER

P. Flace

Medical School, University of Bari 'Aldo Moro', Hospital Structures of Universo Salute Opera Don Uva (Bari, Bisceglie-BT)

The blood brain barrier (BBB) is the morphofunctional structure involved in the control of molecular transport mechanisms between the blood and the central nervous system (CNS). Moreover, the BBB protect the CNS from injurious agents and modulates selectively the passage of pharmacological agents. Furthermore, a structural damage of the BBB in neurologic and psychiatric disorders, has been demonstrated. The BBB is composed by a monolayer of endothelial cells, incompletely covered by pericytes surrounded by an extracellular matrix sheathed by end-feet astrocyte processes. The end-feet astrocytes are the mainly target of neuronal processes. Currently, the neuronal elements involved in the control of the BBB and the neuronal role in the neurovascular unit it is not completely know. Morphofunctional studies demonstrate the existence of perivascular neuronal processes involved in the modulation of the BBB and, only few studies evidenced in several regions of the CNS the presence of neuronal cell bodies in close relationship with the wall of microvessels. Therefore, the goal of this study of chemical neuroanatomy by means of an immunohistochemical approach is to investigate on the presence of monoaminergic and peptidergic perivascular neuronal elements in the human cerebellum. The study was carried out on autoptic fragments of human cerebellum fixed in an aldehyde picric acid solution, embedded in paraffin, cut into 5µm sections and subjected to light microscopic immunohistochemistry with rabbit polyclonal antibodies for serotonin (5-HT), dopamine transporter (DAT), dopamine type 2 receptor (DRD2), neurotensin (NT), neurotensin receptor type 1 (NTR1). The immunoreaction revealed in the molecular layer, in the three zones of the granular layer of the cerebellar cortex, in the dentate nucleus the presence of different neuronal cell bodies and processes in close relationship with the wall of microvessels immunoreactive for NT and NTR1, DAT, DRD2, 5-HT. Although, these results provides further insights, we suggest that in the human cerebellum exist different subpopulations of perivascular neurons may be considered a new specific neuron type of the neurovascular unit involved in the permeability control mechanisms of the BBB.

## NEUROTENSINERGIC NEURONS IN THE HUMAN CEREBELLAR CORTEX: A STUDY OF CHEMICAL NEUROANATOMY

P. Flace[1,5], D. Galletta[2], D. Milardi[3], G. Gennarini[4], V. Coviello[5], M. Di Lernia[5], A. Bizzoca[4], A. Marzullo[6], A. Quartarone[7]

[1]Medical School, University of Bari 'Aldo Moro' (Bari); [2]Unit of Psychiatry and Psychology, Federico II University Hospital (Napoli); [3]Department of Biomedical, Dental Sciences and Morphological and Functional Images, University of Messina (Messina); [4]Department of Translational Biomedicine and Neuroscience "DiBraiN", University of Bari 'Aldo Moro' (Bari); [5]Hospital Structures, Universo Salute Opera Don Uva (Bisceglie-BT); [6]Section of Pathology, Department of Emergency and Organ Transplantation, University of Bari 'Aldo Moro' (Bari); [7]Section of Neurology, IRCCS Centro Neurolesi 'Bonino Pulejo' (Messina)

Neurotensin (NT) is a neuropeptide distributed in the central and peripheral nervous systems (CNS and PNS). NT is involved to hypotension, hyperglycemia, hypothermia, antinociception, intestinal motility, secretion. In the CNS, NT is involved in neurotransmission/neuromodulation mechanisms of the dopaminergic system [1]. Studies evidenced a role of NT in dopamine-related disorders (e.g. Parkinson's disease and schizophrenia) [1]. The cerebellum is not considered a neurotensinergic area, and not are available data on the presence of neurotensinergic neurons. Currently, only few neurotensinergic extrinsic fibers, and the NT receptor subtypes NTR2 and NTR3 has been detected. Therefore, the aim of this study, was to evaluate in the human cerebellar cortex by means of an immunohistochemical approach, the existence and the distribution of a neurotensinergic neuronal subpopulation. The study was carried out on fragments of postmortem human cerebellar cortex 36-48 h after death. Each fragment was fixed in an aldehyde and picric acid solution, embedded in paraffin, cut into 5 µm sections, and subjected to light microscopy immunohistochemical procedures using rabbit and goat polyclonal antibodies respectively against NT and NTR1. For positive controls were used fragments of rat intestine subjected to the same experimental procedure. In the cerebellar cortex, NT and NTR1 immunoreactivity were detected in neuronal cell bodies and processes of all the layers. The NT and NTR1 immunoreactivity were observed in the molecular layer, in stellate and basket neurons; in the Purkinje neuron layer, in a subpopulation of Purkinje neurons; in the granular layer, in a subpopulation of granules and Golgi neurons and in some non-traditional large neurons (e.g. candelabrum, synarmotic, perivascular neurons) [2]. NTR1 immunoreactivity was also observed in form of fine 'puncta' (putative axon terminals) in the neuropil and in close relationship to the wall of microvessels. The present study of chemical neuroanatomy demonstrate the existence of a neurotensinergic neuronal system in the human cerebellar cortex, which could be involved in neurotransmission/neuromodulation mechanisms of intrinsic circuits, in microvascular innervation, and in cerebellar cortico-nuclear projective circuits. In addition, we plan to carry out further studies to evaluate in the cerebellum the presence of NT-dopamine co-transmission mechanisms, and its possible role in cerebellar neuronal circuits related to dopaminergic disorders, such as Parkinson's disease, schizophrenia and autism spectrum disorders.

## MOTOR CORTICAL CORRELATES OF PAIRED ASSOCIATIVE STIMULATION INDUCED PLASTICITY: A TMS-EEG STUDY

F. Marchet, M. Costanzo, G. Leodori, C. Cutrona, M. De Bartolo, M. Mancuso, D. Belvisi, A. Conte, A. Berardelli, G. Fabbrini

Department of Human Neurosciences, Sapienza University of Rome (Roma)

Paired associative stimulation (PAS) is a non-invasive brain stimulation technique that modulates synaptic plasticity in the human motor cortex (M1) [1,2]. The PAS paradigm effectively induces a fast-developing, enduring and stimulus-specific enhancement in corticomotor excitability [2,3]. Since previous studies have primarily used motor evoked potentials (MEPs) as an outcome measure, cortical correlates of PAS-induced plasticity remain unknown.

Aims: This observational study aimed to investigate cortical correlates of a standard PAS-induced plasticity in the primary motor cortex by using a combined TMS-EEG approach in a cohort of eighteen healthy subjects. To this aim, we recorded MEPs and TEPs before and after a PAS intervention, as well as the TEPs evoked during the PAS protocol. To better characterize the relationship between PAS-induced corticospinal facilitation and cortical changes we also investigated possible relationships between MEPs and TEPs measures.

Methods: We determined for all patients the resting motor threshold and the stimulator intensity sufficient to evoke a peak-to-peak MEP amplitude of 1mV in the relaxed FDI at the optimal position of the coil to constantly elicit the largest MEPs in the right resting FDI. PAS intervention was performed by pairing right ulnar nerve stimulation with TMS on left M1 with an interstimulus interval of 25 ms. We collected MEPs before (T0) and at 5 (T1), 15 (T2), and 30 (T3) minutes after PAS. At T0 (pre-PAS) and T2 (post-PAS) we also collected real and sham TEPs by delivering, in two separate blocks, one-hundred real TMS pulses and one-hundred sham TMS pulses, during EEG recording. Finally, EEG was continuously recorded during PAS intervention to record TEPs elicited by the paired stimulation.

Results: In addition to the expected long-lasting facilitatory modulation of MEPs amplitude, PAS intervention also significantly increased transcranial magnetic stimulation evoked potentials (TEPs) P30 and P60 amplitude. No significant correlation between the magnitude of PAS-induced changes in TEP components and MEP amplitude were observed. However, the linear regression analysis revealed that the combined changes in P30 and P60 component amplitudes significantly predicted the MEP facilitation after PAS.

Conclusions: The findings of our study offer novel insight into the neurophysiological changes associated with PAS-induced plasticity at M1 cortical level and suggest a complex relationship between TEPs and MEPs changes following PAS.

## A NEW APPROACH TO THE EVALUATION OF SMALL NERVE FIBERS

S. Massucco[1], S. Stara[1], C. Gemelli[2], A. Schenone[1], M. Grandis[1], M. Leandri[3]

[1]DINOGMI, San Martino Polyclinic Hospital, University of Genoa (Genova); [2]DINOGMI, San Martino Polyclinic Hospital (Genova); [2]DINOGMI, University of Genoa (Genova)

Diagnosing small fiber neuropathy (SFN) remains a challenge due to the relevant limitations of current tests. Recently, a surface electrode for small fiber-selective stimulation was developed. Its specificity relies on an interdigitated micropattern with the conductive leads spaced 150 micrometers (150IDE) and alternately connected to opposite stimulator poles; this cathode-anode distance generates an electric field with a maximum skin depth of 100 micrometers, thus selectively activating the intraepidermal nerve endings. It allows the assessment of the nociceptive system through Nociceptive Evoked Potentials (NEPs) recorded from the scalp. We hereby propose a protocol for SFN diagnosis and monitoring that integrates Sudoscan and 150IDE-NEPs. We enrolled outpatients affected by Charcot-Marie-Tooth disease type 1A (CMT1A) and hereditary transthyretin amyloidosis (hATTR), including hATTR pre-symptomatic carriers. Healthy controls matched by age and sex were also studied with 150IDE-NEPs and Sudoscan. Patients with different neuropathies or skin diseases/lesions which may affect the 150IDE-NEPs were excluded. The medical history was collected and dysautonomia symptoms were reported and quantified using Compound Autonomic Dysfunction Test (CADT) and Composite Autonomic Symptom Scale-31 (COMPASS-31). Neurological examination, electroneurography, Sudoscan, and 150IDE-NEPs test were performed. We investigated eight subjects with CMT1A, 4 males and 4 females, with a mean age of 42 years (range 22-55), six patients with hATTR, 4 males and 2 females, with a mean age of 77 years (range 72-83) and with an average disease duration of 8 years, two presymptomatic Phe64Leu TTR mutation carriers, both females, one aged 54 years, and the other aged 48 years. The fast Aδ fibers had a behavior similar to that of the Aβ fibers in people affected by CMT1A, with an increase in latency or absence of the 150IDE-NEPs. All CMT1A patients had normal Sudoscan results. High interpatient variability was detected in hATTR, possibly due to the different TTR variants. The 150IDE-NEPs results were also mismatched with the Sudoscan findings. All the healthy controls and the two presymptomatic Phe64Leu TTR mutation carriers had normal Sudoscan and normal 150IDE-NEPs. Since the 150IDE allows a low-cost evaluation of small fibers using standard electromyographic material, it is important to confirm its reliability in early SFN detection. SFN diagnosis could have therapeutic implications, for example by identifying early conversion to symptomatic disease in hATTR carriers. Enrollment of more patients is needed to confirm the reliability of the method and a comparison with skin biopsy would be helpful.

## EVALUATION OF PLASMATIC AND CELLULAR REDOX STATE PARAMETERS IN PATIENTS AFFECTED BY AMYOTROPHIC LATERAL SCLEROSIS

A. Mele[1], F. De Marchi[1], C. Comi[1], R. Cantello[1], E. Grossini[2], L. Mazzini[1]

[1]Neurology, University of Piemonte Orientale (Novara); [2]Department of Translational Medicine, University of Piemonte Orientale (Novara)

Background: Oxidative stress, alteration of mitochondrial function, and changes in the neurovascular unit (NVU) could play a role in Amyotrophic Lateral Sclerosis (ALS). Nowadays, no therapy can change ALS course, suggesting the need to test new approaches to slow down disease progression. Acetyl-L-carnitine (ALCAR) has neurotrophic and protective effects, which could be beneficial in ALS [1,2].

Objectives: This study aimed to analyze: 1) the plasma redox system and nitric oxide (NO) in ALS; 2) the plasma effects on peroxidation/mitochondrial function in human umbilical cord-derived endothelial vascular cells (HUVEC) and astrocytes; 3) ALCAR effects on the redox state of ALS patients.

Materials and Methods: We included 32 newly diagnosed ALS patients and five healthy controls. Each patient underwent a clinical evaluation combined with a blood sample, which was used to analyze the aforementioned parameters at diagnosis (T0). After starting ALCAR (T0), the same investigations were repeated at three months (T1) and six months (T2).

Results: In the plasma of ALS patients at T0, an increase in TBARS and a reduction in GSH and NO were found compared to controls. In HUVEC/astrocytes, treated with plasma of 10 ALS patients, mitoROS increased, whereas cell viability and mitochondrial membrane potential decreased. Plasma analyses were repeated at T1 and T2 and showed an improvement in the redox state in all patients involved. No statistically significant correlation was found between clinico-demographic features (e.g., age, sex, site of onset, ALSFRS-R, FVC%, and BMI at baseline) and plasmatic values of TBARS, GSH, and NO at baseline and over time. Interestingly, we found higher levels of TBARS in fast progressor patients compared to slow progressors at T1 (p-value: 0.02). Discussion/Conclusions: Our results show that oxidative stress and NVU play a central role in ALS and suggest that plasma molecules could be involved in the disease pathogenesis. Our data suggest that NVU members may be a possible pharmacological target of ALCAR, which could be protective in ALS. Indeed, ALCAR was able to improve the redox state of ALS patients. TBARS and GSH levels were in fact, respectively, reduced and increased at 3 months after ALCAR start administration, compared to T0. This improvement was confirmed after 6 months. Moreover, ALCAR would act as a protective factor on mitochondrial function of NVU members. Indeed, our results revealed a decrease mitoROS production and a decrease damage in HUVEC and astrocytes.

## FLASH-EVOKED HIGH-FREQUENCY EEG OSCILLATIONS IN MIGRAINE WITH AND WITHOUT AURA

A. Meo, G. Strigaro, G. Avino, B. Gori, A. Mele, F. Cattaneo, C. Varrasi, C. Comi, R. Cantello

Department of Translational Medicine, University of Piemonte Orientale (Novara)

Aim of the study: Scalp-recorded, flash-evoked, high-frequency EEG oscillations (F-HFOs) can be easily extracted from flash visual evoked potentials (F-VEPs) and may represent a convenient measure of visual cortical excitability, as they are markedly enhanced in photosensitive epilepsy. Since migraine patients are also characterized by some degree of altered cortical excitability, aim of the present study is to assess F-HFOs in migraine with (MA) and without aura (MO).

Materials and Methods: 91 migraine patients were consecutively recruited, of which 54 with MO and 37 with MA. 51 healthy subjects (HS), matched for demographic features, acted as controls. F-VEPs were recorded from occipital electrodes in the interictal phase (after dark adaptation, 80 white flashes were delivered through a xenon lamp). F-HFOs were extracted through appropriate filtering (Autosignal ver 1.7, Fourier filtering and reconstruction, in the frequency band of 75-175 Hz, with a latency of 20-110 ms after the flash stimulus, example shown in fig. 1). Time-frequency domain spectrum analysis was subsequently performed. ANOVA was applied for statistical analysis.

Results: F-HFOs showed two consistent spectral peaks (around 85 and 125 Hz) in all three groups. The power of the first peak was significantly enhanced ($p<0.05$) in patients with migraine (MO+MA) compared to HS. However, patients with MA failed to show a significant difference compared to HS ($p>0.05$). The second peak was unaffected.

Discussion and Conclusions: Increased F-HFO spectral power may reflect enhanced visual cortex excitability in migraineurs in the interictal phase. Aura is not associated with an increased excitability as detected by F-HFOs. Other factors, such as the frequency of migraine attacks and central sensitization, might be relevant in affecting F-HFOs.

## EPILEPTIFORM PATTERNS PREDICTING UNFAVORABLE OUTCOME IN POSTANOXIC PATIENTS: A MATTER OF TIME?

F. Misirocchi[1], G. Bernabe[2], L. Zinno[3], A. Zilioli[1], E. Mannini[1], S. Lazzari[1], C. Mutti[3], L. Parrino[1], I. Florindo[3]

Historically, epileptiform malignant EEG patterns (EMPs) have been considered to anticipate an unfavorable outcome, but an increasing amount of evidence suggests that they are not always or invariably associated with poor prognosis. We evaluated the prognostic significance of an EMP onset in two different timeframes in comatose patients after cardiac arrest (CA): early-EMPs and late-EMPs, respectively. We included all comatose post-CA survivors admitted to our intensive care unit (ICU) between 2016 and 2018 who underwent at least two 30-minute EEGs, collected at T0 (12-36h after CA) and T1 (36-72h after CA). All EEGs recordings were re-analyzed following the 2021 ACNS terminology by two senior EEG specialists, blinded to outcome. Malignant EEGs with abundant sporadic spikes/sharp waves, rhythmic and periodic patterns, or electrographic seizure/ status epilepticus, were included in the EMP definition. The primary outcome was the cerebral performance category (CPC) score at 6 months, dichotomized as good (CPC 1-2) or poor (CPC 3-5) outcome. A total of 58 patients and 116 EEG recording were included in the study. Poor outcome was seen in 28 (48%) patients. In contrast to late-EMPs, early-EMPs were associated with a poor outcome ($p = 0.037$), persisting after multiple regression analysis. Moreover, a multivariate binomial model coupling the timing of EMP onset with other EEG predictors such as T1 reactivity and T1 normal voltage background can predict outcome in the presence of an otherwise non-specific malignant EEG pattern with quite high specificity (82%) and moderate sensitivity (77%). The prognostic significance of EMPs seems strongly time-dependent and only their early-onset may be associated with an unfavorable outcome. The time of onset of EMP combined with other EEG features could aid in defining prognosis in patients with intermediate EEG patterns.

## INVESTIGATING INTERHEMISPHERIC CONNECTIONS BETWEEN PRIMARY SOMATOSENSORY AREAS USING PAIRED MEDIAN NERVE STIMULATION AND HIGH-FREQUENCY OSCILLATION ANALYSIS

D. Norata, G. Musumeci, A. Todisco, A. Cruciani, F. Motolese, F. Capone, F. Pilato, V. Di Lazzaro

Department of Medicine and Surgery, Unit of Neurology, Neurophysiology, Neurobiology and Psychiatry, Campus Bio-Medico University of Rome (Roma)

Interhemispheric interactions between the motor cortices are well-established, but evidence regarding interhemispheric connections in other modalities, such as the somatosensory system, remains elusive. This study aimed to investigate and characterize possible interhemispheric connections between the primary sensory areas by studying the responses elicited by bilateral peripheral stimuli delivered with timing dependent on the latencies of each subject's N20. Median nerve somatosensory-evoked potentials (SEPs) were recorded from both median nerves in 15 healthy right-handed subjects using a paired median nerve somatosensory evoked potential (PMNSEP) protocol. The N20-latencies of both hemispheres were evaluated using single median nerve stimulations, and modified interstimulus intervals (mISIs) were computed to elicit SEPs between the two hemispheres at specific N20-latency intervals (5, 10, 20, and 40 ms). The short-latency SEP components (P14/N20 and N20/P25) were analyzed and normalized for each condition. The results revealed significant differences in normalized amplitudes between mISIs, indicating an mISI effect for both N20 components. Post-hoc tests further confirmed specific differences between different mISIs. These findings provide insights into the interhemispheric connections between primary sensory areas and highlight the potential role of interhemispheric interactions in somatosensory processing. Further investigations are warranted to gain a comprehensive understanding of these connections and their functional implications in sensory perception and information processing.

## THETA-ALTERNATING CURRENT STIMULATION MODULATES CEREBELLAR-RELATED MOTOR FUNCTIONS AND CEREBELLO-CORTICAL CONNECTIVITY

G. Paparella[1], A. Guerra[2], M. Passaretti[1], A. Cannavacciuolo[3], L. Angelini[1], D. Costa[1], D. Birreci[1], A. Berardelli[3], M. Bologna[1]

[1]Department of Human Neurosciences, Sapienza University of Rome (Roma); [2]Parkinson and Movement Disorders Unit, Study Center on Neurodegeneration (CESNE), University of Padua (Padova); [3]IRCCS Neuromed (Pozzilli-IS)

Objectives: To evaluate through a double-blind, randomized study, whether transcranial alternating current stimulation (tACS) delivered at θ and γ frequency over the cerebellum modulates upper limb performance and the cerebellum-primary motor cortex (M1) connectivity in healthy subjects.

Materials: We enrolled 15 healthy young subjects. An optoelectronic kinematic system was used to record cerebellar-dependent motor tasks, including rhythmic finger-tapping (FT) [1], and two arm-reaching movements that differed in terms of complexity: reaching-to-grasp (RG) and reaching-to-point an object (RP) [2]. tACS was delivered over the cerebellum through a BrainSTIM (E.M.S.) at θ and γ frequency [3]. Sham-tACS was used as a control condition. Cerebellum-(M1) connectivity was tested using transcranial magnetic stimulation (TMS) for the assessment of the cerebellar-brain inhibition (CBI).

Methods: Participants underwent a single experimental session. We first recorded the three behavioural tasks performed during tACS in the three different stimulation conditions: i) θ-tACS; ii) γ-tACS; iii) sham-tACS. Then, we evaluated the CBI during θ-, γ-, and sham-tACS. The stimulation condition order for both kinematic and TMS assessments was random, and both participants and researchers were blinded to stimulation conditions (double-blind study design). Repeated-measures (rm)ANOVAs were adopted to test the possible tACS effects on each kinematic and TMS variable. Correlation analysis was also performed.

Results: θ-tACS modulated movement rhythm during the FT task, i.e., it incremented rhythm irregularity as compared to sham- ($p=0.02$) and γ-tACS ($p<0.01$). θ-tACS also modified the RP task, as it increased the duration of both the entire movement and the approach-to-the-target phase as compared to sham- ($p=0.02$ and 0.01) and γ-tACS ($p=0.05$ and $p=0.04$). Finally, CBI was more effective (i.e., greater inhibition) during θ-tACS than sham- and γ-tACS (both $ps<0.001$). The effect of θ-tACS on movement rhythm in the FT task correlated with CBI changes, that is, the greater the movement rhythm deterioration, the greater the CBI strengthening during θ-tACS.

Discussion: We here demonstrated that tACS delivered at a cerebellar resonant frequency, i.e., θ frequency, modulates fine finger and arm movements. This modulation may relay on the cerebellar inhibitory output onto M1.

Conclusions: Our results may be interpreted for a better understanding of the physiological mechanisms of motor control in healthy humans. Also, our data offers new cues to design innovative, non-invasive neuromodulation protocols to shape cerebellar–cerebral functions.

## ECULIZUMAB IN REFRACTORY MYASTHENIA GRAVIS: A SINGLE CENTER ONE YEAR EXPERIENCE

D. Ricciardi, F. Tuccillo[2], C. Erra, B. De Martino[2], F. Habetswallner[2]

Department of Neurophysiopathology, A.O.R.N. A. Cardarelli (Napoli)
Objective: To report the results of One-year single center experience regarding Refractory Ab AchR Myasthenia gravis (rMG) patients treated with Eculizumab.

Materials and Methods: Among 500 MG patients followed at our division, 12 AchR refractory MG patients with unstable clinical condition were selected.

Results: Almost all patients have shown a progressive clinical improvement according with approved clinical scales (MG-ADL - QMG). At one year follow-up the average steroid dose has been reduced and, in some cases, the immunosuppressive treatment stopped. No serious adverse effects emerged.

Discussion and conclusions: Eculizumab is proving safe and effective in treating Ab-AChR rMG patients.

Aims: Extracting subject-specific information from the human brain can enhance tailored therapeutic approaches in neurodegenerative diseases. The clinical connectome fingerprint (CCF) has proven valuable in differentiating brain patterns in healthy individuals and those with neurodegenerative diseases [1, 2]. However, its potential to reveal meaningful information about the individual clinical status in Parkinson's Disease (PD) remains largely unknown. Therefore, we analyzed magnetoencephalography (MEG) data of PD patients within the CCF framework, hypothesizing that PD individuals would display reduced fingerprint compared to HC, which might predict motor clinical impairment.

Materials: We recruited 47 PD patients (off medication) and 47 healthy controls (HC). Brain signals were recorded through a magnetoencephalography system. Clinical motor scores were obtained using the Unified Parkinson's Disease Rating Scale (UPDRS-III).

Methods: MEG signals were preprocessed, source-reconstructed, and transformed into frequency-specific functional connectomes (FCs) using phase linearity. FCs were cross-correlated within each group to construct identifiability matrices representing the similarity between FCs. Two parameters were extracted: I-self, representing the similarity between two FCs of the same individual, and I-others, representing the similarity between different individuals. Additionally, the FC of each patient was compared to those of HC, yielding an I-clinical score. Permutation tests were used to compare scores between groups. Multilinear regression was applied to assess the predictive ability of I-clinical for UPDRS-III.

Results: PD patients exhibited lower I-self values ($p = 0.01$) and lower I-others values ($p < 0.001$) compared to HC in beta band. Disease duration ($p = 0.01$, $\beta = 0.4$) and I-clinical ($p < 0.001$, $\beta = -0.48$) resulted to be significant predictors, and the model predicted ~45% of the variance of the UPDRS-III. Finally, I-clinical was significantly correlated (negatively) with the UPDRS-III score ($r = -0.48$, $p < 0.001$).

Discussion: The CCF analysis revealed significant findings in the beta band, known to be altered in PD. The low differentiation found in PD patients suggested impaired large-scale brain dynamics. Furthermore, the relationship between PD-HC brain similarity (i.e., the I-clinical) and the motor score, showed that the greater the similarity between a patient's FC and those of HC, the milder their motor impairment.

Conclusions: Brain fingerprinting allowed us to analyze the specific brain connectivity patterns of each patient, highlighting its potential for guiding tailored therapies in PD [3].

## SMALL FIBERS ASSESSMENT BY THERMAL QUANTITATIVE SENSORY TESTING IN PATIENTS WITH IGM PARAPROTEIN-RELATED NEUROPATHY

G. Tammam, D. Tornabene, L. Diamanti, E. Vegezzi, E. Antoniazzi, C. Zaffina, M. Todisco, G. Cosentino

Department of Brain and Behavioral Sciences, University of Pavia, IRCCS C. Mondino Foundation (Pavia)

Objectives: IgM paraprotein-related neuropathies, also including anti-MAG associated neuropathy, are a wide and heterogeneous group of peripheral nerve diseases. Pain is frequently reported by the patients, and it usually gets worse during disease's progression also being poorly responsive to treatment. The aim of this study was to assess the involvement of small fibers by using thermal Quantitative Sensory Testing (QST) in a group of patients with IgM paraprotein-related neuropathies, also to highlight whether differences between patients with anti-MAG and non anti-MAG associated neuropathy may exist.

Material: Twenty-four patients with IgM paraprotein-related neuropathies have been enrolled in the study. Sensory functions and pain

sensations were assessed by means of clinical evaluation, clinical scales and interview. Small fibers function was evaluated by thermal QST.

Methods: All patients underwent a clinical interview, assessing demographic and clinical data, and neurological examination. Warm, cold and heat pain thresholds (WDT, CDT, HPT) were evaluated on the right thenar eminence and on the right foot dorsum using the reaction-time independent QST method of levels.

Results: Fifteen patients resulted positive for the presence of anti-MAG antibodies whereas the remaining nine patients were negative. Pain was reported in the 40% and 33% of MAG-positive and MAG-negative patients respectively. WDT and CDT resulted frequently abnormal though statistically significant differences were not detected between groups. Indeed, at least one thermal threshold was altered in 66% and 78% of MAG-positive and MAG-negative patients respectively. HPT was abnormally increased in the hand and/or the foot respectively in 20% and 27% of MAG-positive patients. In the MAG-negative group HPT was elevated in only one patient in the hand.

Discussion: Abnormalities of WDT, CDT and HPT observed in our patients are compatible with a small fibers impairment in patients with IgM paraprotein-related neuropathies, both with and without anti-MAG antibodies. Interestingly, the alterations mainly involved the WDT and CDT, which are considered to be mainly mediated by the C fibers. Indeed, especially in the MAG-negative group, non-length dependent alterations in the HPT, which is mainly mediated by A-delta fibers, were less frequently observed.

Conclusions: Thermal thresholds, mainly dependent on C unmyelinated fibers, were altered in most patients with or without MAG positivity, which is in line with the hypothesis of a peripheral small fibers impairment. Finding that HPT, which is mainly mediated by Aδ fibers (myelinated), was less frequently altered in both patients group is an unexpected finding, especially in patients with MAG positivity where peripheral myelin is primarily involved.

## USEFULL OF EVOKED MOTOR POTENTIAL IN EARLY STAGE OF GUILLIAN BARRÉ SYNDROME'S DIAGNOSIS

C. Vitale, C. Pandino, G. Brodini, B. Ferrero

Neurology, Molinette Hospital, City of Science and Health (Torino)

Goals: Benefits of evoked motor potential (MEP) to confirm the clinical suspicion of Guillian Barré syndrome's early stage and its variants, when the traditional instrumental signs are absent, as albumino-cytological dissociation and demyelinating on nerves conduction studies.

Materials: The patient presents acute onset of signs and symptoms compatible to Guillian Barré syndrome, which stock-like numbness, complete loss of reflex, diffuse muscle weakness but asymmetrical (worse on the right of superior limb), dysarthria. The medical history reports an infection of upper respiratory tract, one week previously. It is performed hematochemical tests blood test with research of antibodies against nerves, head CT with angioCT, MRI of the brain and spine with gadolinium, rachycentesis and neurophysiological studies.

Methods: By neurophysiological point of view, blink reflex study, electroneurography, electromyography and evoked motor potentials to all four limbs are done. The patient receives treatment with one cycle of intravenous Immunoglobulin.

Results: Imaging tests are within normal limits. The Lumbar puncture does not show typical albumino-cytological dissociation. The electromyography is not significative as well as blink reflex and nerves conduction studies; in particular, there are not signs of demyelination and the F waves of four limb are symmetrical and regular for persistence and minimal latency. The study of evoked motor potentials are recorded in two ways: with magnetic stimulation both transcranical both transcervical. If transcervical stimulating is normal, the transcranical study highlights alteration of M responses because to reduction of amplitude with chronodispersion signs and delay of absolute latencies and central conduction time, especially on superior right limb. By blood test, it is decteted the presence of specific antibody IgG type against GQ1b protein.

Discussion: The transcranical MEP's positivity, compared with the normal results of transcervical MEP, means that the dysimmune process is localized on that small part of nervous system between the horn cell and the outflow of fibers nerve by conjugation foramens. This site is difficult to study with the only F wave for reason of spatial dispersion. Furthermore, considerating acute onset, cranic nerve involvement with Ab anti GQ1b positive and, mainly, after treatment, the reversible conduction failure with complete recovery (absence of temporal dispersion or conduction block), it is possible to suspect a proximal nodopathy. So, MEP can detect significant abnormalities in early stage of these diseases when the other routine tests can be negative.

## CLINICAL NEUROPSYCHOLOGY AND COGNITIVE BEHAVIORAL NEUROLOGY

## COGNITIVE RESERVE IS ASSOCIATED WITH QUALITY-OF-LIFE CHANGES IN NEWLY DIAGNOSED PEOPLE WITH MULTIPLE SCLEROSIS: AN EXPLORATORY AND LONGITUDINAL STUDY

M. Altieri[1], A. Bisecco[1], A. D'Ambrosio[1], V. Rippa[1], R. Capuano[1], M. Risi[1], R. Borgo[1], T. Cuomo[2], G. Tedeschi[1], G. Santangelo[3], A. Gallo[1]

[1]Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli" (Napoli); [2]Department of Neurology, Umberto I Hospital (Nocera Inferiore-AV); [3]Department of Psychology, University of Campania Luigi Vanvitelli (Caserta, Napoli)

Objectives: The protective effect of cognitive reserve (CR) on cognition in Multiple Sclerosis (MS) has been confirmed in multiple studies [1,2]. It is not clear, however, whether high CR may also counteract a decline of quality-of-life (QoL) over time in recently diagnosed people with MS (pwMS), as demonstrated in studies on older healthy adults [3]. Therefore, the aim of the study was to evaluate the effect of CR on changes in QoL at three years after the onset.

Materials and Methods: Fifty-five newly diagnosed pwMS (women = 58.2%) underwent a neurological and neuropsychological evaluation at baseline (T0; at least 1 month after the onset) and follow-up (T1; at least 3 years from T0). At both time points the evaluation included: Symbol Digit Modalities Test (SDMT), Multiple Sclerosis Quality of Life-54 (MSQoL-54), Beck Depression Inventory II (BDI-II), State-Trait Anxiety Inventory (STAI-Y) to evaluate cognitive status, QoL, depressive and anxiety symptomatology, respectively. A repeated measures MANCOVA with Bonferroni correction for multiple comparison was performed. Within-subject factor was time (T0 vs T1),

between-subject factor was CR (categorized in high [>13 years], medium [13 years] and low [<13 years] CR), whereas the dependent variables were each subscore of MSQoL-54. Covariates of the model included: sex, disease duration, EDSS, BDI-II, STAI-Y and SDMT.

Results: The MANCOVA revealed no significant main effects of CR or time on MSQoL-54 scores; however, an interaction effect between CR and time was found (Wilks' $\Lambda = .22$, $F(32,48) = 1.721$, $p = .043$, partial $\eta 2 = .534$). Univariate analysis showed that the CR*time interaction was significant for social function ($p = .029$), sexual function ($p = .011$), satisfaction with sexual function ($p = .009$) and overall QoL ($p = .021$), meaning that only pwMS with low CR showed a decline of these MSQoL-54 subscales at T1 evaluation.

Discussion: CR may be a protective factor of QoL decline in newly diagnosed pwMS; low CR seems to be associated with a worse perception of their social and sexual functioning and to a more negative evaluation of one's overall QoL levels at T1.

Conclusions: These findings may support the hypothesis that CR may reflect the individual's resilience not only to physical and cognitive damage, but also to changes on perception of social and sexual wellness. Future studies may further investigate this issue by including more proxies of CR and other psychological variables (e.g., coping strategies).

## DEPRESSIVE SYMPTOMS AND ATRIAL FIBRILLATION: CLINICAL, NEUROIMAGING AND COGNITIVE ASSOCIATIONS IN A COHORT OF OLDER PATIENTS WITH ATRIAL FIBRILLATION ON ANTICOAGULANTS. STRAT-AF 2 STUDY

E. Barucci[1], E. Salvadori[1], B. Formelli[1], C. Barbato[1], F. Pescini[2], F. Cesari[3], B. Giusti[3], A. Gori[3], A. Ginestroni[4], E. Fainardi[4], R. Marcucci[3], A. Poggesi[1]

[1]NEUROFARBA Department, University of Florence (Firenze); [2]Stroke Unit, AOU Careggi (Firenze); [3]Atherothromobotic Disease Centre, AOU Careggi (Firenze);[4]Neuroradiology Department, AOU Careggi (Firenze)

Aims: Depression is frequently encountered in older people, represents a risk factor in many cardiovascular diseases, including atrial fibrillation (AF), and finally affects overall prognosis. The term Vascular Depression indicates the possible associations between depressive symptoms and cerebrovascular diseases. Cerebral small vessel disease plays an important role. Our aims were to: 1) investigate the presence of psychiatric disorders, depressive symptoms and quality of life in older patients with AF on anticoagulants for primary and secondary prevention of ischemic stroke; 2) explore which clinical, cognitive, functional and neuroimaging factors were associated with psychiatric disorders and depressive symptoms.

Methods: Strat-AF2 is a single center, longitudinal, observational study evaluating older (≥65 years) patients with AF on anticoagulants. Patients were assessed at baseline by means of a comprehensive standardized protocol (clinical, functional and cognitive data), and brain MRI and/or CT. SVD lesions were visually assessed according to validated scales. Depressive symptoms were evaluated by the Geriatric Depression Scale (GDS).

Results: Out of the 182 patients enrolled (mean age 78.3±8.7 years, males 58%), 88 (48%) had a history of psychiatric disorders. Compared to patients without psychiatric disorders, those with presented a short-lasting AF (138.9±118.1 vs. 102.3±89.7 months, respectively, p=.023), more gait disorders (33% vs. 50%, p=.020), more sedentary lifestyle (48% vs. 63%, p=.047), worse global cognitive efficiency (mean MoCA score 22.5±4.3 vs. 21.2±3.8, p=.040), more memory complaints (37% vs. 62%, p<.001) and higher GDS score (2.5±2.3 vs. 5.3±3.3, p<.001). Forty-three subjects (24%) had mild to severe depressive symptoms according to GDS scores. Higher depressive symptoms were associated with: female sex (rpb=.301), lower education (r=-.291), living alone (rpb=-.260), sedentary lifestyle (rpb=-.224), worse global cognitive efficiency (r=-.249), disability (ADL r=-.246; IADL r=.239), history of psychiatric disorders (rpb=.448), memory complaints (rpb=.256) and worse of quality of life (r=-.296). Regarding neuroimaging, depressive symptoms (GDS scores) were associated with white matter hyperintensities [Fazekas (r=.281) and Scheltens scales (r=.328)].

Discussion: In our cohort of older patients with AF on anticoagulants, history of psychiatric disorders and depressive symptoms seem quite frequent and associated with several environmental, cognitive and behavioral factors that could be the target of prevention and treatment strategies. White matter hyperintensities seem to confirm the vascular depression hypothesis.

## ALTERATIONS OF SPONTANEOUS SPEECH IN PRIMARY PROGRESSIVE APHASIA VARIANTS: A NEUROPSYCHOLOGICAL AND BRAIN MRI STUDY

E. Canu[1], S. Santicioli[1], V. Castelnovo[1], E. Gatti[1], A. Lamanuzzi[1], S. Basaia[1], E. Spinelli[2], G. Cecchetti[2], F. Caso[3], G. Magnani[3], P. Caroppo[4], S. Prioni[4], C. Villa[4], S. Cappa[5], M. Filippi[6], F. Agosta[2]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [2]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [3]Neurology Unit, IRCCS San Raffaele Scientific Institute (Milano); [4]Unit of Neurology 5-Neuropathology, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [5]Department of Humanities and Life Sciences, University Institute for Advanced Studies IUSS Pavia (Pavia); [6]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: The aims of the study were: 1) to identify which features of spontaneous speech most effectively distinguish PPA variants (non-fluent/agrammatical [nfvPPA], semantic [svPPA], and logopenic [lvPPA]) from healthy controls (HC) and each other; 2) to determine whether the

speech measures associated to each variant are related to gray matter (GM) density of specific language brain circuits.

Materials: 95 patients with a diagnosis of PPA (40 nfvPPA, 35 svPPA, and 20 lvPPA) and 25 HC underwent a neuropsychological assessment, the audio-recorded 'Picnic Scene' test from the Western Aphasia Battery, and a brain MRI.

Methods: Stepwise regression models detected the best speech parameters able to distinguish the groups. Multiple regressions were performed between GM volumes and global z-scores of each 'best model' resulting from the Stepwise Regression analysis.

Results: The best model differentiating PPA patients and HC included: false starts, mean production rate, mean frequency, and length of sentences for lvPPA (R2=0.731); production rate and self-corrected sequences for nfvPPA (R2=0.665); mean frequency of produced nouns for svPPA (R2=0.466). In lvPPA, nfvPPA and svPPA, z-scores of each 'best-model' variables were positively associated with the GM density of left postcentral, inferior frontal, and inferior temporal gyri, respectively. The best model to distinguish: lvPPA from nfvPPA cases included incomplete and subordinate sentences (R2=0.295); lvPPA from svPPA included naming and repetition, proportion of sentences and verbs (R2=0.646); nfvPPA from svPPA included naming, repetition, number of produced verbs and sentences, and production rate (R2=0.757).

Discussion: In this study we provided quantitative measures of speech by considering a very large sample of PPA patients. The Stepwise regression models highlight the best speech variables associated to each variant. In the comparisons among PPA variants, the best models were reached when distinguishing svPPA cases from each other variant, mainly when also standard language tests were included in the model. The accuracy in distinguishing lvPPA and nfvPPA cases is still low; however, the proposed models could benefit from including other biomarkers, such as the brain MRI measures.

Conclusions: The speech variables that we identified and that were related to specific GM circuits, may be used in the clinical practice for patients' differential diagnosis, prognosis, and planning pharmacological and non-pharmacological interventions.

## PSYCHOMETRIC PROPERTIES AND CLINICAL CORRELATES OF THE FRONTAL BEHAVIOUR INVENTORY IN PROGRESSIVE SUPRANUCLEAR PALSY: DATA FROM THE PSP-NET

A. Cappiello, S. Cuoco, P. Barone, M. Picillo for the PSP-NET group

Center for Neurodegenerative Diseases (CEMAND), Department of Medicine, Surgery and Dentistry, University of Salerno (Salerno)

Objectives: Behavioural symptoms, such as apathy, disinhibition, dysphoria and anxiety are frequent complains in progressive supranuclear palsy (PSP) [1]. Specific scales evaluating neuropsychiatric disturbances in PSP are lacking. The Frontal Behaviour Inventory (FBI) is widely used to evaluate behavioural issues in dementia. Aims of the present study were to (I) report the psychometric properties of the FBI in PSP and (II) describe the clinical correlates of behavioural symptoms in PSP patients.

Design, Setting and Participants: PSP patients diagnosed according to the Movement Disorder Society Criteria underwent a clinical interview, a motor evaluation, cognitive and behaviour testing. Data were collected from several centres throughout Italy within the PSP-NET supported by Fondazione LIMPE.

Results: Two-hundred and eight subjects, with mean (± DS) age of 63.90 ± 12.25 years and mean (± DS) education of 9.82 ± 3.98, were screened for the present study. One-hundred-twenty-two were men (67,80%) and 59 were women (32,60%). The internal consistency was high (Cronbach's alpha = 0.868) and corrected item-total correlation was > 0.40 for the majority of items. Principal component analysis revealed that five factors with the highest eigenvalues accounted for 54.92% of the total variance. Behavioural aspects measured with FBI associated with less education and more aggressive and apathetic symptoms.

Conclusion: The FBI is a reliable tool for the assessment of behavioural symptoms in PSP. Higher behavioural symptoms scores may represent a marker of prevalence of aggressive and apathetic aspects in PSP. The lack of items exploring depressive symptoms in the FBI may justify the low total variance displayed by factor analysis.

Objectives: To identify which features of spontaneous speech are the most affected overtime in the different primary progressive aphasia (PPA) variants (non-fluent/agrammatical [nfvPPA], semantic [svPPA], and logopenic [lvPPA]).

Materials: Thirty-four patients with a biomarker-based supported diagnosis of PPA (10 nfvPPA, 17 svPPA, and 7 lvPPA) and 25 healthy controls underwent a neuropsychological assessment which included the audio-recorded 'Picnic Scene' test from the Western Aphasia Battery. Patients underwent the same visit at the follow-up within a period between 6 and 24 months.

Methods: At baseline, sociodemographic and speech features (in terms of speech production rate, speech fluency, syntax production, and lexical content) were compared between groups. Linear mixed effect models, which accounted for age, sex, education, and time between visits, investigated significant speech changes overtime within each PPA group and between groups.

Results: At baseline, patients and healthy controls were similar for age, sex and education. PPA cases performed worse than healthy controls in almost all speech parameters. Patients were similar among each other in terms of age, sex, education, and disease severity. At baseline, compared to the other groups, nfvPPA cases showed the most severe speech profile with a reduced performance in speech and syntax production. Compared to the other groups, lvPPA cases showed more

fluency interruptions, such as false starts and full pauses, while svPPA patients produced more verbs than nouns and adopted a high-frequency lexicon. Overtime, nfvPPA patients did no show significant further speech changes; lvPPA cases showed a significant reduced production rate; and svPPA cases produced more semantic errors.

Discussion: In this study, we provided quantitative measures of speech at baseline and speech changes overtime in each variant of PPA. The three PPA variants showed different speech trajectories: at baseline, nfvPPA cases presented severe speech disturbances that were not anymore quantifiable overtime; lvPPA accumulated speech production difficulties which were similar to those presented by nfvPPA cases at baseline; and svPPA cases revealed a focal decline involving lexical content and semantic knowledge only.

Conclusions: The speech variables that we identified as the most affected at baseline and overtime by each PPA variant may be used in the clinical practice for increasing knowledge on disease progression, patients' prognosis and for planning speech language therapy interventions. Funding. European Research Council (StG-2016_714388_NeuroTRACK); Foundation Research on Alzheimer Disease.

## BPSD-SINDEM SCALE, A NEW TOOL TO ASSESS BEHAVIORAL AND PSYCHOLOGICAL SYMPTOMS OF DEMENTIA: ITALIAN VALIDATION AND ASSOCIATION WITH PHARMACOLOGICAL TREATMENTS

F. D'Antonio[1], F. Pozzi[2], M. Panigutti[1], D. Vernè[3], M. Zuffi[4], O. Pelati[4], M. Di Maggio[5], L. Tremolizzo[6], E. Farina[3]

[1]Human Neuroscience, Sapienza University of Rome (Roma); [2]Fondazione IRCCS San Gerardo dei Tintori, University of Milano-Bicocca (Monza); [3]Neurological Rehabilitation, IRCCS Fondazione Don Gnocchi (Milano); [4]Neurology, Multimedica (Castellanza-VA); [5]Nursing Home, Fondazione Istituti Riuniti Airoldi e Muzzi (Lecco); [6]Neurology, University of Milan-Bicocca (Monza)

Objectives: Behavioral and psychological symptoms of Dementia (BPSD) are part of disease course and associated with a high burden for patients and caregivers. Tools assessing BPSD do not usually cover the complete range of BPSD and are based only on caregivers' perception. Our objective was to validate a new scale for BPSD including both clinician and caregivers' observations, and caregivers' perception of their own coping abilities.

Materials: The BPSD SINDEM study group developed a tool to assess BPSD comprising three 17-item parts: two questionnaires completed by the caregiver assessing respectively the BPSD extent (a global concept tied to both frequency and severity) and caregiver's coping abilities, and an observational scale completed by clinicians. 208 patients from four Italian CDCD were included. NPI, CDR, MMSE, ADL, IADL, and CIRS were also administered.

Method: The scale correlation was tested by Person's coefficients between BPSD-SINDEM subscales. For each BPSD-SINDEM subscale we ran linear models to identify possible predictors of scale scores.

Results: The BPSD-SINDEM extent questionnaires (caregiver and observational) were positively correlated ($r = 0.34$, $p < 0.001$). A diagnosis of Lewy Body or Fronto-temporal dementia and the usage of antidepressants and antipsychotics were predictive of higher BPSD-SINDEM extent scale scores. Increased BPSD extent was also predicted by higher fluoxetine and olanzapine equivalent doses. We found that usage of benzodiazepines was predictive of higher score at the caregivers' coping questionnaire. As far as BPSD-SINDEM observational scale is concerned, only the use of antidepressants, but not their dose, was a predictor of higher scores.

Discussion: The correlation between BPSD-SINDEM extent and the observational scales indicates that the BPSD burden perceived by caregivers is at least in part mirrored by clinicians' direct observation. Therefore, the BPSD SINDEM scale could be indeed a reliable tool to assess BPSD. BPSD burden was predicted by antidepressants and antipsychotics use and the BPSD extent in the observational scale was consistently predicted by antidepressant use, supporting a strong association between BPSD severity and pharmacological treatments. Interestingly, caregivers coping was associated with benzodiazepines use, possibly mediated by the idea to have a tool to personally manage BPSD (above all sleep disturbances).

Conclusions: The BPSD-SINDEM-scale can be an innovative instrument for BPSD assessment, considering both clinician's observation and caregivers' perception. The results from this new scale are consistently associated with pharmacological treatments. These findings suggest that the BPSD-SINDEM-scale can represent a valid tool to better manage these distressful symptoms in the clinical context.

## IMPROVING THE DETECTION OF SUBJECTIVE COGNITIVE DECLINE USING NOVEL NEUROPSYCHOLOGICAL TEST PARADIGMS

M. S. De Simone[1], M. Rodini[1], M. De Tollis[1], S. Bonarota[1], L. Fadda[1], C. Caltagirone[1], G. Carlesimo[2]

[1]Department of Clinical Neuroscience and Neurorehabilitation, IRCCS Santa Lucia Foundation (Roma); [2]IRCCS Santa Lucia Foundation, Tor Vergata University (Roma)

Background: Subjective Cognitive Decline (SCD) is defined as a self-experienced persistent decline in cognition relative to previous levels of functioning, in the context of normal performance on standard neuropsychological tests and preserved activities of daily living. A consistent body of evidence indicates that SCD represents a risk factor for cognitive decline and dementia, in that it is associated with higher rate of conversion to MCI and AD as compared to the general population and with an improved likelihood of positive biomarkers and neurodegeneration consistent with AD pathology. Since traditional neuropsychological tests for the evaluation of cognitive impairment have remained largely unchanged for decades, identifying novel cognitive measures that are sensitive enough to objectively detect the subtle cognitive decline associated with AD pathology has become even more crucial for identifying individuals at risk, monitoring disease progression, and ascertaining treatment efficacy.

Objectives: In this light, here we investigated the diagnostic accuracy of novel neuropsychological testing paradigms (which have been proposed as potentially challenging tools for the identification of preclinical AD) in capturing the subtle cognitive changes leading to SCD but not objectively detected by traditional tests.

Methods: The performances of 28 patients with SCD and 28 age and education-matched healthy individuals with no worries of cognitive decline (healthy controls, HC) was compared on demanding tasks that investigated, respectively, associative memory, memory binding, spatial pattern separation processes and semantic memory. The diagnostic power and accuracy parameters of these tests in classifying cognitive status (SCD vs. HC) were calculated. Moreover, possible relationships

between experimental tests and SCD-related worries were investigated using a novel self-report questionnaire designed to assess subjects' global experience of memory decline and the impact of these memory concerns in daily life.

Results: No significant between-group difference was found on the standard neuropsychological tests. Conversely, the performance of patients with SCD and HC differed significantly on specific indexes derived from experimental tasks assessing face–name associative memory and spatial pattern separation. Moreover, these measures correctly classified group membership with good overall accuracy (up to 86%) and were significantly associated with the rate of self-perceived memory functioning.

Conclusions: Our findings suggest that specific measures derived from demanding cognitive paradigms could be sensitive neuropsychological indexes for detecting the subtle cognitive impairment associated with SCD. These observations could be useful for further refining cognitive assessment aimed at early detection of AD.

Objectives: Empathy is the ability to understand and to feel what others feel [1]. The aims of our study were to assess empathy deficit along Alzheimer's Disease (AD) continuum, and to explore if changes in empathy might be an early red-flag of AD pathology.

Material and Methods: Forty-five SCD, 83 MCI and 80 AD demented (AD-d) patients underwent evaluation of empathy in both cognitive and affective domains by means of Informer-rated Interpersonal Reactivity Index (perspective taking, PT, and fantasy, FT, for cognitive empathy; empathic concern, EC, and personal distress, PD, for affective empathy) before (T0) and after (T1) cognitive symptoms' onset. Ekman 60 Faces (EK-60F) Test was administered to investigate emotion recognition ability. Twenty-two SCD, 53 MCI and 80 AD underwent CSF biomarker analysis and/or amyloid-PET and were classified as carriers of AD pathology (AP+) when A+/T+ (regardless of N), or non-carriers (AP-) when they were A- (regardless of T and N), or A+/T-/N-, or A+/T-/N+ according to A/T(N) system.

Results: PD-T1 scores were lower in SCD than in MCI (20.13±5.55 vs 24.03±5.76, p=0.002) and AD-d (25.82±5.77, p<0.001). Δ-PD (T0-T1) was significantly lower in AD-d as compared to SCD (-8.17±6.87 vs -2.50±3.08, p<0.001) and to MCI (-5.13±5.21, p=0.003), while Δ-PT (T0-T1) was higher in AD-d than in SCD (5.12±6.11 vs 0.50±3.50, p<0.001) and MCI (2.05±4.71, p=0.001). In SCD Δ-PD (T0-T1) was lower AP+ than in AP- patients (-7.75±2.63 vs -1.81±2.16, p<0.001). In a multivariate linear regression analysis, AP status was the only variable that significantly influenced Δ-PD (T0-T1) (B=-2.96 [95% CI -5.68:-0.24], p=0.033). In MCI and in AD-d, PT scores decreased T0-T1 (MCI z=-3.82, p<0.001, AD-d z=-6.37, p<0.001). PD scores increased T0-T1 in SCD (z=-4.27, p=0.001), MCI (z=-7.06, p<0.001) and AD-d (z=-7.14, p<0.001). AD-d patients showed lower scores in recognition of all facial emotions than MCI and SCD (p<0.001). No differences were detected in EK-60F scores between SCD and MCI, except for lower scores in recognition of fear in MCI than in SCD (3.08±2.38 vs5.11±2.66, p<0.001).

Discussion: A significant decrease of PT seems to start at MCI stage [2]. On the other hand, we confirm that a significant increase in PD starts from SCD stage [3] and seems to be influenced by the presence of an underlying AD pathology alone.

Conclusions: Empathy is impaired in AD and seems to change along the AD continuum. Changes in personal distress might be a predictive feature of a cognitive decline driven by AD pathology.

## DON'T TOUCH THE FLANKER! A KINEMATIC ANALYSIS OF EYE-HAND MOVEMENTS IN PATIENTS WITH AMNESTIC MCI DUE TO AD

A. Iavarone[1], R. Amato[1], M. Palladino[1], M. La Marra[2], M. Sannino[1], S. Chieffi[2], C. Ilardi[3]

[1]Neurological Unit, CTO Hospital, AORN "Ospedali Dei Colli" (Napoli); [2]Department of Experimental Medicine, University of Campania "Luigi Vanvitelli" (Napoli); [3]Department of Psychology, University of Campania "Luigi Vanvitelli" (Caserta)

Objectives: Although severe movement disorders are traditionally considered pathognomonic of an advanced stage of Alzheimer's disease (AD), patients with MCI (PwMCI) seem to exhibit a certain degree of visuomotor perturbations, resulting in slower, less accurate, and less coordinated in performing eye-hand movements than healthy controls [1]. Such visuomotor difficulties would become more pronounced under high cognitively demanding conditions [2]. All the few studies assessing kinematics of reaching movements in MCI have been conducted under poorly ecological conditions (in the absence of visual distractors). Here, we attempted to compensate for this gap.

Materials and Methods: Eleven patients with amnestic MCI due to AD (5 females; M age=72.36 years, SD=7.09; M education=12.55 years, SD=4.32), 10 healthy older adults (HOA, 4 females; M age=66.70 years, SD=5.35; M education=12.40 years, SD=4.19), and 11 healthy young adults (HYA, 5 females; M age=29.92 years, SD=3.20; M education=18.08 years, SD=0.90) participated in this experiment. All were right-handed. The apparatus consisted of a

digitizer and a non-inking electronic stylus. The stimuli were two vertically-aligned dots (starting and target dot). The axis covering the inter-dot distance (200 mm), referred to as reaching axis (RA), could be flanked by a visual distractor, i.e., a small black square (the flanker), arranged to the left at a distance of 1, 3 or 5 mm, with the flanker side midpoint matching the RA midpoint. Participants were instructed to execute, at a natural speed, right-handed movements to reach the target. Movements could be performed with or without the flanker (40 randomized trials). If present, participants were instructed not to "touch" the flanker.

Results: Bonferroni's adjusted mixed design was used. Trajectories significantly deviated away from the flanker location ($F(3,75) = 11.568$, $p<0.001$), with lateral deviations amplitude being a function of the flanker proximity, i.e., the closer the flanker was to the RA, the greater the rightward deviation of trajectories. When the flanker was 1 mm away, a greater constant lateral deviation was recorded in PwMCI (M diff=0.985, $p<0.001$). Also, patients demonstrated reduced movement consistency regardless of the experimental manipulation ($F(2,25) = 4.887$, $p<0.05$). Both HOA and PwMCI were slower in the "flanked" than in control trials, while HYA reached the target dots with the same average speed across all trials.

Discussion: Our findings are in line with the growing prevalent view that a multidimensional assessment involving both cognitive and motor domains should be taken into account for profiling the clinical picture of individuals with suspected MCI-AD.

## SUPRAMODAL EXECUTIVE ANOSOGNOSIA IN PATIENTS WITH AMNESTIC MCI DUE TO AD

A. Iavarone[1], R. Amato[1], M. Palladino[1], M. Sannino[1], S. Chieffi[2], M. La Marra[2], C. Ilardi[3]

[1]Neurological Unit, CTO Hospital, AORN "Ospedali Dei Colli" (Napoli); [2]Department of Experimental Medicine, University of Campania "Luigi Vanvitelli" (Napoli);[3]Department of Psychology, University of Campania "Luigi Vanvitelli" (Caserta)

Objectives: Despite the seemingly established assumption that the prevalence of anosognosia increases as Alzheimer's disease (AD) worsens, recent evidence has suggested that patients with Mild Cognitive Impairment (PwMCI) may demonstrate poor awareness of their memory deficits. Indeed, the presence of memory complaints/concerns is no longer considered a mandatory prerequisite for amnestic MCI diagnosis [1]. Therefore, the detection of anosognosia has important clinical implications. While studies using offline methods (patient-informant discrepancy) converge on the view that mnemonic anosognosia is commonly encountered in MCI, conflicting findings arise from studies assessing metamemory monitoring [2]. Accordingly, we further investigated executive anosognosia in PwMCI.

Materials and Methods: Sixteen patients with a clinical and etiological diagnosis of amnestic MCI due to AD (9 females; M age=72.06 years, SD=6.32; M education=10.06 years, SD=4.88) and 19 healthy controls (HCs, 10 females; M age=68.11 years, SD=5.81; M education=12.05 years, SD=5.24) took part in this experiment. We administered two isomorphic tasks based on either verbal or visuospatial material according to Galeone et al. [3]. Participants were asked to predict their memory performance over three trials, before (pre-study prediction) and after (post-study prediction) the encoding session. Specifically, they were instructed to rate how many words from a 10-word list, and how many of five spatial positions from a 6x6 random matrix configuration, they would have memorized, respectively.

Results: A Bonferroni-adjusted 2x3x3 mixed factorial design (2 groups vs. 3 trials vs. response type, i.e., pre-study, post-study, recall) was applied. In the verbal task, all participants overestimated their memory performance at both pre- (M diff=1.351, $p<0.001$) and post-study (M diff=0.961, $p<0.001$). While overestimation of HCs was quite negligible (M diff=0.868, $p<0.05$), PwMCI claimed to remember about 1.5 more words than they actually did ($p<0.001$). In the visuospatial task, all participants revised upward their predictions after viewing the spatial matrices (M diff=0.353, $p=0.04$), exhibiting a sort of overconfidence bias. However, PwMCI demonstrated a higher degree of overestimation (M diff=1.813, $p<0.001$) than HCs (M diff=0.772, $p=0.002$). Interestingly, PwMCI substantially revised upward their predictions in the third/last attempt, which is a potential marker of executive anosognosia.

Discussion: PwMCI due to AD may suffer from supramodal executive anosognosia, i.e., unaffected by the type of material to be encoded. Results from this study may support the change of course of international guidelines in the direction of removing the "categorical imperative" of subjective memory complaints/concerns from the criteria used to make diagnosis of amnestic MCI.

## MONOAMINERGIC NETWORK ABNORMALITIES EXPLAIN FATIGUE IN PEDIATRIC MULTIPLE SCLEROSIS

M. Margoni[1], P. Valsasina[1], L. Moiola[2], D. Mistri[1], M. Rocca[3], M. Filippi[4]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [2]Neurology Unit, IRCCS San Raffaele Scientific Institute (Milano); [3]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [4]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: Although fatigue is frequently observed in pediatric multiple sclerosis (pedMS), little is known about its pathological substrates in these patients. The aim of this study is to investigate monoaminergic network abnormalities in pedMS patients according to their fatigue status through a positron emission tomography (PET)-based constrained independent component analysis (ICA) on resting state (RS) functional MRI (fMRI).

Material and Methods: Fifty-five right-handed pedMS and 23 matched pediatric healthy controls (HC) underwent neurological,

fatigue, depression and RS fMRI assessment. Patients were classified as fatigued (F) or non-fatigued (nF) according to their fatigue severity scale (FSS) score. Patterns of dopamine-, noradrenaline- and serotonin-related RS functional connectivity (FC) were derived by ICA, constrained to PET atlases for dopamine, norepinephrine and serotonin transporters, obtained in HCs' brain.

Results: None of pedMS patients had depression and fifteen of them were F. Compared to nF pedMS patients and HC, F pedMS patients showed decreased dopamine-related RS FC in the right postcentral gyrus. In addition, F pedMS patients showed decreased dopamine-related RS FC in the left insula vs HC and increased dopamine-related RS FC in the left middle temporal gyrus and cerebellar lobule VI vs nF pedMS. In the noradrenaline-related network, F pedMS patients showed decreased RS FC in the left superior parietal lobule and increased RS FC in the right thalamus compared to HC and nF pedMS. In addition, F pedMS patients showed decreased RS FC in the right calcarine cortex and increased RS FC in the right middle frontal gyrus vs HC. Finally, in the serotonin-related network, F pedMS patients showed decreased RS FC in the right angular gyrus and increased RS FC in the right postcentral gyrus vs nF MS patients and HC.

Discussion: PedMS patients with fatigue showed diffuse dysregulation in the monoaminergic networks of sensorimotor areas, such as the primary sensorimotor cortex, as well as of cortico-subcortical circuits, including thalamus and cerebellum, which are part of the sensorimotor network and are central to motor planning and execution.

Conclusions: Our findings may provide a pathological marker for fatigue and putative targets for its treatment in pedMS population.

## DEVELOPMENT OF DEPRESSIVE SYMPTOMS AND RESTING STATE FUNCTIONAL CONNECTIVITY MODIFICATIONS IN MONOAMINERGIC NETWORKS IN MULTIPLE SCLEROSIS

D. Mistri[1], P. Valsasina[1], L. Storelli[1], M. Filippi[2], M. Rocca[3]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [2]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [3]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: Growing pieces of evidence suggest that depression in multiple sclerosis (MS) patients might have a neurobiological basis rather than being a mere consequence of disability accumulation. Here, we investigated whether the development of depressive symptoms in MS was associated with changes of resting state functional connectivity (RS FC) within monoaminergic networks.

Materials and Methods: Forty-nine MS patients and 27 healthy controls (HC) underwent clinical and 3.0 T RS functional MRI assessment at baseline and after a median follow-up of 1.6 years (interquartile range=1.0-2.1 years). Depressive symptoms were evaluated using the Montgomery-Asberg Depression Scale (MADRS). MS patients were included if their baseline MADRS was <9 (i.e., no depression). Monoaminergic network-related RS FC was derived by independent component analysis, constrained to PET atlases for dopamine, noradrenaline and serotonin transporters.

Results: Fourteen (29%) MS patients developed depressive (D) symptoms at follow-up, while 35 (71%) remained not depressed (ND). At baseline, MS patients showed decreased RS FC vs HC in all three PET-guided monoaminergic networks in frontal, cingulate and cerebellar cortices, and increased RS FC in parieto-occipital regions. HC showed no significant RS FC changes over time, while ND-MS patients showed limited RS FC changes over time. Conversely, D-MS patients showed a widespread RS FC decrease over time in the PET-guided dopamine network, mainly in orbitofrontal, middle occipital, anterior cingulate and precuneal cortices (all significant at time-by-group interaction analysis), and in calcarine/lingual cortices. They also presented decreased RS FC over time in parahippocampal and occipital regions of the PET-guided noradrenaline network. In MS patients, increased MADRS scores over time correlated with decreased RS FC in the right precuneus ($r=-0.65$, $p<0.001$) of the dopamine network and in parahippocampal gyrus ($r=-0.61$, $p<0.001$) of the noradrenaline network.

Discussion: The results showed that MS patients who developed depressive symptoms exhibited significant decreased RS FC in multiple regions within the PET-guided dopamine and noradrenaline networks. These findings highlight the potential neurobiological basis of depression in MS and emphasize the importance of considering the underlying neural mechanisms when addressing depressive symptoms in MS patients.

Conclusions: RS FC alterations within the monoaminergic networks may contribute to the development of depression in MS.

## GERSTMANN SYNDROME WITH ACUTE, SUBACUTE, AND INSIDIOUS ONSET. A SYSTEMATIC REVIEW AND INDIVIDUAL PATIENT DATA ANALYSIS

G. Polito, M. Russo, S. Melchiorre, C. Cipretti, P. Quintieri, F. Dono, M. Onofrj, S. Sensi

Department of Neuroscience, Imaging and Clinical Science, "G. D'Annunzio" University of Chieti-Pescara (Chieti-Pescara)

Gerstmann syndrome (GS) is a rare neurological condition featuring agraphia, acalculia, finger agnosia, and left-right disorientation. Many pathological conditions, such as focal brain injuries (e.g., stroke, trauma, or tumors) and neurodegenerative diseases, can lead to GS. In this systematic review, we compared the features of GS cases with acute, subacute, and insidious onset. Eighty-eight patients were selected (M 63.6%, mean onset age: 55.2±15.8). Acute onset was the most common presentation of GS (40.9%), followed by the insidious one (39.8%), while the subacute cases were less frequent (19.3%). Of the 36 acute cases of GS, 44.4 % were caused by ischemic strokes, 41.6 % by brain hemorrhages, 5.5 % by brain tumors, and 8.3% by other conditions. Among the 17 subacute cases, 47.0% were associated with brain tumors, 17.6% with encephalitis, and 35.3% with other conditions. Of the 35 cases with insidious progression, 62.8 % were due to neurodegenerative disorders, 14.3% to brain tumors, 2.8 % to encephalitis, and 20.0% to other conditions. Interestingly, patients with subacute onset of GS were younger (49±18,2 yo) than the other two groups (acute onset: 58,9± 14,6 yo; insidious onset: 55,4±15,2). Furthermore, the three categories showed differences in clinical features and concomitant cognitive and non-cognitive symptoms, possibly due to different compensatory mechanisms ensuing in subacute and insidious progressions. Finally, we analyzed and compared the differences among etiological subgroups (vascular, neurodegenerative, tumor-related) to highlight distinctive features.

## COGNITIVE FUNCTION IN NON-RELAPSING MYELIN OLIGODENDROCYTE GLYCOPROTEIN ANTIBODY ASSOCIATED DISEASE (MOGAD): A CASE SERIES

M. Risi[1], M. Altieri[2], A. Bisecco[1], A. d'Ambrosio[1], R. Docimo[1], R. Capuano[1], R. M. Borgo[1], M. Cirillo[3], G. Tedeschi[1], A. Gallo[1]

[1]Division of Neurology, Department of Internal Medicine, Geriatrics and Neurology, University of Campania "Luigi Vanvitelli" (Napoli); [2]Department of Psychology, University of Campania "Luigi Vanvitelli" (Napoli); [3]MRI Research Center SUN-FISM, University of Campania "Luigi Vanvitelli" (Napoli)

Background: MOGAD is an inflammatory antibody-mediated disease, affecting both white and grey matter of CNS. It is more frequent in children and young adults. The clinical course can be either monophasic or relapsing, often with complete recovery. To date, only few studies explored cognitive functions in patients with MOGAD. Patients with relapsing MOGAD have recently been reported to have impaired reasoning skills and overall response time, compared to healthy controls. Aims: To assess cognitive performance in a small cohort of six patients with non-relapsing MOGAD.

Materials and Methods: Six patients with non-relapsing MOGAD were included (4F:2M, mean age 29.6 years). We assessed cognitive functions with the Rao's Brief Repeatable Battery and the Stroop test after at least twelve months from recovery (follow-up=28.3±16.9 months). All test results were adjusted for age, sex and education and converted to Z scores. Patients who failed two tests or more (Z score <-1.5) were defined cognitively impaired (CI).

Results: As clinical manifestation at onset, three patients had acute disseminated encephalomyelitis (ADEM), one had cortical encephalitis with seizures, and two had optic neuritis. Clinical recovery occurred in all patients (mean EDSS at follow-up 1.5). After the first event, no patient experienced relapses, without any further treatment. Improvement in lesions volume on MRI during follow-up occurred in all cases, without new lesions. Cognitive assessment did not reveal CI patients. Discussion: Differently from patients with relapsing MOGAD, in our non-relapsing cohort no patients failed any cognitive tests. These data could suggest that the relapsing course could be a risk factor for the development of long-term cognitive impairment in patients with MOGAD.

## FRAILTY IN ATRIAL FIBRILLATION: IMPACT OF SOCIODEMOGRAPHIC AND COGNITION IN A COHORT OF OLDER PATIENTS ON ORAL ANTICOAGULANTS: STRAT-AF 2 STUDY

E. Salvadori[1], E. Barucci[1], B. Formelli[1], C. Barbato[1], F. Pescini[2], F. Cesari[3], B. Giusti[3], A. Gori[3], A. Ginestroni[4], E. Fainardi[4], R. Marcucci[3], A. Poggesi[1]

[1]NEUROFARBA Department, Florence University (Firenze); [2]SOD Stroke Unit, AOU Careggi (Firenze); [3]Atherothromobotic Disease Centre, AOU Careggi (Firenze); [4]Neuroradiology Department, AOU Careggi (Firenze)

Background and Aims: Frailty is a condition of higher vulnerability to stressful stimuli, characterized by poor homeostatic resolution and reduced resistance to stressors representing one of the most problematic expressions of population aging. In patients with atrial fibrillation (AF), frailty is associated with increased stroke incidence, length of hospitalization, and mortality. In a cohort of older AF patients on oral anticoagulants (OAC), we evaluated: the prevalence of frailty and its association with sociodemographic, psychological, cognitive, clinical, functional, and motor dimensions.

Methods: Strat-AF 2 is an observational prospective study that enrolled patients with AF, age ≥65 years, on OAC. All patients were evaluated by means of a comprehensive standardized protocol, and frailty was assessed using the 5 criteria of the Fried phenotype: weight loss, grip strength, walking speed, exhaustion, and physical activity. Each patient was categorized as robust (no criterion), pre-frail (1-2 criteria), and frail (≥3 criteria).

Results: Out of the 171 enrolled patients (mean age 77.7±8.8, 41% females), 12 (7%) were classified as frail, 70 (41%) pre-frail, and 89 (52%) robust. Compared with robust and pre-frail patients, frail ones were significantly older (75.9±10.2, 78.9±6.2, 83.4±7.3, p=.003, respectively), less educated (10.5±4.5, 10.4±4.5, 5.9±1.7, p=.001), mostly women (28%, 49%, 92%, p=.001), and more frequently not married (18%, 27%, 50%, p=.037) and living alone (12%, 21%, 42%, p=.030). Frail patients presented also higher presence of depressive symptoms (Geriatric Depression Scale: 3.2±2.8, 3.9±3.1, 7.7±3.7, p=.001), psychiatric disorders (42%, 50%, 83%, p=.023), and cognitive impairment (40%, 51%, 83%, p=.015), compared to robust and pre-frail ones, as well as reduced cognitive efficiency in memory (Short Story: 14.5±4.9, 13.9±4.6, 9.6±3.5, p=.004) and executive functions (Stroop execution time: 24±20.3, 29.7±32.1, 60.7±40.2, p=.001). As expected, functional and motor status was worse in frail patients, while comorbidities and vascular risk factors were not different among the 3 phenotypes.

Discussion: In our cohort of older AF patients, frailty was mainly and strongly associated with unfavorable sociodemographic, psychological and cognitive characteristics, stressing the fact that frailty is a real multidimensional construct. Further studies are needed to explore the multifaceted nature of frailty syndrome beyond its physical dimension.

## USEFULNESS OF PERSONALITY INVENTORY FOR DSM-5 IN SUBJECTS WITH MESIAL TEMPORAL LOBE EPILEPSY AND PSYCHOGENIC NONEPILEPTIC SEIZURES

I. Sammarra, I. Martino, F. Fortunato, A. Giugno, L. Marino, C. Fratto, A. Gambardella

Institute of Neurology, Department of Medical and Surgical Sciences, Magna Graecia University (Catanzaro)

Aims: The 5th version of Diagnostic and Statistical Manual of Mental Disorders (DSM-5) introduced a new dimensional, trait-based approach in the Section III to become an emerging model for personality disorders (PDs) [1]. In this work we assessed personality psychopathology through the instrument of personality Inventory for DSM-5 (PID-5) [1] in subjects with mesial temporal lobe epilepsy (MTLE), Psychogenic Nonepileptic Seizures (PNES) and healthy controls (HC).

Material: We consecutively enrolled 30 MTLE patients (female: 18/30; mean age: 43±14.3 years), 36 subjects affected by PNES (female: 25/36; mean age: 41±14.1 years) and 25 HC (female: 15/25; mean age: 32.7±10 years), matched for age and gender.

Methods: In all three groups, the neuropsychiatric evaluation provided Beck Depression Inventory-2 (BDI-2), estimating the severity of depressive symptoms; State-Trait Anxiety Inventory (STAI), measuring state (STAI-S) and trait (STAI-T) anxiety; Toronto Alexithymia Scale (TAS-20), testing alexithymia; PID-5 assessing the pathology model proposed in Criterion B of DSM-5 Section III. Differences among three groups were demonstrated through ANOVA and Kruskal–Wallis test by ranks for normally and not-normally distributed values, respectively.

Results: We found a statistically significant difference in the following PID-5 trait facets: i) Anxiousness ($p=0.014$), showing the PNES group higher values than HC ($p=0.014$); ii) Emotional lability ($p=0.023$), manifesting PNES greater values than HC ($p=0.006$); iii) Impulsivity ($p=0.007$), having PNES higher values than HC ($p=0.002$) and lower than MTLE ($p=0.046$); iv) Cognitive and perceptual dysregulation ($p=0.011$), with greater values in PNES ($p=0.016$) and MTLE ($p=0.005$) groups compared to HC; v) Perseveration ($p=0.037$), with greater values in PNES ($p=0.044$) and MTLE ($p=0.014$) subjects compared to HC. Moreover, we demonstrated a significant difference in Disinhibition PID-5 domain ($p=0.023$), having PNES higher values than HC ($p=0.023$). A statistical difference was proved in STAI-S ($p<0.001$), STAI-T ($p<0.001$) and BDI-2 ($p<0.001$) with higher values in PNES ($p<0.001$) and MTLE ($p<0.001$) groups compared to HC as well as in TAS-20 ($p=0.002$), with greater values in PNES subjects than MTLE ($p=0.001$).

Discussion: In our work, PNES subjects exhibited some personality traits considered as predictive of Borderline PD[1] using the latest tool for fulfil DSM-5 criterion B, as Disinhibition, Anxiousness, Emotional lability, and Impulsivity. Concomitantly, although not satisfying the criteria for a specific PD, MTLE patients manifested aspects of Perseveration and Cognitive and perceptual dysregulation.

Conclusions: Our results contribute to delineate personality profile in MTLE[2] and PNES[3] subjects, in whom assessment of pathological personality traits could have relevant clinical implication in diagnosis and therapeutic intervention.

## EVALUATION OF CAREGIVERS BURDEN IN MULTIPLE SCLEROSIS

G. Schirò, S. Iacono, M. Andolina, G. Sorbello, A. Calì, G. Salemi, P. Ragonese

Department of Biomedicine, Neuroscience and Advanced Diagnostics, University of Palermo (Palermo)

Background: Patients with multiple sclerosis (pwMS) experience an accumulation of disability through a worsening of clinical conditions associated with relapses or through relapse-independent progression. Therefore, many patients need for greater assistance which in the most dramatic cases also concerns the activities of daily life such as dressing, feeding or washing [1].

Aims: To evaluate the impact of disability and disease severity on caregivers of pwMS.

Methods: 148 subjects, 74 patients and 74 caregivers were enrolled. The caregivers were evaluated through two questionnaires, the Hospital Anxiety and the Depression Scale (HADS) and Caregiver Burdy Inventory (CBI), in order to explore the physical and psychological burden of their cares to the patients. We collected demographic data and level of education for each caregiver, and severity of disability assessed by EDSS, disease duration, form of disease (relapsing-remitting (RR) or progressive) and treatment for each patient.

Results: We found that the caregivers of RR pwMS were more frequently male, while for progressive patient the caregivers resulted more often a woman. A higher level of education was found for caregivers of RR pwMS (median [IQR] 13 [12-16] vs 8 [8-13], $p=0.001$). Burden between caregivers of RR pwMS and progressive pwMS was higher in the second group both at HADS ($7.4 \pm 6.3$ vs $12.3 \pm 6.7$, $p<0.002$) and CBI ($8.5 \pm 10.4$ vs $22.4 \pm 16.8$, $p<0.0001$). In particular, caregivers of progressive patients spend much more on patient care as evaluated by Time-dependence burden in CBI (mean value ± SD was $9.9 \pm 6.6$ vs $2.9 \pm 4.5$ $p<0.0001$) and need more to rest.

Discussion and Conclusions: Our study showed that caregivers of pwMS experience high levels of anxiety and depression. In particular, caregivers of progressive patients spent much time on patients care and are a high risk of depression, anxiety and burnout.

## COGNITIVE IMPAIRMENT IS ASSOCIATED WITH GAIT VARIABILITY AND FALL RISK IN AMYOTROPHIC LATERAL SCLEROSIS

G. Senerchia[1], M. Spisto[1], J. Hausdorff[2], G. Aceto[1], V. Iuzzolino[1], S. De Marco[1], L. Marcuccio[3], C. Femiano[3], R. Iodice[1], E. Salvatore[1], G. Santangelo[4], L. Trojano[4], P. Moretta[3], R. Dubbioso[1]

[1]Department of Neurosciences, Reproductive Sciences and Odontostomatology, University "Federico II" of Naples (Napoli); [2]Center for the Study of Movement, Cognition and Mobility Tel Aviv Sourasky Medical Center (Tel Aviv-ISR); [3]Neurological Rehabilitation Unit of Telese Terme Institute, Istituti Clinici Scientifici Maugeri IRCCS (Benevento); [4]Department of Psychology, University of Campania Luigi Vanvitelli (Napoli)

Background: In amyotrophic lateral sclerosis (ALS), gait abnormalities contribute to poor mobility and represent a relevant risk for falls. To

date, gait studies in ALS patients focused on the motor dimension of the disease, underestimating the cognitive aspects.

Materials and Methods: Using a wearable gait analysis device, we compared gait patterns in ambulatory ALS patients with Mild Cognitive Impairment (ALS MCI+; n=18), and without MCI (ALS MCI-; n=24), and healthy individuals (HS; n=16) under two conditions: (1) normal gait (single task), (2) walking while counting backward (dual task). Finally, we examined if the occurrence and number of falls in the three months following the baseline test were related to cognition.

Results and Discussion: In the single task condition, ALS patients, regardless of cognition, displayed higher gait variability than HS, especially for stance and swing time ($p< 0.001$). The dual task condition revealed additional differences in gait variability parameters between ALS MCI+ and ALS MCI- for cadence ($p=0.005$), stance time ($p=0.04$), swing time ($p=0.04$) and stability index ($p=0.02$). Moreover, ALS MCI+ showed a higher occurrence ($p=0.001$) and number of falls ($p<0.001$) at the follow-up. Regression analyses demonstrated that MCI condition predicted the occurrence of future falls ($\beta= 3.649$ $p= 0.01$) and, together with executive dysfunction, was associated with the number of falls (cognitive impairment: $\beta= 0.63$; $p<0.001$; executive dysfunction: $\beta= 0.39$; $p= 0.03$), regardless of motor impairment at clinical examination.

Conclusion: In ALS, MCI is associated with exaggerated gait variability and predicts the occurrence and number of short-term falls, independent of motor impairment.

## "SOMEWHERE BETWEEN AN ACTUAL DISEASE AND A DISEASE": A GROUNDED THEORY STUDY ON COMPREHENDING FUNCTIONAL NEUROLOGICAL DISORDERS DIAGNOSIS IN AN ITALIAN HOSPITAL

F. Sireci[1], V. Moretti[2], S. Ferrari[3], F. Cavallieri[1], L. Ghirotto[4], L. Balestra[4], V. Minardi[1], F. Valzania[1]

[1]Neurology Unit, AUSL IRCCS Reggio Emilia (Reggio Emilia); [2]Department of Mental Health, Ausl Modena (Modena); [3]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, AUSL IRCCS (Reggio Emilia); [4]Qualitative Research Unit, AUSL IRCCS Reggio Emilia (Reggio Emilia)

Aims: Functional neurological disorders (FNDs) refer to several conditions characterised by sensorimotor or cognitive symptoms. For long interpreted as psychogenic, FNDs are increasingly explained through complex models of the interrelation of biological, psychological and social factors. Studies suggest how uncertainty and discrepancies about the diagnosis and the appropriate treatments persist.

Materials: We designed a constructivist Grounded Theory (GT) study to explore the generative questions: "1- How are FNDs understood by health professionals (HPs) and patients and 2- how does that affect the care pathway?".

Methods: The study was conducted in the provincial hospital of Reggio Emilia in Northern Italy, part of the Local Health Authority (Azienda USL-IRCCS di Reggio Emilia). We recruited the participants from the Neurology Department. We performed an initial sampling and a theoretical sampling. Before the initial sampling, a kick-off meeting with all the neurologists recruiters was organised, then seven patients and seventeen HPs were interviewed. We conducted semi-structured interviews: we pre-planned the interview guides, one for patients and one for HP.

Results: Through conceptual data analysis, we generated a theoretical model to explore our questions along four phases: 1- the onset of the symptoms, 2- access to health services, 3- labelling the disease and 4- treatment proposal. We systematised the model into a core category: "negotiating the multiple ontologies of medical practice", and three sub-categories: i) defining the disease, ii) exposing reductionisms, iii) emergence of a pluralist vision.

Discussion: The care process of FNDs arose at the intersection of different ways to understand the problem. Various barriers to the effective delivery of care depended on the way the disease is thought of and defined based on a reductionist mindset that "flattens" it on the body or the mind. Both HPs and the patients felt the need for a more integrated understanding and management of FNDs.

Conclusions: We suggest that proper attention should be given to improve provider-patient communication to build a therapeutic alliance and provide HPs with training on the clinical and relational components of FNDs. Structured multi-professional care pathways must be developed based on integrated biopsychosocial etiological models.

## THE CARE PATHWAYS BEYOND MEDICAL ASPECTS THAT ARE OFFERED TO PATIENTS DIAGNOSED WITH FUNCTIONAL NEUROLOGICAL DISORDER. A SCOPING REVIEW

F. Sireci[1], F. Ragucci[1], M. Cabboi[1], F. Cavallieri[1], L. Ghirotto[2], C. Menozzi[3], F. Valzania[1]

[1]Neurology Unit, AUSL IRCCS Reggio Emilia (Reggio Emilia); [2]Qualitative Research Unit, AUSL IRCCS Reggio Emilia (Reggio Emilia); [3]Department of Primary Health Care, AUSL IRCCS Reggio Emilia (Reggio Emilia)

Aims: The interpretation of care pathways for non-medical issues of Functional Neurological Disorders (FNDs) is challenging. A comprehensive understanding of the illness, considering the interaction between psychological, social, and biological factors, should be promoted to better support non-medical treatment strategies for FNDs. We aimed to map the psycho-social, non-medical interventions targeting FNDs, identifying existing knowledge and major areas of interest.

Materials: We adopted the Scoping Review methodology to provide a comprehensive understanding of how to effectively support individuals with FNDs beyond physical complaints. The final review question

was: "What are the care pathways beyond medical aspects that are offered to patients diagnosed with Functional Neurological Disorder?".

Methods: PPC mnemonic tool (Population, Context, and Concept) was used to define a search strategy. Functional Neurological Disorder patients (Population) and non-medical interventions (Concept) terms were applied. We undertook a comprehensive literature search on electronic databases, plus hand-search, that encompassed a wide range of study designs, from randomized clinical trials to single case reports.

Results: Twenty-eight papers were included. Patients aged approximately 30-50 years old and 68.2% were females. Interventions were usually provided in person at healthcare facilities. Education on the illness, psychotherapy, and treatment adherence improvement were adopted as core intervention strategies to pursue (i) symptoms reduction, (ii) global health status improvement, and (iii) encourage patients' understanding and acceptance of the disorder. Multi-professional care pathways including neurologists, psychiatrists, physiotherapists, occupational therapists, and psychologists were encouraged.

Discussion: By exploring care pathways, a crucial point is to understand how professionals from various disciplines can provide holistic care that meets the patient's needs. Within healthcare facilities, neurological diagnosis is the first step; at this stage, education about the illness is provided to enable patients' understanding and minimize uncertainty. Next, psychiatric consultancy follows, and psychological support or psychotherapy is offered. Patients are then engaged in physiotherapy if motor functionality recovery is needed. Occupational therapy, though helpful to restore daily activities of the individual, is less common. The use of motivational interviewing has been lately evaluated to engage patients in group or individual psychotherapy.

Conclusions: FNDs symptoms can trigger clinically significant distress or impairment in social, occupational, or other important areas of functioning. (Psycho)education is documented as the first-line strategy to give patients a starring role in their own care. Insights about the mind-body connection is supposed to raise awareness of subjective dysfunctional emotional processing and negative appraisals about the disease, with the potential to improve treatment adherence.

## PSYCHOANALYTIC PSYCHOTHERAPY UNCOVERS VERY HIGH PREVALENCE OF STRESSFUL LIFE EVENTS AT THE ORIGIN OF FUNCTIONAL NEUROLOGICAL DISORDERS

M. Stampanoni Bassi[1], G. Galifi[1], M. Lipera[1], C. Antonucci[2], B. Aramini[2], C. Femiano[1], S. Cappellano[1], D. Centonze[1], L. Gilio[1]

[1]Unit of Neurology, IRCCS Neuromed (Pozzilli-IS);[2]Italian Institute of Psychoanalysis for Research and Clinic PSICOMED (Pozzilli-IS)

Objectives: Despite high incidence of adverse life events in patients with functional neurological disorders (FNDs), a considerable proportion of patients report no traumatic events [1,2]. Some difficulties in assessing relevant personal life experiences through standardized evaluations may contribute to the observed variability [3]. We compared the frequency of remote and recent adverse life events assessed by a standardized psychological/psychometric approach and by a brief psychoanalytic intervention (BPI).

Materials and Methods: In 81 newly diagnosed FNDs patients a comprehensive psychological/psychometric assessment of mood, personality disorders, and adverse remote and recent life events was performed using standardized questionnaires (Life Stressor Checklist-R, LSCL-R). Each participant completed 5-8 sessions of psychoanalytic psychotherapy. Psychotherapists, who were blind to psychometric assessment, recorded relevant remote and recent adverse events. To compare the two evaluations, overall agreement, positive and negative percent agreement were calculated along with their 95% exact (Clopper-Pearson) confidence intervals (95% CI). The prevalence of adverse events assessed by the BPI in FNDs patients was compared with a group of 66 patients with organic neurological symptoms and psychological complaints requiring psychotherapy.

Results: Psychological/psychometric evaluation showed a high prevalence of depression (64.2%), state and trait anxiety (59.2% and 71.6% respectively) and personality disorders (10.5%) in patients with FNDs. A high prevalence of remote (54.3%) and recent (39.5%) adverse life events was evidenced, while no adverse events were reported by 33.3% of patients. The BPI identified significant traumatic/adverse life events in 88.9% of patients with FNDs. The BPI and the psychological/psychometric assessment (considered as a non-reference standard) showed a 68% overall agreement (95% exact-CI: 57%; 78%). Among patients reporting adverse events in the psychometric evaluation, the BPI confirmed the finding in a very high proportion of cases (positive percent agreement 93% [95% exact-CI: 82%; 98%]). Conversely the BPI identified a significant traumatic event in 81.5% of patients reporting no adverse life experiences in the psychometric/psychological assessment (negative percent agreement 18% [95% exact-CI: 6%; 38%]). Finally, the prevalence of traumatic events detected during the BPI was significantly higher in FNDs patients than in the control group (88.9% vs 62.1%, p=0.01).

Discussion and Conclusions: An individualized psychoanalytic approach may contribute to a comprehensive evaluation of predisposing or triggering factors in patients with FNDs, revealing a very high prevalence of adverse life experiences. These data could have important implications for the pathogenesis and the treatment of FNDs.

## THE BRIEF REPEATABLE BATTERY OF NEUROPSYCHOLOGICAL TEST (BRB-N) VERSION A: UPDATE OF ITALIAN NORMATIVE DATA FROM THE ITALIAN NEUROIMAGING NETWORK INITIATIVE (INNI)

N. Tedone[1], C. Vizzino[1], A. Meani[1], A. Gallo[2], M. Altieri[2], A. d'Ambrosio[2], P. Pantano[3], C. Piervincenzi[3], S. Tommasin[3], N. De Stefano[4], R. Cortese[4], M. Stromillo[4], M. Rocca[5], M. Filippi[6]

Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [6]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: Cognitive impairment is a frequent manifestation of MS and significantly affects patients' quality of life. Accurate cognitive assessment is of utmost importance for treatment decisions and understanding disease progression. Several neuropsychological batteries are used in MS, including the Brief Repeatable Battery of Neuropsychological Tests (BRB-N), which includes two versions: A and version B for follow-ups; the Minimal Assessment of Cognitive Function in MS (MACFIMS), and the Brief International Cognitive Assessment for MS (BICAMS). Normative data for version A of the BRB-N in Italy were published in 2006 and are outdated. We aimed to revise and update the normative data for BRB-N version A in the Italian population and standardize demographic correction for BRB-N version A to align with other commonly used neuropsychological batteries in Italy, using consistent statistical methods.

Materials and Methods: 320 healthy subjects aged from 18 to 81 years (161 males and 159 females; mean age: 40.96, standard deviation [SD]= 14.25 years; mean education= 15.30, SD= 4.24 years) were recruited from four Italian sites affiliated with the Italian Neuroimaging Network Initiative (INNI). All participants underwent neuropsychological assessment using the BRB-N version A following standardized procedures. Demographic correction for each test of the BRB-N version A was calculated using a regression-based method relying on scaled scores. To normalize all tests' score distribution, raw scores of BRB-N tests were transformed into a scaled score metric (mean= 10, SD= 3) based on the fractional ranks of each test. Then, the resulting scaled scores were regressed on four demographic variables: centered age (agec = age – age mean), agec2, education level, and sex.

Results: No significant differences were found in age, education, and sex distribution among the four different sites (all $p \geq 0.33$). Regression analysis provided the normative data for calculating demographically adjusted z-scores for each BRB-N version A test.

Discussion: The use of a regression-based method and scaled scores ensures consistency with other commonly used neuropsychological batteries in Italy, namely MACFIMS and BICAMS. This study increases the reliability of neuropsychological testing in assessing cognitive functions of Italian MS patients using the BRB-N version A.

Conclusion: This study provides updated normative data for the BRB-N version A in the Italian population. Updated normative data improve the validity and reliability of neuropsychological testing, providing valuable insights for clinical and research applications. Funding: Partially supported by Fondazione Italiana Sclerosi Multipla (grant FISM2018/S/3), and financed or co-financed with the '5 per mille' public funding.

## AFFECTIVE AND COGNITIVE THEORY OF MIND NETWORKS IN YOUNG HEALTHY INDIVIDUALS

C. Tripodi[1], E. Canu[1], A. Marangon[1], V. Castelnovo[1], S. Basaia[1], F. Agosta[2], M. Filippi[3]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [2]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [3]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: Among social cognition sub-domains, Theory of Mind (ToM) refers to the ability to infer others' beliefs (cognitive ToM) and to understand others' emotions (affective ToM). Despite the identification of several brain areas related to these skills, no definitive consensus has been reached as regards the underlying brain networks, and only a few neuroimaging studies investigated functional connectivity (FC) in non-clinical settings, especially in healthy adults at a young age (before 30 years), when brain circuits are still not affected by aging. We aim to identify core regions specifically and differentially involved in the two networks mediating cognitive and affective ToM in young healthy individuals, as well as to determine overlapping areas of FC.

Materials: 50 young healthy subjects (27 males and 23 females, age: 25.25±2.8, education: 15.5±2.7) underwent resting-state functional MRI (RS-fMRI) and a neuropsychological evaluation.

Methods: Based on a recent metanalysis on healthy middle-aged adults [1], two regions of interest were created as main nodes for affective and cognitive ToM, respectively: left medial prefrontal cortex (lmPFC) and right supramarginal gyrus (rSMG). A seed-based RS-FC analysis was performed between the two nodes, separately, and the rest of the brain.

Results: We observed that the lmPFC FC included an anterior and ventral network encompassing left supplementary motor area, left temporal pole, and, bilaterally, precentral gyrus and insula. On the other hand, the rSMG FC encompassed a more posterior and dorsolateral network including right precuneus, left inferior parietal gyrus and middle occipital gyrus, bilateral angular gyrus, and cerebellum crus I and II. Overlapping brain areas shared by both networks were inferior frontal gyrus, middle temporal gyrus, temporoparietal junction, and anterior cingulate cortex bilaterally.

Discussion: In line with existing literature, seed-based RS-FC analysis revealed two distinct, but interdependent ToM systems. Moreover, the involvement of the cerebellum, observed in cognitive ToM network, has been not frequently reported; however this finding is consistent with a growing body of research suggesting the cerebellar role in non-motor functions and, particularly, in social cognition.

Conclusions: By broadening our understanding of the functional circuitry responsible for ToM abilities in healthy individuals, these findings provide a model to evaluate the integrity of such networks also in a clinical scenario. This knowledge may serve to compare network deterioration across different neurodegenerative diseases, with a preferential application in the Frontotemporal Lobar Degeneration Spectrum of disorders.

## DEGENERATIVE DISEASES

## PLASMA BETA-SYNUCLEIN IS A HIGHLY ACCURA TE BIOMARKER FOR THE DIAGNOSIS OF SPORADIC CREUTZFELDT-JAKOB DISEASE

S. Abu Rumeileh[1], S. Halbgebauer[2], G. Bentivenga[3], L. Barba[1], S. Baiardi[3], A. Mastrangelo[3], P. Oeckl[2], P. Steinacker[1], A. Mammana[3], S. Capellari[3], M. Otto[1], P. Parchi[3]

[1]Department of Neurology, Martin-Luther-University Halle-Wittenberg (Halle-D); [2]Department of Neurology, Ulm University Hospital (Ulm-D); [3]Department of Biomedical and NeuroMotor Sciences (DIBINEM), University of Bologna (Bologna)

Background and aims: Beta-synuclein (beta-syn) is an emerging biofluid marker of synaptic damage in neurodegenerative diseases [1,2]. We have recently developed highly sensitive in-house immunoassays for measuring the marker in cerebrospinal fluid (CSF) and blood and reported increased concentrations in patients with prion disease compared to controls and subjects with other neurodegenerative diseases [1,2]. Here, we investigated the diagnostic value of beta-syn compared to that of classic surrogate markers in the context of rapidly progressive dementia (RPD), as well as beta-syn distribution and prognostic performance across sporadic Creutzfeldt-Jakob disease (sCJD) subtypes.

Methods: We analysed CSF and/or plasma beta-syn levels in 150 patients with sCJD, belonging to the most prevalent molecular subtypes [MM(V)1, VV2 and MV2K][3], and in 106 subjects with non-prion RPD. In the same groups, we measured CSF total tau protein (t-tau), CSF 14-3-3 protein, plasma tau and plasma neurofilament light chain protein (NfL). We assessed the diagnostic performance of all biomarkers and the possible associations between CSF/plasma beta-syn and survival in patients with sCJD.

Results: sCJD subjects demonstrated higher CSF and plasma beta-syn levels compared to non-prion RPD patients ($p<0.001$ for both). sCJD molecular subtypes showed different patterns of CSF and blood beta-syn. In the differential diagnosis between sCJD and non-prion RPD, CSF beta-syn outperformed 14-3-3 (AUC 0.95 vs. 0.89, $p=0.028$) but not t-tau (AUC 0.92, $p=0.212$). Moreover, the diagnostic value of plasma beta-syn (AUC 0.91) was superior to that of plasma tau (AUC 0.79, $p=0.001$) and plasma NfL (AUC 0.65, $p<0.001$) and not inferior to that of CSF markers (t-tau, $p=0.765$; 14-3-3, $p=0.447$; CSF beta-syn $p=0.135$). CSF and plasma beta-syn were significantly related to survival in sCJD after accounting for PRNP codon 129 genotype.

Discussion and conclusions: CSF beta-syn might be an alternative first-level diagnostic test in patients with RPD. Further, the comparable performance of plasma beta-syn to that of classic CSF surrogate markers suggests that beta-syn might represent the first highly accurate blood marker for the diagnosis of sCJD in vivo. Moreover, CSF and blood beta-syn might ameliorate stratification and prognostication of patients with sCJD.

## COGNITIVE, BEHAVIOURAL AND MOTOR IMPAIRMENT: COMPARISON BETWEEN FRONTOTEMPORAL DEMENTIA, LEWY BODY DEMENTIA, ALZHEIMER'S DISEASE AND PROGRESSIVE SUPRANUCLEAR PALSY

G. M. Acerra, C. Sorrentino, S. Cuoco, A. Cappiello, R. Erro, M. Pellecchia, P. Barone, M. Picillo

Center for Neurodegenerative Diseases (CEMAND), Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", University of Salerno (Salerno)

Introduction: Neurodegenerative disorders are a heterogeneous group of diseases that involve different anatomical systems, resulting in various clinical phenotypes. In addition to cognitive symptoms, behavioural and motor manifestations also play a crucial role in the diagnosis, having different impact on daily life of patients, leading to a gradual loss of functional independence.

Objective: The aim of this study is to describe motor, cognitive, and behavioural differences among different types of dementia.

Methods: Four groups of patients were used for the analysis: frontotemporal dementia (FTD spectrum), Lewy body dementia (LBD), progressive supranuclear palsy (PSP) and mild cognitive impairment/Alzheimer's disease (MCI/AD). An extensive battery of cognitive and behavioural tests was administered, including Montreal Cognitive Assessment (MOCA) scale and Neuropsychiatric Inventory (NPI) scale. The motor burden was calculated using the Movement Disorder Society-Unified Parkinson's Disease Rating Scale part III (MDS-UPDRS III). Activities of Daily Living (ADL), Instrumental Activities of Daily Living (IADL) and Schwab and England Activities of Daily Living Scale (S&E) were used to assess functional autonomy. The comparison between groups was performed using analysis of variance (ANOVA) and post hoc tests.

Results: Sixty-three patients were included in the study (24 FTD, 8 LBD, 11 MCI/AD, 20 PSP). The population was homogeneous in terms of age, disease duration and level of education. Significant differences of MDS-UPDRS III were found among the groups ($p<0.05$). Specifically, PSP patients exhibited the highest motor burden, while MCI/AD patients had the lowest. MOCA scores were lower in LBD compared to other types of dementia. All LBDs had a score below the median value of the MOCA, compared to 61.1% of FTDs, 40% of MCI/ADs and 26.7% of PSPs. No significant differences were observed among others neuropsychological tests. According to NPI scale, groups vary in their tendency to develop depression ($p<0.05$), with a higher prevalence observed in patients with FTD and PSP. ADL and IADL significantly differ among the groups ($p<0.05$), with PSPs exhibiting the lowest scores. The score on the S&E scale was higher in the MCI/AD group compared to LBD and PSP groups ($p<0.05$).

Discussion and Conclusion: As expected, PSP presented the greatest motor burden with the major impact on ADL and IADL. Global cognition assessed with the MOCA showed worse scores in LBD. Meanwhile, MCI/AD presented lower disease disability measured with S&E compared to other types of dementia. Finally, the behavioural burden assessed with NPI was greater in FTD spectrum and PSP.

## ACCEPTANCE TO INVASIVE THERAPIES: IMPLEMENTATION OF LAW 219/2017 FOR AMYOTROPHIC LATERAL SCLEROSIS PATIENTS IN PALLIATIVE CARE

R. Arlomede, P. Russo, M. Carannante, A. Covino, F. Del Duca, E. Ingegneri, S. Luciano, N. Messina, S. Pirozzi, S. Spinosa, M. Traisci, G. Vitiello, A. Maddalena

U.O.S.D. Palliative Care, Local Health Authority Naples 1 (Napoli)

Objectives: Our study evaluate Amyotrophic Lateral Sclerosis (ALS) patient acceptance to invasive therapies (PEG, Trachestomy) after admission to Palliative Care Unit, analyzing inpatient and outpatient medical records between January 2020 and March 2023 by multiprofessional team approach.

Material: Patients admitted to palliative care average 19.6/year. 90% of cases are sporadic, 10% are familial. The male to female

ratio is 2:1. Mean age of onset of enrolled patients is 64 years. On 2020, 87 patients were admitted and 22 patients died during the year; on 2021, 74 patients and 12 deceased; on 2022, 82 patients and 22 deceased; on 2023, 70 patients, 5 admissions.

Methods: Patients sign an informed consent regarding preference on advanced therapies, i.e. the PAC (Implementation Path of Certifiability), as well as express their wishes on the end of life (DAT Advance Treatment Provisions). Multidisciplinary meeting draw up a PAI (individual Assistance Project) determining patient needs at disease progression. Professional figures involved: 1 neurologist, 2 pulmonologists, 1 medical nutritionist, 1 speech therapist, 1 dietician, 1 health coordination manager, nursing staff.

Results: On 2020, there were 87 patients, 10 with PEG died on average after 8 months; 8 with tracheostomy died on average after 12 months; on 2021, 74 patients, 12 with PEG died and 10 with tracheostomy died on average after 10 months; on 2022, 82 , 10 with PEG died after 10 months, 6 with tracheostomy died after 8 months on average; on January February and March 2023, 70 patients including 13 with tracheostomy and 13 with PEG, 1 patient with naso-gastric tube. Patients who undergo invasive therapies have a median survival of 5 months. Non-invasive therapies have median survival of 3 months. Patients between 36 and 39 years are 2%; between 40 and 50 years are 12% and 20% accepted invasive therapies; patients aged between 51 and 60 years are 23%, 13% accepted invasive therapies; between 61 and 90 years are 63% and 6% accepted invasive therapies.

Discussion: We observed a 10% decline in adherence to invasive therapies over time and as age increases. We highlight greater acceptance of PEG compared with tracheostomy.

Conclusions: Patients must explicit their wills at the time of diagnosis. Decisions on medical treatments [1] in advanced stage and on end-of-life best quality of life must be based on respect for personal dignity and on self-determination.

## MICROSTATES IN MULTIPLE SCLEROSIS: AN ELECTROPHYSIOLOGICAL SIGNATURE OF ALTERED HUBS FUNCTIONING?

S. Baldini, A. Sartori, M. Morelli, F. Pasquin, A. Dinoto, A. Bratina, A. Bosco, P. Manganotti

Neurology Unit, Cattinara University Hospital ASUGI, University of Trieste, Department of Medicine, Surgery and Health Sciences (Trieste)

Objectives: Multiple sclerosis (MS) has variable disease course with disabling symptoms even in absence of a high lesional load. Resting-state (RS) fMRI studies have shown changes in the large-scale brain networks in MS. However, these rearrangements are still debated. In this study, we aimed to investigate the temporal dynamic of large-scale networks in RS-condition by high-density EEG (hdEEG) in relapsing-remitting MS (RRMS) patients compared with healthy subjects (HCs). We pointed to identify a specific set of microstates in both populations and to correlate their activity with clinical and neuropsychological parameters.

Materials and Methods: We enrolled 50 patients with RRMS and 24 HCs, matched for age and gender. All patients performed the Brief International Cognitive Assessment for Multiple Sclerosis (BICAMS); clinical details were also collected. Each participant underwent to hdEEG with 256-channels in RS-condition and we analyzed 15min. of free-artifact segments. Microstates analysis [1] consisted in a k-mean cluster analysis that permitted to identify the most representative topographical maps, which best explain the variance of the RS-hdEEG. Then, these maps were back-fitted on the artifact-free EEG and for each map was computed: mean duration, time coverage, frequency and the global explained variance (GEV). As reported in literature, these microstates were associate to well-known brain networks: auditory (Map-A), visual (Map-B), salience (Map-C/F), attention (Map-D), default mode networks (Map-C/E) [2,3]. Repeated measures two-way ANOVA was run to compare microstates parameters. Pearsons's correlation and stepwise multiple linear regression were performed between clinical and neuropsychological data; alpha=0.05.

Results: Six templates were found across all subjects. A significant increase of temporal dynamic of Map-A ($p<0.001$), B ($p<0.001$) and E ($p<0.001$) and decrease of Map-D ($p<0.001$) and F ($p<0.001$) were observed in patients than controls. The correlation analysis revealed a moderate significant correlation between disease duration and mean duration of Map A ($p<0.05$). A cognitive impairment was also detected in 8% of patients with MS and it was found a strong prediction of Symbol Digit Modalities Test (SDMT) score by the temporal activity of Map-A ($p=0.017$; 11.2%).

Discussion: These findings showed a peculiar increase/decrease pattern of the microstates' activation as also reported in RS functional connectivity studies. The association between SDMT and Map-A may suggest a possible marker of overt cognitive dysfunctions.

Conclusion: The hdEEG microstate analysis offers a new and advanced perspective of large-scale networks functioning in multiple sclerosis patients, indicating a possible electrophysiological signature of brain reorganization.

## ENTRAINING BRAIN OSCILLATORY ACTIVITY AT ALPHA FREQUENCIES IN DEMENTIA WITH LEWY BODIES

A. Benussi, V. Cantoni, J. Rivolta, N. Zoppi, A. Padovani, B. Borroni

Department of Clinical and Experimental Sciences, University of Brescia (Brescia)

Objectives: Dementia with Lewy bodies (DLB) is characterized by a marked shift of electroencephalographic (EEG) power and dominant rhythm, from the alpha towards the theta frequency range. Transcranial alternate current stimulation (tACS) is a novel non-invasive brain stimulation technique that allows entrainment of cerebral oscillations at desired frequencies. The objective of the present study was to evaluate safety and efficacy of occipital alpha tACS in DLB patients.

Methods: We performed a double-blind, randomized, sham-controlled, cross-over clinical trial in 12 DLB patients. Patients were randomized to receive real (60 minutes of 3 mA peak-to-peak stimulation at 12 Hz) or sham stimulation over the occipital cortex (Oz according to the 10-20 international EEG system). Patients underwent clinical evaluation (clock-drawing test, trail-making test part A and B, the quantitative pentagon drawing test subitem), neurophysiological assessment (short-latency afferent inhibition to evaluate cholinergic circuits) and EEG recordings, at baseline and after real/sham stimulation.

Results: Occipital alpha tACS was safe and well tolerated in all patients. We observed a significant increase in clinical performance scores, in neurophysiological measures of cholinergic transmission and in occipital alpha power spectrum density after real stimulation but not sham stimulation.

Conclusions: Occipital tACS delivered at alpha frequencies may be a novel therapeutic approach in patients with DLB.

## FROM VISION TO LANGUAGE: NEUROPSYCHOLOGICAL PROFILE IN A COHORT OF PATIENTS WITH POSTERIOR CORTICAL ATROPHY

E. Bergamin[1], M. Del Chicca[1], F. Petrini[1], E. Del Prete[1], V. Nicoletti[1], L. Giampietri[1], L. Tommasini[1], A. Gayane[2], F. Baldacci[1], D. Volterrani[2], G. Siciliano[1], G. Tognoni[1]

[1]Department of Clinical and Experimental Medicine, Neurology Unit, University of Pisa (Pisa); [2]Department of Translational Research and of New Surgical and Medical Technologies, Nuclear Medicine Unit, University of Pisa (Pisa)

Aims: The aim of this study was to analyze the neuropsychological profile of a group of patients with Posterior Cortical Atrophy (PCA), a neurodegenerative syndrome characterized by progressive and relatively selective decline in higher visual processing and other posterior cortical functions, most commonly associated with the histopathological features of Alzheimer's disease (AD). Unlike typical AD, memory, insight and judgement are relatively preserved until latter stages of the disease but patients commonly report early language difficulties. However, some inconsistencies exist among the cognitive features described.

Materials and methods: Clinical features and neuropsychological profile of 20 subjects (13 females) aged between 49 and 71 years (58.8 ± 7.16) with PCA due to AD have been analyzed. Each patient underwent a battery of neuropsychological tests, brain MRI, brain PET with 18-FDG and alternatively amyloid-PET or research for AD biomarkers on CSF. The average time elapsed between reported onset and assessment was 19.80 ± 12.01 months.

Results: The most frequent symptoms reported were unspecified visual impairment (70%), difficulty in objects manipulation (40%), alexia (40%) and increased anxiety (75%). At the extended neurological and neuropsychological evaluation, all patients showed impairment in visual-perceptual and visual-spatial abilities and visuospatial memory, assessed with VOSP (Visual Object Spatial Perception) and Cubes Test respectively. Only one patient complained speech disturbances, but variable language impairment was detected in 70% of patients.

Discussion: Analyzing the neuropsychological profile of this cohort of patients, we found a considerable variability in the language profile. Specifically, in some patients an impairment of semantic verbal fluency was observed, while in others anomia, repetition deficits and difficulty in naming tasks were detected, in agreement with data in literature describing a logopenic phenotype in some groups of PCA. Moreover, an impairment of other cognitive domains, besides the visuospatial one, was observed from the onset. This feature may be explained, on the one hand, by a late diagnosis due to a belated neurological assessment, when an initial impairment of other cognitive domains has already occurred (advanced PCA) and, on the other hand, by supporting the hypothesis of degeneration of a common core network in all AD profiles.

Conclusion: Further studies are needed to characterize the progressive evolution of the neuropsychological profile of PCA, also in relation to the specific phenotype in the PCA spectrum at the onset, and to eventually schedule distinct management strategies for patients who may have different impairment of cognitive abilities over time.

## CARDIOVASCULAR FACTORS DIRECTLY DRIVE NEURODEGENERATION BUT NOT COGNITIVE DECLINE IN ALZHEIMER'S DISEASE: A LONGITUDINAL STUDY

C. G. Bonomi[1], C. Motta[1], M. Poli[1], M. Di Donna[1], N. Mercuri[2], G. Koch[3], A. Martorana[1]

[1]Memory Clinic, University of Rome "Tor Vergata" (Roma); [2]Neurology Unit, University of Rome Tor Vergata (Roma); [3]Non Invasive Brain Stimulation Unit, IRCCS Santa Lucia (Roma)

Objectives: The heterogeneous course of Alzheimer's Disease (AD) is supported by its multifaceted etiology [1,2]. We first aimed at verifying the association of vascular risk factors with CSF markers of amyloid deposition (p-tau/Aβ42) and neurodegeneration (t-tau), accounting for other factors, namely sex, APOE, and blood-brain-barrier (BBB) integrity measured as Albumin Quotient (Qalb), and stratifying patients according to age-of-onset into early (< 65, EOAD), classic (65-75, COAD), or late (>75, LOAD). Then, we explored their effects on cognitive decline and their interplay with Qalb and neurodegeneration.

Methods: We enrolled 387 patients with a biomarker-based diagnosis of Mild-Cognitive-Impairment (MCI) due to AD. We computed a composite score for 8 vascular risk factors and transformed the output to a 0-to-1 continuous percentage (vascular score, VS). First, we regressed VS on p-tau/Aβ42 and on t-tau, accounting for sex, APOE and Qalb, and repeated the analysis in the subgroups. In a subset of 105 patients, we regressed sex, APOE, Qalb, VS and t-tau on ΔMMSE (negative changes in MMSE at 1 year follow-up) in a multivariate regression. Finally, we tested the indirect association between VS and cognitive decline, using a bias-corrected bootstrapped mediation model to c alculate the indirect effects of t-tau and Qalb as mediators.

Results: No association was found between VS and p-tau/Aβ42 in any group. Instead, we found a positive association with t-tau in the whole sample (β=0.173, p<.001), in EOAD (β=0.264, p=0.016) and LOAD (β=0.350, p<.001), but not in COAD (β=0.042, p=0.580). We also found a negative association of ΔMMSE with Qalb (β=−0.407, p=<.001) and t-tau (β=−0.270, p=0.004), but not with VS (β=−0.040, p=0.662). The mediation model confirmed the absence of global effects of VS on ΔMMSE, despite indirect negative repercussions on ΔMMSE mediated by Qalb (ADE: β=−1.097, p=0.406, ADME: β=−0.678,

p=0.027, total: β=−1.775, p=0.183), but a strong direct positive effect on t-tau, with Qalb acting as a partial negative mediator (ADE: β=293.98, p=0.001, ADME: β=−39.25, p=0.044, total: β=254.74, p=0.006).

Discussion: Vascular risk factors impact the progression of neurodegeneration differently depending on age-of-onset. Higher VS causes a global increase of t-tau, despite the finding of a relative inverse effect, mediated by the increase of BBB permeability. Albeit VS-induced increased t-tau has negative repercussions on ΔMMSE, we found no evidence of a direct role of VS on the progression of cognitive decline. Overall, these results highlight the need to carefully address the actual clinical impact of vascular risk factors in AD.

## ABNORMAL PRESYNAPTIC DOPAMINERGIC IMAGING IN CORTICOBASAL SYNDROME WITH ALZHEIMER'S DISEASE ETIOLOGY: INSIGHTS FROM A CASE-SERIES

F. Calizzano[1], F. Massa[1], R. Mancini[1], A. Murialdo[1], W. Kreshpa[1], M. Losa[1], F. Di Biasio[1], S. Pretta[1], A. Donniaquio[1], S. Morbelli[2], D. Arnaldi[1], A. Uccelli[1], A. Schenone[1], M. Del Sette[1], M. Pardini[1]

[1]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa (Genova); [2]Department of Health Science (DISSAL), University of Genoa (Genova)

Introduction: Corticobasal syndrome (CBS) is a heterogeneous condition with various underlying causes. Besides the most prevalent 4R-tauopathy, Alzheimer's disease (AD) accounts for at least 20% of cases [1]. Presynaptic dopaminergic imaging using SPECT or PET has been employed for differential diagnosis due to the clinical overlap among etiologies. However, recent anecdotal evidence has raised doubts about the traditional association of CBS-AD with normal striatal uptake, questioning the sensitivity of dopaminergic imaging in this condition [2]. This case-series describes four patients with CBS attributed to AD pathology, confirmed through cerebrospinal (CSF) or PET assessment, all exhibiting abnormal striatal uptake in presynaptic dopaminergic imaging.

Case-series: We describe four patients (2 females, age 74±9.8 years, MMSE 17.0±4.3), fulfilling the diagnostic criteria for possible or probable CBS(3) with evidence of underlying AD pathology. This was confirmed either through CSF biomarkers (three patients with pathological levels of both amyloid-β42/40 ratio and phosphorilated-Tau) or positive amyloid-PET (one patient) based on the AT(N) framework. The typical asymmetric cortical hypometabolism was consistent with CBS on [18F]FDG PET, extending to the lateral parietal, temporal, and posterior cingulate regions, additionally. Interestingly, they all exhibited abnormal presynaptic dopaminergic imaging (DaT-SPECT in three patients, [18F]Dopa PET in one patient) with the highest magnitude in the most affected hemisphere. No core or suggestive clinical features of a Lewy body disorder (LBD) were detected, except for parkinsonism, after thorough investigation at baseline and follow-up. Furthermore, one patient also had normal cardiac [123I]MIBG scintigraphy.

Discussion: These findings suggest potential disruption of dopaminergic pathway in AD cases presenting with CBS. Given the absence of suggestive features, it is unlikely that the patients in this case series are affected by an LBD, which seldom manifests clinically as CBS, yet it is associated with abnormal dopaminergic imaging and may coexist with AD pathology in nearly half of cases. It is possible that AD-related pathology spreading into the brainstem or striatum may affect the nigro-striatal pathway, leading to abnormal striatal uptake. The suboptimal accuracy of presynaptic dopaminergic imaging and the lack of standardized thresholds for result interpretation in CBS-AD, as well as the absence of validated biomarkers for 4R-tauopathy, further complicate this scenario. This underscores the need for further research to prevent misinterpretation of the underlying etiology of CBS and guide management strategies.

Conclusion: Caution is recommended when using dopaminergic imaging to differentiate between etiologies within the CBS spectrum, as abnormal findings may be associated with either 4R-tauopathy or AD pathology.

## HEREDITARY SPASTIC PARAPLEGIA 5 (SPG5A) ASSOCIATED WITH LEGG CALVÈ PERTHES SYNDROME

M. Caputo[1], E. Zucchi[1], N. Fini[2], I. Martinelli[1], L. Ferri[1], G. Gianferrari[1], A. Ghezzi[1], J. Mandrioli[1]

[1]Department of Neurosciences, University of Modena and Reggio Emilia (Modena); [2]Department of Neurosciences, Azienda Ospedaliero-Universitaria di Modena (Modena)

Case presentation: A 15 years-old patient presented to our clinic after a long history of orthopedic care for avascular necrosis of femur head (Legg-Calvè-Perthes syndrome), complaining in teenage years difficulty with running and coordination tasks in lower limbs. On history she had autoimmune thyroiditis with subclinical hyperthyroidism. Motor stages of development were normally achieved. At a first neurological examination neither weakness or hypotrophy was noted, whereas pyramidal signs and slight hypertonia were observed in lower limbs with bilateral Babinski. Impaired proprioception and vibration senses in lower limbs with sensory ataxia and positive Romberg sign were found. Her parents were not consanguineous. Her maternal grandmother complained walking impairment from young age, stable over the years. We present a case of autosomal recessive SPG5A hereditary spastic paraplegia (HSP) with an unusual association with Legg-Calvè-Perthes syndrome. Possible explanations of effects of abnormal circulating oxysterol levels on avascular necrosis of femur head are provided.

Materials/Methods: Brain and spine MRI, electromyography and somatosensory and motor evoked potentials (SSEP and MEP) were performed. At 18 years old she performed genetic testing with Next Generation Sequencing (NGS).

Results: NGS revealed two heterozygous point mutations in CYP7B1, the pathogenetic variant c.889A>G (p.Thr297Ala) and missense mutation c.1082G>A(Arg361Gln), classified as a VUS. Segregation studies on proband's parents confirmed combined heterozygosity in CYP7B1.Brain and spinal cord MRI excluded inflammatory abnormalities; no cerebellar or cervical cord atrophy were noted. SSEP and MEP were consistent with a pure form of HSP. Electromyography excluded concomitant neuropathies. After five years

of follow-up the proband is clinically stable and she doesn't require any walking aid.

Discussion and Conclusion: We describe a case of SPG5A with two missense mutations in CYP7B1. The c.889A>G variant determines an amino acid substitution in proximity to key binding residues and has already been extensively described in literature in patients with pure HSP [1], whereas c.1082G>A (Arg361Gln) has been only recently reported [2]. This is the first report of a pure HSP associated with Legg Calve Perthes syndrome. Risk factors for this condition are metabolic liver impairment, hypercholesterolemia, hypercoagulability, altered epiphyseal closure, and elevated steroid levels. CYP7B1 mutations can lead to some extent to all of these conditions, by causing decreased levels of cholesterol through the altered acidic pathway in the liver, which also leads to high levels of 27-hydroxysterol, a selective estrogen receptor modulator with multiple effects on cardiovascular system, cholesterol levels, and bone physiologic processes [3].

## ASSOCIATION OF PLASMA GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP) WITH AD BIOMARKERS

A. Cavaliere[1], S. Mazzeo[2], A. Ingannato[1], S. Bagnoli[1], G. Giacomucci[1], J. Balestrini[1], V. Moschini[2], C. Morinelli[2], G. Galdo[1], F. Emiliani[1], D. Piazzesi[2], C. Crucitti[1], D. Frigerio[1], S. Padiglioni[2], S. Sorbi[1], B. Nacmias[1], V. Bessi[1]

[1]Department of Neuroscience, Psychology, Drug Research and Child Health, University of Florence (Firenze); [2]Research and Innovation Centre for Dementia-CRIDEM, Azienda Ospedaliero-Universitaria Careggi (Firenze)

Objectives: GFAP is a protein expressed by astrocytes in the CNS. Its levels increase in neurodegenerative diseases such as Alzheimer's disease (AD) in both Cerebro Spinal Fluid (CSF) and blood. Nevertheless, few studies explored plasma GFAP in prodromic and preclinical stages of AD. In our cross-sectional study we wanted to demonstrate how the plasma values of NFL and GFAP are able to show with high sensitivity and specificity the presence of Alzheimer's disease in early stages.

Materials and methods: We enrolled 40 patients (11 SCD, 21 MCI, 8 AD dementia). All patients underwent: comprehensive family and clinical history assessment, neurological examination, extensive neuropsychological investigation, ,18F-FDG-PET, CSF biomarkers analysis (Aβ1-42, Aβ1-42/1-40, p-tau, t-tau). Patients were rated according to the ATN system. Blood was collected for measurement of plasma GFAP and NfL concentration and for Apolipoprotein E (APOE) genotype analysis.

Results: SCD and MCI patients were rated based on AD biomarker results as follows: 16 (40.00%, 8 SCD and 8 MCI) had normal AD biomarkers (NB), four patients (10.00 %, 1 SCD and 3 MCI) were carriers of non Alzheimer's pathology (non-AD), 12 patients (30.00%, 2 SCD and 10 MCI) were considered as prodromal AD. All eight patients with clinical diagnosis of AD showed biomarkers consistent with AD and were defined as AD-d (AD-demented). LogGFAP was lower in NB compared to prodromal AD (p=0.003, d=1.463) and AD-d (p=0.002, d=1.695). LogNfL was lower in NB patients than in AD-d (p=0.011, d=1.474). GFAP showed an excellent accuracy in differentiating NB from prodromal AD (AUC=0.901, accuracy=85.71% [95% C.I.=72.75 : 98.67], sensitivity=66.67 [95% C.I.=49.21 : 84.13], specificity=100%) with a cut-off level of 198.13 pg/mL. NfL showed a fair accuracy (AUC=0.718, accuracy=70.37% [95% C.I.=53.46 : 87.28], sensitivity=75.00% [05% C.I.=58.96 : 91.04]), specificity=66.67 [95% C.I.=49.21 : 84.13]) in differentiating between NB and prodromal AD, with a cut-off value of 11.65 pg/mL.

Discussion and conclusions: GFAP showed good accuracy, more than NfL, in differentiating MCI and SCD patients with negative CSF biomarkers from prodromal AD patients. This underlines the possible use of GFAP as an indicator of disease in the very early stages of the disease.

Objective: Sleep microstructure, specifically called cyclic alternating pattern or CAP, could be more informative than standard sleep stage scoring about neurophysiological alterations in neurodegenerative diseases. The main aim of this study was to evaluate CAP in PD patients with different degrees of cognitive impairment, in order to provide an objective measure of sleep microstructure alteration and evaluate possible associations with neurodegeneration progression.

Materials: Patients affected by PD with and without cognitive impairment were recruited at the Neurology Units of Hospital Auxologico Piancavallo of Verbania and C. Mondino Institute.

Methods: MCI or dementia diagnosis was based on recommended criteria of Movement Disorder Society task force (Litvan 2011). All

patients underwent an in-lab full-night Video-polysomnography (PSG). CAP scoring of each patient was revised by an evaluator of the Sleep Medicine Unit of Parma.

Results: We recruited 16 PDMCI patients, 16 PD dementia patients (PDD) and 16 PD without cognitive impairment (PD) as control group. All groups were comparable for age and sex. Concerning sleep macrostructure, REM sleep (% of TST) was significantly reduced in PDD compared to PDMCI and PD (p=0,002). CAP rate was significantly reduced in both PDD and PDMCI groups compared to PD and normative values, with a greater decrease in PDD compared to PDMCI and PD. The proportion of CAP A1, A2 and A3 phases were reduced in both PDD and PDMCI groups, and the same trend of reduction in PDD compared to PDMCI was found. Furthermore REM sleep time, CAP rate and related component A1, A2 and A3 phases correlated with both MMSEc and several neuropsychological tests.

Discussion: Despite the small sample size, sleep microstructure proved to add more information about neurodegeneration progression in PD related dementia. In particular, reduction of both A3 and REM sleep in PD related dementia patients is in accordance with Braak's hypothesis. In this view, combined sleep microstructure parameters and total REM sleep time seemed to better correlate with the degree of cognitive impairment.

Conclusion: Cycling alternating pattern could become a non-invasive and cost effective neurophysiological marker in neurodegenerative diseases.

## A RARE CASE OF DIFFUSE BRAIN CALCIFICATIONS AND LEUKOENCEPHALOPATHY DUE TO BI-ALLELIC MUTATION IN FARSB

E. Cresta[1], M. Imperi[2], P. Prontera[2], A. Bellotti[1], G. Rinaldi[1], M. Alabiso[1], I. Corbelli[1], L. Parnetti[1], P. Sarchielli[1]

[1]Section of Neurology, Department of Medicine and Surgery, University of Perugia (Perugia); Section of Medical Genetics, Department of Medicine and Surgery, University of Perugia (Perugia)

Background: Aminoacyl-tRNA synthetases are essential for the initial stage of protein synthesis and for cellular survival by regulating cellular signalling and metabolism. Phenylalanyl-tRNA synthetase attaches phenylalanine to tRNA and is encoded by two genes: FARSA and FARSB. Biallelic variants in FARSA or FARSB have been implicated in exceedingly rare human diseases characterized by a broad and variable spectrum of multisystem dysfunctions [1,2].

Materials and Methods: A 55-year-old patient came to our attention regarding chronic refractory migraine and recurrent episodes of temporo-spatial disorientation. His medical history was relevant for chronic respiratory failure attributed to pulmonary emphysema and fibrosis with bullous dystrophy, complicated by pneumothorax; splenectomy due to splenic infarction resulting from a thrombosed splenic artery aneurysm. Physical examination revealed skeletal abnormalities, including pectus excavatum, thoracic hyperkyphosis, and dolichostenomelia. Unusual fat distribution was observed in the hips, buttocks, thighs, and forearms, along with cutaneous bullous dystrophy and subcutaneous micronodules. Neurological examination showed diffuse overresponsive osteotendinous reflexes with bilateral Hoffmann sign. A neuropsychological assessment revealed overall poor performance with ideational slowing. Brain MRI examination revealed diffuse and symmetrical calcifications predominantly in the basal nuclei and cerebellum, along with marked leukoencephalopathy. In suspicion of an autosomal recessive form (with unaffected parents and a sister who died suddenly at the age of 27, also with a history of pneumothorax), genetic evaluation was performed. A blood sample was taken for whole-exome sequencing combined with variant analysis within a panel of genes associated with brain calcification disorders.

Results: Two variants of uncertain significance, both in heterozygosity, were identified in the FARSB gene: c.1057C>G (p.Pro353Ala) and c.1394A>C (p.Asn465Thr). To date, no previous descriptions of these variants exist. They are not present in population database (GnomAd, ExAC) and they are predicted to be deleterious by different bioinformatics tools. Moreover, the clinical phenotype fits with the FARSB-related disorder, leading to the classification of these variants as likely causative of the proband's complex clinical presentation.

Discussion and Conclusions: Cerebral calcifications and leukoencephalopathy can have numerous underlying etiologies; however, they are infrequently observed as components of complex clinical presentations like the one described. The presence of concurrent pulmonary involvement, aneurysms, liver disease, skeletal abnormalities and abnormal fat distribution can serve as valuable guiding factors for clinicians. Achieving a precise diagnosis is crucial for therapeutic purposes: recent studies have indicated a partial therapeutic benefit from oral phenylalanine supplementation in individuals with FARSB mutations, particularly in conjunction with infections or fever [3].

## PERSISTENT HYPERSOMNIA AND VERY SLOW PROGRESSION: AN ATYPICAL CASE OF SPORADIC CREUTZFELDT-JAKOB DISEASE

A. De Lorenzo[1], F. Verde[2], A. Maranzano[1], C. Morelli[1], S. Messina[1], V. Patisso[3], C. Gendarini[3], M. Treddenti[3], G. Giaccone[4], F. Brusaferri[5], P. Tiraboschi[4], F. Moda[4], L. Caputi[5], G. Di Fede[4], V. Silani[2], N. Ticozzi[2]

Introduction: Sporadic Creutzfeldt-Jakob disease (sCJD) is a rare and fatal neurodegenerative disorder characterized by rapidly progressive dementia, myoclonus, visual disturbances, ataxia and pyramidal/extrapyramidal signs1. Atypical presentations can also occur,

posing diagnostic challenges2. We present a case of sCJD with unusually slow progression and hypersomnia as the predominant initial complaint.

Case presentation: A 72-year-old woman presented with a 30-month history of excessive daytime sleepiness, word finding difficulty, and mild forgetfulness. No prior neurological history was reported. Six months after symptom onset, neuropsychological examination revealed non-amnestic mild cognitive impairment and brain MRI showed areas of restricted diffusion in parietal-temporal cortex bilaterally, with left predominance. Additionally, brain 18F-FDG PET demonstrated hypometabolism of the left parietal cortex. However, EEG was unremarkable, while cerebrospinal fluid (CSF) analysis revealed only mildly increased protein, with negative 14-3-3 protein immunoblot. After abstaining from seeking medical attention for two years, the patient presented to our center due to progressive symptom worsening. Neurological examination revealed frequent word finding pauses, postural tremor, right-limb spasticity, and hypokinetic gait, while neuropsychological examination demonstrated moderate executive and memory impairment. Restricted diffusion was confirmed on repeat MRI, and periodic triphasic sharp-wave complexes were detected over the left centrotemporal region on EEG. A second lumbar puncture was performed: immunoblot for 14-3-3 protein was again negative, while CLEIA measurements of CSF biomarkers revealed slightly increased total tau (T-tau; 566 pg/ml), phosphorylated tau (P-tau181) within the normal range (47.2 pg/ml), and Aβ42 in the low part of the normal range (612 pg/mL). Real-time quaking-induced conversion (RT-QuIC) yielded a positive result. Based on the CDC criteria, a diagnosis of probable sCJD was made3. Analysis of the PRNP gene revealed methionine/valine heterozygosity at codon 129 without additional mutations. At two-month follow-up, symptoms remained unchanged.

Conclusions: While rapid neurodegeneration is the typical fingerprint of sCJD, slowly progressing cases are infrequently reported1. The protracted course of the present case is consistent with the evidence of only mild neuroaxonal degeneration, as inferred from the relatively modest elevation of T-tau, and the absence of negative prognostic markers such as myoclonus, visual disturbances, or positive 14-3-3 immunoblot1. Despite early MRI findings suggesting sCJD, the atypical clinical presentation and the slow worsening of symptoms could question the diagnosis. RT-QuIC, whose value in case confirmation has recently been highlighted in the diagnostic criteria for sCJD3, played a pivotal role in unmasking this atypical case, definitively leading the clinician to the correct diagnosis.

## SPORADIC CREUTZFELDT–JAKOB DISEASE MANIFESTING AS FATAL SPORADIC INSOMNIA: A CASE REPORT

M. Del Chicca[1], E. Bergamin[1], A. Pascazio[1], V. Nicoletti[1], E. Del Prete[1], L. Giampietri[1], M. Maestri Tassoni[1], P. Parchi[2], G. Siciliano[1], G. Tognoni[1]

Introduction: Human prion diseases are rapidly progressive neurodegenerative disorders caused by prion protein misfolding. Sporadic Creutzfeldt-Jakob disease (sCJD) is the most common form. It comprises six subtypes defined by the genotype at the polymorphic codon 129 in PRNP gene and by the type of prion protein accumulating in the brain. There is an important clinical and biomarkers variability among these subtypes, that is a major problem in diagnosing sCJD, especially the atypical variants.

Case Presentation: A 63-year-old man presented at our Memory Clinic complaining of cognitive impairment and mood disturbances. He reported for the previous 9 months sleep fragmentation, hobbies withdrawal, tendency to social isolation, anxiety and episodic agitation; there was also an alteration in sweating. Patient's family history was silent. He has already performed brain MRI, which was unremarkable and Cerebral FDG-PET which detected a widespread cortical and subcortical hypometabolism including both thalami. Initially he has been diagnosed with Alzheimer's Dementia and Donepezil has been introduced. Our first neurological examination showed postural instability and mild upper limbs postural tremor. MMSE score was 20/30. Neuropsychological tests revealed executive dysfunction with loss of verbal and motor initiative and memory impairment. FlorBetapir PET was negative. EEG showed a diffuse slowing. After two months on neurological examination pyramidal signs, ataxia and startle myoclonus were evident. Speech deteriorated rapidly along with overall cognitive performance, subsequently gait worsened with assistance needed for all daily activities. A subsequent MRI showed mild brainstem atrophy, EEG was unchanged. A dynamic EEG with polysomnography was performed, revealing an abnormal sleep structure with significant reduction in sleep spindles and K-complexes and absence of REM sleep. In CSF Tau protein was normal. Tests were also negative for autoimmune encephalitis and paraneoplastic antibodies. Real-time quaking induced conversion (RT-QuIC) assay in CSF was positive for the pathological prion protein. Genetic analysis revealed MM polymorphism in codon 129 in PRNP gene and no mutations were found in this gene. Patient was thus diagnosed with sCJD. His psychophysical conditions declined and patient's family discontinued contact with our Clinic. Patient's death occurred 21 months after disease onset at the patient's home, so it was not possible to determine the pathological subtype of prion protein.

Conclusion: Brain MRI, EEG and CSF Tau protein value were inconclusive. Clinical evaluation therefore remains fundamental in the diagnostic definition of sCJD. In our case clinical symptoms, disease progression, polysomnography and RT-QuIC were decisive for the confident pre-mortem diagnosis.

## DIVERSE PRESENTATIONS OF PROGRESSIVE MULTIFOCAL LEUKOENCEPHALOPATHY: A COMPARATIVE ANALYSIS OF TWO CASES

R. Di Iorio, R. De Fiores, A. Saraceno, J. Buonocore, G. Spano, C. Mummolo, S. Barone, P. Valentino, M. Trimboli, A. Gambardella

Institute of Neurology, Department of Medical and Surgical Sciences, Magna Graecia University (Catanzaro)

Backgrounds: Progressive multifocal leukoencephalopathy (PML) is a rare and often fatal disease of the Central Nervous System caused by John Cunningham Virus (JCV), affecting immunocompromised individuals. Human immunodeficiency virus (HIV) infection, immunomodulator therapy, lymphoproliferative and autoimmune diseases are accounted as relevant risk factors [1].

Aims: We compared two confirmed cases of PML having different aetiology and clinical onset.

Case-1: A 78-year-old man came to our attention with speech and writing disturbances and short-term memory abnormalities lasting three months. In the previous three years, he suffered from Non-Hodgkin lymphoma which was in clinical remission after receiving Rituximab and Bendamustine treatment until 2022, when the disease relapsed, needing a second-line therapy with R-CHOP regimen (Rituximab plus cyclophosphamide, doxorubicin, vincristine, prednisolone). Neurological examination upon admission revealed global aphasia, apraxia, asomatoagnosia with right hemispatial neglect, spastic muscular tone at the limbs and bilateral Babinski sign. Brain magnetic resonance imaging (MRI) showed hyperintense leukoencephalopathy on T2/Fluid Attenuated Inversion Recovery (FLAIR) weighted images and hypointense on T1 images, primarily involving the left hemisphere and both occipital hemispheres exhibiting the classical "barbell sign". The EEG revealed interhemispheric differences in global slowing, predominantly in the delta frequencies on the left hemisphere. Cerebrospinal fluid (CSF) analysis confirmed the diagnosis of PML with more than 12,000 copies of JCV-DNA.

Case-2. A 40-year-old man, without prior medical conditions, came to our attention with a four-months history of worsening diplopia and vertigo. At admission, neurological examination revealed nystagmus, diplopia in vertical and horizontal gaze, ataxia, bilateral telekinetic tremor and mild adiadochokinesia. Brain-MRI showed FLAIR hyperintensity of the left cerebellar lobe and cerebellar mesial peduncle. The CSF analysis showed more than 5000 copies of JCV-DNA, confirming a PML diagnosis. To investigate immunodeficiency aetiology, an extensive laboratory screening was performed, from which our patient resulted positive for HIV testing with a significant reduction of CD4+ T-cells. Therefore, he started Highly Active AntiRetroviral Therapy (HAART). After one month of therapy, we had a twofold increase in CD4+ T-cell levels and a reduction of HIV-DNA at three thousand copies. However, patient's ataxia and dysarthria worsened despite absence of immune-reconstitution inflammatory syndrome (IRIS) on follow-up MRI, which showed enlargement of previous lesions instead. We suggested the possibility of starting Pembrolizumab [2].

Conclusions: PML should be included in the diagnostic workup of patients showing subacute, nonspecific neurological manifestations given the increased likelihood of underlying predisposing causes that may influence treatment and prognosis.

## CEREBELLAR ATAXIA AND COGNITIVE DEFICIT ASSOCIATED WITH A DE NOVO MUTATION IN THE NALCN GENE

R. Fancellu[1], A. Covone[2], M. Del Sette[3], L. Nobbio[4], D. Coviello[5]

[1]Unit of Neurology, Clinical Center For Diagnosis Orphan Patients, IRCCS Ospedale Policlinico San Martino (Genova); [2]Unit of Human Genetics, IRCCS Istituto Giannina Gaslini (Genova); [3]Unit of Neurology, IRCCS Ospedale Policlinico San Martino (Genova); [4]DINOGMI, University of Genoa (Genova); [5]Unit of Human Genetics, Clinical Center For Diagnosis Orphan Patients, IRCCS Istituto Giannina Gaslini (Genova)

Objectives: Recessive mutations in Sodium Leak Channel, Nonselective (NALCN) gene predominantly cause hypotonia and severe intellectual disabilities like infantile neuroaxonal dystrophy, while dominant mutations cause contractures of limbs and face, hypotonia, and global developmental delay syndrome, or cognitive deficit, ataxia, and arthrogryposis. Mutations in NALCN gene usually cause severe phenotypes in childhood, while recently an adult case with milder phenotype has been described. Here we describe the second adult case with a de novo mutation in NALCN gene and cerebellar ataxia.

Materials and Methods: A 33-year-old young woman presented in early infancy language difficulty and mild intellectual disability; she learned walking quite normally with mild impairment in running; she was able to swim and go by bicycle. Since the age of 23 years, she has had progressive gait and balance impairment. At 26 years the neurological examination showed cerebellar gait ataxia without support, impossible on toes, on heels and in tandem; moderate limb dysmetria; hypodiadokinesia; mild upward ophthalmoparesis; oculomotor apraxia; slurred speech; facial grimaces; inappropriate laughing; moderate cognitive difficulty in several domains. In the successive years the clinical features were slowly progressive.

Results: Brain magnetic resonance imaging showed cerebellar atrophy and asymmetria in occipital skull. Brain positron emission tomography revealed cerebellar hypometabolism. Peripheral neurophysiological study was normal. Molecular analysis excluded spinocerebellar ataxia (SCA)1, 2, 3, 6, 7, 15/16, 17, 28, 36. An extended NGS panel for ataxia genes and, subsequently, a clinical exome sequencing detected a novel missense variant in NALCN gene (c.1514A>T) that is classified as likely pathogenetic according to bioinformatic analysis with predictive software. This variant in NALCN gene was confirmed by Sanger sequencing, was not found in the unaffected parents or in the sister and can be considered a de novo pathogenetic mutation.

Discussion and Conclusions: Our case confirms that mutations in NALCN gene can be associated with adult onset cerebellar ataxia with relatively mild clinical features, thus extending the clinical phenotypes of NALCN mutations.

## HEREDITARY HAEMORRHAGIC TELANGIECTASIA IN A PATIENT AFFECTED BY TURNER'S SYNDROME

R. Fancellu[1], L. Nobbio[2], W. Kreshpa[2], M. Del Sette[1], V. Capra[3]

[1]Unit of Neurology, Irccs Ospedale Policlinico San Martino (Genova); [2]dinogmi, University Of Genoa (Genova); [3]Unit of Medical Genetics, Irccs Istituto Giannina Gaslini (Genova)

Objectives: Hereditary Haemorrhagic Telangiectasia (Hht) is a rare autosomal dominant disease, caused by vascular dysplasia leading to telangiectasias and arteriovenous malformations of skin, mucosa, and viscera, including lung, liver, and brain. The most frequent form of Hht (Type 1, Hht1) maps on chromosome 9q34 and is associated with heterozygous mutation in the gene encoding endoglin (Eng). Turner's Syndrome is characterized by complete or partial loss of an x chromosome in phenotypic females, clinically manifesting with short stature, primary ovarian insufficiency, neurocognitive abnormalities, hearing loss, and cardiovascular, renal, liver, and autoimmune diseases. The objective of our work is to describe a rare association of two genetic diseases.

Materials and Methods: We report the case of a female with known Turner's Syndrome (45,X0/46,Xx) associated with mild cognitive decline, hypothyroidism, diabetes mellitus, hearing loss, short stature, and mild facial dysmorphism; she had been suffering for many years from progressive gait ataxia. At the age of 72 years, she was admitted in Emergency Department because of acute balance worsening. brain MRI showed diffuse vascular leukoencephalopathy, mild cortical atrophy and multiple cavernomas in cerebellar

hemispheres, brain stem, cerebral hemispheres, and thalami, with signs of several microbleeds.

Results: Extended genetic analysis with NGS panel for cerebral vascular malformations detected a novel missense heterozygous variant of unknown significance in Hht1 gene (C.1933g>A), not included in databases (Hgmd, Clinvar). This variant involves a conserved aminoacid and is predicted as pathogenetic variant according to bioinformatic analysis with predictive software (Sift, Polyphen-2). This variant was not found in the younger sister of the proband, not affected by Turner's Syndrome. Interestingly, the older sister, affected by Turner's Syndrome, died for massive cerebral left hemorrhage; however, in this subject the genetic testing for Hht1 were not performed.

Discussion And Conclusions: We described a patient with Turner's Syndrome and Hht1 mutation. In Turner's Syndrome cerebral hemorrhage can rarely occur, usually due to arterial hypertension; in our patient the genetic evaluation contributes both to precise the diagnosis of multiple cavernomas in the proband and to assess the risk of Hht1 for the relatives. this case emphasizes the importance of extending diagnostic investigations particularly when atypical features occur, even in the presence of a genetic diagnosis of a rare disease.

## A CASE OF CREUTZFELDT-JAKOB DISEASE WITH AN ACUTE ONSET AND RAPID PROGRESSION

C. Gendarini, A. Pietroboni, T. Carandini, M. Saetti, A. Arighi, A. Costa, C. Fenoglio, D. Galimberti, F. Triulzi, G. Comi

Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan (Milano)

Aim: To describe a case of Creutzfeldt-Jakob Disease (CJD) with an acute onset and a rapid progression.

Materials and methods: A 57-year-old man was referred to the emergency room for an acute onset of confusion and aphasia, symptoms started 3 days before the first visit and were described as worsening since the onset. He recently returned from a holiday in the USA with his family. His past medical was unremarkable and there was no history of neurological diseases in his family.

Results: Neurological examination showed mild psychomotor slowing, nonfluent aphasia, with frequent hesitations and anomie, gait hesitation due to mild postural instability. Brain computerized tomography (CT) and CT angiography of the extracranial and intracranial large vessels were normal, while EEG showed a non-convulsive status epilepticus (NCSE). Levetiracetam was started with an initial mild improvement of the aphasia, at the subsequent EEG the pattern was unchanged so other antiepileptics were progressively added, without an electroclinical improvement. Magnetic resonance imaging (MRI) showed a hyperintense signal in diffusion-weighted imaging (DWI) of the left caudate, fronto-insular left cortex, temporal inferior, and superior left cortex. In cerebrospinal fluid (CSF) cell count, glucose and protein were normal, polymerase chain reaction (PCR) test for virus and culture were negative. Total body TC and scrotal ultrasonography resulted negative for occulted malignancy. The brain 18-F fluorodeoxyglucose positron emission tomography (FDG-PET) identified hypometabolism of the frontal and parietal left cortex, the posterior cingulate left cortex and the left precuneus.

Discussion: In the hypothesis of autoimmune or paraneoplastic encephalitis, 5 days of high-dose glucocorticoids and 5 days of intravenous immune globulin (IVIG) were attempted, without clinical improvement. Indeed, serum/CSF paraneoplastic and autoimmune antibodies resulted negative afterwards. Clinical condition rapidly worsened and 3 weeks after the admission patient showed severe psychomotor slowing, global aphasia, apraxia, dysmetria and ataxia. EEG displayed periodic sharp wave complexes at 1-1.5 Hz in the frontal and central left cortex. The total tau dosage on CSF was 2216 pg/ml. The suspicion of CJD was confirmed by real-time quaking-induced conversion (RT-QuIC) and a diagnosis of probable sporadic CJD was done. He died almost a month after the onset of symptoms.

Conclusions: NCSE could be an acute onset manifestation of CJD and CJD should be considered as a possible cause of NCSE. [1,2]

## BILATERAL SUBTENTORIAL LEUKOENCEPHALOPATHY IN A PATIENT WITH CENTRAL DIABETES INSIPIDUS: A CASE REPORT

S. Grimaldi, F. Caputo, D. Graziani, M. Sozzo, A. Fraddosio

Department of Basic Medical Sciences, Neurosciences and Sense Organs, University "Aldo Moro" of Bari (Bari)

Objectives: The objective of this case report is to highlight the manifestations of bilateral subtentorial leukoencephalopathy in a patient with central diabetes insipidus (DI) in the absence of neurological clinical manifestations.

Materials: The materials used for this case report include the patient's medical records, MRI scans of the brain, laboratory results, spectroscopy analysis, lumbar puncture, immunophenotypic analysis, computed tomography (CT) scan, ophthalmological examination, mental and intelligence tests, visual evoked potentials, cardiology evaluation, Holter ECG, follow-up MRI scans, and positron emission tomography (PET)-CT scan.

Method: A 38-year-old Caucasian male with uncontrolled central DI was admitted to the clinic for demyelinating diseases of the CNS. Various diagnostic procedures, including imaging scans, laboratory tests, and immunophenotypic analysis, were performed to investigate the patient's condition.

Results: Laboratory results upon admission showed altered erythrocyte sedimentation rate (25 mm/h, normal range: 1-15), IgG4 levels (2.73 g/L, normal range: 0.03-2.01), total cholesterol (249 mg/dL, normal range: <200), and LDL cholesterol (162 mg/dL, normal range: <160)MRI scans revealed bilateral subtentorial leukoencephalopathy with parenchymal alterations in the posterior cranial fossa and deep brain structures. The pituitary stalk was thickened, and the neurohypophysis was absent. Spectroscopy analysis showed abnormal levels of N-acetylaspartate (NAA) and choline. Further investigations, including lumbar puncture, virology tests, and antibody screening, yielded negative results. A small nodule and a lymph node were detected in the CT scan, but no other organ abnormalities were observed. The patient's visual evoked potentials indicated mild nerve conduction disturbance.

Discussion: The case report highlights the parenchymal alterations observed in a patient with uncontrolled central DI. The absence of neurological symptoms and inconclusive investigations posed challenges in determining the underlying cause. The radiological findings did not fit the typical patterns of sarcoidosis, and PET-CT scans showed no abnormal uptake of FDG. Thorough observation over time is crucial to understand the significance of these findings before the onset of neurological symptoms.

Conclusions: This case report highlights the importance of recognizing cerebral parenchymal alterations in patients with central DI, even in the absence of neurological symptoms. Further studies are needed to better understand the underlying pathophysiological

mechanisms of these manifestations and their implications for patient management.

## ALZHEIMER'S DISEASE AS A MOTOR DISORDER

M. Hamedani[1], W. Kreshpa[1], F. Massa[1], F. Licini[1], S. Caneva[1], A. Signori[2], A. Brugnolo[1], A. Schenone[3], G. Mancardi[1], M. Pardini[3]

[1]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa (Genova); [2]Department of Health Sciences, Section of Biostatistics, University of Genoa (Genova); [3]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI); IRCCS San Martino Polyclinic Hospital, University of Genoa (Genova)

In Alzheimer disease (AD) motor disturbances become evident when the disease is manifest and later in the course of the disease. Motor movements that have a strong cognitive component however can be compromised since the initial phase of the disease [1]. Recently, quantitative personalized functional outcome measures are applied in clinical assessments areas but specific or highly sensitive tests that can be easily performed in clinical settings are yet to be determined [2]. The present study evaluated the finger movement in patients with AD spectrum to determine the sensitive digital biomarkers that can identify cognitive-function. Forty-five patients (age 77.7±8.03 years; MMSE 21.6±5.7) were selected. The finger dexterity was assessed using a validated HTS which measures the Touch Duration (TD), Inter-Tapping Interval (ITI), movement rate or the frequency of a complete motor task and number of Correct Sequences (CS) by specific sequences performed at maximum-velocity (MV) and metronome (M) compared with the data of healthy older adults. Mini- Mental State Examination (MMSE), Phonemic Verbal Fluency (PVF), CEP Constructive Apraxia Test (CEP-CAT), Clock Drawing Test (CDT), Digit Span (DS) and Verbal Fluency (VF) were carried out to assess cognitive function, and the association between finger function and the results of cognitive scale was evaluated. The HTS parameters was shown significantly strong correlation between CS and MMSE (Right Hand [RH]: r= 0.37, p= 0.012; Left Hand [LH]: r= 0.31, p= 0.038), including age, gender and education as covariate the correlation was highly significant (RH: rho=0.46, p=0.0021 and LH: rho=0.39, p=0.011). Negative correlation was observed between PVF and TD (RH: r=-0.38, p=0.033 and LH: r=-0.40, p=0.03). CEP-CAT shows a statistically significant correlation with CS (RH: r=0.47, p=0.009 and LH: r=0.41, p=0.02), and negative correlation with TD maximum-velocity (r=-0.41, p=0.04) and TD metronome (r=-0.49, p=0.01) in the RH. No HTS parameters correlated with CDT, DS, VF. Comparing the data of healthy older adults, 36.1% patients had a Rate MV value (RH or LH) that was out of the normal range established for Age and Sex [3]. Regarding TD and ITI with Metronome, 56.4% and 41.0% of patients respectively had the values out of the normal range. The HTS was easy and quick to apply. Patients with the finger dexterity deficits showed impaired cognitive performance, supporting the association between motor performance and cognition.

## CASE REPORT: A FULMINATING CASE OF SPORADIC CREUTZFELDT-JAKOB DISEASE. CAN VIRAL ILLNESSES ACCELERATE THE COURSE OF PRION DISEASES?

G. Iania, G. Furlanis, P. Manganotti

Clinical Unit of Neurology, Department of Medical Sciences, University Hospital and Health Services of Trieste (Trieste)

Goals: Sporadic Creutzfeldt-Jakob Disease (sCJD) is a prion encephalopathy for which no cure is available yet. Its course is extremely variable and different influencing factors capable of shortening the natural history of the disease have already been identified [1]. It has been shown that viral infections and the inflammatory environment they create might be responsible for the onset of status epilepticus [2], but we now suggest they may also contribute to hastening disease progression.

Materials: We present a case of a 50 years-old man who referred to our Emergency Department complaining about a three-weeks history of gradually worsening speech, walking and coordination functions. A throughout anamnesis revealed that patient had had a upper airways viral illness a few weeks before symptoms onset. Neurological examination led to a diagnosis of cerebellar syndrome and patient was hospitalized.

Methods: An extensive diagnostic work-up including head CT scan, blood tests, serology, lumbar puncture with CSF analysis, brain MRI, EEG, polygraphy and genetic testing allowed to exclude cerebrovascular events, oedema, traumas, tumours, paraneoplastic syndromes, cerebellar degeneration, autoimmune diseases, malformations, toxic, metabolic or infective causes and eventually led to a diagnosis of sCJD with cerebellar-predominant presentation. We investigated the levels of inflammatory cytokines at different stages of the disease course and of antibodies against common viruses.

Results: The disease had a fulminant course and patient died 1 month after symptoms onset. Inflammatory cytokines were not relevantly increased at the time of patient's admission, but their levels steeply raised in the more advanced stages of the disease. IgMs against Cytomegalovirus and VZV were positive, and so were also IgGs against SARS-Cov-2, HSV1 and EBV.

Discussion: Our patient had many of the already identified risk factors for an accelerated course - male sex, age >40 years old, typical EEG pattern, cerebellar presentation - and it is likely that these have concurred to determine the extremely short course of 5-6 weeks. While it is unusual for sCJD to cause an increase of inflammatory markers, it has been observed that an inflammatory environment is able to start and propagate prion formations [3].

Conclusions: The rise of inflammatory cytokines we observed is likely correlated with patient's recent exposure to a virus. As already hypothesized [2], systemic inflammation might shorten the time spanning between first occurrence of symptoms and death in patients with sCJD. It would be interesting to see if avoidance of systemic infections

in patients already diagnosed with sCJD could prevent a faster than usual demise.

## ANTI-DPPX ENCEPHALITIS PRESENTING WITH NEURODEGENERATIVE BIOMARKERS: RARE PRESENTATION OR FULL PICTURE?

A. Karantzoulis[1], D. Cereda[2], C. Morotti Colleoni[1], B. Della Santa[1], F. Galbiati[1], G. Ferrero[1], E. Funelli[1], L. Marzorati[2], L. Brighina[2], C. Ferrarrese[1], L. Stanzani[2]

[1]Neurology Department, IRCCS San Gerardo dei Tintori, University of Milano-Bicocca (Monza); [2]Neurology Department, IRCCS San Gerardo dei Tintori (Monza)

Objectives: Anti-DPPX encephalitis is an antibody-mediated disease with a mostly indolent presentation and subacute course, sometimes hindering clinical diagnosis. Moreover, definite diagnosis relies on anti-DPPX antibody testing which is not widely available and is lengthy, complicating diagnosis and hampering therapy initiation. Hence, reported cases in the literature range in the several dozens, making it still relatively under characterized. Through the thorough clinical and test characterization of one single case of anti-DPPX encephalitis which came to our attention, our aim is to shed further light on this disease. Moreover, by presenting unreported instrumental findings we wish to give further impulse in the research of this yet mysterious encephalitis.

Materials: A 56-year-old man was admitted to the ICU at our hospital for acute respiratory distress needing invasive respiratory support. Alongside his respiratory issue, he presented a constellation of neurological signs and symptoms which brought him to our attention. He underwent extensive and repeated neurological examinations and clinical monitoring.

Methods: He also went through a series of tests comprising but not limited to: 3T MRI, serial EMGs including skin reflex, EEGs, general autoimmunity, autoimmune encephalitis antibody testing, CSF tap including neurodegeneration biomarkers, cerebral and total body PET as well as contrast enhanced total-body CT-Scan. The patient was discharged to rehabilitation, however was readmitted to our unit in order to complete diagnostics and evaluate immunotherapy response.

Results: The patient's symptoms included nystagmus, hyperekplexia, pyramidal, and extrapyramidal symptoms as well as very pronounced bulbar muscle weakness. History revealed mood disturbances and weight loss prior to symptom onset. Diagnostic testing was flawless with exception to non-evolutive fasciculations at EMG and a pathological skin reflex, pathological CSF amyloid-beta, pathological DaTScan and serum and CSF positivity to anti DPPX antibodies. Eventually a steroid trial was attempted with partial and gradual symptom amelioration.

Discussion: To our knowledge we are the first to describe a case of anti-DPPX encephalitis with biomarkers also suggesting neurodegeneration. Upon reexamination, although the disease's symptomatic presentation was quite typical, its course was remarkably chronic. Improvement after immunomodulatory therapy however suggested an autoimmune origin. Links between autoimmunity and (neuro)degeneration are beginning to be commonly accepted with examples such as MS, anti-IgLON-5 disease and inclusion-body myositis.

Conclusion: We postulate that neurodegeneration could be implied in anti-DPPX encephalitis, although further studies are warranted for confirmation, since our evidence does not exclude a superimposed neurodegenerative pathology on DPPX encephalitis.

## COMPARING CEREBELLAR TDCS AND CEREBELLAR TACS IN NEURODEGENERATIVE ATAXIAS USING WEARABLE SENSORS: A RANDOMIZED, DOUBLE-BLIND, SHAM-CONTROLLED, TRIPLE-CROSSOVER TRIAL

I. Libri[1], V. Cantoni[1], A. Benussi[1], J. Rivolta[2], C. Ferrari[3], R. Fancellu[4], M. Synofzik[5], A. Alberici[2], A. Padovani[1], B. Borroni[1]

Background: Cerebellar transcranial direct current stimulation (tDCS) represents a promising therapeutic approach for both motor and cognitive symptoms in neurodegenerative ataxias. Recently, transcranial alternating current stimulation (tACS) was also demonstrated to modulate cerebellar excitability by neuronal entrainment. In this randomized, double-blind, sham-controlled, triple cross-over study we compared the effectiveness of cerebellar tDCS vs. cerebellar tACS in patients with neurodegenerative ataxia.

Methods: Twenty-six participants with neurodegenerative ataxia were enrolled. Participants were randomized into three groups in a 1:1:1 ratio. Group 1 received a single session of anodal cerebellar tDCS (real tDCS), group 2 a single session of gamma-tACS over cerebellum (real tACS), and group 3 placebo (sham) stimulation (T0). After one (T1) and two-weeks (T2), stimulation was rotated, so that each patient underwent all of the three stimulations in a randomized order. Before entering the study, each participant underwent motor assessment with wearable sensors considering gait cadence (steps/minute), turn velocity (degrees/second) and turn duration (seconds), and a clinical evaluation with the scale for the assessment and rating of ataxia (SARA) and the international cooperative ataxia rating scale (ICARS). After each intervention, participants underwent the same clinical assessment along with cerebellar inhibition (CBI) measurement, a marker of cerebellar activity.

Results: The gait cadence, turn velocity as well as SARA and ICARS significantly improved after both tDCS and tACS, compared to sham stimulation (all $p<0.010$). Comparable effects were observed for CBI ($p<0.001$). Overall, tDCS significantly outperformed tACS on clinical scales and CBI ($p<0.01$). A significant

correlation between changes of wearable sensors parameters from baseline and changes of clinical scales and CBI scores was detected.

Conclusions: Cerebellar tDCS and cerebellar tACS are effective in ameliorating symptoms of neurodegenerative ataxias, with the former being more beneficial than the latter. Wearable sensors may serve as rater-unbiased outcome measures in future clinical trials.

## SUBCORTICAL MYOCLONUS IN PLA2G6-ASSOCIATED NEURODEGENERATION (PLAN), INAD SUBTYPE

M. B. Luca, A. Battiato, V. Todaro, R. Sgroi, M. Proietto, L. Giuliano, M. Zappia

Neurology Unit, Department of Medical, Surgical Sciences and Advanced Technologies "G.F. Ingrassia", University of Catania (Catania)

Background: Phospholipase A2 group VI (PLA2G6)-associated neurodegeneration (PLAN) is a heterogeneous group of diseases caused by mutations located in PLA2G6 gene, with four clinical phenotypes: infantile neuroaxonal dystrophy (INAD), atypical neuroaxonal dystrophy (ANAD), dystonia-parkinsonism (DP) and autosomal recessive early-onset parkinsonism (AREP). We present the case of a patient with INAD with a homozygous mutation in c.1786C>T (p.L596F) PLA2G6 gene presenting subcortical myoclonus.

Case Presentation: We describe the case of a 24-year-old caucasian woman affected by INAD. She had normal birth and development milestones until the age of 3, when she began to complain progressive gait disorders. At the age of 8, she manifested short episodes of reduction of awareness, treated with lamotrigine with a good response. At the age of 23, for a generalized tonic-clonic seizure, levetiracetam was added. From the same age she started to manifest jerky movements of the upper limbs, mainly during wakefulness triggered by voluntary movements, with a progressive worsening and an increase in frequency over the last month. For this reason, clonazepam and phenobarbital were started; after 3 days she presented a progressive alteration of consciousness with development of dysphagia and aspiration pneumonia. Neurological examination showed spastic hypertonia on four limbs, muscle hypotrophy in the lower limbs, subcontinuous jerky movements characterized by flexion and pronation of the upper limbs, accentuated by active and passive mobilization, bending movements of the head. EEG recordings showed widespread low-amplitude fast activity, widespread slow abnormalities and fronto-central sharp-waves bilaterally. Poligraphic recordings showed pseudo-rhythmic synchronous muscle potentials at 3 Hz frequency with an average duration of 300 msec on the flexor-extensor muscles of the upper limbs bilaterally without an EEG correlation. Brain MRI in T2 and FLAIR sequences showed hypo-intensity of the substantia nigra and globus pallidus consistent with iron accumulation, cerebral and cerebellar atrophy. During hospitalization pneumonia was treated with antimicrobial therapy. We withdrew treatment with clonazepam and phenobarbital and added clobazam 10 mg twice daily with a complete disappearance of movements.

Conclusion: The main clinical symptoms of INAD are tetraparesis, truncal hypotonia, dystonia disorders, mental deterioration, cerebellar ataxia, bilateral limb spasticity, early visual failure, epilepsy. We described the clinical, genetic, neurophysiology and neuro-imaging features of a patient with childhood-onset PLAN, with homozygous c.1786C>T (p.L596F) mutation in PLA2G6. In literature only one case with the same mutation has been described with similar clinical features. However, the presence of subcortical myoclonus seems to be peculiar of our patient.

## HEIDENHAIN VARIANT OF CREUTZFELDT–JAKOB DISEASE: UNCOMMON PRESENATION SIMULATING A STROKE

N. Molitierno, A. Nicotra, F. Masserini, S. Pomati, D. Mattavelli, L. Pantoni

L. Sacco Department of Biomedical and Clinical Sciences, University of Milan (Milano)

Objectives: The Heidenhain variant of sporadic Creutzfeldt-Jakob disease is a distinct clinical manifestation characterized by isolated visual symptoms in the early stages. We report the case of a 58-year-old man presenting with hyperacute onset of visual disturbances mimicking a stroke.

Materials and Methods: The patient, without a relevant past medical history, presented to emergency department after sudden onset of blurred vision lasting from the previous day. A left homonymous hemianopsia was detected at neurological evaluation, while CT and CT angiography were normal. An acute occipital right ischemic stroke was suspected and thus he was admitted to our stroke unit.

Results: During the first days of hospitalization the visual disturbance remained stable. Brain MRI DWI-sequences showed a small subcortical hyperintensity nearby the right occipital horn of the lateral ventricle and mild hyperintensity in right medial occipital cortex that appeared hypointense in ADC and without correlates in FLAIR sequences. For a better definition of these finds of non-univocal interpretation and to analyze their evolution a second MRI performed six days later, which showed ribbon-like hyperintensity on DWI-sequences in right occipito-parietal, bilateral mesial frontal, cingulate cortex and right caudate. Three EEGs performed at 8, 14 and 28 days from the onset showed a generalized slowdown, with subsequent appearance of periodic and triphasic peaks in the right temporo-occipital lobes with ipsi and contralateral diffusion. Total body contrast-enhanced CT and CSF examination were performed to rule out paraneoplastic and infective encephalitis. Elevated levels of proteins 14-3-3 and total tau were found. Neuropsychological assessment showed impairment in visuo-spatial abilities with left neglect and simultanagnosia. In the next few days, a rapid worsening occurred with the appearance of nausea,

ataxia, and an episode of acute psychosis with significant psychomotor agitation. Sedation with benzodiazepines (2 mg delorazepam IM) was performed which caused hypotensive shock and respiratory depression requiring oro-tracheal intubation as a likely expression of autonomic dysfunction. The diagnosis of probable CJD was further supported by positive RT-QuiC assay in CSF. The patient was transferred to intensive care, where exitus occurred one month after the onset.

Discussion: Although Heidenhain variant typically occurs with a subacute onset, our patient showed a hyperacute visual worsening which initially suggested a stroke. Clinical evolution, neuroimaging, EEG abnormalities, and CSF biomarkers led to the correct diagnosis.
Conclusion: It is important considering this rare condition of prion disease in patients with acute onset visuospatial disturbances after ruling out other more common and reversible causes.

## A NOVEL MUTATION IN THE PRESENILIN-1 (PSEN1) GENE IN EARLY-ONSET ALZHEIMER'S DISEASE: ATTEMPTING TO DISENTANGLE THE HETEROGENEITY OF THE MUTATIONS AT CODON 226

B. Pancaldi, A. Zilioli, M. Spallazzi

Department of Medicine and Surgery, Unit of Neurology, University Hospital of Parma (Parma)

Objectives: Variants in the presenilin-1 (PSEN1) gene play a prominent role as genetic triggers of Early-onset Alzheimer's disease (EOAD), contributing to phenotypic variability. In this study, we report a novel 'missense' heterozygous mutation p.Leu226Val at codon 226, aiming to elucidate the clinical heterogeneity associated with mutations in this codon.

Materials and methods: We conducted clinical-neuropsychological assessment, neuroradiological examination which included analysis of volumetric hippocampal subfields using ASHS software and SPECT DAT-SCAN, NGS panel and lumbar puncture with biomarkers analysis.

Results: The index case was a 50-year-old right-handed man with episodic memory deficits, depression, and a familial history of dementia. The clinical examination revealed a left-hand tremor and ipsilateral bradykinesia. The neuropsychological assessment highlighted impairments in memory and visuo-spatial abilities, with a MOCA score of 17/30. Brain MRI showed a posterior gradient of atrophy, parieto-occipital white-matter FLAIR alterations, absence of the "Swallow Tail" sign in the SWAN sequence, and reduced perfusion in the right temporal-parietal-occipital lobe as assessed by ASL. DAT-SCAN (123I-Ioflupane) SPECT revealed decreased uptake in the right basal ganglia. CSF biomarkers indicated an A+T-N- profile and NGS analysis identified a 'missense' heterozygous mutation (c.676 C>G) p.Leu226Val in the PSEN1 gene. According to the American College of Medical Genetics and Genomics guidelines, this mutation is considered likely pathogenic, leading to the diagnosis of monogenic EOAD.

Discussion: Since the discovery of the first pathogenetic variants in the PSEN1 gene, the phenotypic variability of EOAD has been clear, including motor signs like parkinsonism. The Leu226Val mutation had not been previously reported in literature, prompting our investigation into a potential association with other mutations at codon 226. We discovered a high occurrence of parkinsonism features, early behavioral disturbances and psychiatric symptoms. Our report emphasizes the presence of extrapyramidal involvement based on the alterations observed in clinical and neuroradiological assessments. Our index case also showed the onset at the same age of his relatives, in line with the previous literature. The analysis of hippocampal subfields revealed reduced volumetric values in the CA3 and Brodmann area 36, indicating a selective vulnerability of the CA3 and perirhinal cortex to Alzheimer's pathology in the early stages of the disease.

Conclusion: In young adults and middle-aged patients presenting with extrapyramidal symptoms along with behavioral and memory deficits, and a positive family history, we suggest performing an NGS panel to investigate the potential role of PSEN1.

## ACUTE AUTOTOPAGNOSIA: AN UNUSUAL PRESENTATION FOR THE RARE MARCHIAFAVA-BIGNAMI DISEASE

M. C. Pantuliano, V. Pozzilli, F. Motolese, F. Capone, V. Di Lazzaro, F. Pilato

Neurology, Neurophysiology and Neurobiology Unit, Department of Medicine, Campus Bio-Medico University of Rome (Roma)

Objectives: Herein we discuss a peculiar case of Marchiafava-Bignami disease (MBD) that manifested with acute onset autotopagnosia, mimicking stroke.

Materials: A 52-year-old man, heavy smoker and affected by alcohol use disorder presented to our emergency department complaining of a 12-hour history of acute onset autotopagnosia, described as not being able to localize his head and confusion. The neurological examination revealed disorientation, dysarthria, dysphonia, and a positive Romberg test. Head computed tomography (CT) was inconclusive. Only later, during the hospitalization, the patient reported a four months history of progressively worsening dysarthria, hypophonia, dysphagia, weight loss and bilateral hand weakness. According to his wife, in the same period, he had been experiencing short-term memory impairment and frequent but short-lasting episodes of confusion. Furthermore, the patient denied any recent changes in drinking habits.

Method: Blood tests showed macrocytic anaemia and elevated serum gamma-glutamyl transferase and IgA. Among the possible differential diagnoses, we included motor neuron disease or a paraneoplastic syndrome, therefore we completed our diagnostic work-up with electromyography, which was inconclusive, and a full-body CT scan, which excluded malignancies. Encephalitis was also ruled out through cerebrospinal fluid analysis and electroencephalography, which did not show abnormal findings. The hypothesis of posterior circulation stroke was conclusively disproved by brain magnetic resonance imaging, which revealed T2-FLAIR hyperintense lesions in the periventricular white matter bilaterally and in the corpus

callosum, particularly in the splenium, consistent with chronic toxic-metabolic demyelination.

Results: Based on the clinical history and the suggestive radiological findings, MBD was diagnosed. The patient received high-dose thiamine for one week, followed by one-month oral thiamine supplementation after discharge. After a follow-up of two months and a significant reduction in alcohol intake, the patient reported a considerable improvement in symptoms, which further corroborated the diagnosis.

Discussion: MBD is a rare neurological disorder characterized by demyelination and necrosis of the corpus callosum and the adjacent subcortical white matter and is mainly associated with chronic alcohol abuse and malnutrition. The presentation can be acute, subacute or chronic. To our knowledge, this is the first report to describe autotopagnosia as an acute manifestation of MBD.

Conclusions: The singularity of this case is represented by the acute on chronic presentation of MBD in our patient. To avoid a delayed diagnosis in rare neurological disorders that require urgent treatment, such as MBD, attention should be paid to anamnestic information like alcohol consumption even in the acute setting.

## TOWARDS A CLINICAL APPLICATION OF A-SYNUCLEIN SEED AMPLIFICATION ASSAYS IN PARKINSON'S DISEASE

F. P. Paoletti[1], L. Concha-Marambio[2], C. Farris[2], Y. Ma[2], A. Toja[1], L. Parnetti[3], G. Bellomo[3]

[1]Section of Neurology, Dept. of Medicine and Surgery, University of Perugia (Perugia); [2]R&D Unit, Amprion Inc. (San Diego-USA); [3]Lab. of Clinical Neurochemistry, Section of Neurology, Dept. of Medicine and Surgery, University of Perugia (Perugia)

Introduction: Cerebrospinal fluid (CSF) α-synuclein seed amplification assay (αS-SAA) represents the most promising diagnostic tool for Parkinson's disease (PD), demonstrating excellent performance in discriminating PD from healthy controls and other α-synuclein-unrelated disorders [1]. It showed the capability to detect prone-to-aggregate α-synuclein in the prodromal stage of disease, i.e. isolated REM sleep behavior disorders. However, the diagnostic role of αS-SAA in the pre-motor stage of PD is still matter of debate. CSF αS-SAA may be valuable to monitor disease progression and treatment efficacy in clinical trials with disease-modifying therapies targeting α-synuclein misfolding and aggregation. Before this biomarker can be implemented in clinical setting, pre-analytical and analytical variability factors need to be addressed [1]. Preliminary data showed that CSF proteins have an inhibitory effect on α-synuclein aggregation in SAAs. Donor-specific inhibition of CSF on α-synuclein aggregation may explain the lack of correlation between kinetic parameters measured in SAAs and clinical features [2].

Objective: We sought to investigate whether, in a cohort of well-characterized PD patients, CSF protein concentration influences kinetic parameters of aggregation in CSF αS-SAA and their correlation with clinical measures.

Materials and methods: Among patients referring to our Centre, we retrospectively selected a consecutive series of PD patients (n. 94) for whom CSF samples and a thorough clinical characterization were available. Patients with other minor neurological diseases undergoing lumbar puncture within the diagnostic work-up were included as control group (OND, n.112). CSF αS-SAA was performed according to a previously described protocol [3]. In PD patients, motor impairment and disease severity were assessed using MDS-UPDRS III and H&Y, respectively. Cognitive assessment included MMSE and MoCA.

Results: The assay showed 88% specificity and sensitivity in detecting PD vs. OND. Time-to-threshold (TTT), maximum fluorescence (F-max), fluorescence at 24 h (F-24), maximum slope of the sigmoid (S-max) and time to maximum slope (TMS) were significantly correlated with CSF protein concentration ($p<0.05$). After adjusting for CSF protein concentration, MDS-UPDRS III resulted to be negatively associated to TTT ($r=-0.27$, $p = 0.018$) and TMS ($r=-0.27$, $p = 0.02$).

Discussion and conclusion: In our series, CSF αS-SAA confirmed satisfactory accuracy for PD diagnosis. Kinetics of α-synuclein aggregation and its association with some clinical features were significantly influenced by CSF protein concentration. In view of potential clinical applications of αS-SAA, CSF protein content should be taken into account to eliminate possible confounding effects.

## STRUCTURAL VARIATION DETECTION BY GENOME MAPPING: C9ORF72 EXPANSION

B. Perrone[1,2], S. Efthymiou[1], N. Dominik[1], S. Facchini[1], J. Polke[3], L. Zampedri[4], A. Malaspina[5,6], P. Fratta[6], A. Cortese[1], H. Houlden[1], E. Bugiardini[1], F. L. Conforti[2]

[1]Department of Neuromuscular Disorders, UCL Queen Square Institute of Neurology (London-UK); [2]Medical Genetics Laboratory, Department of Pharmacy, Health and Nutritional Sciences, University of Calabria (Rende-CS); [3]Neurogenetics Laboratory, UCL Queen Square Institute of Neurology and The National Hospital for Neurology and Neurosurgery (London-UK); [4]Leonard Wolfson Experimental Neuroscience Centre (London-UK); [5]Centre for Neuroscience and Trauma, Blizard Institute, Queen Mary University of London, Northeast London and Essex Regional Motor Neuron Disease Care Centre (London-UK); [6]UCL Queen Square Motor Neuron Disease Centre, Department of Neuromuscular Diseases, UCL Queen Square Institute of Neurology, UCL (London-UK)

Background: Specific variant types, which are not commonly detectable by currently used analysis methods, such as repeat expansions, variants in non-coding regions and structural variants, are frequent in neurological disorders. Among these, repeat expansions are an important cause of several neurodegenerative diseases [1]. The size of repeat expansions has been proven to quantitively affect disease severity, with larger expansions often associated with earlier onset of disease and more severe symptoms. Hexanucleotide (G4C2)n repeat in C9orf72 is the most common cause of amyotrophic lateral sclerosis (ALS) and familial frontotemporal dementia (FTD) [2]. Genetic counselling for C9orf72 is very complex due to the highly variable

clinical presentation and technical difficulties in determining the size of the large G4C2 expansions. The detection in clinical routine is still based on repeat-primed (RP) - PCR and Southern blot (SB). The disadvantages of these tests are the detection of small expansions (<80 bp) on the one hand and the labor intensive use, background noise and high signal strength required on the other. Furthermore, somatic mosaicism as well as the unclear cut-off between normal alleles and expanded pathogenic alleles can make the diagnosis difficult. Here, we investigated the ability of optical genome mapping (OGM), a novel imaging and mapping tool for high-throughput detection of structural genetic variants and sizing of tandem repeats [3], to detect G4C2 hexanucleotide repeat in C9orf72.

Methods and Materials: Ultra-high molecular DNA from 15 historical C9orf72 ALS patients were selected. Optical genome mapping (OGM) was performed on the Saphyr Genome Imaging Instrument recently established in the Neurogenetics lab at UCL Queen Square Institute of Neurology.

Results: We confirmed C9orf72 - hexanucleotide repeat expansion in 14 of 15 ALS patients. Repeat sizes ranged from 6 to 25 Kbp. The negative case was repeated with RP-PCR and confirmed to be a C9orf72 negative case. In addition, we assessed somatic instability in the tissue examining the size distribution of the molecules in our patients.

Discussion and Conclusion: In this study, a non-sequencing-based technique was used for the first time in C9orf72-ALS patients carrying more than (G4C2)1000 repeats. Our preliminary data showed the potential of OGM to provide a convenient and easy-to-use alternative that would enable comprehensive detection of structural variants and repeat size variability for most patients by better defining cases of somatic mosaicism.

Objective: Synaptic dysfunction is an important early mechanism involved in Alzheimer's disease (AD) but its correlation with neuronal, glial and inflammatory markers is still debated [1]. Objective of this study was to evaluate the levels of synaptic markers Neurogranin, SNAP25 and CAP2 in cerebrospinal fluid of AD and their correlation with neuronal, glial and inflammatory markers in vivo.

Material: Sixty AD patients and 20 age-matched controls underwent CSF analyses for tau, p-tau and amyloid to define A+T+N+ Alzheimer's disease patients

Methods: Each subject underwent an extensive cognitive, behavioral and motor assessment. CSF analyses for neurogranin, SNAP-25, CAP2, NfL, and inflammatory markers were performed using SIMOA and Luminex platforms. Correlations between CSF biomarkers were evaluated using partial correlation adjusted for the effect of age, sex and disease duration.

Results: AD patients exhibited higher synaptic markers namely neurogranin, SNAP-25 and CAP2 levels compared to controls. SNAP-25 showed a stronger correlation with the Neuronal marker NfL compared to neurogranin and CAP2. Neurogranin correlated with tau pathology and inflammatory markers in partial correlation analyses.

Discussion: The synaptic markers neurogranin, SNAP-25 and CAP2 are leveted in AD already in prodromal stages together with mild inflammatory cytokines and neuronal markers.

Conclusion: The preliminary findings indicate a possible correlation between synaptic markers and inflammation in AD, whereas neuronal loss might be related to mild inflammatory alterations in CSF.

## A BAYESIAN RE-ANALYSIS OF LECANEMAB (CLARITY AD) PHASE 3 TRIAL USING INFORMED T-TEST

E. Premi, T. Costa, J. Manuello, F. Cauda, D. Liloia

[1]Stroke Unit, ASST Spedali Civili, University of Brescia (Brescia); [2]GCS-fMRI, Koelliker Hospital and Department of Psychology, University of Turin (Torino)

Objective: Clinical trials for Alzheimer's disease (AD) strive to enhance clinical symptomatology and modify the course of this intricate neurodegenerative disorder. Nonetheless, the conventional approach of null hypothesis significance testing (NHST) generally employed in these trials possesses limitations in evaluating the clinical significance and capturing detailed evidence for effectiveness on a gradual scale. In this study, we re-analyzed the phase 3 (Clarity-AD) trial of Lecanemab, a recently proposed humanized IgG1 monoclonal antibody that binds with high affinity to Aβ soluble protofibrils, using a Bayesian approach with informed t-test priors.

Materials and Methods: We selected data from the trial and obtained effect size estimates for the primary endpoint, the Clinical Dementia Rating Scale-Sum of Boxes (CDR-SB). Then, a set of Bayes Factor analyses was performed to compare the evidence for the null hypothesis (no effect of treatment) and the alternative hypothesis (effect present). Based on previous literature data and Lecanemab phase 3 trial, we used different minimal clinically important difference (MCID) values for the primary endpoint CDR-SB as priors.

Results: Our results indicated anecdotal evidence in favor of the null hypothesis when using a standard prior. Robustness checks showed consistent results. Using informed priors, we found varying evidence for different MCID values, but overall, there was no evidence supporting the effectiveness of Lecanemab compared to the placebo.

Discussion and Conclusion: Our study shows the value of Bayesian analysis in clinical trials while emphasizing the criticality of incorporating minimum clinically important difference (MCID) and effect size granularity when assessing treatment efficacy.

## FRONTOTEMPORAL DEMENTIA IN VALOSIN CONTAINING PROTEIN MUTATIONS: A CASE FAMILY REPORT AND SYSTEMATIC LITERATURE REVIEW

G. R. Rodolico[1], S. Matà[1], D. Leccese[1], M. Sperti[1], S. Torricelli[1], D. Cassandrini[2], M. Bartolini[3], A. Ingannato[1], B. Nacmias[1], L. Bracco[1], A. Malandrini[4], F. Santorelli[2], V. Bessi[1]

[1]Department of Neuroscience, Psychology, Drug Research and Child Health, Careggi University-Hospital (Firenze); [2]Department of Molecular Medicine, IRCCS Fondazione Stella Maris (Pisa); [3]Department of Radiology, Careggi University-Hospital (Firenze); [4]Department of Medicine, Surgery and Neurosciences, University of Siena (Siena)

Aim: Mutations in the Valosin-Containing Protein (VCP) gene cause autosomal dominant multisystem proteinopathy 1 (MSP1), characterized by a variable combination of inclusion body myopathy (IBM), Paget's disease of bone (PDB), and frontotemporal dementia (FTD). Here we report a novel VCP missense mutations in an Italian family, with FTD as the prevalent manifestation, and compared our results with those described in literature.

Materials and Methods: We described clinical, molecular and imaging data from the studied family. We also conducted a literature systematic review (PubMed, Scopus and Web of Science databases using "VCP" as keyword) with the aim to compare our findings with previously reported VCP-related phenotypes.

Results: A novel heterozygous VCP missense mutation (c.473T>C/p.Met158Thr) was found in all the affected family members. The proband is a 69-year-old man affected by progressive muscle weakness since the age of 49. At age 65, he presented a cognitive disorder suggestive of behavioral variant FTD. A bone scintigraphy also revealed PDB. The patient's mother, his maternal aunt and her daughter had died following a history of cognitive deterioration consistent with FTD; the mother also had PDB. No relatives had any muscular impairments. Reviewing the literature, we observed a different sex distribution of VCP-related phenotypes, being FTD prevalence higher among women as compared to men (51.2% vs 31.2%) and IBM prevalence higher among men as compared to women (92.1% vs 72.8%).

Discussion: We described a novel mutation in VCP in an Italian Family, asserting its pathogenicity by analyzing the site of mutation and protein structure, and the correlation between mutation positivity and the clinical manifestation of the affected members. The clinical findings of our proband were suggestive for the complete triad of MSP1 (present in 12% of cases), though the biopsy did not show the pathognomonic inclusion bodies. We showed that FTD affects a higher percentage of VCP mutated patients as compared to what previously reported. We also documented that FTD mainly affects women and a higher incidence of IBM among men.

Conclusion: Sex has been shown to be a potential factor determining FTD and MSP-1 phenotype, although VCP is not biologically related to sex differentiation, suggesting different mechanisms either protective or worsening the neuromuscular system in the two genres. We also emphasized the importance of VCP genetic testing, even in the absence of the full syndromic complex, in atypical neuro-muscular or neurodegenerative pathologies which result negative for the most common genetic alterations.

## RIGHT TEMPORAL VARIANT FRONTOTEMPORAL DEMENTIA AND CEREBROSPINAL FLUID BIOMARKERS FOR ALZHEIMER'S DISEASE: A CASE REPORT WITH A MULTIMODAL MRI ANALYSIS

D. Salvatori[1], C. Gallingani[1], C. Carbone[1], M. Tondelli[2], R. Bedin[3], G. Vinceti[3], A. Chiari[3], G. Zamboni[1]

[1]Department of Biomedical, Metabolic and Neuroscience Sciences, University of Modena and Reggio Emilia (Modena); [2]Primary Care Department, Local health authority (AUSL) Modena (Modena);[3]Neurology Unit, University hospital (AOU) (Modena)

Introduction: Right temporal variant frontotemporal dementia (rtvFTD) is currently defined by a predominant neurodegeneration of the right anterior temporal lobe (ATL) and a peculiar clinical presentation, involving face and emotions recognition deficits, profound behavioral features, memory-loss, and naming difficulties. Having been for long considered a right-sided variant of the semantic variant of primary progressive aphasia (svPPA), it has been linked almost exclusively to TDP-43 type C frontotemporal lobar degeneration (FTLD). However, recent studies have highlighted the pathological variability underlying this syndrome. In particular, little is known about the association between rtvFTD and Alzheimer's disease (AD) pathology. Here we present the case of a rtvFTD patient with cerebrospinal fluid (CSF) biomarkers suggesting AD and FTLD co-pathology.

Case presentation: A 74-year right-handed man with memory-loss, naming difficulties and behavioral disturbances, including apathy, obsessive behaviors, and dietary changes presented to our clinic. An extended neuropsychological evaluation showed semantic deficits for both verbal and non-verbal modalities, and anterograde memory dysfunction, with encoding rather than retrieval difficulties. The magnetic resonance imaging (MRI) documented marked focal atrophy in the right temporal lobe, leading to the diagnosis of rtvFTD, accordingly to the most recent proposed criteria. Surprisingly, CSF analysis showed an elevation in total and phosphorylated tau and a reduction in beta-amyloid 1-42 and 1-42/1-40 beta-amyloid ratio, consistently with AD neuropathology. However, CSF neurofilament light chain (NfL) was 2541 pg/ml, suggesting a co-existing FTLD-TDP pathology. We compared our proband to 3 rtvFTD patients with negative AD biomarkers and to 27 healthy controls, using multimodal MRI analysis, including voxel-based morphometry (VBM) to assess

grey matter (GM) volume and tract-based spatial statistics (TBSS) to assess white matter (WM) microstructural integrity. Compared to controls, rtvFTD patients showed diffuse GM atrophy in the frontal and temporal lobes of both hemispheres, while our patient presented a more lateralized GM loss, involving right fronto-temporal regions. On the contrary, rtvFTD patients had decreased WM integrity affecting predominantly the right hemisphere, in the inferior fronto-occipital, inferior longitudinal, and uncinate fasciculi, while our patient showed reduced WM integrity in the inferior longitudinal and inferior fronto-occipital bundles bilaterally, in the right uncinate and in the left superior longitudinal fasciculi.

Conclusion: We presented the case of a rtvFTD patient with underlying both AD and FTLD-pathology, who shows a pattern of brain atrophy and WM involvement different from rtvFTD AD-negative patients. We speculate that the co-pathology may determine a peculiar phenotype due to greater disruption of WM integrity than GM volume loss.

## FATIGUE IN PARKINSON'S DISEASE: DIFFERENCES BETWEEN CAREGIVER'S REPORT AND SELF-EVALUATION

V. Sant'Elia[1], M. Siciliano[1,2], R. De Micco[1], S. Aloisio[1], S. Aramini[1], E.N. Mosca[1], A. Tessitore[1]

[1]Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli" (Napoli); [2]Department of Psychology, University of Campania "Luigi Vanvitelli" (Caserta)

Objectives: 1) To investigate the differences in fatigue prevalence in Parkinson's disease (PD) according to the point of view from which fatigue is reported self-evaluation (SE) and caregiver reporting (CR); 2) to identify the possible correlates between each of the two evaluations the main motor and non-motor symptoms.

Materials: Eighty-five patients with early PD (45.05% male; age 63.61±9.37 years; disease duration 3.43±2.28 years) were assessed using the Fatigue Severity Scale (FSS) in its SE version (FSS-SE). The FSS-CR was made ad hoc to collect the point of view of the caregiver about the patients' fatigue experience Moreover, all patients underwent a comprehensive examination, including Epworth Sleepiness Scale (ESS), Parkinson's Disease Sleep Scale (PDSS), Beck Depression Inventory (BDI), Parkinson's Anxiety Scale (PAS), Questionnaire for Impulsive-Compulsive Disorders in Parkinson's Disease and Rating Scale, and self-rated/caregiver reporting Apathy Evaluation Scale (AES), and a cognitive evaluation exploring attention and working memory, executive functions, memory, visuospatial abilities, and language domains.

Methods: We used Pearson's chi-square test to investigate the differences in fatigue prevalence estimated by FSS-SE and FSS-CR. We employed the linear regression analyses to identify the possible correlates of FSS-SE and FSS-CR with the main motor and non-motor symptoms. In detail, firstly, we used bivariate regression analyses to identify demographic, clinical, cognitive, and behavioural correlates of FSS-SE and FSS-CR. Secondly, we explored the unique associations of FSS-SE and FSS-CR with the variables that resulted in the first step being statistically significant.

Results: No difference in fatigue prevalence was found between FSS-SE and FSS-CR. The multivariate linear regression analyses showed that FSS-SE was associated with PDSS (B=-0.21, p=0.039), while FSS-CR was related to AES-CR (B= 0.26, p= 0.035).

Discussion: The prevalence of fatigue was between 30-40% for patients and caregivers, with a tentative tendency for overestimation by caregivers. In addition, when the correlates of fatigue were analyzed through multiple regression models and separately for the patient and caregiver, it emerged that the presence of fatigue was associated with sleep disturbance for the patient and associated with indolence toward external reality for the caregiver.

Conclusion: Although no difference was found between SE and CR of fatigue prevalence, the caregivers understood the patients' fatigue experience in terms of anxious or apathetic symptoms. This evidence should encourage involving the caregivers in the assessment and treatment of fatigue to reduce the patients' frustration induced by the lack of understanding of their own experience of fatigue.

## CORTICAL AND EXTRACORTICAL INVOLVEMENT IN POSTERIOR CORTICAL ATROPHY IS SUGGESTED BY ELECTROPHYSIOLOGICAL FINDINGS: LITERATURE REVIEW AND A CASE SERIES

L. Scanu, M. Cotta Ramusino, G. Perini, G. Cosentino, L. Farina, G. Trifirò, A. Costa

IRCCS Mondino Foundation, University of Pavia (Pavia)

Objective: To investigate and describe the neurophysiological alterations of the visual pathways in patients with Posterior cortical atrophy (PCA), reported in literature and from a case series.

Materials: Literature data including findings from Visual evoked Potentials (VEP), Electroretinogram (ERG) and/or Visual field test (VF) in subjects affected from PCA, and data of a cohort enrolled at the IRCCS Mondino Foundation.

Methods: Three-hundred-two articles emerged from the Pubmed search and only one article from the reference re-assessment. Of these articles, we evaluated title and abstract, and 25 were judged to be suitable and were submitted to full-text assessment. (Figure 1). Patients enrolled at our clinic underwent to VF, VEP with 15' and 30' checks and ERG.

Results: Seventeen studies included outcomes of interest. Literature cohort consisted of 140 patients. VF is described in 115 patients (16/17 studies, 94%), the most frequent finding was homonymous hemianopsias or quadrantopsias (12/17 studies, 71%). VEP were performed in 4 patients (4/17 studies, 24%), two were normal, one showed a reduction in amplitude and the last one showed a delayed latency. ERG was performed in 3 cases (3/17 studies 18%), just one showed a delayed latency and low amplitude of both P50 and N95 (Table 1). The study cohort comprised six patients. VF was performed in all patients, three patients showed homonymous lateral hemianopia (50%), the others showed altered values but of low reliability. VEP were performed in

all patients and just one showed normal results (17%). Three patients showed low or borderline amplitude (50%). Five patients had delayed or borderline latency (83%) with involvement of both eyes in 50% of cases. Latency was delayed in 50% of cases with stimulation at 30' check, compared to 33% with stimulation at 15' check. ERG was performed in all cases except one, with normal findings (Table 2).

Discussion: Data related to VEP and ERG are largely absent in literature and when available (2/17 papers, 12%) were normal. VEP from our case series demonstrate an impairment of the central visual pathways (normal ERG). This involvement is mixed, both in amplitude and latency. The latter is partly unexpected and not related to subcortical vascular damage, suggesting a potential involvement of the pre-cortical and post-geniculate axonal component of the visual pathway, not due to cortical neuronal damage.

Conclusions: Our data on a small sample represent a starting point to sensitize the scientific community to pay attention to a possible functional involvement of subcortical structures in patients with PCA for a long time considered spared.

## CHARACTERIZATION OF GAIT COMPARISON WITH WEAREABLE SENSORS IN DIFFERENT TYPES OF DEMENTIAS

C. Sorrentino[1], G. Acerra[1], M. Russo[2], C. Ricciardi[2], M. Amboni[1], R. Erro[1], M. Pellecchia[1], P. Barone[1], M. Picillo[1]

[1]Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Neuroscience Section, University of Salerno (Salerno); [2]Department of Electrical Engineering and Information Technology, University Federico II (Napoli)

Objective: The aim of this study was to characterize gait in three groups of patients with different types of dementia using wearable sensors (OPAL). These sensors have already been applied to have an objective estimate of gait in other neurodegenerative pathologies [1].

Materials: We recruited 13 patients within the Fronto-Temporal Dementia (FTD) spectrum (8 with behavioural variant, 5 with Primary Progressive Aphasia which included 2 with non fluent-agrammatic variant and 3 with semantic variant), 8 patients with Lewy-Body Dementia (DLB) and 9 patients with Alzheimer Disease (AD).

Methods: All patients underwent to an extensive motor evaluation which included MDS-Unified Parkinson Disease Rating Scale part III (MDS-UPDRS III), a video protocol assessment including evaluation of eye movements, myoclonus and dystonia. All patients performed a gait protocol with OPAL applied on both wrists, sternum, lumbar and both feet which consisted in 2 minute walking test, sway and 360 degree turn. Due to the small sample size for each group, Kruskal–Wallis test (Non-parametric testing) was applied to do a comparison of variance between the groups, subsequently an ANCOVA analysis was performed using the statistically significant variables.

Results: The three gruops did not show differences in terms of demographic features and disease duration. As expected, the MDS-UPDRS part III was higher in DLB compared to FTD and AD ($p<0.05$). Then DLB performed worst than FTD and AD on several gait parameters (i.e. gait speed, gait stride length, gait turns duration, gait turns velocity, gait turns steps in turn, 360° angle and 360° turn velocity) ($p<0.05$). Complementary FTD group performed worse than AD group on the same gait parameters ($p<0.05$). Adding the MDS-UPDRS part III as covariate, ANCOVA model still showed gait speed was worse in FTD spectrum compared to AD (0.75 m/s vs 0.97 m/s, $p<0.05$)

Discussion: Our results suggest that most of the gait impairment detected with OPAL in different groups of dementia is related to parkinsonian syndrome. Still, gait speed seemes to be worse in FTD spectrum irrespective to parkinsonism assessed with MDS-UPDRS part III.

Conclusions: Our preliminary data suggest gait speed may differentiate different types of dementia irrespective of the presence of parkinsonism.

## THE CONTRIBUTION OF SMALL VESSEL DISEASE TO CLINICAL PHENOTYPE IN PROGRESSIVE SUPRANUCLEAR PALSY

M. F. Tepedino[1], F. Diana[2], F. Abate[1], A. Avallone[1], M. Caterino[1], R. Erro[1], M. Pellecchia[1], R. Manara[1], P. Barone[1], M. Picillo[1]

[1]Center for Neurodegenerative Diseases (CEMAND), Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", University of Salerno (Salerno);[2]Department of Neuroradiology, Azienda Ospedaliera Universitaria San Giovanni di Dio e Ruggi d'Aragona (Salerno)

Introduction: Emerging evidence has suggested that cerebral small vessel disease (CSVD) may have an impact on motor, cognitive and behavioral symptoms in many neurodegenerative diseases. White matter hyperintensities (WMHs) are considered imaging biomarkers of CSVD but it's still debated whether they reflect atherosclerotic cerebrovascular changes or neurodegenerative-related pathology. A recent anatomopathological study reports CSVD was the most frequent co-pathology found in a cohort of 101 PSP (65%) [1]. However, the contribution of CSVD on clinical features of Progressive Supranuclear Palsy (PSP) remains unknow.

Objectives: This study explores the possible influence of CSVD on presentation of the disease and describes the burden and distribution of WMHs on brain magnetic resonance imaging (MRI) in PSP patients.

Materials and Methods: This study included 60 subjects with PSP diagnosed according to the MDS-PSP criteria and referred to the Center of Neurodegenerative Disease (CEMAND) of the University of Salerno, Italy, from May 2016 to July 2022. Motor (PSP-rating scale, MDS-UPDRS-III, S&E), cognitive (MOCA) and behavioral (NPI) symptoms, Milestones (falls, ocular motor dysfunction, impossible to gait, dysarthria, dysphagia and dementia) and cardiovascular risk factors were assessed in these patients. CVSD imaging markers were captured with MRI and age-related white matter changes scale (ARWMC) score (range 0-30) was calculated. The associations of CSVD with these outcomes were analyzed using Pearson's correlation and linear or logistic regression models.

Results: CVSD was present in 41 (68%) of PSP patients (ARWMC+). Compared to ARWMC-, ARWMC+ did not have major disease severity or more cardiovascular risk factors, except for a trend towards significance for hyperlipidemia ($p=0.008$). Median ARWMC total score was 2 (IQR=4). WMHs were localized in fronto-temporal lobes and were mild in severity (Fazekas I). There were a relationship

between ARWMC total score and PSP-rating scale (β=0.312, p=0.029), MDS-UPDRS-III (β=0.302, p=0.05) and some Milestones (dysarthria OR=1.1, p=0.55 and impossible to gait OR=1.3, p=0.26) but not with S&E (r=-0.191, p=0.23), MOCA (r=-0.145, p=0.407) and NPI (r=-0.068, p=0.789). No differences were found between clinical phenotypes.

Conclusions: Our results may indicate that WHMs in PSP is more related to the physiopathology mechanism of the disease rather than atherosclerotic cerebrovascular risk factors.

## INVESTIGATING α-SYNUCLEIN COPATHOLOGY IN ALZHEIMER'S DISEASE WITH CSF α-SYNUCLEIN SEED AMPLIFICATION ASSAYS

A. Toja[1], G. Bellomo[1], D. Chiasserini[2], A. Wojdala[1], F. Paolini Paoletti[1], L. Concha-Marambio[3], C. M. Farris[3], Y. Ma[3], L. Parnetti[1]

[1]Lab. of Clinical Neurochemistry, Section of Neurology, Dept. of Medicine and Surgery, University of Perugia (Perugia); [2]Section of Physiology and Biochemistry, Dept. of Medicine and Surgery, University of Perugia (Perugia); [3]3R&D Unit, Amprion Inc, (San Diego-USA)

Introduction: Alpha-synuclein seed amplification assays (αS-SAAs) are the most promising techniques for the in vivo detection of synucleinopathy. Several studies reported high accuracy of cerebrospinal fluid (CSF) αS-SAAs in discriminating α-synuclein-related disorders, i.e. Parkinson's disease (PD) and dementia with Lewy bodies (DLB), vs. healthy controls. Notably, neuropathological studies revealed the presence of α-synuclein copathology in Alzheimer's disease (AD).

Objectives: We aimed to investigate the prevalence of CSF αS-SAA positivity in AD patients, also exploring its potential association with clinical features.

Materials: We retrospectively selected, from our cohort, a total number of 456 individuals, including subjects in the AD continuum (n=240), patients with Lewy body disorders (LBD), (n=104), and subjects with other minor neurological disorders (OND, n=112) as control group. All the individuals included underwent clinical and neuropsychological evaluation, CSF AD core biomarkers assessment, and a highly reliable CSF αS-SAA.

Methods: Associations between αS-SAA positivity and AD clinical variants, neuropsychological tests and AD core biomarkers were assessed by means of Fisher's exact test and logistic regression.

Results: In our series, αS-SAA demonstrated high sensitivity (86.5%) and specificity (87%) for differentiating PD and DLB from controls. We observed significantly higher αS-SAA positivity in AD patients (30%) vs. controls (13%) (p=0.0017, adjusted for age and sex). Among the AD clinical variants, patients with posterior cortical atrophy (PCA)-AD exhibited significantly higher αS-SAA positivity with respect to those with amnestic/typical presentation (75% vs. 29.2%, respectively, p=0.0061, adjusted for age and sex). αS-SAA positivity increased across the stages of AD continuum (25% in preclinical AD vs. 36% in dementia due to AD). We found a significant association between the copy of drawing test from the Mental Deterioration Battery and positivity of αS-SAA in AD patients (p=0.00579, adjusted for age). αS-SAA positivity was significantly associated with reduced CSF levels of Aβ40 (p=0.0278, adjusted for age) and Aβ42 (p= 0.023, adjusted for age).

Discussion: Our data revealed that a substantial proportion of AD cases (30%) shows positivity for CSF αS-SAA, which is also linked to clinical presentation and disease stage. Our results suggest the expansion of the A/T/N system to include an A/T/N/S classification, where "S" stands for "synucleinopathy." Detection of α-synuclein copathology in AD holds great relevance for designing personalized disease-modifying therapies. Further longitudinal investigations are warranted to elucidate the potential prognostic value of αS-SAA for AD clinical course.

## BEHAVIORAL AND COGNITIVE ABNORMALITIES IN SECONDARY FRONTOTEMPORAL DEMENTIA ASSOCIATED WITH SPONTANEOUS INTRACRANIAL HYPOTENSION: A CASE REPORT

D. V. Viola, L. Giampietri, R. Ceravolo, G. Siciliano, G. Tognoni, F. Baldacci

Department of Clinical and Experimental Medicine, University of Pisa (Pisa)

Objective: To describe the case of a 59-year-old male patient who experienced spontaneous intracranial hypotension (SIH) and subsequently developed sudden cognitive and behavioral changes.

Materials and Methods: The patient initially complained of orthostatic headache, fatigue, and cognitive difficulties. A brain MRI scan revealed characteristic findings, including "sagging brain," diffuse pachimeningeal enhancement, and tonsillar displacement. A possible cervical leak was identified on the spinal cord MRI. The patient received a diagnosis of SIH and underwent blood patching, which successfully alleviated the headache symptoms. However, cognitive impairments persisted, accompanied by behavioral changes such as apathy and disinhibition. The patient scored 24 out of 30 on the baseline Montreal Cognitive Assessment (MoCA) test. Extensive cognitive assessments indicated deficits in attention, executive functions, and episodic memory. FDG-PET brain scan showed reduced metabolism in the prefrontal cortex, caudates, and thalamus bilaterally. SPECT DATscan revealed no abnormal findings. A follow-up brain MRI after one year showed no changes, and the patient's cognitive impairments remained stable.

Results: Both the radiological and clinical data support a diagnosis of frontotemporal syndrome, likely attributed to SIH. The acute onset of symptoms suggests that an underlying neurodegenerative disorder is less probable.

Discussion and conclusions: While cognitive disturbances and alertness alterations are common in SIH1, fully developed frontotemporal syndrome cases are rare in the existing literature2,3. The stretching of the frontotemporal cortex and/or venous stagnation at the confluence of the straight sinus and vein of Galen may contribute to this condition. Although SIH is an uncommon cause and red-flag symptoms like headache may be absent, it should be considered during the diagnostic evaluation of frontotemporal dysfunction, especially in cases with acute

or sub-acute onset. Identifying SIH is crucial as it is one of the few potentially treatable causes of cognitive decline.

## DEMENTIA

### COULD PSYCHIATRIC DISORDERS PREDICT THE EVOLUTION OF SUSPECTED NON-ALZHEIMER'S DISEASE PATHOPHYSIOLOGY (SNAP) PATIENTS INTO ESTABLISHED DEMENTIA?

A. Antonioni[1], E. Raho[1], F. Castellana[1], G. Desina[2], D. Grasso[2], F. Ciccone[3], E. Calò[2], M. Pugliatti[1], G. d'Orsi[4], R. Latino[4]

[1]Neurosciences and Rehabilitation Department, Ferrara University (Ferrara); [2]Diagnosis and Treatment Services and Transfusion Medicine Department, IRCCS Casa Sollievo della Sofferenza (San Giovanni Rotondo-FG); [3]Health Department, IRCCS Casa Sollievo della Sofferenza (San Giovanni Rotondo-FG); [4]Emergency Department, IRCCS Casa Sollievo della Sofferenza (San Giovanni Rotondo-FG)

Objectives: Suspected non-Alzheimer's disease pathophysiology (SNAP) is a condition characterised by an often subtle cognitive decline and, although it resembles Alzheimer's disease (AD) in some respects, it differs from AD in terms of less impairment of verbal episodic memory and the absence of amyloid pathology in CSF and PET. Even if it often has a benign course, numerous cases have been described with an evolution towards established forms of dementia, such as Fronto-Temporal Dementia (FTD) and Lewy Body Disease (LBD). Therefore, it is still complex to predict the evolution of SNAP patients and, consequently, to tailor their multidisciplinary management. Here, we assess whether the presence of neuropsychiatric disorders at the time of SNAP diagnosis can help predict the patient's subsequent evolution.

Materials: 21 SNAP patients underwent a 3-years follow-up.

Method: All patients underwent an extensive neuropsychological evaluation, diagnostic lumbar puncture, brain MRI and FDG-PET at baseline and annually (with the exception of lumbar puncture). Moreover, clinical, demographic, and pharmacological data were collected.

Results: All patients at recruitment presented a clinical condition compatible with mild cognitive decline (MCI). Furthermore, both FDG-PET data (i.e. significant parietal and limbic hypometabolism) and CSF data (i.e. abnormal values for Tau protein and normal for Beta amyloid protein) were consistent with the clinical suspicion of SNAP. Interestingly, 16 patients had a positive history of psychiatric disease: specifically, 8 were depressed, 5 had a generalised anxiety disorder, 2 had a bipolar disorder and 1 had a schizoaffective personality disorder. Of note, after 3 years, among the 5 patients without psychiatric comorbidity, 3 remained stable as MCI and 2 returned to a normal cognitive profile. In contrast, only 4 of the psychiatric patients remained stable, while the other 12 evolved to dementia, namely 8 FTD, 3 LBD and 1 a cortico-basal syndrome, as demonstrated by clinical, neuropsychological and PET data.

Discussion: Although the sample is limited, our data show that the presence of a psychiatric comorbidity at the time of SNAP diagnosis can predict with a good probability an evolution into an established dementia within a relatively small time span. In particular, the risk of evolution towards a form of FTD is very significant, which is consistent with the link between psychiatric disorders and this form of neurodegeneration.

Conclusions: We suggest that psychiatric comorbidity is an unfavourable prognostic factor in patients diagnosed with SNAP, specifically increasing the likelihood of the SNAP patient evolving into an FTD.

### MONOAMINERGIC SYSTEM DEFICIT AS A CONSEQUENCE OF PATHOLOGICAL PROTEIN ACCUMULATION IN THE ALZHEIMER'S DISEASE CONTINUUM

L. Argenti[1], M. Losa[1], L. Lombardo[1], A. Donniaquio[1], F. Massa[1], D. Arnaldi[1,2], S. Morbelli[2,3], B. Orso[1], M. Pardini[1,2]

[1]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa (Genova); [2]IRCCS Ospedale Policlinico S. Martino (Genova); [3]Department of Health Science (DISSAL), University of Genoa (Genova)

Aim: The alteration of monoaminergic systems in Alzheimer's disease (AD) might be a potential target for pharmacological intervention. However, to date which system is the most clinically relevant and how it progresses from the early to the most severe stage of AD is still unclear. Hence, the interaction between the pathological accumulation of misfolded proteins and these diffuse projection systems in the AD continuum is of clinical relevance.

Materials: We included 50 patients with AD (mean age: 72.66 ± 8.03; 68% males) and 42 Healthy Controls (mean age: 70 ± 8.53; 35% males). We acquired brain [18F]FDG-PET images as a marker of neurodegeneration, CSF for β-amyloid42, β-amyloid40 and tau protein quantification, and MMSE as a measure of global cognitive functioning. We divided the AD patients in two groups based on MMSE score (AD Dementia -ADD- <24; MCI-AD ≥24) to study different stages of the disease.

Method: We performed voxel-based analysis between AD vs HC, both in the whole group, then in ADD and MCI-AD groups, separately. Using JuSpace toolbox we explored the correlation between [18F]FDG-PET images and PET maps of dopamine (DAT), serotonin (SERT), noradrenaline (NAT) and choline vesicular (VAChT) transporters cortical distribution. Moreover, we evaluated relative hypometabolism in the main cholinergic nucleus (Meynert nucleus).

Results: In the whole AD group, the distribution of relative cortical hypometabolism was associated with a significant reduction of VAChT availability ($p = 0.018$) only. This association remained significant when exploring the ADD group ($p = 0.006$), but not the MCI-AD one. β-amyloid42 levels and β-amyloid42/40 ratio was

inversely correlated with VAChT in the ADD group (p= 0.003; p = 0.038, respectively), independently from the damage of the Meynert nucleus. No correlation was found in the MCI-AD group.

Discussion: In the ADD phase we showed a significant damage in the cortical regions targeted by the cholinergic system. This provides an explanation of the reduction of the cholinesterase inhibitors efficiency in the dementia phase.

Conclusions: The damage of monoaminergic diffuse projection systems in the AD continuum primarily impacts the cholinergic system, which, at a more advanced stage of the disease, is too impaired to respond to specific neurotransmitter stimulation.

## FRONTOTEMPORAL INVOLVEMENT IN RAPIDLY PROGRESSIVE DEMENTIA DUE TO INTRAVASCULAR LYMPHOMA: A CLINICAL AND NEUROPATHOLOGICAL DESCRIPTION OF FOUR CASES

G. M. Bentivenga[1], S. Baiardi[1], L. Righini[1], A. Ladogana[2], S. Capellari[1], E. Sabattini[3], P. Parchi[1]

[1]Department of Biomedical and Neuromotor Sciences (DiBiNeM), University of Bologna (Bologna); [2]Department of Neuroscience, Istituto Superiore di Sanità (Roma); [3]Haematopathology Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna (Bologna)

Objectives, materials, and methods: Intravascular large B-cell lymphoma (IVLBCL) is an extranodal lymphoma characterized by the selective growth of neoplastic cells within the lumen of blood vessels, representing a rare but potentially treatable cause of rapidly progressive dementia (RPD). Nevertheless, due to its heterogeneous clinical and instrumental presentation, it is often misdiagnosed with more common causes of RPD, e.g., sporadic Creutzfeldt-Jakob disease (sCJD) or vascular dementia. In this study, we retrospectively analyzed the clinical and histopathological data of the only four IVLBCL cases we diagnosed posthumously over 20 years at our prion disease reference center, among over 600 brain samples received as CJD suspects.

Results: Three patients showed a subacute onset, two with neuropsychiatric symptoms (apathy, depression, emotional lability, and behavioral disturbances), and the third with disorientation and alertness fluctuations. The fourth had an acute onset with transient loss of consciousness followed by a delirium-like state. All patients underwent a rapidly progressive decline, sometimes characterized by ictal episodes with altered alertness and/or focal neurological signs, variably diagnosed as newly-onset seizures, TIA, or stroke. The diagnostic blood work, cerebrospinal fluid (CSF) analyses, electroencephalography (EEG), and neuroimaging, yielded non-specific results. In three patients, the presence of generalized periodic sharp/wave complexes at EEG and positive CSF protein 14-3-3 western-blot assay mistakenly supported a CJD diagnosis. Other common misdiagnoses included epilepsy, vascular dementia, and encephalitis. The stored CSF samples of two patients tested negative at prion RT-QuIC, which we performed retrospectively for research purposes. Neuropathological analysis revealed that frontotemporal neocortices were the most affected brain areas in terms of vascular infiltration, neuronal loss and gliosis, and petechial lesions.

Discussion and conclusions Our results confirm the diverse clinical and instrumental presentation of IVLBCL. The findings underscore the need to consider IVLBCL and other potentially treatable conditions in the diagnostic workup of patients with RPD. Specifically, given the therapeutic implications of its misdiagnosis with CJD, we emphasize the utility of prion RT-QuIC as a confirmatory test for accurate antemortem detection of prion diseases. Neuropathological evidence of preferential involvement of frontotemporal neocortices may explain the neuropsychiatric symptoms and cognitive deficits commonly observed and could be thus relevant to reach an early diagnosis. Further research is needed to validate these findings, improve antemortem recognition, and explore therapeutic approaches for IVLBCL.

## CSF LEVELS OF ENDOTHELIN-1, VEGF AND MMP2 WITHIN THE ALZHEIMER'S DISEASE CONTINUUM

F. Bernocchi[1], M. Assogna[1], C. G. Bonomi[1], G. Koch[2], N. B. Mercuri[1], A. Martorana[1], C. Motta[1]

[1]Neurology Unit, Department of System Medicine, "Tor Vergata" University (Roma); [2]Non-Invasive Brain Stimulation Unit, Department of Behavioral and Clinical Neurology, Santa Lucia Foundation IRCCS (Roma)

Objective: Recent evidences highlighted the involvement of vascular dysfunction and neuroinflammation in the pathogenesis of Alzheimer's Disease (AD). A key role is played by the dysfunction of the Neurovascular Unit (NVU), a functional structure composed by vascular/glial cells and neurons, and by the alteration of several vascular factors, such as Vascular Endothelial Growth factor (VEGF) and Endotheiln1 (ET1), both modulated by amyloid (Aβ) oligomers. Other important factors are matrix metalloproteinases (MMPs), among which MMP2 and MMP9, which are involved in the maintenance of the integrity of the blood brain barrier (BBB) and in the clearance of toxic Aβ aggregates. To better understand the role of the NVU and cerebral blood flow (CBF) regulation in the pathogenesis of AD, the aim of this study was to evaluate levels of Endothelin-1, MMP2, MMP9 and VEFG, which are released by astrocytes, in cerebrospinal fluid (CSF) samples of patients classified by the AT(N) system and by ApolipoproteinE genotype (ApoE3 and ApoE4), compared to age-matched control patients (HC).

Methods: We recruited 159 consecutive patients admitted to our memory clinic for cognitive impairment and that underwent lumbar puncture for diagnostic purposes. They all fulfilled NIA-AA diagnostic criteria for AD continuum (ADc). We measured CSF levels of VEGF, ET1, MMP9 and MMP2. Data were compared to those from 24 aged-matched controls.

Results: Our data showed a significative reduction of VEGF (p<003), MMP2 (p=0.005) and MMP9 (p=0.002) in ADc CSF, compared to HC, whereas we didn't find a significative difference of ET1 CSF compared to HC. Patients stratified both by ATN (A+T+ vs A+T-) and by APOE genotype (E3 vs E4) didn't show any significative difference for all the vascular markers. Interestingly, we found a positive correlation between MMP2 and AD related brain burden ($\tau$ = 0.115, p=0.032), measured as p-tau/Aβ42 ratio. The multivariate analysis highlighted a contribution of diabetes mellitus on CSF levels of VEGF, MMP2 and MMP9 (p<0.05).

Discussion: We suggest that the reduction of MMP2, MMP9 and VEGF in CSF in ADc determines the failure of important protective pathways leading to the progression of the disease, probably due to a dysfunction of astrocytes and is a mechanism amyloid-related and the presence of diabetes may worsen the progression of the disease.
Conclusions: Early vascular dysfunction plays an important role in AD pathogenesis and could be the result of a failure of compensatory mechanisms, thus suggesting a possible contribution to AD neurodegeneration.

## THE SUBJECTIVE COGNITIVE DECLINE MISCLASSIFICATION USING COMMONEST SCREENING TESTS

S. Bonarota[1], G. Caruso[1], C. Di Domenico[1], M. Assogna[2], M. Rodini[3], L. Fadda[2], F. Di Lorenzo[3], G. Koch[4], C. Caltagirone[5], M. Bozzali[6], L. Serra[1]

[1]Neuroimaging Laboratory, Fondazione Santa Lucia IRCCS (Roma); [2]Department of Systems Medicine, University of Rome Tor Vergata (Roma); [3]Experimental Neuropsychophysiology Laboratory, Fondazione Santa Lucia IRCCS (Roma); [4]Department of Neuroscience and Rehabilitation, University of Ferrara (Ferrara); [5]Behavioural and Clinical Neurology Laboratory, Fondazione Santa Lucia IRCCS (Roma); [6]Neuroscience Department "Rita Levi Montalcini", University of Turin (Torino)

Objectives: Subjective Cognitive Decline (SCD) refers to self-perceived cognitive decline experienced by individuals without any objective evidence of impairment on standardized neuropsychological tests [1]. Its potential of reflecting a prodromal stage of neurodegenerative disease and a risk factor for future cognitive decline highlights the importance of distinguishing SCD from normal age-related cognitive changes. Aim of the study was to examine the sensitivity, specificity and accuracy of two widely used cognitive screening tests for dementia, the Addenbrooke's Cognitive Examination Revised (ACE-R) [2] and the Mini Mental State Examination (MMSE) [3], in detecting individuals with SCD and differentiating them from those with objective cognitive impairment.

Materials and Methods: 22 healthy subjects (HS), 25 individuals with SCD, 31 Mild Cognitive impairment (MCI), 32 Alzheimer's Disease (AD) patients were recruited. All participants underwent a neuropsychological battery and the Italian version of the ACE-R, which incorporates the MMSE. By subtracting the MMSE score, partial ACE-R scores were also derived and divided into sub-domain scores. One-way ANOVAs were used for between-group comparisons in total MMSE scores, total ACE-R scores, and ACE-R sub-domain scores. Discriminant analyses were performed to examine the ability of ACE-R and MMSE in discriminating SCD from the other groups by sensitivity (Se), specificity (Sp) and accuracy (A) indices.

Results: Statistically significant group differences and a progressive downward trend across groups on ACE-R and MMSE total scores were observed. SCD and HS reported comparable performances. The discriminant analyses showed that AD, MCI patients and HS are correctly classified by total ACE-R (Se=84.4% Sp=15.6% for AD, Se=51.6% Sp=48.4% for MCI; Se=68.2% Sp=31.8% for HS, general A=59.1%), partial ACE-R (Se=78.1 Sp=21.9 for AD, Se=41.9% Sp=58% for MCI; Se=59% Sp=40.9% for HS, general A=52.7%), MMSE (Se=71.9% Sp=28.1% for AD, Se=41.9% Sp=58.1% for MCI, Se=77.3% Sp=22.7% for HS, general A=53.6). SCD individuals are hardly distinguishable from other groups (Se=28% Sp=72% for total and partial ACE-R; Se=25% Sp=76% for MMSE) and showed an opposite trend, resulting misclassified either as HS or MCI by all considered screening tests.

Discussion: Screening tests that are currently used in clinical practice are unable to identify SCD, who are misclassified as HS or MCI.

Conclusion: This study highlights the need to develop new screening tools to identify those SCD individuals seeking for medical interventions. Validation and implementation of accurate screening-tests for the identification of SCD to be used in primary care settings are essential steps for a successful use of future disease modifying treatments.

## CLINICAL FRAILTY MODULATES COGNITIVE PERFORMANCE IN MCI-AD INDEPENDENTLY FROM PTAU LEVELS

G. Bozzo[1], S. Ottaviani[2], F. Massa[1], B. Orso[1], S. Caneva[1], D. Arnaldi[1], L. Argenti[1], E. Biassoni[1], S. Morbelli[3], A. Chincarini[4], A. Nencioni[1], F. Monacelli[1], M. Pardini[1]

[1]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa (Genova); [2]Section of Geriatrics, Department of Internal Medicine and Medical Specialties (DIMI), University of Genoa (Genova); [3]Department of Health Science (DISSAL), University of Genoa (Genova); [4]National Institute of Nuclear Physics (INFN), University of Genoa (Genova)

Introduction: Frailty is a clinical syndrome in which there is increased vulnerability to endogenous and exogenous stressful events. It is associated with an increased risk of adverse health events and severe loss of autonomy. [1] The elderly show extremely heterogeneous (and often unpredictable) responses to stressors and age-related chronic conditions, such as cognitive impairment. This heterogeneity may (at least in part) be explained by differences in resilience (i.e., the body's ability to cope with stressors)[2] and cognitive reserve. [3] We employed a Comprehensive Geriatric Assessment, focusing on the degree of multimorbidity (Cumulative Illness Rating Scale, CIRS) and clinical frailty (CFS; using the Clinical Frailty Scale) to improve our understanding of the extent to which these variables may affect the development and progression of mild cognitive impairment due to Alzheimer's disease (MCI-AD).

Materials and Methods: The population, consisting of 50 subjects with MCI due to AD was evaluated by multidimensional assessment collecting the following data: educational level, functional autonomy in basal and instrumental activities of daily living, number of prescriptions and associated anticholinergic load (ACB score), degree of

multimorbidity (CIRS) and level of clinical frailty (CFS). We then explored the relationship between MMSE at the time of the first visit and the other variables, including P-tau levels in CSF sampling, using Pearson's correlation test.

Results: Univariate analysis, conducted on both the overall sample and the two populations identified by a median split on P-tau, showed a correlation between MMSE and the CFS scale values severity index ($\rho = -0.67$; $p = < 0.001$). The correlation remained significant correcting for total ptau values as evaluated in a linear regression model. Conversely, CIRS severity presented with a borderline correlation with MMSE scores in the whole MCI group and there was no correlation between MMSE and ACB scores.

Discussion: Our analysis show that in MCI due to AD clinical frailty is a predictor of cognitive performance independently from CSF p-tau levels and outperforms other measures of comorbidity assessments. This finding is in line with the notion that frailty, accompanied by cognitive reserve, is an important modulator of phenotypic expression in cognitive impairment.

Conclusion: The evaluation of clinical frailty via the clinical frailty scale can help refine the assessment of the patient with MCI-AD.

## EXTENDED RT-QUIC ANALYSIS OF OLFACTORY SWAB DIAGNOSTIC ACCURACY IN PATIENTS WITH PRION DISORDERS

E. Bronzato[1], E. Fontana[1], C. Pangrazio[1], F. Cazzaniga[2], C. De Luca[2], L. Sacchetto[3], V. Cirielli[4], S. Portaleone[5], S. Castriciano[6], L. Vaianella[7], D. Tiple[7], E. Colaizzo[7], A. Ladogna[7], F. Moda[2], M. Bongianni[1], G. Zanusso[1]

[1]Department of Neuroscience, Biomedicine and Movement Sciences, University of Verona (Verona); [2]Unit of Neurology 5 and Neuropathology, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [3]Surgery, Dentistry, Maternity and Infant Department, University of Verona (Verona); [4]Forensic Medicine, Vicenza Hospital (Vicenza); [5]Department of Health Sciences, Otolaryngology Unit, ASST Santi Paolo e Carlo Hospital, University of Milan (Milano); [6]Copan Italia Spa (Brescia); [7]Department of Neuroscience, Istituto Superiore di Sanità (Roma)

Objectives: Prion disorders are a group of rare, rapidly progressive, and fatal neurodegenerative diseases, which occur in sporadic, genetic, or acquired forms. Recently, real-time quaking-induced conversion (RT-QuIC) assay has been set up for CJD diagnosis. In previous studies we showed that RT-QuIC assay was around 90% sensitive and 100% specific in detecting prion seeds in olfactory mucosa of patients with prion disorders. This level of diagnostic accuracy was comparable to that of CSF and RT-QuIC combination analyses of both OM and CSF samples provided a 100% diagnostic specificity and sensitivity. Still, RT-QuIC accuracy in a large number of patients with prion disorders has never been evaluated.

Materials and methods: Eighty-four patients with definite, probable CJD or with genetic prion disorders and 238 patients with non-prion neurodegenerative disorders were recruited from 2018 to 2022 in Milan, Verona and Rome neurologic clinics. All patients underwent OM swabbing (FloQBrush, Copan, Brescia) at different sites. CSF was also obtained from sixty-six patients with prion disorders. RT-QuIC analysis in OM and CSF was performed using truncated hamster PrP, but at 42°C and 55°C respectively.

Results: We found that RT-QuIC was positive in 69 out of 84 OM of patients with prion disorders and 0/238 with non-prion neurological disorders resulting in a sensitivity of 82.1% %, and a specificity of 100%. Among patients with prion disorders 18 patients underwent OM swabbing only, because lumbar puncture was impracticable and 15 were RT-QuIC positive. CSF was also obtained in 66 patients with prion disorders and 57 were RT-QuIC positive 86% sensitive. Still, when both OM and CSF samples were considered in the same patient the sensitivity of 97%. In genetic cases RT-QuIC sensitivity was 75% lesser than sCJD but depending on PRNP point mutation.

Conclusions: Here we showed that RT-QuIC diagnostic accuracy in OM sampling is 82% and that olfactory swabbing might replace CSF analysis when lumbar puncture is unpracticable. As we previously showed, the RT-QuIC diagnostic accuracy obtained from the combination of both CSF and OM is nearly to 100%. Of course, among "the other tissues" analyzed by RT-QuIC reported in the diagnostic criteria, OM is the best candidate.

## ADAM17 AND NGFR/P75NTR POLYMORPHISMS INTERACT TO INCREASE THE RISK OF SPORADIC ALZHEIMER'S DISEASE

F. Bruno[1], R. Colao[1], T. Serra Cassano[2], E. Papazarro[2], S. Geracitano[2], M. A. Aceto[2], B. M. Greco[2], F. Vozzo[3], S. Mirante[3], D. Arcuri[3], V. Laganà[1], P. Abondio[2], D. Luiselli[2], F. Frangipane[1], G. Puccio[1], S. M. Curcio[1], R. Di Lorenzo[1], A. C. Bruni[1], R. Maletta[1], A. Montesanto[2]

[1]Primary care, Regional Neurogenetic Center (CRN), ASPCZ (Lamezia Terme-CZ); [2]Department of Biology, Ecology and Earth Sciences, University of Calabria (Rende-CS); [3]Department of Medical and Surgical Sciences, University of Catanzaro (Catanzaro)

Introduction: NGFR/p75NTR represents a similar-affinity receptor for all known mammalian neurotrophins - i.e., NGF, BDNF, NT-3, and NT4/5 - and a higher affinity receptor for their immature forms (i.e., proNGF, pro-BDNF) [1]. Moreover, the binding of Ab1-42 to NGFR/p75NTR increases the extracellular levels of Ab1-42, causes neurotoxicity, mediates Ab-induced tau hyperphosphorylation and neurodegeneration (i.e., synaptic disorder and neuronal loss) and increases the expression of another pro-apoptotic neurotrophin receptor, sortilin, via the RhoA pathway, that in turn could interact with NGFR/p75NTR to induce neuronal apoptosis [1]. NGFR/p75NTR could undergo a three-step proteolytic cleavage that could modify its functional properties. During the first step, the extracellular domain (ECD) of NGFR/p75NTR is cleaved by the sheddase ADAM17, generating a membrane bound C-terminal fragment (CTF). Then, CTF undergoes a second cleavage by the PSEN-dependent -secretase, releasing the intracellular domain (ICD) into the cytoplasm [1]. Beyond NGFR/p75NTR, ADAM17 also participates in the proteolysis of several substrates, such as APP, which play a key role in Alzheimer's disease (AD). Preliminary data indicated that both NGFR/p75NTR and ADAM17 could play a key role in the pathogenesis of sporadic AD (sAD) also from a genetic perspective [1, 2]. The general aim of this study was to characterize the interaction between NGFR/p75NTR and ADAM17 Single Nucleotide Polymorphisms (SNPs) and risk of sAD.

Materials and Methods: This case-control association study was conducted in a Southern Italian cohort consisting of 155 AD patients and 139 age- and sex-matched controls. Nineteen NGFR/p75NTR and seven ADAM17 tag-SNPs were selected and genotyped TaqMan SNP genotyping assays. The epistatic and dominant interactions between SNPs were analyzed by log-likelihood ratio test (LRT) using the SNPassoc package for R [3].

Results: SNP-SNP interaction analysis of NGFR/p75NTR and ADAM17 SNPs yielded statistically significant signals in predicting the onset of sAD. In particular, a total of 3 pairs of SNPs reached the significance, among which the pair composed of rs4648975 and rs7078160 within the NGFR7/p75NTR gene yielded the most significant signals ($p<0.001$) in predicting the onset of sAD. Within the NGFR/p75NTR gene, rs4648975 polymorphism also showed a significant interaction with rs4794056 ($p<0.001$). Finally, SNPs rs11466150 within the NGFR/p75NTR gene showed significant evidence of interaction with rs11690078 of ADAM17 gene ($p<0.001$).

Discussion and Conclusion: Our results reveal a new role of NGFR/p75NTR and ADAM17 genes in sAD from a genetic perspective. SNPs-SNPs of some tag-SNPs on these genes should be considered for the genetic screening of sAD.

## BLOOD-BRAIN-BARRIER PERMEABILITY IS ASSOCIATED WITH DIFFERENT NEUROINFLAMMATORY PROFILES IN ALZHEIMER'S DISEASE

M. Bruno[1], C. Bonomi[1], F. Ricci[1], M. Di Donna[1], G. Koch[2], N. Mercuri[3], A. Martorana[1], C. Motta[1]

[1]Memory Clinic, Tor Vergata Policlinic (Roma); [2]Non Invasive Brain Stimulation Unit, Department of Behavioural and Clinical Neurology, Santa Lucia Foundation IRCCS (Roma);[3]Neurology Department, Tor Vergata Policlinic (Roma)

Introduction: In the recent years, inflammation has emerged as a vital player in Alzheimer's disease (AD) pathogenesis [1]. Previous studies have evidenced how also the Blood-Brain Barrier (BBB), as a gateway for immune trafficking, may play a role in disease pathogenesis. Here, we investigated the relationship between BBB permeability, indicated by cerebrospinal fluid (CSF) plasma albumin ratio (Qalb), and CSF indexes of humoral neuroinflammation in a cohort of biologically defined AD patients.

Materials and Methods: 59 consecutive patients with MCI or early AD (MMSE>22) underwent CSF analysis for inflammatory cytokines (IL-1β, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, Il-10, IL-12, IL-13, IL-17, TNFα, IFN-ϒ, GM-CSF, G-CSF). We used a backward stepwise linear regression analysis to explore the potential influence of each cytokine CSF level on QAlb considering age, sex, and APOE as covariates.

Results: CSF data were expressed in terms of mean ± standard deviation. At each step of the backward regression, variables were excluded based on the highest p-value. Eventually, the candidate variables were reduced to 4: IL-4, IL-8, TNF-a, MIP-1. Among AD patients, higher values of IL-4 (β =0.356, 0.005) and IL-8 (β =0.249, 0.05) were associated with higher Qalb values, while MIP-1 (β=-0.274; p=0.032) and TNF-a (β=-0.248; p=0.031) showed a significant negative association. Age was also positively associated with Qalb (β=0.283; p=0.016).

Discussion: Despite the overall integrity of the BBB, its permeability could either influence or be influenced by central neuroinflammation, reflected by CSF cytokine levels. In particular, CSF levels of IL-4 and IL-8, neuroprotective cytokines, were positively associated with BBB permeability, while levels of TNF-a and MIP-1, proinflammatory and chemotactic, were negatively associated with BBB permeability. This is in line with previous studies that showed that patients with a more intact barrier are those with a more prominent neurodegeneration (e.g. higher CSF tau-pathology), that could in turn support a pro-inflammatory pattern. [2]

Conclusions: Higher levels of intrathecal neuroprotective cytokines are correlated with higher BBB permeability, while a tighter BBB is associated with increased proinflammatory activity in the CSF. These results suggest that BBB integrity and neuroinflammation can influence each other in AD, in a likely non-univocal way. More studies are needed to verify the mechanisms behind this interplay.

## THE RELATIONSHIP BETWEEN VISUAL HALLUCINATIONS AND RESTING-STATE EEG SPECTRAL AND FRACTAL FEATURES IN DEMENTIA WITH LEWY BODIES

A. Cagnin[1], C. Porcaro[1], A. Visalli[2], D. Fasolato[1], F. Rossato[1], C. Busse[1], A. Vallesi[1]

[1]Dpt Neurosciences, University of Padova (Padova); [2]IRCCS San Camillo Hospital (Venezia)

Introduction: Recurrent complex visual hallucinations (VH) are one of the core features of Dementia with Lewy Bodies (DLB) [1]. VH have been shown to have high specificity for DLB especially in differential diagnosis with Alzheimer's disease (AD). Previous work has shown that power spectral density (PSD) analysis of resting-state EEG (rs-EEG) shows correlations between some frequency bands (e.g., θ), individual alpha frequency (IAF) and VH. However, new tools that improve early diagnosis and fine-grained symptom-based stratification also within the DLB population with higher sensitivity and specificity are desirable.

Aim: To assess differences of rs-EEG data between hallucinated and non-hallucinated DLB patients using innovative non-linear approaches and compare findings with AD and healthy controls

Methods: We retrospectively analyzed rs-EEG recording (eyes-closed, 19 channels with 10/20 system) of 49 hallucinated DLB patients (DLB-VH+), 39 non-hallucinated DLB (DLB-VH-), 34 AD patients and 20 healthy controls (HC). Groups did not differ for age, sex, gender and education. EEG data were analyzed using a nonlinear method called Higuchi's Fractal Dimension (HFD) [2,3] and the results were compared with a standard linear method based on PSD and IAF. A repeated-measures ANOVA was performed on band values to investigate the GROUP×BAND interaction effect.

Results: Alpha band power was significantly higher for HC than for the other groups (ps < 0.001). One-way ANOVA showed statistical

differences between groups for IAF [F(3,126)=6.026; p<0.001] and HFD [F(3,131)=8.021; p<0.001]. IAF values were significantly lower for the DLB-VH+ (mean: 7.51 Hz±SE: 0.25 Hz) compared to the other groups (AD: 9.04 ± 0.19; HC: 8.71 ± 0.21; DLB-VH-: 8.58 ± 0.26). No differences were observed among other groups. Fractal dimension values were significantly lower for the DLB-VH+ (mean: 1.71±se: 0.02) compared to the other groups (AD: 1.83 ± 0.01; HC: 1.86 ± 0.01; DLB-VH-: 1.80 ± 0.01). No differences were observed among other groups. A comparison of Bayes factors found that differences between DLB-VH- and VH+ were three times more likely to be detected using HFD than the best-performing linear method (i.e., the IAF) and six times more likely than the theta band.

Discussion: rs-EEG differences between DLB with and without VH might be better characterized by fractal dimension analysis than to a more traditional power spectrum approach. HFD is at least 3 times more sensitive than linear analysis. This suggests that less complex brain dynamics at rest, as expressed by the HFD metric, might be associated with the presence of VH.

## RAPIDLY PROGRESSIVE DEMENTIA ASSOCIATED WITH SIAD AND MYOCLONUS

F. Cancellieri, S. Zagaglia, M. Silvestrini, S. Luzzi

Neurological Clinic, Polytechnic University of Marche (Ancona)

Introduction: We describe a man who developed, after a minor head trauma, SIAD, cognitive disturbances and mild myoclonus. Head trauma is a common cause of SIAD with consequent hyponatremia that causes mental confusion, cognitive impairment and myoclonus. However, the temporal profile should prompt the clinician to investigate further explanations. The man we described did not improve after correction of hyponatremia and allowed our team to explore a broader differential diagnosis.

Case report: A 59-year-old man, with no past medical history, came to our attention complaining about a one-month history of progressive cognitive problems. Neurologic examination revealed mild temporo-spatial disorientation, severe psychomotor slowing, working-memory and attentional deficits with fluctuations and tangential speech. Myoclonic movements were present (limbs and perioral region). Blood examinations showed severe hyponatremia, with reduction of blood osmolarity. About one month before he had an episode of loss of consciousness, with consequent head trauma. The clinical history suggested a post-traumatic Syndrome of Inappropriate Antidiuresis (SIAD) and intravenous sodium infusion and tolvaptan were administered. Brain MRI with gadolinium showed normal findings. The patient developed a gradual improvement; sodium level gradually increased and, when stable, he was discharged. One month later, he was admitted to our hospital because he developed the same symptomatology previously described. At the admission, sodium and blood osmolarity levels were normal. 3-T brain MRI with gadolinium, associated with brain FDG-PET, showed findings compatible with encephalitis. Then we found positive CSF antibodies anti-leucine-rich glioma-inactivated 1 (LGI1). The patient was treated with high dose steroid (methylprednisolone 1 g intravenously for 5 days), associated with a cycle of intravenous immunoglobulins (2 g/kg over 5 days). Symptoms remitted completely and the patient was discharged with a steroid taper. The last neurologic follow-up at 6 months showed complete clinical remission.

Discussion: According to clinical symptoms, radiological signs and laboratory results, we made diagnosis of anti-LGI1 encephalitis. Our first diagnosis of post-traumatic SIAD was the most probable in light of the clinical improvement with the correction of hyponatremia and the normal findings of all the other exams performed, but the clinical evolution took us towards a different direction.

Conclusion: This case-report emphasizes that clinical observation of the patient and the temporal profile of clinical signs are a central key of the diagnostic process.

## AN ATYPICAL PHENOTYPE OF VCP MUTATION WITH EPILEPTIC SEIZURES AND BEHAVIOURAL FRONTOTEMPORAL DEMENTIA

V. Carlucci, A. Salvalaggio, D. Fasolato, P. Riguzzi, C. Busse, D. Cecchin, A. Cagnin

Institute of Neuroscience, University of Padua (Padova)

Introduction: Valosin-Containing Protein (VCP) mutations are rare causes of behavioural frontotemporal dementias (bvFTD) with TDP43-immunoreactive inclusions. This gene encodes for an AAA-ATPase involved in protein quality control and clearance. Studies of phenotype-genotype correlations reported a few cases of isolated bvFTD but never with epilepsy among clinical findings.

Aim: To describe clinical and neuroimaging findings of a patients with VCP mutation presenting with epilepsy and isolated bvFTD.

Case summary: A 58 years-old woman came to our attention for a subacute deterioration of general conditions with psychomotor slowness, marked abulia, perseveration and repeated falls with a progressive loss of autonomy occurring in the last few weeks. In the ten months before she presented important behavioural changes (disinhibition, socially inappropriate behaviour, hyperorality), attentive problem, delusions, sleep disturbances, incontinence and the recrudescence of epileptic seizures appeared for the first time 6 years before. Medical history was positive for psychiatric disturbances (eating disorder and recurrent depression). Her mother and aunt had dementia with behavioural changes and epileptic seizures by the age of 70s (mother and aunt). At the admission her neurologic examination showed prominent negative frontal signs (apathy and reduction of global initiative), perseveration and emotional lability with decontextualized crying fits. Neurological examination showed reduced fluency, rare phonemic paraphasias. Neuropsychological assessment showed executive deficits, constructive apraxia and a dysregulation of emotions (FAB 5/18, MoCA p.c. 7,52). The patient underwent brain FDG-PET/MRI that showed a marked hypometabolism of the frontal lobes, and mild hypometabolism of parietal, lateral temporal lobes and anterior caudates, and only a slight frontal lobe atrophy. CSF analysis showed only a slight hyperproteinorrachia (0.50 g/L) and brain barrier damage, with the absence of auto-antibodies. Finally, the genetic test showed a mutation on the N-terminal domain of the VCP gene (R93C), and it was possible to formulate the diagnosis of definite bvFTD. There were not signs of muscles or bone involvement.

Conclusion: VCP gene mutations have been associated with a plethora of diseases including inclusion body myopathy with Paget's disease and frontotemporal dementia. The VCP R93C mutation is the one of the first 4 more frequent VCP mutations, and it has never been associated with epilepsy. Our report confirms the high degree of heterogeneity of VCP disease and the importance of VCP genetic assay even in cases with seizures and frontal lobe syndrome.

## INTRANASAL ESKETAMINE IMPROVES DEPRESSION AND COGNITIVE DEFICITS IN ELDERLY PATIENTS WITH LATE-ONSET RESISTANT DEPRESSION: A CASE SERIES WITH COGNITIVE AND EYE-TRACKING STUDY

V. Carlucci, A. Zangrossi, E. Maschietto, D. Guante Henriquez, C. Busse, G. Nania, G. Pigato, A. Cagnin

Institute of Neuroscience, University of Padua (Padova)

Introduction: Depression is often accompanied by cognitive dysfunctions, representing a clinical challenge for the differential diagnosis and for the selection of patients that could benefit from new generation antidepressant therapy. [1,2] Eye movement analysis may offer a physiological surrogate marker of brain efficiency. [3]

Aim: To analyse long-term changes of psychiatric and cognitive performances and eye movements patterns in a series of 3 patients with late-onset resistant depression undergoing treatment with intranasal Esketamine.

Materials and methods: Patients were studied at baseline and 3- and 6-months interval after Esketamine treatment with neuropsychological tests, psychiatric scales (Hamilton scale and Montgomery-Asberg Depression Rating Scale) and eye tracker (Eyelink 1000 Plus, SR Research) recordings. The session consisted of a free-viewing task with observation of 20 images with emotional and/or neutral content presented on a PC screen for 10 seconds. The following descriptive parameters were extracted: saccades amplitude and velocity, blink rate, duration of fixations and pupillary dilation.

Results: One woman aged 79 years and two men both aged 71 suffering of resistant major depressive disorder were recruited. At baseline depression was moderate-severe with coexisting impairment of cognitive functions (MoCA: score range 18 - 27), with deficits of executive functions, verbal and visual memory, visuoconstructive functions. All three patients underwent intranasal Esketamine treatment up to maximal doses within 4 weeks, in add-on to standard and stable antidepressant therapy. In all patients a significant psychiatric response was documented already after one month, with marked improvement of depression achieved after 6 months, with regression in one patient. Global cognitive improvement was observed at 3 and 6 months in 2 patients (MOCA values changed from 18 to 24 in the 1st and from 21 to 24 in the 2nd) while the third patient with minimal cognitive deficits remained stable (MOCA: 27). The recording of eye movements suggests improvements towards the values of age-matched healthy controls for blink-rate, speed of saccadic movements and pupillary dilation, despite these results were affected by interindividual variability.

Conclusions: Cognitive dysfunction associated with depression represents a clinical challenge for the differential diagnosis with neurodegenerative disease. The stable improvement of depressive symptoms and cognitive deficits, along with neurophysiological markers of whole brain efficiency such as eye movements, makes esketamine effective as add-on therapy even in late-onset older depressed patients.

## RIGHT TEMPORAL VARIANT OF FRONTOTEMPORAL DEMENTIA AND PAGET'S DISEASE OF BONE IN A PATIENT WITH BIOMARKER FEATURES OF ALZHEIMER'S DISEASE

P. Caroppo[1], C. Villa[1], M. Consonni[2], V. Faltracco[2], A. Astengo[1], G. Rossi[1], D. Rossi Sebastiano[3], G. Giaccone[1]

[1]Neurology V, Neuropathology Unit, Foundation IRCCS Carlo Besta Neurological Institute (Milano); [2]ALS Centre, Neuroalgology Unit, Foundation IRCCS Carlo Besta Neurological Institute (Milano); [3]Neurophysiology Unit, Foundation IRCCS Carlo Besta Neurological Institute (Milano)

Aims: To describe the clinical, neuropsychological, neuroradiological and neurophysiological characteristics of a patient with right temporal variant of frontotemporal dementia (rtvFTD) and Paget disease of bone (PDB) with biomarkers features of Alzheimer's disease (AD).

Materials and methods: The patient underwent complete clinical, neuropsychological assessment, brain MRI and FDG-PET, paired-pulse TMS (pp-TMS) examination, CSF and genetic NGS analysis.

Results: The patient presented at the age of 64 behavioural abnormalities with mild disinhibition and impulsivity associated with episodic memory and attention deficits. He had previously been diagnosed with Paget's disease of bone (PDB). Neuropsychological evaluation 2 years after onset showed deficits in verbal memory, attention and executive skills, and impaired social cognition. Also present were naming and verbal fluency deficits, and prosopagnosia. Visuo-spatial, constructional and perceptive abilities were spared. Brain MRI showed asymmetric right temporal atrophy particularly involving the anterior temporal lobe. The neuropsychological battery specific for the right hemisphere, Batteria sul Linguaggio dell'Emisfero Destro - BLED [1], showed a score below the cut-off (28/60). In pp-TMS, Short-interval IntraCortical Inhibition was reduced, and IntraCortical Facilitation increased only for right cortical stimulation, indicating hyperexcitability, according with atrophy. FDG-PET showed severe cortical hypometabolism in lateral temporal cortex predominant at right, associated with moderate hypometabolism in mesial, lateral frontal and inferior parietal regions. Temporo-mesial regions were spared. CSF markers were consistent with AD pathology, showing increased levels of tau and p-tau and decreased Abeta42. Family history was positive for dementia. However, preliminary NGS analysis of AD/FTD genes did not find any clear pathogenic mutations.

Discussion: rtvFTD is a rare clinical phenotype, characterized by early behavioural disorders, prosopagnosia and episodic memory impairment [2]. FTLD-TDP type C pathology, pure or associated with tauopathy has been demonstrated in almost all rtvFTD patients while Alzheimer's disease is very rare [2]. The association

of rtvFTD, PDB and AD biomarkers, as in our patient, is even more unusual as PDB has been associated with FTD in the so-called multisystem proteinopathies, most of them linked to VCP mutations [3]. The co-occurrence of different neurodegenerative pathologies could explain this complex clinical presentation.

Conclusions: We emphasize the importance of deep clinical characterisation and assessment of amyloid status also in patients with relatively clear rtvFTD.

Background and aims: Alzheimer's disease (AD) is a significant global health concern. Currently, three anti-beta amyloid monoclonal antibodies are approved or under examination in U.S. and in Europe for the treatment of patients with early AD. The increasing need for a reliable aetiological diagnosis of AD has led to the grouping of already available and possible future biomarkers into the AT(N) framework. Considering the high cost-effectiveness, availability and low invasiveness of the technique, we aimed at exploring the usefulness of EEG for stratifying cognitively impaired patients within and outside the AD continuum from a hospital-based cohort.

Materials and methods: We conducted a retrospective evaluation of 212 patients referred to the Memory Center of IRCCS San Raffaele Hospital, Milan, Italy. All patients underwent clinical and neuropsychological assessments, along with lumbar puncture and 19-channel EEG. Structural neuroimaging with MRI or CT scans and brain FDG-PET were also performed. Individual alpha frequency (IAF), i.e., the frequency within the extended alpha range (5–13 Hz) showing a power peak in the parieto-occipital power spectrum, was extracted from the EEG of each patient. The cohort was stratified according to the AT(N) classification, and IAF was compared among patient groups. Correlations between IAF, clinical data and CSF biomarkers were also explored.

Results: Sociodemographic and clinical features were similar across groups. IAF was significantly lower in A+ than in A- patients ($p=0.03$) and in FDG-PET-positive (FDG-PET+) than in FDG-PET-negative (FDG-PET–) patients ($p<0.01$). After stratifying patients according to amyloid and FDG-PET status, IAF could distinguish A+/FDG-PET+ patients from A–/FDG-PET+ ($p=0.02$) and A–/FDG-PET– ($p<0.01$) subjects. The comparison between T+ and T– patients and between subjects showing or not brain atrophic changes at structural neuroimaging did not offer significant differences. IAF correlated neither with MMSE, nor with disease duration, nor with CSF biomarkers levels.

Discussion and conclusions: Findings are in line with previous evidence, showing a global slowing of the cortical electrical activity as a consequence of AD. Furthermore, our results suggest that EEG alteration may be directly linked to amyloid rather than tau accumulation, emerging thus as a possible early biomarker of AD. EEG also showed a close relationship with cerebral metabolic status, further supporting its use for the identification of patients in greater need for further diagnostic and therapeutic interventions. In the upcoming era of disease-modifying therapies for AD, EEG is a valid and cost-effective tool for the stratification of cognitively impaired patients.

## LITHIUM INTOXICATION MIMICKING A RAPIDLY PROGRESSIVE DEMENTIA: CLUES INTO AN IMMUNOMEDIATED ETIOLOGY

G. Cellante, F. Bax, A. Cella, G. Gigli, M. Valente

Clinical Neurology Unit, University of Udine, Medical School (Udine)

Objectives: To present a case of lithium intoxication mimicking a rapidly progressive dementia.

Material: A 68-year-old man with a past medical history of bipolar disorder on chronic lithium therapy and moderate chronic renal failure was admitted due to alterations of his level of consciousness and visual hallucinations started 20 days before. Glasgow Coma Scale upon admission was 10.

Methods: Case report.

Results: Baseline routine blood tests excluded underlying systemic infections, toxic and metabolic causes. Lithium serum concentration was mildly elevated (1.56 mmol/L [range 0.50-1.50]). Electrocardiogram and brain magnetic resonance imaging showed no significant abnormalities and an electroencephalogram (EEG) performed on day 12 showed non-specific encephalopathic signs. Cerebrospinal fluid (CSF) routine analysis including DNA testing for common viral, bacterial, and fungal pathogens did not reveal abnormalities, except for a non-specific mild increase in protein levels. Most serum and CSF cytokines were elevated, except for serum interferon-gamma (IFN-gamma) and IL-17A, and for CSF IL-10, INF-gamma and IL-17A. Lithium was withdrawn and both the patient's neurological state and EEG started gradually to improve.

Discussion: This case highlights the lack of a reliable parameter to support the diagnosis of lithium neurotoxicity. The discrepancy between mildly increased lithium levels and the severe neurological presentation could be partly explained by the delayed lithium elimination from brain parenchyma when compared to plasma, which can be further increased by concomitant renal failure as in the present case. We then provide evidence for a potential role of an immune mediated response in the central nervous system driving this clinical manifestation. In fact, lithium has differential effects on immune cells lines, as it increases granulocytes number and activity, while inhibiting T-cells production. The only non-elevated cytokines in both in serum and CSF were IFN-gamma and IL-17 which are known to be associated with CD4+ helper, CD8+

cytotoxic and Th17 cells but not with granulocytes, suggesting that this immune signature could be driven by lithium itself.

Conclusion: Lithium-induced neurotoxicity can be challenging to recognize due to the lack of specific tests. Its diagnosis is currently based on the exclusion of other causes of neurological impairment and on symptoms regression after therapy discontinuation. This case supports the need for a more reliable laboratory parameter to help detect this condition which can be reversible if promptly recognised, avoiding the development of permanent neurological damages. Finally, we provide clues into the possible role of intrathecal cytokines release in its pathophysiology.

Objective: Orexin-A (OXA) determination in cerebrospinal fluid (CSF) in neurodegenerative dementias (NDs) is an invasive technique and of limited utility when not associated with other biomarkers. The main aim of this study is to evaluate OXA in different biological fluids, in particular serum, in patients affected by several NDs. The secondary aim is to evaluate OXA concentration compared to other neurodegeneration-associated peptides, in particular serum neurofilament light chain (NFL).

Materials: Patients affected by several NDs were enrolled at IRCCS Istituto Auxologico Italiano, Departments of Neurology of Milan and Piancavallo. A group of patients with no evidence of NDs served as controls.

Methods: Both patients and controls underwent OXA determination in CSF and serum (ELISA). Other neurodegeneration-associated peptides measured were: serum NFL (Simoa), CSF total-tau (t-tau, ELISA), CSF phospho-tau (p-tau, ELISA), CSF Amyloid beta 1-40 (Abeta 1-40) and Amyloid beta 1-42 (Abeta 1-42, ELISA).

Results: Sample size was the following: 10 Alzheimer's Disease patients (pts), 19 bv Fronto-Temporal dementia pts, 20 Normotensive Hydrocephalus patients and 20 controls. We found a positive correlation between OXA levels in CSF and blood in the whole group of subjects (ND plus controls; Pearson correlation coefficient CC= 0,32, p=0,026). Mean OXA concentration in CSF was significantly reduced in patients with NDs compared to controls (p=0,04). We also found an inverse correlation between OXA and NFL in ND group (CC= -0,37, p=0,04).

Discussion: Despite the small sample size, combining NFL and OXA measures in serum we found some evidence of a link between neurodegeneration progression and orexin system dysregulation in a non-invasive and cost-effective way. Furthermore, the positive correlation between OXA levels in CSF and blood both in ND and control groups could pave the way to peripheral OXA dosage in neurodegenerative dementias.

Conclusion: OXA level in different biological fluids may represent a biomarker of degeneration in ND, especially when correlated to NFL.

HTT is a gene involved in axon trafficking. It contains a key region of CAG repeats which is responsible, when expanded beyond 39 repeats, of Huntington's disease (HD). CAG expansions ranging from 27 to 35 repeats are termed as intermediate alleles (IAs)[1]. Several studies suggest an association between HTT and AD and we previously showed that IA increase the risk of progression from SCD to MCI [2]. In the present work we aim to explore the association between CAG repeats and the concentration of AD CSF biomarkers and plasma neurofilament light chain (NfL). Ninety-six patients (36 SCD and 60 MCI) underwent blood collection

for measurement of plasma NfL concentration and HTT genotype analysis, CSF collection for Aβ42, Aβ42/Aβ40, total-tau (t-tau) and phosphorylated-tau (p-tau) measurement. They were rated according to the A/T(N) system[3] and classified AP+ when A+ was associated with either T+ or N+, or AP- when they were rated as A- (regardless of T and N classification), or as A+/T-/N. There were no significant correlations between the number of CAG repeats and any CSF AD biomarkers. Nevertheless, in the AP+ group, NfL showed a non-linear distribution in relation to HTT CAG repeats. A quadratic model best fits the relationship between HTT length and NfL (F [2, 34]=5.45, p=0.009, adj.R2=0.243). The relationship was described by the equation: y= -17.86x^2+0.39x+222.61. As there were only four IA carriers in the ATN+ group, for the further analysis we focused on patients in the AI- group. To ascertain that CAG repeats length was independent from other confounding factors, we performed a backward linear regression analysis. We considered plasma NfL as the dependent variable. Age at baseline, age at onset, APOE ε4+, Aβ42, Aβ42/ Aβ40 ratio, t-tau, p-tau and HTT were included as covariates. The final model was significant (F [1,27]=5.18, p=0.031, adj.R2 =0.161) and included only HTT (B = -1.42 [95%C.I. = -2.71: - 0.14, p=0.031) as the significant variable. Several reports showed that increasing repeats length below the disease threshold in HTT confers advantageous changes enhancing the function of HTT, stabilizing the interaction with the brain-derived neurotrophic factor (BDFN). This positive effect seems to decrease in the IA range. In line with this evidence, our data suggest that a higher number of CAG repeats, below the IA threshold, may confer a sort of protection against neurodegeneration associated with Alzheimer's disease.

## FREQUENCY AND ASSOCIATED FACTORS OF SCD IN ITALIAN MEMORY CLINICS: THE PRECLINICAL COGNITIVE IMPAIRMENT STUDY IN THE ELDERLY (PRECISE)

F. D'Antonio[1], R. Baschi[2], V. Boccardi[3], L. Di Giorgi[2], E. Rubino[2], G. Bruno[1], C. Guariglia[2], P. Mecocci[4], R. Monastero[2]

[1]Human Neuroscience, Sapienza University of Rome (Roma); [2]Department of Biomedicine, Neuroscience and Advanced Diagnostics (BiND), University of Palermo (Palermo); [3]Institute of Gerontology and Geriatrics, Department of Medicine and Surgery, University of Perugia (Perugia); [4]Psychology, Sapienza University of Rome (Roma)

Background and objectives: Subjective cognitive decline (SCD) is a condition characterised by the subjective reporting of a deterioration in cognitive abilities, which is not then confirmed by formal cognitive testing. The prevalence of SCD in studies is about 25%, but prevalence estimates vary widely between studies (1). To assess the frequency and clinical factors of SCD in a large hospital cohort of non-demented elderly subjects.

Methods: The Preclinical Cognitive Impairment Study in the Elderly (PreCISE), is a multicentre study on SCD involving three memory clinics located in central and southern Italy. SCD was diagnosed according to the criteria of Jessen et al. (2). Mild Cognitive Impairment (MCI) was diagnosed according to the modified criteria of Petersen et al. (3).

Results: From a total of 1,675 subjects consecutively evaluated over a 5-year period in the three memory clinics, after exclusion of subjects with dementia, low MMSE and parkinsonism/psychosis, 1,080 subjects without dementia were included. Of these, 195 (11.6%) were controls (subjects without SCD and MCI; 47.7% men; mean age 66.3 ± 9.6 years), 269 (16.1%) were subjects with SCD (69.1% men; mean age 65.9 ± 8.7 years) and 616 (36.8%) subjects with MCI (55.2% men; mean age 70.9 ± 8.5 years). Comparing controls and MCI with SCD, the latter group was statistically more frequent in women than in men (p .0001 for both comparisons). In contrast, education was statistically lower in the MCI group than in controls and the SCD group (p .0001 for both comparisons). Similar values were found between controls and SCD in the Montreal Objective Cognitive Assessment, the Geriatric Depression Scale, the number of instrumental ADL lost and the Unified Parkinson's Disease Rating Scale-part III (p 0.1 for all comparisons). In contrast, subjects with SCD and MCI had a higher total burden of neuropsychiatric symptoms (Neuropsychiatric Inventory, total score) than controls (p .0001 for both comparisons).

Conclusions: The frequency of SCD in the PreCISE study was over 15%. SCD appears to be more frequent in women than in controls and MCI. Compared to controls, SCD is associated with a higher burden of neuropsychiatric symptoms, but no differences in overall cognition.

## LANGUAGE VARIANT OF ALZHEIMER'S DISEASE. A TWO CASE SERIES

R. De Rosa[1], A. Di Cecca[2], F. Della Pia[1], S. De Marco[3], M. Migliaccio[2], M. Spisto[4], M. Tedeschi[3], C. Criscuolo[3], E. Salvatore[3]

[1]Department of Neurosciences, Reproductive and Odontostomatological Sciences. University of Naples Federico II (Napoli); [2]IRCCS SDN Synlab, University of Naples (Napoli); [3]CDCD-Neurology, University of Naples (Napoli); [4]Department of Psychology, University of Campania Luigi Vanvitelli (Caserta)

Objectives: Alzheimer's disease (AD) is the most common age-related dementia, and it usually presents with episodic memory impairment at onset. Presenile and atypical forms are described in about 15% of the cases and despite they are increasingly recognized, no universally accepted classification of the phenotypic variants has been established.

Differential diagnosis of atypical forms may be tricky. Here we present our case series of two AD language variants (lAD).

Materials and Methods: We used neuro-psychological profile to assess cognition, neuroimaging tools to detect neurodegeneration, amyloid tracer PET (AMY-PET) and/or tau protein, amyloid-β 40– 42 (Aβ40-42) and Aβ42/Aβ40 in cerebrospinal fluid (CSF), for identify pathology biomarkers.

Results: GM is a 74 years-old male that presented at our Clinic with a 4 years history of dysphonia and 2 years of language fluency reduction and bradyphrenia. Language assessment was likely compatible with the agrammatic non-fluent of primary progressive aphasia (PNFA), mimiking frontotemporal dementia language variant (lvFTD). CSF results allowed us to make a diagnosis of lAD. Phosphorylated tau protein was 66,7 pg/ml; Aβ1-40 was 595 pg/ml; Aβ1-42/Aβ-20 was 0,046. AMY-PET was positive for amyloid plaques. RG is 69 years-old male, who had an onset characterized by anomies which quickly evolved into logopenic aphasia. At neuro-psychological profile semantic and phonological fluency were compromised. 5 years after the onset verbal and visuo-spatial memory were impaired. AMY-PET was positive for amyloid plaques. lAD represents less than 1% of our cases of atypical AD.

Discussion: The differential diagnosis of lAD with others neurodegenerative disease is possible when at least one biomarker of in vivo AD pathology is positive: a CSF profile consisting of decreased Aβ40 together with increased total tau (T-tau) or 181-phosphorylated tau (P-tau) concentrations, or presence of amyloid plaques detected with AMY-PET. Despite the initial symptoms leaded the diagnosis towards other pathologies, the use of CSF biomarkers and PET allowed us a correct diagnosis.

Conclusions: Language disorders may be difficult to classify at onset. Our cases show that CSF biomarkers may be necessary to make a correct diagnosis.

## POSTERIOR CORTICAL ATROPHY VARIANT OF ALZHEIMER'S DISEASE PHEONOTYPES. A SIX CASES SERIES

F. Della Pia[1], A. Di Cecca[1], R. De Rosa[1], S. De Marco[2], M. Migliaccio[3], M. Spisto[4], M. Tedeschi[1], C. Criscuolo[2], E. Salvatore[2]

[1]Department of Neurosciences, Reproductive and Odontostomatological Sciences, Federico II University Hospital (Napoli); [2]Centro Demenze e Disturbi Cognitivi (CDCD), Neurology, Federico II University Hospital (Napoli); [3]IRCCS SDN Synlab (Napoli); [4]Department of Psychology, University of Campania "Luigi Vanvitelli" (Caserta)

Aims: Alzheimer's disease (AD) starts in the seventh decade of life or later, even if early-onset AD (EOAD at age of 64 or younger) is described in about 15% of the cases. EOAD has a more aggressive course and roughly 25% of subjects shows an atypical clinical onset with preserved episodic memory but with focal cortical symptoms like apraxia, visual, executive or language dysfunctions. Visuospatial variant, also called posterior cortical atrophy (PCA), starts typically with the loss of visual and complex visuospatial functions. Diagnosis is challenging due to the wide range of symptoms at onset and the multiple underling pathologies. Neurological and neuropsychological examination, neuroimaging and pathology biomarkers are important for diagnosis. Here, we describe our case series of 6 patients with PCA and in vivo biomarker positivity for Aβ deposition, with various clinical atypical aspects at onset.

Materials & Methods: We conducted a retrospective study of patients incoming in our clinic between January 21 and December 22, in order to characterize AD visuospatial variants with different onset and underling pathologies. Atypical and EOAD patients underwent neurological and neuropsychological evaluation, assessment of neurodegeneration by brain MRI and 18FDG PET and assessment of pathology by amyloid tracer PET and/or cerebrospinal fluid (CSF) biomarkers.

Results: PCA was identified in 40% of our atypical AD patients. Two of them had acalculia as first symptom, then followed by alexia, agraphia, and difficulty with perception of distance in the first patient, while memory disfunction appeared soon after in the second. A third patient had memory impairment and acalculia at onset followed by unilateral mild extrapyramidal symptoms, agraphia, alexia and digital agnosia like a PCA-Corticobasal degeneration phenotype. The fourth patient had deficits of praxic and numerical abilities at onset followed by spatial disorientation and digital agnosia, while the fifth patienthad memory impairment and anomia at onset and subsequently she developed Gerstman Syndrome The last patient had neuropsychiatric onset with hallucination and subsequently acalculia, praxic and memory disfunctions, and extrapyramidal signs like a PCA-Lewy body dementia phenotype.

Discussion and Conclusions: Diagnosis of PCA is challenging, due to different onset and pathologies that can underlie this syndrome. Most of our patients presented numerical deficits at onset as the only common feature, among a wide range of symptoms and they were all EOAD. Neuropsychiatric symptoms were prominent only in one patient. Our data confirm that PCA spectrum is wide, so neuroradiological imaging and CSF biomarker are crucial for diagnosis.

## DOES COVID-19 INFECTION REVEAL OLIGOSYMPTOMATIC DEMENTIA?

R. Di Leo[1], G. Ricciardo Rizzo[1], E. Cracco[2], C. Palestini[1], A. Tonon[1], M. Brocca[1], R. L'Erario[1]

[1]Unit of Neurology, Saints John and Paul Hospital, AULSS3 Serenissima (Venezia); [2]Nuclear Medicine Service, Angelo's Hospital, AULSS3 Serenissima (Mestre-VE)

We report the case of a 62-year-old man, who was referred to the ER for an episode of loss of consciousness followed by persistent psychomotor slowing down and agitation. Two weeks before he experienced COVID-19 infection. In ER were performed TC scan and MRI with gadolinium that did not show any DWI lesions and showed two hemosiderin microbleeds in the contest of diffuse subcortical white matter lesions. EEG showed diffuse right fronto-temporal slowing. In the cerebrospinal fluid were high protein levels; no cellularity, no oligoclonal bands, no neurotropic viruses' infection signs, no onconeural or autoimmune encephalitis antibodies were detected. In the beginning he was treated with iv Ig 0.4/kg for V days. Neuroleptic treatment and VPA for behavioural symptoms were started. Total body CT scan and total body PET scan were unremarkable. Since few months before, relatives noted some behavioural symptoms: the patient was repetitive and anhedonic. Beta2-amyloid,

TAU, p-TAU levels were normal; RT-QuIC for prion disease was negative. PET-FDG showed hypometabolism in the fronto-lateral and in the fronto-parietal regions bilaterally. Genetic panel for inherited dementia did not show any pathogenetic mutations. During hospitalisation frontal behavioural symptoms persisted. The first neuro-psychological examination showed FAB and trail making B measures compromised. One year later neuro-psychological measures improve except for slight working memory deficits and behavioural symptoms improved. Our case report may suggest that covid-19 infection can worse a slight pre-existing cognitive decline through superimposed transient delirium.

## A CASE OF LEWY BODIES DEMENTIA-ALZHEIMER'S DISEASE TYPE CO-PATHOLOGY ASSOCIATED WITH GBA MUTATION

S. Dominici[1], A. Luca[2], G. Mostile[2], C. Cicero[2], G. Donzuso[2], A. Nicoletti[1], M. Zappia[1]

[1]Department "G.F. Ingrassia", Section of Neurosciences, University of Catania (Catania); [2]Department "G.F. Ingrassia", Section of Neurosciences, University-Hospital "Policlinico-San Marco" (Catania)

Introduction: Glucocerebrosidase (GBA) gene encodes for a lysosomal enzyme involved in the degradation of the complex sphingolipid glucosylceramide. Heterozygous GBA variants lead to a partial enzymatic loss of function, associated with a 5-fold increased risk of developing parkinsonism with early and rapidly progressive cognitive decline. In this report, we describe the case of a patient with GBA variant, dementia with parkinsonism and amyloidopathy.

Case description: A 77 years old man presented since 4 years frequent episodes of time and space disorientation and "mental confusion" with fluctuating course. In the last year, he experienced irritability with verbal aggressivity, unjustified fears and complex visual hallucinations (i.e. people, animals…). Moreover, sleep vocalisation and dream enactment were referred. He take sodium valproate, 600 mg/die, and promazine, 20 mg/die, interrupted because he manifested marked psychomotor slowing, tremor and progressive loss of autonomy. He presented altered mental status with fluctuating course, global aphasia with mutism, difficulty in maintaining upright position, akinetic-rigid parkinsonism, bilateral superior arms myoclonic-like movements, bilateral palm-chin reflex and grasping. At the blood tests, low serum levels of transferrin were detected. Electroencephalogram showed parieto-occipital theta rhythm and presence of sub-continuous diffuse sequences of delta rhythm with triphasic morphology. Brain MRI showed cortical and subcortical atrophy. Positron emission tomography with fluorodeoxyglucose (18F-FDG) revealed diffuse hypometabolism, in particular at the frontal regions. At the cerebrospinal fluid examination, a high level of protein (96.8 mg/dL, n.v. 20-45), IgG (12.3 mg/dL, n.v. 0-3.4), intrathecal synthesis (5.35), hyperphosphorylated tau (73.8 pg/mL, n.v. <56.5), total tau (552 pg/mL, n.v. <404) and low level of β-amiloid (Aβ1-40 3089 pg/mL, Aβ1-42 171 pg/mL, n.v. >599, Aβ1-40/Aβ1-42 0.055, n.v. >0.069) protein, were found. The research of GBA gene variants through Dried Blood Spot (DBS) analysis revealed the presence of the heterozygous mutation c.1224 G>A.

Conclusion: To the best of our knowledge, this is the first case of GBA gene heterozygous mutation presenting as a Lewy Body Parkinsonism and Alzheimer's Disease-type co-pathology.

## TMS-EEG BIOMARKERS OF MILD COGNITIVE IMPAIRMENT DUE TO ALZHEIMER'S AND PARKINSON'S DISEASES

F. Ferreri[1], F. Berti[1], C. Porcaro[1], A. Cagnin[1], R. Biundo[1], V. D'onofrio[1], P. Rossini[2], A. Antonini[1], M. Corbetta[1]

[1]Department of Neuroscience, University of Padua (Padova); [2]Department of Neuroscience, San Raffaele (Roma)

Background: Transcranial magnetic stimulation (protocols have demonstrated analytical validity in discriminating different forms of MCI, while the role of navigated transcranial magnetic stimulation (in coregistration with electroencephalogram (i e the TMS EEG technique, is still unknown in this field.

Objective: To investigate neurophysiological hallmarks of sensorimotor cortex function in MCI to determine whether the sensorimotor network shows peculiar alterations in different type of MCI.

Methods: We studied several TMS EEG parameters of the sensorimotor cortex in a group of 30 healthy subjects and 30 MCI subjects, including MCI Alzheimer's disease (MCI AD) and MCI Parkinson's Disease (MCI PD)

Results: MCI subjects showed reduced motor cortex (M 1 excitability and disrupted EEG synchronization (decreased intertrial coherence ITC) in alpha, beta and gamma frequency bands compared to Controls (Ferreri et al 2021 The degree of alteration in M 1 excitability and alpha ITC was comparable between MCI AD and MCI PD Importantly, gamma ITC impairment in the stimulated M 1 was greater in MCI AD than MCI PD, while beta ITC showed an opposite trend

Conclusions: Specific cortical changes reflecting deficit of synchronization within the cortico basal ganglia thalamic cortical loop in MCI may reflect pathological processes underlying different type of neurodegeneration.

– F. Ferreri, A. Guerra, L. Vollero, et al. TMS-EEG Biomarkers of Amnestic Mild Cognitive Impairment Due to Alzheimer's Disease: A Proof-of-Concept Six Years Prospective Study. Front Aging Neurosci. (2021);13:737281

## THE DEGENERATION OF LOCUS COERULEUS OCCURRING DURING OF ALZHEIMER'S DISEASE: A NEUROIMAGING FOLLOW-UP STUDY

A. Galgani[1], F. Lombardo[2], N. Martini[2], F. Frijia[2], S. De Cori[2], G. Tognoni[3], G. Siciliano[3], F. Giorgi[1]

[1]Department of Translational Research and of New Surgical and Medical Technologies, University of Pisa (Pisa); [2]Department of Radiology, Fondazione G. Monasterio (Pisa); [3]Department of Clinical and Experimental Medicine, University of Pisa (Pisa)

Objective: To describe the degeneration of the noradrenergic nucleus Locus Coeruleus occurring during Alzheimer's Disease progression in a group of cognitively impaired patients.

Material and methods: A sub-group of patients belonging to a wider population (N=163) previously submitted to a baseline Locus

Coeruleus MRI, underwent a follow-up assessment after 2.5 years. The integrity of the Locus Coeruleus was evaluated profiting from an already published and standardized template-based approach, and it was expressed through the intensity parameter Locus Coeruleus Contrast Ratio (LCCR) and the volumetric one Locus Coeruleus number of voxels (LCVOX).

Results: The final population which completed the neuroimaging follow-up counted 58 subjects. Forty-six of them had a baseline diagnosis of Mild Cognitive Impairment (MCI), while the other 12 were Alzheimer's Disease Demented patients (ADD). At the end of the follow-up, 19 MCI had converted to dementia (cMCI), while 27 remained stable (ncMCI). LCCR was significantly lower in patients when compared to healthy controls, at the baseline assessment. At the follow-up, a global reduction of LCCR and LCVOX was detected in the whole group ($p<0.001$). Such a reduction was particularly significant in the MCI group and was driven by the cMCI, which had converted to ADD during the follow-up. At baseline, LC parameters were not significantly different between ncMCI and cMCI, while at the follow-up assessment values of the former group were higher than those of the latter one, both in terms of LCCR ($p=0.037$) and LCVOX ($p=0.008$). The percentual reduction of LC volume was significantly higher in cMCI than in ncMCI (67% vs 33%, respectively – $p= 0.039$), and directly correlated with MMSE worsening (Rho=0.277, $p=0.043$).

Discussion: The Locus Coeruleus is the first brain structure involved in Alzheimer's pathology [1] and suffers from a marked degeneration already at the clinical onset of the disease [2]. However, pathological studies show that this nucleus undergoes progressive damage across all the Braak stages [3], with the most severe disruption occurring at the transition from Braak stage III/IV to V/VI [2], which clinically might correspond to the conversion from MCI to dementia. We report, for the first time, this phenomenon in vivo. In our patients, the Locus Coeruleus showed a significant reduction in signal intensity and volume shrinkage that reached their maximum in the group of cMCI, i.e., those who passed from the MCI phase to dementia.

## RIGHT TEMPORAL VARIANT FRONTOTEMPORAL DEMENTIA: A MULTIMODAL MRI ANALYSIS OF A NEW EMERGING SYNDROME

C. Gallingani[1], C. Carbone[1], D. Salvatori[1], M. Tondelli[2], R. Bedin[3], G. Vinceti[3], A. Chiari[3], G. Zamboni[1]

[1]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia (Modena); [2]Primary Care Department, AUSL Modena (Modena); [3]Neurology Unit, Azienda Ospedaliero Universitaria di Modena (Modena)

Introduction: Right temporal variant frontotemporal dementia (rtvFTD) is emerging as a new entity among the FTD-spectrum, characterized by a predominant neurodegeneration of the right anterior temporal lobe (rATL) and a peculiar clinical presentation, involving face and emotions recognition deficits, behavioral features, memory loss, and naming difficulties. Clinical detection is challenging, since rtvFTD shares features with both the behavioral variant FTD (bvFTD) and the semantic variant primary progressive aphasia (svPPA), and there is no consensus yet on its designation and characterization. Although rATL neurodegeneration is a hallmark of this syndrome, only a few studies investigated patterns of grey matter (GM) atrophy. Even less is known about white matter (WM) involvement. We conducted a preliminary study on the rtvFTD neuroimaging features in a small sample of patients using multimodal magnetic resonance imaging (MRI).

Methods: We compared rtvFTD ($n = 3$) and svPPA ($n = 3$) patients with a group of healthy controls ($n = 27$) in GM volume using voxel-based morphometry (VBM) and WM microstructural integrity using tract-based spatial statistics (TBSS). Age and disease duration were considered as covariates of no interest.

Results: We found that svPPA patients showed GM atrophy on the left temporal structures relative to healthy controls. RtvFTD patients, instead, showed not only GM atrophy in the right frontal and temporal structures, but also in the insula bilaterally, and in the temporal and orbitofrontal cortices of the left side. Direct comparison showed that rtvFTD were more atrophic than svPPA patients in the temporal and frontal regions bilaterally, more so on the right hemisphere. TBSS analysis showed that rtvFTD patients had less WM integrity than controls in the corpus callosum and the right inferior fronto-occipital, inferior longitudinal, and uncinate fasciculi, while svPPA patients had decreased WM integrity in the corpus callosum and the left inferior fronto-occipital fasciculus.

Conclusions: In our study we found that rtvFTD patients present greater atrophy compared to svPPA patients both in the right and left hemisphere, independently of disease duration. This suggests that rtvPPA and svPPA do not mirror each other in GM loss, and that a neurodegenerative process starting in the right hemisphere must be more widespread to become clinically evident. We also first document that rtvFTD patients present WM disruption in fasciculi which have been implicated in face recognition, emotion processing, and language functions, in line with the peculiar clinical features of this syndrome.

Objectives: Semantic behavioral variant of frontotemporal dementia (sbvFTD) is a recently recognized entity [1] presenting with specific behavioral and semantic derangements associated with predominant atrophy of right anterior temporal lobe. Our aim was to evaluate clinical, neuropsychological and imaging features of an incident cohort of sbvFTD patients compared to both semantic variant primary progressive aphasia (svPPA) and behavioral variant FTD (bvFTD) patients.

Materials: Fifteen sbvFTD patients were enrolled between June 2017 and January 2023, along with 63 bvFTD and 25 svPPA patients. 40 age- and sex-matched healthy controls were also included. Patients underwent clinical and cognitive evaluations, as well as 3D T1-weighted MRI on a 3 Tesla scanner. Clinical history and emerging symptoms of sbvFTD patients were recorded, based on review of clinical charts.

Methods: Grey matter atrophy was investigated at a whole-brain level using voxel-based morphometry (VBM). Clinical, cognitive and MRI features were compared between groups using ANOVA models corrected for multiple comparisons.

Results: Age at onset and disease duration were comparable among patient groups (p=0.525, p=0.98). Three sbvFTD patients were mutated (n=1 C9orf72, N=1 MAPT, N=1 GRN). 66.7% sbvFTD patients developed person-specific semantic knowledge loss and words/objects semantic loss early in the disease course; 60% presented complex compulsions and rigid thought process; 46.7% developed apathy/inertia. Compared to other groups, bvFTD patients scored higher at CDR-SB (p=0.038), while sbvFTD patients had lower results at an emotion recognition task part of the CATS battery compared to other groups (p=0.025). VBM showed a pattern of prevalent atrophy in the right temporal pole in sbvFTD patients, which was almost specular to the pattern of atrophy of svPPA patients, predominantly left-sided. However, sbvFTD patients also presented a cluster of bilateral orbitofrontal atrophy, which was absent in svPPA. bvFTD patients had a more widespread and bilateral pattern of atrophy in fronto-temporal and parietal regions.

Discussion: We demonstrate that sbvFTD is not merely a right-variant of svPPA, but rather a complex and possibly more extensive disease. The multimodal semantic loss associated with rigidity, compulsiveness and apathy, along with the temporo-frontal pattern of atrophy points towards a disease that unfolds towards frontal networks, which are generally preserved in svPPA.

Conclusions: sbvFTD is a novel and insidious entity that diverges from other forms of FTD. Clinicians should be prompt to recognize early signs of this variant to provide a timely and accurate diagnosis. Funding: European Research Council (StG-2016_714388_NeuroTRACK); Foundation Research on Alzheimer Disease.

## PLASMA P-TAU181 AS A PROMISING NON-INVASIVE BIOMARKER OF ALZHEIMER'S DISEASE PATHOLOGY IN SUBJECTIVE COGNITIVE DECLINE AND MILD COGNITIVE IMPAIRMENT

G. Giacomucci[1], S. Mazzeo[1], S. Bagnoli[1], A. Ingannato[1], S. Padiglioni[2], G. Galdo[1], C. Crucitti[1], F. Emiliani[1], V. Moschini[3], C. Morinelli[3], S. Sorbi[1], V. Bessi[1], B. Nacmias[1]

[1]Department of Neuroscience, Psychology, Drug Research and Child Health, University of Florence (Firenze); [2]Research and Innovation Centre for Dementia-CRIDEM, AOU Careggi (Firenze);[3]Neurology, Department of Neuromusculoskeletal and Sense Organs, AOU Careggi (Firenze)

One of the greatest challenges in Alzheimer's Disease (AD) is the discovery of non-invasive, sensitive and specific biomarkers, which might be useful in the early stages of the disease, as Subjective Cognitive Decline (SCD) might be [1]. Plasma phosphorylated tau (p-tau) 181 is becoming increasingly notable in prodromal stages of AD, as a valuable marker for tauopathy, one of the core features of AD [2]. The aim of this study is to investigate the role of plasma p-tau181 as a potential biomarker for AD pathology in early stages of the disease.

Materials and methods: We included 40 SCD, 38 Mild Cognitive Impairment (MCI) and 16 AD demented (AD-d) patients, who underwent clinical evaluation, neuropsychological assessment, Apolipoprotein E (APOE) genotyping, plasma p-tau181 analysis with SiMoA assay. Twenty-six SCD, 32 MCI and 14 AD-d patients underwent CSF biomarkers analysis (Aβ1-42, Aβ1-42/1-40, p-tau, t-tau) and were classified as carriers of AD pathology (AP+) when A+/T+ (regardless of N), or non-carriers (AP-) when they were A- (regardless of T and N), or A+/T-/N-, or A+/T-/N+ according to A/T(N) system. Plasma p-tau181 levels were significantly lower in SCD (2.15±0.88) as compared to MCI (2.91±1.38, p=0.037) and to AD-d (4.03±1.39, p<0.001). MCI had lower plasma p-tau181 levels than AD-d (p=0.015). In SCD plasma p-tau181 levels were correlated with CSF Aβ1-42 (ρ=-0.516, p=0.008), Aβ1-42/1-40 ratio (ρ=-0.748, p<0.001) and p-tau (ρ=0.779, p<0.001). In MCI plasma p-tau181 levels were correlated with all CSF biomarkers (Aβ1-42 ρ=-0.618, p<0.001; Aβ1-42/1-40 ratio ρ=-0.692, p<0.001; p-tau ρ=0.674, p<0.001; t-tau ρ=0.693, p<0.001). Considering AP status, plasma p-tau181 levels were higher in SCD AP+ than in SCD AP- (2.85±0.53 vs 1.73±0.64, p<0.001), and in MCI AP+ than in MCI AP- (4.03±1.07 vs 2.04±0.87, p<0.001). In a multivariate linear regression analysis, AP status was the only variable that significantly influenced plasma p-tau181 concentration (B=1.670 [95% CI 1.097:2.244], p<0.001). A ROC curve analysis showed that plasma p-tau181 was highly accurate for discriminating between AP+ and AP- patients (AUC = 0.910). We identified a cut-off level of 2.69 pg/mL to distinguish between AP+ and AP- (accuracy=84.21%, sensibility=86.36%, specificity=82.50%, PPV=75.00%, NPV=90.32%). Plasma p-tau181 levels were significantly associated with the presence of underlying AD pathology, independently from the cognitive status. Plasma p-tau181 showed a high accuracy in differentiating SCD and MCI patients who were carriers from non-carriers of AD pathology. Our preliminary results suggest that plasma p-tau181 might be a promising noninvasive biomarker of AD pathology at very early stage [3].

## RAPIDLY PROGRESSIVE DEMENTIA DUE TO HYPOMAGNESEMIA: WHEN RAPIDLY IS NOT IRREVERSIBLE

T. Giannelli, A. Introna, R. Pellicciari, D. Paolicelli, G. Logroscino

Department of Translational biomedicine and Neurosciences (DiBraiN), University of Bari (Bari)

Introduction: Rapidly progressive dementia (RPD) is a heterogeneous group of conditions characterized by a swift decline in cognitive abilities and overall functioning that develops faster than the most renowned dementia syndromes. Common causes include Creutzfeldt-Jakob disease (CJD), autoimmune encephalopathies (AE), infectious diseases and toxic/metabolic conditions.

Case presentation: Hereby, we describe a case of an 84 years-old female who came to our attention for the abrupt onset, three months prior, of behavioural symptoms such as irritability, verbal aggressiveness and loss of empathy, associated with mood deflection and loss of appetite. During the first month of symptoms, an episode of tonic-clonic seizure occurred: her CT-scan was irrelevant and levetiracetam was prescribed. Two months later, she developed bradykinesia and gait ataxia, associated with slurred speech and tremor of upper limbs. Therefore, she was admitted to our unit as confusional state and psychomotor agitation abruptly occurred. At examination, the patient was mildly disoriented and displayed severe attention deficit, apathy, constructive apraxia, gait ataxia, horizontal nystagmus, postural tremor in upper limbs, resting tremor in the right arm and dysmetria. She scored 17 out of 30 at mini-mental score examination [MMSE]. No electroencephalographic alterations were found. No instrumental exams suggested the presence of neoplasms, and CSF exams were unremarkable for antibodies associated with AE and biomarkers for neurodegenerative diseases. The only notable findings were undetectable serum magnesium level and multiple pontine hyperintensities visible in the T2-weighted imaging. Therefore, an intravenous supplementation therapy was immediately started and pantoprazole suspended. At discharge she displayed no attention deficit, was fully oriented and highly engaged with her surroundings. Her neurological exam was normal except for minimal horizontal nystagmus. Her MMSE score raised to 21.

Discussion: Our case testifies the broad range of neurological manifestations associated with hypomagnesemia, including mental status changes, seizures, movement disorders, tetany, muscle weakness. Moreover, a reversible cerebellar syndrome induced by hypomagnesemia has been described and associated to MRI specific abnormalities. Our case is unique because of the prominent cognitive decline and the atypical alterations in the pons, rather than the cerebellum. The diagnosis of RPD associated with hypomagnesemia is supported by the exclusion of other causes and the regression of clinical features following magnesium replacement. Notably, the patient's use of levetiracetam and pantoprazole may have contributed to the development of hypomagnesemia through mechanisms involving diarrhea and reduced absorption, respectively. These findings emphasize the importance of considering hypomagnesemia as a potential aetiology for rapidly progressive dementia associated to cerebellar signs.

## NEUROINFLAMMATION BIOMARKERS AND CLINICAL PROGRESSION IN AMNESTIC MILD COGNITIVE IMPAIRMENT DUE TO ALZHEIMER'S DISEASE

G. M. Giuffrè, D. Quaranta, M. G Vita, S. Citro, T. G Morganti, N. Martellacci, P. Calabresi, C. Marra

Fondazione Policlinico Agostino Gemelli IRCCS, Catholic University of the Sacred Heart (Roma)

Introduction: In addition to the core ATN CSF biomarkers for Alzheimer's disease (AD), novel fluid biomarkers related to neuroinflammation have gained attention in recent years. Higher levels of glial biomarkers, such as soluble Triggering-receptor expressed on myeloid-cells-2 (sTREM2), chitinase-3-like-1-protein (YKL-40), and glial-fibrillary-acidic-protein (GFAP) have been found in subjects with mild cognitive impairment (MCI) and AD-dementia. This study aims to investigate the role of CSF neuroinflammation biomarkers in predicting cognitive decline in individuals with prodromal AD.

Methods: Sixty subjects diagnosed with MCI due to ad were enrolled and underwent a comprehensive clinical and neurological evaluation, an extensive neuropsychological assessment, and a lumbar puncture for CSF biomarkers (Aβ42/40 ratio, p-tau, t-tau, NfL, sTREM2, YKL-40 and GFAP) quantification. Participants were retested after a one-year follow-up (n=59) and a two-year follow-up (n=39). Based on their MMSE score reduction after one year, subjects were classified as "fast-decliners" (n=21) or "slow-decliners" (n=38). Additionally, based on their clinical progression to dementia after two years, they were categorized as "converters" (n=18) or "non-converters" (n=21). Comparisons between groups were performed using the Mann Whitney-U test for mean rank, and binomial logistic regression models were utilized to assess whether CSF neuroinflammation biomarkers could predict cognitive decline.

Results: Age, literacy, and baseline MMSE scores did not significantly differ between "fast-decliners" and "slow-decliners", as well as between "converters" and "non-converters". When comparing CSF biomarker levels between these groups, p-tau, t-tau, and YKL-40 showed statistically significant higher concentrations in "fast-decliners" compared to "slow-decliners" and in "converters" compared to "non-converters". To further evaluate the predictive value of these biomarkers, backward stepwise logistic regression analyses were conducted, considering the three biomarkers along with age, literacy, and baseline MMSE score. The best model for predicting MMSE decline after one year included only YKL-40, while the best model for predicting conversion to dementia after two years included p-tau and baseline MMSE score.

Discussion & Conclusion: The elevated levels of p-tau and t-tau in the "fast-decliners" and "converters" groups confirm the importance of tau pathology in AD progression. Importantly, our results contribute to the growing evidence of the involvement of neuroinflammation in AD pathogenesis and reveal the role of YKL-40 as a predictor of cognitive decline in the short term in the early stages of AD. Future research should focus on validating these findings in larger cohorts, exploring the potential of this biomarker in monitoring therapeutic response, and evaluating the efficacy of interventions targeting neuroinflammation in AD.

## THE IMPORTANCE OF A PROMPT DIAGNOSIS IN COGNITIVE IMPAIRMENT: A CASE REPORT OF CEREBRAL AMYLOID ANGIOPATHY RELATED INFLAMMATION

D. Graziani, A. Introna, F. Caputo, A. Fraddosio, A. Fallacara, S. Grimaldi, F. Luisi, M. Tripaldi, P. Milzi, D. Paolicelli

Department of Translational Biomedicine and Neurosciences (DiBraiN), University of Bari "Aldo Moro" (Bari)

Background: Cerebral amyloid angiopathy-related inflammation (CAA-ri) is a distinct and rare clinical manifestation of cerebral amyloid angiopathy (CAA) characterized by an inflammatory response to amyloid deposition in the brain with subacute and progressive neurological symptoms. The clinical presentation of CAA-ri consists in an acute or subacute cognitive decline paired with headache, seizures or behavioural changes. [1]

Case presentation: A sixty-five-year-old patient presented to emergency room after repeated falls due to a progressively worsening motor deficit. He had a fairly unremarkable clinical history except for a minor neurosurgical procedure. Some days before the admission in an outpatient setting, the neurological examination found bilateral hand tremor and worsening cognitive status, attributed to an extrapyramidal disorder. Thus, L-dopa was prescribed. At the time of admission, the patient was alert but disoriented, exhibiting left hemiparesis and dysarthria. He scored 21/30, 1/6 and 0/8 to MMSE, ADL, IADL, respectively. His MRI brain scan showed diffuse vasogenic oedema in the frontal-temporal-parietal-occipital region bilaterally, predominantly expressed in the right hemisphere, shifting the median line structures with diffuse leukoaraiosis and a large number of hemosiderin deposits in the supratentorial region compatible with micro-haemorrhagic foci. A clinical suspicion of CAA-ri was raised and a lumbar puncture was performed. The results were consistent with mild pleocytosis and increased CSF protein with reduced Amyloid Beta42 and ratio of Abeta42/Abeta40, normal total-Tau and p-Tau181. Five grams of methylprednisolone were administered followed by slow tapering with oral prednisone. Over the next two weeks the motor and cognitive functions were ameliorated with the autonomous reaching of the upright stance, disappearance of tremor and better performances with cognitive testing; MRI imaging improved with the partial resolution of the bilateral oedema. The patient was discharged shortly after to a different institution to continue physical therapy where he made a full recovery. At time of discharge his score were: MMSE 24/30 ADL 5/6 IADL 2/8.

Conclusions: Cerebral amyloid angiopathy related inflammation requires an autoptic specimen for a definitive diagnosis, whereas a probable CAA-ri diagnosis may be inferred using clinical and radiological findings. This condition represents one of the few examples of cognitive decline associated with focal neurological symptoms which can be reversible with adequate therapy [2]. As our case highlighted, the identification of asymmetrical lesions by neuroimaging studies was pivotal for an early diagnosis, but the symptomatology may divert the clinician's attention elsewhere, oftentimes delaying treatment, with dire consequences for the patients.

## APOE GENOTYPE MEDIATES BLOOD-BRAIN BARRIER PERMEABILITY IN DEMENTIA

I. Libri[1], C. Silvestri[1], M. Cosseddu[2], R. Turrone[2], V. Cantoni[1], J. Rivolta[2], S. Caratozzolo[2], A. Alberici[2], A. Pilotto[1], B. Borroni[1], A. Padovani[1], A. Benussi[1]

[1]Neurology Unit, Department of Clinical and Experimental Sciences, University of Brescia (Brescia); [2]Neurology Unit, Department of Neurological and Vision Sciences, ASST Spedali Civili (Brescia)

Objective: The ε4 isoform of ApoE, a major genetic risk factor for developing Alzheimer's disease (AD), has been shown to be associated with increased blood-brain barrier (BBB) permeability in animal models of AD, while in vivo studies have reported conflicting results. The aim of the present study was to evaluate the effects of ApoE-ε4 genotype on BBB permeability in a large cohort of patients with neurodegenerative disorders.

Methods: Two hundred and thirty patients fulfilling current clinical criteria for AD (n=156), frontotemporal dementia (n=36), dementia with Lewy bodies (n=11), vascular dementia (n=11) and subjective cognitive decline (n=16) were recruited. All subjects underwent a clinical and neuropsychological evaluation, routine laboratory examination, cerebrospinal fluid analysis, ApoE genotyping and brain structural imaging (CT o MRI). BBB permeability was assessed with the CSF/plasma albumin and CSF/plasma light chains ratio. The sample was subdivided into three ApoE subgroups according to the number of ApoE-ε4 polymorphism (0, 1 or 2).

Results: The CSF/plasma albumin ratio, corrected for diagnosis, disease duration and disease severity, was increased in patients with two ApoE-ε4 genes ($p<0.001$). When diagnostic subgroups were considered separately, we observed comparable findings. Increased CSF/plasma kappa light chains were found only in patients with AD.

Conclusions: Our results support the hypothesis that ApoE genotype increases BBB permeability in major dementia disorder, having potential implications for disease pathophysiology and blood-based biomarkers measurements.

## ASSOCIATION BETWEEN PRESENCE OF ALPHA-SYNUCLEIN IN THE OLFACTORY MUCOSA AND BRAIN METABOLISM IN DEMENTIA WITH LEWY BODIES

L. Lombardo[1], L. Argenti[1], M. Losa[1], F. Calizzano[1], R. Mancini[1], E. Biassoni[1], A. Donniaquio[1], P. Mattioli[1], F. Canevari[2], G. Schenone[2], D. Arnaldi[1], S. Morbelli[3], M. Bongianni[4], G. Zanusso[4], A. Schenone[1], M. Pardini[1]

[1]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa (Genova); [2]IRCCS, Ospedale Policlinico San Martino, University of Genoa (Genova); [3]Department of Health Science (DISSAL), University of Genoa (Genova); [4]Department of Neurosciences, Biomedicine, and Movement Sciences, University of Verona (Verona)

Objectives: Alpha-synucleinopathy encompasses a very complex spectrum of phenotypic presentations, characterized by the presence of abnormal aggregates of alpha-synuclein in the brain, and two ideally distinct models can be identified: a motor form (Parkinson's Disease, PD) and a cognitive form (Lewy Body Dementia, DLB). In vivo pathological confirmation through minimally invasive collection of easily accessible tissue is a key goal for neurodegenerative disease research. The real-time quaking induced conversion assay (RTquIC) is a novel technique that has been tested for alpha-synuclein in olfactory

mucosa brushing (OMB) and cerebrospinal fluid (CSF). This study aim to investigate the symmetry of alterations observed in dopamine transporter SPECT (DaT-SPECT) in a cohort of DLB patients based on OMB results.

Materials: We enrolled 30 patients (21 males, 9 females) from our Memory Clinic with a clinical DLB diagnosis according to McKeith's criteria [1]. The mean age at the time of OMB procedure was 77 +/- 6 years, and the mean MMSE score was 23.4 +/- 5.4.

Methods: All patients underwent OMB and were divided into positive (n=22) and negative (n=8) groups based on RT-quIC alpha-synuclein results. Of these subjects, 27 underwent DaT-SPECT. DaT-SPECT images were post-processed using free BasGanV2 software and compared with a court of normal to obtain Z-scores. Non-parametric statistics were employed to compare the asymmetry in putamen and caudate Z-scores between the two patient groups.

Results: Our data confirm a statistically significant difference in the absolute value of left-right putamen difference between the positive and negative OMB groups (positive group: mean 0.0977 +/- 0.0867, negative group: mean 0.1785 +/- 0.1014; p=0.03). However, no significant difference was found for the caudate (p=0.3).

Discussion: While specific PET tracers for alpha-synuclein are under development, several hypotheses have been proposed regarding disease spread mechanisms. One emerging hypothesis suggests the distinction between brain-first and body-first patterns [2]. The olfactory bulb represents an ambivalent structure, able to be involved in both spreading patterns. However, some murine studies have shown that unilateral injection of alpha-synuclein seeds result in markedly asymmetrical spreading of the pathology [3]. Our results, limited by sample size, confirm a trend toward greater asymmetry in DaT-SPECT metabolism among patients positive for alpha-synuclein pathology on OMB.

Conclusions: The RT-quIC technique for detecting alpha-synuclein in OMB represents a new diagnostic tool in alpha-synucleinopathies. Further studies are needed to characterize its prognostic value and correlations with other biomarkers.

## METABOLIC AND NEUROCHEMICAL CHARACTERIZATION OF EARLY ONSET VS LATE ONSET BEHAVIORAL FRONTOTEMPORAL DEMENTIA

M. Losa[1], L. Argenti[1], L. Lombardo[1], P. Mattioli[1], S. Morbelli[2], M. Bauckneht[2], A. Brugnolo[1], N. Girtler[1], D. Arnaldi[1], F. Massa[1], B. Orso[1], M. Pardini[1]

[1]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa (Genova); [2]Department of Health Science (DISSAL), University of Genoa (Genova)

Aim: Frontotemporal dementia (FTD) is a highly heterogeneous neurodegenerative disorder, from both the clinical and biological point of view. It is traditionally considered an early onset syndrome, although several epidemiological studies have shown that could also occur later on in life [1]. Currently, whether the early and the late onset might represent different FTD phenotypes is still unclear.

Materials: We enrolled 79 patients with behavioral variant FTD (bvFTD - 34 probable bvFTD, 55 prodromal bvFTD) and 42 Healthy Controls (HC). We acquired brain [18F]FDG-PET images as a marker of neurodegeneration. Patients were divided into three groups based on age at onset, namely early onset-bvFTD (EO-bvFTD, age <70, n = 24, mean age at onset: 62.9±6.4; MMSE: 25.3±2.7; 46% males), late onset-bvFTD (LO-bvFTD, age between 70 and 75, n = 31, mean age at onset: 73.1±1.5; MMSE: 24.2±4.1; 29% males) and very late onset-bvFTD (vLO-bvFTD, age >75, n = 24, mean age at onset: 78.4±1.86; MMSE: 24.2±3.4; 38% males).

Method: We performed a voxel-based analysis between EO-bvFTD, LO-bvFTD, vLO-bvFTD and HC, separately. Using JuSpace toolbox, we explored the correlation between [18F]FDG-PET images and PET maps of dopamine (DAT), serotonin (SERT), noradrenaline (NAT) and choline vesicular (VAChT) transporters cortical distribution.

Results: EO-bvFTD patients showed a typical anterior pattern of cortical hypometabolism, associated with a significant involvement of NAT cortical availability ($p<0.001$) compared to HC. LO-bvFTD and vLO-bvFTD patients showed a similar pattern of hypometabolism, extending to the angular gyrus. LO-bvFTD had a greater involvement of diffuse neurotransmitter pathways, with reduced cortical availability of VAChT ($p < 0.001$).

Discussion: It has been highlighted that cognitive-behavioral profile differs between EO-bvFTD and LO-bvFTD (2). In our work we showed that, in addition to the known anterior pattern well represented in EO-bvFTD patients, a greater involvement of the temporo-parietal junction metabolism is present in LO-bvFTD patients. This is associated with a broader diffuse projection systems involvement. As highlighted in the recent diagnostic criteria [3], this may be related to a more prevalent underlying biological profile of Alzheimer's Disease, either as a single entity or in comorbidity, with subsequent therapeutic implications. Understanding these differences may contribute to improved diagnosis and treatment strategies, particularly in late-onset cases with overlapping features of Alzheimer's Disease.

Conclusion: We highlighted how metabolic and neurochemical patterns differ in bvFTD depending on the age at onset.

## BRAIN LINEAR MEASUREMENTS FOR DIFFERENTIATING NORMAL PRESSURE HYDROCEPHALUS FROM ALZHEIMER'S DISEASE: AN EXPLORATORY STUDY

A. Luca, G. Donzuso, G. Mostile, R. Terranova, C. Cicero, A. Nicoletti, M. Zappia

Department of Medical, Surgical Sciences and Advanced Technologies "GF Ingrassia", University of Catania (Catania)

Background: Easy and reliable tools for the differential diagnosis between idiopathic normal pressure hydrocephalus (iNPH) and Alzheimer's disease (AD) are needed.

Material and methods: In this cross-sectional study iNPH and AD referring to the Neurology Unit of the University of Catania from the 1 st of January 2020 to the 1 st of December 2022 were enrolled. The following brain linear measurements were calculated: Evan's

Index (EI), the Parieto-Occipital Ratio (POR) and the Temporal-Ratio (TR). For each index, sensitivity, specificity and area under the curve (AUC) were calculated. Moreover, a cumulative index, i.e. the brain linear measurement (BLM) index was also considered.

Results: Fifty patients (25 iNPH and 25 AD) were enrolled. In differentiating iNPH from AD, EI had the highest AUC (0.956), POR had the highest specificity (100%), while TR had the highest sensitivity (92%). The BLM index differentiated iNPH and AD with a sensitivity of 96%, a specificity of 92% and an AUC of 0.963 with the optimal cut-off value of 0.303.

Conclusion: EI, POR and TR may be useful in the differential diagnosis between iNPH and AD. At an individual level, the BLM index represents a valid and reliable tool to achieve an accurate differentiation between these two conditions.

## HIGH-DENSITY EEG (HD-EEG) CORRELATES OF CORE CLINICAL FEATURES IN DEMENTIA WITH LEWY BODIES. PRELIMINARY DATA

R. Mancini[1], L. Carini[2], S. Sommariva[2], P. Mattioli[1], F. Famà[1], L. Giorgetti[1], F. Calizzano[1], M. Pardini[1], M. Piana[2], D. Arnaldi[1]

[1]Dept. of Neuroscience (DINOGMI), University of Genoa (Genova); [2]Dept. of Mathematics (DIMA), University of Genoa (Genova)

Objective: To explore the associations between high-density EEG (HD-EEG) features and the core clinical features of dementia with Lewy bodies (DLB).

Materials: Twenty–nine patients with DLB (20 males, mean age: 78±6 years; mean MMSE score: 22.2±3.9, mean MDS-UPDRS score 17.52±13.7) underwent 64 channels HD-EEG recording and a comprehensive clinical and neuropsychological examination.

Methods: Quantitative EEG analysis was performed, and the following features were extracted: individual alpha peak (IAP), theta-to-alpha transition frequency (TF) computed by the semi-automated tool transfreq, mean frequency (MF), and frequency bands power. Frequency bands were estimated with both standard definition and an individual one (delta=[max(1, TF-4), TF-2], theta=[ TF-2, TF], alpha=[TF, IAP+2 ], beta=[IAP+2, 30]). We tested the associations between HD-EEG features and core clinical DLB features.

Results: The computation of individual bands power highlighted that the posterior dominant rhythm is shifted through standard theta range, with a mean IAP of 7.02±0.94 Hz, a TF of 5.03±0.88 HZ and a MF of 7.83±2.02 Hz. TF positively correlated with IAP ($r = 0.58$, $p<0.001$). MDS-UPDRS-III scores positively correlated with individual theta power ($r = 0.38$, $p = 0.03$) and negatively correlated with both individual beta power ($r = -0.36$, $p=0.04$) and standard beta power ($r = -0.4$, $p=0.02$). Standard alpha power positively correlated with MMSE scores ($r = -0.37$, $p=0.03$).

Discussion: Core clinical features and cognitive decline in DLB may depend on different neurotransmitter pathways that could be reflected in HD-EEG alterations. To avoid misinterpretation of qEEG we estimated TF at individual level with transfreq. In fact, frequency bands may variably overlap across subjects, particularly in DLB patients that present a slowing of background activity. Briefly, transfreq is a method based on the identification of the intersection between the spectral profiles of leads with high alpha activity and the ones of leads with low alpha and high theta activity, with just one resting-state EEG. Individual EEG features estimated with transfreq showed promising results as potential correlates of DLB clinical features. Moreover, TF showed to be independent from MMSE; this could be explained considering that background activity slowing may already begin in mild and prodromal DLB stages.

Conclusions: We showed that individual quantitative EEG analysis implemented with transfreq may better describe cortical functions in DLB patients than standard ones. Moreover, TF was not correlated with global cognitive decline, supporting the hypothesis that posterior rhythm abnormalities may already be present in mild and prodromal stages.

## HIPPOCAMPAL ATROPHY CAN PREDICT EVOLUTION TO DEMENTIA IN PATIENTS WITH VASCULAR MILD COGNITIVE IMPAIRMENT

C. Manco[1], R. Cortese[1], M. Leoncini[1], G. Gentile[1], L. Lucchetti[1], J. Zhang[1], D. Plantone[1], I. Di Donato[1], E. Salvadori[2], A. Poggesi[2], M. Cosottini[3], M. Mascalchi[4], A. Federico[1], M. Dotta[1], M. Battaglini[1], D. Inzitari[2], L. Pantoni[5], N. De Stefano[1]

Sacco" Department of Biomedical and Clinical Sciences, University of Milan (Milano)

Background and Objectives: Vascular mild cognitive impairment (VMCI) is a transitional condition that may evolve into vascular dementia (VaD) [1]. A deeper understanding of the mechanisms of cognitive impairment in VMCI is crucial to develop markers of disease progression. Studies have suggested hippocampal atrophy as a putative MRI-based marker in early VaD[2]. Our study aims to evaluate (I) differences in hippocampal volume among patients who converted to VaD vs those who did not convert and (II) to what extent hippocampal involvement correlated with cognitive impairment and vascular white matter lesions (WMLs).

Methods: In this longitudinal multicentre study, 110 subjects with VMCI (mean age [±SD]: 74,33 [± 6,63] years, 61 males/49 females) from the vMCI-Tuscany Study database underwent brain MRI and were scored on cognitive tests. Information on whether patients evolved to VaD after 2 years was recorded. For each subject right and left hippocampi were semi-automatically segmented; the hippocampi masks were obtained using FIRST (https://fsl.fmrib.ox.ac.uk/fsl/fslwiki) and manually refined where occurs using EADC-ADNI protocol. In addition, vascular WMLs volume in different bundles was assessed by intersecting fibers included in the ICBM-DTI-81 white-matter labels atlas

with lesion masks manually segmented. Linear regression models were used to assess differences in hippocampal volumes between groups and their correlations with cognitive tests and lesions volume, corrected for age, sex, center and education, as appropriate.

Results: In the whole cohort, lower hippocampal volume was associated with worse verbal memory assessment scores, such as ray-auditory-verbal learning test delayed recall (beta coefficient: 101.19, p=0.004). At 2 years of evaluation, 32/110 (29%) of VMCI converted to VaD. Lower whole hippocampal volume was found in VMCI patients who converted to VaD (mean volume [±SD]: 4829 [±897] mm3) with respect to those who did not convert (mean volume [±SD]: 5178 [±819] mm3); (p=0.03). No significant correlation was found between hippocampal volume and lesion volume in any white matter bundle.

Conclusions: Data reported here suggest that hippocampal atrophy can be detected in patients with VMCI, is closely related to subclinical memory impairment and can predict evolution to VaD. In contrast, it does not seem to be influenced by vascular WMLs.

## AN OLD MAN WANDERING THE STREETS

F. Manfredini[1], R. Infante[2], L. Mancinelli[2], C. Bomprezzi[2], P. Cortelli[1], F. Cristini[3], M. Longoni[2], M. Romoli[2]

[1]IRCCS Institute of Neurological Sciences of Bologna, University of Bologna (Bologna); [2]UO Neurology, Maurizio Bufalini Hospital, AUSL Romagna (Cesena);[3]Infectious Diseases Unit, Forlì-Cesena Hospitals, AUSL Romagna (Rimini)

Neurosyphilis results from the extension to the central nervous system of an infection caused by Treponema pallidum, leading to consistent heterogeneity in features and time of presentation. Neuroinvasion may resolve spontaneously, given the ability of the immune system to provide full clearance of T. pallidum from CNS, resulting as an asymptomatic stage. Late symptomatic neurosyphilis can manifest decades after primary infection in 10-20% of cases left untreated, and usually presents with tabe dorsalis or general paresis. As the disease can be extremely heterogeneous in presentation, the onset can mimic acute encephalitis, as well as more progressive and subacute encephalopathy, reaching the correct diagnosis might be trickier the more subacute the clinical features become. In our case A 77-year-old patient presented for the sudden occurrence of confusion, memory loss and aggressiveness. The previous medical history was unremarkable, though the patient's daughter had reported similar transient episodes in the previous three months. Neurological examination revealed drowsiness, slight dysarthria, partial disorientation in space and time with short and long-term memory impairment and reiteration. Brain magnetic resonance imaging (MRI) showed mild leukoaraiosis, cortical-subcortical atrophy and bilateral signal change in temporal and insular location, prevalent on the left side, characterized by hypointensity in T1-weighted imaging and hyperintensity in T2-weighted imaging. A total body CT scan revealed a severe dilation of the ascending aorta and aortic arch. CSF analysis revealed unremarkable cell count and proteins, and pattern 3 oligoclonal bands. Acyclovir was started for a possible diagnosis of herpes simplex virus-related encephalitis, but CSF PCR screening turned negative for viruses. VDRL and TPHA serology returned positive. On CSF TPHA was positive, while VDRL was negative, so a final diagnosis of neurosyphilis was made and medical treatment with penicillin G iv was started. This case highlights how non-specific neuroimaging can be in neurosyphilis. Indeed, no brain MRI pattern seems typical, with general atrophy, mesial temporal lobe involvement and diffuse white matter changes have been reported. However, polar temporal white matter changes are rather uncommon, particularly if isolated, and might prompt clinicians to raise suspicion for neurosyphilis in the appropriate clinical context. Reaching the correct diagnosis in patients with a subacute onset of neuropsychiatric symptoms can be complicated and we tend to presume that neuroinfectious diseases represent underdogs. Syphilis cases are rising, and we think that must be considered to avoid missing a potentially treatable cause of cognitive and neuropsychiatric deficit.

## POSTERIOR CORTICAL ATROPHY MISDIAGNOSED AS NEUROMYELITIS OPTICA SPECTRUM DISORDER: A CASE REPORT

C. Marotta, A. Tessitore, A. Gallo, M. Cirillo, G. Tedeschi, A. Bisecco

Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli" (Napoli)

Background and Aims: Here we report a case of a 62-years-old woman, admitted to our Neurology Unit for the insidious onset unspecified years ago of bilateral visual disturbance. Her medical history was remarkable for an amaurosis in the right eye due to a traumatic retinal detachment at the age of 20 and a bilateral cataract surgery in 2005 and in 2014. In 2019 she was diagnosed with Neuromyelitis optica spectrum disorder, by applying 2015 diagnostic criteria (evidence of bilateral vision loss associated with a right optic nerve hyperintensity at brain MRI and the positivity of AQP4-IgG test (ELISA)). For this diagnosis the patient underwent immunosuppressive treatment without clinical benefit. On admission, neurological examination showed space and objects perception deficit, simultanagnosia, oculomotor apraxia, optic ataxia, left/right disorientation, bilateral positive palmomental reflex and urinary urgency.

Methods: We performed blood tests, ophthalmological examination (including VEP and OCT), brain MRI, neuropsychological evaluation, amyloid PET and AQP4-IgG test with cell-based serum assays (CBA).
Results: Ophthalmological examination confirmed complete vision loss in the right eye (exitus of retinal detachment) and normal findings in left eye. Brain MRI showed marked atrophy in bilateral parietal, posterior temporal and lateral occipital cortex and right optic nerve T2-hyperintensity/atrophy. Neuropsychological assessment revealed significant visual, visuoperceptual, and visuospatial dysfunction and a relatively well-preserved episodic memory. Amyloid PET showed the presence of diffuse cortical beta-amyloid plaques. AQP4- IgG test was negative.

Conclusions: Patient was diagnosed with "Posterior cortical atrophy (PCA) associated with Alzheimer's Disease", a clinico-radiological syndrome characterized by progressive decline in visual processing skills and other functions subserved by parietal, occipital and occipito-temporal regions. PCA is characterized by early prominent visual dysfunction that cannot be explained by ocular causes: patients may have a history of repeated visits to optometrists or ophthalmologists and multiple unsuccessful changes in eyeglasses or surgical procedures in attempt to correct acuity.

Discussion: The present case report show as an incorrect application of diagnostic criteria should lead to an incorrect diagnosis. Adult-onset,

progressive visual disturbance often poses a diagnostic challenge between immunological disorders, infectious causes and also degenerative disease. A thorough medical history and correct interpretation of instrumental examinations are essential in the differential diagnosis of visual disorders. In our case the right optic nerve hyperintensity was due to ascending optic atrophy due to previous retinal detachment and AQP4-IgG test was performed with immunofluorescence assays, that have lower specificity and occasionally yield false-positive results compared with the best available detection method (CBA).

## THE UTILITY OF CSF BIOMARKERS MEASURED WITH THE LUMIPULSE SYSTEM IN THE DIAGNOSIS AND MANAGEMENT OF ALZHEIMER'S DISEASE

F. Marrone, A. Buongiovanni, V. Santocchio, G. Montanino, M. Bile, V. Piscopo, L. Minieri, L. Bruno, C. Esposito

Clinical Pathology Laboratory, Azienda Ospedaliera Dei Colli Monaldi-Cotugno-CTO (Napoli)

Objectives: The fundamental biomarkers of cerebrospinal fluid (CSF): total tau (tTau), phospho-tau (pTau), amyloid β1-42 (Aβ 1-42), and the Aβ 1-42/Aβ 1-40 ratio have transformed Alzheimer's disease (AD) research and are now increasingly used in routine. Infact, high levels of tau protein and low levels of amyloid-beta in the cerebrospinal fluid are associated with the presence of amyloid plaques and neurofibrillary tangles in the brain, hallmarks of Alzheimer's disease. Identifying these biomarkers at an early stage can allow doctors to initiate early therapeutic interventions and slow the progression of the disease. [1]

Materials: Seventy-seven CSF samples were collected between December 2019 and May 2023 as part of the subject's routine clinical diagnostic survey. Patients had an average age of 69 years, 58% male and 42% female.

Methods: LUMIPULSE G (Fujirebio) is an automated system for microsphere-based immunoassays, capable of measuring all four AD biomarkers: Aβ 1-42, tTau, pTau and the ratio Aβ 1-42/Aβ 1-40. The four markers were quantified directly from the preservation tubes using Lumipulse G β-amyloid 1-42, β-amyloid 1-40, total Tau, and pTau 181 assays from the automated LUMIPULSE G600 II platform and following the manufacturer's instructions. [2]

Results: The Lumipulse G test showed low intra- and inter-test variability and good agreement with the clinical diagnosis. Quality control was performed at the beginning of each test to ensure that all measured values of each control level (low, medium, and high) were within the target ranges. 11.7% (9/77) of the samples showed low values of Aβ 1-42 with high pTau values which, according to the international bibliography reflect a status of AD. In addition, the clinical diagnosis also confirmed Alzheimer's disease.

Discussion: Fully automated immunoassay instruments with ready-to-use analysis kits and calibrators have simplified their analysis with reproducible, highly specific measurements. Good diagnostic performance was observed for LUMIPULSE G β-amyloid 1-42, β-amyloid 1-40, β-amyloid1-42/40, total Tau and pTau.

Conclusions: The usefulness of CSF biomarkers measured with the Lumipulse system is a valuable resource for the diagnosis and management of neurodegenerative diseases. The accuracy and reliability offered by this technology allows doctors to obtain detailed information about the neurological pathology, facilitating early diagnosis and optimization of treatment.

## CSF NPTX2 DYNAMIC CHANGES AND TOPOGRAPHIC RELATIONS WITH BRAIN METABOLISM ACROSS MCI DUE TO ALZHEIMER'S DISEASE

F. Massa[1], C. Martinuzzo[1], V. Pelagotti[1], P. Mattioli[1], W. Kreshpa[1], B. Orso[1], A. Brugnolo[1], N. Girtler[1], T. Vigo[2], D. Visigalli[2], D. Arnaldi[1], A. Uccelli[2], A. Schenone[1], S. Morbelli[3], A. Chincarini[4], M. Pardini[1]

Introduction: Neuronal pentraxin-2 (NPTX2), a protein involved in synaptic function and plasticity, exhibits decreased levels in the cerebrospinal fluid (CSF) and brain tissue as cognition deteriorates in various dementias [1]. The variations of CSF NPTX2 levels across MCI due to Alzheimer's disease (AD) and their association with brain metabolism remain elusive, albeit relevant for patient stratification purpose. We aimed to investigate changes in CSF NPTX2 levels in relation to progression to AD dementia and explored their correlation with regional brain metabolism using [18F]FDG PET imaging.

Materials: We retrospectively selected a cohort of 49 patients with mild cognitive impairment and high-likelihood of AD (MCI-AD, 30 females, mean age 75.2±5.3) based on CSF biomarkers of amyloidosis and tauopathy (AT+)(2), and divided them into two subgroups based on their progression to dementia within a two-year period (late-MCI, LMCI, n=15 versus early-MCI, EMCI, n=34 patients). For comparison, we included a group of age- and sex-matched individuals with other non-dementing conditions (OND).

Methods: We examined demographic variables and cognitive status (MMSE score) in both the EMCI and LMCI groups. We measured the levels of CSF NPTX2 through a commercial ELISA assay to be compared among the EMCI, LMCI, and OND groups. Through a voxel-based analysis of [18F]FDG PET scans (SPM12 software), we investigated the topographical correlation between brain metabolism and CSF NPTX2 levels, using age as a nuisance.

Results: CSF NPTX2 differed among groups ($p=0.003$), and at post-hoc analysis, EMCI had significantly higher values than either LMCI ($p=0.028$) and OND ($p=0.006$). We found a significant positive correlation between NPTX2 values and metabolism of bilateral precuneus in MCI-AD patients ($p<0.005$ at voxel level, $p<0.05$ with FWE correction at the cluster level, cluster extension 364 voxels).

Discussion: Higher CSF NPTX2 levels in early MCI compared to controls and late MCI may indicate synaptic compensation in response to initial AD pathology. However, as the disease progresses, these mechanisms may become overwhelmed, resulting in decreased NPTX2 levels approaching dementia. Additionally, the positive correlation between NPTX2 and glucose metabolism in the precuneus, an area that is commonly affected early in AD and associated with

cognitive decline [3], highlights a strong relationship between NPTX2 and the metabolic changes related to AD throughout the disease course.

Conclusions: Our study provides valuable insights into the dynamics of CSF NPTX2 and its intricate relationship with metabolic changes across MCI with AD etiology, highlighting its potential as a biomarker for patient staging and stratification of progression risk.

Background and aims: Subjective cognitive decline (SCD) represents a target population to be screened for dementia. Previous studies identified demographic, cognitive and genetic features associated with a higher risk of progression to mild cognitive impairment (MCI) and Alzheimer's disease (AD) [1,2]. We aim to test the accuracy of a machine learning (ML) model, trained on features derived from non-invasive and easily accessible techniques, in predicting conversion from SCD to MCI and AD.

Materials and Methods: We included 150 SCD patients who underwent neuropsychological examination, assessment of cognitive complaint, mood disorders and cognitive reserve, and APOE genotyping at baseline. All the patients underwent clinical-neuropsychological follow-up every 12-24 months for a mean time of 12 years.

Results: During follow-up, 63 patients were classified as progressive SCD (p-SCD, 42.0% [95% C.I.=34.1:49.9], including 41 MCI (27.3% [95%C.I.=20.2:34.5]) and 22 AD (14.7% [95%C.I.=9.0:20.3]). 87 patients were classified as non-progressive SCD (np-SCD, 58.0% [95%C.I.=50.1:65.9]). We split the whole sample into a training (80%) and a test group (20%). A gradient-boosted trees algorithm was trained on 15 selected features including: age, APOE, education, test assessing for global cognition, immediate and delayed verbal, ecological memory and working memory, language, visuospatial abilities, phonemic fluency and cognitive reserve. This model showed a good accuracy (0.83, AUC=0.78) in distinguishing p-SCD and np-SCD in the test group.

Discussion: Previous studies demonstrated that ML algorithms are able to classify images from AD, MCI, and healthy participants with very high accuracy levels but only a few studies focused on predicting the progression of cognitive decline [3]. To the best of our knowledge, this is one of the first longitudinal studies applying ML to an SCD population.

Conclusions: Our machine learning models, including demographic, neuropsychological and genetic features, might represent a reliable, cost-effective and globally scalable tool for a first-step screening of SCD patients before confirmation of AD pathology via more invasive and expensive tests.

## SUBJECTIVE COGNITIVE DECLINE: A PROPOSAL FOR A MANAGEMENT PROTOCOL BASED ON REVIEW OF LITERATURE AND 15 YEARS' EXPERIENCE FROM A MEMORY CLINIC

S. Mazzeo[1], V. Moschini[2], S. Padiglioni[2], S. Bagnoli[1], G. Giacomucci[1], J. Balestrini[1], A. Ingannato[1], C. Morinelli[1], F. Emiliani[1], G. Galdo[1], B. Nacmias[1], S. Sorbi[3], V. Bessi[2]

[1]Department of Neuroscience, Psychology, Drug Research and Child Health, University of Florence (Firenze); [2]Research and Innovation Centre for Dementia-CRIDEM, Azienda Ospedaliera-Universitaria Careggi (Firenze); [3]Department of Neuroscience, Psychology, Drug Research and Child Health, University of Florence, IRCCS Don Carlo Gnocchi (Firenze)

Background and aims: Increasing evidence suggests that subjective cognitive decline (SCD) is a risk factor for dementia [1]. For this reason, the National Institute of Aging-Alzheimer's Association (NIA-AA) included SCD as a first manifestation of the symptomatic stages of AD, preceding MCI [2]. On the other hand, SCD has also been related to non-degenerative diseases [3]. Nevertheless, a consensus is lacking about how to manage patients with SCD. We aimed to: i) describe our experience with SCD; ii) review the literature about the impact and causes of SCD; iii) propose a practical approach for the management of SCD.

Methods: From a sample of 445 SCD patients self-referred to our center, we considered 119 patients followed-up for at least 10 years. All the patients underwent neurological and neuropsychological examination at baseline. A subsample of 78 patients underwent Alzheimer's disease biomarker assessment (CSF or amyloid-PET), rated according to the AT(N) system.

Results: During the follow-up, 55 patients (47.0%) were diagnosed with MCI and 22 (18.8%) with dementia. A patient developed Parkinson's disease and a patient had a brain tumor. Mean progression time was 7.9(5.2) years to MCI and 10.39(4.7) to dementia. Thirty-eight (32.5%) patients still were SCD at the end of the follow-up (15.2[5.4] years). In this group nine patients were diagnosed with depression, six had vascular leukoencephalopathy and two were diagnosed with obstructive sleep apnea syndrome (OSAS). Among 78 patients who

underwent AD biomarker assessment 10 (12.8%[5.4-20.2]) were A+ (seven A+/T+/N- and five A+/T+/N+). The review of the literature allow us to identify other potential causes of SCD including: mood disorder, sleep disorders, use of sleep medication, vitamin B12 deficit and cerebrovascular disease.

Discussion: We elaborated a management protocol to be applied both in clinical and in research settings: at the baseline evaluation, all the conditions possibly associated with SCD should be considered. If none of the baseline exams shows a possible explanation for the SCD, we classify patients as "SCD of unknown cause". We suggest stratifying patients according to age at onset and APOE genotype. Regarding patients who undergo AD biomarker analysis, we suggest applying the ATN classification to classify patients as affected by "SCD not due to AD", "Alzheimer's pathologic changes with SCD" or "AD with SCD".

Conclusions: Our proposal may assist clinicians in managing patients with SCD, enabling them to identify underlying conditions suitable for therapeutic approaches and select patients to participate in clinical trials and upcoming disease-modifying therapies at the earliest stages of the disease.

## COMORBIDITIES IN MILD COGNITIVE IMPAIRMENT DUE TO ALZHEIMER'S DISEASE: EFFECTS ON NEUROPSYCHIATRIC SYMPTOMS AND THERAPY

F. Menegon[1], G. Tondo[2], F. De Marchi[3], D. Aprile[3], P. Serra[2], B. Sarasso[2], C. Comi[2]

[1]Department of Translational Medicine, University of Piemonte Orientale (Novara); [2]Department of Translational Medicina, University of Piemonte Orientale, Neurology Unit, S. Andrea Hospital (Vercelli); [3]Department of Translational Medicine, University of Piemonte Orientale, Neurology Unit, Azienda Ospedaliero-Universitaria Maggiore della Carità (Novara)

Background: Mild cognitive impairment (MCI) is a heterogeneous condition with high variabilities in clinical outcomes related to patient demographics, genetic, fluid biomarker alterations, and concomitant comorbidities (CBs). Although previous studies reported a crucial role for CBs in favouring cognitive decline and conversion from MCI to dementia [1], the individual weight of these potentially modifiable risk factors is not yet established.

Aim: This study aimed to investigate the presence of CBs in a cohort of MCI participants and longitudinally evaluate their impact on global cognition, development of neuropsychiatric symptoms, risk of conversion to dementia, and therapeutic management.

Methods: We retrospectively included n=93 participants with amnestic MCI [2], evaluated between 2018 and 2020 at the Centre for Cognitive Disorders and Dementia of "Sant'Andrea Hospital", Vercelli, Italy. We included only subjects with at least six months of available follow-up. As CBs, we considered: hypertension, coronary artery disease, chronic heart failure, diabetes, respiratory illness, chronic kidney disease, hypothyroidism, hypercholesterolemia, cancer, depression, parkinsonism, visual impairment, stroke, hip fracture, peripheral artery disease, osteoporosis, arthritis. We evaluated: the baseline and follow-up Mini-Mental State Examination (MMSE) as an index of global cognition; the index of progression (calculated as MMSE point loss per year); the conversion to dementia; prescription of anticholinesterases, memantine, antidepressants and antipsychotics.

Results: In the whole cohort, the mean follow-up was 2,5±1,6 years, 68% of subjects converted to Alzheimer's disease (MCI-co), and the mean progression index was 2,2±3,5. Overall, CBs did not impact conversion to dementia. However, by analysing MCI-co, CBs influenced therapeutic management. Prescription of memantine was more frequent in subjects with two or more CBs than in those with no or one CB (p=0,02). Moreover, depression was significantly associated with two or more additional CBs, and consistently a higher number of CBs was associated with a larger use of antidepressant therapy (p=0,03).

Discussion: In our study, CBs in MCI-co subjects were associated with the presence of depression and a consequent larger use of antidepressant therapy. These findings are consistent with previous studies, reporting a higher rate of depression in patients with cognitive decline and concomitant chronic diseases [3]. In addition, we showed a higher prescription of memantine in patients with two or more CBs, probably due to a better safety profile.

## CO-OCCURRENCE OF NPC1 MUTATION AND C9ORF72 REPEAT EXPANSION IN A CASE OF FRONTOTEMPORAL DEMENTIA WITH MILD PHENOTYPE

A. Mignarri[1], D. Gasparini[1], S. Bianchi[1], B. Pucci[2], D. Lopergolo[1], V. Leoni[3], C. Ricci[2], S. Battistini[2], E. Tardelli[4], S. Sestini[4], N. De Stefano[1]

S. Stefano, U.S.L. Toscana Centro (Prato)

Introduction: Frontotemporal lobar degeneration (FTLD) is a progressive neurodegenerative disorder, typically classified into behavioural

variant frontotemporal dementia (bvFTD) and primary progressive aphasia (PPA). At least 30% of patients with FTLD have a positive family history. Intronic GGGGCC hexanucleotide repeat expansion in chromosome 9 open reading frame 72 (C9ORF72) is the most common cause of familial and sporadic MND and FTLD. Furthermore, it has been described in patients with other dementias, parkinsonism or psychosis, as well as in healthy subjects. Previous report described FTLD patients carrying two mutations. Interestingly, in all cases one of them was the C9ORF72 expansion. Here we report a new association leading to a milder form of FTLD.

Case Report: The proband was a 70-year old man with a 5-year history of slowly progressive cognitive disturbances. His father was affected by dementia, clinically diagnosed as Alzheimer's disease (AD). Neurological examination of the proband was normal. Neuropsychological assessment showed impaired attention, memory, speech production, and executive functions, in absence of significant behavioural alterations. A previous brain MRI showed temporoparietal cortical atrophy. Initially, AD was suspected. However, CSF biomarkers profile (A-,T-,N+) suggested a non-AD dementia. Amyloid-PET confirmed absence of brain amyloid deposit. FDG-PET showed frontotemporal hypometabolism. We performed a diagnosis of FTLD. Overlap with MND was clinically and electrophysiologically excluded. Disease-causing expansion in the first exon of the C9ORF72 gene was found. Also, an NGS panel of 31 genes associated to dementia was analysed: we found the heterozygous c.2761C>T (p.Gln921Ter) mutation in NPC1, already described as pathogenic and reported in Italian patients with Niemann-Pick type C disease. Serum oxysterol analysis showed significant increase of 7-Ketocholesterol (7KC) and cholestan-3β,5α,6β-triol (triol), strongly supporting the pathogenicity of the NPC1 mutation.

Discussion: Our case report further supports the hypothesis that co-occurrence of two pathogenic mutations could contribute to the clinical heterogeneity that is detected in subjects with C9ORF72 repeat expansions. Sometimes C9ORF72 repeat expansion is probably not sufficient to develop disease, and an additional mutation or environmental exposure may be needed. Such being the case, FTLD patients carrying C9ORF72 expansion should not be excluded from further genetic studies: both clinicians and genetic counsellors should be aware of this phenomenon when advising patients and their family members. In our patient, the pathogenic variant in the NPC1 gene might have modified the phenotype which was milder than expected in "classical" FTLD and required a thorough differential diagnosis with a frontal variant of AD.

## EARLY-PHASE AMY-PET VERSUS FDG PET IN ATYPICAL VARIANTS OF ALZHEIMER DISEASE: PRELIMINARY DATA FROM A MULTICENTER STUDY (AMY-ITA)

S. Mozzetta[1], I. Bittente[1], L. Vendramin[2], D. Cecchin[1], A. Cagnin[1]

[1]Department of Neurosciences, University of Padua (Padova);[2]Nuclear Medicine, University of Padua (Padova)

Introduction: Amyloid PET and [18F]FDG PET scans are commonly used in patients with uncertain diagnosis of AD. A few studies showed that early frames of amyloid PET correlate well with FDG PET images, providing perfusion-like information, thus being a potential surrogate for FDG-PET. We investigated whether the early frames of the florbetaben-PET (FBB-PET) scan are comparable to the FDG-PET in terms of regional uptake deficits in patients with a clinical suspicion of atypical Alzheimer's disease.

Materials and Methods: AMY-ITA is a still ongoing prospective multicenter study conducted in 9 Italian centres. Until now, 84 patients have been enrolled, collecting FDG-PET and FBB-PET images. The brain was divided into 8 different regions in both FDG and early-frames FBB-PET scans. Each region was visually and blindly analysed in both PET scans, defining the tracer uptake abnormality, using a scale of 0 to 3. A statistical analysis was then performed using Spearman and Wilcoxon tests. Clinical data were collected by neurologist, who estimated the suspicion of AD for all patients before AMY-PET result and then confirmed or not the initial diagnosis. For 18 patients CSF analysis was available. In 50% of cases the neurologist rejected the initial diagnosis and changed the clinical management. AMY-PET resulted useful to confirm AD in case of uninformative CSF.

Results: The most frequent clinical variants of AD were primary progressive aphasia andposterior cortical atrophy. Visual analysis of the brain revealed similar patterns between early-frame FBB-PET and FDGPET images in atypical AD; however, the scores of abnormal uptake were globally higher in FDG-PET. The Spearman test showed a statistically significant correlation in all brain regions (ρ from 0.798 to 0.927, $P < 0.0001$). and clinicians changed baseline clinical diagnosis in 27% of cases after the result of AMY-PET.

Conclusions: Early-phase FBB-PET acquisitions correlated well with FDG-PET scans in atypical forms of dementia, offering a surrogate marker of brain metabolism. As a consequence, AMY-PET with analysis of early frames may convey added information on metabolism thus reducing patient radiation exposure and health costs by avoiding FDG-PET. AMY-PET is a valid biomarker also in detecting amyloid deposition in atypical variants of AD.

## UTILITY OF FIVE-WORD TEST AS A SCREENING TOOL IN CLINICAL PRACTICE TO IDENTIFY MEMORY DEFICIT SPECIFIC OF ALZHEIMER'S DISEASE

R. Mulargia[1], F. Di Stefano[1], C. Serra[2], S. Porcu[2], G. Fenu[1], G. Cossu[1], M. Melis[1]

[1]Neurology and Stroke Unit, Azienda Ospedaliera G. Brotzu (Cagliari); [2]Psicology, Azienda Ospedaliera G. Brotzu (Cagliari)

Introduction: Alzheimer's disease (AD) is the most common form of dementia, usually characterized by progressive memory deficit of hippocampal type, defined by difficulties on coding, storage and retrieval of the informations without benefit by cueing. While there is a validated second level test to investigate these deficits, (Free and Cued Selective Reminding Test, FCSRT), we lack of screening tools specific for this type of memory deficit uniformely used in Italy. The Five Words Test (FWT) by Dubois [1] is a screening memory tool specifically built to discriminate the hippocampal memory deficit typical of AD and it was recently adapted in Italian language [2]. The aim of our study is to evaluate the diagnostic power of the FWT in the detection of memory deficit of the hyppocampal type.

Materials and Methods: We recruited 13 patients (7 men and 6 women) aged between 68 and 87 years consecutively visited in our

CDCD complaining memory deficits. Patients underwent FWT as a screening during the first assessment and, later a second level battery including: FCSRT, Rey figure test, attentive matrixes, verbal digit span, stroop test, fonemic and semantic fluency, copy of simple figures.

Results: In the cohort there were 3 patients with mild AD (clinical dementia rating scale 0.5-1), 1 patient with vascular dementia, 5 affected by psychiatric disorders, 3 amnestic mci, 1 patient with logopenic PPA. Among patients with AD, 3 out 3 scored pathologically both on FWT and FCSRT. Of the 5 psychiatric patients 4 scored in the normal range for FWT but all the patients had normal scores on the FCSRT. The patient with vascular dementia, performed well on the FWT but was pathological on the FCSRT; Among the 3 patients with amnestic MCI two of them were pathologic on the screening test but only one on the FCSRT; the patient with MCI who performed well on the FWT resulted impaired on the FCSRT. The patient with logopenic variant of PPA scored well in both tests.

Conclusions: Our data show that the FWT is a valid screening tool in distinguishing memory deficit between psychiatric disorders and Alzheimer dementia even in early phases. Results on amnestic MCI cases in our cohort were unconclusive suggesting the heterogeinity of patients in this group and probably the necessity to use a specific and sensitive second level test in this type of patients to identify a real hyppocampal memory deficit. Our data need further validation in bigger cohorts.

## A CASE OF CNS VASCULITIS PRESENTING WITH ACUTE-SUBACUTE ONSET DEMENTIA

M. C. Nicolis Di Robilant, G. Liberatore, F. Terenghi, E. Nobile-Orazio

Neuromuscular and Neuroimmunology Unit, IRCCS Humanitas Clinical and Research Institute, Department of Medical Biotechnology and Translational Medicine, Milan University (Rozzano, Milano)

Vasculitis is a group of diseases characterized by infiltration of inflammatory cells with reactive damage to blood vessel walls of different size. Almost all forms of vasculitis can involve the vessels feeding the brain parenchyma and central nervous system involvement usually manifests with an insidious onset with slow progression. The multifocal characteristic of the lesions determines the absence of pathognomonic signs and symptoms, although headache, focal neurological deficits (mostly stroke or hemorrhage) and seizures are more frequently reported. In the case below, we illustrate a case of vasculitis that presented atypically with an acute-subacute onset dementia. A 61-year-old male with a recent severe trivasal coronary artery disease treated with PCI and a history of hematuria presented to ER for altered mental status, spatial-temporal disorientation, ideomotor slowing and mnestic deficits with a subacute onset. To assess the patient's cognitive status, MMSE and MoCa tests were performed with raw scores of 23/30 and 18/30 respectively; a thorough neuropsychological testing showed a moderate cognitive impairment involving executive and mnestic functions. The brain MRI with contrast showed T2-FLAIR hyperintense lesions in the left corona radiata and right thalamo-capsular region with contrast enhancement in T1-gd images and restriction in DWI scans. Also, SWI scans showed diffuse biemispheric microhemorrhages, black-blood imaging showed enhancement of the terminal portion of both internal carotid arteries and middle cerebral arteries compatible with a possible vasculitis of medium-caliber vessels. In the hypothesis of vasculitis an autoimmune panel was performed on serum, which was negative. A cerebral angio-CT was normal. A lumbar puncture was performed showing hyperproteinorrachia with a normal white blood cells count, but the CSF immunophenotype was suggestive of neutrophilia and monocytosis. Steroid therapy with methylprednisolone 500 mg/day for 4 days was started with mild clinical improvement. The patient was discharged with the indication to continue oral steroid therapy with prednisone 50 mg/day and to start azathioprine 50 mg/day. At follow-up neurological examination after one month, the patient reported a marked improvement in cognitive performance and memory, gaining a score of 28 at the MMSE test. Rarely, vasculitis affecting the central nervous system can manifest as acute-subacute onset dementia and treatment with steroid and cytotoxic therapy can play an important role in improving the patient's cognitive performance.

## TRAILBLAZER-ALZ 4: DIRECTLY COMPARING DONANEMAB TO ADUCANUMAB ON AMYLOID LOWERING IN EARLY, SYMPTOMATIC ALZHEIMER'S DISEASE - RESULTS FROM 12-MONTHS

A. Pain[1], M. Ferguson[1], H. Wang[1], S. Salloway[2], E. Lee[3], M. Papka[4], H. Hu[1], M. Lu[1], E. Oru[1], E. Collins[1], D. Brooks[1], J. Sims[1], F. Torelli[5]

[1]Neuroscience, Eli Lilly and Company (Indianapolis-USA);[2]Department of Neurology and Department of Psychiatry, Alpert Medical School of Brown University and Butler Hospital (Providence-USA); [3]Irvine Clinical Research (Irvine-USA); [4]The Cognitive and Research Center of New Jersey LLC (Springfield-USA);[5]Neuroscience, Eli Lilly Italy (Firenze)

Objectives: The primary outcome of TRAILBLAZER-ALZ-4 (NCT05108922) evaluated the potential superiority of donanemab treatment compared to aducanumab on the percentage of participants with amyloid plaque clearance (≤24.1 Centiloids (CL)) at 6 months in the overall study population and subpopulation of participants with intermediate tau deposition [1]. This abstract presents the secondary analyses of 12-month results of the ongoing study.

Material and Methods: Participants (n=148) were randomized 1:1 to receive donanemab (titration: 700mg IV Q4W [first 3 doses], then 1400mg IV Q4W [subsequent doses]) or aducanumab (titration per USPI: 1mg/kg IV Q4W [first 2 doses], 3mg/kg IV Q4W [next 2 doses], 6mg/kg IV Q4W [next 2 doses] and 10mg/kg IV Q4W [subsequent doses]). The study is ongoing with a total duration of 18 months.

Results and Discussion: Baseline demographics and characteristics were well-balanced across treatment arms (donanemab [N=71], aducanumab [N=69]). Twenty-seven donanemab-treated and 28 aducanumab-treated participants had low/medium (intermediate) tau levels based on screening tau PET scans. In all participants at 12 months, 70.3%±6.2% (least square [LS] mean ± standard error [SE]) donanemab-treated vs. 21.4%±5.8% aducanumab-treated participants achieved amyloid plaque clearance ($p<0.001$) assessed by florbetapir

F18 PET scans. In the low/medium tau subpopulation, 80.0%±9.9% donanemab-treated vs. 9.6%±5.4% aducanumab-treated participants achieved amyloid clearance (p<0.001). The percent change (LS mean ± SE) in brain amyloid levels were -82.8%±3.1% (baseline [LS mean ± standard deviation]: 97.59±28.20 CL) and -56.6%±3.1% (baseline: 102.71±35.30 CL) in donanemab and aducanumab arms, respectively (p<0.001). In the low/medium tau subpopulation, percent change in brain amyloid levels were -82.7%±4.6% (baseline: 104.97±25.68 CL) and -57.0%±4.5% (baseline: 102.99±27.87 CL) in donanemab and aducanumab arms, respectively (p<0.001). The 6-month brain amyloid reduction with donanemab treatment is superior to aducanumab at 12 months (LS mean change ± SE, -63.9±2.8 CL; -55.6±3.0 CL, respectively, p=0.044). Adverse events occurred in 78.9% of donanemab-treated and 82.6% of aducanumab-treated participants, respectively. Amyloid-related imaging abnormalities occurred in 29.6% (1.4% serious [n=1]) and 40.6% (2.9% serious [n=2]) of participants in the donanemab and aducanumab arms, respectively, with higher rates in ApoE4 carriers.

Conclusions: TRAILBLAZER-ALZ 4 provides the first active comparator data on amyloid plaque clearance in patients with early symptomatic Alzheimer's Disease and demonstrates the higher brain amyloid reduction of donanemab compared to aducanumab at 12 months when drug titration has been completed and the treatment regime has stabilized.

## DEMENTIA WITH LEWY BODIES ASSOCIATED WITH PROGRESSIVE APHASIA: SUGGESTIONS FROM MOLECULAR IMAGING IN A CASE-SERIES

V. Pelagotti[1], L. Lombardo[1], F. Massa[1], E. Biassoni[1], G. Bozzo[1], B. Orso[1], P. Mattioli[1], D. Arnaldi[1], N. Girtler[1], A. Brugnolo[1], F. Lanfranchi[2], A. Schenone[1], S. Morbelli[2], A. Chincarini[3], M. Pardini[1]

Introduction: Primary progressive aphasia (PPA) is a dementing disorder characterized by predominant language impairment, primarily associated with frontotemporal lobar degeneration (FTLD) or Alzheimer's disease (AD) pathology [1]. Language impairment in dementia with Lewy bodies (DLB) is not the among the more typical symptoms but can occur in the disease course. However, recent evidence on pathological samples suggests that a PPA may rarely be attributed to Lewy-body pathology [2]. Differentiating the etiologies of PPA can be challenging, and molecular imaging biomarkers may assist in the differential diagnosis in vivo. However, the insights that cerebral metabolism evaluation can provide about the alterations in DLB-PPA remain elusive.

Case-series: We describe seven patients (age 72.7±5.5, 2 females, MMSE score 24.4±4.6, education 12.3±3.5, CDR range 0.5-1) who, at their initial evaluation at our Memory Clinic, presented with language impairment as their chief complaint, significantly impacting their lives. Two of the patients met the diagnostic criteria for PPA3 and were initially diagnosed as either non-fluent PPA or logopenic-PPA, within the spectrum of FTLD or AD pathology based on the results of CSF biomarkers for amyloidosis. However, within a 2-year period, they developed parkinsonism and core features consistent with a probable DLB diagnosis. The others revealed slight disturbances in other cognitive domains, and the core clinical features of DLB were already evident during the diagnostic workup. [18F]FDG PET imaging consistently showed a decrease in glucose metabolism in the lateral temporal region of the dominant hemisphere (left) in all patients. Specifically, the hypometabolism was confined to this region in the two patients diagnosed with PPA, while in the remaining patients, it was observed alongside the typical parieto-occipital hypometabolism seen in DLB. In-depth investigation revealed reduced dopamine transporter uptake in the basal ganglia in all patients, and [123]iodine-MIBG cardiac scintigraphy was abnormal in 4 (2/2 of patients with PPA).

Discussion: These findings suggest that a Lewy-body disorder may underlie PPA. Specifically, the integration of clinical and imaging biomarkers provided an in vivo diagnosis of probable DLB in patients with predominant speech impairment at onset. The specific involvement of the left temporal lateral region may explain language disorders in DLB and indicate a distinct spread of Lewy-body pathology.

Conclusions: The diagnostic work-up of PPA should also incorporate an investigation of the core symptoms of DLB to guide the use of biomarkers, taking also into account that hypometabolism may deviate from the typical parieto-occipital pattern.

## CREUTZFELDT-JAKOB DISEASE (CJD) IN A MAN SURVIVING COVID-19: A CASUAL OR CAUSAL LINK?

A. Perna[1], G. Silvestri[2], S. Baiardi[3], A. Ladogana[4], E. Colaizzo[4]

[1]Center for Neuromuscular and Neurological Rare Diseases, Neurosciences Department, San Camillo Forlanini Hospital (Roma); [2]Institute of Neurology, Catholic University of Sacred Heart (Roma); [3]Department of Biomedical and Neuromotor Sciences, University of Bologna (Bologna); [4]Department of Neuroscience, Istituto Superiore di Sanità (Roma)

Objectives: To describe the rare case of a man surviving COVID-19, presenting with ataxia, subsequently associated with a rapidly progressive dementia, eventually diagnosed to have a sporadic Creutzfeldt-Jakob disease (CJD).

Materials: A 54-year-old man came to our observation for a subacute onset of ataxia, gait disturbance, dizziness, headache, anosmia and hallucinations, followed by rapid cognitive decline, reduced verbal fluency, apathy and urinary incontinence. His past medical history included only hypertension. Two months before, he had contracted SARS-CoV2 infection, and had remained in home isolation for about 40 days.

Methods: Diagnostic assessment included blood and cerebrospinal fluid (CSF) microbiological testing, onconeural antibodies and neural surface antigens antibodies, brain MRI, EEG studies, chest CT scan, CSF prion real-time quaking-induced conversion (RT-QuIC) and 14-3-3 protein analysis, and PRNP sequencing.

Results: Blood and CSF screening and microbiological tests resulted all negative. Chest CT scan documented a mild hypodiafania. Brain MRI showed multiple DWI/FLAIR hyperintensities of caudate and globus pallidus, putamina and thalami. EEG showed short sequences of periodic polyphasic delta waves. Treatment with intravenous steroids and immunoglobulins was promptly tried without any clinical

improvement. In the suspicion of CJD, CSF resulted positive for the 14-3-3 protein, and prion seeding activity was demonstrated by the RT-QuIC assay. PRNP sequencing revealed valine homozygosity (VV) at codon 129 and no pathogenic mutations. Our patient progressed up to mutism, akinetic and fully dependent state, and died two months after the discharge. A brain autopsy was performed. The neuropathologic examination revealed spongiform change, gliosis and neuronal loss, predominantly involving the cerebellum, striatum and thalamus. Immunoblotting detected the abnormal, proteinase-K resistant prion protein (type 2 according with Parchi's classification). There were no findings suggesting for COVID-19 related encephalitis.

Discussion: Before the COVID-19 outbreak, the principal cause of rapidly progressive dementia was certainly prion disease, excluding infectious, metabolic, vascular, neoplastic, and autoimmune disorders. Some recent studies demonstrated that patients surviving COVID-19 can show neuroinflammatory activation of microglia and astrocytes, that might favor the fast development of neurodegenerative diseases, such as CJD. In our case, the neuropathological examination allowed the definite diagnosis of CJD and ruled out a specific neuroinflammatory "phenotype" related to COVID-19 infection. Further studies will address whether SARS-CoV-2 infection could trigger or enhance susceptibility in individuals already at risk for neurological syndromes.

Conclusions: This case expands the spectrum of differential diagnosis of rapidly progressive dementia. Whether COVID-19-related neuroinflammation can accelerate neurodegeneration in CJD still remains elusive.

## IDENTIFICATION OF A NOVEL PSEN1 VARIANT ASSOCIATED WITH POSTERIOR CORTICAL ATROPHY: A CASE REPORT

E. M. Piella[1], F. Roveta[1], A. Marcinnò[1], A. Grassini[1], F. Ferrandes[3], A. Cermelli[1], S. Boschi[1], S. Gallone[2], C. Atzori[3], D. Imperiale[3], P. Dentelli[4], B. Pasini[4], A. Brusco[4], E. Rubino[1], I. Rainero[1]

[1]Department of Neurosciences, University of Turin (Torino); [2]Department of Neuroscience and Mental Health, Città della Salute e della Scienza University Hospital (Torino); [3]Neurology Unit, Maria Vittoria Hospital (Torino); [4]Department of Medical Sciences, University of Turin (Torino)

Introduction and Objective: Posterior cortical atrophy (PCA) is a rare variant of Alzheimer's Disease (AD) that mainly affects the posterior regions of the brain, causing visuospatial and visuoperceptual deficits, alexia and apraxia. While most AD cases occur sporadically, a small percentage (<0.5%) are inherited with an autosomal dominant pattern, due to mutations in three main genes (APP, PSEN1, PSEN2). [1] In this study, we describe the case of a 52-year-old female patient with a clinic-neuroradiological diagnosis of PCA due to AD, and we identified a novel mutation in the PSEN1 gene c.1301 C>T p. (Ala434Val) affecting a critical protein domain.

Materials and Methods: Due to progressive difficulties at work, a 52-year-old woman presented to our Cognitive Disorders Centre. The patient underwent neurological and neuropsychological assessment, neuroimaging investigations (brain CT-scan, MRI, 18FDG-PET and Amyloid PET) and lumbar puncture. Furthermore, considering the presence of dementia in the family history, genotyping of the APOE gene and analysis of 25 dementia-associated genes was obtained using next-generation sequencing (NGS).

Results: The neurological and neuropsychological evaluation revealed mild amnestic and attentional deficit, accompanied by constructive apraxia and diminished visual-spatial abilities. Brain MRI showed predominantly posterior pattern atrophy. 18FDG-PET evidenced marked left predominant hypometabolism in the occipital, parietal, and temporal regions. A clinical-radiological diagnosis of PCA was then made. Cerebrospinal fluid analysis showed a reduction of Aβ42 concentration and Aβ42/40 ratio, and increased t-tau level. The presence of cerebral amyloidosis was confirmed through a PET scan with Flutemetamol. The genotype of the APOE gene was ε3/ε4. NGS sequencing identified the c.1301C>T p.(Ala434Val) variant in the exon 12 of Presenilin-1 (PSEN1; NM_000021.4) gene, confirmed by Sanger sequencing. Based on the American College of Medical Genetics (ACMG) criteria, the variant was classified as likely pathogenic.

Discussion and conclusions: We report the case of a patient with PCA associated with a novel likely pathogenic variant p.(Ala434Val) in the PSEN1 gene. The production of Aβ from the amyloid precursor protein requires a series of proteolytic processes. The point mutation identified in this case introduces a variation in a highly conserved motif, which is recognized as critical for the catalytic activity of γ-secretase. This study corroborates the importance of genetic analysis in patients with early-onset AD and expands the clinical phenotype associated with PSEN1 mutations.

Objective: Plasma p-tau and amyloid markers have been validated in large clinical studies for the diagnosis of Alzheimer's disease (AD). Still, the sensitivity of different techniques and the diagnostic utility at single subject level in predicting CSF AD-related pattern is theme of debate. Objective of this study was to evaluate the ability of lumipulse and SIMOA markers assessment to detect Alzheimer's disease related pathology in clinical setting.

Materials: Consecutive patients with AD and other neurodegenerative disorders underwent CSF analyses and plasma collection.
Methods: Plasma p-tau181, T-tau abeta 1-42, Abeta 1-40, were performed using Lumipulse and SIMOA analyses. The ability of different biomarkers to distinguish AD related pattern in neurodegenerative conditions was evaluated using ROC analyses.

Results: Fifty A+T+N+ AD and 40 other neurodegenerative disorders (NDD) and 40 HC were included in the analyses. P-tau181 were elevated in AD and NDD compared to controls. Plasma p-tau181 assessed by Lumipulse exhibited a strong correlation with CSF pattern and high correlation with SIMOA-plasma detection. The combination of p-tau181 and abeta42 exhibited high diagnostic accuracy for identifying CSF AD pattern (ROC AUC 0.78-0.83).

Conclusions: This study confirmed the construct validity of both Lumipulse and SIMOA techniques for the identification of CSF AD pattern in clinical setting.

## THE ATN FRAMEWORK IN ALZHEIMER'S DISEASE. IS IT TIME TO INCLUDE (F)UNCTIONAL CONNECTIVITY MARKERS?

L. Pini[1], F. Cruciani[2], A. Griffa[3], L. Brusini[2], M. Corbetta[4], G. Menegaz[2], I. Boscolo Galazzo[2]

[1]Padova Neuroscience Center, University of Padova (Padova); [2]Department of Computer Science, University of Verona (Verona); [3]Department of Clinical Neurosciences, University Hospital, Lausanne, Switzerland (Lausanne-CH); [4]Department of Neuroscience, University of Padova (Padova)

Introduction: Different neurodegenerative diseases might mimic Alzheimer's disease (AD) behavioral syndrome. Limbic-predominant age-related TAR DNA binding protein 43 (TDP-43) encephalopathy (LATE) account for 15-20% of all clinically diagnosed AD cases. AD and LATE also share temporal atrophy. Therefore, it is crucial the development of effective model of AD pathophysiology. Recently, the ATN framework (A: amyloid; T: tau; N: temporal lobe neurodegeneration) allowed to shift from a clinical to a biological AD perspective. By applying the ATN framework, we can unravel the similarities between AD and LATE. Brain atrophy without amyloid (A-) and tau (T-) pathology but with temporal neurodegeneration (N+) may indicate LATE with no comorbid AD. Based on these assumptions, we investigated the ATN framework in a large dataset of patients within the AD continuum to identify individuals with typical/atypical profile. Dynamic patterns of brain functional connectivity (dFC) were evaluated, as we hypothesize dFC can provide relevant insights to complement the ATN biological fingerprints due to its close association with protein propagation.

Methods: Data were included from the Alzheimer's Disease Neuroimaging Initiative. Patients were included whether ATN information (biochemical markers, and molecular/structural imaging) and resting state functional imaging (rsfMRI) were collected. Patients were categorized into different groups based on a data-driven approach on ATN features. Concerning rsfMRI, dFC was derived by means of co-activation patterns of the posterior cingulate cortex (PCC), a key region linked with memory. Biological, clinical, cognitive, and dFC measures were compared between sub-cohorts. Finally, we investigated whether dFC could predict patient classification computed with ATN features.

Results: A total of 152 controls and 334 patients were included. Three clusters were identified. The first group exhibited mild pathological alterations in the ATN markers. The second cluster showed evidence of clinical/cognitive impairment and AD pathology. The third cluster displayed similar behavioral impairment but more severe temporal atrophy without tau accumulation, suggestive of a LATE-like profile. Different PCC-dFC patterns were observed among these two latter clusters, particularly in the temporo-occipital regions. PCC-dFC states showed an accuracy around 80% in predicting typical/atypical ATN groups.

Discussion: We identified patients with atypical ATN trajectories within the clinical continuum of AD. These findings suggest the presence of different pathophysiological profiles associated with distinct patterns of dFC between the PCC and the rest of the brain.

Conclusion: Functional connectivity (F) markers can complement the ATN framework and aid in identifying patients with AD-like clinical profiles but with separate underlying pathologies.

Objective: To investigate microstructural gray matter (GM) and white matter (WM) alterations in patients with frontotemporal lobe degeneration (FTLD) and to develop a machine learning (ML) algorithm that classifies patients according to NODDI metrics and neuropsychological data.

Materials: Thirty-five behavioral-variant frontotemporal dementia (bvFTD), 20 semantic variant primary progressive aphasia (svPPA),

14 nonfluent variant primary progressive aphasia (nfvPPA), 9 semantic bvFTD (sbvFTD) and 48 controls were enrolled and performed multi-shell diffusion brain MRI and neuropsychological assessment.

Methods: Fractional anisotropy (FA) maps were computed on diffusion-tensor imaging (DTI); the NODDI multi-compartment model was used to estimate Intra-cellular Volume Fraction (ICVF) and Orientation Dispersion Index (ODI) maps, providing information about neurite morphology and integrity. GM and WM voxel-wise comparisons between FTLD groups were performed using, respectively, tract-based spatial statistics (TBSS) and GM-based spatial statistics (GBSS) in FA, ICVF and ODI maps. Support vector machine (SVM), ML algorithm used for classification of different syndrome, was trained on (i) mean GM and WM values of FA, ICVF and ODI maps subdivided in different regions of interest (brain lobes) and (ii) neuropsychological data.

Results: TBSS and GBSS showed significant differences in different groups relative to controls. FA maps showed widespread WM damage in FTLD patients relative to controls, while no significant differences were found in GM maps. Intriguingly, ICVF maps showed specific damage in FTLD patients relative to controls in the areas considered the epicenter of the neurodegeneration process (bilateral frontotemporal for bvFTD, left temporal-frontal for svPPA and nfvPPA, right temporal for sbvFTD). Moreover, ODI maps showed a GM reduction with a similar, but wider, ICVF-GM pattern. WM alterations in patients relative to controls was also observed: (i) WM reduction in corpus callosum and corona radiata (bvFTD, svPPA, nfvPPA) and right corona radiata (sbvFTD) and (ii) WM increase in temporo-occipital WM bundles (bvFTD) and stria-terminalis (svPPA). SVM model (ICVF+ODI+neuropsychological data) showed a 95.9% accuracy in the correct classification of each patient syndrome.

Discussion: NODDI capture subtle microstructural alterations in GM and WM, demonstrating advantages over standard DTI in FTLD. By combining the rich information from NODDI with cognitive data, ML models can learn complex patterns and relationships to differentiate between different FTLD clinical subtypes.

Conclusions: NODDI and ML algorithm hold potential for advancing our understanding of FTLD pathology and facilitating diagnosis, personalized management and treatment strategies at individual level.

## INFLAMMATORY RESPONSE AND NEUROAXONAL DAMAGE IN PATIENTS WITH EARLY ALZHEIMER'S DISEASE

D. Plantone[1], M. Pardini[2], D. Righi[2], M. D'Alessandro[3], F. Massa[2], C. Manco[1], V. Pelagotti[2], A. Brugnolo[2], E. Bargagli[3], N. De Stefano[1]

[1]Dept of Medicine, Surgery and Neuroscience, University of Siena (Siena); [2]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, University of Genoa, IRCCS Policlinico San Martino (Genova); [3]Respiratory Diseases Unit, Dept of Medicine, Surgery and Neuroscience, University of Siena (Siena)

Objectives: Alzheimer's disease (AD) pathology has been associated with an activation of the immune response. From this perspective, the study of proinflammatory cytokines has gained increasing interest. Several studies have investigated the cytokine levels in AD holding inconclusive results. Thus, their clinical significance is still uncertain. Neurofilament light chain (NfL) is a well-established biomarker that indicates neuroaxonal injury and is gaining increasing interest in neurodegenerative diseases. The aim of this study is to assess the CSF concentrations of NfL, and 13 different cytokines in a cohort of AD patients in the early phases of the disease.

Materials and Methods: CSF samples were collected and stored at -80°C until assay. We used the commercially available immunoassay kits for NfL run on the ultrasensitive SR-X Biomarker Detection System (Quanterix). Concentrations of selected cytokines in the CSF were determined by multiplex bead-based flow cytometry assay (LEGENDplex HU Essential Immune Response Panel – 13plex, BioLegend, San Diego, CA, USA) that allows simultaneous quantification of 13 cytokines. The cytokine panel included IL-4, IL-2, CXCL10 (IP-10), IL-1β, TNF-α, CCL2 (MCP-1), IL-17A, IL-6, IL-10, IFN-γ, IL-12p70, CXCL8 (IL-8), TGF-β1 (Free Active Form).

Results: 24 patients were enrolled in this ongoing study. Patient median age (IQR) was 74 years (71.5-77) and 25% were males. Patients were grouped for disease severity, into those with a MMSE<26 (n=14) and those with a MMSE>27. The first group showed higher CSF concentrations of NfL (median, IQR 201.8 pg/ml, 172.1- 322.5 vs 73.2 pg/ml, 35.8-193.8; p= 0.0068) and IL-6 (median, IQR 2.9 pg/ml, 1.5-4.6 vs 1.5 pg/ml, 0.3-3.7; p= 0.0376) than the second. Interestingly, IL-8 tended to be increased in those patients with a MMSE<26 (median, IQR 24.3, 17.1-33.5 vs 18.1, 7.4-26.4; p= 0.0677).

Discussion and conclusion: The findings of this ongoing study, support the notion of a link between neuroinflammatory processes and dementia and further strengthen the hypothesis that IL-6 may be involved in dementia pathology and cognitive decline.

## EXPLORING THE DIFFERENT PATHWAYS OF ALZHEIMER'S DISEASE AND LEWY BODY DEMENTIA: TRANSCRIPTOMIC ANALYSIS IN DIFFERENT AREAS OF THE HUMAN BRAIN

T. Poloni[1], R. Ferrari[1], V. Fantini[1], M. Garofalo[2], F. Dragoni[2], R. Di Gerlando[2], A. Davin[1], A. Angerame[3], X. Profka[4], V. Medici[5], A. Guaita[4], S. Gagliardi[2]

Introduction and Aims: Senescence is often characterized by a progressive loss of cognitive abilities that may lead to major neurocognitive disorders, whose pathogenesis is largely obscure. Alzheimer's Disease (AD) and Lewy Body Dementia (LBD) are the most frequent forms of degenerative dementia. Our aim is to shed light on their pathogenesis, and generate new attractive hypothesis about it, by the use of novel approaches such asomic sciences.

Material and Methods: In this study, a whole transcriptome analysis and a Gene Set Enrichment Analysis (GSEA) have been carried out on brain samples from hippocampus (HI), temporal and parietal

cortex (TC, PC), cingulate cortex (CG), and substantia nigra (SN). All brains have been characterized according to the Abbiategrasso Brain Bank Protocol, including all the main proteinopathies and vascular scoring [1]. The brains belonged to subjects with a clinical and neuropathological diagnosis of AD and LBD (6 per pathology), and to 3 healthy age-matched controls in duplicate.

Results: Transcriptomic results showed major differences in the number of differentially expressed genes (DEGs) between the two pathologies. In particular, the number of DEGs is strongly higher and more heterogeneous in AD brains compared to LBD brains (DEGsAD=3156; DEGsLBD=278). The GSEA showed that in AD it is possible to cluster the analysed areas by biological processes (HI and TC: DEGs primarily related to synaptic transmission; PC, CG and SN: DEGs primarily related to proper protein folding and inflammation). In LBD there is only a strong and peculiar involvement of SN (DEGs primarily related to proper protein folding and inflammation) and PC (DEGs primarily related to myelination and glial system activation). Conclusions and

Discussion: Although AD and LBD are often coexisting and present a clinical overlap due to the same topography of the lesions, they show a completely different pathogenesis, characterized by the involvement of very different pathways according to a specific pattern that is time- and severity-related. Moreover, AD appears as a more heterogeneous disease than LBD. For both diseases it is possible to draw a molecular map that comes before pathology and spreads inside the brain following a specific and individual trajectory, which could unveil unexplored roads and possible shortcuts leading to a better understanding of their pathogenesis. This approach might help to discover novel biological targets in order to develop effective and personalized therapeutical approaches.

## DYNAMICS OF THE 'COGNITIVE' BRAIN WAVE P3B AT REST FOR AD PREDICTION IN MCI

C. Porcaro[1], F. Ferreri[1], F. Vecchio[2], F. Miraglia[2], G. Zito[3], P. Rossini[3]

[1]Department of Neuroscience, University of Padua (Padova); [2]Department of Theoretical and Applied Sciences, Ecampus University (Novedrate-CO); [3]Brain Connectivity Laboratory Department of Neurosciences & Neurorehabilitation, IRCCS San Raffaele (Roma)

Objective: Alzheimer's disease (AD) is the most common cause of dementia that involves a progressive and irrevocable decline in cognitive abilities and social behaviour, thus annihilating the patient's autonomy. The theoretical assumption that disease-modifying drugs are most effective in the early stages hopefully in the prodromal stage called mild cognitive impairment (MCI) urgently pushes toward the identification of robust and individualized markers of cognitive decline to establish an early pharmacological intervention [1, 2, 3].

Materials: Several studies have reliably shown that changes in the amplitude and latency of the P3b are strongly related to cognitive decline and ageing both healthy and pathological. Here, we used a P3b spatial filter to enhance the electroencephalographic (EEG) characteristics underlying 175 subjects divided into 135 MCI subjects, 20 elderly controls (EC), and 20 young volunteers (Y). The Y group served to extract the P3b spatial filter from EEG data, which was later applied to the other groups during resting conditions with eyes open and without being asked to perform any task. The group of 135 MCI subjects could be divided into two subgroups at the end of a month's follow-up: 75 with stable MCI (MCI-S, not converted to AD), 60 converted to AD (MCI C).

Methods: The P3b spatial filter was built by means of a signal processing method called Functional Source Separation (FSS), which increases the signal-to-noise ratio by using a weighted sum of all EEG recording channels rather than relying on a single, or a small sub-set, of channels.

Results: A clear difference was observed for the P3b dynamics at rest between groups. Moreover, a machine learning approach showed that P3b at rest could correctly distinguish MCI from EC (80.6% accuracy) and MCI-S from MCI-C (74.1% accuracy), with an accuracy as high as 93.8% in discriminating between MCI-C and EC.

Discussion: Finally, a comparison of the Bayes factor revealed that the group differences among MCI-S and MCI-C were 138 times more likely to be detected using the P3b dynamics compared with the best performing single electrode (Pz) approach.

Conclusions: We propose that P3b as measured through spatial filters can be safely regarded as a simple and sensitive marker to predict the conversion from an MCI to AD status eventually combined with other non-neurophysiological biomarkers for a more precise definition of dementia having neuropathological Alzheimer's characteristics.

## TRADITIONAL BOARD GAMES AND PREVENTION OF DEMENTIA: A SYSTEMATIC REVIEW AND META-ANALYSIS

F. E. Pozzi, I. Appollonio, C. Ferrarese, L. Tremolizzo

Neurology Department, Fondazione IRCCS San Gerardo dei Tintori (Monza)

Background: Traditional board games can entail significant skills encompassing several cognitive functions across different domains. Therefore, they may represent a potentially effective intervention to slow down cognitive decline in the aging population. To verify this hypothesis, we performed a systematic review of the literature on traditional board games and dementia.

Methods: We searched five databases with tailored search strings, including studies on elderly subjects at risk of or suffering from cognitive impairment. Studies in which the effect of board games was not separated by cards or other games were excluded. A meta-analysis was performed for specific cognitive and non-cognitive outcomes with enough data available.

Results: Board games improved general cognition compared to controls, as measured by MoCA (I2=75%, MD=2.89, 95%CI 0.96-4.82, p=0.003) and MMSE (I2=92%, MD=2.61, 95%CI 0.45-4.76, p=0.02). Ska and go, but not chess, seem to improve Trail Making Test – part A scores. Mahjong, but not go or chess, seems to improve executive functions, measured with the Shape Trail Test – part B. Board games did not improve Digit Span performance. Mahjong improved categorical fluency, while go did not. Chess significantly improved quality of life measured with the WHO-QoL-OLD scale (I2=63%, MD=7.69, 95% CI 4.84-10.54, p<0.00001), while mahjong temporarily improved depressive symptoms. Go practice

increased BDNF levels and metabolic activity in the left middle temporal gyrus and bilateral putamen.

Conclusions: Traditional board games may slow down cognitive decline and improve quality of life in elderly subjects. Specific games have different impacts on different cognitive domains, possibly mediated by peculiar functional and biological factors.

## DELIRIUM MANAGEMENT (BPSD) IN ALZHEIMER'S DISEASE. COGNITIVE OVERLOAD?

E. Pucci[1], L. Modenese[2], A. Sorrentino[2], V. Mameli[3], I. Torello[3]

[1]Department of Nervous System and Behavioral Sciences, University of Pavia (Pavia); [2]Geriatrics and Gerontology Specialization School, University of Pavia, IDR S. Margherita (Pavia); [3]IDR S. Margherita (Pavia)

Definition: BPSD (Behavioral and Psychological Symptoms of Dementia) identifies the psychic and behavioral symptoms that can accompany the cognitive disorders of people suffering from dementia. It includes symptoms such as hallucinations, depression, apathy, agitation, aggression, wandering, busyness. The prevalence of BPSD is very high in patients with Alzheimer's disease. This symptomatology represents the main cause of the "burden of the caregiver" syndrome which, to a greater extent than the decline in cognitive abilities, is reflected in a decrease in the patient's abilities and causes long hospitalizations and consequent increase in costs.

Burden of Caregiver: "Burden of caregiver" refers to a particular response to chronic stress that is perceived by caregivers, due to their caring actions towards sick family members. It's a syndrome with psychophysical manifestations similar to burnout, with an increasing feeling of tiredness and emotional exhaustion and a general worsening of the quality of life.

Purpose of the Study: The study tries to answer an ethical dilemma: is it more correct to try to obtain an improvement in cognitive abilities and motor skills, with an increased onset of BPSD, or to try to control these symptoms by facing a global cognitive deterioration?

Materials and Methods: We analyzed 4 clinical cases (3 males and one female), median age (75.6+9.7 range 63-79) who had been diagnosed with delirium. Evaluated by psychiatrists and stabilized with major tranquilizers, neuroleptics and anesthetics. The short-term result was an increasing onset of BPSD leading to a need for patient containment and caregiver burden syndrome. Patients then were transferred to the Alzheimer Nucleus of the ASP Santa Margherita di Pavia where pharmacological treatment was set up with atypical (low-dose) antipsychotics, antiepileptics and antidepressants. As reference parameters were detected: MMSE, ADL, IADL and BARTHEL at admission and at discharge.

Results: After 4 weeks there was a compensation of the BPSD with improvement or stationarity of the MMSE and partial recovery of autonomy (ADL/IADL/BARTHEL). Consequently, the risk of burden of the care giver syndrome was also reduced.

Conclusions: The restoration of the sleep-wake cycle represents the starting point for the effective continuation of the treatments. The cooperative effect of drugs with different receptor targets can be exploited to achieve this goal. The polyfactoriality, age and complexity of the receptor interactions within a damaged synaptic network in the course of Alzheimer Disease do not allow us to suggest a unique therapeutic algorithm.

## EARLY STAGE COGNITIVE DISORDER CONTROL (PREMCI/MCI) USING QUEEN CHARLOTTE® (OMEGA3/ASTAXANTHIN ASSOCIATION): PRELIMINARY DATA

E. Pucci[1], L. Modenese[2], A. Sorrentino[2], V. Mameli[3], I. Torello[3], L. Pucci[4]

[1]Department of Nervous System and Behavioral Sciences, University of Pavia (Pavia); [2]Geriatrics and Gerontology Specialization School, University of Pavia, IDR S. Margherita (Pavia); [3]IDR S. Margherita (Pavia); [4]Masters in Nutrition and Clinical Dietetics, University of Pavia (Pavia)

Introduction: QUEEN CHARLOTTE is a food supplement consisting exclusively of oil obtained from the sole head of wild Pacific Sockeye salmon. It is rich in biologically essential substances (which our body is unable to produce) among these, the fatty principles of the omega3 series (EPA) and docohexaenoic acid (DHA) and Astaxanthin, to which the unmistakable red-orange colour. Astaxanthin optimizes the biological effects of omega3 through its antioxidant action.

Objectives of the study: The proposed observational study is aimed at determining the efficacy of Queen Charlotte on cognitive disorders in a selected patient population and, furthermore, establishing the most correct dosage.

Materials and Methods: Cognitive status assessment was determined using test tools (neuropsychological tests: MMSE and SF12 Questionnaire). Blood chemistry parameters were examined such as: Cholesterol, Triglycerides, Folate dosage, Vit.12 and Homocysteine. First administration of the tests at the time of the nosographic classification, after specialist neurogeriatric visit, second administration after 90 days. Subjects attending CDCD clinics of the ASP IDR S. Margherita di Pavia - University of Pavia with cognitive disorders (MCI - Pre-MCI) were recruited.

Results: Between January and April 2023, 28 (16F, 12M) patients with MCI/PreMCI with a mean age of 67 (range: 55-74 years) were treated with Queen Charlotte 3 cp/day for 90 days. MMSE (T0): 25.1; (T1): 27.4, ADL and IADL unchanged. Improved quality of life (SF12) and asthenia.

Conclusion: The correct analysis of the cognitive disorders (MCI and Pre-MCI) treated with Queen Charlotte 3 cp/day for 90 days showed a slight improvement in the MMSE, a stability of the ADL and IADL; good tolerability and no reported side effects.

## USE OF VORTIOXETINE AS A POSSIBLE INTEGRATION OF SEROTONERGIC AND DOPAMINERGIC SIGNALING IN THE CONTEXT OF VASCULAR DEMENTIA: CASE-REPORT

E. Pucci[1], L. Modenese[2], A. Sorrentino[2], V. Mameli[3], I. Torello[3]

[1]Department of Nervous System and Behavioral Sciences, University of Pavia (Pavia); [2]Geriatrics and Gerontology Specialization School, University of Pavia, IDR S. Margherita (Pavia); [3]IDR S. Margherita (Pavia)

Introduction: An 82-year-old male patient comes to our observation for rehabilitation hospitalization in the course of cerebrovascular dementia with behavioral disorders and psychomotor agitation (BPSD), with non-executable MMSE, ADL (0/6) and IADL (0/8); classified as CDR4. Describe Investigate Create Evaluate (DICE) protocol applied. Finding of vascular parkinsonism.

Brain CT: Bilateral ischemic lacunar nucleocapsular outcomes, hypodense patches of the periventricular white matter, radiated crowns and semioval centers due to chronic vascular disease. Start therapy with vortioxetine and levodopa. Already in therapy with anticholinesterases (Rivastigmine 4.6 mg patch/24 h), atypical antipsychotics (Quetiapine 75 mg/day), aceinhibitors (Lisinopril 20 mg/day), calcium channel blockers (Amlodipine 5 mg/day), statin (Simvastatin 10 mg/day) 24 hours after admission and taking the therapy, the patient resumed spontaneous movement and continued with increasing doses of levodopa up to (levodopa/carbidopa 100/25 mgx3/day) and vortioxetine (10 mg/day). At 21 days improvement in MMSE (8.1>12.1) and NPI (34>0) and in CDR functional class (4>3). We wondered whether there could be a correlation between damage to specific subcortical regions and the evolution towards dementia, ie whether the administration of multimodal antidepressants could operate in a protective key or induce a recovery of function. In support of this intuition we cite the effects that certain polymodal antidepressants (Vortioxetine) exert on populations of interneurons expressed in the parahippocampal regions and responsible for movement control, which could perform an action on the limbic-emotional sphere and on mnemonic processes, through the modulation of the bioavailability of dopamine. Thus it can be deduced that the multimodal antidepressant (Vortioxetine) has an action on the serotonergic, noradrenergic, dopaminergic and cholinergic systems.

Conclusion: The therapeutic treatment of cognitive impairment associated with behavioral disorders (BPSD) represents an important therapeutic target; the management of BPSD associated with an improvement in humoral and behavioral disorders and in this case-report, also motor disorders, could allow the patient to return home and reduce the caregiver's emotional and care burden. Very important is the restoration of sleep homeostasis.

## VALIDATION OF A STUDY PROTOCOL FOR THE CONTROL OF EARLY STAGE COGNITIVE DISORDERS (PREMCI/MCI) USING QUEEN CHARLOTTE® (OMEGA3/ASTAXANTHIN ASSOCIATION)

E. Pucci[1], L. Modenese[2], A. Sorrentino[2], V. Mameli[3], I. Torello[3], L. Pucci[4]

[1]Department of Nervous System and Behavioral Sciences, University of Pavia (Pavia); [2]Geriatrics and Gerontology Specialization School, University of Pavia, IDR S. Margherita (Pavia); [3]IDR S. Margherita (Pavia); [4]Masters in Nutrition and Clinical Dietetics, University of Pavia (Pavia)

Introduction: QUEEN CHARLOTTE is a food supplement consisting exclusively of oil obtained from the sole head of wild Pacific Sockeye salmon. It is rich in biologically essential substances (which our body is unable to produce) among these, the fatty principles of the omega3 series (EPA) and docohexaenoic acid (DHA) and Astaxanthin, to which the unmistakable red-orange colour. Astaxanthin optimizes the biological effects of omega3 through its antioxidant action.

Study Objectives: The proposed observational study is aimed at determining the efficacy of Queen Charlotte on cognitive disorders in a selected patient population and, furthermore, at establishing the most appropriate dosage.

Materials and Methods: The evaluation of the cognitive state will be determined using test tools (Neuropsychological Tests: MMSE and SF12 Questionnaire). On the basis of the clinical data collected in a special data collection form, it will also be evaluated whether within this selected population of patients it will be possible to witness a reduction in blood chemistry parameters such as: Cholesterol, Triglycerides, Folate dosage, Vit.12 and homocysteine. First administration of the tests at the time of the nosographic classification, after specialist neurogeriatric visit, second administration after 90 days. Subjects belonging to CDCD clinics of the ASP IDR S. Margherita di Pavia - University of Pavia will be recruited.

Inclusion criteria: patients with cognitive disorders (MCI – Pre-MCI). Exclusion criteria: patients already in therapy with anticholisterases, anti-NMDAs and other therapies with food supplements.

Conclusions: At the end of the protocol, the data will be analyzed for a correct analysis of the cognitive disorders (MCI and Pre-MCI) of the possible response to treatment with Queen Charlotte 3 cp/day for 90 days.

## PLASMA AND CSF AMINO ACID PROFILE OF ALZHEIMER'S DISEASE: A METABOLIC SIGNATURE OF DISEASE

M. C. Ramusino[1], M. Verri[2], M. Dossena[2], A. Costa[1], R. Aquilani[2]

[1]IRCCS Mondino Foundation, University of Pavia (Pavia); [2]Department of Biology and Biotechnology, University of Pavia (Pavia)

Objective: Biochemical alterations linked to the neuronal/astroglial dysfunction affect the molecular composition of the interstitial fluid and of the cerebrospinal fluid (CSF). Pathology and nutritional status can influence the amino acids (AA) levels in the CSF compartment and plasma in subjects with Alzheimer's disease (AD). The aim is to search for a distinct AA profile in AD patients taking into account the nutritional status.

Materials and Methods: In 54 patients with AD (69% males, 74.4 ± 8.2 years) and 17 age-matched control (CTRL) subjects, CSF and venous blood samples were taken for AA measurements. Patients were stratified according to the nutritional status (Mini Nutritional Assessment, MNA, scores).

Results: Compared to CTRL, AD patients showed reduced levels of aspartic acid, and increased levels of taurine and 3-methyl-histidine ($p<0.001$). In addition, amyloid correlated inversely with histidine ($p < 0.05$), while p-tau correlated positively with levels of serine and glycine ($p < 0.05$). In the combined group (CG) including malnourished AD (16.7%; MNA < 17) and AD at risk for malnutrition (36.6%, MNA 17−24), essential amino acids (EAAs)/Total AA (TAA) ratio and Branched-Chain AA (BCAA)/TAA ratio were lower compared to normo-nourished AD ($p<0.05$). As for the subjects with available CSF, CG had lower levels of all CSF essential amino acids (EAAs) and 30% of non-EAAs compared to the CTRL ($p < 0.018$ to 0.0001), whereas normo-nourished AD (46.7%, MNA > 24) had lower levels of 10% of EAAs and 25% of non-EAAs ($p < 0.05$ to 0.00021). Finally, compared to normo-nourished AD, CG had lower CSF levels of aspartic acid, glutamic acid and BCAA (all, $p < 0.05$ to 0.003).

Discussion: Low levels of aspartic acid are related to a mitochondrial energetic dysfunction, increased levels of taurine are associated with neuroinflammation, while high histidine and low leucine and glutamic acid with the impairment of the leucine-glutamate shuttle. After deamination, EAAs in particular BCAAs provide carbon skeletons useful for replenishing the Krebs cycle and maintaining an adequate neuronal energy balance.

Conclusion: AD patients had low levels of some AA in plasma and CSF, particularly EAA and BCAA. The amino acid profile is an expression partly of the metabolic signature of the disease, partly of the ongoing nutritional status.

ebrospinal fluid and plasma in Alzheimer's disease and healthy control subjects. Neural. Transm. Park. Dis. Dement. Sect (1990);2:295-304

## PLASMA GFAP LEVELS CORRELATE WITH PHYSICAL ACTIVITY AND BODY COMPOSITION: A BIOELECTRIC IMPEDANCE ANALYSIS STUDY ON HEALTHY ELDERLY POPULATION

A. Rizzardi[1], M. Bugada[2], C. Zatti[1], M. Catania[1], C. Tirloni[3], A. Lupini[1], A. Pilotto[1], A. Padovani[1]

[1]Department of Clinical and Experimental Sciences, University of Brescia (Brescia); [2]General Medicine Unit, Pesenti Fenaroli Hospital (Alzano Lombardo-BG); [3]Neurology Unit, ASST Spedali Civili Brescia (Brescia)

Introduction and Aim: Glial fibrillary acidic protein (GFAP) is a key player in astrocyte functions, thus modulating regeneration, synaptic plasticity and reactive gliosis. Several studies show a strong relationship between CSF GFAP and plasma levels detected by newly developed SIMOA detection methods. Physical activity (PA) enhances the production of neurotrophic factors, neurotransmitters, and hormones but no data about the relationship between PA and GFAP exist yet. The aim of the study is to evaluate the complex interaction between body composition and the plasma biomarker in neurologically healthy population.

Materials and methods: The prospective study included ninety healthy elderly individuals neurologically intact (65.9±7.1 years). Each individual underwent a multidimensional assessment including evaluation of physical activity, cognitive status and comorbidities. All individuals underwent a body composition assessment using bioelectric impedance analysis (BIA) and a blood sample was collected. Plasma GFAP levels were evaluated using SIMOA technique.
Results: According to International Physical Active questionnaire (IPAQ), very active subjects (VA, n=33) showed lower GFAP level in blood ($p<0.02$) than inactive (IN) and active (AC) subjects (n=57). No differences were founded between IN and AC. BIA showed a negative correlation between skeletal muscle index (SMI) ($r= -0.224$, $p<0.05$) and fat free mass index (FFMI) ($r= -0.235$, $p<0.05$) with GFAP levels in plasma.

Discussion and conclusions: This prospective study suggested that high levels of PA and body composition indexes might be neuroprotective trough their indirect action on astrocytes activation. Further on-going studies evaluating subtle inflammatory mediators and longitudinal changes of biomarkers are warranted to understand the predictive value of GFAP in healthy ageing.

## CEREBRAL AMYLOID ANGIOPATHY-RELATED INFLAMMATION: A SINGLE CENTER LONGITUDINAL STUDY ON SURVIVAL AND INCIDENT DEMENTIA

F. Rossato[1], N. Ravì[1], G. Zorzi[1], S. Mozzetta[1], A. Petullà[1], F. Piazza[2], R. Manara[1], A. Cagnin[1]

[1]Department of Neuroscience, University of Padova (Padova); [2]Department of Medicine and Surgery, University of Milano-Bicocca (Milano)

Introduction: Cerebral amyloid angiopathy-related inflammation (CAA-ri) is characterized by an anti-amyloid immune response towards cerebrovascular-deposited amyloid-beta protein (Aβ) and the radiographic appearance of amyloid-related imaging abnormalities due to edema (ARIA-E), often associated with ARIA-H micro-hemorrhagic markers of CAA on magnetic resonance imaging (MRI). Clinically, the condition may present with focal neurological signs, epilepsy and acute and rapidly progressive cognitive impairment. Little is known about the natural history or predictive factors of relapse or clinical worsening, apart from a heightened haemorrhagic risk associated with sulcal siderosis and clinical improvement after immune-suppressive therapy. Aim: To longitudinally assess a cohort of patients with a diagnosis of probable CAA-ri describing clinical presentation, instrumental findings and long-term outcomes.

Methods: Patients with a diagnosis of probable CAA-ri according to current clinical-radiological criteria were recruited at a single center at the Department of Neuroscience in Padova (part of ICAB and SINdem CAA Study Group) from August 2013 to May 2023. Inclusion criteria were: MRI images of good quality on T2*/SWI and FLAIR sequences and clinical and cognitive findings collected both at (sub)acute presentation and at least one follow up visit. ApoE genotyping and CSF chemical-physical and AD-related biomarkers.

Results: Twenty-one patients (mean age 72 years, 57% male) were recruited and followed for a mean time of 2,6 years +/- 2,7 (minimum 0,05, maximum 8,6 years). At presentation, 76% of patients had focal neurological signs (sensitive/motor signs, visual disturbances, aphasia), 38% cognitive deficits, 29% seizures (10% status epilepticus), and 19% alteration of consciousness or headache. CSF analysis was abnormal in 48% patients (mean 12 WBC +/- 31, QAlb at higher normal value). At first 81% had multifocal ARIA-E, 61% with a diameter less than 5 cm. At follow up, 3 patients had a CAA-ri relapse, 14% did not improve after steroid therapy. Kaplan Meier analysis showed a 30% of mortality after 2 years and occurrence of dementia in 55% of cases. Survival was not associated with presence and length of steroid therapy. 75% of patients developing dementia met the biomarker criteria for Alzheimer's disease continuum pathological changes.

Discussion: CAA-ri is an increasingly recognized and diagnosed autoimmune encephalopathy which presents with a wide range of symptoms and may have a poor long-term outcome both for survival and for development of dementia, mainly of AD-type. Early diagnosis and treatments with immune-suppressive therapy and strict surveillance to intercept evolving cognitive decline or inflammatory relapses should be considered.

## A FUNCTIONAL VARIANT IN GRIN2C IDENTIFIED IN AN ITALIAN FAMILY WITH LATE-ONSET ALZHEIMER'S DISEASE

E. Rubino[1], M. Italia[2], E. Giorgio[3], S. Boschi[1], P. Dimartino[3], T. Pippucci[4], F. Roveta[1], C. Cambria[5], G. Elia[1], S. Gallone[6], E. Rogaeva[7], F. Antonucci[5], A. Brusco[8], F. Gardoni[2], I. Rainero[1]

Background: Alzheimer's disease (AD) is the most common type of neurodegenerative dementia, but the cause of AD remained poorly understood. In early-onset Alzheimer disease, positional cloning led to the identification of rare, disease-causing variants in APP, PSEN1, and PSEN2 gene. Late-onset AD represents the most common form of the disease and is associated with several confirmed Alzheimer's

disease loci [1, 2]. The aim of this study is to describe the clinical, genetic and functional studies of an Italian, autosomal-dominant late-onset Alzheimer's disease pedigree carrying a new rare variant in the glutamate ionotropic receptor NMDA type subunit 2C (GRIN2C).

Methods: We describe a targeted exome sequencing analysis of a large Italian kindred with late-onset AD with a typical clinical presentation, negative for APP, PSEN1, and PSEN2 variants. Previous analysis using NeuroX array excluded further mutations linked to neurodegenerative disorders. Whole Exome Sequencing (WES) on the three affected subjects and two healthy relatives was performed. Bioinformatic analysis of WES data followed a general pipeline previously described to identify single nucleotide variants and small insertions and deletions. Functional analysis was performed using neuronal cells cultures, immunocytochemistry, and electrophysiology.

Results: The c.3215 C>T (p.Ala1072Val) in GRIN2C (NM_000835) was identified and validated by Sanger sequencing. The segregation of the variant with the disease in the family was confirmed in a total of 8 affected subjects and in 6 healthy relatives. Primary hippocampal neurons overexpressing GluN2C A1072V showed significantly increased NMDAR-induced currents associated with an increase surface level of the mutant subunit. Furthermore, GluN2C A1072V change is close to the binding motif of 14-3-3 scaffolding proteins, and an impaired colocalization of the mutant GluN2C with 14-3-3 was detected.

Discussion: GRIN2C mRNA is widely expressed in the brain, and the Ala1072Val variant was considered of interest based on DANN pathogenicity scoring, allele frequency in the general population (GnomAD database). Functional whole-cell voltage clamp recording on GluN2C A1072V overexpressing hippocampal neurons clearly showed an increase of NMDAR-induced currents. Moreover, we demonstrated that GluN2C A1072V change impaired GluN2C colocalization with 14-3-3 scaffolding proteins which could result from the fact that the site of the mutated aminoacid is close to the binding motif of these proteins.

Conclusion: In this study, we report for the first time a rare missense variant in GRIN2C causing late-onset Alzheimer's disease, and our study provides interesting data supporting a role for the GluN2C-containing NMDARs and 14-3-3 proteins in Alzheimer's disease pathogenesis.

## REAL-WORLD APPLICATION OF THE AT(N) CLASSIFICATION FOR ALZHEIMER'S DISEASE: A COMPREHENSIVE STUDY OF A HOSPITAL-BASED POPULATION

G. Rugarli[1], E. Canu[1], F. Coraglia[1], S. Basaia[1], S. Calloni[2], P. Vezzulli[2], G. Cecchetti[3], R. Santangelo[4], F. Caso[5], G. Magnani[5], F. Agosta[3], M. Filippi[6]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [2]Neuroradiology Unit and High Field MRI Center, IRCCS San Raffaele Scientific Institute (Milano); [3]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [4]Neurology Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute (Milano); [5]Neurology Unit, IRCCS San Raffaele Scientific Institute (Milano); [6]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objective: Alzheimer's disease (AD) is a significant global health concern with an increasing social and economic burden. The AT(N) classification system was created to stratify patients based on biomarker profiles, including amyloid-beta deposition (A), tau pathology (T), and neurodegeneration (N), providing a research framework for understanding disease heterogeneity. This study aims to apply the AT(N) classification to a hospital-based cohort of patients with cognitive decline and/or dementia, within and outside the AD continuum, to enhance our understanding of the multidimensional aspects of AD and related disorders.

Materials: We conducted a retrospective evaluation of 429 patients referred to the Memory Center of IRCCS San Raffaele Hospital in Milan. Clinical, neuropsychological, and neurobehavioral assessments were performed, along with lumbar puncture, structural imaging with magnetic resonance imaging (MRI) or computed tomography (CT) scans, and functional imaging using positron emission tomography (FDG-PET).

Methods: The cohort was stratified according to the AT(N) classification, and comparisons were performed between groups. The number of eligible cases for anti-β amyloid monoclonal antibodies was also calculated.

Results: Sociodemographic and clinical features were similar across groups. Although the clinical presentation was similar, the A+T+N+ group showed more severe cognitive impairments in memory, language, attention, executive, and visuospatial functions compared to other AT(N) groups. FDG-PET outperformed MRI and CT scan in distinguishing amyloid-positive from amyloid-negative patients. Among the observed cases, only 6% were eligible for amyloid-targeting clinical trials.

Discussion: The findings support the applicability of the AT(N) classification in a real-world clinical setting. The classification system provided insights into clinical management and treatment strategies. Differences in neuropsychological performance and imaging features among the AT(N) groups further contribute to our understanding of the disease. This work provides also a realistic picture of the low proportion of AD patients eligible for disease modifying treatments.

Conclusions: This study emphasizes the need for early detection and personalized treatment approaches to address the challenges of AD.

## APPLICATION OF ARTIFICIAL INTELLIGENCE TO STANDARD CLINICAL DATA IN PRODROMAL ALZHEIMER'S DISEASE: HOW FAR ARE WE?

M. Russo[1], D. Nardini[2], M. Punzi[1], S. Melchiorre[1], G. Polito[1], C. Ciprietti[1], F. Dono[1], M. Onofrj[1], S. Sensi[1]

[1]Department of Neuroscience, Imaging, and Clinical Sciences, "G. d'Annunzio" University of Chieti-Pescara (Chieti); [2]Biotechnology Unit, ASC27 (Roma)

Background and Aim: Machine Learning (ML) techniques are increasingly employed to support research from a data-driven point of view in neurodegenerative conditions, like the Mild Cognitive Impairment-Alzheimer's Disease (MCI-AD) continuum. To achieve optimal accuracy, the algorithms are typically fed with a wealth of data unavailable in the standard clinical practice (e.g., cortical thickness, metabolomics). Thus, their routinary application is debatable and limited. We assessed the feasibility of ML application to standard and readily available clinical data in cognitively normal and Mild Cognitive Impairment (CN, MCI) subjects to predict a 3-year change in their cognitive status.

Methods: CN and MCI were selected from the ADNI dataset according to the availability of demographic, CSF, neuropsychological

measures, and a 3-year follow-up. Subjects were divided into CSF-positive and CSF-negative according to t-tau/abeta ratios (from Hansson et al.). A gradient boosting algorithm was combined with Random Forest's variables ranking and applied to the two cohorts. The goal was to predict the 3-year conversion, assess the model's accuracy, and identify differences in the predictors according to the CSF status. SHAP analysis was then applied to analyze the decisional processes of the algorithm.

Results: Our model achieved 90.0% prediction accuracy in patients with negative CSF, while 87.5% accuracy was obtained in patients with a positive CSF ratio. We also found differences between CSF-positive and negative patients regarding the most valuable predictors and suggested cut-offs.

Conclusions: Our approach yielded remarkable prediction accuracy only using standard clinical data and could be easily implemented.

## VALIDATION AND NORMATIVE VALUE STUDY OF COGNISTAT IN THE ITALIAN POPULATION

F. Saccà, T. Costabile

NSRO Department, Federico II University (Napoli)

Background: Early detection of neurocognitive disorders frequently relies on the Mini Mental State Examination (MMSE) or the Montreal Cognitive Assessment (MoCA) for screening purposes. Unfortunately, both tests have low sensitivity in detecting mild cognitive impairment (MCI) or mild dementia. COGNISTAT is an international test designed to assess intellectual functioning in the five major ability areas: Language, Spatial Skills, Memory, Calculations, and Reasoning. Level of Consciousness, Attention, Memory Registration, and Orientation are assessed independently. In each area, the patient is first presented with a screen test, that is failed by approximately 20% of normal individuals. If the patient passes the screen, no further testing is done in that section. If the screen is failed, the examiner administers the metric, a series of test items of increasing difficulty. In this way, intact areas of functioning are tested briefly, while areas of disability are studied in detail.

Methods: We translated and then tested an Italian version of the COGNISTAT in a population of healthy volunteers enrolled at our outpatient clinic. After signing the informed consent, volunteers underwent a socio-demographic data collection (Age, sex, education, medical history, medication use, employment status, family medical history), and two neuropsychological evaluations with the MoCA and the MMSE, and then the computer based COGNISTAT test. For the aim of this study, COGNISTAT was administered using both the screen and metrics part of the test, even if volunteers passed the screening questions.

Results: We enrolled 210 healthy volunteers aged 18-84 years, and stratified them in 7 age groups, 30 patients for each group: 18-40, 41-59, 60-64, 65-69, 70-74, 75-79, >79. Mean ± Sandard Deviation of the COGNISTAT scores for every age group were: 79.9±2.8 (18-29 years), 79.2±4.5 (30-49 years), 76.1±5 (50-59 years), 76.3±3.2 (60-69 years), 72.3±5.0 (70-79 years), 65.9±3.8 (>79 years). COGNISTAT scores correlated with MoCA (0.656; $p<0.001$) and less with MMSE (0.391; $p<0.001$). Age had a significant impact on all sub scores of COGNISTAT, except for orientation, attention, and registration. Gender had a significant impact on attention ($f = 7.668$; $p=0.007$). We found no impact of the interaction between age and gender. We also calculated normative values corrected for gender, age and education.

Conclusion: COGNISTAT is a reliable and useful tool that can aid in the diagnosis of cognitive disorders in the Italian population. Compared to other screening tools, it combines reduced administration time with a defined output that allows for a neuropsychological diagnosis.

## ENLARGED PERIVASCULAR SPACES ARE ASSOCIATED WITH CEREBROSPINAL FLUID AQUAPORIN-4 AND TAU LEVELS IN PATIENTS WITH NEURODEGENERATIVE DEMENTIA

L. Sacchi[1], M. Arcaro[2], T. Carandini[2], A. Pietroboni[2], G. Fumagalli[3], C. Fenoglio[1], M. Serpente[2], F. Sorrentino[1], C. Visconte[1], M. Pintus[4], G. Conte[2], V. Contarino[2], E. Scarpini[2], F. Triulzi[1], D. Galimberti[1], A. Arighi[2]

Background: Perivascular spaces (PVS) are fluid-filled compartments that dilate in response to many different conditions. A high burden of enlarged PVS (EPVS) in the centrum semiovale (CSO) has been linked to neurodegeneration. Moreover, an increase in cerebrospinal fluid (CSF) levels of aquaporin-4 (AQP4), a water channel expressed on PVS-bounding astrocytes, has been described in patients with neurodegenerative dementia. Our aim was to investigate the relationship between neurodegenerative diseases and two putative glymphatic system biomarkers: AQP4 and EPVS.

Methods: We included 70 individuals, 54 patients with neurodegenerative diseases and 16 subjects with non-degenerative conditions. EPVS were visually quantified on MRI-scans according to Paradise et al. All subjects underwent lumbar puncture for the measurement of AQP4 levels in the cerebrospinal fluid (CSF). CSF levels of

amyloid-β-1-42, phosphorylated and total tau (tTau) were also measured. Linear regression analyses were adjusted for age, sex, education and disease duration.

Results: CSF-AQP4 levels were independent predictors of total (β = 0.33, standard error [SE] = 0.09, p < 0.001), basal ganglia (β = 0.29, SE = 0.08, p = 0.006) and centrum semiovale EPVS (β = 0.53, SE = 0.17, p = 0.002). tTau levels predicted CSO-EPVS (β = 0.40, SE = 0.19, p = 0.046). Moreover, increased levels of AQP4 were strongly associated with higher levels of tTau in the CSF (β = 0.36, SE = 0.13, p = 0.006).

Conclusions: We provide evidence that CSO-EPVS and CSF-AQP4 might be clinically meaningful biomarkers of neurodegeneration secondary to glymphatic dysfunction.

## ASSOCIATION BETWEEN FRAILTY AND NEUROPHYSIOLOGICAL MEASURES OF PERIPHERAL NERVE CONDUCTION

M. Salzillo, M. Canevelli, G. Di Stefano, G. Bruno, A. Truini

Department of Human Neuroscience, Sapienza University of Rome (Roma)

Introduction: Frailty is a marker of biological age and has been associated with a higher risk of adverse neurological outcomes. Specifically, frailty has been shown to increase the risk of for diverse illnesses affecting the central nervous system and to predict unfavourable disease courses. To date, no studies explored its impact on the pathophysiological mechanisms and neurophysiological measures of the peripheral nervous system. The present study aimed at investigating the association between frailty and quantitative neurophysiological parameters in patients with no peripheral nervous system disorders.

Materials: Patients who were subjected to a nerve conduction study at the Department of Human Neuroscience, Sapienza University of Rome were considered for the present analysis. Data about age, date of birth, sex, medical history, current therapies, and diagnostic question were collected.

Methods: Frailty was assessed through a Frailty Index (FI), designed on the model of deficit accumulation. A total of 36 items constituted by symptoms, signs, diseases, disabilities, and laboratory findings were included in the index. For each participant, the FI score was obtained by dividing the number of deficits presented by the subject and the total number of items (i.e., 36). Spearman's correlations were conducted to explore the association between FI and the SNAP amplitude of the right sural and ulnar nerve expressed in mV.

Results: Overall, 25 participants (mean age 59.9, standard deviation [SD] 16.1; 64.7 % women) were recruited. The mean FI score was 0.20, SD 0.13. SNAP amplitudes were significantly, inversely correlated with age (ulnar: rho = -0.48, p = 0.03; sural: rho = -0.73, p < 0.001). A negative correlation was also observed between SNAP amplitudes and FI scores, although not statistically significant (ulnar: rho = -0.09, p = 0.03; sural: rho = -0.73, p = 0.06). In partial correlations adjusted by FI, age was no longer correlated with the SNAP amplitude of the ulnar nerve (rho = -0.35, p = 0.18); the correlation coefficient between age and the SNAP amplitude of the sural nerve decreased to -0.54, p = 0.03.

Discussion: The negative correlation between increasing age and measures of SNAP amplitudes seems to be partly moderated by frailty. The FI may be useful to explore the impact of the ageing process on peripheral nerve conduction, beyond chronological age.

Conclusions: Future studies are needed to clarify how frailty the pathophysiology of the peripheral nervous system and the clinical expression of its disorders.

## DEMENTIA WITH LEWY BODIES FOLLOWING NORMAL PRESSURE HYDROCEPHALUS: COMORBIDITIES OR CAUSAL LINK? CASE REPORTS AND A COMPREHENSIVE REVIEW OF THE LITERATURE

C. Santoro[1], S. Landolfo[1], V. Velucci[1], D. Urso[2], G. Milella[1], A. Introna[1], G. Iliceto[1], G. Logroscino[2]

[1]Department of Basic Medical Sciences, Neuroscience and Organ Sense, University of Bari "Aldo Moro" (Bari); [2]Center for Neurodegenerative Diseases and the Aging, Department of Clinical Research in Neurology, University of Bari "Aldo Moro", "Pia Fondazione Cardinale G. Panico" (Tricase-LE)

Objectives: Reports about comorbidity between idiopathic Normal Pressure Hydrocephalus (iNPH) and neurodegenerative diseases have been recently increased in literature, but mechanism underlying their causal link has not yet fully defined. Many cases of iNPH have been proven to be synucleinopathies such as Dementia with Lewy Bodies (DLB), after several years of follow-up[1].

Materials: Herein we report two our recent clinical cases of DLB patients started as iNPH, and we review literature focusing on potential clinical or fluid biomarkers that could help clinicians to distinguish these two nosological entities.

Methods: We described two male patients that were admitted to our department due to impaired gait and cognitive issues presenting with a NPH radiologic pattern. We also reported all clinical case series that we have found in literature focusing on patients initially described as iNPH who developed clinically or pathologically proven DLB. Motor and non-motor symptoms as well as cerebrospinal fluid (CSF) and serum biomarkers were tested as potential red flags for the diagnosis of DLB.

Results: Among all symptoms and clinical signs, early or late-onset axial parkinsonism together with postural impairment and repeated falls should mostly lead us towards DLB diagnosis, along with an early cognitive involvement and alertness fluctuations. However, visual hallucinations remain the most representative of synucleinopathy. Additionally, transient motor or non-motor improvement after shunt placement does not exclude the possibility of an underlying neurodegenerative process [2]. CSF total-Tau levels of our first patient remained high (>1000 pg/ml) from the prodromal until the dementia stage of DLB history. Both (123I) FP-CIT SPECT with DAT-scan and (123)I-meta-iodobenzylguanidine (MIBG) cardiac scintigraphy tested positive in both patients.

Discussion: Having total-tau levels increased by one standard deviation was 2.5 times more frequent in LBDs relative to iNPH [1]. CSF Alpha-synuclein assay could also be useful for diagnosis, although not always available in routinary clinical practice.

Considering that symmetrically reduced DaT uptakes in the caudate nucleus could be a common finding in the locomotor iNPH subtype [3], MIBG can help in differential diagnosis, being altered only in DLB and not in iNPH.

Conclusions: Hydrocephalus should be considered not only as a single pathology but also as a prodromic pattern of several degenerative diseases. Relying on its link with alpha synuclein, CSF value of tau protein could probably be considered as an early predictive biomarker of motor and non-motor impairment in prodromal DLB patients, allowing clinicians to make a correct differential diagnosis against iNPH.

## CSF BIOMARKERS FOR ALZHEIMER'S DISEASE ON FUJIREBIO'S LUMIPULSE AND ROCHE'S ELECSYS FULLY AUTOMATED PLATFORMS IN CLINICAL PRACTICE: DIAGNOSTIC ACCURACY AND CONCORDANCE

A. Scalese, D. Quaranta, G. Giuffrè, M. Vita, T. Morganti, A. Rosati, G. De Ninno, P. Calabresi, C. Marra

Neurology, Catholic University of the Sacred Heart (Roma)

Background: In the last decades the implementation of cerebrospinal fluid (CSF) biomarkers of amyloidopathy (Aβ42 and Aβ42/40), tauopathy (p-tau) and neurodegeneration (t-tau) in clinical practice has significantly enhanced the identification of Alzheimer's disease (AD) pathological processes in vivo, leading to improved diagnostic accuracy and better selection for clinical trials. CSF biomarkers can be measured using various methods, among which the most widely used in clinical practice are two fully automated platforms: Lumipulse by Fujirebio (based on a chemiluminescent enzyme immunoassay) and Elecsys by Roche (based on an electrochemiluminescence immunoassay). This study aimed to assess the concordance between CSF biomarker measurements obtained from these two methods and evaluate their diagnostic performance in comparison to clinical diagnosis.

Methods: We consecutively recruited 60 subjects who were candidates for CSF biomarker analysis from our Memory Clinic. CSF biomarkers were quantified using both Lumipulse and Elecsys instruments and ratios were calculated. Correlations between CSF biomarkers were performed by the means of Spearman's correlation coefficient and ROC analyses were carried out.

Results: Our results revealed a high correlation between biomarker measurements obtained from the two methods ($\rho$=0.918 for Aβ42; $\rho$=0.984 for p-tau; $\rho$=0.943 for t-tau; $\rho$=0.937 for p-tau/Aβ42; all p values <0.001). When considering the three possible biomarkers of amyloidopathy (Aβ42 and Aβ42/40 ratio for Lumipulse and Aβ42 for Elecsys), we found that 11 subjects tested negative for all amyloidopathy biomarkers, 22 subjects tested positive for all of them, and 27 subjects tested positive for only one or two biomarkers, indicating a low concordance between the manufacturer cut-offs. The p-tau/Aβ42 ratio measured by both instruments showed the highest accuracy in distinguishing AD subjects.

Discussion & Conclusion: Our study demonstrated a strong correlation between CSF biomarkers measured using Lumipulse and Elecsys. However, when considering individual measures of amyloidopathy, the sensitivity and specificity of manufacturer cut-offs differed, leading to relevant false positive and false negative rates. The p-tau/Aβ42 ratio emerged as the most accurate measure, compensating subjects misclassified by individual measures of amyloidopathy. Relying solely on a single biomarker of amyloidopathy can lead to inconsistent results and potentially misclassify individuals, while the use of the p-tau/Aβ42 ratio may enhance the identification of AD. This could be particularly relevant for clinical trials, where subjects are typically selected on the amyloidopathy criteria alone. According to the ATN classification AD is better defined by the presence of both amyloidopathy and tauopathy and our results on the p-tau/Aβ42 ratio support this evidence.

## THE FREQUENCY OF APOLIPOPROTEIN E EPSILON4 ALLELE ACCORDING TO NIA-AA RESEARCH FRAMEWORK: A RETROSPECTIVE COHORT STUDY FROM TOR VERGATA HOSPITAL

C. Serafini[1], S. Falletti[1], C. Bonomi[1], M. Bruno[1], F. Bernocchi[1], C. Motta[1], N. Mercuri[2], A. Martorana[1]

[1]Memory Clinic, Policlinico Tor Vergata, University of Rome "Tor Vergata" (Roma); [2]Neurology Unit, Policlinico Tor Vergata, University of Rome "Tor Vergata" (Roma)

Background and Objectives: According to NIA-AA research framework, based on biomarkers accounting for Amyloid-Beta deposition (A), presence of fibrillar tau tangles (T), and neurodegeneration (N), it is possible to stratify patients in the AD continuum (ADc) [1]. Apolipoprotein E (APOE) is the strongest genetic risk factor for AD, and we know that the epsilon4 allele increases the AD risk compared to epsilon3 and epsilon2 allele [2]. In the NIA-AA research framework genetics is included only as a risk factor for the development of the disease, mainly due to the fact that it is not representative of neuropathologic changes. Nevertheless, it has been demonstrated that APOE epsilon4 is associated to both higher amyloid-beta accumulation and Tau iper-phosphorylation. To our knowledge a report on the prevalence of the APOE epsilon4 according to a biological classification of AD is lacking. The aim of this study is to analyse the frequency of APOE epsilon4 in AD patients, stratified according to NIA-AA, and in subjects with negative AD biomarker.

Materials and methods: We enrolled 1201 patients from Tor Vergata Hospital, which underwent blood screening for APOE genotype and measurement of amyloid-beta, total tau and phosphorylated tau in the Cerebrospinal Fluid (CSF) for diagnostic purpose. According to AD biomarkers all enrolled subjects were stratified in A+T+ (AD, n=263), A+T- ("Alzheimer's pathologic change", n=398), and A-T- (non-AD pathology, n=540).

Results: We observed that the frequency of APOE epsilon4 allele was significantly different in the three groups, in particular the ε4 allele was expressed in the 45.7% of A+T+ patients, 30.4% of A+T- and 15.6% of A-T- ($\chi 2$ test p<0.05).

Discussion and conclusions: APOE epsilon4 allele was significantly more expressed in A+T+ patients than in A+T- group, and in the latter respect to A-T- subjects. The A+T- group represents, in terms of APOE genotype distribution, a population in its own, different from both AD and non-AD subjects. Our data support the necessity to further investigate in the pathophysiological process underlying "Alzheimer's pathologic change" to clarify whether this category is considerable as a stage of AD or a distinct nosological entity.

## INHIBITION AND FACILITATION EFFECTS ALONG THE AD SPECTRUM: A VOXEL-BASED MORPHOMETRY STUDY

L. Serra[1], C. Di Domenico[1], S. Bonarota[1], G. Caruso[1], V. De Sangro[2], M. Assogna[3], M. Rodini[4], L. Mencarelli[4], F. Di Lorenzo[4], G. Koch[4,5], L. Fadda[6], C. Caltagirone[7], M. Bozzali[8]

Objective: In the context of episodic memory, it was proposed that remembering an item implies forgetting for other related items (i.e., retrieval-induced forgetting-RIF) (1), while practicing a certain item induces facilitation for its subsequent retrieval (i.e., facilitation effect-FAC) [1]. However, this paradigm and its underlying mechanisms remain controversial in healthy as well as in pathological aging [1-2]. We aimed here to investigate RIF and FAC and their putative neural correlates in the Alzheimer disease (AD) continuum.

Methods: 28 AD and 29 amnestic mild cognitive impairment (aMCI) patients, 23 individuals with subjective memory complaint (SCD), and 20 healthy subjects (HS) underwent a recognition memory task to assess RIF and FAC effects using verbal/visual material. They also underwent a 3T-MRI scan including a T1-weighthed volume to assess through voxel-based morphometry (VBM) [3] potential associations between regional grey matter (GM) volumetrics and RIF and FAC measures. MANOVAs were used to assess RIF and FAC effects, while One-sample t-test models were used to investigate associations between RIF/FC effects and GM volumes.

Results: The FAC effect was present in all groups when using both, verbal and visual material, while the RIF effect remained undetected. VBM analysis showed associations between verbal RIF effects and regional GM volumes in the AD (i.e., left medio-temporal lobe) and HS group (i.e., bilateral precuneus/posterior cingulate, left parietal lobe). In the aMCI group, when using the visual task, VBM revealed associations for both RIF and FAC with regional GM volumes (i.e., RIF: right fusiform gyrus and cerebellar lobules; FAC: bilateral pre/post central gyri, and right inferior frontal gyrus). Finally, in the SCD group associations were found between GM volumes in the parahippocampal/fusiform gyrus bilaterally and both RIF and FAC effect.

Conclusions: The FAC effect was observed along the AD spectrum independently from the material used. Conversely, the RIF effect was not elicitable. This is probably due to the yes/no recognition paradigm employed here which is unable to induce a significant inhibition. The brain areas involved are those typically related to memory processes. Overall, this study suggests that facilitation/consolidation processes, although at different levels of accuracy, are relatively preserved across AD stages.

## MORE RESERVE HELPS EVERY INDIVIDUAL ACROSS EITHER NORMAL OR PATHOLOGICAL AGING: THE ROLE OF LEISURE'S ACTIVITIES

L. Serra[1], S. Bonarota[1], C. Di Domenico[1], G. Caruso[1], M. Rizzuti[1], M. Assogna[2], M. Rodini[3], L. Mencarelli[4], F. Di Lorenzo[4], G. Koch[4,5], L. Fadda[6], C. Caltagirone[3], M. Bozzali[7]

[1]Neuroimaging Laboratory, Santa Lucia Foundation IRCCS (Roma); [2]Systems Medicine Department/Experimental Neuropsychophysiology Laboratory, University of Roma Tor Vergata/Fondazione Santa Lucia IRCCS (Roma); [3]Behavioral and Clinical Neurology Laboratory, Santa Lucia Foundation IRCCS (Roma); [4]Experimental Neuropsychophysiology Laboratory, Santa Lucia Foundation IRCCS (Roma); [5]Department of Neuroscience and rehabilitation, University of Ferrara (Ferrara); [6]Systems Medicine Department, University of Roma Tor Vergata, Santa Lucia Foundation IRCCS (Roma); [7]Neuroscience Department "Rita Levi Montalcini", University of Turin (Torino)

Background: Brain, cognitive, and neural reserves hypotheses have been introduced to account for the apparent inconsistencies between accumulation of neuropathological damage and clinical manifestations [1]. Leisure's activities pursued during life are theoretically considered as reserves' builders, although their association with actual cognitive efficiency remains to be clarified [2]. We aimed here to assess whether cognitive, social and physical leisure's activities pursued in different life-periods predict the present cognitive functioning during normal and pathological aging.

Methods: Twenty patients with Alzheimer's disease (AD), 19 patients with single domain amnestic mild cognitive impairment (a-MCI), 12 individuals with subjective cognitive decline (SCD), and 17 healthy elderly subjects (HE) underwent an extensive questionnaire to quantify cognitive, social and physical activities pursued during their youth (age range 20-40 years), middle age (age range 40-65 years) and old age (age >65 years) [3]. Neuropsychological assessment was performed using the Addenbrooke's cognitive examination (ACE-R). Categorial principal component analyses (cPCA) were used to extract the main component in the three life-periods for cognitive (C1, C2, C3), social (S1, S2, S3) and physical (P1, P2, P3) activities. CPCA scores were summarised to obtain three scores of the whole leisure's activity (LA1, LA2, LA3) alongside a total score (LAtot). CPCA scores were entered as independent variables, while the ACE-R total score, the MMSE score and different ACE-R subscores (representing different

domains) were entered as dependent variables in a series of regression models for each diagnostic group taken in isolation.

Results: In the a-MCI group C1, C2, and C3 predicted the general cognitive efficiency and cognition (attention, memory and language abilities); in the SCD group, L2 and L3 predicted the general cognitive efficiency and memory and language functioning; in the AD group S2 only predicted attention abilities; in the HE group, S3, P1 and C1 predicted general cognitive efficiency and memory functioning.

Discussion: Cognitive activities pursued during the middle- and old age account for the cognitive efficiency in patients with a-MCI only; in the SCD and HE groups, all recreational activities account for cognitive functioning, while in patients with AD current social interactions predict the cognitive level. These findings may be useful to address tailored interventions during normal and pathological aging.

## SEX DIFFERENCES IN THE SEVERITY AND PROGRESSION OF NEUROPSYCHIATRIC SYMPTOMS ACROSS DIFFERENT DEMENTIA TYPES: A CROSS-SECTIONAL AND LONGITUDINAL STUDY

C. Silvestri[1], I. Libri[1], M. Cosseddu[2], R. Turrone[2], V. Cantoni[1], J. Rivolta[1], S. Caratozzolo[2], A. Alberici[2], A. Pilotto[1], B. Borroni[1], A. Padovani[1], A. Benussi[1]

[1]Department of Clinical and Experimental Sciences, University of Brescia (Brescia); [2]Department of Neurological and Vision Sciences, ASST Spedali Civili (Brescia)

Introduction: Neuropsychiatric symptoms manifest variably across common dementia types, such as Alzheimer's disease (AD), frontotemporal dementia (FTD), dementia with Lewy bodies (DLB), vascular dementia (VaD), mixed dementia (MD), and in the stage of subjective cognitive decline (SCD), often a precursor to clinical dementia. Despite the pronounced impact of NPS on patient quality of life and caregiver burden, the influence of sex on the prevalence and severity of these symptoms remains largely uncharted territory.

Objective: This study seeks to bridge the gap in our understanding of sex differences in the prevalence, severity and progression of NPS across various forms of cognitive impairment assessed retrospectively in a single-center cohort.

Methods: A thousand sixty-eight patients were included (AD n=650, FTD n=166, DLB n=77 and SCD n=175). Hierarchical generalized linear mixed models were utilized to model neuropsychiatric symptoms as a function of disease severity (CDR-SoB), sex, and clinical phenotypes.

Results: We observed significant differences in neuropsychiatric symptoms' prevalence between men and women in AD, FTD, DLB and SCD. In particular, in AD, women reported symptoms more frequently than men (86.3% vs 80.7%), particularly in the early stages of the disease. Apathy was the most common symptom reported by men (53.0%), whereas depression/dysphoria was most common in women (52.3%). In FTD, 97.0% of patients reported experiencing at least one NP, with apathy being the most common. Delusions, hallucinations and depression/dysphoria were more frequently reported by women, while men reported higher instances of agitation/aggression, apathy/indifference and irritability/lability. In DLB, as in FTD, patients exhibited a notably high frequency of NPS on average. The frequency of experiencing any NPS were similar for both sexes (90.9% in men, 94.9% in women). Anxiety was significantly more common in women (60.3%), than in men (44.4%). In patients with SCD, the frequency of NPS was notably lower than in other neurodegenerative disorders (60.3% in men and 64.7% in women). The most commonly reported symptoms were depression, anxiety, and irritability.

Discussion: Critically, NPS can fluctuate and evolve over the disease course, adding a layer of complexity to patient management. Despite this dynamic nature of NPS, longitudinal studies systematically tracking these changes across different dementia types remain exiguous. Although the pathophysiological contribution of sex in neurodegeneration is not characterized yet, our findings highlight its role as possible biological variable in dementias.

## TRANSCRANIAL PULSE STIMULATION (TPS) FOR MILD COGNITIVE IMPAIRMENT: A PRELIMINARY STUDY

P. Sucapane[1], G. Saporito[2], E. Di Sciullo[1], D. Murillo[1], V. Gazzotti[1], C. Marini[1], F. Pistoia[2]

[1]Neurological Unit, San Salvatore Hospital, University of L'Aquila (L'Aquila); [2]Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila (L'Aquila)

Objective: The aim of the present study was to verify the effectiveness and safety of Transcranial Pulse Stimulation (TPS) in improving cognitive performances in Mild Cognitive Impairment (MCI).

Material: A consecutive series of patients treated with TPS at the Neurological Unit of the San Salvatore Hospital of L'Aquila was included in the study. Inclusion criteria were: diagnosis of MCI, no contraindication to Magnetic Resonance Imaging (MRI) preliminary assessment and availability to return for longitudinal follow-up visits.

Methods: All patients performed the stimulation sessions according to the following schedule: six initial stimulations (three times a week for two weeks) followed by a one-week break and four maintenance stimulations (once a week), for a total of ten stimulation sessions. The TPS system consists of a mobile single transducer and an infrared camera system for MR based neuronavigation (NEUROLITH, Storz Medical AG). All patients were assessed through the Mini Mental State Examination (MMSE), the Rey Auditory Verbal Learning Test (RAVLT), Raven's Progressive Matrices, the Verbal and Semantic Fluency Test, the Constructive Apraxia Test, the Immediate Visual Memory Test and the Beck Depression Inventory- II (BDI-II) at baseline (t0), at 15 days (t1) and at one and a half months after the start of the treatment (t2). Data were analyzed by paired t-test or Wilcoxon signed-rank tests. A p-value $<0.05$ was considered statistically significant.

Results: Fourteen patients (mean age$\pm$SD 73.4$\pm$6.73; mean education 10.6$\pm$4.83) completed the 10 stimulation sessions and were assessed through the neuropsychological and behavioral battery at time t0, t1 and t2. No statistically significant changes were found between

the scores obtained at baseline and at the 15 days follow-up. Conversely, a significant improvement was observed in global cognitive function (MMSE 21.80±4.12 Vs 23.49±3.89; p= 0.002), mnestic function (RAVLT: immediate recall 19.21±6.88 Vs 23.86±7.08; p= 0.012) and in visual memory test (15.27±4.47 Vs 17.06±3.99; p= 0.018) at one and a half months after the start of treatment as compared to baseline. No side effects were detected in the managed patients.

Discussion: TPS is a safe and effective brain stimulation technique that may be used as an add-on therapy in MCI.

Conclusions: Future studies are needed to evaluate the long-term effectiveness of TPS in patients with MCI and other clinical populations.

## INTERCEPTING FATIGUE: AN ALERT FOR NEURODEGENERATION AND FRAILTY IN AGING

M. Toccaceli Blasi, A. Alfano, M. Canevelli, G. Bruno

Department of Human Neuroscience, La Sapienza University (Roma)

Introduction: Fatigue is usually defined as a subjective feeling of extreme and persistent mental and physical tiredness, weakness, or exhaustion. It represents a common and distressing symptom in older people and has been associated with poor health outcomes. Nevertheless, its pathophysiological underpinnings and clinical correlates have been scarcely characterized.

Objective: The present study aimed to explore the clinical manifestations and biomarker abnormalities associated with fatigue in a population of older, cognitively unimpaired individuals.

Materials and Methods: Cognitively normal participants in the Alzheimer's Disease Neuroimaging Initiative (ADNI) 2 study were considered for the present analysis. The study sample was divided into two groups according to the presence or absence of fatigue based on self-reported "low energy" at baseline. Univariate analyses were conducted to compare the sociodemographic and clinical characteristics of the two groups and identify possible differences in CSF and neuroimaging biomarkers. A logistic regression analysis was then performed to identify clinical and biological determinants significantly associated with fatigue (bivariate dependent variable of interest). A sensitivity analysis was undertaken to ascertain the influence of sex.

Results: Overall, 291 subjects (mean age 73.0 ± 6.0 years; 54.0% women) were considered. Among them, 44 (15.1%) complained of fatigue. Participants reporting fatigue were more frequently women, more severely frail and depressed, and exhibited lower hippocampus volumes at the MRI relative to their non-fatigue counterparts. At the logistic regression, female sex, increasing frailty index scores, depression, ApoEε4 genotype, and lower hippocampus volume resulted as significantly associated with the presence of fatigue (all $p<0.05$). Relevant sex differences were observed in sensitivity analyses.

Conclusion: Fatigue is a complex symptom in older people, potentially resulting from the interplay between diverse determinants such as genetic traits, frailty, and mood. Moreover, it may represent an early manifestation of incipient neurodegeneration. A comprehensive and multidimensional approach is therefore needed to investigate the nature and role of this common manifestation.

## BRAIN FDG-PET DIFFERENTIATES TYPICAL AND ATYPICAL ALZHEIMER'S DISEASE WITH NEUROPSYCHIATRIC SYMPTOMS: CLINICAL CLASSIFICATION AND PROGNOSTIC PREDICTION

G. Tondo[1], F. De Marchi[2], S. Caminiti[3], F. Menegon[2], B. Sarasso[4], P. Serra[4], R. Matheoud[5], G. Sacchetti[6], C. Comi[7]

[1]Neurology Unit, Sant'Andrea Hospital, University of Piemonte Orientale (Vercelli); [2]Department of Neurology, University of Piemonte Orientale (Novara); [3]Division of Neuroscience, Vita-Salute San Raffaele University (Milano); [4]Center for Cognitive Disorders and Dementia, Sant'Andrea Hospital (Vercelli); [5]Department of Medical Physics, Maggiore della Carità Hospital (Novara); [6]Department of Nuclear Medicine, Maggiore della Carità Hospital (Novara); [7]Department of Neurology, University of Piemonte Orientale (Vercelli)

Background: The amnestic syndrome represents the most common presentation of Alzheimer's disease (AD), named typical (tAD). Atypical AD variants have been increasingly recognized, including the frontal variant (fvAD), described in patients with predominant behavioral/dysexecutive deficits [1]. Neuropsychiatric symptoms (NPS) are common in typical and atypical AD variants, associated with a steeper cognitive decline [2]. NPS may already be present in the early stage of dementia, making diagnosis challenging and meaning prognostic shortcomings. Our study aimed to investigate the brain metabolism pattern in patients with both memory and behavioral/dysexecutive disturbances to provide an early-stage accurate clinical and prognostic classification.

Methods: Based on the clinical evaluation, n=30 patients with memory and behavioral/dysexecutive deficits were included in the study. All patients had neuropathological or biomarker evidence of AD pathology (amyloid-PET or CSF analysis). All patients underwent baseline cognitive and neuropsychological evaluation and FDG-PET. FDG-PET was analyzed following a validated voxel-based SPM procedure, obtaining hypometabolism maps at the single-subject level. Based on previously validated literature, patients were classified according to the adherence of the hypometabolism maps to pre-defined disease-specific anatomical templates in tAD (temporoparietal and posterior cingulate cortex hypometabolism) and fvAD patients (both typical and prefrontal cortex hypometabolism) [3]. Baseline and follow-up cognitive evaluation was carried out by the Mini-Mental State Examination (MMSE), while NPS were investigated through the Neuropsychiatric Inventory (NPI).

Results: According to the single-subject SPM analysis, n=14 patients were classified as fvAD, n=10 as tAD, n=6 patients showed other hypometabolism patterns (limbic, unclassifiable) and were excluded from the analysis. Both fvAD and tAD groups showed baseline mild-to-moderate cognitive impairment. Patients in the fvAD group showed a higher rate of NPS as evaluated by the NPI (including the sum of scores, several NPI sub-scores, and caregiver distress), with a significant longitudinal increase in NPI scores. At follow-up (16.5 ± 7.1 months) mean MMSE score did not differ between groups, but fvAD showed a steeper cognitive decline than tAD as evaluated by the MMSE points lost per year (p=0.03). Prefrontal cortex hypometabolism (especially orbitofrontal cortex and dorsolateral cortex hypometabolism) correlated with NPI global score and sub-scores.

Discussion: In our study, fvAD patients showed higher NPS at onset and a steeper global cognitive and neuropsychiatric decline at follow-up than tAD. Hypometabolism in the prefrontal cortex correlated with the severity of NPS. Brain hypometabolism maps aided differential diagnosis between typical and atypical AD forms at the first evaluation, supporting a more accurate prognostic prediction than clinical evaluation.

## NEUROPSYCHIATRIC SYMPTOMS IN PEOPLE WITH MILD COGNITIVE IMPAIRMENT AND MILD ALZHEIMER'S DISEASE ARE ASSOCIATED WITH ALTERATIONS IN DOPAMINE-ENRICHED FUNCTIONAL CONNECTIVITY PATHWAYS

A. Venneri, R. Manca

Department of Medicine and Surgery, University of Parma (Parma)

Objectives: Alterations in neurotransmission and brain functioning are likely to be among the first neuropathological changes occurring in Alzheimer' disease (AD). However, how such alterations are associated with neuropsychiatric symptoms still remain elusive. The aim of this study is to investigate resting-state functional connectivity based on a priori knowledge of dopamine receptor distribution in the brain as a potential marker of AD-related behavioural problems.

Material and Methods: Clinical, Neuropsychiatric Inventory (NPI) and structural and resting-state functional MRI data were collected for people with either mild cognitive impairment or mild dementia due to AD. Functional MRI data were pre-processed by using the Receptor-Enriched Analysis of functional connectivity by targets (REACT) procedure to obtain functional connectivity (FC) maps informed by dopamine D1 (D1r) and D2 receptor (D2r) PET atlases. The association between NPI total scores and dopamine-enriched FC was tested with multiple regression models in SPM12 by including age, education, sex, MMSE scores and total intracranial volume as covariates. An exploratory analysis was carried out to compare dopamine-enriched FC maps between 10 patients with and 10 without psychotic symptoms.

Results: The total NPI score was negatively correlated with D1r-enriched FC in the brainstem, thalamus, medial and inferior temporal cortices and in the precuneus and with D2r-enriched FC in fronto-parietal and superior temporal areas. Psychotic patients showed primarily lower D1r-enriched FC than non-psychotic patients in occipito- and medio-temporal areas and lateral fronto-parietal areas and lower D2r-enriched FC in occipito-parietal areas. However, psychotic patients also had higher D1r-enriched FC in dorsolateral prefrontal cortices and D2r-enriched FC in the basal ganglia, thalamus and hypothalamus than non-psychotic patients.

Discussion and Conclusions: A widespread decrease in FC influenced by the distribution density of different dopamine receptors, especially in fronto-parietal, occipito-temporal and brainstem areas, may represent the neural process driving behavioural alterations in people with mild AD. Such alterations may be particularly predisposing to psychotic symptoms, although a combination of both downregulation and upregulations in specific dopamine-informed FC pathways may play a pivotal role.

## ELECTROPHYSIOLOGY OF EARLY STAGES OF VISUAL PROCESSING DYNAMICS IN SUBJECT COGNITIVE DECLINE AND MILD COGNITIVE IMPAIRMENT

A. A. Vergani[1], G. Salvestrini[2], C. Fabbiani[2], S. Mazzeo[3], R. Burali[2], M. Lassi[4], L. Amato[4], G. Giacomucci[3], V. Moschini[3], C. Morinelli[3], F. Emiliani[3], M. Scarpino[2], S. Emiliani[3], A. Ingannato[3], B. Nacmias[3], S. Padiglioni[5], S. Sorbi[3], A. Grippo[2], V. Bessi[3], A. Mazzoni[4]

[1]The BioRobotics Institute, Sant'Anna School of Advanced Studies (Pisa); [2]IRCSS Fondazione Don Carlo Gnocchi, University of Florence (Firenze); [3]Careggi University Hospital, University of Florence (Firenze); [4]The Biorobotics Institute and Department of Excellence in Robotics and AI, Sant'Anna School of Advanced Studies (Pisa); [5]Regional Referral Centre for Relational Criticalities, Tuscany Region (Firenze)

Objectives: This study aims to identify Electroencephalography (EEG) markers associated with early processing of visual stimuli in patients with Subjective Cognitive Decline and Mild Cognitive Impairment [1].
Materials: We analyzed event-related EEG potentials in 144 subjects (85 SCD, 41 MCI and 18 age-matched healthy HS subjects) while performing a sustained visual attention task. We measured the information carried about both group and performance by N1 integrals in occipital channels and computed the percentage of extraoccipital channels recruitment (EOR) via Spearman correlation metrics.

Results: N1 integral showed significative differences between HS and patients, i.e., SCD+MCI (KW test=5.838, pvalue=1.568e-02) and, specifically, while comparing HS and SCD (KW test=6.970, pvalue=2.487e-02). Moreover, we found N1 nonmonotonic values associated with dementia progression: HS (247.58[μV*ms]±38.79), SCD (146.50[μV*ms]±11.86) and MCI (171.29[μV*ms]±72, KW test=6.97, p=2.487e-02). EOR measures displayed significative differences between SCD and MCI (KW test=5.808, p value=4.785e-02) with higher values for MCI (25%±0.08) than SCD (21%±0.09).

Discussion: N1 Previous studies associated N1 decrease with dementia [2], but here we report that such decrease is non-monotonous in early stages. EOR is a visual functional connectivity proxy that could indicate specialized reorganization [3] due to worsening pathology, as the transition from SCD to MCI.

Conclusion: The continuum of neurodegeneration associated with loss of cognitive abilities appears to show a discontinuity in visual EEG correlates. Follow-up of patients could indicate the extent to which early dynamics in visual processing could help suggest dementia-related risk factors.

## CHCHD2 AND DNAJC6 GENE MUTATION IN AN ITALIAN PATIENT WITH EARLY-ONSET ALZHEIMER'S DISEASE

F. Vignaroli[1], F. Colombatto[1], F. Menegon[1], F. De Marchi[1], F. Caushi[2], L. Corrado[2], S. D'Alfonso[2], C. Comi[3], G. Tondo[3]

[1]Neurology Unit, Department of Translational Medicine, University of Piemonte Orientale (Novara); [2]Department of Health Sciences, Interdisciplinary Research Center of Autoimmune Diseases (IRCAD), University of Piemonte Orientale (Novara); [3]Neurology Unit, S. Andrea Hospital, Department of Translational Medicine, University of Piemonte Orientale (Novara)

Objectives: We report for the first time a case of a Caucasian woman with a concomitant mutation in CHCHD2 and DNAJC6 genes who developed early-onset Alzheimer's disease (AD). To date, CHCHD2 mutations in AD patients has been described only in Chinese populations.

Materials and Method: A 52 years-old Caucasian woman was evaluated in the Centre for Dementia and Cognitive Disorders at S. Andrea Hospital in Vercelli, Italy. Her disturbances had started one year and a half before and were characterized by memory, concentration, and attention deficits, progressively worsening. Initial disturbances in visuospatial abilities and writing were also present. The patient was admitted to the Neurology Unit for further evaluation. During hospitalization, she underwent neurological and neuropsychological examinations, blood tests, magnetic resonance imaging (MRI), fluorodeoxyglucose-positron emission tomography (FDG-PET), cerebrospinal fluid (CSF) samples, and blood sampling for genotyping.

Results: The neuropsychological assessment revealed severe deficits in memory, language and executive functions. The brain MRI showed a diffuse cortical atrophy. FDG-PET imaging revealed a pattern of marked hypometabolism in the bilateral postero-parietal and temporo-parietal regions, and moderate hypometabolism in frontal left regions. The CSF analysis showed increased total tau and phosphorylated tau and reduction of amyloid β levels. In light of the clinical presentation, laboratory and imaging data a diagnosis of AD was made. Genotyping revealed two rare different heterozygous mutations: c.235 G>A, p.A79T (rs200784526) c.1331A>G, p.D444G (rs761459753) in CHCHD2 and DNAJC6 genes, respectively. Both variants have been classified as of uncertain significance according to the 2015 ACMG criteria.

Conclusions and discussion: The CHCHD2 gene encodes for a multifunctional protein that takes part in the regulation of mitochondrial metabolism. CHCHD2 mutations have been previously associated with familial and sporadic Parkinson's disease (PD). Additionally, CHCHD2 variants were identified in other neurodegenerative diseases including fronto-temporal dementia, amyotrophic lateral sclerosis and AD. To date, CHCHD2 variants in AD patients have been described only in Chinese populations [1] [2]. DNAJC6 encodes for a co-chaperone protein that belongs to the endo-lysosomal pathway. DNAJC6 mutations have been reported in early-onset PD patients. Regarding AD, only one report described a possible association between AD and DNAJC6 mutations [3]. In conclusion, our report described for the first time a concomitant mutation in CHCHD2 and DNAJC6 genes in a Caucasian AD case, with early-onset and rapid disease course.

## LATE-ONSET ALZHEIMER'S DISEASE (AD) WITH PROGRESSIVE BULBAR MOTOR INVOLVEMENT: A COINCIDENTAL ASSOCIATION?

M. Vizziello[1], P. Caroppo[1], S. Prioni[1], G. Giaccone[2], E. Dalla Bella[3]

[1]Division of Neurology 5 and Neuropathology, IRCCS Foundation "Carlo Besta" Neurological Institute (Milano); [2]Division of Neurology 5 and Neuropathology, IRCCS Foundation "Carlo Besta" Neurological Institute, University of Milan (Milano); [3]Third Neurology Unit and Motor Neuron Diseases Center, IRCCS Foundation "Carlo Besta" Neurological Institute (Milano)

Aims: To describe the unusual occurrence of progressive bulbar impairment in a patient with late-onset cognitive decline.

Materials and methods: The patient underwent clinical, neurophysiological and laboratory examination, neuropsychological assessment, and brain MRI and FDG-PET.

Results: An 83-year-old woman with a 4-year-history of cognitive decline with predominant memory impairment consistent with amnestic mild cognitive impairment (MCI) developed progressive dysarthria and dysphagia over the previous 2 years. At admission, her speech was nearly unintelligible, and neurological assessment showed frontal release with disinhibition and pseudobulbar signs, brisk deep tendon reflexes, diffuse muscle wasting and tongue fasciculations. Needle electromyography confirmed the presence of widespread chronic and active denervation of the tongue and motor evoked potentials revealed alterations in both cortico-bulbar and cortico-spinal tracts. The neuropsychological assessment revealed severe deficits of verbal and visuo-spatial memory. Brain MRI showed severe atrophy of mesial temporal lobes and hippocampi and mild posterior parietal atrophy. Brain FDG-PET showed fronto-temporo-parietal, cingular and precuneal hypometabolism. Cerebrospinal fluid analysis revealed increased total tau and p-tau with reduced amyloid beta42, consistent with Alzheimer's disease (AD). Single gene analysis tested negative for pathologic C9orf72 gene expansion.

Discussion: Up to 50% of patients with amyotrophic lateral sclerosis (ALS) show neuropsychological abnormalities, with nearly 10-15% of them fulfilling criteria for behavioral frontotemporal dementia (FTD). Moreover, bulbar involvement is more frequently associated with cognitive disfunction. Our patient showed the unusual association between Alzheimer and bulbar ALS. Increasing evidence suggests that hippocampal volume loss in ALS patients could correlate with amnestic dysfunction, providing clues for a widespread involvement of non-motor cortical areas in ALS. Although patient's advanced age could explain the presence of AD biomarkers, the association with bulbar ALS might be caused by pathogenetic TDP43/tau interactions [1]. The co-occurrence of AD with TDP-43 pathology [2], and the existence of ALS cases that fulfill pathological criteria for AD [3] support the latter hypothesis.

Conclusions: Our findings suggest that further studies are warranted to investigate the association between ALS/FTD and AD.

## DATA-DRIVEN APPROACH REVEALS DIFFERENT PATTERN OF HYPOMETABOLISM IN BEHAVIORAL FRONTOTEMPORAL DEMENTIA AND LATE-ONSET PRIMARY PSYCHIATRIC DISEASES

G. Zorzi[1], G. Pigato[2], I. Pettenuzzo[3], B. Roiter[2], M. Anglani[4], C. Bussè[3], S. Mozzetta[3], C. Gabelli[1], C. Campi[5], D. Cecchin[5], A. Cagnin[6]

[1]Research Center for the Aging Brain (CRIC), Dipartimento di Medicina dei Sistemi, University of Padua (Padova); [2]Psychiatry Unit, Department of Neuroscience (DNS), University of Padua (Padova); [3]Neurology Unit, Department of Neurosciences (DNS), University of Padua (Padova); [4]Neuroradiology Unit, University Hospital Padua (Padova); [5]Nuclear Medicine Unit, Department of Medicine (DIMED), University of Padua (Padova); [6]Neurology Unit, Department of Neurosciences (DNS) and Padova Neuroscience Center, University of Padua (Padova)

Background: Late-onset primary psychiatric diseases (PPD) and behavioural variant frontotemporal dementia (bvFTD) present both with a frontal lobe syndrome Neuroimaging of brain metabolism may have a crucial role among the investigations that could help in the differential diagnosis.

Objective: To compare brain glucose metabolism in bvFTD and late onset PPD mimicking bvFTD and study metabolic correlates of cognitive and behavioural disturbances Methods: Fifty-seven subjects with late-onset frontal lobe syndrome, 37 bvFTD (n= 37) and 20 PPD, were studied with brain FDG-PET/MRI: the variance of regional FDG standard uptake values ratio (SUVr) was evaluated with PCA and correlation analysis between SUVr data and cognitive/behavioural variables was performed.

Results: The degree of metabolism in the frontal regions and caudate explained 44.8% of the variance. 32% of bvFTD showed a spatial pattern of FDG uptake with relative sparing of frontal metabolism and these patients were genetic variants of bvFTD and/or had signs of motor neuron disease. Nearly half of PPD patients showed low-grade FDG hypometabolism in the anterior cingulate and/or parietal regions. In bvFTD lower metabolism of the caudate correlated with severity of compulsive symptoms while higher metabolism on the primary visual cortex correlated with higher disinhibition. There were not metabolic correlates of cognitive or neuropsychiatric symptoms in PPD.

Conclusion: hypometabolism of frontal regions and caudate, but not the cingulate cortex could help in distinguishing bvFTD from PPD, except cases with motor neuron signs and/or genetic forms which mimic PPD patients. No metabolic correlates of clinical features were found in PPD.

## MULTIPLE GENE VARIANTS ASSOCIATED WITH DEMENTIA IN A LARGE COHORT OF ITALIAN PATIENTS WITH COGNITIVE DECLINE

G. Zorzi[1], C. Gabelli[1], M. Perin[2], A. Codemo[1], M. Casa[1], E. Gasparoli[1], M. Cassina[2], C. Ruaro[1], I. Cortella[1], E. Greco[2], L. Salviati[2]

[1]Research Center for the Aging Brain (CRIC), Department of Systems Medicine, University Hospital Padova (Padova); [2]Clinical Genetics Unit, Department of Women's and Children's Health, University Hospital Padova (Padova)

Background: Alzheimer's disease (AD) is related to genetic and environmental factors. Approximately 10% of patients with AD have an early onset presentation (<65 years, EOAD) with 5-10% of cases linked to genetic autosomal dominant variants. Conversely, sporadic late onset AD (LOAD) is genetically more complex and approximately 40 disease associated genes/loci have been reported. Fronto-temporal-dementia (FTD) is probably the most common form of dementia affecting people under the age of 60, and 5 to 10% of all FTD are caused by a genetic mutation. Although many genes have been classified as causative of dementia, there are many other whose prevalence and role in the pathogenesis of dementia remain uncertain.

Aim: To investigate common and uncertain dementia genetic variants of candidate genes in a large cohort of Italian young onset dementia patients or LOAD showing a familial presentation.

Methods: 152 outpatients and inpatients from 2002-to-2022 referred to the Research-Center-for-the-Aging-Brain (CRIC) of the Padua University Hospital were recruited. The cohort consisted of 108 patients with a diagnosis of AD (89 EOAD and 19 familial-LOAD, female 55%) according to 2011-NIA-AA and International-Working-Group-2 criteria and based on the evidence of beta-amyloid (CSF or amyloid PET) and 44 patients with a diagnosis of FTD (female 67%) according to recent FTD-consensus. The genetic analysis was performed using probes (13000) build with the Agilent SureDesign tool (Agilent Technologies Santa Clara, California, USA), binding coding exons and closest regions involving approximately 492.244 Kbp. NGS analysis was performed using NextSeq System e MiniSeq (Illumina, San Diego,CA,USA), and a total of 148 genes were analysed.

Results: We identified a genetic variant in 21/108 (19%) patients with AD. In the EOAD subgroup we found a variant in 18/89(20%) patients: 10PS2, 3PS1, 1APP, 1SPG11(compound heterozygous), 1misGRN, 1SPAST, 1TUBA4a. In the LOAD subgroup we found variants in 3/19(15%) patients: 1GRN, 1SOD1, 1TARDBP. Overall, we found a pathogenetic variant (evidence class 4/5) in 16/21(76%) and uncertain role (evidence class3) in 5/21(23%). In the FTD group we identified a variant in 13/44(29%) patients: 5GRN, 2MAPT, 2C9ORF72, 3TREM2, 1CSF1R. Overall, we found a pathogenetic variant (evidence class 4/5) in 10/13(76%) and uncertain role (evidence class3) in 3/13(23%).

Conclusions: The proportion of patients with a related genetic variant is relevant in familial and young onset cases. However, variants with uncertain role have been found in about 20% of patients. With our work we confirmed that disentangling the genetic contribution in the pathogenesis of dementia is critical to improve screening and therapy.

Dementia-related genetic variants in an Italian population of early-onset Alzheimer's disease. Front Aging Neurosci (2022);14:969817

## DIGITAL NEUROLOGY

### USABILITY OF TELE-MEDICINE PLATFORM AND TELE-REHABILITATION APPLICATIONS AND RELATED DEVICES IN PATIENTS WITH MILD COGNITIVE IMPAIRMENT/EARLY ALZHEIMER'S DEMENTIA AND THEIR CAREGIVERS

G. Arabia[1], R. Di Lorenzo[2], F. Abate[3], L. Arcudi[4], R. Bruno Bossio[5], N. Caravona[6], R. Colao[7], G. Frontera[8], F. Galati[9], P. Insardà[10], M. Lupo[11], A. Gambardella[12], M. Bernardi[13], N. Vanacore[14]

[1]Institute of Neurology, University "Magna Graecia" of Catanzaro (Catanzaro); [2]Neurology, Lamezia Terme Hospital (Lamezia Terme-CZ); [3]CDCD, Crotone Hospital (Crotone); [4]CDCD, Reggio Calabria Hospital (Reggio Calabria); [5]CDCD, ASP of Cosenza, (Serraspiga-CS); [6]CDCD, ASP of Corigliano-Rossano (Corigliano-Rossano-CS) [7]CDCD, Centro Regionale Neurogenetica (Lamezia Terme); [8]CDCD, Catanzaro Hospital (Catanzaro); [9]CDCD, Vibo Valentia Hospital (Vibo Valentia); [10]CDCD, ASP of Reggio Calabria (Cinquefrondi-RC); [11]CDCD, Cosenza Hospital (Cosenza); [12]Neurology Unit, University of Catanzaro (Catanzaro); [13]Department of Health Protection, Social and Socio-Health Services Regione Calabria (Catanzaro); [14]National Center for Disease Prevention and Health Promotion, Italian National Institute of Health (Roma)

Objectives: Tele-medicine and tele-rehabilitation systems are increasingly proposed as useful approaches to improve or stabilize cognitive functions and increase the quality of life of patients with mild or moderate cognitive decline. [1] The aim of the present project was to investigate the usability of tele-medicine and tele-rehabilitation systems designed for remote assistance and treatment of patients with mild cognitive impairment or early Alzheimer's dementia (MCI/early AD) and in their caregivers. This project was founded by the Alzheimer's and Dementia Fund 2021-2023 of the Italian Ministry of Health (Project Line #4) and coordinated by the Italian National Institute of Health.

Methods: The project included two lines of intervention for which usability is analyzed: 1) a program of tele-rehabilitation for the MCI/early AD patients, using at home a dedicated software installed on a tablet, for 4 consecutive weeks, under the supervision of a neuropsychologist; 2) a program of visits in Tele-Medicine, with a neuropsychologist and a social assistant, for educational and psychological support, for patients and caregivers, for 4 consecutive weeks. Ten Cognitive Disorders and Dementia Centers (CDCD), distributed throughout the Calabria territory, participated to the project. Each center was committed to recruit consecutive patients with MCI/early AD and their caregivers, with a minimum of 15 patients and 15 caregivers for center, for a total of an expected number of 150 patients and 150 caregivers recruited at the end of recruitment period (lasting from April to October 2023).

Results: The digital platform of Tele-Medicine of the University of Catanzaro (Pohema Platform) was implemented for the present project, creating a dedicated domain and a related portal. Furthermore, the devices specifically dedicated to tele-rehabilitation (Neurotablets) were integrated into this platform. All operators of the CDCDs, after a training on the use of the Pohema platform and of related devices, started the recruitment of patients and caregivers to consecutively include in the telemedicine and cognitive telerehabilitation interventions. Data on the usability of the platform and of the related devices are currently collected and the analyses results will be available at the end of the project (October 31, 2023).

Conclusions: The results of this project will allow to analyze the strengths and the limitations of the use of tele-medicine and tele-rehabilitation systems in patients with MCI/early AD and in their caregivers. These data are going to be of value in view of the growing diffusion of these technologies and of the increasing needs that the health system has to address.

### VALIDITY OF THE MANCHESTER TRIAGE SYSTEM IN THE PRIORITISATION OF PATIENTS WITH TRANSIENT GLOBAL AMNESIA IN THE EMERGENCY DEPARTMENT

F. Brigo[1], A. Zaboli[2], S. Sibilio[2], G. Turcato[3]

[1]Department of Neurology, Hospital of Merano (SABES-ASDAA) (Merano-BZ); [2]Emergency Department, Hospital of Merano (SABES-ASDAA) (Merano-BZ); [3]Intermediate Care Unit, Department of Internal Medicine, Hospital Alto Vicentino (Santorso-VI)

Background: The Manchester Triage System is one of the most widely used and studied triage systems in Emergency Departments (ED). MTS does not have a specific presentational flow chart for patients with transient global amnesia (TGA). The goal of this study was to determine the adequacy of priority code assignment for patients with TGA presenting at the ED and triaged using the MTS. In addition, the correct application of MTS by triage nurses was assessed through the audit method.

Methods: This is a single-center observational retrospective study from 1 January 2013 to 31 June 2020. All patients with a medical diagnosis of TGA were considered. An audit was conducted on these triages to assess the correct application of MTS by the triage nurses. Correct triage was considered as a patient classified as yellow.

Results: During the study period, 216 patients with a diagnosis of TGA were considered. Of these 49.5% were classified as yellow, 13.0% were undertriage and classified as green or blue and 37.5% were overtriaged and classified as orange or red. The audit demonstrated that 98.8% of overtriaged patients were triaged incorrectly and 57.1% of undertriage patients were triaged incorrectly. In addition, in 38 patients the triage nurse confused TGA with an acute neurological deficit suggestive of Stroke or transient ischaemic attack.

Conclusion: The present study demonstrates an inability of MTS to correctly stratify patients with TGA. The results of the present study indicate the need for a specific flow chart for patients with neurological problems to improve the performance of MTS.

### EXPLORING THE KNOWLEDGE, ATTITUDES AND PRACTICES ON SEXUAL AND GENDER MINORITIES PATIENTS: A SURVEY ON ITALIAN NEUROLOGISTS

C. E. Cicero, L. Giuliano, A. Nicoletti

Department of Medical and Surgical Sciences, and Advanced Technologies "G.F. Ingrassia", Section of Public Health, University of Catania (Catania)

Background: Sexual and gender minorities (SGM) is an umbrella term including the population identifying themselves as part of the lesbian, gay, bisexual, transgender and queer (LGBTQ+) spectrum. In Europe, an estimated 5% of the population identifies itself as belonging to a sexual minority, whereas preliminary the prevalence of transgender persons is estimated between 0.5-1% of the general population. SGM patients experience difficulties in access to care and might face discrimination, impacting their health outcomes.

Improving knowledge is the first step to reduce barriers. While few data are available on knowledge, attitudes and practices of Italian health providers, no information is available for Italian neurologists' preparedness to treat SGM patients.

Aim: To describe the knowledge, attitudes and practices on SGM patients of Italian neurologists.

Materials and Methods: The study has been conducted on the neurologist of the Italian society of neurology (SIN) using a survey instrument comprising 5 multiple choice questions on gender medicine and 24 Likert type questions divided into three sections exploring the knowledge, attitudes and practices towards sexual minorities and gender minorities. Members of the society have been sent an email asking to complete the survey anonymously followed by a reminder one-month after the original email. Likert scales have been analyzed considering scores 1 and 2 as negative response, score 3 as neutral and scores 4 and 5 as positive responses.

Results: Overall 177 neurologists (5.2%) out of the 3.410 neurologists members of the Italian Society of Neurology participated at the survey. The mean age of the respondents was 44.3 ± 14.6 years; 103(58.2%) were female and the majority (106, 59.9%) worked at a University-Hospital or a Hospital. More than half of the respondents identified sexual and gender orientation as social determinants of health, whereas only a minority was aware of a higher burden of physical and mental health problems in SGM populations. Almost all respondents were confident in examining a sexual minority patient, while only half of them was confident when examining a transgender patient. The vast majority of neurologist reported insufficient training and supervision in treating SGM patients.

Conclusion: In order to improve the quality of healthcare for the SGM population, healthcare professionals should receive proper training in how to approach, investigate and treat patients belonging to a SGM.

## ACCESS TO HEALTHCARE IN A HEADACHE/HIV+ POPULATION IN MALAWI AND THE WHO-INTERSECTORAL GLOBAL ACTION PLAN

L. Giani[1], M. Mwazangati[2], D. Uluduz[3], T. Şaşmaz[4], M. Kamponda[2], V. Tamba Tolno[2], G. Guidotti[5], T. Steiner[6], M. Leone[7]

[1]Istituti Clinici Scientifici Maugeri (Milano); [2]DREAM Program, Community of S. Egidio (Blantyre-MW); [3]Neurology Department, Cerrahpasa School of Medicine (Istanbul-TR); [4]Department of Public Health, Mersin University School of Medicine (Mersin-TR); [5]DREAM Program, Community of S. Egidio (Roma); [6]Lifting The Burden, the Global Campaign against Headache (London-UK); [7]Neuroalgology Unit, Foundation IRCCS Carlo Besta Neurological Institute (Milano)

Objectives: Providing access to care is the main goal of the WHO-Intersectoral Global Action Plan (IGAP), yet many in the developing world as sub-Saharan Africa (SSA) have poor access to treatment due to lack of resources. A major issue are costs of transportation. About half of SSA population (1.1 billions) live with less than 2 EUR per day with no public transportation; the fuel costs almost as in Europe so that some patients stop seeking healthcare because they can't afford transportation [1]. We investigated access to healthcare in a HIV+/headache population focusing on transportation issues.

Materials: The study was conducted in Blantyre, Malawi, in collaboration with the DREAM (Disease Relief through Excellent and Advanced Means) program, active in 10 SSA countries providing care for HIV/AIDS and non-communicable diseases (NCDs). Due to the high level of poverty, all services including drugs are free.
Methods: Trained personnel at the Blantyre DREAM centre administered a structured questionnaire about access to the centre to 500 consecutive HIV+ patients who had been followed for at least 1 year under antiretroviral treatment (ART). This represents the extension of a previously published study on headache among HIV+ patients [2].

Results: Among the 495 respondents, 79.8% needed less than 1 hour to reach the centre, 15.8% between 1 and 2 hours, and 4.4% were more than 2 hours (some even more than 3 hours) away. Most of the subjects reached the centre by private minibus (86%) or by foot (11%). The mean expense for reaching the centre was 1933MWK (=1.76EUR; range 0-36'000), compared to a mean yearly national income of 360'000MWK (328EUR). Considering the high cost of transportation, the repeated number of visits per year for each patient and the illness duration (>1year HIV+), the observed percentage of patients who missed one appointment was very low: 28.7%. Main characteristics among the participants were: mean age 41.3±9.9 years, [range 13-65], 1% minors, 75.6% female, viral load undetectable in 92.2%. The overall 1-year prevalence of any headache was 76.6%. In the month preceding interview 56.6% subjects had at least one headache, analgesics were used by 54.5%.

Discussion: In previous studies on HIV+ patients, cost for transportation was a main cause for missing appointments and treatment failure [3]. DREAM offers free services to facilitate access to care. This can explain the limited number of missed appointments compared to other facilities. IGAP requires strategies to improve access, key to retention in care.

## VALIDATION OF EXPANDED NEUROLOGICAL IMPAIRMENT SCALE (ENIS) IN ACUTE SETTING

I. Mattioli[1], A. Pilotto[1], T. Comunale[1], N. Zoppi[1], C. Zatti[1], M. Catania[1], E. Guso[1], S. Gipponi[2], A. Morotti[1], M. Gamba[3], M. Magoni[3], A. Padovani[1]

[1]Neurology Unit, Department of Clinical and Experimental Sciences, University of Brescia (Brescia); [2]Neurology Unit, Department of Continuity of Care and Frailty, ASST Spedali Civili (Brescia); [3]Stroke Unit, ASST Spedali Civili (Brescia)

Objectives: The use of standardised neurological assessment is still lacking in clinical setting and is an important unmet need for both the research and the clinical communities. The Neurological Impairment

Scale (NIS) has been originally developed in neurorehabilitation and might need implementation to be applied in other neurological settings. Aim of this study was to examine the construct validity and inter-rater reliability of an expanded version of the NIS (eNIS) with the inclusion of specific items for cranial nerves, involuntary movements, coordination, and gait disturbances in a clinical acute neurological setting. We also developed a eNIS severity index (SI) to address the validity of the eNIS as a measure of an individual specific and overall neurological impairment.

Materials: In this prospective single-center cohort study, we included all adult inpatients admitted to the Neurology Unit of Spedali Civili, Brescia, in 2022.

Methods: All the subjects underwent a standardised evaluation including premorbid clinical frailty, cognitive function, functional dependency and admission/discharge severity of neurological impairment using the eNIS. Inter-rater reliability was tested by two independent raters in a subset of 40 patients. Construct validity of the eNIS total score and subscores was evaluated in the subset of patients with diagnosis of cerebrovascular disease and other acute neurological conditions.

Results: One thousand -eighty-one patients entered the study, including 675 patients with acute cerebrovascular disease, 72 with encephalitis/encephalopathies, 58 with epilepsy, 46 with brain tumor, 43 with headache, 83 with medically unexplained symptoms, and other disorders. The inter-rater reliability was excellent for eNIS total score and subscores between the different raters (ICC 0.90, 95% CI 0.82-0.95). The eNIS showed a strong construct validity for total score and subscores compared to other severity clinical scales (r 0.47-0.97, $p<0.001$). The new items identified patients with cranial nerves, coordination, gait impairment and abnormal involuntary movements with clinical impact across different diseases in a range of 25 to 65% of cases. eNIS total score and SI exhibited a relevant correlation with both dependency and disability scores independently from premorbid frailty and comorbidity status.

Discussion: These findings demonstrate the eNIS to be a valid and reliable measure of neurological impairment. The four items added to the NIS and the evaluation of both the eNIS total score and SI are pivotal to make the eNIS suitable for use across different neurological conditions.

Conclusions: the eNIS is a valid instrument for the standardisation and stratification of neurological impairment in acute neurological patients.

## PREDICTORS OF OUTCOMES IN ACUTE NEUROLOGICAL SETTING: THE COMPLEXITY MULTIDIMENSIONAL ACUTE NEUROLOGICAL (MAN) MODEL

A. Piotto[1], I. Mattioli[1], T. Comunale[1], N. Zoppi[1], M. Catania[1], E. Guso[1], S. Gipponi[2], M. Gamba[3], M. Magoni[3], A. Padovani[1]

[1]Neurology, University of Brescia (Brescia);[2]Neurology, Asst Spedali Civili of Brescia (Brescia); [3]Vascular Neurology, ASST Spedali Civili of Brescia (Brescia)

Objectives: Clinical complexity is a key issue for healthcare providers and define subjects at higher risk of mortality, in-hospital complications and short-term as well as long-term disability [1]. Clinical complexity might depend on a combination between premorbid vulnerability and resilience and severity of acute vs chronic diseases. No combined scores integrating premorbid vulnerability and disease severity able to stratify patients with different progression is still available. Aim of this study was to define factors related to short-term outcomes in acute neurological setting by adopting a multidimensional assessment evaluating a) premorbid conditions b) acute neurological and c) non-neurological severity.

Material: In this prospective cohort study, we included all adult inpatients hospitalized in a Neurological department.

Methods: All the subjects underwent a standardized assessment evaluating premorbid comorbidities, clinical and multidimensional frailty, cognitive function, functional dependency and the admission/discharge severity of neurological impairment using the Expanded version of NIS scale. Predictors of in-hospital mortality, severe disability and duration of stay were evaluated by both AUC ROC and multivariate logistic and linear regression models.

Results: One thousand -three hundred fifty patients entered the study, including 700 patients with acute cerebrovascular disease, 85 with epilepsy, 80with encephalitis/encephalopathies with very wide range of age, premorbid and acute severity at admission. In -hospital mortality was predicted by a combination of age, acute neurological and non-neurological severity (MAN global score AUC 0.85 IC-0.80-0.89). Duration of stay was related by both neurological severity and premorbid vulnerability, with only fair predictive value (ROAC AUC 0.66 IC 0.61-0.70) MAN score. Premorbid vulnerability impacted on final disability and improvement during hospitalization in logistic regression models adjusted for baseline severity.

Discussion: The MAN complexity model including premorbid vulnerability, acute neurological and non-neurological severity is a valid instrument of stratification of risk of deterioration for neurological patients.

Conclusions: Further ongoing longitudinal studies are warranted to evaluate the impact of MAN stratification of general management of acute and chronic neurological patients in different healthcare settings.

## IMMUNE EFFECTOR CELL-ASSOCIATED NEUROTOXICITY SYNDROME (ICANS): A NEW CAUSE OF STATUS EPILEPTICUS

M. C. Angeletti, F. Cancellieri, M. Cervigni, S. Donzelli, S. Malatini, S. Paolucci, A. Riva, R. Tiberi, N. Zannotti, S. Luzzi, M. Silvestrini, G. Viticchi

Neurological Clinic, Marche Polytechnic University (Ancona)

Introduction: Immune effector cell-associated neurotoxicity syndrome (ICANS) is a clinical and neuropsychiatric syndrome that may occur in the days or weeks following administration of certain immunotherapies, especially CAR-T cell therapies, available for treatment of relapsed and refractory hematologic malignancies. The

clinical presentation of ICANS includes encephalopathy with confusion and behavioral changes, visual and auditory hallucinations, language dysfunction, apraxia, dysgraphia, headache, seizures, and, in severe cases, cerebral edema with coma.

Case report: We describe the case of a 68-year-old woman with refractory diffuse large-B-cell lymphoma who received CAR-T cell therapy. The day after she presented a cytokine release syndrome (CRS) with fever and hypotension. She complained also headache, confusion and aphasia, symptoms compatible with ICANS. The woman was treated by tocilizumab and dexamethasone. On day 5 she developed spatial and temporal disorientation and sudden deterioration in consciousness level, necessitating admission to the neurological ICU. EEG showed fast and diffuse polyspikes and wave discharges, compatible with generalized non-convulsive status epilepticus (NCSE). Cerebrospinal fluid analysis showed increased protein level, without evidence of infection. Cerebral MRI showed T2 hyperintensity within the left inferior frontal gyrus with signs of impaired blood-brain barrier (BBB), compatible with focal cerebral edema. NCSE was treated with midazolam, levetiracetam, lacosamide and fenobarbital. On day 10, the patient mental status improved, even persisting mild aphasia. MRI findings of the brain resulted completely normalized by day 20 with a total regression of language dysfunction.

Discussion: Despite the clinical features of ICANS could be readily recognizable, its pathophysiology remains poorly understood. A possible hypothesis is that high levels of circulating cytokines result in endothelial-cell activation and BBB disruption, which in turn cause an inflammatory cascade within the CNS, subsequent alterations in cortical-subcortical functions, and cerebral edema in some cases. Treatment is supportive and consists of glucocorticoids, antiepileptics and tocilizumab if a concurrent CRS is present. While neurologic deficits are usually reversible with appropriate management, fatal outcomes have been reported secondary to malignant cerebral edema. Since CAR-T cell-therapy rapidly entering in clinical practice, a profound knowledge of the clinical presentation, early identification and prompt therapeutic action is an essential requisite for neurologists. From our experience, EEG is a fundamental diagnostic tool to identify status epilepticus, a rare but relevant manifestation of ICANS. It can be possible that the rate of NCSE is under-diagnosed for the EEG underutilization, yet its identification is crucial to the management of ICANS.

## A NEXT GENERATION SEQUENCING STUDY OF A FAMILIAL EPILEPSY WITH PHENOTYPIC VARIABILITY EVIDENCES A NEW MUTATION IN KCNQ2 GENE

D. Archetto[1], N. Setola[1], E. Signoriello[1], S. Bonavita[1], S. Gambardella[2], C. Coppola[1]

[1]Department of Advanced Medical and Surgical Sciences, University of Campania "L. Vanvitelli" (Napoli); [2]IRCCS Neuromed Mediterranean Neurological Institute (Pozzilli-IS)

Objective: Epilepsy is a neurological disorder that can have different aetiologies including genetics. In recent years, numerous genes associated with various forms of epilepsy have been highlighted with the advent of techniques such as next generation sequencing. One of the most involved genes in epilepsy is KCNQ2, encoding for voltage-dependent potassium channel subunits.

Materials and methods: We describe a 21-year-old woman who, at the age of 17, presented episodes of seizures characterized by throbbing headache followed by loss of consciousness. In addition, she presented some episodes of loss of consciousness, preceded by pallor and algid sweating. The family history was positive for epilepsy: her 11-year-old brother suffered of nocturnal epilepsy since the age of 4 and her 38-year-old mother had episodes of parasomnia from adolescence to adulthood. Her paternal grandfather suffered from late epilepsy after a stroke. The proband was studied by medical history, neurological examination, blood tests, magnetic resonance imaging, angiographic magnetic resonance, electroencephalogram, Head Up Tilt test and NGS.

Results: Neurological examination of the proband was negative. Extensive biochemical, immunological, and hormonal tests were not pathological. The HUTT was positive for neurogenic syncope: therefore, some episodes of loss of consciousness were diagnosed as syncope. EEG documented the bilateral presence of some irritative activities in the occipital derivations. Brain MRI and angio-MRI were not pathological. Due to the family history positive for epilepsy, extensive genetic analysis was performed in the proband by NGS. The results showed a mutation of KCNQ2 gene in heterozygosis: p. Leu425ValfsTer9, a deletion of a cysteine which causes a frameshift and termination. The genetic analysis was carried out to the other members of the family. The same mutation was present in her brother and in her mother.

Discussion: The NGS has redefined the genetic landscape of the epilepsies: the high-definition molecular genetic diagnosis is important to inform patients and healthcare professionals about the prognosis of the disease, the clinical management and the creation of new target therapies.

Conclusions: To date, 296 KCNQ2 variants are known: the variant p. Leu425ValfsTer9 has been discovered for the first time in a familial epilepsy with phenotypic variability within the same family in several generational lines. This feature completely reflects the already known phenotypic variability associated with KCNQ2.

Background: Anxiety is one of the most relevant psychiatric comorbidity in people with epilepsy (PwE). [1-2] The role of resilience (RES) in the development of anxiety is not well understood. [3] We purposed to better characterize RES impact on anxiety severity in PwE.

Materials and Methods: 176 PwE underwent online surveys including a collection of socio-demographic, seizure-related and psychological variables. PwE were grouped according to the data collected; anxiety levels were compared through non-parametric statistics. Hierarchical regression analysis (HRA) and logistic regression were performed to characterize RES contribute in predicting the presence and the severity of anxiety. Mediation/moderation analysis was performed to evaluate causal effects among RES, depression and anxiety.

Results: Anxiety did not differ according to socio-demographic and seizure-related variables, exemption for the presence of drug-related adverse effects. Depression, RES and sleep quality provided the major contribute on anxiety variance. The addiction of RES level in HRA and logistic regression provided a significant increase of R-squared value (p-value=.02) and of Area Under the Curve (p-value=.03), respectively. RES modulated depression/anxiety relationship (p-value<.001), while depression did not mediate RES/anxiety correlation (p-value=.68).

Conclusions and discussion: We demonstrated that RES is a significant independent predictor of anxiety in PwE, able to modulate depression impact on anxiety. Moreover, we confirmed the relevance of depression and sleep quality on anxiety severity.

## CLINICAL-INSTRUMENTAL-RADIOLOGICAL PROGRESSION OF AN EARLY CEREBRITIS PRESENTING WITH FIRST SEIZURE IN AN OTHERWISE HEALTHY MAN: A CASE REPORT

M. R. Bagnato[1], M. Di Donna[2], M. Di Ruzza[3], C. Del Bianco[3], M. Ferrante[3], T. Lo Giudice[3], E. Saggese[3], M. Plocco[3]

[1]Stroke Unit, Tor Vergata University (Roma); [2]Neurology, Tor Vergata University (Roma); [3]UTN, Spaziani Hospital (Frosinone)

Introduction: A 63-year-old man comes to E.R. for secondary generalized seizure, preceded by motor automatism. He is on home antihypertensive therapy. He denies fever and previous seizure. Clinical examination shows mild expressive aphasia. Brain CT and angio-CT are normal. EEG demonstrates frequent left F-C-T irritative waves with contralateral diffusion. Brain MRI-Gd shows small left mesial-frontal T2-FLAIR hyperintensity, T1 isointense, not capturing gadolinium. MRI appears compatible with low-grade glioma. Neurological conditions worsen in 5 days with confabulation and confusion. Thus, MRI with spectroscopy and perfusion studies is repeated. The known lesion has grown with extension to the left orbital gyrus, becoming hypointense at T1 and with peripheral gadolinium impregnation. Perfusion study is normal. Peak of NAA is observed. Given the abrupt change, lumbar puncture is executed. 18 WBCs (neutrophils) and 90 proteins are found in CSF. CSF virological and bacteriological tests are negative. Tests for HIV, VDRL, THPA, Toxoplasma, Cryptococcus Neoformans on blood and CSF are negative. On blood exams anticardiolipin IgM are increased (48 mg/dl N.V. < 10 mg/dl). Given the CSF and clinical-radiological condition, suspicion of infectious early cerebritis is raised. Broad-spectrum antibiotic and antimycotic therapy are started. After about 2 weeks, neurological examination is normal, EEG documents sporadic left F-C-T sharp-theta potentials. At 3 weeks of treatment, MRI-Gd illustrates significant reduction of T2-FLAIR hyperintensity, with absent contrastographic impregnation. EEG shows slow potentials in absence of irritative abnormalities. The patient continues treatment for a total of 5 weeks with complete clinical-instrumental-radiological recovery.

Discussion: Early Cerebritis is a rare condition, caused by fungi or bacteria. It precedes the development of brain abscesses. It is often indistinguishable from a glioma, so the rare case reports, have been diagnosed following cerebral biopsy. It may present with seizures and blurred/absent neurologic signs, without fever or elevation of inflammatory markers; only in 25% of cases the responsible microorganism is identified. In our case, the elevation of anticardiolipin antibodies, which often cross-react with viruses, bacteria and fungi, together with CSF exams and rapid clinical-instrumental-radiological change allowed prompt diagnosis and treatment without brain biopsy.

Conclusion: In case of new, unclear brain lesions, even without infectious markers, Early Cerebritis should be taken into account. In selected cases, a short-distance MRI may be useful to distinguish between cerebritis and neoplasia, without invasive procedures like brain biopsy. Progression to potentially life-threatening infections, which develops in about 2 weeks, can be blocked by tempestive antibiotic therapy, with complete recovery.

## ROLE OF NEW GENERATION WISE CORTICAL STRIP (WCS) IN BOTTOM-OF-THE-SULCUS FOCAL CORTICAL DYSPLASIA: A CASE REPORT.

N. Biagioli[1], S. Morandi[2], E. Moriconi[3], G. Giovannini[4], M. Pugnaghi[4], N. Orlandi[1], A. Vaudano[4], G. Pavesi[3], V. Tramontano[2], S. Meletti[1]

[1]Department of Biomedical Metabolic Sciences and Neurosciences, University of Modena and Reggio Emilia (Modena); [2]SSD of Clinical Neurophysiology, AOU of Modena (Modena); [3]CS of Neurosurgery Department, AOU of Modena (Modena); [4]CS of Neurology, AOU of Modena (Modena)

Background: In epilepsy surgery, intraoperative electrocorticography (iECoG) can add information to identify the epileptogenic zone and guide the surgical resection. Bottom-Of-Sulcus-focal cortical Dysplasia (BOSD) are often difficult to detect with iECoG due to their deep localization. We describe a patient with drug-resistant frontal lobe epilepsy due to BOSD who underwent an iECoG-guided cortectomy using next-generation cortical strips (Wise Cortical strip, WCS) capable of easily adapting to cortical gyri.

Methods: We performed serial iECoG recordings with WCS (4-contact, length: 62 mm; thickness: 0.25 mm; Material: platinum; exposed electrode diameter: 2.3 mm; inter-electrode distance: 10 mm). Strip were placed on the suspected epileptogenic lesion, then on the resection border. Both bipolar and referential electrode montages were

reviewed to identify epileptiform activity (ranked through Palimini's classification).

Results: A right-handed 20-years-old male presented with frontal lobe seizures since he was 8 years-old. Longterm monitoring (LTM) recorded numerous interictal epileptiform discharges (IEDs) and several seizures without loss of consciousness arising from right frontal scalp eletcrotes. A 3T brain MRI showed a FCD on the bottom of inferior frontal sulcus. IECoG, performed on the convexities of the investigated frontal cortex, recorded sporadic spikes (Class. Palmini A). Then WCS was placed on the floor of the sulcus (between precentralis girus and parsoperculari girus) and showed a 3-4 Hz continuous/subcontinuous rhythmic spikes activity from the deepest electrode (Palmini D). Registration after resection of the BOSD didn't show any epileptiform activity. Pathology showed dysmorphic neuron and gliosis. No surgical complications occurred. Patient is seizure free after 6 months.

Conclusions: iECoG can be a useful tool in epilepsy surgery to define epileptogenic zone, especially in lesion-negative patient. However, it's not always easy perform optimal registration on the suspected cortex. This case report showed that WCS features allowed to perform high-quality registration from the bottom of the sulcus, leading to surgical resection of highly epileptogenic cortex.

## ANTISEIZURE MEDICATIONS FOR PRIMARY PREVENTION OF ACUTE SYMPTOMATIC SEIZURES AFTER STROKE: A SYSTEMATIC REVIEW

F. Brigo[1], S. Broggi[2]

[1]Department of Neurology, Hospital of Merano (SABES-ASDAA) (Merano-BZ); [2]Neurological Clinic, Department of Experimental and Clinical Medicine, Marche Polytechnic University (Ancona)

Aims: To evaluate the efficacy of antiseizure medications (ASMs) in primary prevention of acute symptomatic seizures (ASS) after stroke (ischemic or haemorrhagic).

Material and methods: Systematic search of the literature (CENTRAL; MEDLINE; ClinicalTrials.gov) to identify randomized controlled trials (RCTs). Critical appraisal and qualitative synthesis of study results.

Results: We included two placebo-controlled trials (total 114 participants) conducted in haemorrhagic stroke [1,2]. In one RCT, ASS occurred in 1/ 36 patients (2.7%) with valproate and in 4/36 patients (7%) with placebo (p=0.4) [1]. In the other RCT, ASS were electrographic only and occurred in 3/19 (16%) with levetiracetam and in 10/23 (43%) with placebo (p=0.043) [2]. Both RCTs were stopped prematurely, including a lower number than initially planned. In the levetiracetam trial, there was an imbalance of baseline characteristics, with higher prevalence of factors possibly associated with ASS [2].

Discussion: The evidence on ASMs for primary prevention of post-stroke ASS is limited to intracerebral haemorrhage, of low quality, imprecise, and not enough informative to guide clinical practice. The statistically significant result favouring levetiracetam could reflect imbalance of prognostic factors across groups at baseline. Performing studies with a number of patients lower than initially planned increases the risk of covariate imbalance at baseline and imprecise results.

Conclusions: Additional studies are required to evaluate the role of ASMs in preventing post-stroke ASS. It should be clarified whether brief electrographic seizures without any clinical correlate affect functional outcomes and mortality in stroke patients. Finally, it should be evaluated if preventing ASS may have antiepileptogenic effects modifying the risk of post-stroke epilepsy.

## EPILEPTIC SEIZURES PROBABLY ARISING FROM THE CEREBELLUM: A CHALLENGE TO THE TRADITIONAL CORTICOCENTRIC VIEW OF EPILEPSY

F. Brigo

Department of Neurology, Hospital of Merano (SABES-ASDAA) (Merano-BZ)

Objective: To describe a patient with an epileptic seizure whose epileptogenic zone was probably located in the cerebellum.

Methods: Case report.

Results: A 51 years-old healthy male experienced a first-ever apparently generalized tonic-clonic seizure. Seven years earlier he underwent a surgical removal of a cerebellar metastasis (right cerebellar hemisphere) of a renal carcinoma, through a surgical access in the nearby region. His medical history was otherwise perfectly unremarkable. The oncological follow-up was normal. Despite a thorough diagnostic work-up no further explanations for the epileptic seizure were found. Brain magnetic resonance imaging showed only a gliotic area in the right cerebellar hemisphere and the small skull section in the region of prior craniotomy. The EEG recording, including a prolonged sleep-deprived recording, was normal. A treatment with levetiracetam 1000 mg/day was started and the patient did not experience any further epileptic seizure.

Discussion: Traditionally, it is widely believed that epileptic seizures originate in the cerebral cortex, although with some interplay with subcortical structures like the thalamus. However, in recent years evidence has been accumulated for an initiation of epileptic seizures within subcortical structures. In the literature there are few cases of seizures thought to have arisen from the cerebellum [1]. Furthermore, animal studies have shown that it is possible to induce seizures by cerebellar electrical stimulation [2].

Conclusions: The present case adds to the available literature and contributes to challenging the traditional corticocentric concept of epilepsy, suggesting that a cerebellar lesion could have an intrinsic seizure-generating (i.e., epileptogenic) potential leading to epileptic seizures. This hypothesis is supported by the extensive cortico–subcortical anatomical and functional connections between the cerebral cortex and the cerebellum. Further studies are required to confirm this hypothesis.

## "IS IT STRUCTURAL EPILEPSY?" CRITICAL APPRAISAL OF THE ILAE DEFINITION OF EPILEPSY

F. Brigo[1], S. Broggi[2]

[1]Department of Neurology, Hospital of Merano (SABES-ASDAA) (Merano-BZ); [2]Neurological Clinic, Department of Experimental and Clinical Medicine, Marche Polytechnic University (Ancona)

Objective: To critically evaluate the accuracy of the current ILAE practical definition in the setting of a first unprovoked seizure following an acquired static brain lesion.

Methods: Critical appraisal of the Case example n. 2 of the ILAE official report on the practical clinical definition of epilepsy [1] and of the study therein quoted [2] reporting the risk of a subsequent unprovoked seizure after a first seizure following stroke, brain injury or cerebral infection.

Results: According to ILAE definition, epilepsy can be diagnosed after a first unprovoked seizure following stroke, brain injury or cerebral infection due to the "high (>70%) risk of another unprovoked seizure". In the single study used to substantiate this statement, only the risk of recurrence after a first unprovoked post-stroke seizure was ≥60% over the next 10 years. For seizures due to trauma or infection, the values within the 95% confidence intervals do not rule out a long-term risk of recurrence <60%.

Discussion: The application of the current practical definition of acquired structural epilepsy as reported in the ILAE official report is inaccurate. The estimates for risk of seizure recurrence after a first unprovoked seizure due to brain trauma or infection are imprecise and do not automatically support a diagnosis of epilepsy. The current definition carries the risk of overdiagnosing epilepsy, with possible negative psychosocial consequences and unnecessary use of antiseizure medications.

Conclusions: There is an unmet need to clarify which factors modify the risk of seizure recurrence in various clinical situations.

## OCCIPITAL LOBE EPILEPSY AND AN EEG PATTERN SUGGESTIVE OF PROLONGED EYE-CLOSURE SENSITIVITY: A CASE REPORT

F. Brigo[1], B. Nucera[1], D. Flore[1], I. Ferraiuolo[1], A. Bratti[1], S. Broggi[2], F. Rinaldi[1]

[1]Department of Neurology, Hospital of Merano (SABES-ASDAA) (Merano-BZ); [2]Neurological Clinic, Department of Experimental and Clinical Medicine, Marche Polytechnic University (Ancona)

Objective: Description of an adult patient with occipital-onset epilepsy with visual seizures and possible prolonged eye-closure sensitivity.

Methods: Case report

Results: A 35-year-old woman with seizures with simple visual hallucinations ("white dots") in both visual fields since the age of 3 years. They were followed by altered consciousness, and occasionally by occipital headache with nausea. Initially the frequency was weekly, but in adulthood it has become very rare. There are no clear triggering factors, and seizures occur in various light conditions. The neurological examination is normal. Visual field: normal. EEG: diffuse rhythmic (epileptiform?) abnormalities of long duration, constantly present at the closing of the eyes, disappearing at complete darkness and at open eyes with Frenzel glasses. No photosensitivity. Brain MRI: Pineal cyst, nodular heterotopia in mesial occipital cortex links. Therapy: Lamotrigine 150 mg X 2; Levetiracetam 1500 mg X 2; Clobazam 10 mg.

Discussion: In posterior occipital evisual epilepsy of children seizures starting from the occipital lobe can be associated with epileptiform abnormalities on eye closure, mostly attributable to fixation-off phenomenon, scotosensitivity or eye closure sensitivity. However, these are self-limiting forms. Our patient has epilepsy with visual seizures, and with a peculiar EEG pattern that is difficult to classify, not resembling fixation-off or scotosensitivity. Instead it might be interpreted as eye-closure sensitivity, with markedly prolonged and persistent EEG abnormalities lasting as long as the patient keeps her eyes closed. The phenomenon is intriguing due to the possible relationship with the cortical mechanisms of genesis of the posterior dominant rhythm.

## P-GLYCOPROTEIN INHIBITORS AS ADJUNCTIVE TREATMENT FOR REFRACTORY SEIZURES: A SYSTEMATIC REVIEW OF THE LITERATURE WITH SOME METHODOLOGICAL CONSIDERATIONS

F. Brigo[1], S. Broggi[2]

[1]Department of Neurology, Hospital of Merano (SABES-ASDAA) (Merano-BZ); [2]Neurological Clinic, Department of Experimental and Clinical Medicine, Marche Polytechnic University (Ancona)

Objectives: To evaluate the efficacy of the P-glycoprotein inhibitors tariquidar, elacridar or verapamil as adjunctive treatment for refractory seizures.

Method: Systematic search of the literature (CENTRAL; MEDLINE; ClinicalTrials.gov) to identify randomized controlled trials (RCTs) evaluating the efficacy of tariquidar, elacridar or verapamil as add-on treatment for refractory seizures. Critical appraisal and qualitative synthesis of study results.

Results: No RCT on tariquidar or elacridar was found. We identified two pilot RCTs on verapamil (31 patients included) [1,2]. One was an open-label trial comparing two different doses of verapamil (120 mg/day, 13 patients versus 240 mg/day, 6 patients) [1] and the other was a double-blind RCT comparing verapamil (240 mg/day, 7 completers) versus placebo (5 completers) [2]. In the former RCT, 7 patients (36.84%) experienced a > 50% reduction in seizure frequency (3/6, 50% in the 240 mg/day and 4/13, 30.7% in the 120 mg/day) [1]. In the latter, no patient achieved 50% reduction in seizure frequency [2].

Discussion: The lack of a placebo control prevented the RCT that compared two different doses of verapamil from revealing the efficacy of this drug by subtracting and controlling for the variables that can influence clinical outcomes (regression to the mean, changes in seizure frequency due to the natural course of the disease, and placebo effect). Both RCTs were conducted in a small number of patients, with risk of imbalance of prognostic factors at baseline due to random fluctuations in known and/or unknown variables. The small sample size prevented both RCTs from reaching an adequate statistical power to identify a difference in efficacy between the treatment arms.

Conclusions: The evidence on verapamil as an adjunctive treatment for refractory seizures remains preliminary. Enrichment strategies (e.g., based on results of [11C]-verapamil PET scan) could identify patients

with P-glycoprotein overexpression in the brain, possibly increasing the informative value of future RCTs.

## THE INFLUENCE OF PATIENT'S AGE AT FIRST EPILEPTIC SEIZURE ON SEIZURE RECURRENCE: A PRELIMINARY ANALYSIS

F. Brigo[1], A. Zaboli[2], G. Turcato[3], S. Broggi[4]

[1]Department of Neurology, Hospital of Merano (SABES-ASDAA) (Merano-BZ); [2]Department of Emergency Medicine, Hospital of Merano-Meran (SABES-ASDAA) (Merano-BZ); [3]Department of Internal Medicine, Hospital of Santorso (AULSS-7) (Santorso-VI); [4]Neurological Clinic, Department of Experimental and Clinical Medicine, Marche Polytechnic University (Ancona)

Objective: To evaluate whether the patient's age at first epileptic seizure affects the risk of seizure recurrence.

Methods: This is a preliminary retrospective analysis of a large database of all patients accessing the emergency department of our hospital for epileptic seizures from 2001 to 2021. We included data on a randomly chosen subset of patients with a first-ever seizure. We stratified patients according to their age at first seizure: <15 years, 15-65 years, and >65 years. We compared the risk of a first seizure recurrence in different time intervals (30 days, 90 days, 6 months, 1 year after the first seizure) with a Kaplan-Meier survival analysis.

Results: We included data on 377 patients (135 with seizure recurrence, 35.8%). Overall, the risk of seizure recurrence after a first-ever epileptic seizure was highest in patients aged >65 years and lowest in those aged 15-65 years. A significant difference in risk of seizure recurrence was observed in the 30 days (p=0.017), 90 days (p=0.014), and 6 months (p=0.009) after the first seizure; the difference was not significant at 1 year (p=0.09).

Discussion: Our preliminary analysis shows that the patient's age at first seizure affects the risk of recurrence up to 6 months. Overall, in this timeframe the risk appears highest in patients aged >65 years and lowest in those aged 15-65 years.

Conclusions: Future analyses will investigate further the role of age in seizure recurrence, considering the difference between acute symptomatic and unprovoked seizures, seizure etiology, and other prognostic factors.

## USE OF PERAMPANEL IN ORAL SOLUTION IN THE TREATMENT FOR SEIZURES RESISTANT TO INTRAVENOUS ANTI-SEIZURES MEDICATIONS

G. Bruschi[1], F. Ferreri[2], B. Kassabian[1], L. Pellegrino[1], D. Seppi[1], S. Favaretto[1], M. Corbetta[1], F. Dainese[1]

[1]Unit of Neurology, Department of Neuroscience, University Hospital of Padua, University of Padua (Padova); [2]Department of Clinical Neurophysiology, Kuopio University Hospital, University of Eastern Finland (Kuopio-FIN)

Introduction: Perampanel (PER) is a non-competitive receptor antagonist of beta-amino-3propionic acid (AMPA), that has been shown to be useful in treating status epilepticus in animal models. For humans, there isn't much information available.

Aims: The aim of the study is to identify how patients with super-refractory status epilepticus (SESR) respond to therapy with PER at various doses.

Methods: Retrospective study of SESR patients treated with PER. The treatment response was based on (1) attenuation of the EEG-graphic ictal pattern within 96 hours of first administration of PER and (2) survival after hospital discharge. In order to compare treatment responses, the population was then split into two groups depending on PER intake (cut-off 24 mg).

Results: A total of 12 patients were included in the study (83.3% F, 16.7% M, average age 60 years ± 18.14, 25% with focal motor epileptic status, 75% with generalized convulsive epilepsy status). PER was given with an average load dose of 17.16 mg ± 8.26, on average 271 ± 362.21 hours after the beginning of SESR and typically as 4.4 ± 1.5 anti-seizures medication. On the total population, 8 patients resulted responders assessing EEG (66.7%), whereas 11 considering the survival after discharge (91,67%). Response rates were (100%) and (100%) in the PER 24 mg group (7), while they were (20%) and (80%) in the PER < 24 mg group (5).

Conclusion: PER, especially at the dose of 24 mg, showed to be a successful treatment for SESR despite the limitations brought on by the limited sample size.

## FAMILIAL GENERALIZED EPILEPSY WITH BROAD PHENOTYPE, INCLUDING SUNFLOWER SYNDROME

J. Buonocore, A. Saraceno, I. Martino, A. Giugno, I. Sammarra, F. Fortunato, A. Gambardella

Institute of Neurology, Department of Medical and Surgical Sciences, University of Magna Graecia (Catanzaro)

Aims: Sunflower Syndrome (SS) is a rare form of generalized epilepsy characterized by significant photosensitivity, heliotropism, and potential self-induced seizures associated with repetitive movements of the upper limbs in front of the eyes [1].

Materials: An 18-year-old woman with a positive family history of epilepsy presented to our clinic. Her mother and maternal aunt have juvenile myoclonic epilepsy with photosensitivity, while her maternal great-grandfather, another maternal aunt, and a cousin have epilepsy with eyelid myoclonus. Since the age of 8, she has been experiencing weekly episodes characterized by a compulsion to face the light from a window at home and rapidly move her left hand in front of her eyes. This is followed by a cessation of behavior, occasionally accompanied by bilateral tonic-clonic movements. At the age of 13, after visiting another medical center, she began treatment with valproic acid up to 400 mg/day, carbamazepine 800 mg/day, and clobazam 20 mg/day, but the seizures persisted.

Results: Neurological examination and blood tests were normal. Standard EEG showed diffuse paroxysmal abnormalities and Grade IV Waltz photoparoxysmal response. During video-EEG monitoring, 23 generalized epileptic seizures were induced by approaching the window with a curtain-like movement of the left hand. Mild atrophy of the right hippocampus was observed on the brain MRI. Exome sequencing has been performed on affected family members, but results are not yet available. Gradual tapering of carbamazepine was initiated, and the dosage of valproic acid was increased to 1000 mg/day. Perampanel was introduced and gradually titrated up to 8 mg/day.

Discussion: Although the original description of SS suggested that it is characterized by self-induced photosensitive seizures [2], more recent evidence has raised doubts about this assumption by proposing that hand movements themselves may already be an ictal manifestation [3]. In our case, the repetitive temporal association between stereotyped hand movements and the appearance of electroencephalographic abnormalities supports the reasonable hypothesis of seizure self-inducibility. The diagnostic and therapeutic implications of the mutations detected in the genetic analysis are still to be clarified. They could potentially provide crucial information for a more precise diagnosis, prediction of the clinical course, and selection of targeted therapies.

Conclusions: The present family provides strong evidence that genetic factors may play a major role in the pathogenesis of SS. Further research is needed to understand the role of genetics and its impact on the diagnosis and treatment of SS.

## DOES EPILEPSY SURGERY REFLECT THE NEEDS AND EXPECTATIONS EXPRESSED BY PATIENTS? EVALUATION THROUGH THE EPILEPSY SURGERY SATISFACTION QUESTIONNAIRE (ESSQ-19)

M. Burani[1], M. Pugnaghi[2], A. Vaudano[1], G. Giovannini[2], N. Orlandi[1], E. Moriconi[2], G. Pavesi[1], S. Meletti[11]

[1]Neurology, AOU of Modena, University of Modena and Reggio Emilia (Modena); [2]Neurology, AOU of Modena (Modena)

Objectives: Approximately 30% of people with epilepsy do not respond to anti-seizure medications. Epilepsy surgery can be proposed as a treatment option in this population. The efficacy and safety of epilepsy surgery are however, still poorly understood, and the only internationally validated tool is the Epilepsy Surgery Satisfaction Questionnaire (ESSQ-19) (Wiebe et al. 2020), which measures satisfaction with epilepsy surgery. The aim of our study was to apply this measurement tool for the first time in Italy.

Methods: We formally translated the English ESSQ-19 into Italian language. Seventy-five patients that entered the epilepsy surgery program at Modena comprehensive epilepsy centre (2018-2022) were invited to participate during their follow-up outpatient visits. Sixty-six of them accepted and completed four questionnaires: IT-ESSQ-19 (Epilepsy Surgery Satisfaction Questionnaire), PCGI (Patient Clinical Global Impression), QOLIE-31 (Quality Of Life In Epilepsy Inventory), and NDDI-E (Neurological Disorders Depression Inventory for Epilepsy). The ESSQ-19 questionnaire consists of 19 items segregated into four domains. Patients were asked to mark the response that best represented their condition, referring to the four weeks prior to completion. Responses were then converted into a score from 0 to 100, where 0 indicated the worst level of satisfaction possible and 100 indicated the best.

Results: The average values of the four domains and total score were: seizure control (83,4; DS 16,7), psychosocial functioning (79,3; DS 17,1), surgical complications (90,8; DS 14,9), recovery from surgery (81,4; DS 16,9), total score (83,7; DS 13,3). The correlation between the QOLIE-31 score and the ESSQ-19 score was positive ($r = 0.6$; $p = 1.54x10\text{-}7$). Most of the interviewed population was not at risk of depression, and the satisfaction level with their pharmacological treatment was positive (4.58 out of 5).

Discussion: The results of our study reveal a high level of satisfaction among individuals who underwent epilepsy surgery. Overall satisfaction is high, considering all the aspects characterizing the treatment process, as well as the respondents' expectations regarding surgical therapy, freedom from seizures, individual functioning within society, complications of the procedure, and post-operative recovery.

Conclusions: The results and the participants' feedback suggest that evaluating the quality of life and satisfaction with a treatment is crucial in clinical practice. Comparing with the original study by Wiebe et al. also revealed some differences between the two samples that should be considered when interpreting the results. These differences may explain the disparity in outcomes but do not diminish the significance of our findings.

## LACOSAMIDE INDUCED ACNE: A CASE REPORT

C. Cabona[1], G. Gasparini[2], I. Pappalardo[1], F. Villani[1]

[1]Clinical Neurophysiology, IRCCS Ospedale Policlinico San Martino (Genova); [2]Dermatology Unit, IRCCS Ospedale Policlinico San Martino (Genova)

Acne is an inflammatory disease of the pilosebaceous unit, which significantly impacts on patients' quality of life, with a critical psychological burden. Acne presents a complex pathogenesis and a wide number of drugs have been proved to provoke it. Lacosamide (LCS) belongs to a new generation of sodium channel blockers, which has been widely employed in people with epilepsy. In the last ten years, new adverse reactions to this drug have been gradually recognized, among which cardiotoxicity and hyponatremia. Differently from several other antiseizure medications (ASM), LCS has not yet been reported in the literature to cause acne as a side effect. Herein, we describe a case of LCS induced acne. A 21-year-old man, with a family history of epilepsy, affected by drug-refractory focal epilepsy of unknown etiology with onset during childhood, but only diagnosed at the age of 19 years presented a painful papulo-pustular eruption, which appeared two months after the introduction of LCS 150 mg BID. The patient presented multiple focal onset seizures with impaired awareness per day. The patient did not take any new drug in recent times, aside from LCS, prescribed in place of levetiracetam for its ineffectiveness. The patient denied any history of acne vulgaris in his youth. The patient was prescribed

minocycline 100 mg 1 tablet/day, with partial improvement at seven months, but immediate relapse upon discontinuation. Suspecting this acne to be drug-induced, it was decided to discontinue LCS, replacing it with brivaracetam. As LCS was tapered, the acne substantially improved and, at 4 months follow-up, mainly solely scars persists. Various ASMs have been associated to acne eruptions. Cases of acne induced by felbamate (4), lamotrigine, ethosuximide and topiramate have been reported in recent years. The lesions arose from one to three months from the administration of the suspected drugs and rapidly improved as the drugs were discontinued. LCS has been associated to the induction of generally mild skin rashes, dermatomyositis and even toxic epidermal necrolysis. However, to our knowledge, this is the first case of LCS caused acne reported yet in the literature.

## ICTAL FEAR MISDIAGNOSED AS PANIC ATTACK: A VIDEO-EEG STUDY

F. Castellana[1], M. Di Claudio[2], V. Palumbo[2], M. Bianchi[2], C. Reale[2], F. Ciccone[3], G. D'Onofrio[3], A. Pennelli[4], T. Popolizio[4], M. Pugliatti[1], G. D'Orsi[2]

[1]Department of Neuroscience and Rehabilitation, University of Ferrara (Ferrara); [2]Epilepsy Center, Neurology Unit, I.R.C.C.S. Casa Sollievo della Sofferenza (San Giovanni Rotondo-FG); [3]Department of Clinical Psicology, I.R.C.C.S. Casa Sollievo della Sofferenza (San Giovanni Rotondo-FG); [4]Neuroradiology, I.R.C.C.S. Casa Sollievo della Sofferenza (San Giovanni Rotondo-FG)

Objectives: To describe the electro-clinical features of a patient with focal epilepsy misdiagnosed for years as panic attacks (PA), highlighting the role of video-EEG monitoring in the differential diagnosis.

Materials: A 25-year-old young patient admitted to our epilepsy centre in early 2023; since the age of eight, she has experienced episodes of visual and olfactory hallucinations accompanied by intense fear. For approximately ten years, she has been under psychiatric follow-up for panic disorder, without deriving significant benefit from treatments.

Methods: The patient was evaluated by a multidisciplinary team and underwent the following: prolonged polygraphic video-EEG monitoring (18 hours) during wakefulness and REM/NREM sleep (using additional bilateral zygomatic electrodes), neuropsychological assessment, brain MRI with targeted study of the temporal lobes and perfusion MRI study.

Results: We recorded 5 focal seizures characterized clinically by intense feeling of fear, epigastric discomfort with nausea/vomiting, visual and auditory hallucinations, oroalimentary and gestural automatisms with the right hand, accompanied by corresponding EEG patterns characterized by paroxysmal activity predominantly in the right temporal and zygomatic derivations. The neuropsychological evaluation revealed a mild visuospatial disorganization, while the brain MRI documented a dysplastic lesion of the right amygdala with concurrent hyperperfusion.

Discussion: The overlapping semiological features between PA in patients with panic disorder and affective epileptic seizures (CA) in patients with focal temporal epilepsy represent a diagnostic challenge. In fact, in approximately 10-15% of patients with temporal epilepsy, sudden sensations of fear can be observed among the ictal symptoms [1]. The epileptogenic focus of "ictal fear" is typically localized in the right temporal lobe [2], particularly in the amygdala and anterior cingulate cortex [3]. Our electroclinical, neuropsychological, and neuroradiological data support a right temporal epileptogenic focus responsible for the symptoms experienced by the young patient for years.

Conclusions: Prolonged video-EEG monitoring allowed us an accurate diagnostic classification of affective ictal manifestations that were mistakenly interpreted for years as PA.

## A CASE SERIES OF LATE-ONSET EPILEPSY, COGNITIVE DECLINE AND MRI FLAIR TEMPORAL HYPERINTENSITY: WHERE TO GO FROM HERE?

A. Castelli, F. Placidi, A. Pagano, G. Di Mauro, C. Liguori, C. Ferrazzoli, F. Avvento, N. Mercuri, F. Izzi

Epilepsy Centre, Neurology Unit, University of Rome Tor Vergata (Roma)

Introduction: The etiological diagnosis of late-onset epilepsy(LOE) is a challenge for neurologists, especially when it is associated with non-specific clinical and radiological features that can be found across several neurological conditions.

Methods: Between January and April 2023 we evaluated four patients diagnosed with LOE, all presenting with Mild Cognitive Impairment and MRI T2-FLAIR hyperintensity in the mesial temporal lobe. We evaluated EEG findings, results from CSF analysis, neuroradiological and Fluorodeoxyglucose (FDG) whole-body PET imaging features.

Results: The four patients were all women (mean age 63.5±3.1 years) with recent onset of memory deficits and FLAIR hyperintensity at the left temporo-mesial lobe. Patient n°1 presented generalized seizures, FDG hypermetabolism in the left temporal lobe, focal subclinical epileptiform activity on EEG, increase of t-tau (876pg/ml) and LGI1 antibodies positivity at CSF evaluation. Patient n°2 had focal impaired awareness seizures, FDG hypometabolism in the left temporal structures, minimal interictal focal EEG discharges and increased CSF t-tau (535pg/ml). Patient n°3 had generalized seizures, normal FDG PET, subclinical epileptiform activity on EEG. Patient n°4 had focal seizures and nonconvulsive status epilepticus, both FDG PET and CSF were normal. Both patient n°1 and patient n°4 underwent significant amelioration after the administration of empirical therapy with steroids.

Discussion: Despite our efforts, we were able to reach a definite diagnosis only in patient n°1 (anti-LGI1 encephalitis). In fact, hyperintense temporal signal in MRI FLAIR weighted images can underpin different disorders (i.e. herpetic encephalitis, temporal glioma, or autoimmune encephalitis), and,while some radiological features are more common in certain diseases(such as unilateral involvement and loss of differentiation between grey and white matter in tumours), MRI alone cannot discriminate between different aetiologies. Thus, reaching a definite diagnosis can be difficult in the absence of neuropathological confirmation. Brain metabolic patterns at FDG-PET could help investigating MRI findings, but distinct types of lesions can lead to different findings (es. a paradoxical hypometabolism in case of necrotic

tumours) and timing of FDG injection can also influence its results, since FDG hypermetabolism can also be caused by ongoing seizure activity. Moreover, case 4 offers proof that, as supported by literature, the autoimmune aetiology should always be considered, and that empirical immunotherapy could help preventing permanent structural damages and long-term sequelae, even in the absence of CSF antibodies positivity.

Conclusions: The triad formed by LOE, cognitive impairment, and MRI temporal alterations should prompt to carefully consider of all diagnostic possibilities, including lesser-known ones, as they are potentially reversible with pharmacological treatment.

## SLEEP-RELATED HYPERMOTOR EPILEPSY IN A PATIENT WITH SKANK 2 MUTATION: A CASE REPORT

P. Chessa[1], M. Usai[1], C. Fois[2], P. Solla[2], D. Corda[2]

[1]Department of Medical Sciences and Public Health, University of Cagliari (Cagliari); [2]Department of Medical, Surgical and Experimental Sciences, University of Sassari (Sassari)

Objective: SHANK genes encode for postsynaptic scaffold proteins which are involved in excitatory synapse development, function and plasticity. Mutations of SHANK family genes are typically associated with intellectual disability, speech delay and autism spectrum disorders. Epilepsy is commonly reported in patients with SHANK3 gene mutations, while association with SHANK2 remains unclear. We report a case of a 36-year-old man with sleep-related hypermotor epilepsy (SHE) carrying a de novo SHANK2 pathogenic mutation.

Case report: A 36-year-old left-handed man presented with a history of seizures that began at the age of 15. He was diagnosed with specific language impairment and learning disability at the age of 2. The past medical history was insignificant for febrile seizures, status epilepticus, head injury, central nervous system infections and skin lesions. His family medical history was negative for seizures. Seizures were brief, mostly during sleep, and characterized in sequence by sensation of throat constriction, fear, epigastric aura, grimacing, moaning, rhythmic pelvic thrusting, left hand opening, hyperkinetic movements of the right upper limb ending with him covering his face with his hands. Electroencephalography (EEG) and video-EEG showed ictal and inter-ictal discharges in the frontocentral regions, predominant over the left hemisphere. After being seizure-free for 7 years on carbamazepine monotherapy, he developed drug-resistant seizures. Brain magnetic resonance (3T) was negative for structural abnormalities. Genetic analysis performed with Next Generation Sequencing panel for epilepsy revealed de novo heterozygous pathogenic variant c.1869_1873dup of SHANK2 gene, determining the introduction of a premature stop codon p.Ala625GlyfsTer8.

Discussion and Conclusions: Clinical phenotype of SHANK2 gene mutation is variable and very few data are available about its correlation with epilepsy. Indeed, a single case of a patient with generalized tonic-clonic seizures and de novo pathogenetic mutation of SHANK2 has been reported so far. This report enlarges the phenotypic spectrum of SHANK2 mutations and may expand the possible genetic causes of SHE.

## ANTI-LGI1 LIMBIC ENCEPHALITIS, A TREATABLE ENTITY WITH POTENTIAL GOOD PROGNOSIS: A CASE-SERIES

V. Ciampana[1], G. Filisetti[1], D. Vecchio[1], C. Varrasi[2], E. Schintone[3], M. Ravagnani[3], M. Mongiovetti[3], M. Coletti-Moja[3], D. Laterza[3], R. Cantello[4], G. Gusmaroli[3], L. Godi[5], C. Comi[6]

[1]Department of Neurology, University of Eastern Piedmont (Novara); [2]Department of Neurology, University Hospital "Maggiore Della Carità" (Novara); [3]Department of Neurology, Hospital "Ospedale Degli Infermi" (Biella); [4]Department of Neurology, University Hospital "Maggiore Della Carità", University of Eastern Piedmont (Novara); [5]Department of Neurology, Hospital Santissima Trinità (Borgomanero-NO); [6]Department of Neurology, Hospital "Sant'Andrea", University Hospital "Maggiore Della Carità", University of Eastern Piedmont (Novara)

Anti-LGI1 encephalitis is a rapidly progressive Limbic Encephalitis (LE) with LGI1-antibodies in serum and CSF, although their positivity is not necessary for the diagnosis but helpful to predict prognosis. Main clinical features are seizures, including Facio-Brachial Dystonic Seizures (FBDS), short-term memory loss and cognitive impairment. The aim of this case-series is to compare three patients diagnosed for LGI1-LE with regard to clinical presentation, diagnosis and prognosis. We retrospectively analyzed data of three patients diagnosed in the Department of Neurology at Hospital of Novara, Biella and Borgomanero. We compared clinical presentation and data from blood and cerebrospinal fluid (CSF) tests, electroencephalogram (EEG), brain Magnetic Resonance Imaging (MRI) and total-body Positron Emission Tomography with Fluorodeoxyglucose (PET-FDG). All patients were tested for onconeural and anti-surface receptors antibodies on serum and CSF. We compared cognitive outcomes in short-term follow-up. Two of three patients are male, the average age at onset is 65 years. All patients had a subacute onset of confusion and short-term memory loss; moreover, the woman developed seizures, both men developed involuntary stereotyped movements on upper limbs. One case had flu twenty days earlier, another was positive for SARS-Cov2 infection. Only one had hyponatremia at blood tests. EEG in two cases proved positive for abnormalities in temporal lobes; in the third, a video-EEG proved positive for lateralized FBDS without EEG-abnormalities. MRI proved positive for temporal-medial-hippocampal abnormalities in two cases. Total-body PET was negative for occult neoplasia for all. Everyone had negative virological panel and positive anti-LGI1 Antibodies in both serum and CSF. In the suspicion of LE, they were treated with high-dose intravenous methylprednisone followed by intravenous immunoglobulines with benefit. Only one developed a recurrence of FBDS after flu, treated with steroid. At short-term follow-up, they returned at the pre-morbidity status reporting no residual cognitive impairment. All patients were diagnosed for LE without delay, as on the basis of Graus et al. criteria, and confirmed with anti-LGI1 antibodies positivity. Even

if LGI1-LE is known to be a rapidly progressive disease, early treatment in these cases contributed to achieve good short-term prognosis, even if a long-term follow-up is still ongoing. In conclusion, our case-series confirms literature data about the clinical, laboratory and instrumental presentation and helps clinicians to place the right suspicion of the rare entity of LGI1-LE, in order to start promptly immunosuppressive treatments, to achieve better short-term outcomes and reduce irreversible deficits in the long-term.

## CANNABIDIOL IS ASSOCIATED WITH THE IMPROVEMENT OF NEUROPSYCHIATRIC PROFILE IN PATIENTS WITH LENNOX-GASTAUT SYNDROME

S. Cipollone, F. Dono, G. Evangelista, S. Consoli, S. De Angelis, C. Corniello, D. Liviello, F. Anzellotti, M. Onofrj, S. Sensi

Department of Neuroscience, Imaging and Clinical Science, "G. D'Annunzio" University of Chieti-Pescara (Chieti)

Introduction: Lennox-Gastaut syndrome (LGS) is a severe, refractory epilepsy syndrome with onset in early childhood. Treatment of LGS is challenging and most of the available anti-seizure medications (ASM) currently available fail to control seizures. LGS is also associated with an increased frequency of psychiatric comorbidities such as depression and anxiety. Cannabidiol (CBD) is a phytocannabinoid with antiseizure properties in absence of psychoactive effects. This study aims to evaluate CBD neuropsychiatric effects in adult patients suffering from LGS.

Methods: Patients with a diagnosis of LGS according to International League against Epilepsy (ILAE) criteria were consecutively enrolled at the Epilepsy Center of "G. d'Annunzio" University of Chieti-Pescara. Neuropsychiatric effects of CDB were monitored using the Beck Inventory Scale (BDI) and Beck Anxiety Inventory (BAI) at the baseline visit and the 6-month follow-up.

Results: Seven patients were enrolled (mean age:25.4±8.2 years). Mean CBD dosage was 7,5 mg/kg/die (IQR:5-10). Median epilepsy duration was 18.2±5.2 years. At the baseline, 3 patients showed mild depression according to BDI score (median:17, IQR:8-18). At a 6-month follow-up visit, BDI evaluation showed a great improvement in depressive symptoms (median: 8; IQR: 5-10). BAI evaluation at baseline highlighted low anxiety in just one patient. The median BAI score was 9 (IQR:5-22). At a 6-month follow-up visit, CBD treatment was associated with a notable improvement in BAI score (median:4; IQR:2-10). A seizure frequency reduction of>50% was observed in the entire cohort.

Conclusion: Treatment with CBD is associated with a decreased frequency and severity of neuropsychiatric symptoms in patients with severe epilepsy.

Introduction: NAA20 is the catalytic subunit of NatB, which is responsible for N-terminal acetylation. Pathogenic variants in NAA20 are associated with human disorders characterized by developmental delay, intellectual disability and microcephaly.

Objective: Five patients carrying two different variants in NAA20 have been described with limited clinical information. We report two Italian siblings carrying biallelic novel variant and their clinical data, expanding the phenotype of this neurodevelopmental disorder and of this epileptic syndrome.

Material and Methods: Whole Exome sequencing (WES)with triobased approach was performed in both. Brain Magnetic Resonance Imaging (MRI)and electroencephalogram (EEG)were performed in both.

Results: In Patient I epilepsy started at age 14, with focal motor to bilateral tonic–clonic seizures, occurring in clusters, several times a month. A partial response to oxcarbazepine, lamotrigine and valproate was observed. EEG showed epileptiform discharges over the frontal regions, both synchronous and asynchronous, and a low amplitude background rhythm. Brain MRI revealed microcephaly with a simplified gyral pattern and marked calvarian thickening, corpus callosum dysgenesis, anterior commissure agenesis, frontal periventricular nodular heterotopias, periventricular white matter signal alterations and cerebellar dysplasia associated with focal areas of cortical gliosis. Patient II presented a single short focal motor episode at age 15. Valproate was started with no seizure recurrence. EEG showed generalized epileptiform discharges and a moderately slow background rhythm. Brain MRI revealed superimposable brain malformations to ones of Patient I. The stepwise filtering identified compound heterozygous variants in NAA20(NM_016100.5): c.100C>T(p.Gln34Ter) of maternal origin and c.11T>C(p.Leu4Pro) of paternal origin. These mutations have never been described in the literature in unrelated parents.

Discussion: Siblings developed epilepsy during adolescence suggesting this could be part of syndrome evolution. In these two patients, we found a similar pattern of brain malformations characterized by microcephaly with a simplified gyral pattern, corpus callosum dysgenesis with an aberrant anteroposterior white matter bundle, cerebellar dysplasia and malformations of cortical development. Similar callosal abnormalities were described in one subject with a NAA20 variant, suggesting a possible role in the development of telencephalic commissures. Furthermore, cerebellar dysplasia with foliar abnormalities was noted, suspected of a possible role of NAA20 in the development and cortical organization of the cerebellum.

Conclusion: Our patients have in common with others previously described microcephaly, limited ability to speak and mild to moderate ID, but they present compound heterozygous variants in NAA20 never been described in the literature in unrelated parents. We expanded the phenotypic and mutational spectrum of NAA20-related syndrome, characterized by epilepsy.

## IDENTIFICATION OF RISK FACTORS FOR DRUG-RESISTANT EPILEPSY

R. Coa[1], R. Lecca[2], F. Arippa[3], D. Fonti[4], L. Polizzi[1], A. Muroni[1], M. Melis[1], M. Figorilli[1], M. Puligheddu[1]

[1]Epilepsy Centre, AOU Cagliari (Cagliari); [2]S.C Neurorehabilitation, PO SS Trinità ASL Cagliari (Cagliari); [3]Department of Medical Sciences and Public Health, Department of Mechanical, Chemical Engineering, University of Cagliari (Cagliari); [4]U.O. Neurology, PO Sirai, ASL Sulcis (Carbonia-SU)

Purpose: Drug-resistant epilepsy (DRE) is a therapeutic challenge for epileptologists and affects 30% of epilepsy subjects. Early identification of people at risk of drug resistance would help tailor pharmacological and nonpharmacological management. The aim of our study was to identify risk factors for DRE in the population of people with epilepsy afferent to the Epilepsy Center of Cagliari University Hospital.

Methods: Data were extracted from the medical records of subjects treated at our Epilepsy Center. Several conditions related to DRE were analyzed by a combination of univariate analysis and logistic regression to assess the effects of different factors: gender, age at onset, etiology (structural, genetic, immune, etc...), history of status epilepticus, seizure type (focal, generalized or combined), learning disability, comorbidities, duration of illness and family history of epilepsy.

Results: 804 people with epilepsy were examined: 201 of them were DREs (26%). Univariate analysis demonstrated a statistically significant association between DRE and age of onset, structural etiology, presence of status epilepticus, type of seizure, presence of psychiatric and neurological comorbidities, learning disability, and family history of epilepsy. Multiple regression analysis showed a significant association between DRE and age of onset, structural etiology, psychiatric and neurological comorbidities, and learning disability.

Discussion: Our data showed that the presence of a structural etiology, psychiatric and neurological comorbidities, learning disabilities, and an early age of onset were statistically significant risk factors for DRE.

Conclusion: Early identification of these factors could guide clinicians in a personalized management of these subjects and improve tailored therapeutic strategies.

Background: Hormonal replacement therapy (HRT) is used for symptomatic treatment of menopause. Some evidence suggests a proconvulsant effect of estrogen and an anti-convulsant role of progesterone. Thus, the use of exogenous sex steroid hormones might influence the course of epilepsy in peri- and postmenopausal women with epilepsy (WWE). We conducted a systematic review on the impact of HRT on the frequency of seizures of WWE.

Materials and Methods: PubMed and Scopus were searched for articles published from inception until August 2022. Abstracts from the last five years from the European Academy of Neurology and European Epilepsy Congresses were also reviewed. Article reference lists were screened, and relevant articles were retrieved for consultation. Interventional and observational studies on WWE and animal models of estrogen deficiency were included. Critical appraisal was performed using the Revised Cochrane risk-of-bias tool for randomized trials and ROBINS-E tools.

Results: Of 497 manuscripts screened, thirteen studies were included, including three human studies. One cross-sectional study showed a decrease in seizures' frequency in WWE using combined HRT, a case-control study showed an increase in comparison with controls and a Randomized Clinical Trial found a dose-dependent increase in seizures' frequency in women with focal epilepsy taking combined HRT. Ten studies addressing the impact of HRT in rat models were also included, which showed conflicting results.

Discussion and Conclusion: There is scarce evidence of the impact of HRT in WWE. Further studies should evaluate the harmful potential and prospective registries are needed for monitoring in this population.

## DIAGNOSIS AND TREATMENT OF LATE-ONSET MYOCLONIC EPILEPSY IN DOWN SYNDROME (LOMEDS): A SYSTEMATIC REVIEW WITH INDIVIDUAL PATIENTS' DATA ANALYSIS

C. Corniello[1,2], F. Dono[1,2,3], G. Evangelista[1,2,3], S. Consoli[1,2,3], S. De Angelis[1,2], S. Cipollone[1,2], D. Liviello[1,2], G. Polito[1], S. Melchiorre[1], M. Russo[1,3], A. Granzotto [1,3], F. Anzellotti[1], M. Onofrj[1,3], A. Thomas [1,3], S. L. Sensi[1,3,4]

[1]Department of Neuroscience, Imaging and Clinical Science, "G. d'Annunzio" University of Chieti-Pescara (Chieti); [2]Epilepsy Center, "SS Annunziata" Hospital (Chieti); [3]Behavioral Neurology and Molecular Neurology Units, Center for Advanced Studies and Technology – CAST, University "G. d'Annunzio" of Chieti-Pescara (Chieti); [4]Institute for Advanced Biomedical Technologies, University of Chieti-Pescara (Chieti)

Introduction: The late onset myoclonic epilepsy in Down Syndrome (LOMEDS) is a peculiar epilepsy type characterized by cortical myoclonus and generalized tonic-clonic seizures (GTCS), in people undergoing cognitive decline associated with dementia in Down syndrome (DS). In this review, we analyzed available data on the diagnostic and therapeutic management of individuals with LOMEDS.

Methods: We performed a systematic search of the literature to identify the diagnostic and therapeutic management of patients with LOMEDS. The following databases were used: PubMed, Google Scholar, EMBASE, CrossRef. The protocol was registered on PROSPERO (registration code: CRD42023390748).

Results: Data from 46 patients were included. DS was diagnosed according to the patient's clinical and genetic characteristics. Diagnosis of Alzheimer's dementia (AD) preceded the onset of epilepsy in all cases. Both myoclonic seizures (MS) and generalized tonic-clonic seizures (GTCS) were reported, the latter preceding the onset of MS in 28 cases. EEG was performed in 45 patients, showing diffuse theta/delta slowing with superimposed generalized spike-and-wave or polyspike-and-wave. A diffuse cerebral cortical atrophy was detected in 34 patients on neuroimaging. Twenty-seven patients were treated with antiseizure medication (ASM) monotherapy, with reduced seizure frequency in 17 patients. Levetiracetam and valproic acid were the most used ASMs. Up to 41% of patients are unresponsive to first-line treatment and need adjunctive therapy for seizure control.

Conclusions: Brain structural changes induced by AD may play a role in LOMEDS onset, although the mechanism underlying this phenomenon is still unknown. EEG remains the most relevant investigation to be performed. A significant percentage of patients developed a first-line ASM refractory epilepsy. ASMs which modulate the glutamatergic system may represent a good therapeutic option.

## DYSPHAGIA, DYSARTHRIA AND OCULOMOTOR DISTURBANCES IN A YOUNG MAN WITH HISTORY OF EPILEPSY: COINCIDENT SYMPTOMS OR COMPLEX SYNDROME?

S. Corsi[1], E. Del Prete[1], C. Milano[1], F. Iannaccone[1], C. Pizzanelli[1], G. Siciliano[1], F. Torri[1], A. Di Fonzo[2], E. Monfrini[3]

[1]Department of Clinical and Experimental Medicine, Neurology Unit, University of Pisa (Pisa); [2]Neurology Unit Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, (Milano); [3]Dino Ferrari Center, Neuroscience Section, Department of Pathophysiology and Transplantation, University of Milan (Milano)

Objective: We present the case of a 43-year-old man with history of generalized epilepsy who presented slowly progressive dysarthria, dysphagia and oculomotor disturbances, describing the clinical reasoning behind this complex and yet unresolved case.

Case Description: The patient did not have family history of neurological disorders nor neurodevelopmental diseases. Previous cocaine abuse was reported. The patient started to suffer from generalized tonic-clonic seizures at the age of 20 years. The EEG showed diffuse 3 Hz spike-polyspike and wave abnormalities while brain MRI was normal. Epilepsy was diagnosed as idiopathic generalized epilepsy and valproic acid was started. Last seizure occurred at the age of 37 years. Aged 40 years, he started to complain dysarthria and dysphagia, which were evident at the neurological examination together with a limitation in vertical saccadic eye movements, particularly affecting downward saccades; muscle trophism, strength, tone, and reflexes were normal; no muscle fasciculations were observed. These disturbances slowly progressed during the next 6-8 months. Recently, worsening of bulbar symptoms, postural instability, falls and mild right extrapyramidal syndrome became evident.

Neurological Reasoning and Diagnostic Work-up Results: As first diagnostic hypotheses we evaluated: i) CNS stroke/vasculitis possibly related to cocaine abuse, ii) motor neuron disease, iii) junction neuromuscular disease, iv) myopathy due to mitochondrial disease or oculopharyngeal muscular dystrophy. Brain MRI and MR angiography (3T) were unremarkable. Electromyography demonstrated a mild myopathic pattern, which was characterized later as non-specific by muscular biopsy. Anti-acetylcholine receptor and anti-Musk antibodies were negative. None of the previous hypotheses were confirmed. Marked hyperthyroidism due to Graves' disease was then identified. A possible thyroid-associated ophthalmopathy was suspected. However, despite treatment with tapazole, his symptoms persisted even after normalization of the thyroid profile. Thus, further diagnostic hypotheses were considered: v) genetic disease, vi) neurodegenerative disease, vii) autoimmune encephalitis. Cerebrospinal fluid analyses were normal including absence of intrathecal immunoglobulin synthesis; TAU, p-TAU, and β -amyloid were normal. Brain FDG-PET revealed bilateral hypometabolism of the putamen. Genetic tests for Niemann Pick type C, SCAs, DRPLA, Friedreich ataxia, and NGS panel for mitochondrial diseases were negative. First-line analyses exploring the hypothesis of an autoimmune encephalitis were also negative.

Conclusions: Summarizing, our patient presented a Progressive Supranuclear Palsy-like phenotype in association with generalized epilepsy. Diagnosis is still uncertain and second-line investigations both for neurogenetic disorders - including whole-exome sequencing - and autoimmune neurologic disorders are now ongoing.

## EFFECTIVENESS OF CANNABIDIOL IN DEVELOPMENTAL AND EPILEPTIC ENCEPHALOPATHIES BEYOND DRAVET AND LENNOX GASTAUT SYNDROMES: REAL-WORLD EVIDENCE FROM A LEVEL 3 EPILEPSY CENTER

C. Cuccurullo, M. Rubino, L. Bilo, A. Coppola

Epilepsy Center, Department of Neuroscience, Reproductive and Odontostomatological Sciences, Federico II University (Napoli)

Purpose: The highly purified CBD oil (Epidiolex) is licensed as adjunctive antiseizure treatment in patients with Dravet (DS) or Lennox Gastaut (LGS) syndromes and Tuberous-Sclerosis-Complex [1]. Nevertheless, evidence about CBD effectiveness in other Developmental and Epileptic Encephalopathies (DEEs) have been provided in few cases [2]. The aim of our study was to assess the effectiveness of CBD as adjunctive treatment in a cohort of patients with DS, LGS and other drug-resistant epileptic syndromes, particularly genetic DEEs.

Materials and Methods: We conducted a 12 months observational prospective clinical trial. We enrolled 13 patients (aged 13-52 years) affected with drug-resistant epilepsy of different etiology. Patients received CBD 5mg/kg/day for two weeks, then titrated up to 20 mg/kg/day. Seizures' frequency, EEG and blood exams were assessed at 3, 6, 9 and 12 months. Further effects were evaluated using QoLIE-10P, QoLCE-16, Pittsburgh and Epworth Scales, BDI-II, PGIC, CGIC. The primary endpoints were median percent change from baseline in weekly seizure frequency and responder rate at 6, 9 and 12 months. Comparison for percent change was over time was done using a Friedman test.

Results: Four patients presented with LGS or LGS-like phenotype, one with DS, four with genetic DEEs (of these one related to MEF2C, one to PCDH19, one to STXBP1 and one to dupXq28), four with cryptogenic DEEs. Whole-Exome-Sequencing is ongoing in 4 patients with no genetic diagnosis to date. Nine patients concluded the 12 months study; two discontinued CBD after one month owing to lack of compliance, the patients with STXBP1 and MEF2C-related DEE discontinued after six and ten months respectively owing to lack of efficacy and minor adverse effects (AEs). We observed a significant reduction in seizure's frequency at 6, 9 and 12 months in all the nine patients who completed the study ($\chi 2$ (3)=17,67, p<0,001), with no significant differences between 6 and 12 months ($\chi 2$ (2)=0,5, p=0,48). At 12 months the median percent change was 66%, the responder rate 66,7% (6/9), the retention rate 70% (9/13). Seizure freedom was achieved in three patients, particularly in the individual with PCDH19-related DEE it correlated with an improvement in quality of life. In one patient with cryptogenic DEE we observed improvement in gross motor skills with reacquisition of autonomous walking. No serious AEs were registered; the most frequent was somnolence.

Discussion and Conclusion: CBD adjunctive antiseizure treatment is effective and well tolerated in DEEs beyond LGS and DS and, particularly in PCDH19-related DEE.

## GENDER VARIABILITY OF CARDIOVAGAL OUTPUT ACCORDING TO HEART RATE VARIABILITY (HRV) ANALYSIS IN PATIENTS WITH TEMPORAL LOBE EPILEPSY

S. De Angelis[1], F. Dono[1], C. Evangelista[1], C. Corniello[1], C. Vollono[2], S. Sensi[1]

[1]Department of Neuroscience, Imaging and Clinical Science, "G. d'Annuzio" of Chieti-Pescara (Chieti); [2]Unit of Neurology, Department of Geriatrics, Neurosciences and Orthopedics, IRCCS Policlinico Universitario Agostino Gemelli, Catholic University (Roma)

Objectives: Heart rate variability (HRV) analysis evaluates cardiac autonomic control and may represent a biomarker for sudden unexpected death in epilepsy (SUDEP). SUDEP is more frequent in males. It is plausible that female sex hormones may influence HRV. These changes may be more pronounced in patients with drug-resistant epilepsy. This study aims to compare changes in HRV in two groups of patients with drug-resistant epilepsy differentiating them according to gender.

Methods: 60 adult patients (mean age 41.9 ± 15.7, 30 M and 30 F) with drug-resistant epilepsy were enrolled. Each patient underwent a 20-min resting state EEG + ECG recording. Patients were divided into two subgroups based on gender: EPI-M and EPI-F. HRV parameters were calculated with a short-lasting ECG analysis. Patients treated with drugs that interfere with the functioning of the autonomic nervous system (ANS), had a history of heart disease, endocrine disorders, metabolic deficits, uremia, or any other known disease that may affect autonomic functions, including sleep-related apnea, were excluded from the study. Time-domain and frequency-domain HRV short-term analysis was performed on EKG records.

Results: When comparing EPI-M and EPI-F groups, no differences were observed according to age, clinical characteristics (comorbidities and concomitant medications), and epilepsy-related features (seizure frequency, ASM type, and treatment response). Compared to the EPI-M group, the EPI-F subjects showed a significant decrease in low-frequency naturalized units (LF n.u.) (p=0.0067), in low-frequency percentage (LF %) (p=0.0174) and LF/HF ratio (p=0.002), In addition, an increase in root mean square of the difference between contiguous RR intervals (RMSSD) (p=0.04), high-frequency naturalized units (HF n.u.) (p=0.068) and high-frequency percentage (HF%) (p=0.0117) were reported, parameters indicative of increasedin cardiac vagal tone.

Conclusions: Compared with EPI-M, EPI-F is associated with an increase in cardiac vagal tone. These results support the biological base of a possible difference incidence of SUDEP between males and females.

## PERI-ICTAL NEUROIMAGING OF STATUS EPILEPTICUS: PRELIMINARY RESULTS OF A PROSPECTIVE STUDY

E. De Santis[1], S. Gasparini[1], P. Zoleo[1], R. Cutelle'[1], O. Marsico[1], L. Manzo[1], A. Pascarella[1], E. Africa[2], V. Cianci[3], E. Ferlazzo[1], G. Tripodi[3], A. Armentano[2], U. Aguglia[1]

[1]Department of Medical and Surgical Sciences, Magna Graecia University (Catanzaro); [2]Neuroradiology Unit, Great Metropolitan Hospital (Reggio Calabria); [3]Regional Epilepsy Centre, Great Metropolitan Hospital (Reggio Calabria)

Objectives: Peri-ictal MRI abnormalities (PMAs) following status epilepticus (SE) show variable prevalence (12%-100%) in the literature. These alterations are frequently transitory, but the timing of appearance and disappearance is poorly investigated. We aimed to further characterize the type and timing of the MRI findings associated with SE.

Materials and methods: In this prospective, observational, controlled study we enrolled all consecutive patients with SE, cluster of seizures, or a single seizure referring to our tertiary Epilepsy Centre in Reggio Calabria. All patients underwent video-EEG monitoring (21 channels, International 10-20 system) and they were treated as per standard guidelines. Brain MRI was performed in all patients within 24 hours from seizure termination, acquiring axial T1-weighted, T2-weighted, fluid-attenuated inversion recovery and DWI images; the ADC maps was obtained from the diffusion images. A follow-up MRI with a more extended protocol including GRE and IR sequences was performed in all patients after at least 14 days from seizure termination or later. All patients were clinically followed for at least 1 year after the event. The primary outcome was to evaluate the timing of onset of cortical high DWI signal during or immediately after an epileptic event, when present. For subjects with MRI abnormalities, additional follow-up studies until normalization have been performed.

Results: We recruited 90 patients with a mean age of 63,2 years. Thirty-two (36%) had SE, 21 (23%) had cluster of seizures and 37 (41%) had a single seizure. First MRI was positive in 16 patients (50%) from the SE group, 9 (43%) for the cluster group and 18 (54,3%) for the single seizure group. There was no statistical difference among the three groups for the primary outcome (p value= 0.3672). Thirteen patients completed the follow-up MRI. In seven cases the follow-up was terminated for identification of a specific etiology of the lesion (vascular, neoplastic). In six patients the alterations were no longer present (confirming as PMAs). Seven patients presented persistent anomalies and follow-up is still ongoing.

Discussion and conclusions: Our findings emphasize that PMAs are not specific to SE given the non-significant differences in prevalence between the three groups investigated. These preliminary data warrant further investigation.

## EFFECTIVENESS OF HIGHLY PURIFIED CANNABIDIOL IN SUPER-REFRACTORY STATUS EPILEPTICUS (SRSE): A CASE-SERIES

G. Di Mauro, G. Vietri, A. Castelli, F. Izzi, A. Pagano, F. Placidi, N. Mercuri, C. Liguori

Department of Systems Medicine, University of Rome "Tor Vergata" (Roma)

Objectives: Super-refractory status epilepticus (SRSE) is a medical emergency that must be promptly treated to prevent irreversible brain damage and death. [1] Nevertheless, the evidence of effective treatments is scarce, deriving from case series. Among these, highly purified cannabidiol (CBD), approved for the treatment of Lennox-Gastaut syndrome, Dravet syndrome, and tuberous sclerosis complex-related epilepsy demonstrated significant efficacy in reducing seizures. [2] Here we present two cases describing the effective use of CBD in the treatment of SRSE.

Materials and methods: A 51 y.o. woman affected by drug-resistant focal epilepsy secondary to limbic seronegative encephalitis, and treated by brivaracetam 250 mg/die, phenobarbital 200 mg/die, lacosamide 400 mg/die, carbamazepine 400 mg/die and clonazepam 4 mg/die, presented with generalized status epilepticus. Following administration of diazepam in iv bolus, her first neurological examination showed drowsiness, aphasia, and right arm hyposthenia with continuous myoclonus of the homolateral shoulder. Blood testing, head CT scan, and lumbar puncture, with microbiological tests, showed no abnormalities. EEG showed frequent bilateral frontotemporal paroxysmal slow waves. Brain MRI confirmed bilateral temporo-mesial gliotic lesions of previous encephalitis. Despite the optimization of antiseizure treatment (lacosamide 400 mg/die iv, phenobarbital 200 mg/die im, valproic acid 1400 mg iv, levetiracetam 3000 mg/die iv) critical episodes persisted and nasogastric tube was placed and treatment with CBD 8 ml/die was started and 24 hours later increased to 12 ml/die (20 mg/kg/die) with full recovery from the status epilepticus, and change in neurological examination 36 hour later the first administration of CBD (vigilance, coordination, verbal fluency, no motor deficit). A 18 y.o. man affected by Lennox-Gastaut-like epileptic encephalopathy (structural origin), in treatment with valproic acid 1600 mg/die and clonazepam 3 mg/die presented with generalized tonic-clonic seizures refractory to the administration of diazepam 10 mg in iv bolus, requiring intubation and sedation with propofol. Levetiracetam 3000 mg/die iv, valproic acid 3600 mg/die iv and lacosamide 400/die mg iv were prescribed, but EEG showed synchronous ad rhythmic bilateral spikes, polyspikes and waves, indicative of SRSE. Nasogastric tube was placed and CBD was started at 5 mg/kg/die and then titrated up to 20 mg/kg/die in 24 hours. 48 hours later, the patient's conditions markedly improved, allowing the tapering of sedatives and extubation. EEG also improved showing residual bilateral fronto-centro-temporal interictal abnormalities.

Conclusions: According to our experience, CBD may be used in case of SRSE considering the possible beneficial effects of it when used as oral solution administered in nasogastric tube.

## CLINICAL CHARACTERISTICS AND TREATMENT APPROACH OF ESTABLISHED NEW-ONSET STATUS EPILEPTICUS (ENOSE): A REAL-WORD MULTICENTER EXPERIENCE

F. Dono[1], G. Evangelista[1], D. Rodorigo[1], E. Rollo[2], M. Romozzi[2], C. Corniello[1], D. Liviello[1], S. Servidei[2], G. Della Marca[2], P. Calabresi[2], S. Sensi[1], C. Vollono[2]

[1]Department of Neuroscience, Imaging and Clinical Science, "G. d'Annunzio" University of Chieti-Pescara (Chieti); [2]Unit of Neurology, Department of Geriatrics, Neurosciences and Orthopedics, Catholic University (Roma)

Background: Status Epilepticus (SE) can occur in patients without a previous epilepsy diagnosis, a condition identified as "new-onset status epilepticus" (NOSE). Treatment with benzodiazepine may fail in

NOSE termination, requiring anti-seizure medication (ASM) employment. In this context, the term "established NOSE" (eNOSE) is generally employed. This study aims to describe the main clinical characteristics of a large sample of patients suffering from eNOSE comparing the ASM efficacy and exploring the risk factors associated with ASM treatment unresponsiveness and eNOSE associated mortality.

Methods: Adult patients with diagnosis of eNOSE were retrospectively selected between January 2016 and December 2022. Demographics and clinical data as well as diagnostic work-up and treatment were reviewed. We considered effective the last ASM introduced or increased in dose before the eNOSE termination.

Results: 123 patients were included (age: 67.9 ± 17.3). eNOSE etiology was defined in 109 cases and the acute one was the most frequent. In the total cohort, phenytoin showed the highest response rate. The comparison among all the employed drugs (i.e., phenytoin, valproate, levetiracetam, and lacosamide) showed phenytoin as the most effective ASM (p=0.005). In the pairwise comparisons, valproate was superior to levetiracetam (p=0.02), but not to lacosamide (p=0.65). Phenytoin had a significantly higher resolution rate compared to levetiracetam (p=0.0005) but not to lacosamide (p=0.16). Thirty patients (25%) were refractory to ASM treatment. No predictors of refractoriness were identified. Thirty-nine patients died. Age and GCS were identified as eNOSE related mortality risk factors.

Conclusion: eNOSE frequently shows an acute etiology with several associated semiologies. PHT show the higher effectiveness in eNOSE management, even if LCM and VPA can represent further therapeutic options. eNOSE can eventually become refractory and being associated with a higher burden of SE-related complications. Age and GCS represent the main risk factor of eNOSE associated mortality.

## ASSOCIATION OF CSF AND PET MARKERS OF NEURODEGENERATION WITH ELECTROCLINICAL PROGRESSION IN LAFORA DISEASE

G. d'Orsi[1], A. Farolfi[2], L. Muccioli[3], O. Palumbo[4], P. Palumbo[4], S. Modoni[5], V. Allegri[2], V. Garibotto[6], M. Di Claudio[1], C. Reale[1], M. Bianchi[1], E. Di Muro[4], M. Benvenuto[4], F. Bisulli[7], M. Carella[4]

[1]Neurology Unit, Fondazione IRCCS Casa Sollievo della Sofferenza (San Giovanni Rotondo-FG); [2]Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna (Bologna); [3]Department of Biomedical and Neuromotor Sciences, University of Bologna (Bologna); [4]Division of Medical Genetics, Fondazione IRCCS Casa Sollievo della Sofferenza (San Giovanni Rotondo-FG); [5]Nuclear Medicine Department, Policlinico Riuniti (Foggia); [6]Diagnostic Department, University Hospitals of Geneva, CIBM Center of Biomedical Imaging and NIMT-Lab, University of Geneva (Geneva-CH); [7]Department of Biomedical and Neuromotor Sciences, University of Bologna; IRCCS Istituto delle Scienze Neurologiche di Bologna, Epilepsy Center (full member of the European Reference Network EpiCARE) (Bologna)

Purpose: Although progressive and fatal evolution of Lafora Disease (LD) has been previously reported, full data on long-term electro-clinical follow-up is very rare. We evaluate the electro-clinical features in association with laboratory and instrumental correlates of neurodegeneration to detect the progression of LD.

Methods: We investigated the electro-clinical longitudinal data and CSF Aβ42, p-tau181 and t-tauAg, amyloid and 18F-FDG PET of 5 unrelated LD families.

Results: Three progressive electro-clinical stages were identified. The early phase was characterized by rare generalised tonic-clonic and focal visual seizures, followed by the occurrence of myoclonus after a period ranging from a 2 to 12 months. The intermediate stage, usually occurring after two years from the onset of epilepsy, was characterized by a worsening of epilepsy and myoclonus associated with a progressive dementia and cerebellar signs. Finally, the late stage, evolving after a mean period of 7±1.41 years from the onset of the disease, was characterized by gait ataxia resulting in bedriddenness, severe dementia, daily/pluri-daily myoclonus, drug-resistant epilepsy and clusters of seizures or status epilepticus and medical complications. Amyloid (CSF Aβ42, amyloid PET) and neurodegenerative (CSF p-tau181 and t-tauAg, FDG-PET) biomarkers suggest a pattern of cognitive impairment of non-Alzheimer disease type. Eighty per cent of the LD patients showed a more severe hypometabolism in the second FDG-PET compared to the first scan performed in a lower phase; lateral temporal lobe and thalamus hypometabolism were associated with the presence of phase intermediate or late.

Discussion: An early diagnose of LD is essential because patients will be more likely to benefit from promising new therapeutic strategies. It is therefore important to develop biomarkers that are sensitive to this early stage, but also during the progressive evolution of the disease. We identified four main and progressive symptoms (epilepsy, myoclonus, ataxia, dementia), included in three evolutive electroclinical stages. Dementia presented during the second electro-clinical stage with a non-Alzheimer pattern. The combination of CSF traditional biomarkers and 18F-FDG PET findings biomarkers may improve the diagnostic accuracy of cognitive decline in LD patients, suggesting also the implication of the thalamus in the LD pathogenetic mechanisms.

Conclusions: Three electroclinical and 18F-FDG PET evolutive stages are useful biomarkers for the progression of LD and could help to evaluate the efficacy of new disease-modifying treatments. The combination of CSF traditional biomarkers improves the diagnostic accuracy of cognitive decline in LD patients, suggesting a cognitive impairment of non-Alzheimer disease type.

## IMPACT OF FIRST-LINE ANTI-SEIZURE MEDICATION (ASM) ON HEART RATE VARIABILITY (HRV) IN PATIENTS WITH NEWLY DIAGNOSED TEMPORAL LOBE EPILEPSY (TLE): A COMPARISON BETWEEN LEVETIRACETAM, LAMOTRIGINE, LACOSAMIDE AND CARBAMAZEPINE

G. Evangelista[1], F. Dono[1], D. Liviello[1], C. Corniello[1], C. Vollono[2], S. Sensi[1]

[1]Department of Neuroscience, Imaging and Clinical Science, "G. D'Annunzio" University of Chieti-Pescara (Chieti); [2]Department of Geriatrics, Neurosciences & Orthopedics Unit of Neurophysiopathology and Sleep Medicine, IRCCS Policlinico Universitario Agostino Gemelli Catholic University (Roma)

Objectives: Temporal lobe epilepsy (TLE) is the most common form of focal epilepsy. The temporal lobe plays a central role in regulating the "Central Autonomic Network" and cardiovascular functions. Heart rate variability (HRV) is a non-invasive method to evaluate cardiovagal output, which reduction may represent a risk factor for sudden death. Anti-seizure medications (ASM) can alter HRV. This study aims to evaluate the impact of first-line ASM treatment in patients with newly diagnosed temporal lobe epilepsy (TLE).

Methods: We consecutively enrolled 75 adult patients with a new diagnosis of TLE treated with LEV (LEV-group, 30 patients), Lamotrigine (LMT-group, 15 patients), Carbamazepine (CBZ-group, 15 patients) or Lacosamide (LCS-group, 15 patients) as monotherapy. Each patient underwent a 20-minute EEG + EKG recording in resting state at baseline at most 1 month (mean interval: 15 days) before introducing the ASM therapy (pre-ASM) and a second standard EEG+EKG at six months after starting the specific treatment (post-ASM). Patients treated with drugs that interfere with the functioning of the autonomic nervous system (ANS), had a history of heart disease, endocrine disorders, metabolic deficits, uremia, or any other known disease that may affect autonomic functions, including sleep-related apnea, were excluded from the study. Time-domain and frequency-domain HRV short-term analysis was performed on EKG records. Linear Mixed Models (LMM) were used to analyzed HRV variables according to time (baseline and 6-months follow-up) and groups.

Results: In the four groups, no differences were observed according to demographics (age and sex), clinical characteristics (comorbidities and concomitant medications), and epilepsy-related features (seizure frequency, ASM response, lateralization of epileptic focus). According to HRV comparative analysis, treatment with LEV showed significantly increased LnRMSSD (natural logarithm of the root mean square of the difference between contiguous RR intervals) (p-value=0.05), LnHF ms2 (natural logarithm of high-frequency absolute power) (p-value=0.03), and HF n.u. (high-frequency power expressed in normalized units) (p-value=0.05). In addition, the LEV group exhibited decreased LF n.u. (low-frequency power expressed in normalized units) (p-value=0.04) and LF/HF (low frequency/high frequency) ratio (p-value=0.05).

Conclusions: Treatment with LEV as first-line ASM is associated with an increased vagal tone in patients with newly diagnosed TLE. The result of this study may support the use of LEV to reduce the risk of cardiovagal imbalance in patients with newly diagnosed TLE.

[1]Istituto delle Scienze Neurologiche di Bologna, University of Bologna (Bologna); [2]Medical Genetics Unit, Polyclinic Sant'Orsola-Malpighi University Hospital (Bologna); [3]IRCCS Istituto delle Scienze Neurologiche di Bologna, Epilepsy Center, full member of the European Reference Network EpiCARE (Bologna); [4]Clinical Epileptology and Experimental Neurophysiology Unit, IRCCS Foundation Neurological Institute "C. Besta" (Milano); [5]Neuropathology Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [6]Department of Medical and Surgical Sciences, University of Bologna (Bologna); [7]Medical Genetics Unit, Polyclinic Sant'Orsola-Malpighi University Hospital, Department of Biomedical and NeuroMotor Sciences (DIBINEM) (Bologna); [8]Department of Biomedical and NeuroMotor Sciences (DIBINEM), University of Bologna (Bologna); [9]Claudio Munari Epilepsy Surgery Center, Niguarda Hospital (Milano)

Objective: Epileptogenic lesions, such as focal cortical dysplasia (FCD) and low-grade epilepsy-associated neuroepithelial tumors (LEAT), are two of the main cause of drug-resistant structural epilepsy [1]. Recent studies have disclosed a growing number of pathogenic somatic and germline variants responsible for these lesions especially in genes encoding components of PI3K-AKT-mTOR and RAS-MAPK pathway, respectively [2]. However, the exact prevalence of pathogenic variants and their role in surgical outcome have still to be clarified.

Materials: Consecutive patients who underwent epilepsy surgery at Claudio Munari Epilepsy Surgery Center and at IRCCS Istituto delle Scienze Neurologiche between 2018-2021 were included in the study. For each patient were analyzed the DNA obtained from Fresh Frozen (FF) brain specimen resected during surgery and matched peripheral blood. Retrospective formalin-fixed paraffin-embedded (FFPE) brain tissues obtained from the Clinical Epileptology and Experimental Neurophysiology Unit IRCCS, Neurological Institute "C. Besta" were also analyzed.

Methods: We designed 2 target panels of genes associated to FCD and LEAT using single molecule Molecular Inversion Probes (smMIPs). The FCD panel comprised 14 genes (AKT1, AKT3, CASK, DEPDC5, MTOR, NPRL2, NPRL3, PIK3CA, PTEN, RHEB, SLC35A2, TSC1, TSC2, KRAS) while LEAT panel includes 10 genes (TRX, BRAF, FGFR1, GFAP, IDH1, KRAS, NF1, PDGFRA, RB1, TEK, TP53, PTEN).

Results: A total of 164 pediatric and adults patients were included (72F, mean age 30,6 range 6-65). FF brain specimen was available for 143, FFPE for 21. Based on histopathological analysis patients were classified in 4 group: FCD 60 patients, LEAT 28, Scars 10, other-lesion or not-lesional 66. We performed preliminary genetic analysis on 127 brain and blood specimens (30 FCD, 28 LEAT patients and 10 Scars). We identified 11 pathogenic variants in FCD group (36%): 2 germline in TSC1 and 9 somatic (7 in MTOR with Variant Allele Frequency (VAF) 1-3%, 1 in RHEB (VAF: 2%) and 1 in SLC35A2 (VAF: 2,49%). Ten patients in LEAT group showed pathogenic somatic variant in BRAF (VAF 2-9%) and 1 in IDH1 (VAF 25%). None of patients in scar group had positive results for both panels.

Discussion: We confirm that mTOR and BRAF mutations account for the majority of FCDII and LEAT cases, further contributing to recognize a genetic basis of these epileptogenic lesions. Somatic mutations of SLC35A2 are increasing detecting in FCDI-related epilepsy.

Conclusion: Our study reports the optimal diagnostic accuracy of smMIP in the identification of somatic variants with low VAF both in FCDI, FCDII and LEAT patients underwent epilepsy surgery.

## OCULOLEPTOMENINGEAL AMYLOIDOSIS PRESENTING WITH PROLONGED POST-ICTAL STATE AND RELAPSING VISUAL LOSS

A. Francia[1], D. Mattavelli[2], M. Braga[2], L. Pantoni[1]

[1]Department of Biomedical and Clinical Sciences, University of Milan (Milano); [2]Neurology Unit, Luigi Sacco Hospital (Milano)

Aim: To describe a rare case of possible oculoleptomeningeal amyloidosis presenting with prolonged post-ictal state.

Methods: Oculoleptomeningeal amyloidosis (OLMA) is a rare phenotype of hereditary transthyretin (ATTRv) amyloidosis, which is caused by transthyretin (TTR) mutations that decrease the stability of the TTR tetramer thereby forming amyloid fibrillar aggregates that lead to organ dysfunction. Here, we present the case of a 40-year-old man who presented in the emergency room with altered mental status, right gaze paresis, right hemiplegia, and global aphasia, followed by a gradual recovery over 5 days.

Results: After the post-ictal phase resolution, neurological examination revealed impaired word retrieval for less commonly used nouns, brisk deep tendon reflexes in all four limbs and mildly decreased vibration sense in the distal lower limbs. Moreover, a weak pupillary reflex was present in the left eye, compatible with the severe visual loss after a previous episode of acute angle closure glaucoma, and bilateral decreased visual acuity. On head CT scan two small non-traumatic convexity subarachnoid haemorrhagic foci located along the fronto-parietal cortex were visible. Brain MRI and CT angiography ruled out ischemic lesions and focal arterial stenoses. Interestingly, the patient had a history of recurrent panuveitis and retinitis without a clear etiology and a poor response to immunosuppressive treatments that lead to re-consider infectious and inflammatory CNS processes among the possible causes. CSF analysis showed a xanthochromic fluid, mild pleocytosis (15 cells/μL), and an increased protein level (1350 mg/L). Brain MRI with gadolinium showed diffuse leptomeningeal enhancement. EEG monitoring revealed lateralized delta slowing over the left temporal region that progressively abated, paralleling the clinical improvement. Optical coherence tomography and fluorescein angiography findings were consistent with ocular amyloidosis, corroborated by the disease relapse after vitrectomy. Nerve conduction studies showed bilateral carpal tunnel and sensory-motor axonal distal symmetric polyneuropathy. Systemic screening for amyloid light chain amyloidosis was negative. Given the highly suggestive positive family history, consistent with an autosomal dominant transmitted disease, genetic testing of the TTR gene and genetic counselling were offered.

Discussion: ATTRv classically presents with cardiac and peripheral nervous system involvement but can also be a great mimicker by disproportionately affecting the central nervous system and eyes, as TTR protein is also produced by the choroid plexus and retinal pigment epithelium. Recognition of this syndrome is important to avoid unnecessary treatment and ensure enrolment in clinical trials with recently emerging therapies.

## ANTI-LGI1 AUTOIMMUNE ENCEPHALITIS PRESENTING AS ADULTHOOD-ONSET TEMPORAL LOBE EPILEPSY

C. Fratto, I. Sammarra, A. Giugno, L. Marino, I. Martino, G. Magro, F. Fortunato, A. Gambardella

Institute of Neurology, "Magna Graecia" University (Catanzaro)

Aims: We report a case of LGI1-antibody encephalitis started with adulthood-onset temporal seizures as first symptom, associated with mild memory loss.

Materials: A previously healthy 42-year-old woman developed focal seizures characterized by motor arrest, left head version, flexion of the right arm and fixed gaze. These episodes lasted approximately 10 seconds, were followed by confusion and in a single occasion progressed into a bilateral tonic-clonic seizure. The patient also complained of mild short-term memory loss and irritability. She had no family history of epilepsy or febrile seizures.

Methods: Neurological examination revealed mild attention and memory impairment. An extensive work-up, including routine blood tests and cerebrospinal fluid (CSF) analysis was carried out. The patient also underwent neuropsychological assessment with electroencephalography (EEG). Furthermore, a 3-Tesla brain Magnetic Resonance Imaging (3T-MRI) was acquired.

Results: Routine blood tests, including electrolytes, were unremarkable. At admission, neuropsychological assessment documented severe impairment of anterograde memory skills, anxiety, emotional lability and irritability. A previous brain MRI, acquired 4 weeks before admission, showed hyperintense left mesial temporal lobe on T2/Fluid Attenuated Inversion Recovery (FLAIR) weighted. Standard EEG recorded a seizure originating from left temporal lobe, so we started levetiracetam up to 1000 mg/day. Serum and CSF analysis detected LGI1 auto-antibodies, fulfilling diagnosis of anti-LGI1 limbic encephalitis. Thus, she received intravenous immunoglobulin (IVIGs) combined with methylprednisolone 0,4 g/kg/day and 500 mg/day for 5 consecutive days respectively. Immunotherapy led to a significant resolution of cognitive and psychiatric symptoms. At one-week follow-up, neuropsychological assessment documented improved memory performances and brain 3T-MRI reported a T2/FLAIR hyper-intensity combined to T1 atrophy of left hippocampal region, configuring a left hippocampal sclerosis. Standard and prolonged EEG recordings were unremarkable. To rule out the paraneoplastic etiology, the patient performed a total body Computerized Tomography (CT) scan, with no significant findings.

Discussion: Leucine rich glioma inactivated 1 (LGI-1)-IgG encephalitis is a well-shaped immune-mediated disorder often presenting as cognitive impairment, epileptic seizures and behavior disturbances, responding to immunotherapy. Nonetheless, anti-LGI1 encephalitis includes a wide spectrum of cognitive and psychiatric manifestations, until rapidly progressive dementia and mental status changes. [1] This case contributes to understand the wide spectrum of this condition and emphasizes the importance of neuronal antibodies investigation in suspected immune-mediated encephalitis.

Conclusions: An immune pathophysiology should be routinely considered in individuals with adult-onset temporal lobe epilepsy, combined with memory impairment and behavior abnormalities, even mild. Awareness of electroclinical features of anti-LGI1 encephalitis has important implications for diagnosis and treatment. [2,3]

## THE USE OF CENOBAMATE FOR THE TREATMENT OF DRUG-RESISTANT FOCAL EPILEPSY: A SINGLE CENTRE REAL-LIFE EXPERIENCE

E. Fronzoni[1], M. Magliani[1], G. Giovannelli[2], C. Tanzarella[1], O. Malanga[1], G. Pastorelli[1], L. Massacesi[1,2], E. Rosati[2]

[1]Department of Neurosciences, Drug and Child Health, University of Florence (Firenze); [2]Department Neurology 2, Careggi University Hospital (Firenze)

Pharmacoresistance affects approximately 1/3 of patients with epilepsy and, despite the availability of many antiseizure medications (ASM), the percentage of seizure-freedom in this population is less than 5% after the second pharmacological trial. [1] Cenobamate (CNB) is a new ASM that has demonstrated high efficacy in drug-resistant focal epilepsy in regulatory clinical trials. [2] We report the real-life experience of the Careggi Epilepsy Center in the use of CNB. We evaluated 39 patients with drug-resistant focal epilepsy, most affected by long-term epilepsy, treated with Cenobamate. The seizure frequency was assessed before and at 3-6-9 months after the start of treatment. Associated drugs and side effects were also evaluated. Out of the 39 patients treated, one dropped the treatment before the end of the titration. At the follow-up, among 33 patients evaluated at 3 months, 5 were seizure-free and 8 had a 50% reduction in seizure frequency; among the 23 patients evaluated at 6 months, 3 were seizure-free and 10 had a 50% reduction in seizure frequency; 1 of the 8 patients treated for 9 months was seizure-free and 3 had a 50% reduction in seizures. Of the 27 patients with side effects 16 reported dizziness (14/16 in therapy with sodium channel blockers), 10 drowsiness (7/10 in concurrent therapy with GABAergic ASMs), 5 instability in 3 cases associated with vomiting and in 2 with ataxia (in all 5 patients experienced before reducing concomitant sodium channel blockers), in 5 diplopia/blurred vision, in 3 irritability, in 4 fatigue. All the side effects were mild and the most resolved after reducing the dosage of concomitant sodium channel blockers and GABA-ergics ASMs, without impact on the therapeutic efficacy of CNB. In this case series of patients with a long history of illness and significant drug resistance, Cenobamate confirm to be an effective drug, yielding excellent results in terms of seizure reduction, consistent with data obtained from clinical trials. The data also suggest that tolerability is good and could be improved by reducing the dosage of concomitant ASMs during the titration phase, without affecting the efficacy of CNB but further improving compliance and quality of life.

Besta (Milano)

Introduction: There are more than 70 million people with epilepsy (PWE) worldwide, 80% in low income countries (LIC) as sub-Saharan Africa (SSA) where more than 75% have no access to treatment. The WHO-Intersectoral Global Action Plan (IGAP) 2022-2031 aims to increase access to epilepsy care particularly in LIC and SSA. In SSA the vast majority of PWE are managed by non-physician clinicians (NPC) with poor education in epilepsy hampering proper diagnosis and treatment to PWE. In the last few years, we conducted an intensive education and training programme on epilepsy to NPC in Malawi and Central African Republic. A teleneurology system was initiated along between Italian neurologists and the SSA NCP. We report the results of this international cooperation on epilepsy.

Method: Disease Relief through Excellent and Advanced Means (DREAM) is a public health program in ten SSA countries. In Malawi and Central African Republic (CAR), DREAM follows 18836 patients, more than 85% are HIV+. In 2020, an epilepsy program was started in Malawi and CAR DREAM centers in partnership with the Italian Society of Neurology, the "Besta Neurologic Institute", the "Mariani Foundation" and the Global Health Telemedicine (GHT). Several remote education sessions and 12 in-person training courses were provided to local NPC. Teleneurology platforms were installed along with two video-EEGs. Italian Volunteers neurologists actively answer from remote to the teleneurology consultation requests sent by SSA NPC; they also analyzes EEGs sent through the telemedicine platform.

Results: The number of teleneurology consultations requests from SSA NCP to Italian neurologists have gradually increased: 141 in 2020, 802 in 2021 and 815 in 2022. And the number of PWE under care is increasing: 1064 in 2022, 5.6% of the DREAM patients in Malawi and CAR; 68,6% of the PWE are under the age of 18 (median age is 19,8 years), 11% are older than 40 years. More than 500 EEGs have been transmitted to the Italian neurologists.

Conclusions: Teleneurology and digital systems coupled with education and training-on-the-job to SSA NPC are a cost-effective tool to bring neurologists where there are no neurologists. Our partnership is contributing to improve access to care to an increasing number of PWE in SSA thus fulfilling IGAP goals. A long term approach is necessary to apply IGAP indications, a shift from projects to programs.

## EPILEPSIA PARTIALIS CONTINUA FOLLOWING GUNSHOT WOUND

A. Giugno[1], M. Trimboli[2], M. Sturniolo[2], S. Barone[2], I. Sammarra[1], F. Fortunato[1], A. Gambardella[1]

[1]Neurology Institute, Department of Medical and Surgical Sciences, Magna Graecia University (Catanzaro); [2]Institute of Neurology, Department of Medical and Surgical Sciences, AOU Renato Dulbecco (Catanzaro)

Aims: Epilepsia partialis continua (EPC) is a rare focal status epilepticus arising from a variety of lesions in the perirolandic area. EPC presents as continuous unilateral or, more rarely, bilateral jerks over hours, days, or even years. [1] Several etiologies have been addressed, including structural, immune-mediated, neoplastic, toxic-metabolic causes. [2-3] Here, we propose a unique case of EPC in a man who developed myoclonic jerking in the upper limbs related to a penetrating gunshot head injury.

Materials: The patient is a 63-year-old man. At the age of 12, he reported a head gunshot wound. Thereafter, he developed isolated repetitive episodes of jerking in the upper limbs. Neurologic examination revealed continuous jerking in the arms bilaterally, without evidence of loss of consciousness. He had no family history of neurological disorders.

Methods: An extensive clinical, neurophysiological assessment, and brain computed tomography (CT), was carried out. The neurophysiological study included video electroencephalography-electromyography (v-EEG-EMG) polygraph and somatosensory evoked potentials (SEPs) with cortical-reflex (c-reflex).

Results: Routine blood analysis, including screening for infectious and toxic-metabolic diseases, was all unremarkable. The v-EEG-EMG polygraph revealed abrupt brief myoclonic jerks time-locked to sub-continuous focal epileptiform discharges over the fronto-centro-parietal regions bilaterally, with a maximum in the right hemisphere. The background activity was normal. He also depicted giant SEPs with no c-reflex. The electroclinical findings fulfilled the criteria of EPC. Interestingly, the brain CT showed retained bullets with metal artifacts in the left fronto-temporo-parietal regions. Intravenous therapy with levetiracetam dramatically resolved EPC.

Discussion: To our knowledge, our patient represents a unique case of EPC in a man without a previous history of epilepsy. EPC includes a wide spectrum of etiologies, but its pathophysiology is not fully established and is largely driven by the underlying cause. [2,3] We identified a unique case of EPC related to a head gunshot wound, further broadening its clinical spectrum. In our case, the evidence of epileptiform discharges at EEG time-locked to the muscle jerks and the giant SEPs confirmed the cortical origin of the myoclonic jerks. The underlying mechanism remains to be elucidated. It is conceivable that the localization of the bullets may lead to cortical disequilibrium, resulting in the oscillatory epileptic activity characterizing EPC.

Conclusion: Overall, the present case is unique as it further enlarges the wide spectrum of etiologies underlying EPC. Intriguingly, it highlights the importance of carefully investigating its potential pathophysiology. Indeed, awareness of this unusual ictal semiology has important implications for diagnosis and treatment.

## POSTURAL TREMOR IN JUVENILE MYOCLONIC EPILEPSY: A NEUROPHYSIOLOGIC ASSESSMENT

A. Giugno, I. Sammarra, I. Martino, M. Sturniolo, C. Fratto, L. Marino, G. Magro, F. Fortunato, A. Gambardella

Institute of Neurology, Department of Medical and Surgical Sciences, University Magna Graecia (Catanzaro)

Objectives: Juvenile myoclonic epilepsy (JME) is a genetic generalized epilepsy in which cortical hyperexcitability plays a major role [1]. Subjects with JME may depict postural tremor, typically considered as side effect of valproic acid (VPA) and underrecognized in clinical practice [2]. However, tremor has been recently related to cortical hyperexcitability in JME [2]. In this study, we aim to explore the neurophysiological features of postural tremor in JME.

Materials: We prospectively recruited 53 consecutive subjects with JME (32 female, mean age 30.22+12.99 years; mean age at onset 12.51+12.99 years) from October 2020 to May 2023.

Methods: All subjects underwent clinical, neurophysiologic assessment, 3T brain MRI. The neurophysiologic assessment included: standard electroencephalography (EEG), median somato-sensory evoked potentials (SEPs) with long-loop reflex (C-reflex), tremor analysis. Student's t test verified the differences among groups for normally distributed data otherwise Mann-Whitney was applied. Pearson's correlation coefficient verified association between variables for normally distributed data, otherwise Spearman's rho was applied. A p-value $<0.05$ was considered significant.

Results: Thirty-one/fifty-three (59%) subjects depict postural tremor with frequency of 8.05+1.56 Hz. Forty-four/fifty-three subjects had normal SEPs: 24 with postural tremor (JME+tremor: 14 female, mean age 32.90+14.33 years; mean age at onset 11.77+4.95 years); 20 without postural tremor (JME: 12 female, mean age 27.30+10.25 years; mean age at onset 13.58+7.63 years). The two groups matched for age at time of observation, epilepsy onset, gender, anti-seizures medications (ASMs) and VPA assumption. In the JME+tremor group, the short (N20, p=0.01; P22, p=0.01) and the long (P25, p=0.002) latencies, the central conduction time (N20-N13: p=0.005) were significantly increased than the JME group, regardless VPA. In the remaining 9/53 subjects (16.98%), we observed giant SEPs. Among these, 7/9 subjects (77.78%) with postural tremor displayed significantly higher N20-P25 amplitudes than those with giant SEPs in absence of tremor (p=0.01).

Discussion: Our findings demonstrated that subjects with JME exhibited postural tremor, regardless VPA assumption. Most important, our study suggests that tremor may underlie two different mechanisms: the association of tremor with giant SEPs led to identify a group of patients with cortical hyperexcitability signs. On the other hand, in the absence of cortical hyperexcitability, the postural tremor may characterize those patients with more altered thalamo-cortical pathways and primary somatosensory cortex.

Conclusions: Overall, our study confirms the theory of JME as a network disorder. A careful and systematic clinical and neurophysiologic assessment of tremor may help to detect phenotypes that are more homogeneous and clarify the pathophysiology underlying JME.

## ROLE OF AMBULATORY EEG RECORDING IN JUVENILE ABSENCE EPILEPSY (JAE), JUVENILE MYOCLONIC EPILEPSY (JME) AND GENERALIZED EPILEPSY WITH TONIC CLONIC ALONE (GTCA)

D. Hoxhaj, F. Turco, E. Annuzzi, C. Pizzanelli, C. Milano, G. Siciliano, E. Bonanni

Department of Clinical and Experimental Medicine, Neurology Unit, Azienda Ospedaliero Universitaria Pisana, University of Pisa (Pisa)

Objectives: In JME, the occurrence of longer epileptiform discharges (EDs) on prolonged ambulatory EEG (paEEG) displays a characteristic relationship with sleep-wake cycle (mainly at the awakening) and possibly predict seizure recurrence [1]. Less is known about JAE and GTCA [2]. The aim of this study is to compare clinical and EEG characteristics between these syndromes 1) describing the occurrence of seizures in long term follow up, 2) describing the EDs distribution over the sleep-wake cycle 3) defining the use of paEEG for predicting seizures.

Materials and Methods: Clinical data, generalized tonic clonic seizure (GTC) occurrences from the time of diagnosis and antiseizure regimen (ASM), were analysed by Kruskal-Wallis ANOVA and multiple comparisons with Bonferroni-correction. PaEEG recordings lasting 24 hours have been reviewed marking and measuring the length of each ED; sleep have been scored according to AASM criteria.

Results and Discussion: We included 34 and 22 JAE, 44 and 17 JME, 23 and 10 GTCA, for the 5 and 15 years follow up, respectively. The total number of GTCs was higher for GTCA compared to JAE and JME in the 5 years follow up period ($p=<0.01$) and to JAE in the 15 follow up period. In JME A higher number of adequate ASM-trials were required for seizure-freedom and drug resistance was more common in the longer follow-up (1% in JAE, 27% in JME, 0% in GTCA, $p<0.01$). Thirty-two, 20 and 23 paEEG with an available clinical outcome were analysed for JME, JAE and GTCA respectively. EDs were longer in wake but more frequent in sleep in all groups. None of the paEEG or clinical variables was able to predict GTC in JAE and GTCA. It was even more difficult to predict absences in JAE considering people often misreport their seizures [3]. Conversely, in JME, we found longest EDs as a marker of seizure risk. The absence of GTC predictors in GTCA and JAE may be due to underpowered testing, indeed, we calculated a sample size of 40 patients for each syndrome to assess the effectiveness of longer EDs in this regard.

Conclusions: JAE carried the more benign prognosis. GTCA could experience more GTCs in the first five years of follow up. JME required the highest number of adequate ASM trials and were more drug resistant. Sleep wake cycle has a similar effect on EDs. A small increase in sample size could help to establish if longest EDs predict seizures in GTCA and JAE, as it does in JME.

## SOCIAL COGNITION IN THE SPECTRUM OF MESIAL TEMPORAL LOBE EPILEPSY

F. Iannaccone, F. Lorenzini, C. Milano, L. Tommasini, G. Tognoni, S. Corsi, F. Turco, E. Bonanni, G. Siciliano, C. Pizzanelli

Neurology, Azienda Ospedaliero-Universitaria Pisana (Pisa)

Purpose: Increasing evidence suggests that social cognition is impaired in mesial temporal lobe epilepsy (MTLE). Refractory MTLE (rMTLE) has been found to affect (i) Theory of Mind (ToM), which is the ability to recognize and comprehend others' mental states, and (ii) facial emotion recognition. Milder forms of MTLE (mMTLE), characterized by response to antiseizure medications (ASMs) and seizure-freedom, have not been evaluated. The aim of this study was to analyze social cognition in the spectrum of MTLE.

Methods: Forty-five patients with MTLE (25 mMTLE, 25 rMTLE) were compared to 25 healthy controls (HC). ToM was explored using the Faux Pas Test (FP) and Reading the Mind in the Eyes Test (RMET). Facial emotion recognition was studied using the Ekman Faces Test (EFT). Additionally, a specific battery of tests was performed as a screening for cognitive and mood disturbances.

Results: Compared to HC, both mMTLE ($p=0.025$) and rMTLE ($p<0.001$) patients had lower scores on the RMET, with no differences identified between the two subgroups of patients. Moreover, only rMTLE patients had lower performances in FP recognition when compared to HC ($p=0.002$). In EFT, mMTLE patients had lower scores in fear ($p<0.001$) and anger ($p=0.013$) recognition, while rMTLE underperformed in happiness ($p=0.006$), sadness ($p=0.002$), fear ($p<0.001$), anger ($p=0.004$), and disgust ($p=0.005$) recognition. Considering all patients and the main clinical variables (age of onset, duration of disease, number of ASMs used, and seizure frequency), our findings indicate that an earlier age of onset independently predicts poorer performance on the EFT ($p=0.008$).

Conclusions: MTLE affects the circuitries of ToM and emotion recognition even in subjects with mMTLE, albeit to a more limited extent compared to rMTLE. This supports the idea that epilepsy itself, even when seizure control is achieved, could damage key areas involved in the complex neural circuits of social cognition.

## LONG-TERM EFFECTIVENESS OF PERAMPANEL AS ADD-ON TREATMENT IN SLEEP-RELATED SEIZURES: REAL-WORLD EVIDENCE FROM A SINGLE CENTER

F. Izzi, A. Castelli, A. Pagano, A. D'Elia, G. Di Mauro, C. Ferrazzoli, C. Liguori, N. Mercuri, F. Placidi

Epilepsy Center, Neurology Unit, Policlinico Tor Vergata, University of Rome Tor Vergata (Roma)

Objectives: In view of the evidence in the literature about the positive effects of perampanel (PER) on sleep assessed by both objective and subjective parameters [1,2], the aim of the study is to verify effectiveness and discontinuation rate in patients with sleep-related epilepsy (SRE) [3] compared with patients with non-sleep-related epilepsy (nSRE).

Methods: Retrospective analysis of medical records of consecutive patients treated with PER in add-on at the Epilepsy Center of Policlinico Tor Vergata from 2018 to 2022. Only patients who completed diaries concerning the seizures frequency and who underwent periodic follow-up visits were included. Based on seizure onset pattern, patients were divided into SRE and nSRE. Patients were classified as seizure-free, responders (seizure reduction >50% compared to baseline) or non-responders at follow-up. Efficacy of PER and retention rate were compared in SRE vs nSRE patients and subgroups (focal epilepsy, generalized epilepsy, first-add-on, late add-on). Statistical analysis was set at $p > 0.05$.

Results: 94 patients (48M, 46F, 72 with focal epilepsy and 22 with generalized epilepsy) were included. According to epilepsy onset 49 were SRE (26 females, mean age 41.45±17.16 y.o., 38 with focal epilepsy and 11 with generalized epilepsy) and 45 nSRE (23 females, mean age 42.3±15.72 y.o, 34 with focal epilepsy and 11 with generalized epilepsy), who did not differ in age, age at seizure onset, number of previously taken anti-seizure medications (ASMs), monthly seizure frequency at baseline, mean PER daily dose (5.18±1.95 vs 5.2±1.67 mg/day) and follow-up (21.91 ± 19.93 vs 18.09 ± 17.61 months). PER was administered as adjunctive treatment and slowly titrated (2 mg every two weeks). A significant higher responder rate was observed in SRE than nSRE patients (87.76% vs 71.11%, $p<0.05$), with no significant differences in seizure freedom rate (55.1 vs 44.4%) and discontinuation rate (18.3% vs 15.5%). There were no significant differences when comparing subgroups (patients with focal vs generalized epilepsy, first add-on vs late add-on).

Conclusions: Our results demonstrate the effectiveness of PER as adjunctive treatment, especially in patients with SRE, which seems to be independent of the type of epilepsy and timing of PER introduction. The effectiveness maintained over the long term, can be attribute to both the direct and indirect effect of PER, probably mediated by the improvement of nighttime sleep quality.

## ACUTE TOXIC-METABOLIC ENCEPHALOPATHY OR NONCONVULSIVE STATUS EPILEPTICUS? IFOSFAMIDE-INDUCED NEUROTOXICITY IN A PATIENT WITH TYPE 1 NEUROFIBROMATOSIS

M. Lazzari, S. Fanara, A. Covelli, D. Ferrandi.

Department of Neurology, AO SS. Antonio e Biagio e Cesare Arrigo, University of Eastern Piedmont (Alessandria)

Introduction: Acute toxic-metabolic encephalopathy and nonconvulsive status epilepticus (NCSE) are two neurological emergencies both characterized by impairment of consciousness and altered electroencephalogram (EEG), whom differential diagnosis could be challenging for clinicians. Neurofibromatosis type 1 (NF1) is an autosomal dominant genetic multisystem disorder characterized primarily by multiple cutaneous and plexiform neurofibromas; also, optic nerve, central nervous system and soft tissues can develop both benign and malignant tumors. Furthermore, compared with the general population, NF1 patients have twice the risk of developing seizures and epilepsy [1].

Case Report: Here we describe the case of a 47-years-old male affected by NF1, on neoadjuvant chemotherapy with ifosfamide and epirubicin for a retroperitoneal sarcoma, who came to our attention after his first tonic-clonic seizure. He had no previous history of epilepsy; he had undergone ifosfamide infusion the previous day. The patient was admitted to our emergency department; his brain computed tomography scan and a routine complete blood test were negative. On neurological examination, he presented an altered mental status with confusion, disorientation and ideomotor slowdown. No other neurological signs were detected. An EEG recording was performed, that showed the presence of diffuse generalized 2 Hz discharges with an atypical triphasic morphology, that promptly responded to diazepam administration. Electrical response was not followed by a fair clinical improvement. Even though Salzburg criteria for SENC were not satisfied [2], a first line antiepileptic therapy with levetiracetam was started (at 2000 mg/daily). The patient was admitted to our neurological department. His Magnetic Resonance Imaging was also negative. In the suspicious of a pharmacological acute neurotoxicity, according to our oncologists, a Methylthioninium chloride (or "methylene blue") infusion was started as antidote. The patient began to improve in the subsequent 24 hours. His EEG record also showed a clear improvement. We concluded for an acute toxic-metabolic encephalopathy caused by ifosfamide infusion.

Conclusion: Acute toxic-metabolic encephalopathy and NCSE could share both clinical and electroencephalographic features, as atypical triphasic waves [3]; an electrical response to benzodiazepine is not univocal suggestive for an epileptic origin. Ifosfamide-related encephalopathy is generally characterized by impaired consciousness, with disorientation, delirium, or lethargy and distinct pattern of generalized periodic discharges on EEG [4]. In our case, patient medical and pharmacological history, a negative brain imaging and a defined response to a specific antidote clarified the etiology.

## ANTI-SOX1 ENCEPHALITIS AS A PREDICTOR OF OCCULTED CANCER: A CASE REPORT

S. Lazzari, S. Romano, I. Florindo, L. Zinno

Operating Unit of Neurology, Department of Medicine and Surgery, University of Parma (Parma)

Paraneoplastic neurological syndrome (PNS) is a rare immune-mediated consequence of an immune cross response between a tumour and the nervous system. Interestingly, PNS can predates a cancer diagnosis, therefore determining whether anti-SOX1 antibodies (abs) are present could be useful for localizing underlying malignancy. We present a case of a 60-years-old man with an history of cognitive and memory impairments from about a month, hospitalized because of aphasia and confusion, followed by bilateral tonic-clonic epileptic seizures, evolving into a non-convulsive status epilepticus, which required anti-seizure therapy with Levetiracetam 3000 mg/die and Lacosamid 300 mg/die. Brain angio-CT excluded acute vascular events. EEG showed diffuse mild alterations of cerebral electrogenesis with prevalence on the left fronto-temporal region, without any epileptiform discharges. Brain MRI/Intracranial Angio-MRI showed multiple FLAIR-T2 hyperintensity areas in the retro and bilateral supratrigonal regions, mixed with small areas of reduced diffusivity of ischemic nature and a general aspect of chronic vasculopathy and microangiopathy-hypertensive of severe degree. The angiographic study was normal, biopsy of vessels was not performed. Lumbar puncture revealed mild pleocytosis (96 mononuclear cells), hyperproteinorrachia (126 mg/dl), very mild hypoglycorrhachia (43 mg/dl with pre-procedure stick 96 mg /dl), negativity of bacteriological, viral PCR, oligoclonal bands and autoimmunity panel. Laboratory investigations on serum excluded acute infectious and systemic rheumatologic diseases but revealed a positivity of anti-SOX1 abs at Line Blot immunoassays. Chest-abdomen CT-scan was negative for neoplasms but highlighted multiple mediastinal and mesenteric lymph nodes. Body-PET was negative for oncological findings but revealed hypometabolism of the right lateral prefrontal region, bilateral posterior cingulate and left inferior parietal area. Anti-SOX1 paraneoplastic autoimmune encephalitis was supposed, although the hypothesis of a cerebral amyloid angiopathy-related inflammation (CAARI) was not totally excludable. The patient received solumedrol 1g /day IV for 5 days and immunoglobulin IV followed by Rituximab 1000 mg IV, with only partial benefit and persistence of important space-time disorientation, aphasia, and apathetic state. PNS includes neurological syndromes such as paraneoplastic cerebellar degeneration (PCD), Lambert-Eaton myasthenic syndrome (LEMS), encephalomyelitis, sensory neuronopathy and paraneoplastic limbic encephalitis (PLE). The evidence of positivity to anti-SOX1 abs in association with one of these syndromes should lead to the suspicion of an occult neoplasm. High titres of anti-SOX-1 is associated with an improved response to treatment in patient with SCLC. Usually, patients with NSCLC or non-lung cancers have a better outcome. In light of the above, a clinical-radiological surveillance of patients with serum anti-SOX1 abs should be carried out to early detection of an occult tumour.

## EPILEPSY OCCURRENCE AMONG HIV POSITIVE PATIENTS IN MOZAMBIQUE: A PILOT STUDY

M. Leone[1], M. Rafael[2], F. Corsi[3], N. Majid[4], F. Ciccacci[5], G. Guidotti[6]

[1]Foundation C. Besta Neurologic Institute IRCCS (Milano); [2]Polivalente Beira, Dream Program (Beira-MZ); [3]Neurology, Salvator Mundi (Roma); [4]Zimpeto Maputo, Dream Program (Maputo-MZ); [5]Health and Medical Science, Unicamillus International University (Roma); [6]Health Department, Azienda Sanitaria Locale (Asl) Roma 1, Regione Lazio (Roma)

Introduction: Prevalence of epilepsy in sub-Saharan Africa (SSA) is higher compared to high-income countries due to consequences of bad delivery conditions, brain infections, stroke, road trauma and others. In Mozambique seizure disorders have been estimated between 1,6% and 4,9% among urban and rural population (2% standardized prevalence ratio) [1] in accordance with recent door-to-door prevalence studies in other SSA countries [2]. HIV is highly prevalent (>10%) in Mozambique, and it is a risk factor for epilepsy. Aim of this pilot study was to investigate epilepsy occurrence in a HIV positive population in Mozambique.

Patients and Methods: The study was conducted at the Disease Relief through Excellent and Advanced Means (DREAM) centre in Beira, Mozambique. DREAM is a public health program operating in ten SSA countries treating HIV/AIDS as well as non-communicable diseases as hypertension, diabetes, stroke, cancer and recently also epilepsy. To screen for epilepsy a previously validated questionnaire for SSA patients was employed [3]. The questionnaire contains five questions that were translated into local language. The healthcare personnel received two teaching courses on epilepsy followed by training with the questionnaire. To make the healthcare personnel more familiar with neurologic disorders and the epilepsy questionnaire repeated teaching was dedicated to better distinguish among tremors, involuntary movements, absence, loose of contact, loss of consciousness, syncope and others. Then the questionnaire was administered to 315 consecutive HIV+ patients. The questionnaire was considered "positive" if one or more of the answers to the 5 questions was YES. Positive questionnaires and patients were checked by a neurologist to confirm the diagnosis of epilepsy.

Results: 99,3% (313) of the screened patients were HIV+; 8 (2,53%) were positive at the epilepsy screening questionnaire. The diagnosis of epilepsy was then confirmed. No one of the healthcare providers had previously received a teaching course on epilepsy; less than one quarter of the healthcare providers knew that two thirds of people with epilepsy (PWE) become seizures free if properly treated and that the disease is more common among children and in HIV+ patients. After the teaching courses certain beliefs about the supernatural nature of epilepsy and that it could be contagious were still present among the healthcare providers.

Discussion: This study shows high epilepsy occurrence among HIV+ patients. Further studies are necessary to confirm this preliminary result. Integration of epilepsy and HIV treatment is necessary to accomplish the WHO-Intersectoral Global Action Plan on epilepsy in SSA.

## QUANTITATIVE ANALYSIS OF EEG IN EPILEPTIC PATIENTS TREATED WITH PERAMPANEL

S. M. Lima, E. Lo Mauro, L. Vassallo, F, Brighina, M. Gangitano

Department of Biomedicine, Neuroscience and Advanced Diagnostics, University of Palermo (Palermo)

Goals: Perampanel is a non-competitive antagonist for ionotropic glutamate receptor AMPA type primarily indicated for the adjunctive treatment of partial onset seizures with or without secondary generalization and for primary generalized seizures [1]. We evaluated the changes in the spectral maps induced by the therapy.
Materials: Ten patients followed by our center affected by focal and generalized epilepsy and who undertook perampanel therapy in ADD ON.

Methods: We recorded two serial EEG performed on day T0 (first prescription of the drug) and on day T1 (after one year). The basic traces were evaluated and the quantitative analysis was performed using "EEGLAB" on MATLAB extrapolating the spectral maps at the frequencies 4Hz, 8Hz, 10Hz and 12Hz for each patient in the two times. Then, a comparison study was carried out between the spectral maps at times T0 and at T1 on the same frequencies and studied in statistical comparison by means of a t-test, with the drug administration time as factor.

Results: There is a variation of the frequencies 4-8-10-12 Hz from T0 to T1 which becomes statistically significant for the faster frequencies in the mid-rear areas. Furthermore, there has been a reduction in crisis assessments at subsequent follow-ups.

Discussion: The chromatic variation of the spectral maps for a single patient on the frequencies 4-8-10-12 Hz, in agreement with the statistical analysis carried out on the same frequencies, shows that the perampanel is able to modify the excitability of the cortex with an increase in the frequencies rapids especially in the mid-rear areas. In general, the slowing of background EEG activity has been interpreted as an indicator of brain dysfunction and related to cognitive impairment. The increase of alpha frequencies on qEEG analysis is in agreement with previous results with consequent improvement of attentional functions and complex cognitive processes [2-3].

Conclusions: Increased alpha frequencies on qEEG analysis can clinically lead to increased attention and complex cognitive processes. Furthermore, the aforementioned modification of the cortical activity is in agreement with the reduction of the number of seizures in the patients analysed, confirming the efficacy of the drug.

## CANNOT STOP MOVING! EPILEPSIA PARTIALIS CONTINUA AND SUBSEQUENT "BELLY DANCE" SYNDROME IN A PATIENT WITH NON-KETOTIC HYPERGLYCEMIA: A CASE REPORT

D. Liviello, F. Dono, S. Cipollone, G. Evangelista, S. Consoli, S. De Angelis, C. Corniello, M. Onofrj, S. Sensi, F. Anzellotti

Department of Neuroscience, Imaging and Clinical Sciences, University "G. D'Annunzio" of Chieti-Pescara (Chieti)

Introduction: Severe hyperglycemia can be associated with a wide spectrum of movement disorders ranging from epilepsia partialis continua (EPC), chorea-ballismus, myoclonus, rubral tremor, dyskinesia, restless leg syndrome, hemifacial spasm to parkinsonism. These neurological manifestations might herald the onset of acute ketotic or non-ketotic complications among previously undiagnosed diabetics. Although hemiballismus-hemichorea has fairly been reported as a direct complication of hyperglycemia, EPC and diaphragmatic myoclonus (DM) are rare.

Case report: A 73-years old woman was admitted to our Emergency Room due to the sudden appearance of continuous unremitting clonic movements involving the left forearm. A concomitant electroencephalogram (EEG) recording showed rhythmic medium amplitude 5 Hz theta bursts evolving in 8 Hz monomorphic sequences with superimposed diphasic sharp waves, over the right central regions. A diagnosis of epilepsia partialis continua (EPC) was made. Blood analysis showed a marked non-ketotic hyperglycemia (827 mg/dL). The brain MRI showed a hypointense cortico-subcortical signal in T2-weighted and FLAIR images over the right central region. The CSF examination was normal. The patient was treated with intravenous (i.v.) boluses of Lorazepam 4 mg and subsequentially with Levetiracetam 3000 mg and Lacosamide 400 mg, with resolution of the symptoms. Two days later, the patient developed left hemi-diaphragmatic myoclonus. A further EEG was performed which was unremarkable. Jerk-locked back-averaging and EMG-EEG coherence analysis showed no correlation between brain activity and myoclonus. Myoclonus progressively improved after introducing Clonazepam at 2 mg/day and adjustment of glycemic values. At 6-month follow-up visit, anticonvulsant therapy was progressively suspended without the occurrence of any relapses.

Conclusion: EPC and DM may represent two neurological symptoms associated with hyperglycemia. Acute treatment of these condition consists of a combined therapy of ASM and adjustment of glycemic values. Long-term seizure prophylaxis is questionable.

## ELECTRICAL SIGNAL MODULATION IN PATIENTS WITH FOCAL FRONTAL EPILEPSY AND BEHAVIORAL DATA

E. Lo Mauro, S. Lima, L. Vassallo, F. Brighina, M. Gangitano

Department of Biomedicine, Neuroscience and Advanced Diagnostics, University of Palermo (Palermo)

Background: Patients with frontal deficits may have automatic and compulsive behaviors (Environmental dependency syndrome with utilization and imitation behaviors [1]). The aim of this study is to analyze whether subjects affected by focal frontal epilepsy present such dysregulations of frontal functions.

Materials: We recruited 9 patients affected by focal frontal epilepsy. We selected only patients treated with less than 3 antiepileptics who did not require the addition of another drug and that did not present more than 5 seizures in the previous twelve months. We also included a group of 9 healthy controls. All patients had a Mini Mental State Examination score $\geq$ 25.

Method: In a preliminary session, we evaluated frontal functions through a neurocognitive test battery (Frontal Assessment Battery, trail making test, the modified Wisconsin Card Sorting Test and the

Stroop interference task). Then, we used a paradigm that involves pointing on luminous targets placed in different positions on the surface of a table. Patients were instructed to touch luminous targets following specific array, that could be interfered or not by other lights. At the same time, we recorded the electroencephalogram; the signal was processed by averaging the periods preceding the execution of the motor task. The EEG signal elaborated was correlated with the data obtained during the motor task and with the scores of neurocognitive tests.

Results: Patients with focal frontal epilepsy have a significant tendency to increase the number of errors in pointing task compared to controls. We have found a large heterogeneity in the results of neurocognitive tests. The number of errors in pointing task was not related with neurocognitive tests score in correlation analysis.

Discussion: Our results support the hypothesis of behavioral frontal dysfunctions in patients with focal frontal epilepsy that causes a tendency to be distracted by spatially irrelevant targets during the execution of motor tasks. However, it is not possible to disentangle whether these results depend on drugs effects or disease per-se. Consequently, a further control study will be necessary in which we will include patients with the same therapy but without focal frontal epilepsy.

Conclusion: This study provides new insights about patients with focal frontal epilepsy and their tendency to have typical frontal lobe disorders (behavioral disorders) during the interictal phases.

## IS BLOOD-BRAIN BARRIER IMPAIRMENT AN EARLY SIGN OR A RISK FACTOR FOR NEURODEGENERATION IN PATIENTS WITH LATE ONSET EPILEPSY OF UNKNOWN ORIGIN?

S. Maio[1], M. Fernandes[2], C. Calvello[2], F. Placidi[3], F. Izzi[3], N. Mercuri[2], C. Liguori[3]

[1]Neurology Unit, Policlinico "Tor Vergata", University of Rome "Tor Vergata" (Roma); [2]Department of Systems Medicine, University of Rome "Tor Vergata" (Roma);[3]Epilepsy Centre, Neurology Unit, Policlinico "Tor Vergata" (Roma)

Objectives: The incidence of new-onset epilepsy increases with age, especially over age 50, with 15-20% of late-onset cases with unknown aetiology (LOEU) [1]. Growing attention has been given to LOEU since an association with biomarkers of cerebral amyloidopathy has been demonstrated, as well as the possibility to develop a neurodegenerative disorder [2]. Blood-brain barrier (BBB) is essential for maintaining brain health, and in the early stages of neurodegeneration its dysfunction may concur to the neuropathological processes underlying cognitive impairment and dementia. In the present study, cerebrospinal-fluid (CSF)/serum albumin ratio, as a marker of BBB functionality [3], and biomarkers for Alzheimer's disease (AD) pathology were analysed in patients with LOEU compared to a group of elderly controls.

Materials: This observational retrospective study included patients diagnosed with LOEU who were admitted to the Epilepsy Centre of the University Hospital of Rome "Tor Vergata".

Methods: Patients were classified in accord with the classification of seizures by the International League Against Epilepsy – ILAE. Patients and controls underwent a neurological visit, cognitive evaluation (to exclude cognitive impairment) and a lumbar puncture for CSF biomarker analysis [β-amyloid42 (Aβ42); total-tau (t-tau); phosphorylated tau (p-tau); CSF/serum albumin ratio]. Lumbar puncture was performed at least 3 days following the last seizure.

Results: Thirty LOEU patients (mean age 68.63±7.78) and twenty-five controls (mean age 65.64±8.10) were included. LOEU patients showed lower CSF Aβ42 levels (p=0.036) and higher CSF/serum albumin ratio (p=0.011) than controls. Seven patients (23.33%) showed a pathological value of CSF Aβ42 and 8 patients (26.66%) had a pathological value of CSF/serum albumin ratio. No significant differences were found between LOEU patients and controls on CSF t-tau and p-tau levels. Considering the subanalysis between patients with pathological CSF Aβ42 compared to those with normal levels, no difference in CSF/serum albumin ratio was evident. Moreover, distributing patients on the basis of the t-tau/Aβ42 ratio suspected for AD (>0.52), no differences in the CSF/serum albumin ratio were evident.

Discussion: Patients with LOEU exhibit BBB impairment, with more than one fourth of patients showing pathological values of CSF/serum albumin ratio. This BBB alteration was independent of the pathological reduction of both CSF Aβ42 and CSF t-tau/Aβ42 ratio suspected for AD.

Conclusions: Whether BBB impairment may represent an early marker of neurodegeneration or a seizure-related manifestation inducing neuropathological processes in patients with LOEU remains an unresolved question and further studies also hypothesizing treatments aimed at preserving BBB integrity in patients with LOEU should be planned.

Introduction: Stroke-like Migraine Attacks after Radiation Therapy (SMART) syndrome is a very rare late complication of radiation therapy in cerebral neoplasms. Approximately 150 cases have been reported in the literature.

Case presentation: We describe the case of a 60-year-old man with a grade 2 WHO oligodendroglioma of the left temporal lobe, presented in 2018 with an aphasic seizure with bilateral tonic-clonic evolution, and treated with neurosurgery, radiotherapy and chemotherapy at progression. After two years of complete seizure freedom with BRV 175 mg/day and stability on clinical-radiological follow-up, in November 2022, he developed a focal motor status epilepticus, associated with confusion, headache, and aphasia. Brain MRI showed extensive vasogenic edema at the site of the previous lesion and focal and meningeal contrast enhancement located in the anterior side of surgical cavity,

suggestive for disease recurrence. After the resolution of status epilepticus with BRV 200 mg, LCS 200 mg, and CNZ 8 mg and the implementation of steroid therapy, aphasia and confusion progressively improved and the aforementioned MRI contrast enhancement disappeared at follow-up.

Discussion and Conclusion: The clinical expression and the radiological pattern and evolution plus the dramatic response to corticosteroid therapy questioned the disease recurrence and supported the diagnosis of SMART syndrome. This entity, though extremely rare, should be considered among the differential diagnoses in the case of neurological deterioration in patients affected by cerebral neoplasms treated with radiotherapy, in order to choose the optimal treatment.

## HIPPOCAMPAL AND STRIATAL SYNAPTIC DYSFUNCTIONS IN A MOUSE MODEL OF LAFORA DISEASE

A. Mancini[1], M. Sciaccaluga[1], L. Zafra-Puerta[2], L. Bellingacci[1], J. Canonichesi[1], V. Imperatore[1], M. Di Filippo[1], A. Tozzi[31], P. Prontera[4], M. Sanchez[2], J. Serratosa[2], L. Parnetti[1], C. Costa[1]

[1]Section of Neurology, University of Perugia (Perugia); [2]Laboratory of Neurology, Universidad Autónoma de Madrid (IIS-FJD, UAM) (Madrid-E); [3]Section of Physiology, University of Perugia (Perugia); [4]Medical Genetics Unit, S. Maria della Misericordia Hospital (Perugia)

Background and objectives: Lafora disease (LD) is a rare, fatal and recessive form of progressive myoclonic epilepsy caused by mutations in the EPM2A or EPM2B genes [1,2], which code for laforin and malin respectively. Dysfunctions in either laforin or malin result in the formation, in the brain and other tissues, of aberrant polyglucosane aggregates, known as Lafora bodies, which constitute the histopatological hallmark of the disease and are considered the main cause of its progression [3]. The physiopathological mechanisms underlying LD are still poorly understood. We performed an electrophysiological study on a mouse model of LD in order to identify, in a temporal and region-specific manner, the molecular mechanisms underlying LD and driving its course.

Materials and methods: We performed ex vivo patch-clamp and extracellular recordings to investigate possible alterations of the intrinsic membrane properties, neuronal excitability and synaptic transmission and plasticity, in two different brain areas particularly involved in the mechanisms of epileptogenesis and synaptic plasticity (cognitive and procedural): the hippocampus (dentate gyrus -DG- and CA1) and the nucleus striatum.

Results: Our electrophysiological data demonstrated enhanced excitability and lower epileptic threshold, along with pathological LTP, only in the DG of LD mice, whereas basal membrane properties and synaptic plasticity in CA1 were not impaired. In the nucleus striatum, we found alterations of the cortico-striatal transmission and LTP impairment.

Discussion: Our electrophysiological data demonstrated a region-specific impairment of the hippocampus, in which the hyperexcitability of the granule cells is at the basis of the hyperplasticity observed, which is related to cognitive deficits. In the nucleus striatum we demonstrated age-dependent alterations of synaptic transmission and plasticity possibly related to cortico- and nigro-striatal network dysfunctions. Conclusions: Our electrophysiological study lead to the identification of region-specific and time-dependent alterations in a mouse model of LD. The identification of the mechanisms underlying hyperexcitability and neurodegeneration in these animal models is fundamental not only to define possible therapeutic targets, but also to delineate a "time window" in which a therapeutic approach may be most effective.

## A CASE OF BRAIN ABSCESS CAUSED BY NOCARDIA ABSCESSUS

G. Marini, S. Paolucci, A. Riva, N. Zannotti, F. Cancellieri, C. Di Felice, S. Malatini, M. Bartolini, M. Silvestrini, G. Viticchi

Neurological Clinic, Marche Polytechnic University (Ancona)

Introduction: Nocardia are aerobic gram-positive bacteria that can infect humans, mostly immunocompromised individuals, through inhalation or inoculation into the skin. Its epidemiology is not well established, even if most of the cases were signaled in United States, India and Mexico. An immunocompromising state, due for example to immunosuppressive medications, HIV infection or primary immune deficiencies, is the principal predisposing condition to nocardial infection. Dissemination occurs in 20-50% of cases. The brain abscess is the most common form of dissemination disease involving the 20-58% of the infected by Nocardia, even if it constitutes only the 1-2% of all brain abscess. The cerebral lesions may manifest with focal neurologic deficits, altered mental status, headache, seizures and ataxia. Brain MRI typically shows ring-enhancing lesions which can be surrounded by edema in the 40-50% of cases.

Case report: We present the case of a 69-year-old man, affected by a B-cell Non-Hodgkin Lymphoma treated with chemotherapy (CHOP-Rituximab) in 2003, arrived to our emergency department for confusion and bradipsychia. When he was hospitalized in Neurological Clinical, he presented focal seizures at left arm and leg associated with head version and impaired awareness. A first cerebral CT scan showed lesions compatible with metastasis. The radiological exam was repeated using contrast and multiple ring-enhancing lesions were revealed. Furthermore, an enhancing pseudo nodular lesion was found in the right lung at chest-abdomen CT scan with contrast. Laboratory examinations showed non alterations in oncological markers but low value of CD 4+ lymphocytes indicating an immune reconstitution post chemotherapy. Hence, cerebral lesions were better characterized through brain MRI which displayed perilesional edema, central hyperintensity on diffusion-weighted images and ring enhancement. This aspect was suggestive both for metastasis and for brain abscess. Culture of bronchoscopy was decisive for the diagnosis. It demonstrated the presence of a Nocardia abscesses on lung. Antibiotic therapy, based on Imipenem, was began. The patients presented a clinical improvement

and was discharged after two weeks. Actually, he was in radiological follow-up.

Discussion: Thanks to radiological exams and cultural examination, we could remove the suspect of cerebral metastasis and make diagnosis of Nocardia brain abscess in an immunocompromised patient with an oncological history.

Conclusions: Nocardia brain abscess is a rare but possible cause of cerebral expansive process. Clinicians have to consider this hypothesis, especially in immunocompromised subjects, in order to start as soon as possible a correct antibiotic therapy.

## BENIGN ADULT FAMILIAL MYOCLONUS EPILEPSY (BAFME) PRESENTING AS FAMILIAR TREMOR AND PHOTOMYOCLONIC RESPONSE

L. Marino, M. Trimboli, I. Sammarra, M. Sturniolo, F. Fortunato, A. Giugno, I. Martino, C. Fratto, A. Gambardella

Institute of Neurology, University "Magna Graecia" (Catanzaro)

Objectives: Benign adult familial myoclonus epilepsy (BAFME) is an autosomal dominant condition characterized by onset in the second-third decade of life, tonic-clonic seizures, and spontaneous or stimulus-sensitive cortical myoclonus at a variable frequency [1]. Mood disorders, predominantly anxiety and depression, are commonly observed. The clinical course is overall benign with a normal life expectancy. However, the severity of cortical tremor and myoclonus usually increases with aging [2]. We describe a family with a clinical pattern resembling benign adult familial myoclonus epilepsy phenotype with hand tremor as prominent feature.

Materials: a 44-year-old woman presented to our Epilepsy Center with a 4-year history of involuntary jerks involving the upper limbs. She referred a positive family history for hand tremor and epilepsy, being the mother, maternal aunt, uncle, and grandmother affected. At the age of 43 years, she developed hand tremor and dizziness. Concomitantly, the arm jerks worsened over time and an electroencephalographic recording (EEG) revealed diffuse spike-waves. In the following months, she experienced clinical worsening, having a more severe hand tremor with superimposed myoclonic jerks involving all limbs and face.

Methods: We performed a comprehensive clinical and laboratory work-up, including EEG and polygraphic video-EEG recording, somatosensory evoked potentials (SEPs), cortical reflex (C reflex), and 3-T brain magnetic resonance imaging (MRI). Genetic investigations were also performed on other family members. Informed consent was obtained according to the protocols approved by the local ethics committee.

Results: At admission, neurological examination revealed severe postural and action hand tremor, as well as myoclonus of the upper limbs during action. EEG showed diffuse spike-waves and photomyoclonic response at low-medium stimulation frequencies. The polygraphic EEG recordings demonstrated hand tremor with myoclonic jerks of upper limbs related to spike-waves. SEPs study showed giant potentials. The 3T-brain MRI was unremarkable. Therefore, an antiseizure therapy with levetiracetam at 2000 mg/day and clonazepam 0,5 mg/day was started.

Discussion: BAFME is rare form of epilepsy syndrome, with infrequent generalized tonic-clonic seizures, myoclonus and cortical tremor. The cortical tremor often resembles the clinical characteristics of essential tremor, leading to misdiagnosis. Our study illustrates the heterogenous phenotypes in BAFME, ranging from milder phenotypes to more severe clinical phenotypes.

Conclusions: Our findings confirm the cortical origins of hand tremor, besides of myoclonic jerks. Furthermore, considering the positive family history with hand tremor and epilepsy, we interpreted our family case as clinically indicative of BAFME, a rare form of epilepsy syndrome, often misdiagnosed.

## SLEEP DISORDERS IN PEOPLE WITH EPILEPSY. AN OBSERVATIONAL STUDY IN A TERTIARY SLEEP AND EPILEPSY CENTER

P. Mattioli[1], S. Chiappori[2], A. Donniaquio[3], R. Mancini[3], F. Calizzano[3], L. Argenti[3], V. Costa[3], L. Lombardo[3], M. Losa[3], A. Giberti[3], F. Villani[4], D. Arnaldi[1]

[1]IRCCS Ospedale Policlinico San Martino, Dept. of Neuroscience (DINOGMI), University of Genoa (Genova); [2]University of Genoa (Genova); [3]Dept. of Neuroscience (DINOGMI), University of Genoa (Genova); [4]IRCCS Ospedale Policlinico San Martino, Division of Neurophysiology and Epilepsy Centre (Genova)

Objectives. To describe the prevalence and associations of sleep disorders in people with epilepsy (PWE) in a tertiary Sleep and Epilepsy center.

Materials: All patients admitted to the Sleep and Epilepsy outpatient clinic of the IRCCS Ospedale Policlinico San Martino from January to April 2023 were asked to fill three self-administered sleep questionnaires, namely the Pittsburgh Sleep Quality Index (PSQI) along with its subitems (total score, duration of sleep, sleep disturbances, sleep latency, day disfunction, sleep efficiency, sleep quality, need of sleep-medication), the Epworth Sleepiness Scale (ESS), and the Insomnia Severity Index (ISI). The following clinical characteristics of PWE were systematically collected: seizure freedom (yes/no), mono/polytherapy, need for changes in anti-seizures medication (ASM; yes/no), new versus old generation ASM, number of ASM, and changes in ASM in the last visit (yes/no).

Methods: First, the prevalence of abnormal questionnaires' scores in PWE was assessed. Then, the associations between sleep and epilepsy features were evaluated.

Results: Among the 191 patients assessed, 85 (52 females, 56±21yo) had a diagnosis of epilepsy, of whom 4.71% had abnormal ISI, 18.82% abnormal ESS%, and 62.35% abnormal PSQI. Concerning PSQI sub-items, 25.88% had abnormal sleep duration, 84.71% sleep disturbances, 45.88% abnormal sleep latency, 18.82% daytime disturbances, 84.71% abnormal sleep efficacy, 12.94% reported abnormal sleep quality, and 17.64% reported the need for sleep-inducing medications. Sleep quality abnormalities were more frequent in patients without (21.7%) compared with patients with (2.6%) seizure freedom ($p=0.010$), and in patients with (24.1%) compared with those without (7.1%) the need of a change in ASM ($p=0.040$). Patients with the need of ASM changing also reported a higher frequency of sleep

disturbances (96.6%, p=0.030) and daytime disturbances (31.0%, p=0.046). At multivariate analysis, seizure freedom inversely correlated with sleep quality abnormality and the use of old generation ASM, and directly with monotherapy ($p<0.05$).

Discussion. Sleep disorders can be both a consequence and a cause of epilepsy [1]. In agreement with current literature [2], we found a high prevalence of sleep disorders in persons with epilepsy. Interestingly, while PSQI and ESS were frequently found abnormal, ISI was normal in the vast majority of patients. Epilepsy features were variably associated with sleep disorders, but as expected, seizure freedom was associated with a better sleep quality.

Conclusion: A systematic and standardized evaluation of sleep quality in patients with epilepsy is needed, especially in patients without seizure freedom.

## PROGNOSTIC PATTERNS AND LONG-TERM SEIZURE OUTCOME OF NON-SURGICALLY TREATED PATIENTS WITH CORTICAL DYSPLASIA

A. Mazzeo, A. Morano, E. Cerulli Irelli, C. Catania, A. Petrungaro, C. Panzini, B. Orlando, E. Salamone, A. Giallonardo, C. Di Bonaventura

Human Neurosciences, Sapienza University of Rome (Roma)

Objectives: Malformations of cortical development represent a common cause of surgically remediable focal epilepsy [1]. However, little is known regarding the long-term prognosis of non-surgically treated patients. The objective of the study was the identification of prognostic patterns and long-term seizure outcome in a cohort of patients with neuroimaging features suggestive of cortical dysplasia who did not undergo surgery.

Materials: Data from patients with focal epilepsy followed from 1975 to 2022 were retrospectively reviewed. We included patients with MRI-documented cortical dysplasia who did not undergo surgical treatment due to their choice or clinical reasons, followed up for more than 5 years from epilepsy diagnosis.

Methods: After revision of their electroclinical data, we defined the following prognostic patterns: early remission (no seizures within 2 years from diagnosis), late remission (after 2 years), relapsing-remitting (2 periods free of seizures for more than 2 years), non-remitting. Univariate analysis was conducted to identify electroclinical variables associated with remission.

Results: 38 patients were included (18 females and 20 males). The median age at diagnosis was 10 years, with a median age at the last evaluation of 49.5 years and a median follow-up of 11.5 years. The most common prognostic pattern observed was non-remitting (52.6%), followed by relapsing-remitting and late remission patterns (18.4% each), and by early remission (10.5%). 16% of patients presented seizures with daily frequency. Remission was associated with the parietal localization of the dysplasia, whereas no remission course was associated with the presence of focal seizures with impaired awareness and epileptiform abnormalities on baseline EEG ($p < 0.05$).

Discussion: While surgery represents the gold-standard treatment for cortical dysplasias [2], our findings indicate that up to 30% of patients can achieve remission with anti-seizure medications. This is consistent with previous studies examining prognostic patterns in focal epilepsy [3]. The presence of focal seizures with impaired awareness and epileptiform abnormalities on baseline EEG may be associated with the non-remitting pattern because of a wider epileptogenic network involved in this subgroup of patients.

Conclusions: Our study highlights the heterogeneity of prognostic patterns of patients with non-surgically treated cortical dysplasia and shows that remission can be achieved in up to 30% of patients.

## HOME ULTRA-LONG-TERM EEG MONITORING IN RARE EPILEPSIES: AN OPEN-LABEL PROSPECTIVE STUDY USING MINIMALLY INVASIVE WEARABLE EEG DEVICE. THE EMIRE TRIAL

S. Meletti[1], S. Maffei[1], A. Coppola[2], L. Bilo[2], P. Manganotti[3], G. Giovannini[1], A. Vaudanno[1], M. Trivisano[4], N. Specchio[4]

[1]Neurology, AOU Modena (Modena); [2]Neurology, AOU Federico II (Napoli); [3]Neurology, AOU Trieste (Trieste); [4]Child Neurology, Ospedale Pediatrico Bambino Gesù (Roma)

Objectives: A fundamental aspect that limits the clinical management of patients with difficult to treat epilepsy is the phenomenon of the undersampling of seizures. It is in fact known that ascertaining the frequency of seizures from the patient's subjective report diaries detects about 50% of the seizures that actually occur, with great variability (i.e. seizures in sleep are not reported in 80% of cases). To overcome these limits, a long-lasting recording of EEG activity is expected to greatly improve our clinical management of the patient.

Methods: This project aims to develop a personalized medicine approach to improve the management of rare epilepsies and developmental and epileptic encephalopathies (DEE) by means of ultra-long-term EEG monitoring. We will use a minimally invasive subcutaneous implanted EEG device (sqEEG) to record the EEG activity for 3 to 6 months, while the patient is at home.

Results: We expect and test the following hypothesis: (1) subscalp EEG is be able to correctly detect more than 80% of the seizures of the enrolled patients compared with the gold-standard represented by traditional video-EEG monitoring. (2) that ultra-long-term home monitoring will be able to detect more ictal events than the patient's clinical diary. (3) that the information obtained from the subscalp EEG can be translated into useful information in the patient's clinical management that are not gained by the standard of care. Specifically, in assessing the response to drug treatments, and in being able to identify patterns for predicting seizure risk on an individual basis. (4) we expect the device to be well tolerated and more than 80% of subjects to be able to terminate home monitoring for 3-6 months.

Discussion: The development of subscalp EEG devices is motivated by an unmet clinical need that neither scalp nor intracranial EEG addresses. This may have many advantages for personalized epilepsy care. These goals are of particular relevance in patients with rare epilepsies and DEE. If the expected goals are confirmed, clinical trials using this technology can be developed to objectify the effects of pharmacological interventions from a precision medicine perspective in these patient populations.

Conclusions: A majority of patients and caregivers want some form of seizure monitoring, either at night only or 24/7, to feel safer and less stigmatized. This is where subscalp EEG is most likely to improve the everyday life of a person with epilepsy and DEE in particular.

## A CASE OF SERONEGATIVE AUTOIMMUNE LIMBIC ENCEPHALITIS WITH SUPERIMPOSED HYPERKINETIC SYNDROME DUE TO PHENYTOIN TOXICITY

E. Minerva[1], V. Pacoova Dal Maschio[1], G. Pellegrino[1], M. Vigliani[2], A. Chiò[1]

[1]Department of Neurosciences Rita Levi Montalcini, University of Turin (Torino); [2]Neurology 1 Unit, Città della Salute e della Scienza di Torino (Torino)

Background: Autoimmune limbic encephalitis (ALE) is an increasingly recognized cause of refractory status epilepticus. Seronegative forms without any identifiable antibody constitute a major subtype of ALE and encompass a heterogenous group of disorders. Treatment requires antiepileptic drugs and immunotherapy. Antiepileptic combination therapy is burdened by many adverse effects, including neurological ones, which can smear the clinical picture and sometimes be hardly distinguished from those due to the underlying neurological disorder.

Case report: We report the case of a previously healthy 39 y/o woman who was hospitalized in Belgium for cluster seizures, impaired consciousness and repetitive facio-brachial dystonic episodes, a few days after developing fever and skin rash with a positive Influenza B swab. Seizures hastily evolved into a refractory status epilepticus requiring various combinations of sedative and antiepileptic drugs. MRI, EEG, clinical and laboratory findings led to a diagnosis of definite ALE according to Graus criteria, with bilateral involvement of mesial temporal lobes and basal ganglia. The patient tested negative for infectious and immuno-rheumatological diseases and for antibodies against CNS intracellular or cell-surface antigens in blood and CSF. After a failed high-dose steroid treatment, she was successfully weaned from deep sedation following five sessions of plasma exchange. Final seizure control was achieved with four antiepileptic medications, including phenytoin, at its maximum allowed dosage (600 mg/day). Then the patient was transferred to our Unit for additional treatment and care. She presented executive, language and memory deficits, and hyperkinetic syndrome with sporadic dystonic-like limb postures. Antiepileptic drug monitoring found toxic phenytoin blood levels (40.5 mg/L, therapeutic range 10.0-20.0); therefore this drug was gradually discontinued with complete resolution of hyperkinesia. Given the persistent pleocytosis in CSF and residual increase in hippocampal FDG-uptake at PET scan, further immunotherapy was started, firstly with IV immunoglobulins (2 g/kg in 5 days), then with Rituximab (375 mg/m2 once a week for 4 weeks), with gradual improvement of cognitive impairment. The patient was finally discharged with a combination of only two antiepileptic medications, lacosamide and sodium valproate, without seizure recurrence in the subsequent month.

Conclusions: This case provides a useful insight into management pitfalls in ALE, in terms of efficacy and tolerability of both immunotherapy and antiepileptic drugs, burdened by many insidious neurological side effects. Wise medication and clinical choices are thus essential to discern drug adverse reactions from manifestations of the underlying disease.

## DRUG-RESISTANT TEMPORAL LOBE EPILEPSY DUE TO HIPPOCAMPAL SCLEROSIS AND SEIZURE OUTCOME AFTER SURGERY: PREDICTIVE VALUE OF ICTAL EEG PATTERNS

R. Missione[1], S. Casciato[2], A. D'Aniello[2], A. Mascia[2], P.P. Quarato[2], L. Grammaldo[2], G. Malinconico[2], S. Fratini[2], V. Esposito[2], G. Di Gennaro[2]

[1]Second Division of Neurology, Department of Advanced Medical and Surgical Sciences, University of Campania 'Luigi Vanvitelli' (Napoli); [2]IRCCS NEUROMED (Pozzilli-IS)

Background and aims: To assess the predictive value of ictal EEG pattern on seizure outcome in a group of consecutive subjects with drug-resistant temporal lobe epilepsy associated to hippocampal sclerosis (TLE-HS) who underwent presurgical evaluation and subsequent resective surgery (anterior temporal lobectomy).

Methods: We retrospectively included all consecutive adult subjects with refractory TLE-HS who underwent presurgical assessment, subsequent resective surgery and met the following inclusion criteria: 1) at least one seizure recorded during presurgical video-EEG study and available for revision; 2) histological confirmation of hippocampal sclerosis 3) at least 12 months post-operative follow-up. Based on literature data, the following different EEG patterns were considered for case classification: Type 1: antero–temporal 5–9 Hz discharge, with a minimum duration of 10 seconds, associated with a highly probable onset in the mesial temporal structures; Type 2: temporal 2–4 Hz discharge, with a minimum duration of 10 seconds, associated with a highly probable onset in the lateral temporal structures; Type 3: combination of type 1 and type 2 EEG patterns, indicating an early involvement of both mesial and neocortical structures. Demographic, clinical data and seizure outcome were systematically collected; subjects who were in Engel Class Ia at the last visit were classified as having a favorable outcome.

Results and Conclusions: A total of 111 TLE-HS cases surgically treated were included in this study: 59 males (65.5%) and 52 females (34.5%). Mean number of recorded seizures: 2.8 (range 1-10). In 69/111 subjects classified with Type 1 pattern, 57 (82.7%) were seizure free, 12 (17.3%) experienced post-operative seizures (in 3/12 cases only aura were reported). By contrast, 42 subjects were classified having Type 2 and 3 patterns. A favorable outcome were reported in 12 (28.6%) cases, seizure persistence in 30 (71.4%). The mesial pattern is associated with a better surgical prognosis compared to other ictal EEG patterns. This study provided preliminary data on the role of EEG seizure pattern as a possible predictor of post-operative outcome in drug resistant TLE-HS. In particular, this data could suggest a more "discrete" epileptogenic zone in the Type 1 group, limited to the hippocampal structures. By contrast, the Type 2 and 3 patterns may suggest, in selected cases, the opportunity to perform further presurgical

investigations, such as brain PET or exploration by using intracranial electrodes.

## CLUSTER TONIC-CLONIC SEIZURES IN AN LGI1 ENCEPHALITIS: A CASE REPORT

C. Morotti Colleoni, V. Aprea, G. Ferrero, A. Montisano, E. Funelli, F. Galbiati, B. Della Santa, D. Cereda, S. Beretta, C. Ferrarese

Neurological Department, IRCCS San Gerardo, University of Milan-Bicocca (Monza)

Objectives: LGI1 encephalitis represents the second most frequent subtype of autoimmune encephalitis. Clinical features usually include memory impairment and faciobrachial dystonic seizures, but tonic-clonic or focal aware seizures are frequently described [1].

Materials: We presented the case of a 66 years old woman admitted to our ER because of a first episode of tonic-clonic seizure at home, followed by two more episodes during the delivery to hospital. A month before she complained of influenza-like symptoms, followed by confusion, disorientation and visual hallucinations.

Methods: Electronic medical records, neuroimaging, neurophysiological reports and laboratory results were reviewed.

Results: After a first line ASM with midazolam the patient remained in a status of impairment of consciousness. She was intubated and taken to the Intensive Care Unit. She started ASM with levetiracetam with a complete regression of seizures. The EEG shown a diffuse cerebral dysfunction, without epileptic abnormalities. The plasma sodium level upon admission was 136 mmol/L. The patient was extubated the next day and she was subjected to a lumbar puncture. The preliminary analysis of the liquor did not show pathologic results or evidences of infections. At the brain MRI there was evidence of T2/FLAIR hyperintensity in the left temporo-mesial cortical-subcortical region, suspected for auto-immune encephalitis. The patient was admitted to the Neurology Department in good conditions: she was confused, disoriented in time with a short term memory impairment. She was subjected to immunotherapy with methylprednisolone 1g/day for a week, follow by 3 cycles of plasmapheresis. The brain FGD-PET shown an hypermetabolism in the left mesial temporal and parahippocampal regions. A paraneoplastic syndrome was excluded by negative results of total body imaging, such as CT and FDG-PET. After a few days it was confirmed the presence of LGI1 auto-antibodies in liquor and serum.

Discussion: The patient was discharged after 30 days of hospital stay with an high dose of oral dexamethasone. After 6 months there remained a significant short term memory deficit. The subsequent EEGs showed a bitemporal slowing activity. During the follow up, the dosage of levetiracetam and dexamethasone was gradually reduced until the medication was discontinued.

Conclusion: Cluster tonic-clonic seizures could be the clinical presentation of anti-LGI1 encephalitis. Specific imaging and neurological tests, included the lumbar puncture, must be performed to obtain the diagnosis. Immunotherapy with steroids is usually necessary to achieve clinical improvement. Long-term memory impairment is a common finding in these patients [2].

## EPILEPSY POWER: SURVEYS FROM A MULTICENTRIC EUROPEAN STUDY ABOUT EPILEPSY AND EMPLOYMENT

F. Narducci[1], G. Baker[2], D. Walsh[3], F. Sofia[3], N. Casalino[4], B. Borin[4], F. Pigni[5], S. Louissi[5], M. Kateva[6], I. Filipova[6], S. Duttenhöfer[7], M. Tombini[1], V. Di Lazzaro[1], G. Assenza[1]

[1]Neurology and Neurophysiology Unit, Campus Bio-Medico University (Roma); [2]Department of Molecular and Clinical Pharmacology, University of Liverpool (Liverpool-UK); [3]International Bureau of Epilepsy (IBE) (Dublin-DK); [4]Department of Business and Management, Luiss Guido Carli University (Roma); [5]Management and Technology, Grenoble Ecole de Management (Grenoble-F); [6]Chamber of Commerce and Industry (Vratsa-BG); [7]Emcra GmbH (Berlin-D)

Objectives: Epilepsy affects all aspects of individual life, including employment. Despite good seizure control, unemployment and underemployment are more common among people with epilepsy (pwE), for several reasons including stigma and misconceptions. The Epilepsy-POWER is a European project, financed by the programme Erasmus+, involving five Countries (Italy, Bulgaria, France, Ireland, Germany), aimed to improve the workplace inclusion of PwE in Europe. We created surveys to explore employment conditions among European pwE and conceptions of Higher Educational Institutions (HEI).

Methods: We developed two anonymous surveys for each target group: pwE and HEI. Questions focused on demographic and clinical features, employment, stigma and disclosure in workplace for pwE, general knowledge and attitudes about epilepsy for HEI. We translated surveys from English in each partner language (Italian, French, Deutsch, and Bulgarian) and shared them throughout e-mails and official websites.

Results: We collected 567 answers from PwE (183 from Italy, 38 from Ireland, 123 from France, 25 from Germany and 198 from Bulgaria) and 291 from HEI (100 from Italy, 14 from Ireland, 67 from France, 10 from Germany and 100 from Bulgaria). For pwE unemployment rates were 7,9% in Italy, 6,7% in Ireland, 8,5% in France, 15% in Germany, 9% in Bulgaria; while people employed full time were 42,9% in Italy, 53% in Ireland, 31,7% in France, 40% in Germany, 47,9% in Bulgaria. As for disclosure, in Italy 24,2% of pwE did not disclose their condition at work; in Ireland 17,9%; in France 21%; in Germany 15% and in Bulgaria 48,5%. About the 70% of pwE in all countries thought that stigma impair finding and keeping a job. As regards HEI, most of respondents defined epilepsy as a neurological disorder, treatable in most cases, in all countries. They also thought that unemployment is more common among pwE. Although most respondents have seen a seizure in person, in some countries (Germany and Bulgaria), they did not know how to give medical aid to a person experiencing a seizure.

Discussion: In this study we illustrated unemployment rates in five European countries, and we proved that stigmatization and disclosure still stand as issues for pwE in workplaces. Complete knowledge of epilepsy and its consequences remains challenging for HEI.

Conclusion: Exploring pwE work conditions and HEI perspectives could help to spread a good culture of inclusion and fight marginalization of pwE in workplaces, allowing them to get the right job position and better quality of life.

## MANAGEMENT OF NON CONVULSIVE STATUS EPILEPTICUS: DATA FROM THE STATUS EPILEPTICUS PROJECT IN EMILIA-ROMAGNA (STEPPER)

N. Orlandi[1], G. Giovannini[1], L. Di Vito[2], P. Tinuper[2], R. Michelucci[2], F. Bisulli[2], L. Vignatelli[2], S. Meletti[1]

[1]Neurology Department, Baggiovara Civil Hospital, AOU Modena (Modena); [2]IRCCS Istituto delle Scienze Neurologiche di Bologna, Unit of Neurology, Bellaria Hospital (Bologna)

Objective: To evaluate the incidence, clinical features and outcomes of Non Convulsive Status Epilepticus (NCSE) in Emilia-Romagna.

Materials: Prospective multicentric observational study of adults patients with NCSE. Data collection occurred from October 2019 to October 2021 in 17 Italian neurology units.

Methods: The diagnosis and classification of NCSE were performed according to the 2015 ILAE proposal. The information collected for every NCSE included: demographic variables, site and date of SE observation and onset, etiological and semeiological classification of SE, duration of SE before treatment, ASMs and any other therapies used to treat SE, SE resolution and type of treatment response, functional outcome and mortality either at hospital discharge and at 30 days from SE onset. Categorial variables were analysed with X2 test, whereas parametric or non-parametric tests were used to analyse continuous variables, as appropriate.

Results: 285 NCSE episodes were included (64% female; mean age: 71.6 ± 14.9 y/o), 157 of whom occurred outside the hospital setting. Cerebrovascular diseases (80/285; 28%), brain tumors (25/285; 9%) and anoxic brain injury (21/285; 7%) were the most frequent causes of NCSE. Median times from NCSE onset to EEG execution and treatment initiation were 11.1 and 10.3 hours, respectively. Comparing NCSE with in-hospital and out-of-hospital onset, both times were significantly more delayed in the latter group (9.2 vs 11.8 hours [$p = 0.009$] and 9.1 vs 11 hours [$p = 0.041$]). Even if 47% of cases were refractory to first- and second-line agents, SE finally resolved in all but 15 cases. On the other hand, 30-day mortality rate was 24% and it significantly increased in case of in-hospital onset ($p=0.0001$), severe consciousness impairment ($p<0.0001$), acute symptomatic aetiologies ($p=0.01$) and SE refractoriness ($p=0.009$).

Discussion: Status Epilepticus (SE) is a neurologic emergency with high mortality and morbidity rates. As concerns epidemiology, clinical and demographic features of NCSE in Emilia-Romagna patients are consistent with the results of previous studies [1-2]. Diagnosis and treatment of NCSE frequently required several hours, leading to a delay in treatment initiation especially in case of out-of-hospital onset. However, NCSE aetiology and clinical features, were the main predictors of short-term outcome.

Conclusion: Our prospective multicentric study confirmed that the diagnosis and treatment of NCSE are challeging with extremely prolonged time-to-evaluation and treatments times. NCSE aetiology and clinical features, as well as treatment refractoriness, are confirmed to be strong predictors of short-term outcome.

## EFFICACY AND TOLERABILITY OF PERAMPANEL IN ADULT PATIENTS WITH DRUG-RESISTANT EPILEPSY AND SEVERE INTELLECTUAL DISABILITY

A. Pagano, F. Placidi, A. Castelli, G. Di Mauro, C. Ferrazzoli, G. M. D'Amico, C. Liguori, N. B. Mercuri, F. Izzi

Epilepsy Center, Tor Vergata Hospital, Department of Systems Medicine, University of Rome Tor Vergata (Roma)

Rationale and Objectives: To evaluate the efficacy and safety of Perampanel (PER) in add-on in adult patients with drug-resistant epilepsy and severe intellectual disability. Irritability and other psychiatrics symptoms are counted among the common adverse effects of this drug, and patients with intellectual disabilities are at higher risk of developing such behavioural disorders.

Methods: Retrospective analysis of patients with severe intellectual disability treated with PER at the Epilepsy Center of Policlinico Tor Vergata in Rome from 2018 to 2022.

Results: 14 patients (9 males and 5 females, with a mean age of 28.64 years (range 19-58) and mean age at epilepsy onset of 7±5.9 years), including 5 with severe autism, 2 with genetic mutations, and 5 with a history of perinatal distress. All patients with drug-resistant epilepsy (4 generalized, 3 focal with structural etiology, 6 focal with unknown etiology) with mean number of drugs previously taken 2.8±1.42. PER in add-on, at mean dosage of 4.85±2.32 mg/day, induced a significant reduction in monthly seizure frequency (from 7.46±15.45 vs. 0.8±2, $p< 0.05$) with 92.8 % responders and 78 % seizure free patients. Mean follow-up of 23.14±19 months with only one case of discontinuation. The caregiver was administered the CGIC (Clinical Global Improvement or Change) (2), showing global clinical improvement after therapy with PER in 12 out of 14 patients. Behavioral disturbances evident at baseline in 5 of 14 patients, remained unchanged or improved in 4 of 5 cases. The occurrence of irritability and/or aggressiveness was not observed in the remaining 9 patients.

Conclusions: PER, even at low doses, shows long-term efficacy and safety in a particular and fragile population at high risk for psychiatric comorbidities.

## THE ROLE OF MACHINE LEARNING IN PREDICTING SEIZURE RECURRENCE AFTER A DE NOVO STATUS EPILEPTICUS

F. Pasini[1], M. Quintana[2], M. Rodrigo[2], D. Campos[2], L. Abraira[2], E. Fonseca[2], M. Toledo[2], E. Santamarina[2]

[1]IRCCS San Gerardo dei Tintori, University of Milano-Bicocca (Monza); [2]Vall d'Hebron University Hospital, Universitat Autonoma de Barcelona (Barcellona-E)

Objectives: The incidence of seizure recurrence after Status Epilepticus (SE) in patients without a history of epilepsy (de novo SE) is unknown to date, so tools to predict it and guide clinicians' decisions are lacking [1]. Machine Learning (ML) is the artificial intelligence application providing systems the capability to learn from experience without being explicitly programmed. In this study, we explored the ability of ML models to predict seizure recurrence after a de novo SE.

Materials and Method: Consecutive SE patients aged ≥16 years without previous history of seizures admitted to Vall d'Hebron University Hospital (Barcelona, Spain) from 2011 to 2021 were reviewed. Different Machine Learning techniques (k-NN, Naïve Bayes, Artificial Neural Networks, Support Vector Machines, Decision Trees, Random Forests) and the classic Logistic Regression (LR) model were applied to develop one- and two-year predictive models of seizure recurrence. 70% of the total sample was randomly selected to train the models; the remaining 30% was used for validation. The area under receiver operating curves (AUROC) with 95% confidence interval (95%CI) were performed to assess their predictive capability.

Results: 268 patients were included, of which 73 (27.2%) and 88 (32.8%) had seizure recurrence within one and two years, respectively. Factors significantly associated with two-year seizure recurrence were progressive symptomatic SE etiology ($p<0.001$) and time from diagnosis to SE treatment >1.5 hours ($p=0.001$). Among ML techniques, all were superior to the LR model in predicting two-year seizure recurrence (overall accuracy >70%, compared to 67.2% in the LR model). K-NN (AUROC 0.801, 95%CI = 0.687–0.915), Support Vector Machines (AUROC 0.803, 95%CI = 0.693–0.914), Random Forests (AUROC 0.822 (95%CI = 0.709–0.935) algorithms proved the best predictive ability in the validation dataset, showing a better performance than the LR model (AUROC 0.738, 95%CI = 0.618–0.858). No ML technique was superior to LR in predicting one-year seizure recurrence.

Discussion and Conclusions: In our study, ML techniques were superior to the LR model in predicting two-year seizure recurrence after SE in adults without previous history of seizures.

Background and aims: Epilepsy represents the third most common neurological diagnosis in elderly patients after dementia and stroke. Management of epilepsy in elderly individuals represents a likely common situation in daily practice, due to the rapidly growing of this segment of population [1]. Perampanel (PER) is a third generation ASM, highly selective, noncompetitive α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptor antagonist. The aim of this study was to assess 12-month effectiveness and tolerability of adjunctive Perampanel (PER) in elderly patients (≥65 years of age) with focal or generalized epilepsies treated in a real-world setting.

Materials: This study was a subgroup analysis of elderly patients involved in a previous 12-months multicenter, retrospective, longitudinal study, including adult patients receiving PER as only add-on treatment (PEROC study) [2].

Methods: We evaluated seizure response (≥50% reduction of frequency), seizure-freedom, retention rate, incidence of adverse events (AEs) and rate of treatment discontinuation at 3, 6 and 12 months after PER introduction.

Results: The sample included 64 subjects (34 female, 53.1%; median age: 74.6 years), with focal (87.5%), generalized (10.9%) and undetermined (1.6%) epilepsy. Median daily doses of PER at 3, 6, and 12 months were 4, 6, and 8 mg, respectively. Only 27 patients reached the 12th month follow-up visit. At 12 months 18/27 (66.7%) patients had at least 50% reduction of seizure frequency, with a seizure freedom rate of 9/27 (33.3%). Retention rate was 80%, 84%, and 86% after 3, 6, and 12 months, respectively. The reasons of treatment withdrawal were insufficient efficacy in 3 (4.7%) patients and poor tolerability in 7 (10.9%) patients. AEs were reported by 27 (42.2%) patients, the most common being dizziness and irritability. One patient only had a serious AEs (suicidal ideation).

Discussion: All efficacy measures confirmed the usefulness of PER as single add-on treatment. The high retention rates and the low rate of serious AEs proved that the treatment with PER was effective and well tolerated in elderly patients.

Conclusions: In elderly patients with epilepsy, adjunctive PER may represent a suitable therapeutic option.

## DESCRIPTION AND PHENOTYPIC CHARACTERIZATION OF A CASE OF DRUG-RESISTANT EPILEPSY ASSOCIATED WITH A DE NOVO MUTATION OF THE MED13L GENE

G. Pastorelli[1], E. Fronzoni[1], O. Malanga[1], C. Tanzarella[1], M. Magliani[1], G. Giovannelli[2], L. Massacesi[2], R. Guerrini[3], F. Mari[3], D. Mei[3], E. Parrini[3], E. Rosati[2]

Meyer Children's Hospital, University of Florence (Firenze)

Introduction: MED13L haploinsufficiency syndrome is a rare condition caused by mutations in the MED13L gene, characterized by intellectual disability, language impairment, muscle hypotonia, facial dysmorphisms, and more rarely associated with heart defects and epilepsy. Epilepsy has been described in association with de novo missense variants and characterized by febrile seizures, late-onset infantile spasms, and Lennox-Gastaut syndrome.

Case presentation: We report the case of a 40-year-old patient followed for epilepsy and severe psychomotor delay. The epilepsy, started at the age of 3, is characterized by tonic, atonic, spasms, absences, and multi-daily generalized tonic-clonic seizures despite a complex polytherapy with Carbamazepine, Valproic Acid, Brivaracetam, Perampanel, and Clonazepam with numerous previous therapeutic failures. The EEG shows a disorganized background activity with superimposed and frequent polymorphic and multifocal epileptiform discharges and rapid and diffuse paroxysmal activity during sleep. Brain MRI has revealed a picture of mild atrophy. In addition to epilepsy, the patient presents dysmorphisms, psychomotor delay with severe intellectual disability and autistic traits, absence of language acquisition, muscle hypotonia and ligamentous laxity and dysphagia. Genetic analysis with WES has only recently revealed the presence of the 3482C>T variant in heterozygosity of the MED13L gene. The mediator complex subunit 13-like gene MED13L encodes for a subunit of a mediator that functions as a transcriptional coactivator for almost all RNA polymerase II-dependent genes. This is a mutation that has not yet been described and is not present in international databases, likely responsible for the patient's clinical picture.

Discussion and conclusion: The case underlines the importance of genetic investigation in epilepsy of unknown etiology, especially in patients affected by developmental encephalopathy. It also confirms the phenotypic variability in relation to the type of mutation of the MED13L gene and, in particular, that severe epilepsy is a manifestation related to missense mutations.

Introduction: Vagal nerve stimulation (VNS) represents a palliative surgical treatment for drug-resistant epilepsy (DRE), able to reduce frequency and severity of seizures, overall improving patients' quality of life. Aim of this study is to assess efficacy, safety, and tolerability of VNS on medium-long term follow-up in a cohort of patients affected by DRE.

Methods: Retrospective study on 74 patients underwent VNS surgery for DRE, recruited from four Epilepsy Centres in Nord-Est Italy, with a follow-up period up to 10 years. Data concerning epilepsy syndrome and etiology were collected from 59 patients, considering seizures frequency at baseline and during the follow up period for every patient. Furthermore, data concerning neurological and psychiatric comorbidities, settings of stimulation, side effects, and antiseizure medications at the moment of follow-up.

Results: This study shows the reduction of seizures frequency of 38.53 at 18 months, up to 62.56% at 120 months. Non-significant side effects were reported; in only 1 case, VNS was turned off due to continuous and severe side effects. Our study reports an equal efficacy of VNS in both focal and generalized onset seizure (67.3% vs 61.66% at 120 months). In our cohort, the median number of ASMs used remained constant during all through the follow-up period.

Conclusions: Our study demonstrates efficacy, safety and tolerability of VNS in a medium-long term follow-up, with a reduction of frequency above 50% of focal and generalized onset seizure at 10 years in patients affected by drug-resistant epilepsy.

## EPILEPSY IN 6P TRISOMY SYNDROME: A CASE REPORT AND REVIEW OF LITERATURE

F. Pinna[1], G. Farina[2], V. Floris[1], P. Solla[3], D. Corda[2]

[1]Department of Medical Sciences and Public Health, University of Cagliari (Cagliari); [2]Neurology Unit, AOU Sassari (Sassari); [3]Dept of Medicine, Surgery and Pharmacy, University of Sassari (Sassari)

Objective: Pure partial trisomy 6p is considered a clinically distinct syndrome and can be caused by tandem duplications, inverted duplications, a supernumerary marker chromosome, interchromosomal insertions, and unbalanced chromosome rearrangements. [1] The phenotype is heterogeneous depending on the gene contents of the duplicated region, mainly dosage sensitive genes can be involved. [2] Epilepsy or seizures have only been reported in a few cases of 6p trisomy [2]. We described epilepsy in a case of duplication of the proximal part of chromosome 6p and reviewed all cases of epilepsy in 6p duplication syndrome.

Materials and Methods: The patient is a 21-year-old female born by spontaneous vaginal delivery at the 40th week of unremarkable pregnancy. She is the second child of non-consanguineous parents. Clinical examination showed growth retardation, microcephaly and various anatomical dysmorphisms already described in other patients with the same genetic syndrome. She also had anal atresia and aortic valvular stenosis, pigmentary dystrophy of the retina. The patient developed epilepsy at the age of 14, seizures were characterized by version of the head to the right with impaired of awareness and a duration of a few minutes. Ictal EEG showed spikes and polispikes waves in left fronto-temporal region, interictal EEGs showed theta activity in the same region. MRI was normal. Now seizures occur once a month and she is treated with lacosamide, levetiracetam and clobazam.

Results: Conventional cytogenetic analysis (SNP-array) showed a duplication of the 6p region in the patient. The rearrangement was confirmed by FISH (Fluorescent in situ hybridization) showing a gain of 27.5 Mb from 6p12.1 to 6p22.1.

Discussion and Conclusions: Presence of epilepsy, although rare in patients with 6p duplication, may be linked to genes involved in brain function and synaptic transmission (GABBR1, BRD2 and GRM4) [3]. Evidence has been obtained for loci predisposing to juvenile myoclonic epilepsy on chromosomes 6p and linkage studies provided evidence for juvenile myoclonic epilepsy (JME)/idiopathic generalized epilepsy (IGE) susceptibility loci at 6p11-p12 and linkage to the HLA complex on chromosome 6p21.3 [3]. The fact that epilepsy is rare in patients with 6p trisomy could be to low life expectancy of some of the patients, who may have died before developing epilepsy. Identification of 6p duplication in a child should aware the physicians to the possibility of the patient to develop epilepsy.

## CHARACTERISATION OF ANTIEPILEPTIC DRUG EFFECTS ON THE EEG NEUROYNAMICS BY FRACTAL DIMENSION

C. Porcaro[1], S. Maatta[2], G. Pellegrino[3], C. Luisi[4], F. Dainese[1], B. Kassabian[1], L. Pellegrino[1], G. De Nardi[1], A. A. Grego[1], M. Corbetta[5], F. Ferreri[1]

Objectives: Many linear indices are used to improve the diagnosis and monitoring in epileptic patients, such as spectral power and individual alpha frequency peak. On the other hand, more needs to be explored in electroencephalography (EEG) neurodynamics by using nonlinear approaches [1]. Therefore, this work aims to monitor drug-responder epileptic patients using a nonlinear Fractal Dimension (FD) method [2,3]. We show that FD is more sensitive than linear based on spectral power methods.

Materials: Twenty-five drug-responder Temporal Lobe Epilepsy (TLE) were studied before (T1, named FR1) and after (T2, from 4 to 8 months, named FR2) the introduction of the anti-seizure medications (ASMs). FR1 and FR2 EEG results were compared against 25 age-matched healthy controls (HC).

Methods: EEG data were investigated from two different angles: (1) Frequency domain - spectral properties were investigated in δ, θ, α, β, and γ bands and the individual alpha frequency (IAF) peak, and (2) time-domain - fractal dimension (FD) was used as a signature of neurodynamics underlying nonlinear brain functions. Those features were compared between T1 and T2 among the three groups (FR1 vs Fr2 vs HC). Rm-ANOVA was performed to investigate the interaction effect GROUP (FR1, FR2 and HC) × BAND (δ, θ, α, β, γ). ANOVA was also applied to investigate the GROUP effect on HFD and IAF. Finally, Bayesian analysis was used to test sensitivity across the significant features extracted between FR1 and FR2.

Results: Post-hoc tests revealed that the δ band was different between FR1 and HC ($p<0.001$) and between FR2 and HC ($p<0.001$). θ band was different between FR1 and FR2 ($p=0.015$) and between FR1 and HC ($p=0.01$). IAF value was lower for the FR1 ($9.712 \pm 0.184$, $p < 0.048$) compared to the FR2 ($10.173 \pm 0.157$) and HC group ($10.188 \pm 0.107$). HFD value was lower for the FR1($1.639 \pm 0.013$, $p < 0.0158$) compared to the FR2 ($1.687 \pm 0.013$) and HC group ($1.685 \pm 0.008$). Bayes Factor (BF) among the three significant features discriminating between FR1 and FR2 showed values as follows FD-BF: 973.069, IAF-BF: 4.220 and θ-BF: 4.994.

Discussion: A comparison of BF showed that differences between FR1 and FR2 were 231 times more likely to be detected by FD than the IAF and 195 times by the θ band.

Conclusion: Our work suggests that FD could be used as a sensitive marker to discriminate between drug responder epileptic patients and help decrease misdiagnosis in clinical practice.

Aim: Lennox-Gastaut Syndrome (LGS) is a severe Developmental and Epileptic Encephalopathy (DEE) invariably leading to drug-resistant seizures and intellectual disability. It is caused by an heterogenous group of aetiologies, encompassing structural, genetic, and metabolic disorders3. Here we analyse the aetiological landscape and the age at aetiological diagnoses, and the electro-clinical features of a cohort of LGS adult patients, in order to optimise the clinical management.

Materials and methods: We recruited patients satisfying the diagnostic criteria for LGS3 afferring to our Adult Epilepsy Center in San Giovanni Rotondo. We collected electro-clinical, genetic, and neuroradiological data.

Results: We included twenty-two patients (F/M: 12/10), with a mean age of 25 years [range 15 – 50]. Six (27%) were diagnosed with genetic and/or genetic-structural disorders, in form of monogenic disorders (TSC1 variants), chromosomopathies (Trisomy 21, partial tetrasomy of 15q), and Xq28 microduplication. A primary structural abnormalities, was detected in 7 patients (32%). Aetiology is still undetermined in 9 of them. No metabolic aetiologies were identified. Genetic diagnosis was assessed after 16 years of age in 5 of them. Main electro-clinical features were frequent epileptiform abnormalieties with activation during NREM-sleep. Multiple seizure types were recorded (epileptic spasms, tonic, focal and tonic-clonic seizures).

Discussion: LGS is a DDE with high impact on Quality of Life of patients and caregivers. Management is often frustrating because of intractable seizures, cognitive impairment, and behavioral disorders. An eatiological definition is recommended, and the diagnostic work-up is usually performed in childhood, when the symptoms arise2,3. However, in a group of our patients, the aetiological diagnosis was achieved in adulthood despite the previous extensive diagnostic work-up. The recent advantages in neuroradiologic and genetic tests, along with their cost reduction, allow to expand the diagnostic possibilities with remarkable clinical impact.

Conclusions: Reinvestigation of adult patients with LGS could be useful in order to achieve a specific aetiologyical diagnosis. Although a precision therapeutical approach is only available for a few causes1, the identification of a specific aetiology allows a focused follow-up strategy, a complete diagnosis communication to the caregiver, and the possibility of a genetic/surgical consultation. Last but not least, the aetiological definition in adulthood could expand DEE natural history knowledge.

## NILOTINIB-RELATED POSTERIOR REVERSIBLE ENCEPHALOPATHY SYNDROME

R. Renna[1], M. Pagliuca[2], F. Pagliuca[3], V. Andreone[1]

[1]Uosc Neurology, Stroke Unit, AORN A. Cardarelli (Napoli);[2]Outpatient Clinic, Emicenter (Napoli); [3]Department of Neurology, University of Campania (Napoli)

Introduction: Posterior reversible encephalopathy syndrome (PRES) is a clinical entity characterized by acute neurological symptoms including headache, seizures, and visual disturbance, and by typical reversible lesions on brain magnetic resonance images (MRI). Tyrosine-kinase inhibitors (TKI) family includes sunitinib, sorafenib, erlotinib, gefitinib, lapatinib, dasatinib, and nilotinib. Nilotinib is a second-generation TKI that selectively inhibits autophosphorylation of BCR-ABL, thus inhibiting cellular proliferation of imatinib-sensitive and -resistant chronic myeloid leukemia (CML) cell lines. [1] It is used for the first-line treatment of newly diagnosed CML patients and the second-line treatment of most CML patients who are resistant or intolerant to prior therapy (included imatinib). Nilotinib common adverse reactions include headache, rash, fever, nausea, vomiting, increased levels of liver enzymes and bilirubin, upper respiratory infections, QTc prolongation. Long-term use of nilotinib shows some cardiovascular toxicity. We present a case of PRES in a patient with LCM treated with nilotinib.

Clinical case: We report a 67-year-old woman with CML. She had no previous history of systemic hypertension, renal dysfunction, or autoimmune disease. She was treated with nilotinib. She presented to the emergency department for acute confusional state, visual disturbances with blurred vision and epileptic seizures with focal onset and bilateral evolution. Her blood pressure was 125/80 mmHg on admission. Blood tests, including complete blood count, blood chemistry, and coagulation showed no abnormal findings, in particular renal function was in the normal range and urine analysis showed no proteinuria. Brain MRI revealed hyperintense signals in the bilateral parieto-occipital lobes on FLAIR. Under a diagnosis of PRES, she was treated with anti-seizure medication (levetiracetam 2500 mg/day) and low-dose anti-hypertensive drug (ramipril 5 mg/day for one week), with clinical benefit. Levetiracetam was gradually withdrawn and brain MRI and electroencephalogram controls showed no pathological findings, with resolution of prevoius documented abnormalities.

Conclusion: PRES may be caused by hypertension alone, but may also occur due to toxicity of immunosuppressive and chemotherapeutic drugs. The most common drugs are tacrolimus and cyclosporine. However, PRES has also been associated with sirlimus, methotrexate, interferon, rituximab, bevacizumab, sorafenib, sunitinib, fingolimod, and IVIG, and with chemotherapy drugs such as cisplatin, cyclophosphamide, cytarabine, doxorubicin, gemcitabine, and vincristine. [2,3] To our knowledge this is the first report of a case of nilotinib-related PRES, thus widening the drug-related causes of PRES, a clinical entity

due to different possible causes determining vasogenic edema in the subcortical white matter and cortex, predominantly in the bilateral parieto-occipital lobes.

## PERAMPANEL FOR THE TREATMENT OF PEOPLE WITH IDIOPATHIC GENERALIZED EPILEPSY IN CLINICAL PRACTICE

R. Renna[1], T. Alsaadi[2], H. Goji[3], T. Maehara[4], S. Takahashi[4], J. Jacobs[5], F. Gil-Lopez[6], R. McMurray[7], R. Sainz-Fuertes[7], V. Villanueva[8], E. Trinka[9]

[1]Neurological Clinic and Stroke Unit, "A. Cardarelli" Hospital (Napoli); [2]Department of Neurology, American Center for Psychiatry & Neurology (Abu Dhabi -AE); [3]Neuropsychiatric Department, Aichi Medical University (Aichi -J); [4]Department of Neurosurgery, Tokyo Medical and Dental University (Tokyo-J); [5]Alberta Children's Hospital (Calgary-CDN); [6]Epilepsy Unit, Department of Neurology, Hospital Universitari Sagrat Cor (Barcelona-E); [7]Eisai Europe Ltd (Hatfield-UK); [8]Refractory Epilepsy Unit, Hospital Universitario y Politecnico La Fe (Valencia-E); [9]Department of Neurology, Christian-Doppler University Hospital, Paracelsus Medical University, Centre for Cognitive Neuroscience (Salzburg-A)

Objective: The PERaMpanel pooled analysIs of effecTiveness and tolerability (PERMIT) study included approximately 5200 people with focal and generalized epilepsy who were treated with Perampanel (PER) in clinical practice. [1] The purpose of this study was to assess the real-world effectiveness and safety/tolerability of PER when used to treat people with idiopathic generalized epilepsy (IGE) included in PERMIT.

Methods: The multinational, retrospective, pooled analysis PERMIT explored the use of PER in people with focal and generalized epilepsy treated in clinical practice across 17 countries. This subgroup analysis included PERMIT participants with IGE. Timepoints for retention and effectiveness measurements were 3, 6, and 12 months (last observation carried forward, defined as 'last visit', was also applied to effectiveness). Effectiveness was evaluated by seizure type (total seizures, generalized tonic-clonic seizures [GTCS], myoclonic seizures, absence seizures) and included ≥50% responder rate and seizure freedom rate (no seizures since at least the previous visit). Safety/tolerability was evaluated by documenting the incidence of adverse events (AEs), including psychiatric AEs and those leading to treatment discontinuation.

Results: The Full Analysis Set included 544 people with IGE (51.9% women; mean age 33.3 years). At 3, 6 and 12 months, 92.4%, 85.5% and 77.3% of participants were retained on PER treatment, respectively. At the last visit, responder and seizure-freedom rates were, respectively, 74.2% and 54.6% (total seizures), 81.2% and 61.5% (GTCS), 85.7% and 66.0% (myoclonic seizures), and 90.5% and 81.0% (absence seizures). AEs occurred in 42.9% of patients and included irritability (9.6%), dizziness/vertigo (9.2%) and somnolence (6.3%). Treatment discontinuation due to AEs was 12.4% over 12 months.

Conclusion: This subgroup analysis of the PERMIT study demonstrated that PER was effective and generally well tolerated when used to treat people with IGE under real-world clinical practice conditions. Treatment with PER resulted in statistically significant reductions from baseline in the monthly frequencies of total seizures, GTCS, myoclonic seizures, days with myoclonic seizures, and absence seizures. At the last visit, rates of seizure freedom ranged from 54.6% for total seizures to 81.0% for absence seizures, and responder rates ranged from 74.2% for total seizures to 90.5% for absence seizures. PER effectiveness was also similar in the subgroups of different IGE syndromes. The most frequent AEs and AEs leading to discontinuation were consistent with PER's known safety profile. [2] These findings support data from clinical trials, providing further evidence of the potential use of PER as a broad-spectrum anti-seizure medication for the treatment of IGE.

## SUPER-REFRACTORY STATUS EPILEPTICUS IN A PATIENT WITH LAFORA DISEASE

R. Renna[1], M. Pezzella[2], M. Pagliuca[3], S. Barbato[1], P. Candelaresi[1], G. Servillo[1], F. Habetswallner[2], V. Andreone[1]

[1]Department of Neurology-Stroke Unit, A.O.R.N. A. Cardarelli (Napoli); [2]Department of Neurophysiopathology, A.O.R.N. A. Cardarelli (Napoli); [3]Emicenter (Napoli)

Rationale and Objectives: Lafora disease (LD) is a rare autosomal recessive glycogen metabolism disorder, characterized by the inclusion bodies (Lafora bodies), within the cytoplasm of the cells in heart, liver, muscle, and skin. It presents as a neurodegenerative disorder that causes impairment in the development of cerebral cortical neurons, progressive myoclonus epilepsy (PME), and progressive cognitive and motor impairment. We describe a case of LD that presented for super-refractory status epilepticus (SE), resolved with Perampanel (PER), a non-competitive antagonist of AMPA-receptors.

Methods: A 28-year-old woman, affected by LD treated with valproic acid (VPA) 1000 mg daily, levetiracetam (LEV) 1000 mg daily and Clonazepam 2 mg daily, presented to the Emergency Department for multiple tonic-clonic seizures occurring without recovery of consciousness between them, consisting with convulsive SE.

Results: The patient was treated with diazepam 10 mg, repeated after 10 minutes; due to SE persistence, a load of LEV 30 mg/kg i.v. was administered, without clinical benefit. Fifteen hours after SE onset, midazolam (MDZ) 0.3 mg/kg i.v. load, followed by infusion at 0.3 mg/kg/h, was administered as third line therapy. As SE persisted, 16 hours after the onset, patient was transferred to Intensive Care Unit (ICU) for sedation. A load of Propofol (PPF) 2 mg/kg, followed by infusion at 2 mg/kg/h, was administered. On discontinuation of PPF, after 48 hours, the incoming epileptic seizures reappeared. Patient was diagnosed with super-refractory SE and sedation with MDZ and PPF was continued. Subsequent attempts to suspend MDZ and PPF resulted in SE reappearance. Fifteen days after SE onset, with patient in coma induced with MDZ/PPF, 12 mg of PER oral suspension was loaded with progressive reduction of MDZ and PPF, in the absence of SE reappearance. After a month from the recovery in ICU the patient returned to the sub-intensive Neurology ward. She was discharged with

PER 8 mg, Clonazepam 3 mg, VPA 2400 mg, Brivaracetam 200 mg, Phenobarbital 100 mg daily. Seizure control was satisfactory until the last follow-up one year later.

Conclusions: Status epilepticus may have serious long-term consequences and is potentially fatal. Super-refractory SE is a SE that has continued or recurred despite 24-hours of general anesthesia and has a mortality rate of 30%-50%. Perampanel is not currently licensed for treatment of SE, but many evidence support that it might be a therapeutic option for established SE, refractory and super-refractory SE. Our case adds more evidence even in SE associated with PME.

## EEG CONNECTIVITY AS A THERAPEUTIC BIOMARKER IN DRUG-RESISTANT EPILEPSY: CORRELATION WITH CLINICAL OUTCOME AND CENOBAMATE THERAPY

L. Ricci[1], G. Assenza[1], C. Vico[1], F. Narducci[1], M. Boscarino[2], B. Sancetta[1], J. Lanzone[2], P. Menna[3], C. Liguori[4], N. Mercuri[4], V. Di Lazzaro[1]

[1]Neurophysiology and Neurobiology Research Unit, Department of Medicine and Surgery, University Campus Bio-Medico of Rome (Roma); [2]Department of Medicine and Surgery, Neurorehabilitation Unit, Istituti Clinici Scientifici Maugeri IRCCS (Milano); [3]Operative Research Unit of Clinical Pharmacology, University Campus Bio-Medico of Rome (Roma); [4]Sleep Medicine Centre, Neurology Unit, University Hospital of Rome Tor Vergata (Roma)

Objective: Epilepsy is a neural network disorder, and the use of quantitative EEG offers measures of cortical connectivity to study its dynamics. EEG connectivity demonstrated high sensitivity to the clinical outcome after a first anti-seizure medication and after surgery in people with epilepsy, suggesting its potential as a response biomarker [1-2]. The clinical usefulness of such a marker needs to be confirmed also in people with epilepsy who are already on treatment. Clinical trials on cenobamate (CNB) have reported excellent efficacy in drug-resistant people with epilepsy (DRE), offering an ideal molecule to test the role of EEG connectivity as a therapeutic biomarker in people with DRE.

Materials: We enrolled 18 DRE (8 females, 47±16-year-old) and twenty-five matched healthy controls (HC). Two DRE participants dropped out, leaving sixteen participants who underwent 19-channel EEG before (T0) and after 6 months (T1) of CNB therapy.

Methods: Power spectral density (PSD) and phase locking value (PLV) connectivity for delta, theta, alpha, beta and gamma frequency bands were calculated. Cognitive performance was evaluated by the Epitrack® test, and seizure frequency was collected.

Results: After CNB therapy, 11 out of 16 (69%) DRE participants were responders (>50% reduction in seizure frequency). PLV EEG connectivity modulation accurately predicted DRE responders (Accuracy 87%, AUC 94%, Sensitivity 91%, Specificity 80%). Reduction of PLV significantly correlated with seizure reduction in all frequency bands, except for alpha (p=0.39-0.004). None of the participants with epilepsy showed cognitive worsening after CNB therapy.

Discussion: EEG connectivity reduction induced by CNB accurately predicted the clinical outcome in DRE participants and corroborated its role as a response biomarker in people with epilepsy. Wider and urgent studies are needed to clinically validate EEG connectivity as a response biomarker in epilepsy.

Conclusion: Our study provides evidence supporting the use of EEG connectivity as a response biomarker in people with epilepsy, particularly in those with drug-resistant seizures. Cenobamate is an efficacious drug choice for DRE patients without impacting their cognitive performance.

## A CASE OF STROKE LIKE MIGRAINE ATTACKS AFTER RADIATION THERAPY SYNDROME (SMART)

A. Riva, N. Zannotti, F. Cancellieri, M. Cervigni, S. Malatini, M. Bartolini, M. Silvestrini, G. Viticchi

Neurological Clinic, Marche Polytechnic University (Ancona)

Introduction: Stroke like migraine attacks after radiation therapy (SMART) syndrome is one of delayed complications of brain radiation therapy. This is a rare condition that can occur till 35 years from radiotherapy. This is a diagnosis of exclusion, according to the criteria proposed by Black et al. SMART can manifest with a series of reversible signs and symptoms like confusion, seizures, headache, motor and sensory deficits, aphasia, visual-spatial deficits, migraine with or without aura not-responsive to therapies. Radiological additional criteria include the presence of transient gadolinium enhancement of the cerebral gyri in the gray matter in a previously radiated field. Some patients who experimented SMART were successfully treated with steroid therapy, but treatment recommendations actually are not well established.

Case report: We present the case of a 70 year-old man with migraine not-responsive to FANS from several days, that arrived to our emergency department with a left hemiparesis. The patient presented a right frontal lobe glioma in the 1986, treated with radical resection and then with of radiotherapy along two months. He assumed prophylactic therapy with levetiracetam. He declined hospitalization and began intravenous steroid therapy (dexamethasone 4 mg/die) at home. After four days he manifested first a focal seizure at the left arm, then bilateral seizures, for which he returned to the emergency department and was admitted to Neurological Clinic. Brain MRI revealed presence of gadolinium enhancement of the right fronto-parietal cortex, suggestive for blood-brain damage. We continued intravenous steroid therapy for another week and increased anti-seizures therapy with levetiracetam(3000 mg/die) and valproic acid(1500 mg/die). The patient showed complete resolution of the symptoms. A brain MRI repeated after three months showed resolution of the enhancement in the fronto-parietal region.

Discussion: According to clinical symptoms and radiological signs, we made a diagnosis of SMART syndrome in a patient with a history of brain irradiation. In this case he showed hemiparesis resolution, probably due to the steroid therapy, but in literature there are patients recovered without any therapy.

Conclusions: SMART is a rare but relevant complication of radiotherapy. It is important to know and recognize this syndrome, in order to understand the better treatment to reverse severe neurological symptoms.

## CANNABIDIOL IN THE DEVELOPMENTAL EPILEPTIC ENCEPHALOPATHIES: A POSSIBLE THERAPEUTIC STRATEGY FOR EPILEPSY AND COGNITIVE, BEHAVIORAL AND MOTOR SYMPTOMS. A CASE REPORT

M. Rubino, C. Cuccurullo, A. Catone, E. Nicolella, L. Bilo, A. Coppola

UOC Neurology and Epilepsy Center, AOU "Federico II" (Napoli)

Objective: Cannabidiol (CBD) in its 100% purified form, is approved for the treatment of epilepsy in Lennox-Gastaut and Dravet syndromes associated to Clobazam, and in Tuberous Sclerosis. Some recent evidence suggests Cannabidiol may be used in the treatment of seizures in other Developmental Epileptic Encephalopathies (DEEs). However, we still lack sufficient data about the use of CBD in the treatment of other clinical features of DEEs, and particularly in cognitive, behavioral and motor symptoms. In this case report, we are presenting a patient with DEE treated with CBD, and the global clinical benefit he experienced.

Case discussion: Our case is of a 14 yo boy, affected by a DEE tbd (Whole Exome Sequencing is undergoing). His clinical history started at two years six months old when he experienced a hemisomic clonic seizure. After, he started to manifest more-than-daily focal with secondary generalization drug-resistant seizures. Moreover, he had a regression in developmental psychomotor: he lost speech at the start of the epileptic features, and autonomous deambulation by age six. He was also diagnosed with Autism Spectrum Disorder, and also suffered from a severe sialorrhea resistant to botulinum toxin. He performed multiple MRIs by his third year of life, with signs of progressive left brain hemisphere atrophy. By the age of thirteen his seizures had a frequency of 7-18 per day, with EEG features of subcontinous diffuse epileptiform activity. We decided to add to his therapeutic regimen Cannabidiol, titrating up to 15 mg/kg/day, monitoring on his clinical response (frequency of seizures and their severity, quality of life) and performing EEG controls at two, six, nine and twelve months.

Results: Since the introduction of Cannabidiol, his epilepsy improved: daytime seizures gradually stopped, and his nighttime seizures became less severe and frequent (between 2 and 7 a day, lasting only few seconds). His EEG improved concordantly, with less continuous epileptiform activity restricting itself in right centro-temporal areas. His global functioning ameliorated too: He regained his ability to deambulate autonomously, and his social skills improved (more visual contact interactions, and more gesture and vocal communication). Finally, his botulinum-resistant sialorrhea disappeared.

Conclusion: The response of his epilepsy is in line with medical literature with a 60% reduction of his seizures. We though highlight the global significant benefit our patient had in his cognition and behavior, on sialorrhea disappearance and on deambulation recovery. Further studies will be needed to investigate effectiveness of CBD on these symptoms.

## USE OF FUNCTIONAL CONNECTIVITY DYNAMICS TO DIFFERENZIATE DRUG-RESISTANT AND NOT DRUG-RESISTENT PEOPLE WITH EPILEPSY

B.M. Sancetta[1,2], J. Lanzone[3], L. Ricci[1,2], M. Boscarino[1,3], F. Narducci[1,2], V. Di Lazzaro[1,2], M. Tombini[1,2], G. Assenza[1,2]

[1]University Campus Bio-Medico of Rome, Neurology, Neurophysiology and Neurobiology Research unit, Department of Medicine and Surgery (Roma); [2]Fondazione Policlinico Universitario Campus Bio-Medico, Neurology Unit, University Campus Bio-Medico of Rome, Department of Medicine and Surgery (Roma); [3]Istituti Clinici Scientifici Maugeri IRCCS, Neurorehabilitation Department of the Milano Institute (Milano)

Background: Recent studies evidenced that electroencephalogram (EEG) functional connectivity (FC) could become a promising tool for a better comprehension of neurophysiological changes induced by epilepsy. [1-2] The aim of this study was to explore temporal dynamics of FC in people with epilepsy (PwE) to identify possible measures able to identify drug-resistant epilepsy (DRE) condition.

Materials and Methods: We retrospectively collected resting-state 19-channel EEGs of 29 PwE affected by DRE and 31 without DRE (nDRE) who underwent two anti-seizure medications trials at the time of recording. EEGs were preprocessed, 180s were selected and Laplacian surface was applied to minimize volume conduction. Inter-site phase clustering (ISPC) was computed for each 200 ms epoch to visualize global connectivity changes in time domain. ISPC was calculated for delta (0-4 Hz), theta (5-7 Hz), alpha (8-12 Hz) and beta (13-30 Hz) frequency bands. Avalance analysis on waiting time (WT, time below threshold, i.e. median connectivity values) and life-time (LT, time above threshold) were computed to characterize the obtained connectivity series. Distribution of avalanches followed a power-low shape; thus, slopes and intercepts of best-fitting lines were compared between PwE with DRE and nDRE via permutation testing (iterations=10000). Significant results (after Bonferroni-Holmes correction) were imputed in a support vector machine (SVM) classification algorithm (radial basis function kernel) to test machine learning accuracy in predicting DRE/nDRE conditions. Accuracy was validated with leave-one-out cross-validation.

Results: LT slopes were lower in PwE with DRE compared to those with nDRE in all frequency bands, with a statistically significant difference in delta band (p-value=.008). LT intercepts in PwE with DRE were always lower compared to PwE with nDRE. WT slopes and intercept of delta band revealed to behave in a completely opposite way (p-value=0.02). SVM algorithm trained with LT and WT slopes was able to discriminate PwE with DRE from those with nDRE with an accuracy of 0.89.

Discussion: Avalance analysis condensate in a single relationship (the slope) the amount of time spent above threshold and the probability

linked to this occurrence. Thanks to this analysis, we demonstrated that PwE with DRE are more likely to exhibit high consecutive FC values during resting state, especially in low-frequency bands (well-known to be associated with epilepsy). [5] Moreover, these features were able to identify DRE condition with great accuracy when implemented in machine-learning algorithm.

Conclusions: We hypnotize that FC could become a promising diagnostic biomarker of DRE, even though further studies are required.

## SUBACUTE ENCEPHALOPATHY WITH SEIZURES IN ALCOHOLICS (SESA) SYNDROME: A CASE REPORT

G. Sansone, D. Fasolato, L. Pellegrino, N. Ravì, A. Cagnin

Department of Neuroscience, Neurology Unit, University Hospital of Padua (Padova)

Objectives: Alcohol abuse predisposes to alcohol-withdrawal seizures. Moreover, unusual cases of encephalopathy with generalized, focal motor seizures or non-convulsive status epilepticus have been designated as subacute encephalopathy with seizures in alcoholics (SESA) [1,2]. Here we present a case of SESA, describing clinical, neuroimaging and neurophysiological findings.

Case report: A 65-year old man with a history of alcohol abuse was found at home stuporous, dehydrated and in poor hygienic conditions; last time seen in health was 3 days earlier. In the ED, blood tests revealed undetectable ethanol levels and hypernatremia (163 mmol/L), gradually corrected with mild responsiveness improvement, although he remained confused, producing unintelligible speech. Brain CT scan was negative. During hospitalization, the patient developed fever, respiratory distress and progressive decline of vigilance and empirical ceftriaxone, ampicillin and acyclovir were started along with thiamine. Therefore, he was sedated, intubated and transferred to the ICU three days after the admission. Standard and microbiological CSF analyses were negative. The EEGs showed generalized slowing of the tracing (5-6Hz), with frequent isolated diffuse frontal-predominant sharp waves. One week later, the patient started presenting pseudo-rhythmic jerks of the upper limbs. The EEG showed an ictal-interictal continuum pattern with diffuse left-predominant sharp and slow waves. Levetiracetam 750mg x2/day and valproate 400 mg x3/day were started, with conversion of the EEG (day 10) to an anterior-predominant generalized periodic discharge pattern of 1-Hz triphasic slow waves, interrupted by diffuse theta activity after external stimulations. Valproate was then gradually suspended. On day 11, brain MRI showed confluent chronic vasculopathy (Fazekas 3) and three-minute acute cortical lesions in the right cingulate, left parietal and occipital cortex, with restricted diffusion. Sedation was thus interrupted, leaving the patient under low-dose remifentanil, yet he remained in a coma state until one month after the admission. He eventually became responsive to verbal stimuli and able to inconstantly perform simple tasks. The EEG at day 35 showed reappearance of 8-Hz dominant rhythm, with superimposed frequent bursts of polymorphic bilateral theta-delta central-temporal slow waves. Given the personal history of alcohol abuse, the initial lateralization of EEG abnormalities, the chronic and acute brain lesions at the MRI, in the absence of other plausible causes, we diagnosed a probable SESA.

Conclusions: SESA should be included in the differential diagnosis of encephalopathies with seizures in patients with alcohol abuse history. It is not always related to alcohol withdrawal and prosecution of antiseizure medications is necessary to avoid relapses.

## AMYLOID ANGIOPATHY RELATED INFLAMMATION AND PAROXISMAL EVENTS REFRACTORY TO ANTI-SEIZURE THERAPY: AMYLOID SPELLS OR SEIZURES?

C. Tanzarella[1], M. Magliani[1], G. Giovannelli[2], O. Malanga[1], E. Fronzoni[1], G. Pastorelli[1], V. Berti[3], G. Carlucci[1], L. Massacesi[1], E. Rosati[2]

[1]Department of Neurosciences Drugs and Child Health and Department of Neurology 2, Careggi University Hospital (Firenze); [2]SOD Neurology 2, Neuromusculoskeletal and Sense Organs Department, Careggi University Hospital (Firenze); [3]Department of Biomedical, Experimental and Clinical Sciences "Mario Serio", Nuclear Medicine Unit, Careggi University Hospital (Firenze)

Introduction: The accumulation of amyloid within the walls of intracerebral vessels can cause recurring and stereotyped transient focal neurological episodes (TFNE) with positive or negative symptoms, once defined as "amyloid spells". Although the etiopathogenesis is not yet clearly defined [1], TNFE are a differential diagnosis of epileptic seizures. We report the case of a 72 year-old patient who presented late-onset paroxysmal neurological episodes refractory to anti-seizure medications (ASMs), resulting in complex management and difficult interpretation.

Case Presentation: A 72-year-old woman was admitted for an episode of transient mental confusion and aphasia. In anamnesis, some similar transient episodes were present in the previous 2 years, associated with hemiparesis and left hemianopsia or visual hallucinations. For the suspected cerebrovascular origin, ASA was introduced, then associated with Clopidogrel. After following recurrences, an epileptic nature was hypothesized and Levetiracetam was started. In the subacute phase, EEGs demonstrated slow wave abnormalities, which were attributed to post-ictal dysfunction. Hematochemical and cerebro-spinal fluid examinations were negative for inflammatory (including markers of autoimmunity) and infective signs and contrast-enhanced brain MRI shows cortical-subcortical signal alterations in the FLAIR sequences, located in the parieto-occipital region, prevalent on the right where was associated with edema, and right temporo-basal area, in the presence of leukoaraiosis and rare cortical microbleeds. The EEG and neuroradiological findings improved only after high-dose ev corticosteroid therapy and worsened during the recurring episodes. Cognitive functions also temporarily improved, but showed a progressive decline over the two years observation (MoCa test from 25/30 to 21/30). Given the neuroradiological findings and the response to steroids, a "Cerebral amyloid angiopathy-related inflammation" (CAARI) [2] was hypothesized. The cerebral amy-Pet confirms the presence of a widespread accumulation of beta-amyloid [3]. A low-dose corticosteroid therapy was begun and the patient is currently free from paroxysmal episodes for about a year.

Conclusions: The differential diagnosis of transient neurological events like that one reported is challenging, including TIA, amyloid spells, or epileptic seizures in the course of CAARI. This case underlines the importance of considering the presence of amyloid angiopathy

when suspecting late-onset epileptic seizures, resistant to ASMs, especially if in conjunction with cognitive deterioration, in order to establish the most appropriate therapy.

## SLEEP QUALITY AND COGNITIVE IMPAIRMENT IN IDIOPATHIC GENERALIZED EPILEPSY

V. Todaro, S. D'Urso, A. Battiato, R. Sgroi, A. Luca, C. D'Agate, M. Proietto, D. Fatuzzo, L. Giuliano, M. Zappia

Neurology Unit, Department of Medical, Surgical Sciences and Advanced Technologies "GF Ingrassia", University of Catania (Catania)

Introduction: The link between sleep and epilepsy is complex and influenced by different factors. A recent meta-analysis about sleep quality in patients with Idiopathic Generalized Epilepsy (IGE) has shown a reduction in quality of sleep efficiency (SE), total sleep time (TST), proportion of N2 stage and prolonged REM onset latency. Moreover, different studies have demonstrated that patients with IGE present impairment in multiple cognitive domains. The objective of our study was to assess the presence of a possible association between quality of sleep and cognitive performances in patients with IGE.

Materials and methods: We enrolled patients with IGE at the Epilepsy center of the Neurology clinic of Policlinico G. Rodolico in Catania. All patients underwent an overnight polysomnography. Patients with a complain of sleep disorders have been excluded. Sleep macrostructure has been evaluated. In particular, TST, sleep latency (SL), SE, wake after sleep onset (WASO) and percentages of N1, N2, N3 and Rapid Eye Movements (REM) sleep have been calculated. Moreover, patients underwent a neuropsycological assessment including global functioning (Mini Mental State Evaluation - MMSE), memory (Rey Auditory Verbal Learning test), attention (Stroop test), executive functions (F-A-S, Frontal Assessment Battery) and praxis (clock drawing test).

Results: Twenty-five IGE patients (mean age 28.8±13.5 years, 64% women) have been entrolled in the study. Mean age of disease onset was 13.7 years. Mean disease duration was 13.6 years. The majority of patients presented juvenile myoclonic epilepsy (n=10, 40%) or IGE with generalized tonic-clonic seizures only (n=10, 40%). Other diagnoses were epilepsy with eyelid myoclonia (n=4, 16%) and juvenile absence epilepsy (n=1, 4%). Four patients (16%) had a positive family history for epilepsy. At the time of the evaluation, about a half of patients (n=12, 48%) were drug naïve. A significant association has been found between lower scores in F-A-S and a higher WASO (p= 0.024).

Conclusions: The result of our study highlights that a worse quality of sleep is associated to a longer WASO in patients with IGE. An appropriate management of sleep issues could lead to better cognitive outcomes in this population.

## RESILIENCE AND PSYCHOSOCIAL FACTORS IN ADULTS WITH EPILEPSY: A LONGITUDINAL STUDY

M. Tombini[1], F. Narducci[1], L. Ricci[1], B. Sancetta[1], L. Quintiliani[2], M. Boscarino[3], J. Lanzone[3], M. Straffi[1], V. Di Lazzaro[1], G. Assenza[1]

[1]Research Unit of Neurology, Department of Medicine and Surgery, Campus Bio-Medico University (Roma); [2]Clinical Psychological, Fondazione Policlinico Campus Bio-Medico (Roma); [3]Neurorehabilitation, IRCCS Fondazione Salvatore Maugeri (Milano)

Objectives: Resilience is defined as 'a dynamic process that includes a positive adaptation in the context of significant adversity'. The aim of our study was to measure the resilience, through a dedicated scale, in a group of people with epilepsy (PWE) and to prospectively evaluate its impact on psychosocial factors, in particular the presence of feelings of stigmatization.

Material and Methods: We consecutively enrolled 78 adult PWE (52 F; mean age 42,61 ± 16,11 y). 46 were seizure free (SF, 59%) and 32 were not-seizure free (NSF, 41%). All subjects completed at baseline (T0) the Resilience Scale (RS-14) [1] and questionnaires for the assessment of depressive symptoms, anxiety and quality of life: respectively, Beck Depression Inventory-II (BD-II), Generalized Anxiety Disorder-7 (GAD-7) and QOLIE-31 (Q31). The patients were prospectively followed up and re-evaluated after 6-12 months (T1); at follow up they also completed the Stigma Scale of Epilepsy (SSE) for assessment of stigma associated with epilepsy. Therefore, we correlated RS-14 values with all psychosocial aspects at both times, in particular feelings of stigmatization.

Results: The results showed for the RS-14 a significant direct correlation with the Q31 ($p < 0.001$) at baseline (T0) and inverse with the depressive and anxiety symptoms, as evaluated with BDI-II ($p < 0.001$) and GAD-7 ($p < 0.001$) at both times (T0 and T1). Finally, for the first time, a significant inverse correlation was evidenced between RS-14 at baseline and the levels of stigmatization, assessed with SSE at follow up (p=.005). No correlation was observed between resilience/stigma and seizure frequency at both times (T0 and T1) as well as changes of seizure rate or clinical outcome. Finally, against a significant reduction in the total number of seizures (p=.035) at follow up (T1), we didn't observe significant changes in depressive and anxious symptoms.

Conclusions: Our study showed that in PWE depressive symptoms, anxiety and quality of life were significantly associated with resilience, which was found to be able to prospectively influence the perception of stigma related to epilepsy more than seizures. Finally, the longitudinal evaluation showed that depressive and anxious symptoms were also not affected by seizure frequency, although it improved at follow-up.

## A CASE REPORT EXTENDING THE PHENOTYPIC SPECTRUM OF VARS2-RELATED MITOCHONDRIAL ENCEPHALOPATHY

M. L. Usai[1], P. Chessa[1], V. Floris[1], S. Todesco[2], P. Solla[2], D. Corda[2]

[1]Department of Medical Sciences and Public Health, University of Cagliari (Cagliari); [2]Unit of Neurology, Department of Medical, Surgical and Experimental Sciences, University of Sassari (Sassari)

VARS2 gene encodes the mitochondrial valyl-tRNA synthetase, a mitochondrial aminoacyl-tRNA synthetase (mtARSs), key enzyme in the synthesis of mitochondrial respiratory chain proteins. Rare, pathogenetic variants of this gene have been associated with various forms of mitochondrial encephalopathies [1]. Specifically, VARS2 homozygous c.1100C > T (p.Thr367Ile) mutation has been so far described in eight patients, with variable clinical phenotype, mostly characterized by severe psychomotor development delay, hypotonia, microcephaly and seizures. [2] We describe two brothers, born from nonconsanguineous parents, affected by this rare mutation, with atypical clinical features, known to our unit for drug-resistant epilepsy in follow-up. Patient 1. Male, 38 years old. During childhood he was diagnosed with speech delay. At four years old an extrapyramidal syndrome with bradykinesia and rigidity was evident. Later emergence of cerebellar ataxia (6 years old), myoclonus and upward gaze deficit (8 years old). At 10 years seizures began, during sleep, characterized by head version to the left followed by generalized tonic-clonic seizures. In the following years he was often hospitalized for status epilepticus. The current clinical picture is characterized by bradikynesia, limbs rigidity (mainly of the lower limbs) and cognitive impairment with a partial control of seizures. Patient 2. Male, 45 years old. Development delay and ataxic gait were evident since childhood. At 9 years old emergence of tonic-clonic seizures. At 11 years old, evidence of parkinsonism, with dystonia of the upper limbs and myoclonus. In the next years his conditions aggravated progressively, and clinical presentation is now characterized by quadriplegia and spasticity with severe cognitive impairment and no control of seizures. Patient 1 underwent genetic analysis for inherited cerebellar ataxias and genes associated with dystonia which resulted negative. Both patients carry VARS2 homozygous c.1100C>T (p.Thr367Ile) mutation. In conclusion, since very few clinical data are available regarding this rare condition, with our report we might contribute to extend the phenotypic spectrum of this disorder including infantile-onset parkinsonism, which interestingly, has been related also to another mtARS, mitochondrial tryptophanyl-tRNA synthetase (WARS2) [3]. Moreover, it is noteworthy that out of ten patients with this mutation described so far worldwide, five are from North Sardinia.

## AUTOIMMUNE ENCEPHALITIS (AIE) WITH ANTI-AMPA-GLUR3 ANTIBODIES IN A PATIENT WITH OPSOCLONUS-MYOCLONUS SYNDROME (OPS): A CASE REPORT

G. Vietri, I. Petitta, G. Nardino, G. Greco, M. Goglia, F. Gruosso, E. Frezza, L. Boffa, F. Placidi, N. B. Mercuri, R. Massa

Unit of Neurology, Department of Systems Medicine, University of Tor Vergata (Roma)

Case presentation: The patient was a 67 years-old woman, suffering from hypertension, chronic cardiomyopathy with PMK implant and surgically treated thyroid cancer. The patient complained of asthenia and migraine, unresponsive to medications. Brain MRI showed mild chronic microvascular disease involving the basal ganglia bilaterally. After two weeks, she developed gait and cognitive impairment with episodic and fluctuating confusional state. As two months passed, the patient showed altered state of consciousness, frequent epileptic crisis, opsoclonus and myoclonus of the upper limbs, so she needed hospitalization.

Methods and results: On admission, clinical evaluation demonstrated axial rigidity, opsoclonus and bilateral myoclonus prevalently involving the upper limbs. After few days she was scarcely responsive to stimulation and showed severe psychomotor agitation. During hospitalization, routine blood tests were mostly normal, only showing slightly elevated liver enzymes. A CT scan of the brain showed no pathological signs; EEG showed frequent slow and paroxysmal intercritical anomalies on the bilateral frontal-central-temporal regions; CSF analysis showed mildly elevated proteins and 16 lymphocyes; virologic and intracellular autoimmune screening were negative. Due to the oncologic history of the patient, oncomarkers were tested on blood sample, resulting in a mild positivity for CA125 antigen. Prion protein and neurodegenerative markers were also negative. Suspecting an autoimmune encephalitis (AIE), screening for extracellular antigen autoantibodies was carried out, demonstrating positivity for anti-AMPA-GluR3 antibodies in both serum and CSF. The patient was treated with high dose corticosteroids and multiple antiepileptic drugs, with poor clinical response. A week later, she suffered from bilateral pneumonia and septic shock, leading her to death.

Discussion and conclusion: OPS in adults is a rare disorder with the clinical features of opsoclonus, myoclonus, ataxia, and behavioral and sleep disturbances. The pathophysiology is thought to be immunological and rarely it may occur in a setting of AIE. Antibodies directed against glutamate receptors are frequently correlated with AIE but, according to current literature, only few cases are reported associated with anti-AMPA-GluR3B antibodies [1-2]. Anti-AMPA-GluR3B antibodies are present in 25–30 % of patients with different types of epilepsy, but in vitro and in animal models they may cause neuroexcitotoxicity and cause brain damage, aggravate chemoconvulsant-induced seizures, and also induce behavioral/motor impairments [3]. In the present case, the clinical manifestations of opsoclonus-myoclonus in AIE, with high serum and CSF GluR3 antibodies suggest a possible pathogenetic correlation, in the absence of other diagnostic cues.

## HEADACHES

## ONE MONTH OF A VERY LOW-CALORIE KETOGENIC DIET CAN ALTER THE PROPAGATION OF IMPULSES ALONG THE SOMATOSENSORY PATHWAY IN MIGRAINEURS

C. Abagnale, G. Sebastianelli, F. Casillo, M. Serrao, C. Di Lorenzo, G. Coppola

Department of Medico-Surgical Sciences and Biotechnologies, Sapienza University of Rome, Polo Pontino-ICOT (Latina)

Introduction: A very low-calorie ketogenic diet (VLCKD), which stimulates fat metabolism and ketone production by severely limiting lipid and carbohydrate intake, is helpful as a migraine preventive

strategy in obese subjects. Uncertainty surrounds the primary processes causing the clinical response. In this study, we assessed the levels of thalamocortical and cortical activity in a sample of episodic migraine sufferers before and during VLCKD therapy.

Methods: After stimulating the median nerve at the wrist, we recorded somatosensory evoked cortical potentials (SSEPs) in a group of 18 MO patients between attacks. In order to analyze the two bursts of high frequency oscillations (HFOs) reflecting the thalamocortical (early HFO) and cortical (late HFO) activity of the somatosensory system before and after one month of VLCKD treatment, we applied a band-pass filter between 450 and 750 Hz to the SSEP signal. We determined the latency and amplitude of the negative oscillatory maximum and duration, frequency, and number of oscillations for each of the two bursts from the signal acquired.

Results: We saw an increase in the latency of the highest peak of both the early burst and the late burst of HFOs after 1 month of VLCKD ($p = 0.017$ and $p = 0.005$, respectively). No changes were seen in the other HFOs parameters.

Discussion: The results of this study demonstrate that a single month of VLCKD treatment can change how high-frequency impulses propagate along the thalamus-somatosensory cortex loop. It is unclear if ketogenesis has a direct impact on each hub of the somatosensory pathway or only has a cortical effect that may indirectly affect thalamocortical afferents.

## ERENUMAB TREATMENT IN A PATIENT WITH RAYNAUD PHENOMENON: A CASE REPORT OF AN UNEXPECTED AORTIC DISSECTION AFTER TWO YEARS OF TREATMENT

M. Alabiso, A. Bellotti, E. Cresta, G. Rinaldi, I. Corbelli, L. Parnetti, P. Sarchielli

Neurological Clinic, University of Perugia (Perugia)

Backgroud: Anti-CGRP monoclonal antibodies (mAbs) represent a new promising, effective and safe weapon in the treatment of patients with migraine resistant to conventional prophylactic therapies. CGRP, a potent vasodilator, plays a key role in migraine pathogenesis. CGRP deficiency is involved in Raynaud's phenomenon (RP), consisting of abnormal vasoconstriction of the fingers, and the use of anti-CGRP mAbs in these patients is now not recommended [1,2]. Recent concerns have been raised following postmarketing case reports of elevated blood pressure (BP) associated with the use of anti-CGRP mAbs and there are data supporting an increase in BP in patients receiving this treatment, thus being able to increase the risk of hypertensive crises, dissection phenomena and arteriosclerosis [3].

Case presentation: We present the case of a 59-year-old woman with chronic migraine, treated with several prophylactic therapies (amitriptyline, topiramate, flunarizine, propranol, botulinum toxin) and occipital analgesic blocks without efficacy. The patient was also affected by an anxiety-depressive disorder, systemic hypertension with good pressure control and Raynaud's phenomenon (in the absence of systemic autoimmune diseases). In February 2021, in relation to the presence of pharmacological overuse and high MIDAS values (110), prophylactic therapy with erenumab was introduced, with clear clinical benefit (from 15 attacks/month to 3 attacks/month) and no reported side effects. The patient continued this therapy for two years (with a three-month suspension in between). After 23 total doses of erenumab 140 mg s.c., the patient was urgently hospitalized for abdominal pain and a syncopal episode with evidence on CT angiography of acute Stanford A - De Bakey II aortic dissection, extended to the right common carotid and subclavian arteries. The patient underwent surgery to replace the ascending aorta with a regular post-operative course and in the absence of residual focal neurological deficits. Four months later, the patient made a follow-up visit at our Headache Center; we suggested a brain MRI wich showed hypertensive encephalopathy and multiple ischemic lesions in the right emisphere. The treatment with anti CGRP mAbs was therefore discontinued.

Conclusion: This case report suggests that there may be a potential correlation between RP, the use of anti-CGRP mAbs and acute vascular events such as arterial dissection. Future clinical studies in an adequate sample of patients with RP and an history of hypertension may confirm this relationship suggesting a great caution when prescribing CGRP antagonists to these patients.

## CSF-HYPOTENSION RELATED HEADACHE: AN ATYPICAL PRESENTATION

G. Alfieri[1], A. Fasolino[1], A. Ranieri[1], V. Andreone[1], M. Muto[2]

[1]Neurology, AORN A. Cardarelli (Napoli); [2]Neuroradiology, AORN A. Cardarelli (Napoli)

Objective: To describe an atypical case of CSF hypotension headache.

Methods: A 46-year-old patient with a history of hypercholesterolemia currently not on therapy, dysmenorrhea treated with estroprogestogens for 2 months; no history of headache. In March 2023 acute onset, during the night, of intense headache at the top, thunderclap-type, which woke her up from sleep; nausea and vomiting, phono and photophobia were associated. For this reason, she had hospitalization and practiced CT + angioCT, which were negative; the neurological examination at the time of access showed no signs of ongoing neurological pathology. Discharged with indication to perform brain MRI with angio sequences, practiced 7 days after onset and negative.

Results: The patient came to our observation for diplopia due to VI cranial nerve palsy that began 15 days after the onset of headache. She performed in emergency CT and angio-CT, negative, and was admitted to the Neurology department. The MRI carried out at our department highlighted an apparently somewhat stretched aspect of the ventricles with subdural bihemispheric subdural seroematic effusion predominantly parieto-occipital, interhemispheric and tentorial, diffuse thin smooth dural thickening with enhancement after contrast; interpeduncular angle of about 37°, pontomesencephalic angle of about 43°, perioptic liquor film was not clearly demonstrable; all these findings oriented, at least in the first instance for phenomena related to CSF hypotension. She underwent a blood patch procedure, completed without complications. The clinical control at 30 days showed complete regression of the cephalalgic symptoms type thunderclap, diplopia in

the lateral gaze over 45 degrees laterally for VI deficiency; MRI control brain showed no signs of residual intracranial hypotension.

Discussion: The clinical presentation of the patient did not suggest, given the lack of anamnestic elements (trauma, intense physical exertion), the onset of a CSF hypotension headache. Other causes (e.g. cerebral venous thrombosis associated with estroprogestogen use) were more likely, with focal neurological deficits coexisting.

Conclusions: The symptoms of SIH resemble intracranial hypotension from other causes such as postdural puncture, postsurgical and post-traumatic CSF leaks, but in SIH the leak occurs spontaneously in the spine at a site which is unknown at the time of presentation. Our case presents clinical particularities related to onset and neurological symptoms not associated with evidence of risk factors for CSF hypotension.

## IMPACT OF ATOGEPANT ON MIGRAINE DAY REDUCTION, RESPONDER RATE, AND PATIENT-REPORTED OUTCOMES IN PARTICIPANTS WITH CHRONIC MIGRAINE AND MODERATE TO SEVERE SYMPTOMS OF DEPRESSION AS MEASURED BY PATIENT HEALTH QUESTIONNAIRE-9

S. Ashina[1], P. Gandhi[2], B. Dabruzzo[2], Y. Liu[3], M. Seminerio[3], J. Stokes[2], D. Cazzorla[4], E. Seng[5], D. C. Buse[5], M. F. Peres[6], R. B. Lipton[5], P. Pozo-Rosich[7]

[1]Department of Anesthesia, Harvard Medical School (Boston-USA); [2]AbbVie (Madison-USA); [3]AbbVie (North Chicago-USA); [4]AbbVie, University of Tor Vergata (Roma); [5]Department of Neurology, Albert Einstein College of Medicine (New York-USA); [6]Institute of Psychiatry, University of Sao Paulo (Sao Paulo-BR); [7]Headache Unit, Neurology Department, Vall d'Hebron Hospital and Institute of Research (Barcelona-E)

Objectives: Atogepant is an oral CGRP receptor antagonist approved in US for preventive treatment of adult episodic migraine, with demonstrated efficacy also for chronic migraine (CM). Depression is common in people with migraine and predicts increases in headache-related disability and poor health-related quality of life. Using data from the PROGRESS CM trial, this analysis evaluated atogepant effect in CM participants with baseline moderate to severe depressive symptoms.

Materials: In a phase 3, 12-week, double-blind controlled trial, CM participants were randomized to atogepant 30 mg twice daily (BID), 60 mg once daily (QD) or placebo.

Method: Post-hoc analysis evaluated the impact of atogepant on change in monthly migraine days (MMDs), ≥50% and ≥75% responder rates, change in MSQ v2.1 domain scores, and PGIC in CM participants with moderate to severe depression symptomatology (PHQ-9 cut-off score of ≥10). For endpoint change from baseline in MMDs and each MSQ v2.1 domain score, comparison between treatment groups were analyzed using a restricted maximum likelihood-based mixed model for repeated measures. Logistic regression models were used to analyze PGIC responder at week 12 and ≥ 50% or 75% responder rates across 12-week double-blind treatment period. ANCOVA model was used to analyze change from baseline in PHQ-9 score at week 12.

Results: 109 (42.6%) in the atogepant 60 mg QD arm and 89 (36.2%) in the placebo arm were CM participants with moderate to severe depression symptoms at baseline. A greater proportion of CM participants with moderate to severe depression on atogepant 60 mg QD, compared to placebo: had greater reduction in migraine days over the 12-week treatment period, least squares mean differences (LSMDs): −3.04 (95% CI: −4.78, −1.29; p=0·0007); achieved ≥50% (OR = 3.7 [95% CI: 1.86, 7.37; p=0.0002]) and ≥75% reductions (OR = 13.64 [95% CI: 1.75, 106.2; p=0.01]) in MMDs; had greater improvement in the MSQ v2.1 domain scores at week 4 and the effect was maintained through week 12; reported much better or very much better on the PGIC at week 12; had greater reduction in PHQ-9 scores at week 12.

Discussion: In CM participants with moderate to severe symptoms of depression, atogepant 60 mg QD demonstrated a greater treatment benefit over placebo in MMD reduction, ≥50% or ≥75% responder rates, MSQ v2.1 domain scores, and PGIC.

Conclusions: In CM participants with moderate to severe symptoms of depression, atogepant demonstrated a greater treatment benefit compared to placebo.

Mater Domini (Catanzaro); [16]Headache Center, ASST Santi Paolo Carlo (Milano)

Objective: Responders (>50% response rate at 12 weeks) to monoclonal antibodies (mAbs) targeting the calcitonin gene-related peptide (CGRP) in migraine are roughly 60%. Notably, half of non-responders at 12 weeks do indeed respond 24 weeks, being considered late-responders. We assessed frequency and characteristics of migraine patients responding to anti-CGRP mAbs only >24 weeks (ultra-late responders).

Materials and Methods: In this multicenter (n=16), prospective, cohort, real-life study, we enrolled all consecutive patients affected by high-frequency episodic migraine (HFEM: >8 days/month) or chronic migraine (CM) with >3 therapeutic failures, treated with any anti-CGRP mAbs for >48 weeks. Patients were interviewed face-to-face using a semi-structured, shared, web-based questionnaire exploring sociodemographic and clinical characteristics. We defined ultra-late responders those patients achieving a >50% response only >24 weeks. Patients detailed monthly migraine days (MMD) during a 28-day run-in period and throughout the entire study period using a paper-pencil headache diary.

Results: 572 migraine patients (M/F=140/432; age=48.2±10.6; HFEM/CM=154/418;) completed >48 weeks of treatment with anti-CGRP mAbs (erenumab 527 pts; fremanezumab 40 pts; galcanezumab 5 pts). Responders were 60.5% (346/572), late responders 15% (86/572) and ultra-late responders 15.7% (90/572). Among ultra-late responders, 46.7% (42/90) responded at all time intervals following week 24 (weeks 28, 32, 36, 40, 44, 48), whereas 53.3% (48/90) only at some of them (fluctuating ultra-late responders). Only 8.7% patients (50/572) did not respond at any time interval <48 weeks. Differences between ultra-late responders and responders included higher BMI (23.8±4.2 vs 23.0±3.1; p=0.033), less common unilateral pain (46.7% vs 62.3%; p=0.010), longer medication overuse duration (78.4±110.7 vs 35.9±81.7 months; p<0.001), dopaminergic symptoms (78.9% vs 61.3%; p=0.003), psychiatric comorbidities (44.4% vs 30.1%; p=0.014), Numeric Rating Scale (7.3±1.3 vs 7.7±1.3; p=0.017) and HIT-6 scores (63.7±11.6 vs 66.9±7.7; p=0.002).

Discussion and Conclusions: One-sixth (15.7%) of migraine patients treated with antiCGPR mAbs are ultra-late responders (>50% response >24 weeks). Patients refractory to long-term treatment with antiCGRP mAbs are exceedingly rare (8.7%).

## RIPETITIVE TREATMENTS WITH ANTI-CGRP MONOCLONAL ANTIBODIES COULD MODIFY MIGRAINE COURSE: A MULTICENTER, PROSPECTIVE, OBSERVATIONAL STUDY

C. Aurilia[1], G. Egeo[1], S. Proietti[2], P. Torelli[3], S. Cevoli[4], A. Carnevale[5], V. Favoni[4], B. Orlando[1], G. Fiorentini[1], S. Bonassi[2], P. Barbanti[1]

[1]Headache and Pain Unit, IRCCS San Raffaele (Roma); [2]Clinical and Molecular Epidemiology, IRCCS San Raffaele (Roma); [3]Unit of Neurology, Department of Medicine and Surgery, Headache Center, University of Parma (Parma); [4]IRCCS Istituto delle Scienze Neurologiche (Bologna); [5]Headache Center, Neurology Unit, San Filippo Neri Hospital (Roma)

Objective: A single 12-month treatment with anti CGRP monoclonal antibodies (anti CGRP mAbs) is not disease modyifing because migraine frequency increases soon after treatment discontinuation. We evaluated the effect of a second 12-month treatment cycle with anti-CGRP mAbs on the course of high-frequency episodic migraine (HFEM: >8 days/month) or chronic migraine (CM).

Materials and Methods: In this multicenter (n=5), prospective, real-life study we considered consecutive patients affected by HFEM or CM with >3 previous preventive medication failures, treated with two consecutive 12-month treatment cycles with anti-CGRP mAbs. Duration of treatment discontinuation was reduced from 3 to 1 month by the Italian Medicines Agency. Thus, we compared migraine changes at D2 (weeks 1-4 of the second treatment discontinuation) with D1 (weeks 1-4 of the first treatment cessation). Primary endpoint was the change in monthly migraine days (MMD) at D2 compared to D1. Secondary endpoints were variation in monthly headache days (MHD), monthly analgesic medications, Numerical Rating Scale (NRS) and HIT-6 scores at the same time intervals.

Results: Sixty-seven migraine patients (M/F: 19/48; mean age: 47.3±11.6; HFEM/CM: 11/56) completed two 12-month treatment cycles with anti-CGRP mAbs (erenumab: 58 pts; fremanezumab: 7 pts; galcanezumab: 2 pts;). Anti-CGRP mAbs treatment significantly reduced (p<0.001) MMD, MHD, monthly analgesic intake, NRS and HIT-6 score at 12 months (weeks 45-48: 5.6±2.2, 5.7±2.4, 5.7±4.2, 4.3±0.8, 52.6±8.8), D1(weeks 1-4: 12.6±4.1, 12.6±4.1, 12.0±4.1, 6.6±1.2, 60.8±6.7) and D2 (weeks 1-4: 10.1±3.9, 10.2±4.0, 9.7±4.2, 6.0±1.7, 57.6±7.6) compared to baseline (19.4±6.1, 20.3±6.3, 20.5±9.5, 7.9±0.9, 68.2±5.5). At D2, patients showed a significant greater reduction (p<0.001) in MMD (10.1± 3.9 vs 12.6±4.1), MHD (10.2±4.0 vs 12.6±4.1), monthly analgesic intake (9.7±4.2 vs 12.0±4.1), NRS score (6.0±1.7 vs 6.6±1.2) and HIT-6 score (57.6±7.6 vs 60.8±6.7) compared to D1.

Discussion: The second anti-CGRP mAbs 12-month treatment cycle significantly reduces MMD, MHD, monthly analgesic intake, NRS and HIT-6 score compared to the first 12-month treatment cycle, at least comparing the first months of treatment discontinuation. Anti-CGRP treatment effects are reduced during the posttreatment periods, but do not return to baseline.

Conclusions: Prolonged or repetitive treatments with anti-CGRP mAbs could modify migraine course.

## CEREBRAL VASOREACTIVITY CHANGES IN MIGRAINE PATIENTS AFTER THERAPY WITH ANTI-CGRP MABS

A. Bellotti[1], A. Vaiano[2], E. Cresta[2], G. Rinaldi[2], I. Corbelli[2], L. Parnetti[1], P. Sarchielli[2]

[1]Neurology Clinic, University of Perugia (Perugia); [2]Headache Center, Neurology Clinic, University of Perugia (Perugia)

Aim of the study: The present study was aimed to assess variations in cerebral blood flow and vasoreactivity in migraine patients before and during anti-CGRP monoclonal antibodies (mAbs) treatment.

Materials and methods: In the January 2022 -January 2023 period, 44 chronic or high-frequency episodic migraine patients (37 females, 7 males), eligible for anti-CGRP mAbs treatment, were recruited. They underwent transcranial Doppler (TD) examination before starting (T0), and at one month (T1), three months (T2), six months (T3) and twelve months (T4) of treatment. Scores of migraine related disability and headache impact scales (MIDAS, HIT-6) were assessed at each visit.

Results: The basal mean attack frequency/month was 17.8±7 days. The mean MIDAS and HIT-6 scores were 124.6±42 and 66.9±6.75, respectively. All patients completed the T2 treatment period, 7 ended one year of treatment. A significative reduction in headache frequency and MIDAS scores was detected in 95,4% of patients after three months of treatment. An increase in vasoreactivity index (VRI) of the middle cerebral artery (MCA) was found compared to baseline, with significant differences already at T2 (p=0.046).

Discussion: The VRI expresses the ability of cerebral blood vessels to dilate or constrict in response to metabolic stimuli and is considered an indirect indicator of endothelial dysfunction. The few studies on the effects of anti-GCRP ligand or receptor mAbs on cerebral hemodynamics reported that responders had increased mean velocity values in large intracranial arteries compared to baseline, unlike nonresponders [1]. Our study showed an increase in the MCA VRI during anti-CGRP-mAbs treatment, bringing the values of migraine patients more in line with those of non-migraine population. It is conceivable that intracranial vessel endothelium in migraineurs is in a condition of reduced vascular tone and potentially of maintained vasodilation due to the excessive stimulus exerted by CGRP. CGRP receptor or ligand blockade would counteract this effect on intracranial vascular tone, thus inducing an increase in the values of MCA VRI. If confirmed on a larger number of patients, this finding would suggest that the lower availability of CGRP can potentially limit its protective action against hypoxic and ischemic conditions [2,3].

Conclusions: Anti-CGRP-mAbs therapy may induce modifications in cerebral vasoreactivity consistently with the clinical benefit for the patients. TD is a rapid and non-invasive tool to verify these modifications before and during anti-CGRP-mAbs treatment. Based on our results a pivotal attention should be paid to migraine patients with cardiovascular risk factors or the elderly population.

Objectives: Previous studies have shown an association between migraine, cardiovascular disease, and cardiovascular risk factors; however, there is no evidence on the safety of oral calcitonin gene–related peptide receptor antagonists in the preventive treatment of chronic migraine in those with cardiovascular risk factors. The objective of this study is to evaluate the safety of atogepant in PROGRESS trial participants with chronic migraine (CM) and cardiovascular risk factors (CV-RFs).

Materials: A 12-week, international, randomized, double-blind, placebo-controlled phase 3 trial (PROGRESS; NCT03855137) enrolled participants (18-80 years) with ≥1-year CM (≥15 monthly headache days [MHDs] for 3 months before screening; ≥15 headache days [≥8 migraine days] during the 4-week screening period).

Method: Participants treated with atogepant 30mg twice-daily, 60mg daily, or placebo were stratified by 0, 1, or ≥2 baseline CV-RFs. CV-RFs included age (men: ≥45; women: ≥55), smoking, body mass index (BMI) ≥25kg/m2, hypertension, diabetes, dyslipidemia, sleep apnea, concomitant CVD or diabetes medicines, and history of stroke, myocardial infarction, transient ischemic attack, or peripheral arterial disease. CV treatment-emergent adverse events (TEAEs) were assessed.

Results: Of 773 participants, 518 (1 missing data) comprised the pooled atogepant group (0 CV-RFs: 110[21.2%]; 1 CV-RF: 146[28.2%]; ≥2 CV-RFs: 261[50.4%]) and 255 comprised the placebo group (0 CV-RFs: 47[18.4%]; 1 CV-RF: 92[36.1%]; ≥2 CV-RFs: 116[45.5%]). Among all participants, the majority had ≥2 CV-RFs compared to 0 or 1 CV-RFs. At baseline, participants with ≥2 CV-RFs had higher mean age, BMI, and MHDs versus those with 0 or 1 CV-RFs. Most common CV-RFs were dyslipidemia (47.6%), BMI ≥25kg/m2(43.1%), and hypertension (40.9%). CV-TEAEs occurred at low frequencies among participants with ≥2 CV-RFs (placebo: 3/116[2.6%]; pooled atogepant: 9/261[3.4%]), and none were serious. Treatment-related CV-TEAEs included palpitations (n=2) and increased blood pressure (n=1) in the pooled atogepant group (all 30mg twice-daily) and flushing (n=1) in the placebo group. Palpitations led to 1 discontinuation (assessed as not treatment-related) in the pooled atogepant group.

Discussion: This post hoc analysis demonstrates that CV-TEAEs occurred at low frequencies among atogepant-treated participants with CM and CV-RFs. All CV-TEAEs were nonserious, most were not treatment-related, and only 1 led to discontinuation.

Conclusion: This study provides evidence of the safety of an oral calcitonin gene–related peptide receptor antagonist among a cohort of participants with chronic migraine and cardiovascular risk factors.

## THE ROLE OF ANTI-INFLAMMATORY AGENTS AS SYMPTOMATIC THERAPY FOR PRIMARY HEADACHES: AN ANALYSIS OF UTILIZATION AND THERAPEUTIC EFFICACY

A. Bonura, A. Alesina, E. Sapio, M. Marcosano, N. Brunelli, C. Altamura, F. Vernieri

Neurology Department, Headache and Neurosonology Unit, Campus Bio-Medico University of Rome (Roma)

Purpose: This study aimed to gather data on the utilization of anti-inflammatory drugs as acute therapy for primary headaches: migraine with or without aura, and tension-type headache [1], at the Headache Center of the Fondazione Policlinico Campus Bio-Medico. The aim was to identify factors influencing drugs efficacy, the most commonly utilized molecules, and potential interactions with other migraine's treatments [2][3].

Methods: This is a retrospective study involved the medical records of 76 patients followed by Headache Center for one year

(2022) diagnosed with migraine and/or tension-type headache. The initial medical visit in the year 2022 (t0) and the subsequent visit after 3-6 months (t1) were evaluated. Collected data included headache frequency, MIDAS, anti-inflammatory drugs type and effectiveness (assessed on a scale of 0 to 2: ineffective, pain relief, pain free), frequency of use, use of triptans and prophylactic therapies.

Results: Population mean age was 43 years (± 13.4 years), predominantly females (90.7%). Chronic migraine was present in 52.6% of patients, and 7.8% experienced aura. Only 2 patients exhibited tension-type headache characteristics. The most frequently employed anti-inflammatory drugs were ketoprofen (40.8%) and ibuprofen (30.3%), followed by indomethacin-proclorperazine-caffein (21.1%), nimesulide (11.8%), paracetamol (10.5%), naproxen (9.2%), indomethacin (9.2%), diclofenac (6.6%), metamizole (6.6%). Prophylactic therapy was used by 18.4% of patients at t0 and by 71.1% at t1. Amitriptyline was the most frequently prescribed drug at both t0 (11.8%) and t1 (26.3%), while topiramate was the most commonly added therapy (t0=1.3%, t1=21.1%). Four patients received monoclonal antibody therapy (Erenumab, Galcanezumab, Fremanezumab) at t0, whereas 13 patients (17.3%) were under this therapy at t1. Statistical analysis indicated an overall reduction in the frequency of migraine attacks (t0=14.7 ± 8.5, t1=6.9 ± 5.8) and a decrease in anti-inflammatory drugs use (t0=13.2 ± 10.4, t1=5.1 ± 3.9). An increase in the efficacy of anti-inflammatory drugs and a reduction in their utilization were observed among patients in whom prophylactic therapy was added or modified between t0 and t1 ($\chi$2=7.706, p=0.006, 95% CI=1.5-21.9). The addition of amitriptyline to prophylactic therapy was significantly associated with increased drug efficacy ($\chi$2=6.792, 95% CI=1.3-12.2, p=0.018).

Conclusions: These preliminary findings suggest that the inclusion of prophylactic therapy, particularly amitriptyline, may enhance the efficacy of anti-inflammatory drugs in the treatment of primary headaches. These results are still preliminary, and the study is ongoing. Future investigations will further explore the effects of initiating monoclonal antibody therapy (infrequently utilized in this population) and factors influencing the efficacy of anti-inflammatory drugs in primary headaches.

## ANTI-CALCITONIN GENE-RELATED PEPTIDE MONOCLONAL ANTIBODIES FOR THE TREATMENT OF MIGRAINE WITH AURA: A PROSPECTIVE OBSERVATIONAL COHORT STUDY

S. Braca, C. Russo, A. Miele, A. Stornaiuolo, G. Cretella, R. De Simone

Department of Neuroscience, Reproductive Sciences and Odontostomatology, University of Naples "Federico II" (Napoli)

Objectives: About 15% of migraineurs experience aura symptoms. Aura is a reversible focal neurological phenomenon involving visual, sensory, speech and motor symptoms that usually precede migraine pain [1]. Monoclonal antibodies against calcitonin-related peptide (anti-CGRP mAbs) are effective in preventing chronic and episodic migraine, but little is known about their effectiveness on specifically preventing migraine with aura. This study aims at evaluating the effectiveness of anti-CGRP mAbs on migraine with aura, and aura symptoms.

Methods and Materials: This is a prospective observational cohort study, aiming at evaluating the efficacy of Erenumab, Fremanezumab or Galcanezumab for the treatment of migraine with aura. We enrolled 14 patients at the Headache Centre of University Federico II of Naples, with a history of multiple failed treatments with validated migraine preventatives. Duration of follow-up was 12 months. We assessed mean monthly days with aura symptoms, with or without subsequent headache, as well as mean monthly days with headache and mean monthly MIDAS score, by reviewing standardized paper patient headache diaries every three months.

Results: We observed a mean reduction of mean monthly days with aura symptoms of - 8.17 (- 5.76, - 10.57; CI 95%) and a mean reduction of mean monthly days with headache of - 15.92 (- 11.09, - 20.75; CI 95%) after 12-month treatment with anti-CGRP mAbs. No significant differences were found between Erenumab, Fremanezumab or Galcanezumab in terms of effectiveness.

Discussion: CGRP has been implicated in the activation of cortical spreading depression (CSD), a wave of neuronal hyperactivity followed by a period of depression that is associated with migraine aura [2]. CSD is thought to be a key mechanism underlying the development of aura. CGRP can increase neuronal excitability and promote the release of other neurotransmitters that may contribute to the initiation of CSD. Furthermore, CGRP has been found to enhance the susceptibility of brain tissue to CSD, possibly making it more likely to occur and propagate [3]. In this study we observed a significant reduction of mean monthly days with aura symptoms, further strengthening this hypothesis.

Conclusions: Our findings show that anti-CGRP mAbs are highly effective in migraine with aura, both in reducing mean monthly headache days and mean monthly days with aura symptoms.

## ASSESSING BARRIERS TO CARE IN EPISODIC AND CHRONIC MIGRAINE: RESULTS FROM THE CHRONIC MIGRAINE EPIDEMIOLOGY AND OUTCOMES (CAMEO) STUDY

D. C. Buse[1], C. E. Armand[1], L. Charleston IV[2], M. L. Reed[3], K. M. Fanning[3], D. Cazzorla[4], A. Manack Adams[5], R. B. Lipton[1]

[1]Department of Neurology, Albert Einstein College of Medicine (Bronx-USA); [2]Department of Neurology and Ophthalmology, University of Michigan (Ann Arbor-USA); [3]Vedanta Research (Chapel Hill-USA); [4]AbbVie, University of Tor Vergata (Roma); [5]AbbVie (Irvine-USA)

Objectives: Barriers to good outcomes in migraine include lack of appropriate medical consultation, failure to receive an accurate diagnosis, not being offered a regimen with acute and preventive pharmacologic treatments, and not avoiding acute medication overuse. This study aims to assess rates of traversing fundamental barriers to good medical outcomes in individuals with episodic (EM) and chronic migraine (CM) and evaluate the potential impact of sociodemographic barriers.

Materials: Respondents to the US Internet-based Chronic Migraine Epidemiology and Outcomes (CaMEO) Study who met modified International Classification of Headache Disorders, 3rd edition, criteria for migraine, had a Migraine Disability Assessment score of grade ≥2, and provided health insurance status were included.

Methods: Proportions of EM and CM respondents who successfully traversed each barrier were calculated and the effects of sociodemographic characteristics were examined.

Results: Among 16,789 respondents with migraine, 9184 (EM: 7930; CM: 1254) met eligibility criteria. Current headache consultation was reported by 27.6% (2187/7930) of EM and 40.8% (512/1254) of CM respondents. Among consulters, 75.7% (1655/2187) of the EM sample and 32.8% (168/512) of the CM sample were accurately diagnosed. Among diagnosed consulters, 59.9% (992/1655) of the EM group and 54.2% (91/168) of the CM group reported minimally appropriate acute and preventive pharmacologic treatment. Among diagnosed and treated consulters, 31.8% (315/992) of persons with EM and 74.7% (68/91) of those with CM met acute medication overuse criteria. Only 8.5% (677/7930) of EM and 1.8% (23/1254) of CM respondents traversed all 4 barriers. Higher income was associated with increased rates of traversing each barrier ($P<0.05$).

Discussion: These results show that less than 8% of people with migraine traverse all 4 treatment barriers, and sociodemographic factors were significantly associated with the likelihood of traversing these barriers.

Conclusions: Previous research evaluated barriers to care in either episodic migraine or chronic migraine. These data are the first to evaluate barriers to care in both types of migraine within the same study population and to assess the effects of sociodemographic characteristics. Efforts to improve care should focus on increasing consultation and diagnosis rates, improving delivery of guideline-based acute and preventive treatment, and avoidance of medication overuse.

## HEADACHE, BRAIN ABSCESS AND A RARE CAUSE OF WEAKENED IMMUNE SYSTEM: A CASE REPORT

A. Callea, S. Villa, J. Marotta, F. Mazzucchelli

Neurology, ASST Valle Olona (Gallarate-VA)

Background: Brain abscess is a frequent infectious disease of the central nervous system. Headache, fever, and fatigue are the most common initial manifestations. A weakened immune system is the main predisposing factor for brain abscess development.

Material and methods: A 37-year-old male with no prior history of headaches referred to hospital for the onset of severe right-sided headaches behind the eye. He had a two-week history of fatigue and slight fever but neurological examination was unremarkable.

Results: Routine blood analysis showed leukocytosis and an increase of C-reactive protein. Brain Magnetic Resonance Imaging (MRI) revealed the presence of a right frontal lobe circular space-occupying lesion with a ring wall contrast enhancement and large patches of edema. Brain frontal mass was drained completely under general anesthesia and microbiology testing of the specimen revealed Nocardia Farcinica. Treatment with trimethoprim-sulfamethoxazole and imipinem was started. HIV 1 and 2 antibody tests were negative and other common predisposing conditions causing brain abscess were ruled out [1]. However, patient past medical history included pulmonary alveolar proteinosis (PAP), a rare autoimmune syndrome caused by anti- GM-CSF (granulocyte–macrophage colony-stimulating factor) antibodies [2].

Discussion: Clinicians should always consider a diagnosis of brain abscess when dealing with a new onset headache associated with fever and fatigue. The great clinical challenge for the physician is recognizing the predisposing factors associated with brain abscess development.

Conclusion: PAP is a rare autoimmune syndrome characterized by high concentrations of anti-GM-CSF antibodies, decreasing its level and biological activity. The brain is highly susceptible from bacterial invasion during GM-CSF depletion. Regarding brain abscess predisposing factors, immunodeficiency secondary to anticytokine autoantibodies should always be reminded especially considering that patients with anti GM-CSF antibodies may have CNS involvement as their first clinical manifestation [3].

## "DIM LIGHT MELATONIN ONSET" AND CHRONOTYPE PROFILING IN PATIENTS WITH EPISODIC AND CHRONIC MIGRAINE

F. Cammarota, R. De Icco, S. Cerri, C. Ghezzi, G. Vaghi, E. Capriglia, M. Corrado, F. Bighiani, V. Grillo, R. Cremascoli, M. Terzaghi, R. Manni, D. Martinelli, M. Allena, E. Guaschino, N. Ghiotto, G. Sances, C. Tassorelli

Headache Science & Neurorehabilitation Center, IRCCS Mondino Foundation, Department of Brain and Behavioral Sciences, University of Pavia (Pavia)

Objectives: Chronic migraine with medication overuse headache (CM-MOH) represents one of the most disabling phenotypes across the migraine spectrum. Patients with CM-MOH suffer several comorbidities, including sleep disorders. The aim of this study is to better define the chronotype of migraine patients by means of subjective clinical scales and salivatory melatonin measurements.

Materials: We enrolled 40 CM-MOH patients, 18 episodic migraine (EM) patients and 32 healthy controls (HCs).

Methods: All subjects completed the Morningness–Eveningness Questionnaire (MEQ), the Pittsburgh Sleep Quality Index (PSQI) and a prospective sleep diary. They also underwent 5 saliva melatonin samplings (at hourly intervals with the first sample collected 3 hours before the subject's regular bedtime). We calculated the "Dim Light Melatonin Onset" (DLMO), namely the time of the day at which salivatory melatonin reaches 3 pg/ml, a well-known biological marker of circadian phase in humans.

Results: EM patients were younger when compared to CM-MOH patients and HCs. MEQ score was higher (suggesting a morning-oriented chronotype) in CM-MOH (59.6±7.7) when compared to EM (53.3±11.9, p=0.045) and HCs (51.0±10.1, p=0.001). According to MEQ, a subjective morningness profile was more prevalent in CM-MOH (56.8%) when compared to EM (33.3%) and HCs (17.2%) (p=0.001). Noteworthy, DLMO occurred earlier in CM-MOH (20:31±52 minutes) and in EM (20:28±0:49 minutes) when compared to HCs (21:17±63 minutes; p=0.05 and p=0.014, respectively). This was confirmed in a multinominal regression corrected for age and sex. DLMO did not differ between CM-MOH and EM groups (p=1.000).

According to DLMO, a biological morningness profile was more prevalent in CM-MOH (32.4%) and in EM (33.3%) when compared to HCs (7.4%) (p=0.019). Finally, according to the PSQI, sleep quality was more impaired in CM-MOH when compared to EM.

Discussion: Migraine patients showed a morning-oriented subjective and objective chronotype when compared to HCs. The chronotype based on DLMO revealed no discernible differences between CM-MOH and EM groups, although CM-MOH patients described themselves as more morning oriented.

Conclusions: Our results suggest that chronotype in migraine patients is primarily influenced by an inherited biology rather than disease severity. CM-MOH patients are more inclined towards morningness, indicating that behavioral and environmental factors still play a significant role.

## THE CRYPT OF NANA'

C. Carelli[1], M. Bernardo[2], M. Campese[3], A. Catalani[3], R. Candido[1], G. Monsurro'[1], A. Senese[1], C. Testa[3], N. Valenti[1], M. Guarino[1], G. Cristiano[1]

[1]Emergency Department, C.T.O. Hospital (Napoli); [2]Microbiology and Virology Unit, A.O.R.N. Ospedali dei Colli (Napoli); [3]University of Naples (Napoli)

Background: Cryptococcus neoformans is a leading cause of fungal meningitis in immunocompromised patients and it often occurs when the CD4+ T cell count is less than 100 cells/microL. Cryptococcosis, the infection caused by C. neoformans, is usually contracted through the inhalation of fungal spores, but the pulmonary infection could remain sub-clinical. Instead, its first manifestation among those with advanced immunosuppression is the meningitis (CM), or often the meningoencephalitis.

Case Report: Nana', a 43-year-old Georgian woman, came to our emergency department for worsening headache, ideomotor slowdown, seizures and visual reduction. In anamnesis, nothing noteworthy, despite some difficulties with the language barrier; vital parameters were altered with evidence of arterial hypertension, bradycardia and tachypnea with a saturation in room air equal to 92%. The objective examination revealed hindrance to neck movements without a real neck stiffness and an oropharyngeal candidiasis. At the ABG, there were no electrolyte alterations or increased lactates; blood tests revealed a neutrophilic leukocytosis with lymphopenia and a slightly increased CRP; the instrumental examinations, skull CT and chest x-ray, were negative. However, during the clinical observation, there was a worsening of her state of consciousness with new episodes of blood hypertension associated with a visual reduction and an absence episode. EEG and brain MRI with contrast agent were performed, for the suspect of a Posterior Reversible Encephalopathy Syndrome, but both were negative. After a new clinical evaluation, the doubt of an intracranial hypertension arose and an ultrasound exam of optic nerve was executed, highlighting its dilatation and confirming the suspect. Therefore, lumbar puncture was performed and tested the cerebrospinal fluid (CSF). The CSF pressure was elevated, with a clear look and evidence of hypoglycorrhachia. Blood culture and HIV test were required considering the presence of oropharyngeal candidiasis and lymphopenia. The tests were positive for Cryptococcal meningitis and HIV infection. She started the specific therapy, and a lumbar CSF drainage was placed. The patient was hospitalized at the infectious department, where a concomitant pneumocystosis and cytomegalovirus infection were observed, and discharged after three months.

Conclusion: CM has the strongest association with patients with HIV infection, but other immunocompromised patients including those with cancer, iatrogenic immunosuppression, autoimmune disease, chronic kidney disease and diabetes are at high risk. Therefore, we must pay attention on this disease considering that developed countries have observed an increase in non-HIV associated cases of CM compared to other immunosuppressed patients by virtue of access to antiretroviral therapy.

## SOMATOSENSORY EVOKED POTENTIALS IN TENSION-TYPE HEADACHE

F. Casillo, G. Sebastianelli, C. Abagnale, C. Di Lorenzo, M. Serrao, G. Coppola

Department of Medico-Surgical Sciences and Biotechnologies, Sapienza University of Rome (Latina)

Methods: A prospective cohort of 19 TTH patients (9 with episodic and 10 with chronic presentation) along with 20 healthy controls were recruited for this study. All participants underwent somatosensory evoked potential (SSEP) recordings, enabling the calculation of N20-P25 amplitude and its habituation across three sets of 100 responses. Additionally, by applying a band-pass filter (450-750 Hz) to the SSEP signal, we extracted two distinct bursts of high-frequency oscillations (early and late HFOs), reflecting thalamo-cortical and primary cortical activity, respectively.

Results: The latency and amplitude values of SSEPs, as well as the habituation patterns assessed between the initial two and three sets of 100 responses, demonstrated normal findings in TTH patients, including both the episodic and chronic subgroups. However, TTH patients, regardless of the episodic or chronic nature, exhibited a notable increase in cortical HFO amplitude burst ($p<0.001$) while maintaining normal thalamo-cortical activity.

Discussions: Considering that TTH is a painful pathological condition capable of eliciting sensory neurons to the extent of sensitizing them, it is unsurprising to observe that it indeed does so, as indicated by the findings of increased amplitude of cortical high-frequency oscillations (HFO). However, it is also noteworthy to highlight the presence of thalamocortical activity comparable to that observed in the control group, in contrast to what is typically observed in migraine [1]. Further investigations are warranted to establish the potential association between these observed manifestations and pericranial muscle tension, encompassing the activation or sensitization of nociceptive nerve endings through the release of chemical mediators.

Conclusions: Our findings indicate that TTH patients exhibit electrophysiological evidence of central sensitization and show no differences in their habituation pattern compared to controls.

## DISABILITY IN MIGRAINE: MULTICOUNTRY RESULTS FROM THE CAMEO-INTERNATIONAL STUDY

D. Cazzorla[1], Z. Katsarava[2], D. Buse[3], E. Leroux[4], M. Lanteri-Minet[5], F. Sakai[6], M. Matharu[7], K. Sommer[8], M. Seminerio[9], K. Fanning[10], R. Lipton[3]

[1]AbbVie, University of Tor Vergata (Roma); [2]Department of Neurology, Evangelical Hospital Unna (Unna-D); [3]Department of Neurology, Albert Einstein College of Medicine (Bronx-USA); [4]Brunswick Medical Center (Montreal-CND); [5]Pain Clinic, CHU Nice and Côte Azur University (Nice-F); [6]Saitama Neuropsychiatric Institute, Saitama International Headache Center (Chuo-ku-J); [7]Institute of Neurology, UCL Queen Square (London-UK); [8]AbbVie (Irvine-USA); [9]AbbVie (North Chicago-USA); [10]MIST Research (Wilmington-USA)

Objectives: Although individual studies evaluating headache burden are available from many countries, few studies have been conducted across multiple countries using the same methodology. This cross-sectional, multicountry analysis, aims to describe disability among individuals with migraine.

Materials: Chronic Migraine Epidemiology and Outcomes-International (CaMEO-I) was a cross-sectional, web-based survey conducted in 2021-2022 in Canada, France, Germany, Japan, the United Kingdom, and the United States. The American Migraine Study/American Migraine Prevalence and Prevention Study diagnostic questionnaire identified respondents with migraine based on modified International Classification of Headache Disorders, 3rdedition, criteria.

Methods: This analysis evaluated migraine burden using the Migraine-Specific Quality of Life Questionnaire (MSQ) and the Work Productivity and Activity Impairment Questionnaire (WPAI). The MSQ is a 14-item questionnaire that measures the effect of migraine on daily functioning across 3 domains, with higher scores corresponding to better quality of life. The WPAI evaluates the impact of migraine on work productivity and regular activities.

Results: This analysis included 14,492 respondents with migraine (~2400 from each country). Mean (SD) MSQ scores ranged from 57.7 (23.4) in Canada to 63.3 (21.1) in France for the role function restrictive domain, 67.6 (22.9) in Germany to 77.3 (22.7) in Japan for the role function preventive domain, and 63.9 (29.1) in the US to 69.2 (24.8) in France for the emotional function domain. Based on the WPAI, the mean (SD) percentage of work missed (absenteeism) ranged from 4.3% (16.2) in France to 9.0% (21.7) in Germany, percentage of work impaired (presenteeism) ranged from 31.2% (28.0) in France to 47.8% (28.6) in Japan, percentage of overall work impaired ranged from 33.5% (30.3) in France to 49.4% (29.4) in Japan, and percentage of activity impaired ranged from 39.3% (30.2) in France to 50.7% (28.4) in Japan.

Discussion: For every country surveyed, migraine is associated with substantial burden, including poor quality of life and work/activity impairment.

Conclusions: This international study demonstrated that migraine is associated with substantial disability, including poor quality of life, work/activity impairment, and losses in productivity across multiple countries. Further research is warranted to explore reasons for potential differences between countries in the prevalence of specific headache disability.

## SWITCHING FROM ONABOTULINUMTOXIN-A TO ANTI-CGRP MONOCLONAL ANTIBODIES IN CHRONIC MIGRAINE PREVENTION

G. Ceccardi, F. Schiano di Cola, M. Bolchini, M. di Pasquale, S. Caratozzolo, R. Rao, A. Padovani

Neurology, ASST-Spedali Civili di Brescia, University of Brescia (Brescia)

Objectives: Aim of the present study was to evaluate clinical outcome in patients currently in treatment with anti CGRP monoclonal antibodies (mAbs), previously treated with onabotulinumtoxin-A.

Materials and Methods: This retrospective study was performed at the ASST Spedali Civili of Brescia, between November 2014 and May 2023. All patients had a diagnosis of chronic migraine according to the International Classification of Headache Disorders III (ICHD-III) [1] and currently in prophylactic treatment with anti-CGRP mAbs. The primary endpoint was to evaluate the reduction of monthly headache days (MHDs), monthly migraine days (MMDs) and clinical disability according to MIDAS score in patients previously treated with onabotulinumtoxin-A. The secondary endpoints were to evaluate: (1) whether clinical response to anti-CGRP mAbs was affected by the number of previous onabotulinumtoxin-A administrations; (2) clinical outcome in patients currently in treatment with anti-CGRP mAbs previously treated with onabotulinumtoxin-A compared to those who failed only oral preventive treatments.

Results: One-hundred and thirty-nine patients were enrolled, of which 62 previously treated with onabotulinumtoxin-A. Regarding this latter group, baseline (introduction of anti-CGRP mAbs) mean MHDs was 22.0 (6.5), mean MMDs was 11.1 (8.7) and mean MIDAS score was 92.9 (77.6). Following three months (T3) of anti-CGRP treatment, 66% of patients obtained a reduction of MHDs >=50%. A significant reduction in MHDs (10.3±7.4; p<0.0001), MMDs (3.2±3.6; p<0.0001) and MIDAS score (22.5±20.1 p<0.0001) was found from baseline to T3. Mean onabotulinumtoxin-A cycles received before switching to anti-CGRP mAbs was 5, ranging between 1-11. Patients who discontinued before 3 cycles (minimum number to detect a significant clinical response) did so due to personal choice or scarce tolerance to the injections. At T3, patients who received ≤ 3 onabotulinumtoxin-A cycles documented a higher reduction of MIDAS scores, compared to those who received ≥ 4 treatment cycles (-89.7 versus -68.7, p=0.049). Compared to onabotulinumtoxin-A naïve patients, patients who previously received onabutlinumtoxin-A, documented less MMDs (3.3±3.7 versus 5.2±5.0; p=0.017) and a lower MIDAS score (respectively 23.2±20.9 versus 37.4±39.6; p=0.013).

Discussion: Anti CGRP mAbs are effective in chronic migraine patients' prophylaxis. According to our data, previous treatment with onabotulinumtoxin-A might improve subsequent response to anti CGRP mAbs preventive treatment.

Conclusion: In chronic migraine patients prophylactic treatment with onabotulinumtoxin-A represents a valid option to be considered also in those patients eligible for anti CGRP mAbs prophylaxis, as it might improve their clinical response.

Backgrounds: The terms "resistant" and "refractory" identify patients who do not respond to preventive medication. However, it is common experience in headache centers that patients may have multiple failures of acute medication. We evaluated the response to acute migraine medication, their frequency of use, and treatment satisfaction in patients with resistant migraine (Res), refractory migraine (Ref), and non-resistant, non-refractory migraine (Nres/Nref) in an international study.

Methods: We reported the baseline data of the prospective multicenter observational REFINE study, which included consecutive patients with Res, Ref and Nres/Nref. Patients with Nres/Nref were matched by age with those with Res and Ref. We assessed demographics, medical history, and history of medication overuse in each patient. We assessed the number of symptomatic drugs taken in the last three months, both overall and by class, and patient satisfaction with acute treatment based on questions 1-5-6 of the Headache Under-Response to Treatment (HURT).

Results: We included 671 patients (82,4% women) with a median age of 46 years (interquartile range – IQR, 37-54) and a median age at migraine onset of 17 (IQR 13-23) years. Two-hundred and fifty-three (37.7%) had Res, 73 had Ref (10.9%) and 345 (51.4%) Nres/Nref. Patients with Res and Ref had a higher prevalence of medication overuse than those with Nres/Nref (47.4% vs 45.2% vs 20.0%; $p<0.001$). Patients with Res, Ref, and Nres/Nref had a median intake of 14 (IQR 10-24), 17.5 (IQR 10-21.5), and 10 (IQR 5-18) monthly doses of analgesics ($p<0.001$). At the HURT questionnaire, in the last month Res, Ref and Nres/Nref patients with headache days ≥6 were respectively (95.6% vs 98.6% vs 58.5%; $p<0.001$). In Res and Ref patients, a single dose of medication was often not sufficient to relieve headache, unlike those with Nres/Nref (73.5% vs 93.1% vs 47.4%, $p<0.001$), and they also reported less feeling control over their headaches (85.1% vs 94.9% vs 61%; $p<0.001$).

Discussion: According to our results, patients with Res or Ref have more headache days and use more acute medications than those with Nres/Nref and have achieved less success and satisfaction with these therapies.

Conclusion: Res and Ref patients should be recognized quickly to find better management to prevent them from having poor headache control. In headache centers, they should be given appropriate and immediate treatment opportunities.

## MIGRAINE WITH AURA AS EARLY MANIFESTATION OF CEREBRAL AMYLOID ANGIOPATHY: A CASE REPORT

E. Colombo[1], A. Doretti[1], A. Maranzano[1], D. Ungaro[1], M. Sodano[1], G. Demirtzidis[1], F. Verde[2], N. Ticozzi[2], V. Silani[2], S. Messina[1]

[1]Neurology, Istituto Auxologico Italiano IRCCS (Milano); [2]Neurology/Pathophysiology and Transplantation, Istituto Auxologico Italiano IRCCS, "Dino Ferrari" Center, University of Milan (Milano)

Objectives: Migraine has been described in different cerebrovascular syndromes as an early hallmark or even isolated symptom, supporting the presence of a link between migraine and microvascular changes in early stages of angiopathies. To our knowledge very few studies investigated the correlation between migraine and cerebral amyloid angiopathy (CAA) and to date little is known about prevalence, clinical features and pathophysiology of this association. Here we describe a case of a 55-year-old man affected by migraine with aura and diagnosed with probable CAA (according to the Boston criteria version 2.0).

Material and Methods: We present the case of a 55 years-old man suffering from migraine with visual aura since he was 7 years old. When he was 38 years old, the patient performed an MRI that was unremarkable. After the age of 50, migraine attacks became more frequent, disabling and less responsive to medical treatments.

Results: For these reasons, the patient underwent a brain MRI that revealed small diffuse haemosiderin deposits (microbleeds) in the lobar portion of cerebral hemispheres, especially in the occipital lobes, and in the left cerebellar lobe on gradient echo sequences, suggesting the diagnosis of CAA. For the progressive worsening of symptoms, the patient was admitted to our Department at the age of 55. During hospitalization, the patient underwent EEG and thrombophilia screening, which were unremarkable, and brain MRI, which showed an increased number of the previously described haemosiderin deposits.

Discussion: Migraine is an early manifestation in many cerebrovascular syndromes such as subcortical infarcts and leukoencephalopathy or retinal vasculopathy with cerebral leukoencephalopathy. To our knowledge, the association between CAA and this primary headache syndrome has been only rarely reported in the literature [1,2]. A recent study confirmed that migraine has a relatively high prevalence and is often a prodromal symptom in patients with hereditary Dutch-type CAA, a genetic variant of CAA [1]. It may be hypothesized that migraine in cerebrovascular disease can be caused by vascular changes associated with damage to the intracerebral small vessels leading to

impaired vasoreactivity and increased susceptibility to cortical spreading depression. However, to date, the underlying pathophysiological basis is still not fully understood and further studies are required.

Conclusion: In this context, our report supports the existence of a link between these two conditions and suggests that migraine with aura can be regarded as an early marker of CAA that precedes the occurrence of intracerebral hemorrhages by several years.

## PAIN PROCESSING AND MODULATION IN EPISODIC MIGRAINE AND MEDICATION OVERUSE HEADACHE. A THERMAL QUANTITATIVE SENSORY TESTING STUDY

G. Cosentino[1], E. Antoniazzi[1], C. Zaffina[1], S. Mulvoni[1], L. D'Amico[2], E. Guaschino[3], N. Ghiotto[3], R. De Icco[1], M. Todisco[3], C. Tassorelli[1]

[1]IRCCS Mondino Foundation, University of Pavia (Pavia); [2]University of Pavia (Pavia); [3]IRCCS Mondino Foundation (Pavia)

Background and aim: The offset analgesia (OA) phenomenon refers to the disproportionately large decrease in the perceived pain following a slight decrease in intensity of a noxious warm stimulus. This is considered as expression of activation of the endogenous pain-modulation system, whose dysfunction is supposed to be involved in the pathophysiology of migraine and chronic cephalalgias such as medication overuse headache (MOH). Aim of this study was to investigate pain processing mechanisms in patients with episodic migraine (assessed during the different phases of the migraine cycle) and MOH by using the OA paradigm.

Methods: Forty patients with episodic migraine (20 assessed in the interictal period, 10 in the pre-ictal period, and 10 in the ictal period), 10 patients with MOH, and 15 healthy control subjects were enrolled. All subjects underwent an experimental paradigm consisting of 3 stimulus offset trials and 3 constant temperature trials based on the individual heat pain threshold. Both the trigeminal area (supraorbital region) and an extratrigeminal site (ipsilateral hand) were tested in a single session.

Results: The magnitude of OA phenomenon was calculated by subtracting pain ratings from the constant trial from those of the offset trial. OA phenomenon was not observed in patients with MOH when the trigeminal area was tested. No significant differences in the OA phenomenon were observed between patients with episodic migraine evaluated during the different phases of the migraine cycle. Between group comparisons made to assess pain ratings changes during the constant trial showed a significant difference between episodic migraine patients evaluated in the interictal vs peri-ictal phase, i.e. a marked adaptation to the stimulus was observed only in patients in the ictal and pre-ictal phase.

Discussion and conclusions: These data show that a dysfunction in the endogenous pain-modulation system could play a pathophysiological role in patients with medication overuse headache. Changes in adaptation and sensitization phenomena in response to thermal stimuli were also observed throughout the migraine cycle, suggesting a complex interplay between different aspects of painful sensations processing and modulation in migraine.

## PREVALENCE OF PRIMARY STABBING HEADACHE IN CHRONIC MIGRAINE, CLINICAL FEATURES AND ITS ASSOCIATION WITH VENOUS SINUS STENOSIS

G. Cretella, C. Russo, S. Braca, A. Stornaiuolo, A. Miele, R. De Simone

Department of Neuroscience and Reproductive and Odontostomatological Sciences, Federico II University (Napoli)

Objective: Primary stabbing headache is a condition whose prevalence is not well defined, as well as its pathophysiology. The aim of this study is to calculate the prevalence of idiopathic stabbing headache and assess the clinical features of the stabs. The study also evaluated the association between stabbing headache and the presence of dural sinus stenosis, a highly sensitive and specific radiological marker of idiopathic intracranial hypertension. Lastly, it analyzes whether the side of the stenosis corresponds to the site of the stabbing pain.

Material and methods: Data from 579patients referred to the Headache Centre of the AOU Federico II in Naples from 2017to 2021were retrospectively analyzed. The study enrolled patients who showed an MRI with venographic sequences at the follow-up visit. Magnetic resonance was examined for each patient and the venous sinus stenosis of the dura mater were graded according to the "combined conduit score". The characteristics of stabbing headache attacks were assessed in terms of monthly frequency, daily frequency, duration and location. Statistical analyses were carried out with the aid of Microsoft Excel.

Results: 37.6%of patients presented with idiopathic stabbing headache. The monthly frequency is 7, and the daily frequency varies from 1attack per day to more than 10attacks per day. Pain sites among the various patients are distributed throughout the head. The majority of patients presented with stabbing headache in comorbidity with other headaches, mainly chronic migraine. Patients with stabbing headache had significantly more venous stenosis than patients without stabbing headache. In addition, a correlation was observed between the site of stenosis and the site of stabbing pain.

Discussion: There are several hypotheses about the pathophysiological mechanism underlying stabbing headache, including irritation or spontaneous discharge of trigeminal nerve neurons. Some cases in the literature identify the stabbing headache as a presenting symptom of intracranial hypertension, a condition associated with stenosis of the dural venous sinuses. These results support the hypothesis that stabbing headache may underlie a state of intracranial hypertension.

Conclusions: The results suggest that primary stabbing headache is common in patients with migraine and is associated with stenosis of the dural sinuses, which could represent a pathophysiological link with a condition of intracranial hypertension and this could open the way to new therapeutic scenarios. The correspondence between the site of the stenosis and the fit is a new finding, which certainly needs further investigation to be confirmed. Further studies are needed to deepen the understanding of this kind of headache.

## EFFECTIVENESS OF TRANSCRANIAL DIRECT CURRENT STIMULATION AND MONOCLONAL ANTIBODIES ACTING ON THE CGRP AS A COMBINED TREATMENT FOR MIGRAINE (TACTIC) – PRELIMINARY RESULTS

F. De Santis[1], R. Ornello[1], A. D'Atri[1], C. Rosignoli[1], V. Caponnetto[1], F. Salfi[1], D. Corigliano[2], R. De Icco[3], V. Grillo[3], M. Corrado[3], F. Bighiani[3], G. Vaghi[3], G. Sances[4], M. Ferrara[1], C. Tassorelli[3], S. Sacco[1]

[1]Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila (L'Aquila); [2]Department of Psychology, University of Rome Sapienza (Roma); [3]Department of Brain and Behavioral Sciences, Headache Science & Neurorehabilitation Center, IRCCS Mondino Foundation, University of Pavia (Pavia); [4]Headache Science & Neurorehabilitation Center, IRCCS Mondino Foundation (Pavia)

Background and aims: Transcranial direct current stimulation (tDCS) is a promising non-invasive neuromodulation technique for migraine prevention. tDCS exerts its effects trough modulation of brain cortex, while monoclonal antibodies acting on the calcitonin gene-related peptide pathway (CGRP-MAbs) are an established migraine treatment acting on peripheral targets. Thus, it is reasonable to hypothesize a synergistic effect of tDCS and CGPR-MAbs. We aimed to assess whether tDCS, as an add-on treatment to CGRP-MAbs, improves migraine prevention. We also measured electroencephalographic (EEG) power changes to estimate the biological effects of this combined therapeutic approach.

Materials and Methods: TACTIC (NCT05161871) 1 is an ongoing randomized, double-blind, multicenter, sham-controlled trial including patients with migraine treated with CGRP-MAbs for ≥90 days and still reporting ≥8 monthly migraine days. We performed a 5-day tDCS protocol with bilateral cathodal electrodes on occipital area and anodal electrodes positioned on the primary motor areas (sham/active sessions lasting 20 minutes) and we followed up patients for 28 days. We also recorded 64-channel EEG at day 1 (pre-stimulation) and day 5 (end of stimulation). We analyzed change in monthly migraine days, clinical scales, and EEG changes in spectral power in the delta (2-4Hz), theta (5-7Hz), alpha (8-12Hz) and beta bands (13-30Hz).

Results: At state of art, we included 13 patients (mean age=46.2 ±12.5, 92.0% female), 7 in active session and 6 in sham. tDCS led to a decrease in monthly migraine days that was more pronounced – although not significant – in the active group (mean difference 3.57, standard error (SE)=1.91, p=0.089). An improvement in the HADS-D scale for depression was found in the active group (mean difference 2.85, SE=0.85 p=0.007) compared with sham (mean difference 1.3, SE=0.92, p=0.17). tDCS induced a significant reduction in the alpha band power – representing most of the occipital cortical activity with eyes closed – and a decrease in delta power over the motor areas only in the active stimulation group (both $p<0.05$); no difference was found in the sham group. No adverse events were reported.

Discussion and conclusions: We described scarce clinical effect of tDCS when combined with CGRP-MAbs. The strong peripheral action of CGRP-MAbs might hinder subtle clinical effects of tDCS. These results must be taken with caution due to the small sample size recruited to date or to the short duration of the stimulation period. According to our preliminary results, tDCS changed basal cortical activity on stimulated areas without any significant improvement in headache in patients treated with CGRP-MAbs.

## THE EPIDEMIOLOGY AND UNMET NEEDS OF DIAGNOSED MIGRAINE RESPONDENTS USING THE NATIONAL HEALTH AND WELLNESS SURVEY IN ITALY

S. Di Ciaccio[1], C. Bianchini[1], K. De Iaco - Mc Cord[1], J. Brown[2], G. Coppola[3]

[1]Department of Medical, Pfizer Italy (Roma); [2]Department of Medical, Pfizer, Inc. (New York-USA); [3]Department of Medico-Surgical Sciences and Biotechnologies, Sapienza University of Rome Polo Pontino ICOT (Latina)

Background: Migraine is a prevalent disease in Italy impacting the quality of life (QOL) of a relatively young age group, making it a public health priority.

Objectives: We aimed to leverage a retrospective cross-sectional database including self-reported migraine status and health covariates within the Italian subgroup of a European survey, to observe the epidemiology and migraine burden in the Italian population.

Methods: We descriptively analyzed a sample of the 2020 EU National Health and Wellness Survey (NHWS, Cerner Enviza) [1], capturing adult patient-reported data on health indicators including migraine disease status. We included only respondents with a self-reported physician's diagnosis of migraine and stratified their disease impact based on the Migraine Disability Assessment Test (MIDAS) scores and the frequency of attacks in the previous 30 days (1 to 3: acute; 4 to 7: low-frequency episodic, 8 to 14: high-frequency episodic and >15 days: chronic). Additionally, we examined their reported medication use for managing migraines, psychiatric comorbidities and mental wellbeing.

Results: There were 10'026 total survey respondents in Italy of which 1'287 had a diagnosis of migraine. This translated to a prevalence of 12.8% (65% females). The proportion of acute, low-frequency episodic, high-frequency episodic and chronic sufferers were 52%, 27%, 13% and 7%, respectively. More than 43% reported a MIDAS grade of III thus indicating an important disease burden. The most frequently used medications were OTC NSAIDs (66%), followed by OTC paracetamol (28%), triptans (19%) and other medications (22%). The corresponding treatment satisfactions for these migraine medication classes were 27%, 22%, 29% and 35% (where the respondents were extremely or very satisfied). With increasing migraine frequency and MIDAS score, the prevalence of psychiatric comorbidities also increased, for example depression (greater than 5 in PHQ-9 questionnaire) was reported by 64% of MIDAS grade I and 78% of MIDAS grade IV migraine sufferers. All psychiatric comorbidities were reported at higher frequencies in the migraine group than in the general population, for example anxiety was reported by 57% of migraine sufferers vs 28% of non-migraine sufferers, and depression by 36% and 14%, respectively.

Conclusions: In the Italian landscape, migraines cause significant disability and disease burden, especially when comorbid with psychiatric disorders. There are still unmet needs to be addressed in the migraine patient population, such as improving the satisfaction to medications by reducing the frequency and intensity of the attacks and assessing the bidirectional impact between migraines and the patient's mental health.

## EVALUATION OF THE EFFICACY AND TOLERABILITY OF FREMANEZUMAB: REAL LIFE SINGLE-CENTRE EXPERIENCE

M. Di Pasquale, G. Ceccardi, F. Schiano Di Cola, M. Bolchini, S. Caratozzolo, R. Rao, A. Padovani

Spedali Civili of Brescia, University of Brescia (Brescia)

Objectives: Aim of the present study was to evaluate the efficacy and tolerability of Fremanezumab 225 mg/monthly in migraine prevention following three months of treatment.

Materials and Methods: This retrospective study was conducted at the Headache Centre - ASST Spedali Civili of Brescia. Data were collected between January 2019 and June 2022. Inclusion criteria were the following: age ≥ 18 years old, migraine frequency ≥ 8 migraine days per month, MIDAS score ≥ 11, monthly treatment with fremanezumab 225 mg. The following variables were evaluated: mean monthly headache days (MHDs), mean monthly migraine days (MMDs), analgesics consumption, pain intensity (Numerical Rating Scale – NRS), MIDAS and HIT-6 scores. Patients were assessed at baseline (T0) and following three months (T3). Tolerability and side effects were also recorded at T3. Possible response predictors were also analysed.

Results: Fifty-four consecutive patients were enrolled, of whom 43 (79.6%) females. Mean age at baseline was 48.0 years (±12.6; range 20-67). 16 patients (29.6%) had a diagnosis of episodic migrain, whereas 38 patients (70.4%) of chronic migraine. On average, disease duration was 26.0 (±12.6) years. Twenty-one patients (38.9%) have a psychiatric comorbidity (major depressive disorder, bipolar disorder type II and generalized anxiety disorder). Medication overuse was observed in 29 patients (53.7%). Compared to baseline, at T3 a significant reduction in MHDs (19.8±6.96 vs 10.56 ± 9.04; p<0.001), MMDs (11.1±6.06 vs 4.22±5.43; p<0.001), monthly analgesics consumption (17.4±12.45 vs 6.66±6.90; p<0.001), pain intensity (NRS - 7.7 ±0.85 vs 6.25±1.56; p<0.001), MIDAS score (104.6±63.48 vs 29.34±27.69; p<0.001) and HIT-6 (64.98±5.76 vs 57.80±8.27; p<0.001). At T3, 34 patients (63%) documented a > 50% reduction of baseline MHDs, whereas 5 (9.2%) documented a partial response (30-50% reduction). Side effects were reported by 5 patients (9.2%), mainly constipation. A significant clinical response to fremanezumab was more frequent in triptans responders (90.6%) compared to triptans non responders (9.4%, p=0.006).

Discussion: Fremanezumab is an effective prophylactic treatment in patients with migraine, both episodic and chronic. A significant response in terms of migraine associated disability and analgesics consumption was also observed. A significant response to fremanezumab response was more frequent in patients who also document a significant response to triptans for migraine acute treatment.

Conclusion: Our real-life data supports previous clinical trials [1] regarding the efficacy and tolerability of Fremanezumab as a prophylactic treatment in patients with migraine.

## RECEPTOR ENRICHED FUNCTIONAL CONNECTIVITY ABNORMALITIES OF DOPAMINERGIC AND NORADRENERGIC CIRCUITS IN PARKINSON'S DISEASE RELATED-FATIGUE

I. A. Di Vico[1], M. Moretto[2], A. Tamanti[1], G. Tomelleri[1], D. Martinis[3], O. Di Pasquale[3], M. Veronese[3], A. Bertoldo[4], S. Ottaviani[1], F. Pizzini[5], M. Castellaro[4], M. Tinazzi[1]

[1]Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona (Verona); [2]Center for Mind/Brain Sciences, University of Trento (Trento); [3]Department of Neuroimaging, Institute of Psychiatry, Psychology and Neuroscience, King's College (London-UK); [4]Department of Information Engineering, University of Padova (Padova); [5]Department of Diagnostics and Public Health, University of Verona (Verona)

Background: Fatigue affects up to 50% of patients with Parkinson's disease (PD), significantly decreasing their quality of life [1]. Unfortunately, pathophysiological mechanisms and treatment options for fatigue are largely unknown. Functional MRI studies have shown abnormal connectivity of brain areas involved in sensory-motor integration in de-novo PD, and multiple neurotransmitter systems have been involved in the pathogenesis of fatigue [2, 3].

Aim: We aimed to investigate associations between fatigue and functional connectivity within dopamine and noradrenaline functional networks in PD patients.

Methods: We enrolled 29 patients with PD, Hoehn and Yahr stages I-III, without significant cognitive decline or severe neuropsychiatric symptoms. Fatigue was measured with the Fatigue Severity Scale (FSS). We used resting-state MRI data and functional connectivity within dopamine transporter (DAT) and noradrenaline transporter (NET)-defined functional networks by applying a recently developed multimodal framework: "Receptor-Enriched Analysis of Functional Connectivity by Targets."

Results: We found a negative linear correlation between fatigue and noradrenaline-enriched functional connectivity in regions of the sensorimotor and salience networks and a positive linear trend between fatigue and dopamine-enriched functional connectivity in regions of the default mode network. FSS scores and NET-enriched functional connectivity were anticorrelated (Pearson's r=-0.48), while a positive correlation was found between FSS scores and DAT-enriched functional connectivity (Pearson's r=0.33).

Conclusions: These preliminary findings might suggest that fatigue in Parkinson's patients is sustained by a disruption in the sensory-motor circuits and a dysfunction of monoaminergic NET and DAT-related connectivity. Medication involved in noradrenergic modulation might open new avenues for targeted-treatment of this disabling and poorly responsive symptom.

## REFRACTORY MIGRAINE PROFILE IN CGRP-MONOCLONAL ANTIBODIES SCENARIO

V. Dortucci, M. Silvestro, A. Tessitore, F. Scotto di Clemente, G. Battista, G. Tedeschi, A. Russo

Headache Centre, Department of Medical, Surgical, Neurological, Metabolic and Aging Sciences, University of Campania Luigi Vanvitelli (Napoli)

Objective: Despite the advent of even more novel and specific therapeutic strategies, refractory migraine (Ref-M) still represents a conundrum that headache experts have to face with. Indeed, it has been estimated

that from 5 to 30% of migraine patients could be considered as refractory. Nevertheless, the pathophysiological mechanisms underlying Ref-M are still matter of debate, although the prominence of pathways on which the existing drugs seem not to act has been suggested. Among these, the dopaminergic pathway, poorly targeted by current preventive migraine medications, seems to play a critical role in more resistant migraine endophenotypes. We aim to investigate whether a peculiar profile may characterize patients with Ref-M according to 2020 European Headache Federation criteria. Furthermore, to substantiate a dysfunctional dopaminergic pathway involvement in these patients, we explored the effectiveness of olanzapine.

Materials: Eighty-four patients (fitting previous Ref-M criteria of the 2014) were treated with erenumab for six months. In fifteen patients with Ref-M not-responders to CGRP-mAbs, olanzapine was administered (5 mg/die) for 3 months.

Methods: Differences between demographic and clinical features of responder (Ref-M according to 2014 criteria) and not-responder (Ref-M according to 2020 criteria) to CGRP-mAbs were investigated after 6-months of treatment with erenumab and their predictive values assessed. Furthermore, clinical parameters of disease severity such as headache days per month, pain intensity and acute pain medication intake were evaluated in patients with Ref-M treated for three months with olanzapine.

Results: Patients with Ref-M not-responsive to CGRP-mAbs (29/84) when compared with Ref-M responsive to CGRP-mAbs showed higher baseline frequency of migraine attacks, medication overuse and pain catastrophizing scale (PCS) scores. Logistic regression analyses showed that frequency of attacks, medication overuse and PCS score represent independent negative predictors of CGRP-mAbs response. A ≥50% reduction of headache days/month was observed after olanzapine treatment in 67% of patients with Ref-M not-responsive to CGRP-mAbs.

Discussion: We outline that higher frequency of migraine attacks, medication overuse and pain catastrophizing characterize patients with Ref-M not responsive to CGRP-mABs. In this frame, olanzapine effectiveness on frequency and pain intensity of migraine attacks supports the hypothesis that migraine refractoriness may be subtended by a prominent involvement of the dopaminergic pathway.

Conclusion: Future specific therapies able to modulate also dopaminergic pathways could be employed in migraine treatments, further reducing the percentage of patients falling into the category of Ref-M.

Mater Domini (Catanzaro); [10]Neuroalgology Unit, Headache Center, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [11]Neurology Unit, S. Maria Delle Croci Hospital-AUSL Romagna (Ravenna); [12]Headache Center, Hospital F. Spaziani Frosinone (Frosinone);[13]Department of Neurology and Laboratory of Neuroscience, Istituto Auxologico Italiano, IRCCS (Milano); [14]Headache Center, Cardinal Massaia Hospital (Asti); [15]Clinical and Molecular Epidemiology, IRCCS San Raffaele (Roma); [16]Clinical and Molecular Epidemiology; Department of Human Sciences and Quality of Life Promotion, IRCCS San Raffaele; San Raffaele University (Roma); [17]Headache and Neurosonology Unit, Campus Bio-Medico University Hospital (Roma)

Objectives: Results from randomized controlled trials (RCTs) need to be confirmed by real life studies because of their close association with routine clinical practice. We aimed to assess the long-term effectiveness, safety, and tolerability fremanezumab in patients affected by high-frequency episodic (HFEM: 8-14 days/month) or CM in in real-life.

Material and Methods: This is a multicenter (n=9), prospective, cohort, real-life study. We considered all consecutive HFEM or CM patients with ≥3 prior preventive treatment failures, who were prescribed fremanezumab (225 mg monthly/675 mg quarterly) for ≥ 48 weeks. Primary endpoint was the change in monthly migraine days (MMD) in HFEM and monthly headache days (MHD) in CM at weeks 45-48 compared to baseline. Secondary endpoints were variation in monthly analgesic intake (MAI), Numerical Rating Scale (NRS), Headache Impact Test-6 (HIT-6) and Migraine Disability Assessment Scale (MIDAS) scores, and ≥50%, ≥75% and 100% responder rates at the same time intervals.

Results: 470 migraine patients received ≥1 subcutaneous fremanezumab dose and were considered for safety analysis, while 54 patients completed 48 weeks of treatment and were included also in the effectiveness analysis. In both HFEM and CM, fremanezumab significantly ($p<0.001$) reduced MMD (-6.8±3.9), MHD (-14.3±7.3), MAI (-7.4±3.7, 15.0±11.4), NRS (-2.8±2.6, -2.5±2.6) and HIT-6 (-10.0±6.8, -11.6±11.3). The proportion of ≥50%, ≥75% and 100% responders were 72.2%, 38.9% and 16.7% in HFEM and 86.1%, 55.6 and 5.6% in CM. Adverse events emerged in 12.9% (7/54) of the patients: injection site erythema (3.7%), asthenia (3.7%), constipation (1.9%), amenorrhea (1.9%) and nausea (1.9%). No patient discontinued fremanezumab for any reason.

Discussion and conclusions: Long-term (48 weeks) fremanezumab treatment provides sustained effectiveness, safety and tolerability in real-life patients affected by HFEM or CM with multiple prior therapeutic failures. Fremanezumab's long-term effectiveness/tolerability ratio in real-life is considerably greater than that documented in the corresponding RCT.

Cardarelli (Napoli); [11]Neurology Unit, San Giovanni Addolorata Hospital (Roma); [12]Headache Center, Sandro Pertini Hospital (Roma); [13]Headache Center, UOC Neurology, Belcolle Hospital (Viterbo); [14]Neurology Unit, S. Camillo de Lellis Hospital (Rieti); [15]Pediatric Headache Center, Neurology Unit, University of Sassari (Sassari); [16]Department of Biomedicine, Neurosciences, and Advanced Diagnostics, University of Palermo (Palermo); [17]Headache Center, F. Spaziani Hospital (Frosinone); [18]Scientific Directorate, IRCCS San Raffaele (Roma); [19]Clinical and Molecular Epidemiology, IRCCS San Raffaele (Roma); [20]Clinical and Molecular Epidemiology and Department of Human Sciences and Quality of Life Promotion, IRCCS San Raffaele (Roma)

Objective: Randomized controlled clinical trials (RCTs) with antiCGRP monoclonal antibodies (mAbs) document that treatment emerging adverse events (TEAEs) occur in 42% to 55% of migraine patients, and serious adverse events (SAEs) in 0.9%-2%. We aimed to assess safety and tolerability of antiCGRP mAbs in a large series of patients affected by high-frequency episodic migraine (HFEM: 8-14 days/month) or CM.

Material and Methods: Multicenter (n=26), prospective, cohort, real-life study across 9 Italian regions. We enrolled all patients affected by HFEM or CM who had previously failed >3 preventive medications classes (according the rules of the Italian Medicines Agency) receiving >1 dose of erenumab (70 mg or 140 mg), galcanezumab (120 mg) or fremanezumab (225 mg monthly or 675 mg quarterly) from 01/02/2019 to 31/03/2023. All patients were visited by specifically trained headache specialists using a shared web-based semistructured questionnaire. Patients asked to record any adverse event on a paper pencil diary.

Results: A total of 1635 patients had received >1 dose of erenumab (928 pts; 56.8%), fremanezumab (479 pts; 28.7%), galcanezumab (237; 14.5%). Sixty-three patients (3.8%) reported >1 TEAE. The most common were constipation (2.5%), injection site erythema (0.6%) and back pain (0.6%), followed by alopecia (0.2%), dyspepsia (0.1%), asthenia (0.1%), nausea (0.1%), amenorrhea (0.06%), and paresthesias (0.06%). TEAEs occurred more frequently in patients treated with erenumab (5.0%) compared to those receiving galcanezumab (4.2%) or fremanezumab (1.6%). SAEs events occurred in 3 patients (0.18%) treated with erenumab who discontinued the treatment. Two individuals witn CM and medication overuse manifested non-ST segment elevation myocardial infarction unrelated to the treatments. A 58-year-old woman presented with an acute coronary syndrome (7 days after the fifth erenumab 70 mg administration) while learning that her apartment was on fire. A 54-year-old, man with a positive family history for cardiovascular disorders, overweight, affected by hypercholesterolemia and hypertension, developed a myocardial infarction 10 days after the seventh erenumab 140 mg administration. A 58-year-old man suffering from CM and medication overuse developed a treatment-related paralytic ileus 20 days after the injection of the first erenumab 70 mg dose.

Discussion and Conclusion: This real-life prospective study confirms that antiCGRP mAbs are safe and well-tolerated. The occurrence of TEAEs and SAEs is much lower than in RCT.

## BOTULINUM TOXIN AS AN EFFECTIVE TREATMENT IN ANTI-CGRP MONOCLONAL ANTIBODIES FAILURE

G. Ermanis[1], Y. Tereshko[1], E. Belgrado[2], C. Lettieri[2], G. Gigli[1], M. Valente[1]

[1]Clinical Neurology Unit, Department of Medical Area, Udine University Hospital (Udine); [2]Neurology Unit, Udine University Hospital (Udine)

Goal: Anti-CGRP monoclonal antibodies (anti-CGRPAb) represent a highly effective prophylactic treatment for chronic migraineurs, but in some rare cases they are ineffective. Our case series aims to determine whether patients that did not respond to anti-CGRPAb could benefit from OnabotulinumtoxinA (BoNT/A) treatment.

Materials: We collected data from eight chronic migraineurs that attended our headache tertiary center and did not benefit from anti-CGRPAb treatment. Before this therapy, six of them had never been previously treated with BoNT/A, whereas three patients had already made use of it without achieving a good control over headache symptoms. After anti-CGRPAb failure, all these patients underwent at least one BoNT/A treatment according to the PREEMPT protocol.

Methods: We compared the reduction in migraine days, intensity, and symptomatic medication intake obtained before and after anti-CGRPAb therapy and BoNT/A treatment. Results: all patients did not benefit from anti-CGRPab therapy in terms of days of headache (19.566±8.546 days vs 19.111±9.584; p=0.977), pain intensity (NRS 7.444±0.527 vs 7.000±1.000; p=0.346) and the number of symptomatic intake (46.667±58.496 assumptions vs 48.667±59.569; p=0.675). All of them started BoNT/A therapy after discontinuing anti-CGRPAb; there was a significant reduction in migraine frequency (21.67±6.65 vs 9.000±5.701 days per month, p=0.002) and symptomatic medication intake (48.667±59.569 vs 19.000±23.749, p=0.022) while pain intensity NRS did not improve significantly (7.444±1.236 vs 6.222±1.481, p=0.057).

Discussion: BoNT/A improved migraine frequency and symptomatic drug intake; the difference in pain intensity resulted in borderline

significance. It is not well established on which basis pharmacological resistance to anti-CGRPAb exists, but in these cases BoNT/A seems to be effective by bypassing a purely CGRP-mediated pathogenetic mechanism of pain, thus being a good rescue therapy in resistant headache management.

Conclusions: BoNT/A could be useful in chronic migraineurs when anti-CGRPAbs are ineffective.

## COMPLICATIONS AFTER LUMBAR PUNCTURE PERFORMED AT THE OUTPATIENT NEUROLOGY FACILITY: A SINGLE CENTER EXPERIENCE

E. Falato[1], S. Carbone[2], M. Pantuliano[2], L. Celani[2], F. Capone[1], F. Pilato[1], V. Di Lazzaro[1]

[1]Operative Research Unit of Neurology, Fondazione Policlinico Universitario Campus Bio-Medico (Roma); [2]Research Unit of Neurology, Department of Medicine and Surgery, Campus Bio-Medico University of Rome (Roma)

Objectives: To report and discuss post-lumbar puncture (LP) complications observed in our outpatient neurology facility.

Materials and Methods: We report post-LP complications of patients who underwent diagnostic LP according to standard healthcare guidelines and regulations from the 15th of November 2020 and the 30th of May 2023 at the Neurology Day Hospital of Fondazione Policlinico Universitario Campus Bio-Medico. LP was performed conforming to international consensus guidelines (ref.1). We used a 22-gauge 0,7x90mm cutting bevel spinal needle and ice spray as topical analgesia. Before home discharge, patients remained on bed rest, monitored for 3 hours, with saline infusion. Patients were advised not to perform any heavy activity or exercise for at least two days after the procedure and to stay hydrated.

Results: 96 subjects (46F, 50M) of age (mean+SD) 56.60+17.15 years underwent diagnostic LP with our standard-of-care procedure. Indications for LP were inflammatory central nervous system disease (45,83%), polyneuropathy (30,20%), motor neuron disease (12,5%), and cognitive decline (11,5%). LP was performed in the left lateral recumbed position in 79,17% of cases and in the sitting position in the remaining cases. The number of LP attempts was 1.74+0.59. The amount of cerebrospinal fluid (CSF) withdrawn was 7,50+0,89 mL/subject. Complications were reported by fourteen (14,58%) subjects; none were serious. Post lumbar puncture headache (PLPH, ref.2) was the most frequent complication, with an incidence of 11,46%. Mean time of PLPH onset after LP was 28,4+14,29 hours; mean PLPH duration was 83,63+52,14h (range 24–168). Subjective pain intensity ranged from mild to moderate (managed with bed rest and hydration only) in 63,63% of cases and from moderate to severe (requiring over-the-counter medications) in 36,36% of cases. PLPH was associated with low back pain (LBP) in 18,18% of cases, orthostatic dizziness (OD) in 9,00%, and nausea in 18,18% of cases. Other post-LP complications were isolated LBP (incidence 2,08%, onset time 13,5+12,37h, duration 45,6+45,22h), isolated OD (one case, incidence 1,04%, onset time 24,5h, duration 84,0h), and one case of skin ice burn. Total LBP incidence (LBP associated with PLPH or isolated) was 4,17%. The presence of PLPH correlated with age (r=0,348; p<0,001) being more frequent in younger subjects, female gender (chi2=4,604; p=0,03), number of LP attempts (chi2=6,150;p=0,04) and was higher in subjects who reported not having followed rest instructions after discharge (chi2=10,500;p=0,001).

Discussion and conclusions: Acting on procedural risk factors (number of LP attempts) and on patient education (avoiding heavy activity or exercise after LP) may reduce the incidence of PLPH.

## LONGITUDINAL SALIENCE NETWORK CONNECTIVITY CHANGES ASSOCIATED WITH MINDFULNESS-BASED TREATMENT ADDED TO TREATMENT AS USUAL IN MEDICATION OVERUSE HEADACHE PATIENTS (MIND-CM STUDY)

D. Fedeli[1], G. Ciullo[1], G. Demichelis[1], J. Medina Carrion[1], M. Bruzzone[1], E. Ciusani[2], D. D'Amico[3], A. Erbetta[1], S. Ferraro[4], M. Grisoli[1], E. Guastafierro[5], A. Raggi[5], A. Nigri[1], L. Grazzi[3]

[1]Department of Neuroradiology, Foundation IRCCS Neurological Institute C. Besta (Milano); [2]Department of Diagnostic and Technology, Foundation IRCCS Neurological Institute C. Besta (Milano); [3]Neuroalgology Unit and Headache Center, Foundation IRCCS Neurological Institute C. Besta (Milano); [4]School of Life Science and Technology, MOE Key Laboratory for Neuroinformation, University of Electronic Science and Technology of China (Chengdu-CN); [5]Neurology, Public Health and Disability Unit, Foundation IRCCS Neurological Institute C. Besta, (Milano)

Aims: Mindfulness-based therapy has recently gained considerable interest in the management and treatment of migraine [1]. Increasing evidence suggests that mindfulness practice induces a modulatory effect on the Default Mode Network (DMN) and the Salience Network (SN) functional connectivity [2]. Our longitudinal study tested SN and DMN connectivity changes associated with a mindfulness-based therapy added to pharmacological treatment as usual in a group of patients with Medication Overuse Headache (MOH).

Materials: 34 well-matched adult MOH patients were randomized in 17 patients following Treatment as Usual (TaU group, 15 F) and 17 patients practicing mindfulness added to Treatment as Usual (MIND group, 15 F). All partecipants were scanned with a 3T scanner with a rs-fMRI sequence before the treatment (T0) and after one year (T1). Clinical and psychiatric variables were collected for all patients at T0 an T1.

Methods: Functional data were analysed with CONN toolbox. Longitudinal comparisons of DMN and SN seed-to-voxel connectivity were performed between MIND and TAU groups. Age and sex were considered as covariates. All results were corrected for multiple comparisons. Longitudinal connectivity modifications were correlated with changes in clinical variables.

Results: Both groups showed an improvement in all the main clinical variables. After one year of mindfulness practice, MIND patients showed increased SN functional connectivity with the left posterior insula and sensorimotor cortex compared to TaU patients. Moreover, in MIND patiens only, greater SN-insular connectivity was associated with improved depression scores (Beck Depression Inventory) at follow-up.

Discussion: Mindfulness is characterized by present-moment self-awareness and relies on attention control and emotion regulation, possibly allowing a better headache-related pain management [2]. We observed a longitudinal functional connectivity change only in the SN of MIND patients. This network, mainly anchored in the bilateral insula and cingulate cortex, helps in directing attention to relevant information and filtering out irrelevant or distracting information. Enhanced SN-sensorimotor connectivity might represent improved body-awareness of painful sensations. Moreover, the increase of SN functional connectivity with the posterior insula, might be involved in chronic pain and emotional processing of nociceptive input [3], and could suggest that mindfulness practice may improve the management of negative emotions associated with pain.

Conclusions: Our results highlight the beneficial effects of the Mindfulness therapy in patients with MOH, potentially paving the way for future research on non-pharmacological interventions in chronic headache treatement.

Cardarelli (Napoli); [9]Headache Center, ASST Santi Paolo Carlo (Milano); [10]Department of Neuroscience, Mental Health and Sensory Organs (NESMOS), Sant'Andrea Hospital, Sapienza University (Roma); [11]Center for Headache and Intracranial Pressure Disorders, Neurology Unit, A.O.U. Mater Domini (Catanzaro); [12]IRCCS San Raffaele (Roma); [13]Neurological Unit, Belcolle Hospital (Viterbo)

Objective: The Italian Migraine Registry (I-GRAINE) is aimed at collecting detailed information on socio-demographic characteristics, patient's journey, clinical government and healthcare resource use of people with migraine. Here we detail diagnostic investigations and specialist visits performed by migraine patients in Italy, considering their impact on our National Health System (NHS)

Material and Methods: The Italian Migraine Registry (I-GRAINE) is a multicenter, prospective, observational, non-interventional study whose aim is to ensure a proper disease management, according to scientific and sustainability criteria. Consecutive patients affected by episodic or chronic migraine seen between 19/4/21 and 31/12/22 at 39 participating center were enrolled according to the systematic random method. Information on sociodemographic characteristics, migraine features, patient's journey and healthcare resource use were collected by specifically trained headache specialists with face-to-face interviews using a shared semistructured web-based questionnaire.

Results: At the date of 31 December 2022, we enrolled 867 patients. Most of them were females (85.5%), had high migraine frequency (9.3 ± 7.8 days/month) and severe disability (MIDAS score: 48.3 ± 50.7; HIT-6 score: 60.9 ± 9.1). Two-thirds of patients (63.1%) underwent at least 2 specialist visits (2.4 ± 0.2) over the last 3 years. The specialists most frequently consulted were neurologists (85.6%), ophthalmologists (33.6%) and dentists (15.9%). The number of different neurologists, ophthalmologists and dentists consulted by each patient were 3.5 ± 3.9, 1.5 ± 0.9 and 1.8 ± 4.0. The proportion of specialists visits subsidized by the NHS were 52.9%, 21.5% and 7.5%, respectively. Patients who underwent diagnostic investigations for migraine during lifetime were 81.8% (68.8% over the last 3 years). Brain neuroimaging was the most common investigation (95% of the patients; self-prescribed in 12.5% of the cases) followed by spine MRI/X-Rays (22.8%; self-prescribed in 17.2%) and EEG (11.4%; self-prescribed in 2.8%). The number of diagnostic investigations performed by each patients were 5.3 ± 3.5 (brain neuroimgaging), 2.2 ± 0.6 (spine MRI/X-rays) and 1.8 ± 1.4 (EEG). Investigations subsidized by the NHS in >50% of the cases were 27.7%–86.3% for brain neuroimaging, 67.6% – 81.3% for spine MRI/X-Rays, and 84.7% for EEG.

Discussion and Conclusion: A large number of diagnostic investigations and specialist visits for migraine are inappropriate, redundant, self-prescribed and subsidized by the NHS. Despite current guidelines, almost all patients undergo brain neuroimaging. The I-GRAINE registry is expected to contribute to improve the clinical management of migraine, rationalizing healthcare resource allocation, and reducing its economic burden.

## VERY-LOW-CALORIE KETOGENIC DIET VS HYPOCALORIC BALANCED DIET IN THE PREVENTION OF HIGH-FREQUENCY EPISODIC MIGRAINE: THE EMIKETO RANDOMIZED CONTROLLED TRIAL

G. F. Fiorentini[1], M. Caprio[2], E. Moriconi[3], E. Camajani[4], A. Feraco[2], V. Marzolla[3], G. Egeo[1], C. Aurilia[1], B. Orlando[1], L. Vitiello[4], S. Proietti[5], C. Tomino[6], P. Barbanti[7]

[1]Headache and Pain Unit, IRCCS San Raffaele (Roma); [2]Laboratory of Cardiovascular Endocrinology, Department of Human Sciences and Promotion of the Quality of Life, IRCCS San Raffaele, San Raffaele Roma Open University (Roma); [3]Laboratory of Cardiovascular Endocrinology, IRCCS San Raffaele (Roma); [4]Department of Human Sciences and Promotion of the Quality of Life, - San Raffaele Roma Open University (Roma); [5]Laboratory of Flow Cytometry, IRCCS San Raffaele (Roma); [6]Clinical and Molecular Epidemiology, IRCCS San Raffaele (Roma); Scientific Direction IRCCS San Raffaele (Roma); [7]Headache and Pain Unit, Department of Human Sciences and Promotion of the Quality of Life, IRCCS San Raffaele, San Raffaele Roma Open University (Roma)

Objective: To compare the effects of Very-Low-Calorie Ketogenic Diet (VLKD) vs Hypocaloric Balanced Diet (HBD) in the prevention of high-frequency episodic migraine (HFEM: 8-14 days/month).

Material and methods: Prospective, 24-weeks, single center, randomized, controlled study. HFEM patients with a Body Mass Index (BMI) ranging from 27 to 35 kg/m2 were randomly assigned (1:1) to VLCKD or HBD. Patients on the VLCKD treatment arm used VLCKD during the first 8 weeks, shifting to a low calorie diet (LCD) containing carbohydrates during weeks 9-12, and to a HBD during weeks 13-24. Patients assigned to HBD remained on the same dietary regimen for all 24 week. Anthropometric indexes, urine and blood chemistry were assessed at enrollment (-28 days), baseline, 10 days after treatment onset and at weeks 4, 8, 12, and 24. Migraine characteristics were evaluated at baseline, weeks 8, 12 and 24. Change in monthly migraine days (MMD) at weeks 5-8 compared to baseline was the primary endpoint. Secondary endpoints encompassed change in MMD at weeks 9-12 and 21-24, and change in Numerical Rating Scale (NRS), Headache Impact Test-6 (HIT-6) and Short Form Health Survey-36 (SF-36) scores at weeks 5-8, 9-12 and 21-24 compared to baseline.

Results: We enrolled 57 patients (VLCKD: 29; HBD: 28). Patients assigned to VLCKD showed a greater MMD reduction than those allotted to HBD at weeks 5-8 (-6.4±4.8 vs -2.2±5.0, p=0.008), weeks 9-12 (-7.2±5.42 vs-3.13±3.58, p=0.007) and weeks 13-24 (-6.8±6.42 vs-3.6±3.3, p=0.042). No difference emerged in MIDAS, HIT-6 and NRS scores between the two groups at weeks 5-8 and 9-12. SF-36 score significantly improved at week 8 in VLCKD group and at week 12 in the HBD. Weight-loss and BMI reduction were significantly higher in VLCKD compared to HBD at week 8 (-8.2±4.5 vs -4.3±2.9, p=0.002; -3.0±1.6 vs-1.5±1.1, p=0.002) and week 12 (-9.1± 6.4 vs -4.9 ±2.7, p=0.020; -3.3 ± 2.2 vs -1.8±1.0, p=0.016). At week 24, weight loss was maintained in VLCKD (-9.1± 6.4) whereas a slight increase (-4.3 ± 2.9) was found in HBD. Inflammatory indexes, were significantly reduced ($p<0.05$) in VLCKD group at week 12.

Discussion and Conclusions: VLCKD is more effective than HBD in reducing MMD, BMI and inflammatory indexes. VLCKD superiority over HBD in MMD reduction persists for 16 weeks after VLCKD discontinuation, suggesting that VLCKD could positively influence not only neuronal metabolism but also brain dysexcitability in migraine patients.

## PERSISTENT FAMILIAL HEMIPLEGIC MIGRAINE AURA DUE TO PRRT2 GENE DELETION: THE FIRST CASE REPORT

G. Garascia, A. Granato, L. Bartole, P. Manganotti

Clinical Unit of Neurology, Headache Centre, Department of Medicine, Surgery and Health Sciences, University Hospital and Health Services of Trieste, ASUGI, University of Trieste (Trieste)

Background: Familial Hemiplegic Migraine (FHM) is a rare genetical disorder in which migraine pain is accompanied or followed by stroke-like symptoms, frequently long-lasting, and at least one first- or second-degree relative suffers from migraine aura with motor weakness. The majority of FHM cases have been attributed to mutations of three genes, CACNA1A, ATP1A2 and SCN1A. Recently, alterations of PRRT2 gene have been highlighted as another main cause of FHM. The different PRRT2 mutations induce a loss of function of the encoded protein, which is implicated in neurotransmission.

Objectives: Aim of this study is to describe the first case of a sensorimotor persistent aura related to PRRT2 gene deletion.

Results: A 27-year-old male migraineur afferent to the Headache Centre of Trieste was evaluated. He has suffered from migraine since he was 4-year-old. His sister was hospitalized for stroke-like symptoms and subsequently clinically diagnosed at the Headache Centre as having hemiplegic migraine. At its onset, patient's headache presented with typical migraine without aura symptoms. Since he was 15, a right hemibody strength deficit starting about 15 minutes after the onset of pain and during up to 12 hours has been associated. Since he was 21, a right hemibody hypoesthesia has also developed. Then, strength and sensitive deficits have always been temporarily associated and had approximately the same duration, up to 12 hours. Seldom, speech and visual disturbances were added. Frequency of attacks were up to 3 days/month. Due to a weakness and hypoesthesia in the right limbs started three months before, at 27 he was neurologically evaluated and a right sensorimotor hemisyndrome was objectified. Cerebral CT, brain MRI and EEG were normal. He was treated with lamotrigine 50 mg bid and he began to improve, but after two months the drug was stopped because of suicidal ideation. Lamotrigine was replaced with valproic acid 300 mg bid and the resolution of aura symptoms was reached after two months. Genetic MLPA analysis detected a heterozygous deletion of the whole PRRT2 gene both in patient and in his sister.

Conclusion: We described the first case of sensorimotor persistent aura related to PRRT2 gene deletion. Lamotrigine and valproic acid were effective.

## LONG TERM EFFECTIVENESS AND TOLERABILITY OF GALCANEZUMAB AND FREMANEZUMAB ON COMORBID CHRONIC CLUSTER HEADACHE AND MIGRAINE: A PROSPECTIVE CASE SERIES

M. Gentile, M. Roca, G. Liaci, D. Paolicelli, M. Prudenzano

Headache Center, "L. Amaducci" Neurological Clinic, DiBrain Department, Aldo Moro University (Bari)

Background: Cluster headache (CH) and Migraine (M) are considered distinct primary headaches as they differ in multiple aspects such as gender-relation, specific headache features and therapies. However an overlap between CH and M has been reported [1]. In fact CH may occur with migrainous symptoms such as nausea, photophobia, and phonophobia while M can manifest itself with symptoms of trigeminal-autonomic activation. Moreover CH and M can be comorbid in the same individual. Up to now some cases of patients with CH and M treated with antiCGRP antibodies (antiCGRP mAbs) and observed for short periods have been described [2,3].

Case Series: We describe five adult patients, one female and four males, with both CH and M treated with antiCGRP mAbs (2 with Galcanezumab and 3 with Fremanezumab), for a period ranging from one to three years. Four of these patients had high-frequency M, one

had chronic M and all of them were also affected by chronic CH. All patients underwent baseline and quarterly follow-up visits with clinical evaluation and administration of Migraine Disability Assessment Score Questionnaire (MIDAS) and Headache Impact Test -6 item score (HIT -6 Fremanezumab and Galcanezumab both reduced in all patients the monthly number of migraine days, of CH attacks, the number of days with acute medications use and the patient's disability as measured by MIDAS and HIT-6 showing sustained long-term efficacy. No adverse events were reported by 4 patients. Only the female patient reported a slight slowdown in hair growth rate after Fremanezumab but this adverse event was not so serious to interrupt the treatment.

Results and Discussion: Our results are in agreement with those of previous studies conducted on similar case series for shorter observation periods, and demonstrate the long-term efficacy and well tolerability of antiCGRP mAbs in case of comorbidity between M and CH. Common pathophysiological mechanisms including the Calcitonin Gene-Related Peptide (CGRP) role in trigeminal-vascular system activation have been proposed to explain antiCGRP mAbs effectiveness in both CH and M. Further studies on large case series are needed to provide stronger evidence for the use of antiCGRP mAbs as first-line therapy in CH and M comorbidity.

## TRIGEMINAL INVOLVEMENT IN CONVENTIONAL MRI IS UNDISTINGUISHABLE BETWEEN TRIGEMINAL NEURALGIA AND SUNCT SYNDROME

G. Giuliani[1], G. De Stefano[1], C. Zilli[1], M. Altieri[1], F. Caramia[1], G. Di Stefano[1], A. Truini[1], V. Di Piero[1,2]

[1]Department of Human Neurosciences, Sapienza University of Rome (Roma); [2]University Consortium for Adaptive Disorders and Head Pain (UCADH), Fondazione Mondino (Pavia)

Objectives We compare neuroradiological findings in two couple of patients with the same structural abnormalities but with different clinical pictures. Two patients presented a short-lasting unilateral neuralgiform headache attacks with conjunctival injection (SUNCT) while the others were affected by trigeminal neuralgia (TN). Our aim was to identify any difference in neuroradiological picture that could influence clinical presentation.

Materials and methods: The first couple presented a pontine lesion involving trigeminal root entry zone, due to multiple sclerosis. First patient was a 68-years-old man who developed a SUNCT syndrome, characterized by shooting pain in the orbital region associated with prominent ipsilateral autonomic symptoms. Attacks, that were both spontaneous and triggered by tactile stimulation, disappeared after the introduction of lamotrigine. The second MS patient, with an indistinguishable lesion at MRI, reported electric shock like triggered pain in the maxillary region, with occasional ipsilateral autonomic symptoms, that responded to carbamazepine. In the second couple, brain magnetic resonance imaging (MRI) showed a neurovascular contact in which the superior cerebellar artery dislocated the fifth nerve without clear signs of atrophy; brainstem lesions were absent. Patients developed two different clinical pictures, consistent respectively with a SUNCT syndrome and a trigeminal neuralgia.

Results: Routine neuroradiological exams of our cases showed no apparent difference between SUNCT and TN patients.

Discussion: SUNCT and TN significantly overlap. Both conditions are characterized by similar pain pattern, typically very short lasting and strictly unilateral. Presence of pain paroxysms triggered by innocuous stimuli is a hallmark of TN and it is also reported in SUNCT; autonomic symptoms, characteristic of SUNCT, are commonly present in TN patients, mainly when V1 territory is involved [1]. These craniofacial syndromes may share a damage in the trigeminal primary afferents at the root entry zone, justifying the strong similarities. On the contrary, slight clinical differences could be explained by the additional role of hypothalamus in SUNCT.

Conclusions: Although SUNCT and TN are traditionally considered as different disorders, shared neuroradiological and clinical features suggest a common pathophysiological mechanism. To better understand the real nature of this link, future advanced neuroimaging studies are necessary.

## SUBCUTANEOUS INJECTION OF BOTULINUM NEUROTOXIN TYPE A IN REFRACTORY CHRONIC MIGRAINE: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY

G. Idone, D. Tedeschi, V. Laterza, G. Magro, A. Gambardella, F. Bono

Botulinum Toxin Therapy Center, Neurology Unit, AOU R. Dulbecco, Institute of Neurology, Magna Grecia University (Catanzaro)

Aims: In this randomized, double-blind, placebo-controlled study, we evaluated the efficacy of an individualized technique of subcutaneous injection of botulinum toxin type A (BoNT-A) targeted (SjBoT) to the occipital or trigeminal skin area in non-responder patients with chronic migraine (CM).

Methods: Patients who had not previously responded to at least two treatments of intramuscular injections of BoNT-A were randomly assigned (2:1) to receive two subcutaneous administrations of BoNT-A (up to 200 units) with the SjBoT injection paradigm or placebo. Following the skin area where the maximum pain began, treatment was given in the trigeminal or occipital region bilaterally. The primary endpoint changed in monthly headache days from baseline to the last 4 weeks.

Results: Among 139 randomized patients, 90 received BoNT-A and 49 received placebo, and 128 completed the double-blind phase. BoNT-A significantly reduced monthly headache days versus placebo ($-13.2$ versus $-1.2$; $p < 0.0001$) in the majority of patients who had cutaneous allodynia. Other secondary endpoints, including measures for disability (Migraine Disability Assessment questionnaire from baseline 21.96 to 7.59 after treatment, $p = 0.028$), also differed.

Conclusions: In non-responder patients with CM,[1] BoNT-A significantly reduced migraine days when administered according to the "follow the origin of maximum pain" approach using SjBoT injection paradigm. This is the first randomized, double-blind, placebo-controlled study demonstrating the efficacy and safety of the "follow the origin of maximum pain" approach using subcutaneous injections of BoNT-A targeted (SjBoT) to the occipital or trigeminal skin area in patients with chronic migraine.This is a new injection strategy developed by F.B. for the preventive treatment of chronic migraine.

## SEX DIFFERENCES IN RESPONSE TO TREATMENT WITH ANTI-CGRP DRUGS IN PATIENTS WITH MIGRAINE AFTER 1 YEAR: A PILOT STUDY OF REAL LIFE

V. Laterza[1], G. Idone[2], D. Tedeschi[2], P. Bruno[2], A. Gambardella[2], F. Bono[2]

[1]Institute of Neurology, Department of Medical and Surgical Sciences, Magna Graecia University (Catanzaro); [2]Neurology Unit, Aou "R. Dulbecco", Magna Graecia University, (Catanzaro)

Introduction: Recent evidence shows sex differences in migraine characteristics [1]. However, there is a lack of data comparing over a long period the response to treatment with anti-CGRP mAbs in relation to sex [2].

Aims: We conducted a single center prospective observational study to evaluate sex differences in response to treatment with anti-CGRP mAbs for migraine prevention after 1 year.

Methods: Patients with chronic migraine (according to the criteria of International Headache Association) were treated with anti-CGRP mAbs and followed up for 12 months. The outcomes were: decrease in monthly headache days (MHD), rate of treatment stopping, monthly days of acute medication use, Headache Impact Test 6 (HIT-6) score and intensity of headache pain assessed with the visual analogue scale (VAS 0-10). Decrease of MHDs was evaluated on percentage of decrease and classified in four classes of response: 0-29% (low responders), 30-49% (medium-low responders), 50-74% (medium-high responders) and ≥75% (high responders). Patients who interrupted the treatment were considered as non-responders. All included patients were followed for 12 months, regardless of treatment discontinuation. Baseline was considered as the 4 weeks before the start of treatment with monoclonal antibodies (erenumab, fremanezumab, galcanezumab), while outcomes were assessed at 12 months after the start of treatment and compared with baseline.

Results: We recruited 208 patients with chronic migraine (169 F; 39M) treated with anti-CGRP mAbs. After one year of treatment, we found that 25% of men were low responders, 17,9% were medium-low responders, 24% were medium-high responders, 15,3% were high responders, while 17% interrupted the treatment. On the other hand, 20,7% of women had low responders, 14,2% had medium-low responders, 43,7% had medium-high responders, 16,5% had high responders, while 4,7% interrupted the treatment.

Conclusion: Our pilot study demonstrates the presence of sex differences to anti-CGRP treatment for migraine after 1 year. These results can be explained by the relationship that exists between estrogen receptors and CGRP in the trigeminal vascular system, and they suggest the development of sex-specific therapies in migraine.

## RECURRENT IDIOPATHIC INTRACRANIAL HYPERTENSION TREATED BY BARIATRIC SURGERY: A CASE REPORT

S. Lenti, C. Manfredi, E. Groppo, C. Gambini, A. Priori, M. Secchi

Clinical Neurology Unit, San Paolo University Hospital (Milano)

Introduction: Idiopathic intracranial hypertension (IIH) or pseudotumor cerebri is a debilitating condition that causes severe headaches, tinnitus, radicular pain and progressive visual loss, that typically affects young overweight females. The standard of care is weight loss and acetazolamide; also, in severe or refractory cases may be needed invasive procedures, such as spinal fluid diversion, optic nerve sheath fenestration or venous sinus stenting. However, losing weight is often very difficult to achieve and acetazolamide carries numerous undesirable side effects that can result in medical noncompliance. Bariatric surgery is a safe and effective treatment modality for IIH, leading to excellent weight loss and reversal of related comorbidities.

Case report: A 31-year-old female presented at Emergency Department for an episode of syncope, pulsatile tinnitus, nausea and headache for 2 weeks. Her BMI was 40.5 and she took estroprogestinic medications for an endometrial polyp. Neurologic examination was negative except for headache, while neurophthalmological evaluation revealed bilateral papilledema. Cerebral computerized tomography (CT) and cerebral CT angiography detected a partial empty sella and patency of transverse venous sinuses; while brain magnetic resonance (MR) with gadolinium showed minimal distention of optic nerve sheaths. We performed a lumbar puncture withdrawing 35 ml of cerebrospinal fluid (CSF) and we detected an opening pressure of 65 mmHg and a closure one of 50 mmHg. Hence, we made diagnosis of IIH and set treatment with acetazolamide and weight loss. Four months later, despite the medical treatment and the diet, the patient had not lost weight and presented a return of clinical symptoms of IIH associated with papilledema and an increase of CSF pressure. After the evaluation by a multidisciplinary team, she underwent sleeve gastrectomy surgery, without complications. At her six-month follow-up after bariatric surgery, she had lost a total of 20 kg with a significant reduction in headache, the absence of clinical signs of intracranial hypertension and no evidence of papilledema at the neurophthalmological evaluation.

Discussion: Current literature about the efficiency of bariatric surgery for the treatment of IIH has been raising over the course of the past years, suggesting that bariatric surgery is superior compared to medical management and cerebrospinal fluid pressure reducing procedures which have high rates of recurrence.

Conclusion: The case demonstrate that bariatric surgery could be an effective and long-lasting method of treating idiopathic intracranial hypertension. It should be considered in overweight patients with typical features of IIH who don't respond to life-style modification and medical treatments.

## ASSESSMENT OF CEREBRAL HAEMODYNAMICS DURING KINETIC OSCILLATION STIMULATION (KOS) TREATMENT ON CHRONIC MIGRAINE: A PILOT STUDY

G. Liaci[1], C. Altamura[1], N. Brunelli[1], M. Prudenzano[2], M. Roca[2], F. Vernieri[1]

[1]Headache and Neurosonology Unit, Neurology, Campus Bio-Medico University (Roma); [2]Headache Center, Amaducci Neurological Clinic, Policlinico General Hospital (Bari)

Objectives: KOS is a minimally invasive method of neuromodulation able to regulate the trigeminal-autonomic reflex (TAR), which is believed to play a significant role in migraine pathophysiology. The sphenopalatine ganglion stimulation through the mucous membrane of the nasal cavity with low-frequency mechanical vibrations has been shown to be effective in both tempering acute pain and reducing the number of monthly headache days from baseline to week 6 of treatment compared to sham stimulation. The aim of this study was to verify any changes ongoing or at the end of a six weeks treatment cycle with KOS, as well as to correlate any improvement obtained from the treatment to any changes in the hemodynamic indices.

Materials: We enrolled four patients with refractory chronic migraine and we offered them a six weeks treatment with the Chordate System S220 at weekly intervals.

Methods: In the first and last week, and halfway through the course of treatment, patients underwent non-invasive Doppler tests to record cerebral blood flow parameters (mean flow velocity, pulsatility index, resistance index) in the middle cerebral artery (MCA) during the period of KOS stimulation. Before each session and during the follow-up period each patient was requested to fill in a questionnaire with validated clinical scales (BS-11, PPI, BRS-6, SF-MPQ, H.A.D.S.) to evaluate any benefits occurred during and after the treatment.

Results: We recorded a downward trend in the resistance index of the MCA during the stimulation period in 3 of the 4 enrolled patients. No significant difference in any other derived index was observed intersubjectively at different times of the treatment cycle, nor remarkable modifications in the clinical scales emerged between T0 and T6, apart from a single patient in which the scores related to the subjective intensity of pain and the effects of pain on behaviour (BS-11, BRS-6) were significantly reduced from the beginning to end of the treatment cycle.

Discussion: Albeit on a smaller scale, we have not confirmed the preliminary data regarding the improvement of chronic migraine after a six-week treatment with KOS. The activation of TAR could be responsible for the acute variation of the resistance index during stimulation, as in response to compensatory vasodilatation secondary to activation of the trigeminovascular system by brainstem afferents.

Conclusions: Although KOS may be a viable alternative for migraine treatment, the precise mechanism by which it modulates the TAR is still speculative and further studies on a larger cohort will be needed.

## ANTI-CGRP MONOCLONAL ANTIBODIES IN MIGRAINE PREVENTION: REDUCTION OF THE FREQUENCY OF ADMINISTRATION DOES NOT MODIFY EFFICACY. PROPOSAL FOR A TAILORED THERAPY

C. Lovati[1], S. Liguori[1], L. Pantoni[2]

[1]Headache Center, Neurology Unit, Luigi Sacco University Hospital (Milano); [2]Department of Biomedical and Clinical Sciences, Neurology Unit, Luigi Sacco University Hospital, University of Milan (Milano)

Background: Anti-CGRP monoclonal antibodies (CGRP-mAbs) enlarged migraine prevention options and modified global health condition of patients with migraine. These drugs are specifically targeted and work safely and efficiently in many patients with the standard dosing schedule.

Objective: To identify if a progressive reduction in the frequency of administration may modify the efficacy of anti-CGRP-mAbs migraine prophylaxis.

Methods: We evaluated headache frequency (monthly headache days – MHD) in patients treated with an anti CGRP or antiCGRP-R molecule. Patients were classified as: i) non-responders (nonR) when the reduction was <30% vs. baseline; ii) partially responders (PR) (30-49% reduction); iii) normal responders (NR) (reduction 50-74%) and iv) super responders (SR) (>75% reduction). The entity of reduction was evaluated after 3 months of standard schedule and 6-9 months after a reduction in administration frequency.

Results: 38 patients (6M and 32F, mean age 48yrs) changed their dosage schedule from the standard monthly injection to a one performed every 40 days (26 directly and 12 through a 3-month period at the intermediate schedule, i.e., one shot in 35 days). At the standard schedule, 20 patients were SR, 13 NR, 4 PR, and 1 NonR. After a 3-month period with the reduced administration frequency schedule (1 injection / 40 days), 21 were SR, 10 NR, 5 PR, and 1 NonR.

Discussion: A progressive partial reduction in administration frequency seems to be possible without a reduction of efficacy in the larger proportion of patients, at least among good responders. It may be an option when side effects, although globally few and not particularly relevant, have to be minimized.

## FAMILIAL HEMIPLEGIC MIGRAINE: IS CARDIAC INVOLVEMENT POSSIBLE?

L. Mancinelli[1], G. Prandin[1], I. Scali[1], F. Palacino[1], E. Vincis[1], G. Furlanis[1], P. Caruso[1], M. Naccarato[1], P. Manganotti[1], B. Giometto[2]

[1]Clinical Unit of Neurology, Department of Medicine, Surgery and Health Sciences, University Hospital and Health Services of Trieste, ASUGI, University of Trieste (Trieste); [2]Department of Neurosciences, Neurology Operative Unit, Hospital S. Chiara of Provincial Authority for Health Services of Trento, APSS, University of Trento (Trento)

Purpose: Hemiplegic migraine (HM) is a rare subtype of migraine with aura, characterized by motor weakness as aura manifestation, often accompanied by impairment in vision, speech, or sensation. Symptoms typically last 4–72 hours. HM is a clinically and genetically heterogeneous condition that can simulate more severe neurological diseases like stroke. The familial variant is associated with 3 main genes (CACNA1, ATP1A2, SCN1A) [1]. The mechanism of cortical spreading depression (CSD) for the development of the aura is known, however there are few data regarding a possible concomitant cardiac involvement. Materials: We report a case of familial hemiplegic migraine with prolonged motor-sensitive aura lasted 21 days, showing also cardiac involvement.

Methods: We performed a Pubmed search using the following MeSH terms "(Hemiplegic migraine) AND (electrocardiographic

changes)", looking for articles in which influence of CSD on heart rate has been explained.

Results: A 24-year-old girl was admitted to the ED of the Hospital of Trento with an acute onset of right hemiparesis, right lateral hemianopia and aphasia, concomitant severe headache. She had a past history of paediatric hospitalizations for questionable clear liquor encephalitis with symptoms of right motor-sensory hemiplegia and aphasia. At the time of admission, brain CT scan, CT angiography and MRI perfusion did not show any focal lesion, vessel occlusion or areas of restricted diffusion on diffusion-weighted imaging sequences. In the suspicion of a HM she was kept under observation and treated with Methylprednisolone 100 mg/kg/day [2]. Cardiac involvement was immediately suspected as she presented significant hypotension, bradycardia (35 bpm) and T-wave abnormalities. Troponin levels and echocardiography didn't show any abnormalities. The patient's symptoms persisted with mild improvement of the aphasia for 21 days. The ECG, on discharge, was characterized by negative T waves in the anterolateral and inferior areas. Heart MRI was normal. Genetic analysis was positive for the SCN1A gene.

Discussion: We report the case of HM and concomitant cardiac involvement. In literature, there are no direct correlations between HM and cardiac involvement, less is known about how long the ECG changes last after aura resolution and whether there are any permanent changes [3]. A mechanism linked to the membrane channels involved both in the brain and in the heart has been postulated.

Conclusions: HM is an uncommon subtype of migraine; it would be interesting to study whether this syndrome could also be considered a heart-brain syndrome as a univocal entity.

## PREDICTORS OF EARLY EFFICACY OF MONOCLONAL ANTIBODIES THERAPY IN MIGRAINE: INVESTIGATING THE CENTRAL ROLE OF GCRP THROUGH STRUCTURAL EQUATION MODELLING

A. Marcinnò, F. Roveta, S. Boschi, E. Piella, F. Ferrandes, G. Grassini, I. Rainero, E. Rubino

Department of Neurosciences "Rita Levi Montalcini", University of Turin (Torino)

Aim: Migraine represents nowadays one of the leading causes of disability and loss of working days in the world. Innovative therapies targeting the CGRP signaling opened and established a new era in preventive treatment of migraine. Post marketing efficacy evidences are convincing, although a large variability in treatment response could be observed. Emerging evidences suggest a role of circulating factors to unravel the neurobiological causes of this variability. This study aim to combine the use of baseline biochemical (plasmatic neuropeptides) and clinical factors to develop a prediction model of response to anti-CGRP monoclonal antibodies (mAbs).

Materials: We enrolled 41 patients (34 females, 7 males; age 52.16 ± 12.47 years; 24 diagnosed with chronic migraine, and 17 with episodic migraine) who started mAbs therapy (7 Erenumab, 17 Galcanezumab and 17 Fremanezumab). During the first visit (T0) they underwent plasmatic CGRP, Orexin-A (OxA) and PACAP-38 measurement and collection of clinical-anamnestic information. The clinical course was re-evaluated at 3 months (T3), based on monthly migraine days (MMD), monthly medication use, mean pain intensity (NRS) and MIDAS.

Methods: Data were analyzed by S.E.M. (Structural Equation Modeling) to develop a predictive model of treatment response based on T0 clinical and biochemical characteristics. This multivariate analysis defines new composite variables (called latent variables) through quantitative relationships with the observed variables. Thus, we obtained the latent variables NeuP, i.e. "Neuropeptides" (CGRP, PACAP-38 and Orexin-A) and MigBurd T0 i.e. "Migraine burden" (MIDAS and MMD at T0). Then, via S.E.M., we correlated them with T3 clinical outcome.

Results: CGRP plasmatic concentration at T0 emerged as a unique independent predictor of therapeutic response at T3 through direct correlation with MMD (100 pg/ml per 1,7 MMD at T3; $p = 0.032$). Through S.E.M. we found a similar correlation also with monthly medication use and MIDAS at T3. The latent variable MigBurd T0 was directly correlated with all three above mentioned parameters, while baseline CGRP prevailed over NeuP latent variable as predictor of MMD and MIDAS at T3.

Discussion and conclusions: The neurobiological setting may be crucial in the variability of clinical response to mAbs therapy even in the short term (first trimester). Though further data are needed to generalize these results, the present study confirms our previous findings about the predictive role of baseline GCRP plasmatic concentration in the context of preventive anti-CGRP therapy.

## HYPOTHALAMIC INVOLVEMENT IN THE MIGRAINE CYCLE: A TASK-FREE FMRI ANALYSIS DURING NITROGLYCERIN-INDUCED ATTACKS

D. Martinelli[1], M. Pocora[1], R. De Icco[1], M. Allena[2], A. Bacila[3], G. Sances[2], A. Pichiecchio[4], G. Castellazzi[2], C. Tassorelli[1]

Mondino Foundation (Pavia); [3]Neuroradiology Unit, IRCCS C. Mondino Foundation (Pavia); [4]Neuroradiology Unit, IRCCS C. Mondino Foundation, Department of Brain and Behavioural Sciences, University of Pavia (Pavia)

Objective: The hypothalamus plays a crucial role in migraine pathophysiology, contributing to pain perception modulation, circadian rhythm disturbances, autonomic dysfunction, and neuroendocrine alterations. [1] In this resting-state functional magnetic resonance imaging (rs-fMRI) study, we assessed the relationship between the hypothalamus and the cortex during various phases of a nitroglycerin-induced migraine attack (NTG).

Material and Methods: Ten episodic migraine patients (EM) and 10 healthy controls (HC) underwent 3T MRI scans during subsequent phases of the NTG migraine attack (baseline, prodrome, full-blown attack, recovery). A seed-based correlation analysis assessed the relationship between the hypothalamus and the cortex during the different phases of the attack in EM and at pre-specified time points in HC. A comparison between each scan and the baseline (pain-free) condition was performed, also testing whether there was a correlation between mean functional connectivity (FC) and anamnestic features.

Results: At baseline, compared to HC, EM presented a reduced FC between the hypothalamus and supramarginal gyrus, middle frontal gyrus and angular gyrus, and left crus II; FC was increased with the posterior cingulate cortex. No significant FC changes were detected during the prodromal phase when compared to the pain-free condition at baseline. In the full-blown phase instead, EM expressed increased FC between the hypothalamus and right frontal lobe (orbitofrontal and

middle frontal gyrus, frontal pole), pons and crus II. These alterations persisted during the painful and the recovery phases. The FC alteration observed during the full-blown phase correlated with the presence of nausea in EM at the time of the scan.

Discussion: These findings help to highlight the disease-specific and phase-specific contribution of the hypothalamus in migraine attacks [2]. In our experimental setting, the hypothalamus did not show a role in attack initiation, given the lack of changes observed in the prodromal phase. Contrary, during the ictal phase of the attack, the disruptions in the FC between the hypothalamus and the frontal lobe may contribute to pain perception, autonomic dysfunction, such as nausea, and emotional disturbances, which persist over the painful experience. The hypothalamus relationship with the crus II suggests the role of this latter in pain processing, modulation of pain perception, and integration of sensorimotor information, possibly playing a crucial role in the definition of the attack end.

Conclusions: fMRI studies [3] have shown increased hypothalamic activation during migraine attacks, suggesting its involvement in generating pain. This study focuses on its role in pain maintenance and its impact on the autonomous system.

## THE REGIONAL OUTREACH PROGRAMME OF THE INTERNATIONAL HEADACHE SOCIETY IN SUB-SAHARIAN AFRICA IN PARTNERSHIP WITH THE DREAM PROGRAM: FIRST ON-SITE COURSE IN MALAWI

D. Martinelli[1], C. Tassorelli[1], F. Dodd-Glover[2], M. Matharu[3], D. Uluduz[4], V. Tolno[5], G. Guidotti[6], M. Leone[7]

[1]Headache Science and Rehabilitation Center, IRCCS C. Mondino Foundation, Department of Brain and Behavioural Sciences, University of Pavia (Pavia); [2]Department of Neurology, Korle Bu Teaching Hospital (Accra-GH); [3]Headache and Facial Pain Group, UCL Queen Square Institute of Neurology and National Hospital for Neurology and Neurosurgery (London-UK); [4]Neurology Department - 5Istanbul University, Cerrahpasa School of Medicine (Istanbul-TR); [5]Blantyre, Dream Program (Blantyre-MW); [6]Dream Program, Sant'Egidio Comunity (Roma); [7]Neuroalgology Unit, IRCCS C. Besta, Dream Program (Milano)

Objectives: Recent studies confirm that headache disorders are highly prevalent in sub-Saharan Africa (SSA) countries as Malawi [1]. Due to doctors' shortage in SSA, primary care non-physician clinicians (NPC, called clinical officers, (CO)) provide most of the care to the population but their education on headaches is poor. In November 2022, the Regional Outreach Programme of the International Headache Society (IHS) organised the first on-site teaching course in Malawi "Headache, head pain syndromes, migraine and related disorders" in partnership with the Disease Relief through Excellent and Advanced Means (DREAM) program to improve CO headache education and headache management in SSA.

Material: A 2-day course was organised in Blantyre, Malawi, and was attended by COs from several primary care facilities. The teaching modules foresaw a high degree of interaction with the audience; the treatment approach was focused on the use of the WHO list of essential drugs. The final session involved the group discussion of multiple clinical cases.

Methods: Here we report the results of a survey to evaluate the participants' education and needs, and their knowledge about headache before and after the course.

Results: Thirty-four CO (10 women), who had been practising medicine for an average of 9 years, participated (median age 37 years; median duration of education 3 years). The pre-course survey highlighted the lack of proper training and experience in neurology, headache and pain. After the course, trainees demonstrated much-improved knowledge of both neuroanatomy and headache science as well as skills in differential diagnosis and treatment of primary and secondary headaches. The trainees were highly satisfied and appreciated the lectures and the provided practical tips. They strongly recommended the course and wished to change their approach to headache patients.

Discussion: In Malawi, there are no teaching courses on headache disorders notwithstanding their high prevalence. Our study shows that tailored teaching courses improve headache knowledge of primary healthcare CO. Comprehensive CO training in diagnosing and managing headaches effectively is a crucial step to address the huge treatment gap of highly prevalent non-communicable diseases in SSA.

Conclusions: The partnership between the IHS and the DREAM program in Malawi is effective in providing headache education at the primary care level where most patients are seen and managed. Long-term follow-up, tailored task-shifting and task-sharing are necessary. The IHS-DREAM program in SSA adheres to and contributes to the objectives of the WHO Intersectoral Global Action Plan. [2]

## WHEN A CAVERNOUS ANGIOMA MIMICS MIGRAINE: A CASE REPORT

F. P. Mazzeo, M. Gentile, A. La Neve, D. Paolicelli, M. Prudenzano

Department of Translational Biomedicine and Neuroscience (DiBraiN), University of Bari "Aldo Moro" (Bari)

Background: Cavernous angioma (CCM) is a cerebral vascular malformation that may occur sporadically or in a familial pattern, characterized by clusters of dilated, thin-walled blood vessels. CCMs are often asymptomatic, but they can occasionally present with seizures, focal neurological deficits, and headache, with or without associated hemorrhage.

Case report: A 37-year-old man, with unmarkable medical history except for detection of MORC2 mutation, of which the patient is a healthy carrier, had never experienced headaches until the age of 30, when the first sporadic episodes of throbbing headache appeared. The pain started in the right temporo-occipital region, radiating bilaterally to the frontotemporal regions, more severely on the right side, and was accompanied by photophobia, phonophobia, sometimes nausea, vomiting, dizziness. The first pain episodes were responsive to medical therapy, occurring approximately five times a year in the absence of clear triggering factors. On prescription from the family doctor the patient underwent an electroencephalogram reporting normal results. The last two episodes, that lasted approximately 3 days, were more severe and disabling and they were followed by intense fatigue, photophobia, and objective vertigo forcing the patient to stay in bed for a week. After a few days from the last episode, the patient underwent neurological consultation. Neurological examination was unmarkable.

A brain magnetic resonance imaging (MRI) showed a right temporal region cavernoma with signs of recent intracerebral hemorrhage.

Discussion: The first headache episodes were suggestive of migraine without aura. Due to the sporadic occurrence of the episodes and the good response to medical therapy, further diagnostic investigations were not performed. However, some atypical characteristics, such as persistent fatigue and an increase in severity prompted further investigation with MRI. The identification of a cavernous angioma in the right temporal region explained the patient's symptoms. Reports of isolated cases suggest that some cavernous angiomas can trigger migraine-like attacks. In a series of 126 symptomatic patients with cavernous angioma and KRIT1 mutation, only 4% reported headache as a presenting symptom, while headaches are commonly reported as a consequence of cerebral hemorrhage or epileptic seizures in patients with cavernous angiomas.

Conclusions: This case report highlights the importance of considering alternative diagnoses in patients presenting with atypical or refractory migraine symptoms. CCMs can mimics migraine, leading to diagnostic challenges. MRI plays a critical role in identifying structural lesions and ensuring appropriate management.

## DENTATE NUCLEUS CAVERNOMA AS A CAUSE OF TINNITUS AND VERTIGO: A CASE REPORT

C. Messina, A. Salerno, E. Ferraro, F. Patti, M. Zappia

Department GF Ingrassia, Section Neuroscience, University of Catania (Catania)

The dentate nucleus is the largest deep cerebellar nucleus. It is responsible for the planning, initiation and control of voluntary movements, but it also involved in nonmotor function, such as cognition and visuospatial function. Furthermore, it represents a short-latency relay of a primary auditory transmission pathway since cochleovestibular fibers pass through this station to go to the contralateral side of the auditory cortex. Consequently, every damage affecting dentate nucleus could potentially cause contralateral auditory problems such as tinnitus. In this paper, we report the case of a patient presenting 10-year-lasting tinnitus caused by a dentate nucleus cavernoma. A 33-old-year woman suffering from arterial hypertension was admitted to our clinic because of a left tinnitus for ten years and history of headache. In the last three months, she also complained daily transitory episodes of vertigo. Her neurological exam, blood tests and audiological and vestibular assessment were unremarkable. Brainstem Auditory Evoked Potentials did not show any alterations. Brain Magnetic Resonance Imaging (MRI) showed a circular signal of hyperintensity in Fluid Attenuated Inversion Recovery (FLAIR) sequences and spotting hypointensity inside the area of the lesion in Gradient Echo (GRE) sequences affecting the right dentate nucleus; brain imaging did not highlight the presence of gadolinium enhancement. MRI allowed us to make a diagnosis of tinnitus secondary to a contralateral dentate nuclei cavernoma, probably complicated with vertigo due to a blood pressure peak in the last months which had caused bleeding of the lesion. This is the first reported case of dentate nucleus cavernoma presenting with tinnitus and vertigo. We hypothesize that tinnitus and vertigo were due to the selective involvement of the cochleovestibular fibers. We suggest the clinician to consider a pathological involvement of the dentate nucleus in case of vertigo or tinnitus.

Objective: Monoclonal antibodies targeting the calcitonin gene-related peptide (CGRP) pathway, like erenumab, are believed to prevent migraine attacks via the block of CGRP activity in the periphery. In this study, we explored the effect of erenumab treatment on the functional connectivity (FC) of brain networks involved in migraine and investigated the persistence of such an effect following treatment discontinuation.

Materials: This was a randomized, double-blind, placebo-controlled, multicenter trial with a crossover design performed in adult episodic migraine patients with previous treatment failure. Patients were randomized (1:1) to 12 weeks of treatment with erenumab 140 mg or placebo, followed by a 12-week crossover. Clinical and safety outcomes were assessed every 4 weeks.

Methods. Resting state (RS) FC changes of brain networks were investigated at baseline, week 12 and week 24 using a seed-based correlation approach.

Results: Sixty-one patients were enrolled and randomized to treatment. In each treatment sequence, 27 patients were included in the analyses. We observed a carry-over effect of erenumab treatment on

clinical and MRI variables during the placebo treatment and therefore data analysis was performed as a parallel comparison of erenumab vs placebo for the first 12 weeks of treatment. From baseline to week 12, compared to placebo, patients receiving erenumab showed RS FC changes within the cerebellar, thalamic and periaqueductal gray matter networks, significantly associated with clinical improvement. Compared to non-responders, patients achieving a 50% reduction in migraine attack frequency had distinct patterns of thalamic and visual network RS FC. Brain RS FC changes tended to revert when erenumab was stopped. A lower baseline RS FC of the pontine network identified patients responding to erenumab. No safety concerns emerged during the study.

Discussion: This study showed that in episodic migraine the clinical efficacy of a 12-week erenumab treatment is associated to RS FC changes within clinically relevant brain networks mediating migraine manifestations. In line with previous clinical studies, we showed that ereunmab-related brain functional changes are temporary and tend to revert when erenumab is stopped.

Conclusion: Erenumab modulates RS FC of networks involved in migraine pathophysiology. These functional changes are temporary and strictly related to erenumab administration. Funding. Novartis Pharma Acknowledgments. The authors thank Donatella Vassellatti of Novartis Farma for the oversight of all the aspects related to the conduction of the clinical study and OPIS for providing clinical trial support as CRO assigned to the study.

## EFFICACY OF MINDFULNESS ADDED TO TREATMENT AS USUAL IN PATIENTS WITH CHRONIC MIGRAINE AND MEDICATION OVERUSE HEADACHE: A RANDOMIZED CLINICAL TRIAL, EARLY RESULTS

D. A. Montisano[1], L. Grazzi[1], D. D'amico[1], D. Montisano[2], E. Guastafierro[3], B. Del Corso[4], A. Raggi[3]

[1]Neuroalgology Dpt, Headache Centre, Besta Foundation (Milano); [2]Headache Center, Foundation IRCCS Institute Carlo Besta (Milano); [3]Neurology, Public Health and Disability Unit, Besta Foundation (Milano); [4]Neuroscience Institute, National Research Council (Padova)

Objective: To assess the efficacy of a six-session mindfulness-based treatment added to treatment as usual (TaU) on headache frequency reduction and medication intake.

Materials: 177 patients from the third-level headache center IRCCS "C. Besta", with Chronic Migraine and Medication Overuse Headache (CM and MOH) were enrolled in between November 2018 and December 2021.

Methods: This is a phase-III single blind RCT single-center study. Patients were randomized 1:1 to either TaU or mindfulness added to TaU (TaU+MIND) and followed-up for 12 months. Exclusion criteria were psychiatric comorbidities; pregnancy; secondary headaches; withdrawal from MOH at least twice in the previous two years; previous experience with mindfulness. TaU consisted of withdrawal from overused drugs, patients' education, and prescription of prophylaxis. Patients attending mindfulness sessions were taught to focus their attention on the present and enhance awareness of body sensations, which enabled tackling the pain-pill automatism, and were encouraged to engage in a 7-10 minute/day self-practice. The primary endpoint was the achievement, at 12 months of ≥50% headache frequency reduction compared to baseline. Secondary endpoints included medication intake.

Results: Out or the 177 participants (median age 47.9 years [Q1-Q3: 40.1-54.2]; 19 [11.3%] males; median CM duration 14.6 years [Q1-Q3: 4.9-22.2]) 89 were randomized to TaU and 88 to TaU+MIND. Patients in the TaU+MIND group outperformed those in TaU for the primary endpoint, achievement of ≥50% headache frequency reduction (78.4% vs 48.3%; $p<0.0001$). They also showed superiority in some secondary endpoints, namely headache frequency and medication intake.

Discussion: Our results demonstrated that adding on a mindfulness-based protocol to TaU implemented for the treatment of CM associated to MOH produced a superior and statistically significant reduction in headache frequency, all-drug intake and NSAIDs intake.

Conclusion: These findings show that a six-week mindfulness-based treatment as add on to TaU is superior to TaU for the treatment of patient with CM and MOH.

## FEASIBILITY AND EFFECTIVENESS OF A SPECIFIC APP TO DELIVERY MINDFULNESS SESSIONS TO PATIENTS WITH DIFFERENT KINDS OF PAIN CONDITION: A PILOT STUDY

D. A. Montisano[1], L. Grazzi[1], D. Montisano[1], I. Frigione[2], M. Marra[2], F. Lombardi[2], A. Maravita[2]

[1]Neuroalgology Dpt, Headache Centre, Besta Foundation (Milano); [2]Department of Psychology, University of Milan Bicocca (Milano)

Objective: Chronic pain is a difficult condition to manage, affecting a significant percentage of population; in particular, neuropathic pain and chronic migraine are problematic diseases that imply disability, medication overuse and low response to preventive pharmacological therapies. Clinical results can be improved when traditional therapies are combined with behavioral approaches, in particular mindfulness, that help patients to become more conscious about their symptoms and able to manage pain avoiding medications. Also, this practice can be effective to reduce anxiety related to pain condition. In the last years different clinical experiences reported that intervention like advice or brief interview and education of patients and behavioral approaches like mindfulness can improve significantly clinical benefit and the efficacy of pharmacological treatments, also in telemedicine or web modality. Mindfulness in particular is a perfect tool for patients to learn management of pain, to be educated to the adequate use of medications, to arrange correct life habits that can improve wellbeing and good health.

Material and Methods: We propose a pilot study to enforce the application of a Home-program for patients with pain conditions, to learn mindfulness practice, by using technology with android to deliver mindfulness sessions for daily practice. This study has been conducted on 60 patients (30 naïve for mindfulness practice; 30 familiar with mindfulness practice) with diagnosis of Neuropathic Pain or Chronic Migraine, diagnosis performed at our institute after a regular visit at our hospital. They received a specific APP for mindfulness practice on their phone. Daily standardized guided 12-minutes mindfulness sessions delivered on mobile phones recorded by the experts who generally manage sessions at the hospital. Patients have been evaluated for different outcomes.

Adherence: patients have been asked to practice every day by recording time of their practice; adherence tested and measured a specific questionnaire (MORISKY scale for adherence -adapted for this study). Moreover, FFMQ questionnaire to determine mindfulness competence (Baer, 2006) before and after the APP application. SUS scale: the usability scale (Brooke, 1996) to measure the usability of the APP. GSE: global self-efficacy questionnaire (Scholz, 2002; Sibilia, 2021). Pain level (NRS scale) and Medication intake on the daily diary. The outcomes have been evaluated at the end of the training at 2 months.

Conclusions: Data collected demonstrated that the APP is an effective and helpful tool to reduce pain and to induce the adherence the mindfulness practice.

## HEADWORK AS INNOVATIVE TOOL FOR MONITORING MABS EFFICACY IN MIGRAINE AND THEIR INFLUENCE ON WORK ACTIVITY: A MULTICENTRIC EXPERIENCE

D. A. Montisano[1], G. Vaghi[2], A. Raggi[1], G. Sances[3], C. Tassorelli[2], C. Altamura[4], F. Vernieri[4], C. Ferrarese[5], L. Grazzi[1]

[1]Neuroalgology Dpt, Besta Foundation (Milano); [2]Headache Center, Foundation IRCCS Mondino (Pavia); [3]Headache Center, Foundation IRCCS Institute Carlo Besta (Pavia); [4]Headache Unit, Campus Biomedico (Roma); [5]Neurological Clinic, Bicocca University (Milano)

Objective: The efficacy of monoclonal antibodies (mAbs) anti-CGRP is generally rated with disease related metrics, but the impact of treatment on the global burden of disease needs to be assessed. HeadWork (HW) is a new evaluation tool developed to assess the impact on work tasks and reduced productivity of migraineurs. Aim of this study is to test the validity of HW and to compare its performance with usually used clinical indexes.

Materials: We enrolled 108 patients receiving mAbs treatment at the Headache Centres of IRCCS C. Besta (Milan), IRCCS C. Mondino (Pavia) and Campus-Biomedico (Rome).

Methods: Patients were followed up on a three-month basis, at each time point they filled in diaries about headache frequency (MMD), medication intake (MMI) and HW. HW questionnaire consists of two sections: "Work-related difficulties"(HW1), 11 items dealing with the degree of difficulty in general skills, problems solving or starting new task; "Factors contributing to work-related difficulties"(HW2), 6 items to address the degree to which some factors, such as noise and brightness of the workplace, negatively impact work-related tasks. Friedman and Wilcoxon repeated measure tests were used for the analysis ($p<.005$). We assessed the presence of a correlation between T0-T3 and T0-T6 deltas with SpearmanRho.

Results: 108 patients (79%females, age 50y±9, disease duration 16±8, age at onset of disease 18y±8) completed the 6-months evaluation. For each of the parameters a significant reduction was observed in the first three and six months of treatment ($p<.001$). MMD decreased from 16.8±6.5 days to 8.1±6.2; MMI from 17.8±9.7 to 7.8±6.5; HW1scale from 23.8±10.5 to 15.2±10.0; HW2scale from 11.3±6.3 to 8.1±5.4. 60 patients out of 108(56%) reduced monthly headaches by 50% or more, and 29(27%) by 75% or more. Correlation for HW1 is moderate and significant with deltas 0-3 and 0-6 for MMD and MMI; for HW2 it is significant for 0-3 changes for MMD, and only with MMI for 0-6 change.

Discussion: Our results confirm the strong efficacy of mAbs as early as 6 months of treatment. HW has a parallel reduction with indexes usually used to monitor treatment efficacy in clinical practice, suggesting good reliability and fidelity. We observed that the reductions in headache frequency, medication intake and HW scales were generally moderately correlated: although a causal direction cannot be stated, it is reasonable to presume that improvement in work-related activities might be due to improved clinical course.

Conclusion: HW seems can evaluate the effectiveness of these treatments on work productivity.

## REAL-WORLD EFFECTIVENESS OF ANTI-CGRP MONOCLONAL ANTIBODIES COMPARED TO ONABOTULINUMTOXINA. THE RAMO STUDY: EARLY RESULTS

D. A. Montisano[1], D. Montisano[1], R. Giossi[2], M. Cenella[3], C. Altamura[4], M. Vernieri[4], C. Ferrarese[5], L. Grazzi[1]

[1]Neuroalgology Dpt, Headache Centre, Besta Foundation (Milano); [2]Analisi Chimico Cliniche, ASST Ospedale Metropolitano Niguarda (Milano); [3]Headache Center, Besta Foundation (Milano); [4]Headache Unit, Campus Biomedico (Roma); [5]Neurological Clinic, Bicocca University (Milano)

Objective: Chronic migraine (CM) is a disabling condition with huge impact on the quality of life. OnabotulinumtoxinA (BoNT-A) is an effective treatment for CM. Recently, monoclonal antibodies (mAbs) against calcitonin gene related peptide (anti-CGRP) pathways have been approved to. Aim of this study is to compare the effectiveness and safety of anti-CGRP mAbs and BoNT-A after 6 and 12 months of treatment.

Materials: We enrolled patients from IRCCS Neurologic Institute C. Besta and Bio-Medic Campus University.

Methods: This is an interim, preliminary analysis, of an ongoing retrospective, observational, multicentre, cohort study. Inclusions criteria: diagnosis of CM, received anti-CGRP mAbs or BoNT-A, with at least 6 months follow-up, age 18-65y≥2 preventive treatment failures, starting MIDAS ≥11. Exclusion criteria: serious psychiatric diseases, received BoNT-A before anti-CGRP mAbs treatment (for mAbs arm). Study outcomes: difference from baseline in monthly migraine days (MHD), number of monthly acute medications (MAM) and MIDAS.

Safety assessment: report of serious adverse events (SAE), treatment discontinuation. Wilcoxon rank-sum and Fisher's exact tests were used for the analyses($p<0.05$).

Results: At the time of this interim analysis, we screened 140 patients:110 included,43 mAbs arm,67 BoNT-A arm. Population: mean age 51.1(8.6) y,80 female,90 medication overuse (non-significant differences between groups). At baseline the BoNT-A group presented significantly higher mean MHD (23.0[6.3]vs17.4[32.2]), MAM (24.1[13.7]vs16.5 [2.8]), and MIDAS (93.0[66.8]vs55.6[36.8]) compared to mAbs group. MHD reduction was significantly greater in the mAbs group (-12.4[4.8]vs -9.0[8.8]) at 6 months compared to BoNT-A. Adverse events'(AE) discontinuation: 1(4.8%) patient mAbs arm, 3(4.5%) patients BoNT-A arm.

Discussion: Our preliminary results show a comparable effectiveness between mAbs and BoNT-A at 12months follow-up, with significantly higher efficacy for mAbs at 6 months. Discontinuation due to AE were similar.

Conclusion: From these preliminary data the effectiveness and sustainability of the two treatments appear to be overlapping.

## BENEFIT-RISK ASSESSMENT OF ATOGEPANT: A POST HOC ANALYSIS OF THE ADVANCE TRIAL

S. Nahas[1], J. Ailani[2], P. McAllister[3], R. Halker Singh[4], R. Lipton[5], J. Ma[6], P. Gandhi[6], D. Cazzorla[7], J. Smith[8], Y. Liu[8], N. Chalermpalanupap[6], B. Dabruzzo[6]

[1]Department of Neurology, Jefferson Headache Center, Thomas Jefferson University (Philadelphia-USA); [2]Department of Neurology, MedStar Georgetown University Hospital (Washington-USA); [3]New England Institute for Neurology & Headache (Stamford-USA); [4]Department of Neurology, Mayo Clinic (Scottsdale-USA); [5]Department of Neurology, Albert Einstein College of Medicine (Bronx-USA); [6]AbbVie (Madison-USA); [7]AbbVie, University of Tor Vergata (Roma); [8]AbbVie (North Chicago-USA)

Objectives: The number needed to treat (NNT) and number needed to harm (NNH) are clinically relevant measures of treatment efficacy and safety, and can help inform treatment decisions. The NNT and NNH for atogepant for the preventive treatment of migraine have not yet been reported. This analysis aims to determine the NNT and NNH for atogepant for the preventive treatment of episodic migraine (EM).

Materials: Atogepant is an oral calcitonin gene–related peptide receptor antagonist approved for the preventive treatment of EM in adults. NNT and NNH are clinically relevant assessments of effect size that can inform management. The Migraine-Specific Quality of Life Questionnaire (MSQ v2.1) Role Function-Restrictive (RFR) domain assesses impacts of migraine on daily functioning that are important to people with migraine.

Methods: The ADVANCE trial (NCT02848326) was a 12-week, randomized, double-blind, placebo-controlled trial that evaluated the efficacy and safety of atogepant for the preventive treatment of EM. The NNT was calculated based on achievement of a $\geq$50% decrease in mean monthly migraine days (MMDs) (NNT$\geq$50%) across 12 weeks. A second NNT was calculated based on achievement of a $\geq$10.9-point clinically relevant improvement from baseline in MSQ-RFR score (NNTMSQ-RFR) at week 12. NNH was calculated using the proportion of participants reporting a treatment-emergent adverse event (TEAE) leading to discontinuation.

Results: A 50% reduction of MMDs from baseline was achieved by 56%-61% of atogepant participants versus 29% of placebo participants. The calculated NNTs$\geq$50% for atogepant 10 mg, 30 mg, and 60 mg were 3.8, 3.4, and 3.1, respectively. The NNTsMSQ-RFR for the atogepant dose groups were 5.9, 5.7, and 6.3, respectively. TEAEs leading to discontinuation in participants treated with atogepant 10 mg, 30 mg, and 60 mg were reported by 4.1%, 1.8%, and 2.6% of participants, respectively, versus 2.7% of placebo-treated participants. The NNH was 73.0 for atogepant 10 mg. In the atogepant 30 mg and 60 mg dose groups, a lower percentage of participants discontinued versus placebo, resulting in negative NNT calculations ($-105.5$ and $-949.7$, respectively).

Discussion: These findings show a positive benefit-risk profile with atogepant for the preventive treatment of EM.

Conclusions: Atogepant has demonstrated efficacy in the preventive treatment of migraine. As measured by NNT and NNH, a positive benefit-risk profile is associated with atogepant.

## MESOCORTICOLIMBIC FUNCTIONAL CONNECTIVITY DYSREGULATIONS IN CHRONIC AND EPISODIC CLUSTER HEADACHE PATIENTS

A. Nigri[1], G. Demichelis[1], D. Fedeli[1], G. Ciullo[1], J. Medina Carrion[1], M. Bruzzone[1], B. Becker[2], L. Chiapparini[1], A. Erbetta[1], A. Cecchini-Proietti[3], L. Giani[4], S. Ferraro[2], M. Leone[3]

[1]Department of Neuroradiology, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [2]School of Life Science and Technology, MOE Key Laboratory for Neuroinformation, University of Electronic Science and Technology of China (Chengdu-CN); [3]Neuroalgology Unit and Headache Center, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [4]Neurology Unit, Istituti Clinici Scientifici Maugeri IRCCS (Milano)

Aims: Cluster headache is a primary neurovascular headache characterized by excruciating short-lasting unilateral craniofacial pain episodes associated with autonomic oculofacial phenomena. The hypothalamus has been shown to play a major role in the pathophysiology of the disease even if underlying mechanisms need to be better clarified. Converging evidence suggests that functional alterations of the dopaminergic mesocorticolimbic system plays a role in onset and chronification process of pain disorders [1]. Our aim was to study the functional connectivity alterations of the mesocorticolimbic system in both forms of cluster headache (CH), chronic (cCH) or episodic (eCH) CH.

Materials: 24 cCH patients (4 F), 45 eCH patients (6 F) and 26 matched adult healthy controls (CTRL) (5 F) were scanned with a 3T scanner using a rs-fMRI sequence.

Methods: Functional data were analysed with CONN toolbox. The MRI images of patients with attacks on the right side were flipped on the left side. Region of interest (ROI)-to-ROI analyses were performed to investigate connectivity differences between patients and controls in the following structures of mesocorticolimbic system: Frontal Pole, Medial Frontal Cortex (MFC), Frontal Orbital Cortex, Hippocampus, Amygdala, Nucleus Accumbens, Ventral Tegmental Area (VTA) and Hypothalamus. Age and sex were considered as covariates. All results were $p<0.05$ FDR-corrected for multiple comparisons.

Results: In cCH patients we observed decreased connectivity between bilateral hypothalami and the ipsilateral-to-the-pain hippocampus and amygdala, and between frontal regions and the ipsilateral hippocampus and controlateral amygdala compared with CTRL; increased connectivity was observed between the VTA and controlateral-to-the-pain hippocampus and amygdala. In eCH patients, with respect to CTRL, we observed reduced connectivity between the hypothalami and the ipsilateral-to-the pain hippocampus-amygdala complex, and between the MFC and bilateral hippocampi and amygdalae; increased connectivity was observed between VTA and controlateral hippocampus. No differences between eCH and cCH were observed.

Discussion: The present study confirms previous findings of disrupted connectivity between the hypothalamus and brain areas of the mesocorticolimbic circuit in CH [2]. This suggests an imbalance of frontal areas control over dopaminergic pathways [3]. In addition, cCH patients showed specific abnormalities consisting of increased VTA-amygdala connectivity: the latter finding may represent a signature of the disease chronification.

Conclusion: In this study, we confirmed a mesocorticolimbic connectivity dysregulation in both episodic and chronic cluster headache patients.

## CEREBRAL VENOUS SINUS STENTING IN INTRACRANIAL IDIOPATHIC HYPERTENSION: AN INSTRUCTIVE CASE REPORT

M. Olivero[1], C. Manfredi[1], V. Ercolano[1], R. Ronco[1], G. Torregrossa[2], C. Rosci[1], L. Valvassori[3], A. Priori[1]

[1]Clinical Neurology Unit, San Paolo University Hospital (Milano); [2]Eye Clinic, San Paolo University Hospital (Milano); [3]Department of Neuroradiology, San Carlo Borromeo Hospital (Milano)

Introduction: Idiopathic intracranial hypertension (IIH) or pseudotumor cerebri is characterized by clinical findings of intracranial hypertension in the absence of an alternative cause [1]. Despite the usually benign course, IIH can lead to significant morbidity, above all visual loss [1]. The standard treatment includes lifestyle changes, weight loss and intracranial pressure lowering medications, but invasive procedures, such as spinal fluid diversion, optic nerve sheath fenestration or venous sinus stenting may be needed in severe or refractory cases [2, 3].

Case presentation: A 28-year-old female presented at Emergency Department for the subacute onset of diplopia and neck pain irradiated to the left hemicranium. She had a normal BMI, had never smoked nor taken any estroprogestinic medications, tetracycline or vitamin A-derived drugs. Neurologic examination showed diplopia in distant fixation and bilateral abducens palsy. Neurophthalmological evaluation revealed bilateral papilledema and alternating esotropia without visual loss. Cerebral computerized tomography (CT) was normal, while cerebral CT angiography revealed reduced caliber of transverse venous sinuses; magnetic resonance (MR) brain imaging with gadolinium was normal. We performed a lumbar puncture in lateral decubitus and we withdrew 5 ml of cerebrospinal fluid (CSF), detecting an opening pressure of 30 mmHg and a closure one of 15 mmHg. Thus, we made diagnosis of IIH. Notwithstanding the starting of medical treatment with acetazolamide, there was a further clinical deterioration. Cerebral venography with venous pressure measurement was executed, showing bilateral transverse sinuses stenosis with a trans-stenosis pressure gradient of 29 mmHg on the right and 39 mmHg on the left. The right transverse venous sinus, being the dominant, was the one chosen for the endovascular stenting procedure. Whereupon cerebral venous pressure values normalized. At one-month outpatient follow-up, the patient reported improvement of symptoms, neurological examination was normal and papilledema decreased.

Discussion: We report a case of pseudotumor cerebri with finding of venous sinus stenosis undergoing stenting, followed by clinical benefit. There is a debate regarding whether venous sinus stenosis is consequence or cause of increased intracranial pressure and the role of sinus venous stenting is still unsettled [2, 3].

Conclusions: In cases of IIH showing scarce response to medical treatment and venous sinus stenosis on non-invasive neuroimaging, a cerebral venography with venous pressure measurement should be conducted and cerebral venous stenting could be beneficial.

Objective: The Italian Migraine Registry (I-GRAINE) is the first nationwide clinical registry whose core mission is to provide big data on migraine, detailing sociodemographic aspects, patient's journey, disease characteristics and governance, and healthcare resource use. Here, we describe the second annual I-GRAINE report.

Material and Methods: I-GRAINE is an observational, prospective, multicenter (n = 39), non-interventional study. Adults affected by episodic or chronic migraine, seen at each participating headache center, were enrolled. For each outpatient day, the first incident patient (first visit) and the first prevalent patient (follow-up visit), were recruited according to the "systematic random" method. Detailed patient's information was collected by a specifically trained board-certified neurologist using a shared web-based questionnaire.

Results: At the date of 31/12/2022, a total of 867 patients were enrolled (M/F:126/741; age 45.0±12yrs; EM/CM:718/149; medication overuse:131). Most of them had > high school degree (86.8%) and were employed/students (75.7%). Only 8.1% of the patients had consulted (lifetime) a general practitioner due to migraine and 36.2% a headache center (age at first headache center access: 31.5±13.5 yrs; number of centers consulted: 1.3±0.6), whereas 9.2% had been admitted to the Emergency Department within the last 12 months (1.7±1.5 admissions). Age at migraine onset was 17.6 ±8.7 yrs. Comorbidities were present in 41.4% of the patients. Body mass index was 23.1±3.7. Patients referred unilateral pain (70.3%), high migraine frequency (9.3±7.8 days/month) and severe disability (HIT-6 score 60.9±9.1, MIDAS score 48.3±50.7). Many patients complained of migraine-associated symptoms such as photophobia (87.3%), phonophobia (85.8%), osmophobia (42.1%), dopaminergic symptoms (40.4%), allodynia (40.3%), cephalalgiophobia (33.5%), unilateral cranial autonomic symptoms (25.8%) and vertigo (17.1%). Two/thirds of patients (66.7%) used triptans as acute treatment (responders: 74.6%). Migraine prophylaxis was taken by 67.0% of the patients: most of them (46.9%) were treated with anti-CGRP monoclonal antibodies (mAbs) (erenumab 42.4%, galcanezumab 31.7%, fremanezumab 25.4%, eptinezumab 0.5%). The proportion of anti-CGRP mAbs responders ranged from 77.3% to 85.7%.

Discussion: The 2° report of the I-GRAINE registry documents that 1) migraine diagnosis and treatment are delayed due to poor disease awareness; 2) migraine phenotype frequently includes symptoms not listed in the current headache classification; 3) specific/selective acute and preventive drugs (triptans, anti-CGRP mAbs) are now the most frequent treatments among patients visited in the Italian headache centers, and are characterized by high responder rates.

Conclusion: Big data collection is crucial to move migraine out of the shadow cone of marginalization in which it has been relegated up to now.

## ALTERED NEUROVASCULAR COUPLING WITHIN VISUAL CORTEX IN PATIENTS WITH MIGRAINE WITH AURA: A MULTIDELAY-3D-PSEUDOCONTINOUS-ASL STUDY

I. Orologio[1], M. Silvestro[1], A. Tessitore[1], G. Tedeschi[1], M. Cirillo[2], F. Esposito[2], A. Russo[1]

[1]Headache Centre, Department of Advanced Medical and Surgical Sciences, University of Campania Luigi Vanvitelli (Napoli); [2]Advanced MRI Neuroimaging Centre, Department of Advanced Medical and Surgical Sciences, University of Campania Luigi Vanvitelli (Napoli)

Aim: Converging evidences from advanced neuroimaging studies have identified functional abnormalities of occipital cortex in patients with migraine with aura (MwA). However, several concerns remain about the mechanisms underlying the "tendency" of the visual cortex to allow the beginning of aura phenomenon. Considering that the aura phenomenon triggers are associated with increased global (such as physical activity, stressors and sleep abnormalities) or local (such as bright light visual stimulations) cerebral energy demands, it could be argued that the vascular supply is unable to satisfy the increased energy requirement. We aimed to evaluate whether a dysfunctional neurovascular coupling (NVC) of visual areas could characterize patients with MwA representing the "primum movens" of aura ignition when functional demand increases as following trigger factors.

Materials: 23 patients with MwA and 25 patients with MwoA, naïve for commonly prescribed preventive migraine medications, were recruited. Finally, 20 subjects with less than a few spontaneous non-throbbing headaches per year were recruited as HC. Methods: All patients and HC underwent a 3-Tesla MRI. We considered two multi-delay-3D-pcASL acquisitions, obtaining for each the CBF maps corrected for the transit time. Finally, we combined the two CBF maps into a single statistical analysis by calculating the mean estimated CBF per region and the local NVC from the correlation between the CBF and a functional connectivity measure called REgional HOmogeneity. Results: We observed a reduced NVC in the occipital cortex (ROI 27 and 30) in patients with MwA compared with both patients with MwoA and HC ($p<0.001$). No differences were observed in rCBF comparing patients with MwA with HC ($p=0.36$). Similarly, no differences were observed in rCBF comparing patients with MwA with patients with MwoA except for significantly increased rCBF of ROI 27 and 30 within the visual network in patients with MwA when compared with patients with MwoA ($p<0.001$).

Discussion: The reduced visual cortex NVC could represent the "missing-link" between the exposure to trigger factors and the development of MwA attacks. As a proof of the concept, preventive strategies as antiepileptic drugs exert their antimigraine activity by inhibiting the cortical hyperexcitability probably restoring the trade-off between brain energy demands and rCBF within the visual network.

Conclusion: The inadequate NVC observed in the visual network of patients with MwA, leading to aura phenomenon in response to trigger factors, can shed a light on the mechanisms underpinning the tendency of brain cortex to allow the aura ignition in these patients.

## GUT MICROBIOTA PROFILING OF PEDIATRIC PATIENTS WITH MIGRAINE

L. Papetti[1], F. Del Chierico[2], I. Frattale[3], M. Scanu[2], F. Toto[2], S. Levi Mortera[2], F. Ursitti[1], G. Sforza[1], G. Monte[1], M. Valeriani[1], L. Putignani[2]

[1]Developmental Neurology, Bambino Gesù Children Hospital IRCCS (Roma); [2]Units Of Parasitology and Human Microbiome, Bambino Gesù Children Hospital IRCCS (Roma); [3]Child Neurology and Psychiatry Unit, Systems Medicine Department, Tor Vergata University (Roma)

Objectives: To verify if gut microbiota in children with migraine shows differences in the profiling when compared with age-matched controls. To verify if different migraine phenotype (aura or not aura; presence of nausea/vomiting during the attacks; duration of disease and frequency of monthly days with headache) are associated with differences in the profiles of gut microbiota.

Methods: Patients aged between 6 and 18 years with diagnosis of migraine (ICHD-3 criteria) were recruited. The GM profiling was obtained by the 16S rRNA region sequencing from faecal samples of migraine patients (n = 98) and of HCs (n = 100). QIIME2 v2022.2 software was used to obtain Amplicon Sequence Variants (ASV) with 99% of identity and taxonomic assignations by the sequence matching with Greengenes database. α and β diversity analyses and multivariate and univariate tests were applied to compare the GM profiles by R v4.0.2.

Results: Alpha diversity, assessed by Shannon-Weiner and Simpson indexes, was not significantly different between patients with migraine and HC (Mann-Whitney test, p-value > 0.05). However, the median of these two indices were higher in patients respect to HC. The analysis of β-diversity, which was performed by Bray-Curtis and Unweighted Unifrac algorithms, revealed a dissimilarity statistically significant among two groups (PERMANOVA, p-value = 0.001), suggesting a different gut microbiota profile of patients compared with HCs. The PCA evidenced the presence of gut microbiota fingerprints specific of patients' and HC. Furthermore, the PLS-DA model confirmed the two differential profiles for migraine and HC cohorts, each characterized by different distribution of bacteria. The low Root Mean Square Error value (RMSE = 0.347) and the high R2 (0.525) and Area Under the Receiver Operating Characteristics (AUROC = 0.87) values suggested a high accuracy of the model to predict the subject classification. Finally, the LEfSe test confirmed the presence of features that characterize the gut microbiota composition of patients affected by migraine. By matching the results from these different statistical approaches, we assigned, Bacteroides, Faecalibacterium, Butyricicoccuus, Lactobacillus and Enterobacteriaceae as biomarker of the patient's microbiota, while Bifidobacterium, Akkermansia, Collinsella, Eggerthella, Clostridium, Erysipelotrichaceae, Mogibacteriaceae and Coriobacteriaceae to gut microbiota of HCs.

Conclusions: Our study shows that pediatric migraine patients have a very different GM composition compared to HCs. These differences do not appear to be related to disease characteristics such as duration, presence of aura, or neurovegetative or sensory symptoms.

## REVERSIBLE CEREBRAL VASOCONSTRICTION SYNDROME: DIAGNOSIS AND TREATMENT MONITORING WITH TRANSCRANIAL ULTRASOUND

A. Pes, C. Baracchini

Stroke Unit and Neurosonology Laboratory, University of Padua (Padova)

Introduction: Reversible cerebral vasoconstriction syndrome (RCVS) is characterized by sudden onset of thunderclap headache with or without focal neurological deficits, and it is most common among females aged 20-50 years. Typical brain imaging finds multifocal, segmental narrowing of the cerebral arteries, lasting several weeks to months.

Methods: A retrospective chart review of the patient's electronic health record and a literature review were conducted to elucidate the details of this case.

Case report: A young woman with a history of hypertension and medication-overuse headache (MOH) was hospitalized due to bilateral blurred vision followed by total blindness and alteration of consciousness during one of her usual headaches. On admission cerebral CT was unremarkable, conversely MRI documented bilateral occipital ischemic lesions. Fast track Transcranial Ultrasound (TCD) showed multifocal stenosis of both MCA's (PSV 250 cm/s on the right; PSV 280 cm/s on the left) and both PCA's (PSV 220 cm/s on the right; PSV 250 cm/s on the left). Cerebral DSA confirmed the ultrasound findings. Total body CT did not document neoplasias. CSF examination and extensive blood tests including plasma levels of indomethacin, urinary levels of catecholamines and toxicological screening were negative. The diagnosis of probable RCVS was made and infusion therapy with nimodipine, aminic support and anti-seizure treatment were administered. Daily monitoring of cerebral hemodynamics by TCD was performed. At discharge the patient was asymptomatic except for a mild blurred vision. Due to the persistence of a moderate stenosis on the left PCA (Soustiel index > 2.25), oral nimodipine therapy was continued for one month. At follow-up visits TCD showed a complete normalization of blood flow velocities in all major intracranial arteries and treatment was stopped.

Conclusions: Even in a rare disease, such as RCVS, TCD plays a crucial role in early diagnosis and non-invasive monitoring of vasoactive therapy.

## WHEN THE PAST COMES BACK

A. Pes[1], N. Ravì[1], M. Bonifati[2], F. Giopato[2]

[1]Neurology Department, University of Padua (Padova); [2]Neuroloy Department, Ca' Foncello Hospital (Treviso)

Introduction: Stroke-like migraine attacks after radiation therapy (SMART syndrome) is an uncommon late complication of cerebral radiation therapy. Headache, seizures, focal neurologic deficits are common clinical presentations.

Materials and methods: A retrospective chart review of the patient's electronic health record and a literature review were conducted to elucidate the details of this unusual case.

Case report: A 52 years-old woman, with a history (20 years earlier) of right posterior parietal cerebral ependymoma excision and irradiation, was hospitalized for left faciobrachiocrural weakness, headache and subsequent stuporous status that disappeared after antiepileptic therapy.

On admission cerebral CT excluded recent ischemic lesions and an electroencephalogram showed epileptiform activity on the right fronto-central region. Total body CT revealed no signs of systemic inflammation. Extensive blood tests and cerebrospinal fluid (CSF) examinations were negative. Furthermore, considering a possible inflammatory etiology, a short course of high dose intravenous steroid therapy was administered, followed by gradual tapering. Thickening of the dura mater with swelling of the parietal cortex was documented on cerebral MRI, while an alteration of perfusion was present in the post-radiotherapy area. At discharge persisted a mild cognitive-motor slowing even if the headache had completely resolved. The patient never had new seizures at the last follow up after one months. According to this, serial EEG showed an improvement of the traces.

Conclusions: In summary, in patients with a history of cerebral radiation therapy and a new presentation of neurological deficits, SMART syndrome should be suspected. Given the reversibility of symptoms and radiological findings, an appropriate diagnosis of this syndrome is essential to avoid unnecessary and invasive tests and treatments.

Disclosures: I hereby certify that, to the best of my knowledge, no aspect of my current personal or professional circumstance places me in the position of having a conflict of interest with this presentation.

## ANTIEPILECTIC DRUGS AND OPERABILITY IN EPILEPSY

F. Pietrocarlo, D. Pietrocarlo

University Sapienza Rome (Latina)

Objectives: It is possible to find an antiepilectic drug without toxic effects?

Material: Patient 45-year-old tracted with levetiracetam, having partial seizures. When generalized it is used fenobarbital.

Method: collateral effects: sedation, atassia, mental confusion. result toxicity in fenobarbital and partial inefficacy in levetiracetam.

Discussion: A sinergic effect is possible using combinated drugs, such as fenobarbital, sodium valproate and diazepam. these drugs act a mechanism of gabamediated inibitory control. Fenobarbital in monoterapy is not the only solution because of the toxic effects.

Conclusion: For the toxic effects of antiepilectic drugs, is possible and correct to choose the surgery.

## INSOMNIA AND MIGRAINE: HOW HEADACHES AFFECT SLEEP PROFILE

L. Pilati, A. Torrente, A. Gagliardo, P. Alonge, v. di Stefano, l. vassallo, C. Camarda, F. Brighina

Department of Biomedicine and Clinical Neuroscience, University of Palermo (Palermo)

Background: Migraine and sleep show a complex and bidirectional relationship: migraineurs often report insomnia due to attacks, but poor sleep quality is one of the main triggers for a migraine attack. In migraineurs sleep appears to be characterized by a reduction in quality and efficiency. [1,2]

Methods: Data are collected by a telephonic interview of migraineurs patients, enrolled in Headache center in Policlinico of Palermo. Were asked number of headache days per month, pain intensity ranging from 0 to 10, and were administrated Insomnia Severity Index (ISI). [3] Quantitative variables were analyzed using Pearson coefficient to find any significant correlation. Were asked number of headache days per month, pain intensity ranging from 0 to 10, and were administrated Insomnia Severity Index (ISI). In our study we analyzed the relationship between insomnia and headache's days per month.

Results: We interviewed 157 patients with a mean age of 43±12 years: 88(56%) had chronic migraine and 53 (33%) episodic migraine, 112 without aura. In our migraine patients, sleep disorder ($p<0.001$) the difficulty in falling asleep score (ISI1a) and in staying asleep (ISI1b), were significantly correlated with headache days per month ($p<0.005$). In our sleep profile waking up too early (ISI1c: $p > 0.005$), and interference of the sleep problem with their daily functioning (ISI5: $p >0.005$) were not correlated with headache days. Insomnia was not significantly associated with the intensity of pain.

Conclusion: Our data confirmed the relation between sleep and migraine in particular initial and middle insomnia was significantly related with the number of headache for months. The intensity of the headache didn't affect insomnia. More studies are necessary to demonstrate this relationship between insomnia and migraine.

Objective: The objective of this multicenter observational study was to evaluate the 6-month effectiveness and tolerability of antibodies targeting the calcitonin gene-related peptide (CGRP-MoAbs) when combined with other MoAb for different diseases.

Materials and Methods: Outpatients included in the "Italian Headache Registry" (RICe) and treated with CGRP-MoAbs for high frequency episodic migraine or chronic migraine, while simultaneously assuming other monoclonal antibodies for additional pathologies, were screened for the inclusion. Patients were included if they had a 6-month follow-up after the start of therapy with the two co-prescribed drugs. Effectiveness outcomes for migraine included reduction from baseline of Monthly Headache Days (MHDs), Migraine Disability Assessment (MIDAS) and HIT-6 questionnaire total scores. The Patients' Global Impression of Change (PGIC) scale was used to quantify the patient's evaluation of the efficacy of treatments. Safety outcomes included the observation of side effects different from those expected in monotherapy.

Results: Twenty-six patients (21 women and 5 men; mean age±SD, 50.3±9.7) were included. In most of cases (n=16; 61%) the CGRP-MoAb (erenumab, galcanezumab or fremanezumab) was added to a previously ongoing treatment with another MoAb (namely adalimumab, ocrelizumab, omalizumab, natalizumab, ustekinumab, risankizumab, tocilizumab, etanabercept, denosumab, certolizumab, evolocumab). The most frequent diseases associated with migraine were psoriatic arthritis (n=6; 23%) and osteoporosis (n=6; 23%), followed by ankylosing spondylitis (n=4; 15%), rheumatoid arthritis (n=3; 11%), multiple sclerosis (n=2; 8%), asthma (n=2; 8%), ulcerative colitis (n=1; 4%), vasculitis (n=1; 4%) and dyslipidemia (n=1; 4%). MHDs significantly decreased from baseline to 6 months (20.7±6.1 vs 11.8±8.0; p<0001) as well as the MIDAS score (75.0±41.9 vs 30.3±27.7; p=0.001) and the HIT-6 score (66.5±10.5 vs 53.4±8.7; p=0.002). The PGIC score was high for both the treatments (anti-CGRP mAbs: mean±SD 5.48±2.6; other MoAbs mean±SD 5.5±2.9). Mild side-effects associated with the introduction of the second MoAb were detected in two cases only: the combination of evolocumab with the previously prescribed erenumab was associated with the appearance of gastrointestinal symptoms while the combination of galcanezumab with the previously prescribed ustekinumab was associated with the appearance of alopecia.

Discussion: Preliminary findings confirm the efficacy and safety of CGRP-MoAbs even when used in combination with other MoAbs. The low incidence of mild side-effects following the introduction of a second MoAb should be better investigated to establish whether a causal relationship between the two events must be suspected.

Conclusions: The combination of different MoAbs may be considered safe and effective in daily clinical practice.

## PARAMAGNETIC RIM LESION BURDEN AND CHOROID PLEXUS ENLARGEMENT CONTRIBUTE TO COGNITIVE IMPAIRMENT AND FATIGUE IN MULTIPLE SCLEROSIS

P. Preziosa[1], Y. Yudin[1], E. Pagani[1], A. Meani[1], L. Storelli[1], M. Margoni[2], N. Tedone[3], D. Biondi[1], M. Rocca[4], M. Filippi[5]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute (Milano); [2]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute (Milano); [3]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [4]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano); [5]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University (Milano)

Objectives: Chronic inflammation may contribute to worse cognitive performance and fatigue in multiple sclerosis (MS) patients. Paramagnetic rim lesions (PRLs) and choroid plexus (CP) enlargement have been proposed as markers of chronic inflammation in MS and are associated with a more severe disease course. However, their relation with cognitive impairment and fatigue has not been fully explored yet. In this study we investigated the contribution of PRL number and volume and CP enlargement to cognitive impairment and fatigue in MS patients

Material and Methods: Brain 3T magnetic resonance imaging (MRI), neurological evaluation and neuropsychological assessment, including the Brief Repeatable Battery of Neuropsychological Tests and Modified Fatigue Impact Scale were obtained from 129 MS patients and 73 age- and sex-matched healthy controls (HC). PRLs were identified on phase images of susceptibility-weighted imaging (SWI), whereas CP volume was quantified using a fully automatic method on brain three-dimensional (3D) T1-weighted and FLAIR MRI sequences. Predictors of cognitive impairment and fatigue were identified using random forest.

Results: Thirty-six (27.9%) MS patients were cognitively impaired and 31/113 (24.0%) had fatigue. Fifty-nine (45.7%) MS patients had ≥1 PRLs (median=0, interquartile range=0;2). Compared to HC, MS patients showed significantly higher T2-hyperintese white matter (WM) lesion volume, lower normalized brain, thalamic, hippocampal, caudate, cortical and WM volumes, and higher normalized CP volume (p from <0.001 to 0.048). The predictors of cognitive impairment (relative importance) (out-of-bag area under the curve [OOB-AUC]= 0.727) were lower normalized brain volume (100%), lower normalized caudate volume (89.1%), higher normalized CP volume (80.3%), lower normalized cortical volume (70.3%), higher number (67.3%) and volume of PRLs (66.7%) and higher T2-hyperintense WM volume (64.0%). Higher normalized CP volume was the only predictor of the presence of fatigue (OOB-AUC=0.563).

Discussion: Chronic inflammation, in terms of higher number and volume of PRLs and enlarged CP may contribute to cognitive impairment in MS in addition to atrophy. The contribution of enlarged CP in explaining fatigue supports the relevance of immune-related processes in determining this MS-related manifestation independently from disease severity.

Conclusion: The evaluation of PRL number and volume and CP enlargement may contribute to understand the pathophysiology of cognitive impairment and fatigue in MS. Moreover, they may represent clinically-relevant therapeutic targets to limit the impact of MS on both these clinical manifestations.

## COST-EFFICACY OF A SIX-WEEK MINDFULNESS-BASED TREATMENT ADDED TO TREATMENT AS USUAL VS. TREATMENT AS USUAL IN PATIENTS WITH CM-MOH: THE MIND-CM STUDY

A. Raggi[1], L. Grazzi[2], E. Guastafierro[3], B. Corso[4], E. Ciusani[5], A. Nigri[6], D. Fedeli[6], A. Erbetta[6], G. Demichelis[6], D. D'Amico[2]

[1]Neurological Institute C. Besta IRCCS Foundation, Catholic University of Milan (Milano); [2]Headache Center, IRCCS Foundation "Carlo Besta" Neurological Institute (Milano); [3]Neurology, Public Health and Disability Unit, IRCCS Foundation "Carlo Besta" Neurological Institute (Milano); [4]Neuroscience Institute, National Research Council (Padova); [5]Department of Research and Technology, IRCCS Foundation "Carlo Besta" Neurological Institute (Milano); [6]Neuroradiology Department, IRCCS Foundation "Carlo Besta" Neurological Institute (Milano)

Objectives: To assess the cost-efficacy of six-week mindfulness-based treatment added to treatment as usual (TaU) vs. TaU, which showed clinical superiority in terms of headache frequency and medication intake reduction [1-3].

Materials: A full protocol evaluating disease cost was implemented, and it accounted for: a) direct healthcare cost (medications, medical consultations, diagnostic procedures, and other treatments connected to headaches, including non-pharmacological ones); b) direct non-medical costs, which included costs of informal care for housework and for baby-sitting; c) indirect costs, which are based upon loss of productive time.

Methods: Phase-III single-blind RCT. 177 patients with CM and MOH were randomized 1:1 to either TaU (withdrawal from overused drugs, education, and tailored prophylaxis) or TaU + Mindfulness, the latter consisting of six group session of mindfulness practice and 7-10 minute daily self-practice. Follow-ups were planned at 3, 6 and 12 months from baseline. We calculated the average three-month cost before and after randomization, and the average cost during the 12 months' follow-up period after randomization. The reimbursement foreseen by Lombardia Region for the implementation of such a group intervention as organized for the MIND-CM project, i.e. 6 group sessions of 6-8 persons each, corresponds to 9.5€ per patient and per session [see note below], i.e. 57€ per patient for the entire period; the analyses were referred to study completers only.

Results: A total of 154 patients (79 of those in TaU and 75 of those in TaU + Mindfulness) completed the study. For those in TaU, the baseline 3-month cost was 2284€ (95%CI: 1059-3399€), after randomization it was 1168€ (95%CI: 469-1951€); the same figures were 2122€ (95%CI: 980-3694€) and 515€ (95%CI: 291-879€) for those in the TaU + Mindfulness group. The total average cost during the 12 months' follow-up period after randomization was 4671€ (95%CI:1875-7805€) for those in TaU and 2062€ (95%CI:1163-3517€) for those in TaU + Mindfulness, the delta being around 217€ per month.

Discussion: The cost-efficacy analysis herein presented thus witnesses that, considering the little cost of implementation in public bodies of Lombardia Region, there is adequate room for implementing a protocol based on the MIND-CM project.

Conclusions: This study showed the cost-efficacy of a six-week mindfulness-based treatment added on to TaU Vs. TaU alone. Note. Lombardia Region "Nomenclatore tariffario di specialistica ambulatoriale". ## QUALITATIVE MIDAS SCORE AS A NOVEL ALTERNATIVE TOOL FOR TREATMENT EFFICACY EVALUATION IN CHRONIC MIGRAINE

A. Ranieri, G. Alfieri, M. Napolitano, P. Candelaresi, A. De Mase, G. Maniscalco, R. Renna, S. Salvatore, E. Spina, V. Andreone

Neurology and Stroke-Unit, "A. Cardarelli" Hospital (Napoli)

Introduction: One of the goal of migraine preventive therapy consists in the improvement of quality of life (QoL). MIDAS scale [1] measures migraine-related disability and its score>11 is needed for the reimbursement of the monoclonal antibodies blocking CGRP pathway (mAb-CGRP), according to the Italian Agency of Drug (AIFA). Also, MIDAS reduction rate (MIDAS-RR)>50% has to be documented for treatment continuation. Chronic Migraine (CM) patients usually score high MIDAS and difficulty reach a MIDAS-RR>50%, although they refer therapy benefit. Improvement of 30% has been proposed as a good outcome in CM [2].

Materials and Methods: We proposed to 17 consecutive CM patients undergoing mAb-CGRP treatment a modified MIDAS scale we called "Qualitative MIDAS"(Q-MIDAS). The Q-MIDAS is composed by five question exploring the same five domains of the standard MIDAS (reduction/impossibility to attend work or study and impossibility to his own social affairs). Instead of reporting the number of days with disability within 3 months for each question, the Q-MIDAS prompts the patients to choose an answer in a qualitative manner, indicating the self perceived variation with respect to a previous period (without therapy). To such an answers a point was attributed in the subsequent way: a) zero= (-0.20); b) very diminished (-0.15); c) quite diminished (.-0.10); d)the same(0); e)quite incremented(+0.10); f)very incremented(+0.20). The Q-MIDAS score, ranging between -1 and +1, is assumed to represent MIDAS variation from 100% reduction (-1) to 100% increase (+1). Treatment has been considered effective if Q-MIDAS score was <-0.5. Standard MIDAS and Q-MIDAS were administered after 3 months of mAb-CGRP therapy. A comparison between mean MIDAS-RR and Q-MIDAS was performed as well as the number of responders with MIDAS-RR >50% vs Q-MIDAS< -0.5; concordance between the two scales has been calculated.

Results: Mean MIDAS score was 67,1 (+/-57,4) at baseline and 24,5 (+/-31,4) at 3rd month. MIDAS-RR was -0,54 (+/-0,4) compared to Q-MIDAS that was -0.64(+/-0.22) and this difference was significant (p<0.01). Number of patients reaching MIDAS-RR>50% was 10/17 while whose reaching Q-MIDAS<-0,5 was 13/17 (p<0.05).

Concordance between the two scales was 0,82 with a Cohen Kappa value of 0,61 (good concordance).

Discussion and Conclusions: Q-MIDAS resulted a very easy scale to be applied with a possible advantage to estimate MIDAS variation in a qualitative manner. In 3 out 17 patients there was not a concordance between MIDAS-RR>50% and Q-MIDAS<-0,5. In such a cases the Q-MIDAS revealed a significant self reported improvement in QoL, non demonstrated by standard MIDAS. This experience, if confirmed in a more extensive study, would give the possibility to continue a treatment in a boarder part of patients affected by CM.

Despite advances in migraine treatment, some patients suffer from resistant (RES) and refractory (REF) disease forms [1], which pose a significant social and economic burden. The Resistant and rEFractory migraINE (REFINE) study aims to validate 2020 EHF definitions of RES and REF migraine [1] in the real-world. This analysis aims to detect differences in the journey of RES and REF patients compared with not resistant and not refractory (NRNR). The REFINE is a prospective study including RES and REF patients from 15 European Centres between February 2021 and December 2022. We reported descriptive statistics of baseline and disease characteristics of the entire study cohort and compared RES, REF and NRNR patients through the $\chi 2$ test and Wilcoxon signed rank test. Centres included 671 patients with a median age of 46 years (Interquartile range [IQR] 37-54); 253 (37.8%) were RES, 73 (10.8%) REF, and 345 (51.4%) NRNR. RES and REF patients were older than NRNR (median age of 49, IQR 39-56 vs 51 IQR 43-58 vs 43, IQR 34-52; p<0.001), were more frequently diagnosed with chronic migraine (CM) (70.4% vs 83.6% vs 40%; p<0.001), with a longer CM history (median months of chronification=36, IQR14-96 vs 36, IQR 12-84 vs 24, IQR 12-60; p<0.001). RES and REF patients also had higher rates of medication overuse (47.4% vs 45.2% vs; 20%; p<0.001) that led more frequently to detoxification treatment compared with NRNR (21,9% vs 27.8% vs 9.3%; p<0.001), both home oral (11.9% vs 12.3% vs 4.9%; p<0.004) and hospital day service detoxification (5.5% vs 11% vs1.7%; p<0.001). Furthermore, these patients were more frequently misdiagnosed (30.4% vs 36.4% vs 28.7%; p=0.032), received more frequently inappropriate drug treatments in the past (6.7% vs 8.2% vs 3.2%; p=0.065) and accessed more than once to emergency department (39.1% vs 49.3% vs 28.7%; p<0.001). A higher proportion of RES and REF patients underwent radiological examinations such as brain MRI compared with NRNR patients (48.2% vs 54.8% vs 47.8%; p<0.001). RES and REF patients experienced longer and more complex migraine history and required higher use of health care resources than NRNR. Their management still represents an unmet need and a challenge for migraine experts. Further efforts are needed to detect these patients in advance and optimise their management.

## PERSISTENT OPHTHALMOPARESIS IN PEDIATRIC ONSET RECURRENT PAINFUL OPHTHALMOPLEGIC NEUROPATHY (RPON). A REVIEW OF THE LITERATURE, A PEDIATRIC CLINICAL REPORT, AND AN ANALYSIS OF THE RELATED CLINICAL FEATURES

C. Reale[1], L. Rinaldi[1], E. Ramon[1], J. Proietti[2], G. Talenti[3], A. Arbune[4], E. Gusson[5], T. Lo Barco[6], M. Ruggiu[1], E. Fiorini[6], A. Cossu[6], G. Cantalupo[1]

[1]Child Neuropsychiatry Unit, University of Verona (Verona); [2]Child Neuropsychiatry Unit; PhD program Applied Sciences of Life and Health, University of Verona (Verona); [3]Neuroradiology Unit, Azienda Ospedale-Università of Padua (Padova); [4]Neurology Clinic, Fundeni Clinical Institute (Bucharest-RO); [5]Ophthalmic Unit, University of Verona (Verona); [6]Child Neuropsychiatry Unit, AOUI Verona (Verona)

Aim: Recurrent Painful Ophthalmoplegic Neuropathy (RPON) is a rare disorder, characterized by episodes of ophthalmoparesis and ipsilateral headache. The etiology is still debated, and clearcut evidence of treatment efficacy is lacking. Although ophthalmoplegia is typically reversible, there is an unpredictable risk of residual motor deficit. We present a review of pediatric reports published so far and a pediatric clinical report, in order to explore predictive features of residual ophthalmoparesis.

Methods: The literature review was performed on PubMed, using the search terms "ophthalmoplegic migraine" and "Recurrent Painful

Ophthalmoplegic Neuropathy". We selected reports published until 30th June 2022, with onset under 16 years of age.
Review of the literature and clinical report: A nine-year-old boy was diagnosed with RPON after the third episode of III cranial nerve palsy and headache. The first two episodes, preceded by flu symptoms, remitted spontaneously. The third, preceded by a herpes labialis eruption, remitted with corticosteroids. The MRI revealed thickening and gadolinium-related enhancement of the right III cranial nerve. Twenty-two months later the patient presented a fourth episode, treated with intravenous immunoglobulin. Eight months after the fourth episode, a residual motor impairment was observed. To our knowledge, 129 cases of pediatric onset RPON have been reported so far; 35/102 (34%) were reported with permanent oculomotor deficits, after a mean of 15 months since the last episode. Patients with persisting ophthalmoparesis had an earlier age at onset (mean 4,8 years, range 0,3-15) compared to those with complete resolution (mean 5,9 years, range 0,8-13; p 0.044*), and more frequently several recurrences (p 0.003*, 14/57 patients versus 15/25). Gender distribution, age at follow-up, follow-up duration, episodes frequency, other concomitant forms of headache, acute treatment with corticosteroids, prophylactic therapy, preceding infectious symptoms, Schwannoma or vascular disorder detection, did not differ between the two groups.

Discussion: Our findings, show that the age at onset and the number of recurrences represent predictive factors for persisting oculomotor deficit. A correlation among deficit persistence and episode recurrence has been already described even though complete recovery after several episodes has been reported. Age at onset, so far not considered as major risk factor, was earlier (p*0.044) in patients with persistent motor impairment. Acute treatment or prophylactic therapy were not associated to ophthalmoparesis remission.

Conclusion: The age at onset and the number of recurrences represent predictive factors for persisting oculomotor deficit. Future evidence about etiopathogenetic mechanisms would allow better attacks management and a more favourable long-term outcome.

## PUPILLARY LIGHT RESPONSE IN MIGRAINE PATIENTS: A STUDY OF AUTONOMIC FUNCTION

M. Romozzi, C. Sottani, V. Guglielmino, G. Della Marca, S. Servidei, P. Calabresi, C. Vollono

Department of Neuroscience, Catholic University of Sacred Heart (Roma)

Objective: To assess the autonomic function through automated pupillometry, a non-invasive and rapid test able to provide objective and reproducible data on pupil size and reactivity in patients with migraine compared to healthy controls (HC). We investigated whether the measurement of the pupillary light reflex provides further information on the pathophysiology of migraine.

Methods: We performed automated pupillometry in a cohort of patients with a diagnosis of migraine without and with aura in the interictal phase, compared to age-matched HC. The following pupillometric parameters were recorded: Baseline pupil diameter (BPD), Minimum Pupil Diameter (MPD), Constriction Index (CI), Reflex Latency (RL), Constriction Velocity (CV), Maximum Constriction Velocity (MCV), Dilation Velocity (DV) and Neuro-pupillary index (NPi). Demographical and clinical data on migraine were collected. The severity and disability of migraine were assessed through the headache impact test (HIT-6) and the migraine disability assessment (MIDAS) scale.

Results: We included 220 eyes from 110 patients with a diagnosis of migraine and a mean age of 38.1 ±14.0 and 152 eyes from 76 HC with a mean age of 41.0 ±12.8. In the migraine group, we found significantly lower values of NPi ($p < 0.001$), CH ($p < 0.001$), DV ($p=0.021$) and MCV ($p=0.043$) and significantly higher values of MPD ($p=0.023$) compared to HC. In the migraine group, we did not find significant correlations between pupillometric parameters and demographic, clinical features, HIT-6 and MIDAS. The pupil changes were not correlated with the interval since the last migraine attack.

Discussion and Conclusion: The results suggest subtle sympathetic and parasympathetic pupil dysfunction in the interictal phase of migraine. Automated pupillometry may play a role as a reliable and non-invasive tool to evaluate patients with migraine and may also provide insights into the pathophysiology of migraine.

## MIGRAINE AND ARTHRITIS: ASSOCIATING MONOCLONAL CGRP AND INTERLEUKIN-17A ANTIBODIES

P. Rossi[1], G. Toldo[2]

[1]Neurology Department, San Bassiano Hospital (Bassano Del Grappa-VI); [2]Neurology Department, Alto Vicentino Hospital (Santorso-VI)

Background: Preventive treatment of migraine with CGRP-mAbs is a valid option in polypharmacy because they degrade into amino acids, thus they do not interact with other drugs by bypassing hepatic and renal elimination steps. There are no clinical studies about their association with biologics for arthritis. Secukinumab is a highly selective IL-17A antagonist and it is the first non-TNF alpha inhibitor agent licensed for the treatment of psoriasis, psoriatic arthritis, and axial spondyloarthritis, in which IL-17A has been implicated in the pathogenesis [1].

Case Presentation: We report the case of a 56 years old woman with chronic migraine, migraine with visual aura, and MOH. During the anamnestic interview, she reported a clinical history of axial spondyloarthritis, bipolar disorder, arterial hypertension (under control), fibromyalgia, hypercholesterolemia, restless legs syndrome, mitral valve prolapse, and previous surgery. She had recently started taking secukinumab. She received a beta-blocker, a calcium channel blocker, a diuretic, an atypical antipsychotic, a dual serotonin and norepinephrine reuptake inhibitor, a hypolipidemic agent, a dopamine agonist, benzodiazepines and an anti-seizure drug (for bipolar disorder and migraine prophylaxis). At the time of her first evaluation, she had been taking combination analgesics daily for a month (MIDAS 220). It would have been difficult adding a prophylactic medication for migraine to avoid interactions with her complex polypharmacy. We opted for CGRP-mAbs (fremanezumab), even though there were no studies describing their interaction with secukinumab. After 1 month the patient reported the same frequency of headaches but a better efficacy of the acute medication (Eletriptan, taken daily). After 2 months, she reported a lower attack frequency. At the first trimester evaluation, she reported a MIDAS of 65, which remained constant at the six months follow-up. A month after the suspension of the first cycle she reported the worsening of her headache (MIDAS 100). She started a second cycle of

fremanezumab, associated with a low dose of pregabalin. Notably, she reported no migraine with aura after she started taking fremanezumab.

Discussion/Conclusion: CGRP-mAbs could be a good option for complex patients. The contributions of CGRP to human arthritis pain are incompletely defined. Targeting CGRP or its receptors within joint tissues might prevent persistent inflammation and relieve arthritis pain [2]. It's been recently shown in rats that IL-17 crosses the blood-brain barrier to trigger neuroinflammation, suggesting that it might be a novel target in the treatment of migraine [3].

## VISUAL WORKING MEMORY AND VISUAL SPATIAL PERCEPTION IN MIGRAINE PATIENTS WITHOUT AURA

A. R. Sangiorgio, A. Bargagli, E. Del Sorbo, D. Plantone, N. De Stefano, A. Rufa

Department of Medicine, Surgery and Neuroscience, University of Siena (Siena)

Objective: To investigate visual spatial abilities and visual working memory in patients with migraine during the interictal phase.

Materials and Methods: A total of 15 migraineurs and 15 well-matched healthy controls. Visual spatial abilities were assessed using (VOSP). This test investigates both space perception and object identification. A Change Detection test was presented to each patient to test visual working memory. Clinical features and neuropsychological measures were calculated for patients and HC. Differences between the two groups were evaluated using Mann Whitney and Chi- Square ($\chi 2$ test).

Results: VOSP: In this ongoing test, no significant differences between groups were observed for the object recognition task. However, a significant difference between migraine patients and healthy controls was seen in the sub-task: number location (p=0.0082) and cube analysis (p=0.0080). In Both Tasks HC obtained more correct answers than migraine patients. In addition, at the Change Detection test significant differences were found between the two groups. HC achieved a rate of sure responses greater than migraineurs (p= 0.0238), whereas migraine patients obtained more uncertainty responses (p= 0.0041).

Discussion: New biomarkers are needed in migraine for both early diagnosis and monitoring of therapeutic intervention. Data reported here suggest that an accurate investigation of high-level visual functions in migraine patients may offer potential biomarkers of disease evolution and response to treatments and an opportunity to provide new insights into the understanding of important clinical and behavioral aspects of migraine.

## THE OTHER SIDE OF THE COIN: AN AGGRESSIVE FORM OF IGG4-RELATED DISEASE PRESENTING WITH ACUTE BILATERAL SUNCT-LIKE HEADACHE-CRISIS

E. Sbragia[1], N. Romano[2], G. Novi[3], M. Del Sette[4], A. Castaldi[2], M. Poeta[5]

[1]Neurology Department, Galliera Hospital, DiNOGMI University of Genoa, (Genova); [2]Department of Diagnostic and Interventional Neuroradiology, Galliera Hospital (Genova); [3]Department of Neurology, IRCCS Ospedale Policlinico San Martino (Genova); [4]Department of Neurology, IRCCS Ospedale Policlinico San Martino, University of Genoa (Genova); [5]Department of Neurology, Galliera Hospital (Genova)

Introduction: IgG4-related disease (IgG4-RD) is an insidious immune-mediated disorder characterized by tissue-invasion of IgG4-producing plasmacells causing inflammatory infiltrates, tissue fibrosis and therefore organs-enlargment [1]. Central nervous system (CNS) can be rarely affected and hypertophic pachymeningitis (HP) is one of the most recognized entity. As a general concept, IgG4-RD is not associated with acute, inflammatory clinical presentation.

Methods: A case of an aggressive form of IgG4-RD is described.

Results: A 43-years-old man came at our attention in 08/2021 because of right-orbital headache-attacks associated with omolateral neurovegetative trigeminal-activation and, initially, lateral rectus muscle transient paresis. Brain-magnetic resonance imaging (MRI) showed modest thickening of right-sided cavernous region, prepontine cistern and alongside of right-uditive duct, without pathological contrast enhancement (c.e.). Interpreted as Tolosa-Hunt syndrome, he was treated with high dose intravenous steroid with initial complete benefit. Nevertheless, after steroid-therapy weaning, the symptoms acutely relapsed with bilateral, violent, steroid-resistant periorbital pain-attacks associated with intense neurovegetative trigeminal activation, sometimes lasting just few seconds and resembling those of Short-lasting Unilateral Neuralgiform headache attacks with Conjunctival-injection and Tearing (SUNCT) syndrome. Brain-MRI lesions, stable and non-enhancing at a first control, evolved within one month in extension, thickness and c.e., erosion of the underlying bone and hypophysis-involvement. Liquoral IgG4-levels resulted elevated and therefore IgG4-RD was diagnosed. He was successfully treated with rituximab. One-year follow-up showed clinical-remission and radiological stability.

Conclusions: A case of aggressive IgG4-RD presenting with bilateral SUNCT-like symptoms is described. Taking into account a possible acute, highly inflammatory clinical presentation of these rare patients is warranted.

## EVIDENCE OF HIGHLY SENSITIZED CENTRAL NEURONAL CIRCUITS IN MEDICATION OVERUSE HEADACHE: A STUDY OF THALAMOCORTICAL ACTIVATION AND LATERAL CORTICAL INHIBITION

G. Sebastianelli, F. Casillo, C. Abagnale, C. Di Lorenzo, M. Serrao, G. Coppola

Department of Medico-Surgical Sciences and Biotechnologies, Polo Pontino, ICOT, Sapienza University of Rome (Latina)

Objective: The objective of this study was to determine whether cortical hyperexcitability in chronic migraine with medication overuse headache (CM-MOH) is related to increased thalamocortical drive or aberrant cortical inhibitory mechanisms.

Materials and Methods: Somatosensory evoked potentials (SSEPs) were performed by electrically stimulating the median nerve (M), the ulnar nerve (U), and both nerves simultaneously (MU) in 27 CM-MOH patients and for comparison in 23 healthy volunteers (HVs). We

calculated the degree of cortical lateral inhibition using the formula [100–(MU/(M+U) *100)], and the level of thalamocortical activation by analyzing the high-frequency oscillations (HFOs) embedded in parietal N20 median SSEP.

Results: Compared to HV, CM-MOH patients showed higher lateral inhibition (CM-MOH 52.2% ± 15.4 vs HV 40.4% ± 13.3; p= 0.005), which positively correlated with monthly headache days, and greater amplitude of pre-synaptic HFOs (p= 0.010) but normal post-synaptic HFOs (p= 0.122).

Conclusion: Our findings suggest that central neuronal circuits are highly sensitized in CM-MOH patients, at both thalamocortical and cortical levels. These observed changes may arise from a combination of dysfunctional central pain control mechanisms, hypersensitivity, and hyperresponsiveness directly linked to the chronic use of acute migraine drugs.

## HOW PCS SCORE CAN INFLUENCE CLINICAL RESPONSE TO MONOCLONAL ANTIBODIES AGAINST CGRP: A SINGLE CENTER THREE YEARS REAL-LIFE EXPERIENCE

F. Sepe[1], C. Lanni[1], D. Michelis[1], G. Lancia[2]

[1]Department of Neurology, Azienda Sanitaria SS. Antonio e Biagio e Cesare Arrigo (Alessandria); [2]Mathematics Department, University of Genoa (Genova)

Objectives: Catastrophic thought, defined as “an exaggerated negative mental set brought to bear during actual or anticipated painful experience” [1], plays a crucial role in pain chronification, especially in migraine patients. We aimed to evaluate how pain catastrophizing, measured using the Italian version of the “Pain Catastrophizing Scale (PCS)”, could influence clinical response to anti CGRP monoclonal antibodies (Erenumab, Galcanezumab, and Fremanezumab) in patient with chronic migraine with or without abuse. We are furthermore interested in evaluating a possible relationship between tendency to ruminate (measured by Rumination subscale) and response to therapy [2].

Materials/Methods: We collected sociodemographic and clinical data from 20 consecutive patients attending at our headache clinic from July 2021 since now. Patients are diagnosed as chronic migraine with or without MOH, according to ICDH III criteria. All patients in the court were randomly assigned between Galcanezumab (120 mg), Erenumab (140 mg) and Fremanezumab (125 mg), respecting AIFA and EAN guidelines. PCS was measured at the beginning of therapy (T0) and repeated at three (T1) and six months (T2). Clinical response was measured by the HIT-6 “Headache Impact Test-6” scale and the MIDAS “Migraine Disability Assessment Test” scoring. Comorbid depression was assessed by BDI II “Back Inventory II” scale. All patients were treated by a psychologist. We utilized the Spearman’s test to analyze PCS and Rumination correlation with the other variables included. Statical analysis was performed using Python 3. Here are reported T0 data.

Results: The study included 20 patients (3 men and 17 women) with or without medication overuse. Migraine impact was moderate (HIT-6≥56) except for three cases. Disability is severe in the whole sample except for one patient (MIDAS 12). We also observe mild to severe level of depression (BI II ≥ 10). PCS and rumination are mildly correlated with HIT6 (0.65 and 0.58, respectively) but lowly with BACKII (0.49 and 0.39, respectively). While for the leftover variables (i.e., Sex, Age, and MIDAS) no correlation was found.

Discussion: In our court, composed by patients with chronic migraine, PCS and Rumination seem not to be correlated to depression, measured by BACK II scale. Surprisingly, PCS is not related to MIDAS scoring as sex.

Conclusions: In this real-life setting, rumination can predict clinical response to monoclonal anti CGRP Ab, regardless of depression burden.

## LATE-ONSET MIGRAINE MIMICKING SECONDARY HEADACHES: TWO CASES SUCCESSFULLY TREATED WITH ONABOTULINUMTOXINA

C. Sottani[1], M. Petracca[2], M. Romozzi[1], E. Rollo[1], P. Calabresi[1], C. Vollono[1]

[1]Department of Neurosciences, Catholic University of the Sacred Heart (Roma); [2]Department of Neurosciences, Gemelli University Hospital (Roma)

Objectives: Migraine is one of the most common neurological disorders and its typical onset is in young adult age. [1] Among the elderly population, its prevalence varies from 3 to 8%. [2] Headache onset in older age requires an accurate diagnostic process to exclude secondary forms and a careful management considering age and comorbidities often present in this subgroup of population. Goal of this report is to describe two patients with late onset migraine mimicking secondary headaches and to evaluate the effect of OnabotulinumtoxinA (BT-A) on their condition.

Materials: We describe two female patients with chronic migraine (CM) ab initio with onset over 50 years old. Because of atypical features and late onset, further investigations were performed to exclude secondary forms. Patient 1 had almost exclusively nocturnal attacks; patient 2 often experienced a vertiginous syndrome associated with headache. Also, many attacks lacked typical migraine features such as nausea/vomiting and phonophobia/photophobia. They both underwent repeated injections with BT-A after first-line prophylaxis failure, especially for difficulties in tolerability.

Methods: Patients were treated with BT-A following the PREEMPT protocol3 with additional specific "follow-the-pain" sites every three months for at least one year. We collected sociodemographic data and prospectively gathered clinical data at baseline and at every scheduled treatment. Outcomes measures included days of migraine and number

of acute medications before the treatment (t0) and after three (t1), six (t2), twelve months (t3) and HIT-6 and MIDAS scores at t0 and t3.

Results: Days of headache/month decreased in both patients (patient 1: t0=20; t1=6; t2=3; t3=2; patient 2: t0=25; t1=18; t2=8; t3=5), just as acute medications intake (patient 1: t0=10; t1=5; t2=3; t3=2; patient 2: t0=25; t1=18; t2=7; t3=2). MIDAS score lowered after one year of treatment (patient 1: t0=55; t3=15; patient 2: t0=53; t3=11), as well as HIT-6 score (patient 1: t0=63; t3=52; patient 2: t0=62; t3=50).
Discussion: Our results show that BT-A was an effective prophylaxis, as it reduced number of headache days, medications intake, MIDAS and HIT-6 scores, improving the quality of life. The excellent response to BT-A in these patients suggests that, despite atypical features, a migraine physiopathological mechanism probably underlies their headache.

Conclusions: BT-A might be a valid prophylaxis option for elderly patients suffering from late onset CM mimicking secondary headaches, not only for its effectiveness but also for its high tolerability profile and lack of interactions with other drugs frequently used in this subgroup of population.

## MIGRAINE DURATION AND RESPONSE TO MONOCLONAL ANTIBODIES TARGETING CALCITONIN GENE-RELATED PEPTIDE (ANTI-CGRP MABS) IN PATIENTS WITH CHRONIC MIGRAINE (CM): REAL-LIFE DATA

V. Taranta[1], L. Iannone[2], F. Baldini[1], V. Caponnetto[1], C. Rosignoli[1], A. Burgalassi[2], A. Onofri[1], R. Ornello[1], P. Geppetti[2], S. Sacco[1]

[1]Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila (L'Aquila); [2]Section of Clinical Pharmacology and Oncology, Department of Health Sciences, University of Florence (Firenze)

Monoclonal antibodies targeting calcitonin gene-related peptide (anti-CGRP mAbs) represent an effective therapeutic option in patients with chronic migraine (CM). However, it is unclear whether an early treatment with CGRP-mAbs can revert the mechanisms of CM more easily than late treatment, thus improving clinical outcomes. This real-world study aimed to evaluate whether the duration of migraine – and particularly of CM - influence the effectiveness of anti-CGRP mAbs. We included consecutive patients with CM treated with anti-CGRP mAbs in two third level Italian headache centers between 2019 and May 2023. We included in the analysis only patients with CM completing at least one year of treatment. We classified patients into "responders" - if reporting a ≥50% decrease in MMDs from baseline to Month 6 of treatment - and "non-responders" - if they not achieved a ≥ 50% reduction in MMDs. We compared the median duration of migraine from onset and the diagnosis of CM in responders with non-responders. We also tested the non-parametric correlation between the absolute decrease in MMDs from baseline to Month 6 of treatment and the duration of migraine or CM. We enrolled 375 patients (82% females, median age 49, IQR 38-57 years), with 31 years (IQR 21-40 years) of migraine duration and 12 years (IQR 6-22 years) of CM duration. At Month 6, 194 patients (52%) were responders and 181 (48%) non-responders; responders and non-responders had similar disease duration (30.0 years, IQR 21.0-40.5 vs 31.0, IQR 21.75-40; p=0.698) and CM duration (12.0 years, IQR 6-24 vs 11.0, IQR 6-20; p=0.256). We found no difference in MMD reduction from baseline in responders compared with non-responders. No correlation was found between the decrease in MMDs from baseline (rho=0.009, p= 0.874) and migraine duration (rho=0.069, p=0.252). Our data suggest that patients with CM achieve a significant clinical response to anti-CGRP mAbs independently from CM duration. This result is in contrast with the higher effectiveness of onabotulinumtoxinA in patients with shorter CM duration compared with those with long disease history [1]. According to our data from a multicenter real-world study, mAbs CGRP could be an effective therapeutic option for patients with CM even after a long disease history.

## PERCEIVED EASE-OF-USABILITY AND LOCAL TOLERABILITY USING CGRP MONOCLONAL ANTIBODIES AUTOINJECTORS VERSUS SYRINGE: AN ONLINE QUESTIONNAIRE-BASED STUDY IN PATIENTS WITH MIGRAINE

L. Tartaglione, M. Silvestro, I. Orologio, P. Sozio, M. Siciliano, F. Trojsi, A. Tessitore, G. Tedeschi, A. Russo

Headache Center, Department of Advanced Medical and Surgical Sciences (DAMS), University of Campania "Luigi Vanvitelli" (Napoli)

Aims: Monoclonal antibodies acting on the CGRP pathway (CGRP-mAbs) are characterized by subcutaneous administration via autoinjector pens or prefilled syringes. Unfortunately, significant local tolerability concerns about injection site pain may degrade patient comfort, increase the fear and stress of dose administration and negatively impact patient adherence. The aim of the present cross-sectional study was to assess the experience of patients with migraine using either CGRP-mAbs prefilled syringes or autoinjector pens, regarding local tolerability and ease of usability. Materials: In the present cross-sectional study, an electronic questionnaire was created using "Google questionnaires" and sent to all patients treated with CGRP-mAbs referring to the Headache Centre of the University of Campania "Luigi Vanvitelli".

Methods: The self-administered questionnaire was sent to 405 patients to collect: i) demographic and clinical parameters such as age, headache diagnosis, disease duration, frequency of attacks, ongoing preventive CGRP-mAbs treatment and interictal cutaneous allodynia; ii) data related to CGRP-mAbs administration as ISP (injection site pain, with numerical rating scale), site of injection (shoulder, leg, periumbilical area), local reactions at administration site, simplicity of administration and administration modality (self-administered or not); iii) data related to putative previous onabotulinumtoxin-A administration as ISP.

Results: After 10 days, 283 (69.87%) patients filled-in the electronic form. No significant differences were found among groups in data related to ease-of-usability and local tolerability of CGRP-mAbs regarding simplicity and modality of administration, ISP and other reactions at the sites of administration. Nevertheless, we identified young women with chronic migraine as the phenotype more prone to experience ISP during the CGRP-mAbs treatment. Among 96 patients who previously received at least 3 OnabotulinumtoxinA administrations, injections site pain was significantly higher with Onabotulinumtoxin-A compared to CGRP-mAbs ($6 \pm 4$ vs $4 \pm 5$; $p<0.001$).

Discussion: Devices used for CGRP-mAbs administration (autoinjector and prefilled syringes) are each characterized by several strengths and downsides, balancing each other so that no differences in easy-of-usability and local tolerability can be observed. The cranial localization of the administration as well as the higher number of injections could explain the difference in terms of ISP with Onabotulinumtoxin-A.

Conclusion: These findings may also arise economic and ecological implications, considering the lower impact on costs and environmental pollution of prefilled syringes compared to more expensive and polluting plastic autoinjector pens. Furthermore, since ISP represents a reason for discontinuation of Onabotulinumtoxin-A therapy, this data should be considered by the authorities regulating the modalities of access to therapy with CGRP-mAbs.

## COMPARATIVE EFFICACY, QUALITY OF LIFE, AND SAFETY/TOLERABILITY OF ATOGEPANT AND RIMEGEPANT IN MIGRAINE PREVENTION: A MATCHING-ADJUSTED INDIRECT COMPARISON

C. Tassorelli[1], K. Onishchenko[2], M. Duan[3], M. Hemstock[4], C. Voller[5], P. Gandhi[6], D. Cazzorla[7], L. Dupont-Benjamin[8]

[1]Headache Science & Neurorehabilitation Centre, C. Mondino Foundation and University of Pavia (Pavia); [2]AbbVie (London-UK); [3]AbbVie (North Chicago-USA); [4]Lumanity (Sheffield-UK); [5]Lumanity (London-UK); [6]AbbVie (Madison-USA); [7]AbbVie, University of Tor Vergata (Roma); [8]AbbVie (Courbevoie-F)

Objectives: Evaluate relative efficacy, quality of life, safety, tolerability of atogepant compared with rimegepant for prevention of episodic migraine (EM) using a matching-adjusted indirect comparison (MAIC) analysis.

Materials: Data were pooled from two phase 3 atogepant trials (PROGRESS and ADVANCE) and one phase 2/3 rimegepant trial (BHV3000-305). Participants receiving atogepant 60 mg once daily (QD) and rimegepant orally disintegrating tablet 75 mg once every other day (QOD) were included. Patients receiving placebo were also included.

Method: To make adjusted comparison between pooled atogepant and rimegepant trial populations, anchored MAIC was conducted utilizing patient level data from atogepant studies. Efficacy assessment of interest was change in MMDs, assessed for atogepant across weeks 1-12 relative to rimegepant across weeks 1-12. In scenario analysis, change in MMDs for atogepant across weeks 9-12 was compared relative to rimegepant across weeks 9-12. Change from baseline in Migraine-Specific Quality of Life Questionnaire v2.1 (MSQ v2.1) Role Function−Restrictive (RFR) domain score was assessed at week 12, safety/tolerability outcomes were evaluated across the 12 weeks.

Results: 252 patients were included in pooled atogepant 60 mg QD group, 348 patients in rimegepant 75 mg QOD group. Across weeks 1-12, atogepant 60 mg QD demonstrated statistically significant greater reduction in mean MMDs vs rimegepant 75 mg QOD (mean difference [MD] [95% CI]: −1.65 [−2.49, −0.81]; P<0.001). In scenario analysis, atogepant 60 mg QD demonstrated statistically significant greater reduction in mean MMDs across weeks 9-12 (MD [95% CI]: −1.5 [−2.55, −0.43]; P<0.01) vs rimegepant 75 mg QOD, confirming findings of base case. Atogepant 60 mg QD demonstrated significantly higher MSQ v2.1 RFR domain score (MD [95% CI]: 7.36 [1.88, 12.82]; P<0.01) vs rimegepant 75 mg QOD. While patients treated with atogepant 60 mg QD had similar odds of experiencing a treatment-emergent adverse event (OR [95% CI]: 0.91 [0.56, 1.45]; P=0.7366) and numerically higher odds of discontinuing treatment due to any reason (OR [95% CI]: 1.43 [0.69, 3.06]; P=0.3284) vs rimegepant 75 mg QOD, neither difference was statistically significant.

Discussion: Atogepant 60 mg QD group had significantly larger reductions in MMDs across weeks 1-12 and weeks 9-12, significantly greater improvement in the RFR domain score of MSQ v2.1, no statistical difference in treatment-emergent adverse events or all-cause discontinuation compared with rimegepant 75 mg QOD group.

Conclusions: Atogepant 60 mg QD demonstrated significant improvements in efficacy and quality of life endpoints compared with rimegepant 75 mg QOD, and similar safety/tolerability profile.

## SPONTANEOUS INTRACRANIAL HYPOTENSION ASSOCIATED WITH LUMBOSACRAL DURAL ECTASIA

M. Trimboli[1], E. Ferrante[2]

[1]Institute of Neurology, AOU Renato Dulbecco (Catanzaro); [2]Department of Neurology, IRCCS San Camillo (Venezia)

Objective: To describe the syndrome of orthostatic headache, alterations in hearing, and nausea associated with spontaneous intracranial hypotension (SIH) and lumbosacral dural ectasia and propose potential pathogenetic mechanisms.

Background: SIH is typically characterized by orthostatic headaches, low CSF pressure, and distinct abnormalities on MRI. Other symptoms can include diplopia, neck stiffness, alterations in hearing and nausea, and rarely, numbness and coma.

Materials and Methods: Among 460 patients referred to one of us (E.F.) over a 28-year period for evaluation of orthostatic headache (OH) and suspected SIH, we identified one patient with an absence of direct or indirect signs of CSF leak detectable on head and spinal MRI. We reviewed her medical record.

Results: A 20-year-old woman, a competitive volleyball player, standing at 180 cm tall and weighing 60 kg, with ligament laxity, experienced anterior and vertex headaches rated at 7/10 on the Numeric Rating Scale (NRS). These headaches were associated with nausea and bilateral muffled voice during a workout. The headaches and auditory disturbances disappeared after a few minutes in a horizontal position but reappeared after about 5 minutes of standing up. The symptoms resolved after approximately 12 hours of bed rest. Over a period of 2

months, the patient had five similar episodes with intervals ranging from 5 to 20 days and short durations of symptoms, ranging from 6 hours to 5 days. All episodes resolved with conservative treatment (strict bed rest ranging from about 12 hours to 5 days and overhydration). Physical examination showed ligament laxity, while neurological examination was normal. Brain MRI with gadolinium was normal. Spine MRI and MRI myelography showed only a large lumbosacral dural ectasia. After 31 months of follow-up, the patient remained asymptomatic and continued to play competitive volleyball.

Conclusions: In the described case, we speculate that the congenital dural ectasia resulted in a disequilibrium between the content (unchanged CSF volume) and the increased container's volume (the dural space). It has been postulated that the orthostatic headaches seen in SIH result from an altered distribution of craniospinal elasticity. The spinal loss of CSF leads to spinal dural sac collapse and increased compliance of the spinal CSF space. The same mechanism may be involved in our patient's case.

## EFFECTIVENESS OF GALCANEZUMAB VS. TRADITIONAL ORAL MIGRAINE PREVENTIVE MEDICATIONS (TOMP): INTERIM 3-MONTH DATA FROM REAL-WORLD TRIUMPH STUDY

L. Vatteone[1], D. Novick[2], F. Torelli[3], F. Battisti[3], C. Buzzoni[4], F. Vernieri[5], A. Russo[6], P. Barbanti[7], C. Tassorelli[8]

[1]Eli Lilly and Company, Medical Affairs (Firenze); [2]Value Evidence Outcome, Eli Lilly and Company (Bracknell-UK); [3]Italy Hub Medical Affairs, Eli Lilly and Company (Firenze); [4]Value Evidence Outcome, Eli Lilly and Company (Firenze); [5]Neurology, University Campus Biomedico (Roma); [6]Neurology, University L. Vanvitelli (Napoli); [7]Neurology, University S. Raffaele Pisana (Roma); [8]Neurology, IRCCS C. Mondino Foundation, University of Pavia (Pavia)

Objectives: The primary objective of TRIUMPH study is to evaluate effectiveness of galcanezumab, a calcitonin gene-related peptide (CGRP) monoclonal antibody, and traditional oral migraine preventive (TOMP) medications. We present the TRIUMPH [Italy] results, focusing on the 3-month timepoint.

Materials and Methods: TRIUMPH is an ongoing, prospective, international, observational study of adult patients with migraine who switched to or initiated a new preventive medication. The TRIUMPH interim data cut included all patients with baseline and available 3-month data (from Feb-2020 to Aug-2022), first patient enrolment in TRIUMPH [Italy] was Jul-2021 and continued to Oct-2022. Patients received CGRP antagonists including galcanezumab (at approved local dose/regimen), TOMP medication (beta blockers, anticonvulsants, tricyclic antidepressants, calcium channel blockers or angiotensin II receptor antagonists), botulinum toxin or other migraine preventives. In the effectiveness analysis set, patients had ≥4 monthly migraine days (MMDs) in the ≤30 days preceding baseline, started index preventive treatment ≤56 days after prescribed, and completed baseline patient-reported outcomes before, or ≤3 days after, starting treatment. According to the primary objective, treatment effectiveness was assessed as a reduction from baseline in MMDs at 3-months (response) of at least 30% in chronic and 50% in episodic migraine. The difference in proportion of responders between treatments was assessed using a weighted Chi-squared test (alpha 5%). Weights were derived from a least absolute shrinkage and selection operator (LASSO) model fit of propensity scores using 65 baseline covariates.

Results: Of 2573 patients in the TRIUMPH longitudinal phase, 37.0% (n=953) and 46.2% (n=1189) received galcanezumab and TOMP, respectively. For TRIUMPH [Italy] (n=195), 61.0% (n=119) and 25.1% (n=49) received galcanezumab and TOMP. Most patients were female (83-86%) and diagnosed with chronic migraine (TRIUMPH: galcanezumab=72.0%, TOMP=60.1%; TRIUMPH [Italy]: galcanezumab=70.6%; TOMP=34.7%). At baseline, mean(SD) MMDs for each cohort were: TRIUMPH: galcanezumab=14.4(7.5), TOMP=11.4(6.4); TRIUMPH [Italy]: galcanezumab=17.0(6.8), TOMP=13.3(6.8). Topiramate and amitriptyline were the most common TOMP. At 3-months, treatment effectiveness was greater in patients receiving galcanezumab than TOMP in TRIUMPH (weighted response rate 45.8% vs 34.1%; p<0.0001) and TRIUMPH [Italy] (69.2% vs. 39.7%; p=0.0012). Mean(SD) MMDs were: TRIUMPH galcanezumab=8.2(7.8), TOMP=7.3(5.8); TRIUMPH [Italy]: galcanezumab=8.5(8.0)[n=108], TOMP=8.8(6.7)[n=36]. Change from baseline in the mean number of MMDs with acute medication use were: TRIUMPH: galcanezumab=-4.98, TOMP=-3.47; TRIUMPH [Italy]: galcanezumab=-8.62, TOMP=-5.02.

Discussion and Conclusions: Global TRIUMPH and TRIUMPH [Italy] results show a significantly better galcanezumab effectiveness at 3-month in comparison with TOMP.

## TRANSITIONAL CARE FOR STROKE SURVIVORS FROM HOSPITAL TO HOME AND THEIR CAREGIVERS' CONTRIBUTION: A SYSTEMATIC REVIEW

M. Veronese, E. Vellone, R. Alvaro, G. Pucciarelli

Department Of Biomedicine and Prevention, University of Rome Tor Vergata (Roma)

Introduction: Stroke represents one of the first causes of disability and mortality worldwide and the increased number of strokes will lead to expanded stroke-related health costs. After a stroke, survivors experience functional and cognitive disabilities such as depression, anxiety, fatigue, and difficulty communicating and impact negatively on physical, phycological, and social abilities in survivors' and caregivers' health, especially during discharge from hospital to home. Returning home after hospitalization can be chaotic and associated with many challenges.

Aim: To describe transitional care strategies from hospital to home in stroke survivors and their caregivers. In stroke survivors for improving, physical functions, quality of life, self-efficacy and social inclusion, and reducing hospital readmission and post-discharge adverse events, as well as reducing caregiver burden.

Methods: A systematic review was conducted on October 2022 on Pubmed, CINAHL, Scopus, and Web of Sciences. A PRISMA Flow Diagram was used to report the selection process. Randomized controlled trials (RCTs), and quantitative and qualitative studies, were extracted using the standardized data extraction tool from the Joanna Briggs Institute (JBI).

Results: The literature search yielded 699 records. After reading the full text, 30 articles were selected: twelve RCTs, two RCT designs, nine qualitative studies, two texts and opinions, two mixed method studies, one cross-sectional study, one pragmatic priority setting, and one retrospective study. The RCTs included the intervention as an educational intervention, coaching activities, home visits and telephone follow-up. These interventions started during hospitalization and continued at home after discharge and improved the quality of life, self-efficacy, and physical function in stroke survivors. The theme issue that emerged

in the other studies was the experience of stroke survivors and their caregivers regarding unmet needs and social integration.

Discussion and conclusions: This systematic review provides support for intervention programs during the transitional period from hospital discharge to home for improved stroke survivors' physical functioning, quality of life, self-efficacy, and caregiver burden. In addition, it has benefits in caregiver burden where health systems transfer the responsibility. Information about survivor or caregiver needs, abilities, and support, once they are transitioned home from the acute setting, rehabilitation facility, or skilled nursing facility, is important to evaluate.

## DIFFERENT EFFECTS OF PROPHYLAXIS THERAPIES ON SLEEP QUALITY: AN ITALIAN MULTICENTER STUDY

G. Viticchi[1], V. Di Stefano[2], C. Altamura[3], L. Falsetti[4], A. Torrente[2], N. Brunelli[3], S. Salvemini[1], P. Alonge[2], M. Bartolini[1], M. Adragna[2], C. Di Felice[1], A. Lupica[2], F. Vernieri[3], F. Braghina[2], M. Silvestrini[1]

[1]Neurological Clinic, Marche Polytechnic University (Ancona); [2]Department of Biomedicine, Neuroscience and Advanced Diagnostics (Bind), University of Palermo (Palermo); [3]Unit of Headache and Neurosonology, Department of Medicine and Surgery, Campus Bio-Medico University (Roma); [4]Internal and Subintensive Medicine, Azienda Ospedaliero-Universitaria delle Marche (Ancona)

Objectives: Sleep alterations are closely linked to migraine, especially when a headache lasts several years. Pharmacological prophylaxis has a relevant impact on migraine frequency and associated symptoms. Also, monoclonal antibodies have an excellent effect on associated symptoms, such as sleep alterations, but conclusive data are unavailable. This study aimed to compare a population of migraine patients treated by pharmacological prophylaxis therapies with a group treated by monoclonal antibodies to evaluate the different impacts on sleep quality.

Methods: this was a multicenter study (Neurological Clinic, Marche Polytechnic University, Ancona; Department of Biomedicine, Neuroscience and Advanced Diagnostic, University of Palermo; Unit of Headache and Neurosonology, Campus Bio-Medico di Roma University, Roma;). We enrolled in the three Headache Specialistic Centers all the patients with a migraine diagnosis (with or without aura) and a migraine frequency of more than four attacks monthly. Each patient at enrolment (T0) was assigned to a pharmacological prophylaxis therapy (beta-blockers, calcium antagonists, antiepileptics, and antidepressants) or to monoclonal antibodies, according to international guidelines. We submitted each patient to general and neurological examinations and to different scales, including the Pittsburgh test, a scale to evaluate sleep quality specifically. After three months (T3) of therapy, we re-evaluated the patients and submitted them to the same battery. We excluded all the patients that had not regularly assumed prophylaxis therapies or subjects assuming sleep-inducing drugs.

Results: We enrolled 264 patients (168 treated with pharmacological therapies and 96 treated with Monoclonal antibodies). Pittsburgh score decreased significantly between T0 and T3 (mean difference 1,841 points; $p<0,0001$), and the use of monoclonal antibodies was associated with a greater decrease in Pittsburgh score (mean difference 1,491; $p=0,010$) in respect to pharmacological prophylaxis. Moreover, we observed a significant difference in the number of crises in three months at T0 between the monoclonal antibodies group and the pharmacological drugs group ($p<0,0001$), with a difference that remained significant also at T3 ($p<0,0001$).

Conclusions: Monoclonal Antibodies have updated the management of migraine with a well-documented, stable efficacy. Our data showed a probable good effect on sleep quality based on different etiopathologic and psychological aspects. Improving different features of migraine could contribute to an improved quality of life and better treatment compliance.

## IMPACT OF MONOCLONAL ANTIBODIES AGAINST CALCITONIN GENE-RELATED PEPTIDE ON PAIN SYSTEM: A LASER EVOKED POTENTIALS STUDY

C. Vollono[1], E. Rollo[1], M. Romozzi[1], C. Sottani[1], S. Servidei[1], P. Calabresi[1], M. Valeriani[2]

[1]Neurology, Catholic University (Roma); [2]Developmental Neurology Unit, Bambino Gesù Children's Hospital IRCCS (Roma)

Introduction: Anti-calcitonin gene-related peptide (anti-CGRP) monoclonal antibodies have opened a new scenario in the preventive treatment of migraine.

Objective: The aim of the study was to assess, using laser evoked potentials (LEPs), the impact on pain-processing pathways of a preventive treatment with Anti-CGRP monoclonal antibodies in migraine.

Methods: We studied 11 patients (10 women, mean age: $35,6 \pm 12,4$ years) affected by migraine, before and after 3-6 months of prophylactic scheme (Galcanezumab 120 mg monthly, with a starting dose of 240 mg). All subjects received stimulation over the right-hand dorsum and the right perioral region. Two scalp electrodes placed along the midline in the frontal (Fz) and in the vertex (Cz) regions and one electrode in the left temporal region (T3). The reference electrode was placed at the nose and the ground on the forehead (Fpz). Three consecutive repetitions were obtained for each stimulation site. The interstimulus interval varied randomly between 8 and 12 s. Repetitions were separated by a 5-minutes time interval. The stimulation sites were changed after 10-min intervals. Absolute values of N1, N2 and P2 latencies and amplitudes were compared before and after treatment. For the analysis of LEP amplitude habituation, the LEP amplitudes in the second and third repetition of each stimulation site were expressed as percentages of the amplitudes of the corresponding LEP components recorded in the first sequence, which were assumed as 100%.

Results: Data reported in diaries showed, after treatment when compared to baseline, a significant reduction of the mean number of monthly headache days ($p<0.0001$), monthly drug intake of acute medication ($p<0.0001$), and MIDAS score ($p=0.0019$). No significant differences were found, between pre and post treatment, for the VAS pain rating score, thresholds, LEP latencies and absolute amplitude of N1 potential and N2-P2 complex. A statistically significant modification (normalization) of the amplitude habituation of both N1 ($p=0.001$ after hand stimulation; $p=0.0052$ after face stimulation) and N2-P2 ($p=0.0019$ after hand stimulation; $p<0.0066$ after face stimulation).

Discussion and Conclusions: Our main finding is that patients with migraine showed a restore of habituation to repetitive stimuli after a prophylactic treatment with Galcanezumab. Several hypotheses can explain the normalization of the habituation phenomenon, including the re-modulation of central sensitization. The evidence of increased GABA levels in anterior cingulate cortex, associated with a decrease in migraine frequency, intensity and disability obtained by CGRP mAbs therapy, suggests a possible role of these central structure and neurotransmission.

## USE OF GALCANEZUMAB FOR MIGRAINE PREVENTION IN A PATIENT ON CONCOMITANT NIVOLUMAB FOR MELANOMA SKIN CANCER: A CASE REPORT

L. Zanandrea, R. Messina, I. Cetta, S. Guerrieri, F. Genovese, B. Colombo, M. Filippi

Neurology Unit, IRCCS San Raffaele Scientific Institute (Milano)

Objectives: The use of monoclonal antibodies (mAbs) has renewed the treatment landscape of many diseases. MAbs targeting the calcitonin-gene related peptide (CGRP) are currently used for migraine prevention. In real-life practice, treating migraine patients with comorbidities is challenging. To date, real-life experience of concomitant use of anti-CGRP mAbs and other mAbs with a different therapeutic indication in multimorbid patients is missing.

Materials: We describe the case of a 56-year-old female migraine patient treated with galcanezumab, a mAb blocking the CGRP, on concomitant treatment with nivolumab, a mAb targeting the anti-programmed death-1 (PD-1), because of melanoma skin cancer.

Clinical case: The patient came to our Headache Center in July 2021 because of a chronic migraine resistant to oral preventives; she had a history of melanoma skin cancer on the right leg surgically treated in 2016. Galcanezumab was initiated for her migraine. The patient had 30 monthly migraine days of severe intensity with daily assumption of analgesics before treatment with galcanezumab. After three months of treatment, a mean of 10 monthly migraine days of mild intensity was reported with a reduced related disability. After six months, the same result was observed. In February 2022, after the surgical remove of a locally recurrent melanoma, treatment with nivolumab was introduced. Galcanezumab was continued and monthly follow-up phone calls were scheduled since nivolumab was introduced. The clinical benefit of galcanezumab continued after introduction of nivolumab. No adverse event was reported.

Discussion: We describe a case of concomitant use of galcanezumab for migraine prevention and nivolumab for cancer prevention in a patient with migraine and a history of melanoma skin cancer. This is the first case-report of concomitant anti-CGRP mAb and another mAb with a different target in a multimorbid patient. No drug-drug interaction was observed, nor in terms of lack of effectiveness of galcanezumab, neither in terms of adverse events.

Conclusion: Galcanezumab proved to be effective and safe for migraine prevention when used in a patient with concomitant nivolumab. A wider real-life experience of use of anti-GCRP mAbs in multimorbid patients on concomitant treatment with other mAbs should be provided in order to be confident in treating these patients.

## COGNITIVE IMPAIRMENT AND BULBAR FEATURES IN AMYOTROPHIC LATERAL SCLEROSIS: A RETROSPECTIVE STUDY

E. N. Aiello[1], F. Solca[1], S. Torre[1], V. Patisso[2], A. De Lorenzo[2], M. Treddenti[2], E. Colombo[1], A. Maranzano[1], C. Morelli[1], A. Doretti[1], F. Verde[3], V. Silani[3], N. Ticozzi[3], B. Poletti[4]

[1]Department of Neurology and Laboratory of Neuroscience, IRCCS Istituto Auxologico Italiano (Milano); [2]Neurology Residency Program, University of Milan (Milano); [3]Department of Neurology and Laboratory of Neuroscience & Department of Pathophysiology and Transplantation, IRCCS Istituto Auxologico Italiano & University of Milan (Milano); [4]Department of Neurology and Laboratory of Neuroscience & Department of Oncology and Hemato-Oncology, IRCCS Istituto Auxologico Italiano & University of Milan (Milano)

Objectives: To clarify the role of bulbar involvement (BI) as a risk factor for cognitive impairment (CI) in non-demented amyotrophic lateral sclerosis (ALS) patients.

Materials: Data on N=347 patients were retrospectively collected. Cognition was assessed via the Edinburgh Cognitive and Behavioural ALS Screen (ECAS). Patients were free of 1) frontotemporal dementia, 2) ALS-unrelated brain disorders, 3) severe general-medical conditions and 4) uncorrected hearing/vision deficits. On the basis of clinical records and ALS Functional Rating Scale-Revised (ALSFRS-R) scores, BI was characterized as follows: 1) BI at onset – from medical history ; 2) BI at testing (an ALSFRS-R-Bulbar score $\leq$11); 3) dysarthria (a score $\leq$3 on item 1 of the ALSFRS-R); 4) severity of BI (the total score on the ALSFRS-R-Bulbar); and 5) progression rate of BI (computed as 12-ALSFRS-R-Bulbar/disease duration in months).

Methods: Logistic regressions were run to predict a below- vs. above-cutoff performance on each ECAS subscale based on BI-related features while accounting for sex, disease duration, severity and progression rate of respiratory and spinal involvement, disease stage and ECAS response modality.

Results: No predictors yielded significance on ECAS-Language/-Fluency/-Memory or -Visuospatial subscales (ps$\geq$0.118), albeit BI at

testing predicted a higher probability of an abnormal performance on the ECAS-Executive Functioning (OR=4.33, CI 95% [1.6, 11.93]). The raw relative risk of an impaired performance on such a subscale in patients with vs. without BI at testing was 2.62 (CI 95% [1.64, 4.19]). No other BI-related features affected ECAS performances.

Discussion: This study contributed to the clarification of the role of BI as a risk factor for CI in non-demented ALS patients by simultaneously encompassing BI-related predictors and motor-functional covariates and by addressing an ALS-specific measure of cognition (i.e., the ECAS) [1]. This reports suggests that, net of overall motor-functional status, BI itself, and neither its presence at onset, severity, progression rate or phenotype (i.e., the occurrence of dysarthria), increases the probability of executive deficits in non-demented ALS patients – by, nevertheless, not representing a risk factor for cognitive dysfunctions within other domains.

Conclusions: The occurrence of BI itself, but neither its specific features nor its presence at onset, selectively represents a risk factor for executive impairment in ALS patients – even when executive functions are assessed with motor disability-compensating tests and when covarying for other disease-related features.

## NEUROPSYCHOLOGICAL FEATURES AND ACTIVITIES OF DAILY LIVING IN AMYOTROPHIC LATERAL SCLEROSIS

E. N. Aiello[1], F. Solca[1], S. Torre[1], F. Gentile[2], F. Scheveger[2], M. Olivero[2], E. Colombo[1], A. Maranzano[1], M. Manzoni[3], C. Morelli[1], A. Doretti[1], F. Verde[4], V. Silani[4], N. Ticozzi[4], B. Poletti[5]

[1]Department of Neurology and Laboratory of Neuroscience, IRCCS Istituto Auxologico Italiano (Milano); [2]Neurology Residency Program, University of Milan (Milano); [3]Child Psychopathology Unit - Scientific Institute, IRCCS E. Medea – La Nostra Famiglia (Bosisio Parini-LC); [4]Department of Neurology and Laboratory of Neuroscience & Department of Pathophysiology and Transplantation, IRCCS Istituto Auxologico Italiano & University of Milan (Milano); [5]Department of Neurology and Laboratory of Neuroscience & Department of Oncology and Hemato-oncology, IRCCS Istituto Auxologico Italiano & University of Milan (Milano)

Objectives: To determine whether, net of motor confounders, neuropsychological features affect functional independence (FI) in activities of daily living (ADLs) in non-demented amyotrophic lateral sclerosis (ALS) patients.

Materials: N=88 ALS patients without frontotemporal dementia were assessed for FI (Katz ADL and Lawton-Brody IADL scales), cognition (Edinburgh Cognitive and Behavioural ALS Screen, ECAS) and behaviour (Beaumont Behavioural Inventory and Dimensional Apathy Scale). Patients were free of 1) ALS-unrelated neurological/psychiatric disorders, 2) severe/unstable general-medical conditions and 3) uncorrected sensory deficits. The two ADL scores were summed up to obtain an overall Functional Independence Index (FII) – thus ranging 0-14 –, whose reciprocal (computed as 14-FII, i.e. the Functional Dependence Index, FDI) was herewith addressed as the outcome.

Methods: By means of Negative Binomial models, the effect of cognitive and behavioural measures on the FDI was assessed net of demographics, anxiety and depression levels (as measured by the State- and Trait-Anxiety Inventory Form-Y and the Beck Depression Inventory, respectively), disease duration and motor confounders – i.e., ALS Functional Rating Scale-Revised (ALSFRS-R) scores, progression rate and both King's and Milano-Torino stages.

Results: Besides ALSFRS-R scores, the Language subscale of the ECAS was the only extra-motor predictor of the FDI (b=-.11, z=-3.32, p<.001; OR=.90, CI 95% [.84, .96]). When re-running the same model by substituting ECAS-Language scores with a below- vs. above-cutoff ECAS-Language performance, patients performing defectively (21.34%) were more functionally dependent (M=2.84; SE=.96) when compared to those performing normally (M=1.14; SE=.39). At αadjusted=.017, the FDI correlated with Naming (rs(88)=-.29; p=.009) and Comprehension tasks (rs(88)=-.30; p=.007), whilst not with Spelling scores (rs(88)=-.23; p=.043).

Discussion: This study suggests that, besides disease severity – as assessed by the ALSFRS-R –, language functioning – as assessed by the ECAS-Language – represents the only extra-motor factor affecting FI in ADLs in this population. To account for this, it can be hypothesized that language impairment (LI) might have undermined patients' communicative skills, thus in turn reducing their FI. This would also be supported by the fact that naming and comprehension abilities herewith proved to be selectively associated with FI – both these functions being ubiquitously engaged within everyday-life scenarios. Notably, this study did not replicate previous evidence pointing towards behavioural, rather than cognitive, dysfunctions impacting on FI in ALS [1].

Conclusions: FI in ADLs is dependent on both disease severity and LI in non-demented ALS patients, thus highlighting the ecological relevance of language changes in this population.

## PREGNANCY EXPERIENCE IN WOMEN WITH SPINAL MUSCULAR ATROPHY: AN OVERVIEW IN THE COHORT OF THE UNIVERSITY OF NAPLES "FEDERICO II"

R. P. Bencivenga, D. Zoppi, A. Russo, E. Cassano, S. Tozza, R. Iodice, R. Dubbioso, F. Manganelli, L. Ruggiero

Department of Neurosciences, Reproductive and Odontostomatological Sciences, University of Naples "Federico II" (Napoli)

Background and Aim: Female SMA patients reach fertile age with a different clinical picture. Many patients with SMA Type III are ambulatory during pregnancy, while the totality of women with Type II phenotype are wheelchair-bound. Little data is available about the possible effects of pregnancy on SMA course. In this study, we analyzed outcomes in the different stages of the pregnancy, with a special focus on maternal and fetal complications, mode of delivery, anesthesiological risk and respiratory function.

Results: Our cohort is compound by 10 SMA female (7 SMA III and 2 SMA II). The number of pregnancies was 9 (six term-pregnancy, three abortion). No one had medical assisted procreation. All have done genetic counseling, one of which was pre-conception. Two SMA II patients had two pregnancies each, all of which resulted in pre-term labor. Two SMA III patients had one pregnancy each, resulted in full-term labor. All pregnancies resulted in cesarian delivery performed under epidural anesthesia, except one under general anesthesia. Two patients referred motor symptoms worsening after delivery and chronic back pain during pregnancy. One had pneumonia after delivery. In three cases there were birth complications, but newborn outcomes were all healthy. Only two patients breastfed.

Conclusions: Our experience testify that a successful pregnancy is possible with SMA. Anyway, particularly the sitter patients experienced pregnancy or birth complications. A correct approach should include a standardized multidisciplinary team, with an obstetrician, neurologist, neonatologist, genetist, anesthesiologist, pneumologist and trained nurses, Our results focus on the need to consider motherhood experience in the management of SMA female patients and in the next future we will include the currently disease modifying therapies in this taking charge.

## CORTICO-SPINAL TDCS IN AMYOTROPHIC LATERAL SCLEROSIS: A RANDOMIZED, DOUBLE-BLIND, SHAM-CONTROLLED TRIAL FOLLOWED BY AN OPEN-LABEL PHASE

A. Benussi[1], V. Cantoni[1], M. Grassi[2], I. Libri[1], M. Cotelli[3], B. Tarantino[2], A. Datta[4], C. Thomas[4], N. Huber[5], S. Kärkkäinen[6], S. Herukka[6], A. Haapasalo[5], M. Filosto[1], A. Padovani[1], B. Borroni[1]

[1]Department of Clinical and Experimental Sciences, University of Brescia (Brescia); [2]Department of Brain and Behavioural Sciences, University of Pavia (Pavia); [3]Neurology Unit, Valle Camonica Hospital (Esine-BS); [4]Research & Development, Soterix Medical, Inc (New York-USA); [5]A.I. Virtanen Institute for Molecular Sciences, University of Eastern Finland (Kuopio-FIN); [6]Institute of Clinical Medicine, University of Eastern Finland (Kuopio-FIN)

Objective: To investigate whether anodal bilateral motor cortex and cathodal spinal transcranial direct current stimulation (tDCS) could mitigate symptoms in amyotrophic lateral sclerosis (ALS) patients by modulating intracortical connectivity in the short and long-term via a randomized, double-blind, sham-controlled trial, followed by an open-label phase.

Methods: Thirty-one participants were randomized into two groups for the initial controlled phase. At baseline (T0), Group 1 received placebo stimulation (sham tDCS), while Group 2 received cortico-spinal stimulation (real tDCS) for five days/week for two weeks (T1), with an 8-week (T2) follow-up (randomized, double-blind, sham-controlled phase). At the 24-week follow-up (T3), all participants (Groups 1 and 2) received a second treatment of anodal bilateral motor cortex and cathodal spinal stimulation (real tDCS) for five days/week for two weeks (T4). Follow-up evaluations were performed at 32-weeks (T5) and 48-weeks (T6) (open-label phase). At each time point, clinical assessment, blood sampling, and intracortical connectivity measures using transcranial magnetic stimulation (TMS) were evaluated. Additionally, we evaluated survival rates.

Results: Compared to sham stimulation, cortico-spinal tDCS significantly improved global strength, caregiver burden, and quality of life scores, which correlated with the restoration of intracortical connectivity measures. Serum neurofilament light levels decreased among patients who underwent real tDCS but not in those receiving sham tDCS. The number of completed 2-week tDCS treatments significantly influenced patient survival.

Conclusions: Cortico-spinal tDCS may represent a promising therapeutic and rehabilitative approach for patients with ALS. Further larger-scale studies are necessary to evaluate whether tDCS could potentially impact patient survival.

## RARE FUS MUTATION IN AN ALS-FTD PATIENT: CASE REPORT DESCRIPTION AND GENOTYPE-PHENOTYPE CORRELATION

V. Bettoni[1], D. Tornabene[2], I. Palmieri[3], M. Bordoni[4], E. Scarian[4], R. Di Gerlando[5], F. Dragoni[6], S. Gagliardi[5], O. Pansarasa[4], L. Diamanti[7]

[1]IRCCS Fondazione Mondino, University of Pavia (Pavia); [2]Department of Brain and Behavioral Sciences, University of Pavia (Pavia); [3]Neurogenetics Research Center, IRCCS Mondino Foundation (Pavia); [4]Cellular Model and Neuroepigenetics Unit, IRCCS Mondino Foundation (Pavia); [5]Molecular Biology and Transcriptomics Unit, IRCCS Mondino Foundation (Pavia); [6]Genomic and post-Genomic Unit, IRCCS Mondino Foundation (Pavia); [7]Neuroncology Unit, IRCCS Mondino Foundation (Pavia)

Background: Since 2009, over 50 different FUS mutations have been discovered to be linked to ALS and were thought to cause a stereotyped clinical phenotype characterized by early onset, aggressive course, and pure motor clinical presentation. However, some different presentations were reported. Recently, Grassano et al. analyzed data from literature and from an Italian cohort of genetically confirmed FUS-ALS cases, identifying 3 phenotype clusters arising from different specific FUS variants. These mutations were in the nuclear localization signal (NLS) domain, encoded by exon 14 and 15, at the C-terminal end of the gene; a genotype-phenotype correlation was not found for non-NLS FUS variants [1]. Nonetheless, among literature, some pathogenetic non-NLS FUS variants were reported, with various clinical presentation.

Objective: We present the case of a 62-year-old patient affected by FTL-ALS, in which a non-NLS FUS pathogenic variant was found. Case presentation: He presented with a marked speech disorder, started one year before and progressively worsening, characterized by speech-slowness, difficulties in words articulation and rhinolalia. Frequent choking in swallowing liquids were also present. Neurological examination showed severe spastic dysarthria, lingual hyposthenia, lingual fasciculations, and brisk jaw reflex. Mild spastic hypertonia of upper limbs, hypotrophy and hyposthenia of interosseous muscles were also present; there were spontaneous fasciculations in both forearms and symmetric hyperreflexia of upper and lower limbs. Needle electromyography (EMG) showed a marked denervation activity in every muscular district. Cognitive evaluation showed an impairment in non-ALS-specific ECAS domains and an FTD-compatible profile. The disease presented an aggressive course, and survival was 42 months since onset and 28 months since diagnosis. The search for genetic mutations was performed by molecular analysis of C9orf72 and by NGS of main ALS-related genes. A FUS missense mutation was found in exon 6 (c.760A>G variant), determining a methionine to valine substitution at codon 254 (p.Met254Val), which was probably pathogenetic according to ACMG criteria.

Discussion: Among literature, there is only one reported case of this mutation, in a patient affected by FTD and without signs of ALS [2]; only few other mutations were reported in the nearby region in exon 6 [3]. This region is highly evolutionarily conserved among species.

Conclusions: This case points out the importance of mutations in exon 6 in causing ALS. Further studies could be useful to better

understand the pathogenic mechanism giving this pathology and the prognostic value of each mutation.

## RETINA ATROPHY IN AMYOTROPHIC LATERAL SCLEROSIS AND KENNEDY'S DISEASE. A LONGITUDINAL STUDY

L. Blasi[1], A. Miscioscia[1], M. Puthenparampil[1], F. Rinaldi[2], P. Perini[2], G. Sorarù[1], P. Gallo[1]

[1]Neuroscience Department, University of Padua (Padova); [2]Neuroscience Department, Padua University Hospital Company (Padova)

Background: To what extent retinal atrophy in neurodegenerative diseases reflects the severity and/or the chronicity of brain pathology or rather is a local independent phenomenon remains to be clarified. Moreover, the clinical (diagnostic and prognostic) value of retinal atrophy in these diseases needs to be further investigated.

Aim of the study: To add light on the pathological significance and on the possible clinical value of retinal atrophy in patients with amyotrophic lateral sclerosis (ALS) and Kennedy's disease (KD, bulbo-spinal muscular atrophy).

Methods: Thirty-five ALS, thirty-seven KD, and forty-nine age-matched healthy controls (HC) were included in a one-year longitudinal study. Spectrum-domain optical coherence tomography (OCT) was performed at study entry (T0) and after 12 months (T1). Possible correlations between retinal thicknesses and disease duration and functional rating scale (FRS) were investigated in both groups of patients.

Results: Compared to HC, peripapillary retinal nerve fiber layer (pRNFL) was significantly thinner in both ALS (p=0.034) and KD (p=0.003). pRNFL was also thinner in KD compared to ALS, but the difference did not reach the significance. In KD, pRNFL atrophy significantly correlated with both disease severity (r=0.296, p=0.035) and disease duration (r = -0.308, p=0.013) while no significant correlation was demonstrated in ALS (disease severity: r=0.147, p=0.238; disease duration: r=- 0.093, p=0.459). During the 1-year-follow-up, pRNFL thickness remained stable in KD while significantly decreased in ALS (p=0.043).

Conclusions: Our study provides further evidence of retinal atrophy in both ALS and KD and suggests that a primary local neurodegenerative phenomenon takes place in retina in motoneuron diseases. Our data seems to indicate that the analysis of pRNFL thickness may have a clinical significance in KD, but this aspect needs further investigation.

## A LONGITUDINAL EVALUATION OF EARLY SLEEP AND RESPIRATORY IMPAIRMENT IN ALS PATIENTS

A. Bombaci[1], A. Iadarola[2], E. Fattori[2], F. De Mattei[3], C. Gojani[1], A. Calvo[3], A. Chiò[3], A. Cicolin[2]

[1]"Rita Levi Montalcini" Department of Neuroscience, University of Turin (Torino); [2]Sleep Center, "Rita Levi Montalcini" Department of Neuroscience, University of Tuin (Torino); [3]Cresla Centre, "Rita Levi Montalcini" Department of Neuroscience, University of Turin (Torino)

Objective: To evaluate early impairment of sleep and breath in patients affected by amyotrophic lateral sclerosis (ALS) in order to do early treatments, for longer survival and a better quality of life (QoL).

Background: ALS is a neurodegenerative disease characterized by motor neuron death. 30% present a bulbar onset, while 70% a spinal one. Extra-motor systems involved in ALS include circuits regulating sleep; the early identification of sleep impairment and his better definition could improve patient's quality of life (QoL). One of the most important prognostic factors in ALS is respiratory impairment. Its early recognition and an early starting of non-invasive ventilation (NIV) allow prolongation of survival.

Methods: Between August 2021 and December 2022 we enrolled 45 ALS patients and 45 healthy controls (HC). At baseline and at month six, patients underwent neurological examination, polysomnography (PSG), arterial blood gases (ABG), spirometry and filled sleep and respiratory questionnaire (RLSRS, STOP-BANG, ISI, ESS, PSQI, PIRS, MEQ, STAI, BDI). SPSS software was used for data analysis.

Results: At baseline, ALS patients without respiratory symptoms showed an increase of the AHI-index and of the ODI-index compared to HC (respectively, p=0.001 and p=0.04). Contrarily, spirometry and ABG were not so altered. Longitudinally we observed a significant worsening of PSG parameters ($p<0.05$). Patients who started nocturnal-NIV (15 out of 45) showed a significant improvement of PSG parameters. At baseline we also observed an excess of periodic limb movement in ALS vs HC (p=0.01). Direct correlation between progression rate of disease and both AHI and ODI (r=0.546 and r=0.442 $p<0.05$).

Discussion: Classical spirometry and ABG parameters are not good markers of early respiratory impairment in ALS and are not good markers to evaluate respiratory muscle progression of the disease. Between them only pH and HCO3- seem to be associated with an early respiratory impairment. PSG data (in particular AHI and SpO2< 90%) are important in identifying muscle respiratory impairment when not clinically manifest. AHI and SpO2< 90% seem to be good biomarkers to evaluate the respiratory progression of disease in ALS. Sleep macro-structure and micro-structure are altered in ALS patients compared to HC, in particular an increase of deep sleep (with concomitant reduction of REM sleep) and an increase of arousal.

Conclusion: This preliminary study showed the presence of respiratory and sleep impairments in ALS patients since the beginning of the disease. Their identification is fundamental for early treatment and for the improvement of QoL.

## AUTONOMIC CARDIOVASCULAR IMPAIRMENT IN ADULT PATIENTS AFFECTED BY SPINAL MUSCULAR ATROPHY: TOWARDS THE UNDERSTANDING OF MULTISYSTEM INVOLVEMENT IN SMA

S. Bonanno[1], G. Devigili[2], M. Corradi[2], R. Togni[3], A. Elia[2], R. Eleopra[2], L. Maggi[1]

[1]Neuroimmunology and Neuromuscular Diseases Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [2]Parkinson and Movement Disorders Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [3]Neurophysiopathology Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano)

Objectives: In this single center observational study, we aimed to evaluate whether adult spinal muscular atrophy (SMA) patients present a cardiovascular autonomic dysfunction.

Materials and Methods: Two type-2 and 14 type-3 adult SMA patients followed up at the C. Besta Neurological Institute underwent an extensive cardiovascular autonomic assessments (CATs) which included 10 min head-up tilt after 10 min supine rest, Valsalva manoeuvre (VM), deep breathing, sustained handgrip, cold face test, mental stress, and completed the COMPASS-31 autonomic questionnaire. Heart rate variability (HRV), baroreceptor sensitivity, sympatho-vagal balance, were continuously evaluated during the CATs. Results were compared with aged and sex matched controls and normative data.

Results: Adult SMA patients presented a higher COMPASS-31 score compared to controls ($p<0,0001$), reflecting the presence of symptoms of dysautomomia. Cardiovascular reflexes indices were significantly more affected in SMA population compared with healthy subject, with a peculiar pattern characterized by increased bradycardic drive during deep breathing ($p<0.00002$), increased variability of blood pressure during rest and head up tilt test ($p<0.0001$). Moreover, we found an adrenergic hypofunction during VM ($p<0.0001$). Finally, a relative increased of HR at rest was found in 14 of 16 patients (87.5%).

Discussion: Systemic pathology is gaining prominence in SMA after the advent of new disease-phenotypes due to survival motor neuron protein (SMN)-rescue therapies [1]. Previous reports of a defective autonomic nervous system (ANS) in preclinical models of SMA [2] and severely-affected patients [3] suggested an involvement of the ANS in the disease, which remains to be elucidated. Detecting autonomic nervous system alterations becomes more important since new therapeutic strategies will improve functional abilities and increase stress on the cardiovascular system. It might be also relevant to take these evidences into account for optimal clinical success of the therapeutic approaches.

Conclusions: Our data indicate the presence of autonomic cardiovascular dysfunction in adult SMA patients, probably related to impaired inhibitory drive on sympathetic outflow and sympato-vagal unbalance, contributing to properly define SMA phenotypic expression.

## MANAGEMENT OF LONG-TERM TREATMENT IN PATIENTS WITH ANTI-HMGCR IMMUNE-MEDIATED MYOPATHY

G. Brodini[1], G. Gadaleta[1], G. Urbano[1], L. Chiadò-Piat[1], T. Manetta[2], F. Rumbolo[2], T. Mongini[1], L. Vercelli[1]

[1]S.S. Neuromuscular Unit, Department of Neurosciences "Rita Levi Montalcini", AOU Città della Salute e della Scienza, Molinette Hospital (Torino); [2]Clinical Biochemistry Laboratory, AOU Città della Salute e della Scienza, Molinette Hospital (Torino)

Objectives: This study aimed to report the long-term immunotherapy results in patients with immune-mediated necrotizing myopathy (IMNM).

Material: A retrospective study was conducted involving 12 patients with an IMNM diagnosis in the period 2013-2022. Patients were selected based on clinical presentation, muscle biopsy and/or serological testing.

Methods: Medical records were systematically reviewed, extracting age at diagnosis, gender distribution, clinical presentation, statin exposure, laboratory results (creatine kinase levels and autoantibody profiles), magnetic resonance imaging (MRI), muscle biopsy findings and treatment approaches.

Results: We collected 12 patients with anti-HMGCR related myopathy (autoantibodies range 63-343 UA/ml), 7 were males, age at onset ranged from 17 to 79 years. 83% presented a progressive proximal muscle weakness particularly in the pelvic girdle. Three patients were paucisymptomatic but had elevated serum creatine kinase (CK) values. CK levels ranged 1000-28.000 IU/L. Ten patients had a history of statin exposure (mainly atorvastatin); the two youngest patients had no previous statin exposure. Cardiopulmonary involvement was excluded, dysphagia was reported in 25% of patients, mild dyspnoea by one female patient only; two male patients had a neoplastic history. Muscle biopsies (7 cases) showed a necrotic pattern with minimal inflammation signs. Steroid therapy was administered to all patients; three cases needed to add azathioprine. Intravenous immunoglobulin (IVIg) treatment was initiated in all patients, with a good recovery both in clinical aspects and CK levels. Five patients discontinued IVIg treatment, only one patient successfully, while four cases had to restart it due to increased CK levels and/or symptoms deterioration.

Discussion: Anti-HMGCR myopathy is a form of IMNM characterized by muscle weakness, elevated CK levels, necrotic pattern in muscle biopsy; statin usage is frequent [1,2]. The onset may occur acutely or subacutely with a progressive muscle weakness. Treatment strategies for IMNMs are based on immunomodulant/immunosuppressive therapy but are not well-established and rely on clinical experience [3]. Our findings confirm these known clinical and serological features. Moreover, in our cohort, the discontinuation of IVIG therapy (even in patients who achieved a successful remission) led to worsening in CK values and/or muscular symptoms, while resumption of IVIG therapy often resulted in a rapid amelioration.

Conclusion: Anti-HMGCR myopathy is a subtype of necrotizing myopathy whose pathophysiological substrate relies on a likely persistent dysimmune process; thus patients may require repeated cycles of treatment to manage their condition effectively, with strict clinical and serological follow-up.

## BRAIN "NEUROVASCULAR COUPLING" IN AMYOTROPHIC LATERAL SCLEROSIS: CORRELATIONS WITH COGNITIVE IMPAIRMENT AND DISEASE PROGRESSION

F. Canale[1], A. Canna[2], M. Sharbafshaaer[3], C. Passaniti[3], G. D'Alvano[1], F. D'Ammora[1], M. Siciliano[3], G. Tedeschi[1], F. Esposito[3], F. Trojsi[1]

[1]Department of Advanced Medical and Surgical Science, MRI Research Center; First Division of Neurology, University of Campania "Luigi Vanvitelli (Napoli); [2]Department of Advanced Medical and Surgical Science, MRI Research Center; Center for Magnetic Resonance Research, University of Campania "Luigi Vanvitelli"; University of Minnesota (Napoli, Minneapolis-USA); [3]Department of Advanced Medical and Surgical Science, MRI Research Center, University of Campania "Luigi Vanvitelli (Napoli)

Advanced magnetic resonance imaging (MRI) techniques have been previously used to detect structural and functional abnormalities of the brain of patients with Amyotrophic Lateral Sclerosis (ALS). In particular, patients with ALS may show decreased spontaneous brain activity on resting-state functional MRI (RS-fMRI), for example in the Default Mode Network (DMN). Moreover, relatively few studies have addressed the role of neuroimaging in predicting the prognosis of ALS. Functional/metabolic alterations of the brain in ALS may be evaluated investigating the "neurovascular coupling" (NVC), which measures the interplay existing between local cerebral perfusion and neural activity within a given brain region or network. We aim at exploring the potential NVC alterations across different RS-fMRI networks via the above spatial combination of "cerebral blood flow" (CBF) and amplitude of low frequency fluctuations (ALFF) maps, respectively derived from arterial spin labeling (ASL) and blood oxygen level dependent (BOLD) RS-fMRI measurements, in a sample of ALS patients compared to healthy controls (HC). Additionally, we compared the NVC data at baseline in subsets of patients with different disease progression. Fifty-one right-handed ALS patients (31 males), and twenty-five right-handed healthy control subjects (HCs) (10 males) were enrolled. ALS patients were screened by clinical and neuropsychological (Italian version of the Edinburgh Cognitive and Behavioural ALS Screen, ECAS) scales. Furthermore, ALS patients were classified a posteriori as very fast, fast, and slow progressors (VFPs, FPs, and SPs), monitoring disease progression over 12 months according to change in the disability score (ΔALSFRS-R). MRI images were acquired on a 3 Tesla scanner. No patient was affected by dementia, and 17 patients had cognitive impairment (ALSci) according to Strong Criteria (2017). Among 7 RSNs, a statistically significant reduction of NVC was found in the DMN in the ALS patients compared to the HC. We found significant correlations between the NVC in the DMN and the executive function, memory, and visuospatial ability ECAS subscores, and ALS-non-specific subscale. We identified significant differences in NVC at baseline in the DMN between VFPs and SPs groups. Our findings suggest that significant changes in NVC occur outside the motor areas in correlation with changes in cognitive performances in ALS patients. So NVC measures might represent a valuable tool for exploring the early signature of cognitive/extra-motor impairment in ALS, thus allowing us to better characterize the complex phenotype of these patients. Moreover, NVC alterations in DMN could play a role in the detection of patients presenting faster clinical progression.

## USE OF BRAIN 2-[18F]FDG-PET TO DISCRIMINATE ALS AND ALS-MIMICS

A. Canosa[1], A. Martino[2], A. Giuliani[3], C. Moglia[1], R. Vasta[1], M. Grassano[1], S. Cabras[1], F. Di Pede[1], P. Salamone[1], G. Marchese[1], F. Casale[1], G. Polverari[4], U. Manera[1], A. Calvo[1], M. Pagani[5], A. Chiò[1]

[1]ALS Centre, "Rita Levi Montalcini" Department of Neuroscience, University of Turin (Torino); [2]Department of Business and Management, LUISS University (Roma); [3]Environment and Health Department, Istituto Superiore di Sanità (Roma);[4]Positron Emission Tomography Centre, AFFIDEA-IRMET S.p.A. (Torino); [5]Institute of Cognitive Sciences and Technologies, C.N.R. (Roma)

Aims: Some studies showed the capability of brain 2-[18F]FDG-PET to discriminate ALS patients and healthy controls [1,2]. Nevertheless, in clinical practice neurologists face the issue of distinguishing ALS from disorders mimicking ALS. A previous study reported that the combination of brain and spinal cord 2-[18F]FDG-PET achieved a 81.5% accuracy in discriminating ALS and ALS-mimics, while the accuracy was 65.4% for brain metabolism alone [3]. Our study evaluated the capability of brain 2-[18F]FDG-PET as a single marker to discriminate ALS and ALS-mimics.

Methods: We considered eligible ALS patients who underwent brain 2-[18F]FDG-PET at diagnosis at the ALS Centre of Turin between 2009 and 2019, and a group of subjects with ALS-mimics (including cervical spondylogenic myelopathy, multifocal motor neuropathy, myasthenia gravis, etc). Since further analyses considered each voxel as a single feature, by using Automated Anatomical Labeling Atlas only the whole brain volume has been retained from entire PET scans reducing the amount of candidate voxels to 226954. Intensity normalization was performed at individual level averaging each voxel for the mean value of the whole brain. The dataset included 663 ALS and 40 ALS-mimics. We randomly collected 40 ALS from the whole group to calculate Laplacian scores. Subsequently, features were extracted from ALS and ALS-mimics. Finally, the dataset (40 ALS and 40 ALS-mimics) was split in a training set (80%) and a test set (20%). A Support Vector Machine (SVM) approach was used as classifier. The procedure was randomly repeated 10 times.

Results: SVM showed 85% specificity and 81% sensitivity on the test set, with an error rate of 17%. The classification was based on three cerebellar clusters, situated in left anterior lobe, right uvula and right culmen.

Conclusions: Our data support the possible role of brain 2-[18F] FDG-PET as a single diagnostic marker to discriminate ALS and ALS-mimics.

## INTERPLAY BETWEEN COGNITIVE AND MOTOR PHENOTYPES IN AMYOTROPHIC LATERAL SCLEROSIS PHENOTYPES

M. Cillerai[1], P. Ferraro[1], M. Ponzano[2], C. Gemelli[1], C. Cabona[1], A. Signori[2], C. Caponnetto[1], A. Schenone[3]

[1]Department of Neurology, IRCCS Ospedale Policlinico San Martino, University of Genoa (Genova); [2]Department of Health Sciences (DISSAL), University of Genoa (Genova); [3]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), Neurology Unit, IRCCS Ospedale Policlinico San Martino, University of Genoa (Genova)

Objectives: Amyotrophic lateral sclerosis (ALS) is an heterogeneous disease in terms of both motor and cognitive manifestations. While some studies have suggested that the degree of upper motor neuron involvement might be the main driver of the severity of cognitive/behavioral changes in ALS, other works have rather observed a strong link between the site of disease onset, namely bulbar onset, and the occurrence of these extra-motor symptoms. In this study we therefore aimed at examining profiles of cognitive/behavioral impairment and their association with disease severity across diverse ALS motor phenotypes.

Materials: 101 ALS patients were classified as classic (N = 43), bulbar onset (N = 20), predominant-upper motor neuron (PUMN; N = 17), and predominant-lower motor neuron (PLMN; N = 21) phenotypes. Cognition was assessed using the Edinburgh Cognitive and Behavioural ALS Screen (ECAS) and disease severity with the ALS Functional Rating Scale-Revised (ALSFRS-R). According to the revised consensus criteria patients were classified as pure motor ALS, ALS with isolated cognitive impairment (ALSci), ALS with isolated behavioral impairment (ALSbi), ALS with combined cognitive and behavioral impairment (ALScbi) and ALS with frontotemporal dementia (ALS-FTD).

Methods: Negative Binomial regressions were applied to test the effect of motor phenotypes on the ECAS-total and its sub-scores, and Pearson correlation analyses were used to examine the association between ECAS total and ALSFRS-R scores.

Results: Below cut-off ECAS-total scores were detected across all the diverse phenotypes, namely in 40.00% of bulbar onset, 18.60% of classic, 19.04% of PLMN, and 11.76% of PUMN patients. Bulbar onset patients performed worse than classic ALS (p=0.02) and PLMN patients (p=0.03) on the ECAS visuospatial domain. No other significant differences were observed between groups across the investigated domains. Worse ASLFRS-R scores correlated with poorer ECAS-total scores only in classic ALS patients (R=0.36; p=0.01).

Discussion and Conclusions: Cognitive impairment occurs across all the ALS phenotypes but is associated with greater disease severity only in classic disease forms. Notably, while the occurrence of deficits in ALS specific functions is common to the diverse phenotypes, bulbar onset patients exhibit more severe impairment in ALS non specific functions, suggesting a state of more generalized and advanced cognitive impairment in this clinical phenotype.

## GENOTYPE-PHENOTYPE CORRELATION IN A POPULATION OF FUS-RELATED AMYOTROPHIC LATERAL SCLEROSIS PATIENTS: THE IMPORTANCE OF A MULTIDISCIPLINAR APPROACHE

G. Colacicco[1], F. Cerri[1], A. Lizio[1], F. Gerardi[1], L. Mosca[2], V. Sansone[3]

[1]The NeMO Center, Fondazione Serena (Milano); [2]Medical Genetics Unit, ASST Grande Ospedale Metropolitano Niguarda (Milano); [3]Neurorehabilitation Unit, University of Milan (Milano)

Introduction: Mutations in fused in sarcoma (FUS) are among the most common genetic causes of amyotrophic lateral sclerosis (ALS) and often cause aggressive early-onset forms (juvenile-ALS, J-ALS) or late-onset ALS with slow progression usually associated with frontotemporal dementia (FTD).

Methods: We identified and analyzed 14 FUS known mutations ALS patients from a single-center cohort, of 1182 patients genetically tested for the four major genes mutated in ALS in the last ten years.

Results: Three patients presented a juvenile onset of ALS: in this group all patients had a spinal onset, one patient a familiar history, a median age of onset of 16.31 years [9.38-29.90], a median diagnostic delay of 5 months [4.60-28.37]; one patient is still alive after 54 months from the onset, one was died after 24 months and one after 8 years, 1 [33.33%] underwent enteral nutrition by gastrostomy, 3 [100%] underwent non-invasive ventilation, and 2 [66.67%] underwent invasive ventilation. Symptoms were preceded by learning disability or mild mental retardation in all the three patients. Eleven patients presented adult onset of ALS: in this group median age onset was 51.24 years [43.66-68.05], median diagnostic delay was 21.27 months [9.10-35.47], familial ALS was found in 3 subjects[27.27%].The onset was on bulbar site on 5 patients [45.45%] , spinal site on 6[54.55%] ; 6 patients [54.55%] underwent enteral nutrition by gastrostomy, 4[36.36%]underwent invasive ventilation. Median survival was 89.27 months [15.30-97.60] (reduced at 57.50 in the subgroup of 7 patients who refused invasive ventilation). We found 11 different known mutations in our cohort; p.R521C was the most frequent, express in 3 individuals. Two patients presented a second mutation in other genes ALS-related (one in TDP43, one in C-9orf-72). On the J-ALS group we found three different mutations (two missense and one deletion).

Discussion and Conclusions: The analysis of our FUS mutated ALS population shows a high genotipic heterogeneity without a particular mutations more common than other. These are above all missense mutation, but we evidence also a delection in a j-ALS patient. Although all j-ALS patients were all characterized by aggressive history and by a mental retardation (many years before motor symptoms appear), also in this group we found different involvement and progression.

## CLINICAL AND GENETIC FEATURES OF CCNF GENE IN AN ITALIAN ALS COHORT: A SINGLE CENTER STUDY

[1]Neurology Department, Catholic University of the Sacred Heart of Rome (Roma); [2]Adult NEMO Clinical Center, Unit of Neurology, Department of Aging, Neurological, Orthopedic and Head-Neck Sciences, Fondazione Policlinico Universitario A. Gemelli IRCCS (Roma); [3]Unit of Medical Genetics, Department of Laboratory and Infectious Disease Sciences, Fondazione Policlinico Universitario A. Gemelli IRCCS (Roma); [3]Research & Innovation (R&I Genetics) srl (Padova)

Background and Objectives: Genetic variants in the gene CCNF, encoding cyclin F, a component of an E3 ubiquitin-protein ligase complex involved in centrosomal duplication, gene transcription and DNA synthesis, stability and repair, are associated to amyotrophic lateral sclerosis (ALS) in familial (fALS) and sporadic (sALS) cases and/or to frontotemporal dementia (FTD). Objectives of this study were to determine the contribution of CCNF gene in a large monocentric cohort of Italian ALS patients, to assess the CCNF-associated clinical features and to look for genotype-phenotype correlation and penetrance of the mutations.

Materials and Methods: We applied next generation sequencing technologies on 847 unrelated Italian ALS patients referred to our

Center from November 2018 to May 2023 and we filtered results in CCNF gene.

Results: In total, 12 different rare variants, all in a heterozygous state, were identified in 14 index cases (1 fALS and 13 sALS) with a cumulative mutational frequency of 1.6%. 10 CCNF variants have never been described. The most prevalent variant was the novel p.Phe197Leu, found in three patients. The clinical presentation was heterogeneous, with a classic phenotype observed in 9 patients, UMN-D phenotype in 4 patients and flail arm in 1 patient. Clinical evaluation for cognitive impairment using the Edinburgh Cognitive and Behavioural ALS Screen (ECAS) test was performed in 11 patients, demonstrating that 7 patients (64%) had variable degree of frontal dysfunction.

Discussion: In our cohort, we observed CCNF variants in 1.6% of patients (14/847), a percentage similar to that found in other series. Clinical presentation was heterogeneous but, as previously reported, CCNF variants are significantly associated to cognitive impairment.

Conclusions: Our study expands the CCNF genetic variant spectrum identified in a large cohort of Italian ALS patients. As previously reported, CCNF variants were common, especially in SALS patients. Further studies are needed to assess genotype-phenotype associations of CCNF variants.

## SERUM TROPONIN T AND CREATININ KINASE MB IN AMYOTROPHIC LATERAL SCLEROSIS: A CASE-CONTROL STUDY

S. Cotti Piccinelli[1], B. Labella[2], B. Risi[1], F. Caria[1], L. Ferullo[2], E. Olivieri[2], L. Poli[3], A. Padovani[2], M. Filosto[4]

[1]Nemo-Brescia Clinical Center for Neuromuscular Diseases (Brescia); [2]Unit of Neurology, ASST Spedali Civili, Department of Clinical and Experimental Sciences, University of Brescia (Brescia); [3]Unit of Neurology, ASST Spedali Civili (Brescia); [4]Nemo-Brescia Clinical Center for Neuromuscular Diseases, Department of Clinical and Experimental Sciences, University of Brescia (Brescia)

Objectives: To analyze the differences in serum troponin T (cTnT) levels between patients with amyotrophic lateral sclerosis compared to other conditions and to analyze the role of serum troponin T and CK-MB as possible biomarkers of diagnosis and progression in patients with ALS.

Patients: We included patients with a probable, possible, probable laboratory-supported, or definite diagnosis of ALS according to El Escorial and Awaji criteria. We excluded patients with a history of cardiac disease that may lead to an increase in blood troponin T or CK-MB. As a control group, we recruited patients with diagnosed myopathies and axonal neuropathies.

Methods: We performed a case-control analysis comparing cTnT levels in ALS patients (n=48) and controls affected with other neuromuscular diseases (n=27), followed-up at the Unit of Neurology, Spedali Civili (Brescia, Italy), and the NeMO-Brescia Clinical Center for Neuromuscular Diseases (Brescia, Italy) between June 2022 and January 2023. Demographic and clinical variables were expressed as medians (first and third quartiles) or frequencies. The Mann–Whitney U test was used to test differences between two groups. To evaluate the diagnostic performance, we calculated the area under the curve (AUC).

Results: Serum cTnT was elevated in 94.3% of ALS patients (normal value: 14 pg/mL). We observed statistically significant higher levels of cTnT among ALS patients compared to controls (median value 37 vs. 14, p= 0.001). The optimal cut-off of cTnT to distinguish ALS from controls was set at 16 pg/mL with a sensitivity of 92% and a specificity of 68%. The AUC value was 0.82. In the ALS patient group (n=26), we also tested CK-MB levels, which showed no statistically significant difference from controls (median value 6.25 vs. 4.30/L, p= 0.53). Serum cTnT in the ALS cohort showed a strong direct correlation with ALS progression rate (r = 0,76) and patients weight (0,83), while a strong inverse correlation was evident with disease duration (r = -0,73).

Discussion: Serum cTnT and CK-MB are chronically elevated in ALS compared to other neuromuscular diseases. TroponinT's direct correlation with ALS progression rate and inverse correlation with disease duration could suggest a possible role for this molecule as a biomarker, especially for prediction of disease evolution.

Conclusion: Serum cTnT elevation in ALS may reflect lower motor neuron degeneration and re-expression of isoforms of TnT in skeletal muscle during remodeling of the motor unit, suggesting that its determination could be helpful in the diagnostic process and follow-up of ALS. Larger studies with a wider number of patients and longer follow-up are mandatory to confirm our preliminary findings.

## DEPICTING THE EYE MOVEMENT ABNORMALITIES IN AMYOTROPHIC LATERAL SCLEROSIS

F. Cozza[1], A. Lizio[1], G. Garassino[2], L. Greco[1], J. Casiraghi[1], C. Lunetta[3], V. Sanson4, F. Cerri[1]

[1]Neuromuscular Omnicentre (NEMO), Serena Onlus Foundation (Milano); [2]Department of Materials Science, University of Milano-Bicocca (Milano); [3]Neuromuscular Omnicentre (NEMO), Serena Onlus Foundation, ALS Unit, Neurorehabilitation Department, ICS Maugeri IRCCS (Milano); [4]Neuromuscular Omnicentre (NEMO), Serena Onlus Foundation, Neurorehabilitation Unit, Department of Biomedical Sciences of Health, University of Milan (Milano)

Objectives: To compare the fixation and saccadic eye movements between Amyotrophic Lateral Sclerosis (ALS) patients and Healthy Controls (HCs), and to investigate how the ocular data are related to clinical impairment in ALS patients.

Materials: Optometric instrumentation and an advanced screen-based eye tracker capturing gaze at 600Hz were used to perform the tests.

Methods: Subjects with definite, probable and probable laboratory supported ALS were enrolled, together with 21 age and sex-matched HCs. Each subject underwent a set of clinical, optometric and eye tracking assessments which includes calibration, fixation, saccades, horizontal and vertical anti-saccades, and delayed saccades. For each task, in addition to the inter group comparison and the correlation with clinical features, patients' performances were also considered on single patient level (values outside the mean ± 1.645 times standard deviation of normal controls were considered abnormal).

Results: 40 consecutive ALS patients were recruited (median age 59.32yrs], M/F ratio of 2.08). No significant differences emerged in the calibration between ALS and HC groups. Considering the fixation task, 14% of patients were out of normal range. Moreover, a significantly shorter time of fixation was detected in ALS patients if compared to HCs. In the horizontal and vertical saccades test, both peak velocity and average amplitude were significantly lower in ALS patients compared to HCs, with 20% of patients out of normal range

in each task. Finally, 40% and 20% of patients were out of normal range in the horizontal anti-saccades and in the delayed saccades test, respectively and ALS patients reported a significantly higher error rate in both tasks compared to HCs. Analysing the clinical variables, patients with the worse functional impairment documented by ALS Functional Rating Scale–revised reported a significantly higher error rate in horizontal and vertical anti-saccades, and delayed saccades. A faster disease progression was related to a significantly higher horizontal anti-saccades error rate. Finally, a worse functional impairment was significantly related to less accurate eye movements in fixation task.

Discussion: The comparison between ALS and HCs confirmed the involvement of the visual system in ALS; moreover, the worse the functional impairment is and the faster the disease course is, the more specific oculomotor abnormalities can be detected within the ALS cohort.

Conclusion: This study supports the evidence of oculomotor impairment in ALS. How and why the ocular impairment is related to ALS progression is under investigation, together with the influence of cognitive impairment on eye tracking tests.

## COGNITIVE AND NEUROPSYCHOLOGICAL CORRELATION WITH BRAIN METABOLISM IN C9ORF72 AMYOTROPHIC LATERAL SCLEROSIS PATIENTS

F. De Marchi[1], L. Mazzini[1], M. Sarnelli[2], L. Corrado[3], R. Matheoud[4], S. D'alfonso[3], R. Cantello[5], G. Sacchetti[6], C. Comi[7], D. Perani[8], G. Tondo[7]

[1]Als Centre, Department of Neurology, Maggiore della Carità Hospital, University of Piemonte Orientale (Novara); [2]Als Centre, Department of Neurology, Maggiore della Carità Hospital (Novara); [3]Department of Health Sciences, Interdisciplinary Research Center of Autoimmune Diseases (Ircad), University of Piemonte Orientale (Novara); [4]Department of Medical Physics, Maggiore della Carità Hospital (Novara); [5]Department of Neurology, Maggiore della Carità Hospital, University of Piemonte Orientale (Novara); [6]Department of Nuclear Medicine, Maggiore della Carità Hospital (Novara); [7]Department of Neurology, S. Andrea Hospital, University of Piemonte Orientale (Vercelli); [8]Division of Neuroscience, Vita-Salute San Raffaele University (Milano)

Background: Hexanucleotide repeat expansion (GGGGCC) in the first intron of the C9ORF72 gene accounts for a significant proportion of autosomal dominant amyotrophic lateral sclerosis (ALS)-frontotemporal dementia (FTD) spectrum disorders. In ALS, mutations in the C9ORF72 gene are present in 40% of familial and 5–10% of sporadic forms. Although not always clinically distinguishable from sporadic forms, ALS patients' carriers of the C9Orf72 mutation (C9+) more commonly have an earlier disease onset, a bulbar phenotype, and a high frequency of severe cognitive impairment. In our preliminary report, we compared the 18F-FDG-PET imaging findings in a group of genetic patients, observing an extensive motor and prefrontal hypometabolism in fast progressors, compared to a more limited hypometabolism in patients showing the same mutation but grouped as slow progressors, and several correlations between hypometabolism brain pattern and score in neuropsychological tests. This study aimed to confirm and expand the neuropsychological findings in a larger C9+ group.

Methods: We included ten C9+ patients who underwent a complete neuropsychological evaluation and an 18F-FDG-PET scan at baseline. Patients were recruited at ALS Tertiary Centre in Novara, Italy. We obtained hypometabolism maps at a single-subject level following a validated voxel-based Statistical Parametric Mapping procedure. The corresponding 18F-FDG-PET regional hypometabolism was extracted by anatomo-functional ROIs: prefrontal, temporoparietal, occipital, rolandic cortex, and supplementary cortical and subcortical regions. Patients, classified based on Strong criteria, were divided into ALS-normal (ALS-no, n=2), ALS-behavior (ALS-bi,n=2), and ALS-cognitive (ALS-ci, n=6). The ROIs' hypometabolism was compared with scores in neuropsychological tests. Also, a mean hypometabolism map was derived in each cognitive group to underline brain metabolism differences between ALS-no, ALS-bi and ALS-ci.

Results: We observed several correlations between hypometabolism and anatomo-functional ROIs, such as: prefrontal areas and phonological fluency test (PFT) (r=-0.86, p=0.03), Frontal Assessment Battery (FAB) (r=-0.87, p=0.002) and Clock Drawing test (CDT) (r=-0.79, p=0.01); temporoparietal area and Short Story Test (0.73, p=0.04), CDT (r=-0.80, p=0.001), and FAB (r=-0.88, p=0.002); insula and Raven's Progressive Matrices (r=-0.70, p=0.03), PFT (r=-0.80, p=0.008), and FAB (r=-0.88, p=0.02). Focusing on the hypometabolism maps, the ALS-no have hypometabolism confined in motor regions; the ALS-bi group showed prominent hypometabolism in temporoparietal and limbic areas, and the ALS-ci group showed extended hypometabolism in motor and prefrontal regions.

Discussion: The brain metabolism showed specific correlations with neuropsychological impairment in C9+ patients, confirming our preliminary results, and different hypometabolism maps based on the cognitive group. The results support the role of 18F-FDG-PET in revealing patterns of neuronal dysfunction, aiding the diagnostic workup in ALS.

## ROLE OF TDP-43 IN THE DIAGNOSIS AND PHENOTYPIC CHARACTERIZATION OF AMYOTROPHIC LATERAL SCLEROSIS: COMPARISON BETWEEN CSF AND PLASMA DATA

F. De Marchi[1], D. Profico[2], A. Abate[2], S. Ferrari[1], R. Cantello[1], M. Gelati[2], L. Mazzini[1]

[1]Department of Neurology, "Maggiore Della Carità" University Hospital (Novara); [2]Advanced Therapies Production Unit, Fondazione Irccs Casa Sollievo Della Sofferenza (San Giovanni Rotondo-FG)

Background: The diagnostic work-up for Amyotrophic Lateral Sclerosis (ALS) diagnosis is complex and often associated with diagnostic delay. Scientific research focused on the neurodegeneration biomarkers that can anticipate the diagnosis and phenotypically characterize patients is necessary. Among these, TDP-43, which accumulates in the neuronal cytoplasm in most ALS patients, is one of the most promising. This study aimed to compare the data obtained from the cerebrospinal fluid

(CSF) and blood TDP-43 dosage and to correlate the results obtained from the assays with clinical and laboratory data.

Methods: 14 patients were recruited, and CSF and serum TDP-43 were determined by the ELISA method. Clinical-phenotypic and functional data (ALSFRS-R, BMI, FVC%), blood chemistry, and genetic data were also collected.

Results: A strong negative correlation (r=-0.70; p=0.03) was observed between CSF and serum levels. There was also a significant positive correlation (r=0.67; p=0.03) between CSF and Creatine phosphokinase (CPK) and a negative correlation (r=-0.90; p=<0.01) between serum TDP-43 and CPK values. Patients with the bulbar phenotype appear to show lower levels of CSF TDP-43 compared to spinals (p=0.04); moreover, there was a positive correlation between CSF TDP-43 and the bulbar subscore of the ALSFRS-R (r=0.67; p=0.03). Correlating with the genetic data, the patient carries the lowest absolute CSF TDP-43 concentration within the cohort characterizes a SOD1 mutation.

Conclusions: Data from this study support the utility of TDP-43 as a biomarker in ALS, both at CSF and plasma levels, also showing significant correlation with clinical and genetic data.

## UPPER MOTOR NEURON INVOLVEMENT IN ALS: A CORRELATION BETWEEN NEUROPHYSIOLOGICAL AND METABOLIC BRAIN PATTERN

F. De Marchi[1], G. Tondo[2], C. Gallo[1], R. Matheoud[3], G. Sacchetti[4], C. Comi[2], R. Cantello[1], D. Perani[5], L. Mazzini[1]

[1]Department of Neurology, "Maggiore Della Carità" University Hospital (Novara); [2]Department of Neurology, Sant'Andrea Hospital (Vercelli); [3]Medical Physics, "Maggiore Della Carità" University Hospital (Novara); [4]Nuclear Medicine, "Maggiore Della Carità" University Hospital (Novara); [5]Division of Neuroscience, Vita-Salute San Raffaele University (Milano)

Background: In Amyotrophic Lateral Sclerosis (ALS) diagnostic work-up, the involvement of lower motor neurons (LMNs) is easily demonstrated by electromyography; on the contrary, finding markers of upper motor neuron (UMN) suffering is harder. Transcranial magnetic stimulation (TMS)-induced motor-evoked potentials (MEPs) are one of the proposed markers of (sub)clinical UMN damage.

Aim: Our study aimed to verify a possible correlation between the metabolism brain pattern and the MEPs findings for highlighting the UMN damage.

Methods: A total of 20 ALS patients who underwent FDG-PET and TMS-MEPs at diagnosis were retrospectively enrolled in the study. Patients were enrolled between 2018 and 2022 at the ALS Tertiary Center, Novara, Italy. For each patient, we collected clinical-phenotypical variables (focusing on the UMN signs). We measured the motor latency, amplitude, and central motor conduction time (CMCT) for TMS-MEPs from the upper and lower limbs. For FDG-PET, following a validated voxel-based Statistical Parametric Mapping procedure, we obtained hypometabolism maps at the single-subject level, correlating the regional hypometabolism with clinical and neurophysiological values.

Results: Of enrolled patients, the mean age was 57.2±12.63 years (30% bulbar and 70% spinal onset). 14/20 patients (70%) had abnormal MEPs in at least one limb: 8/20 (40%) had unreliable MEPs, and 12/20 (60%) had delayed CMCT. Regarding the lower limbs, we observed a direct correlation between lower limbs CMCT and precentral, frontal superior, and supplementary motor areas (r=0.65, p=0.05; r=0.76, p=0.02; r=0.72, p=0.03). For the upper limbs, the correlation is limited with the supplementary motor area (r=0.78, p=0.02).

Discussion: Our data suggest an essential single and additive role of TMS-MEPs and FDG-PET in highlighting the UMN suffering in ALS patients at diagnosis.

## A CASE OF SPASTIC PARAPLEGIA CAUSED BY ERLIN2 NOVEL VARIANT, WITH PROGRESSIVE EVOLUTION IN AMYOTROPHIC LATERAL SCLEROSIS

V. Dell'Era[1], M. Vedovello[1], G. Negro[1], A. Negroni[2], D. Martinelli[3], M. Sessa[1]

[1]Neurology Unit, Asst Papa Giovanni XXIII (Bergamo); [2]Rehabilitation Medicine Unit, ASST Papa Giovanni XXIII (Bergamo); [3]Headache Science and Rehabilitation Center, IRCCS C. Mondino Foundation (Pavia)

Objective: ERLIN2 mutation is known to cause SPG18, a group of recessive or dominant hereditary spastic paraplegia, characterized by lower-extremity weakness and spasticity, due to upper motor neurons degeneration. Only a few reports have shown that patients with spastic paraplegia due to mutations in ERLIN2, can evolve to rapid progressive ALS.

Methods and Results: We described a case of a 64 year-old woman, with diagnosis of spastic paraparesis associated with a novel variant c.406G>A, p.Val 136IIe in the ERLIN2 gene. She developed progressive weakness and spasticity to lower limbs during the fifth decade of life. The same genetic variant was described in other three members of her family (her sister, son and nephew), also affected by lower-extremity weakness and spasticity. After 5 years from symptoms onset, the patient developed rapid bulbar involvement with dysphagia, dysarthria, associated with weakness and atrophy of upper limbs. Electromyographic data showed lower motor neuron involvement, in spinal and bulbar regions. This clinical evolution allowed the diagnosis of clinically defined ALS according to the Awaji criteria.

Discussion: Our case supports the results of previous few reports, showing that spastic paraplegia caused by ERLIN2 variants, can convert to ALS in time. These findings support the hypothesis that ERLIN2 mutations can present with a wide spectrum of motoneuron clinical disorders, including HSP and ALS.

## TRANSCRIPTOME SIGNATURE IN AMIOTROPHIC LATERAL SCLEROSIS (ALS) PHENOTYPES

L. Diamanti[1], M. Garofalo[2], E. Scarian[1], F. Dragoni[3], R. Di Gerlando[3], M. Busacca[3], G. Fiamingo[4], D. Tornabene[4], J. Garau[2], M. Bordoni[2], O. Pansarasa[2], S. Gagliardi[2]

[1]IRCCS Mondino Foundation, Dep. of Brain and Behavioral Sciences, University of Pavia (Pavia); [2]IRCCS Mondino Foundation (Pavia); [3]IRCCS Mondino Foundation, Dep. of Biology and Biotechnology "L. Spallanzani", University of Pavia (Pavia); [4]Dep. of Brain and Behavioral Sciences, University of Pavia (Pavia)

Introduction and Objectives: Unmeet needs for ALS patients includes both the identification of criteria for clinical stratification, and the discovery of reproducible biomarkers. We aim to identify a transcriptome signature in homogenous MND sub-groups obtained using specific phenotype classification.

Materials and Methods: We have stratified n=48 newly-diagnosed sporadic ALS patients by Chiò et al [1] criteria, and enrolled n=19 age-matched healthy controls. We have isolated PBMCs, performed RNA sequencing, and compared the transcriptome profiles for all the subjects compared to healthy controls.

Results: We have collected the following phenotypes: n=12 classic, n=10 bulbar, n=7 flail arm, n=10 flail leg, n=9 pyramidal. We have observed a different gene expression between patients and controls ($p<0.05$), particularly for the flail leg subgroup. Moreover, bulbar phenotype has been characterized by a great number of altered genes ($p>0.05$). Finally, we have noticed a single gene altered in all the phenotypes (Y-RNA, a component of the Ro60 ribonucleoprotein involved in cellular response to interferon-alpha and in regulation of gene expression) while the other genes seem to be phenotype-specific, and many of them are involved in inflammatory pathways.

Discussion and Conclusions: The identification of phenotype-specific pathogenic mechanisms could be pivotal for the study of progression biomarkers. Future development of this work will regard the longitudinal evaluation of transcriptomic patterns.

## DIAGNOSTIC CUES IN MULTIFOCAL MOTOR NEUROPATHY

C. Erra, D. Ricciardi, B. De Martino, F. Tuccillo, F. Habetswallner

Neurophysiology Unit, AORN A. Cardarelli (Napoli)

Objectives: Our objective was to describe clinical and neurophysiological follow up course and nerve ultrasound picture of our patients with Multifocal motor neuropathy (MMN), in order to describe correlations within clinical, neurophysiological and US pictures. Is a rare acquired immune mediated neuropathy with progressive motor multifocal neuropathy without sensory involvement. MRI and nerve US are emerging as useful tools in the diagnostic process. In particular, nerve and cervical root US has showed multifocal peripheral nerve or single fascicle enlargement in both clinically and electrophysiologically affected and unaffected segments, as well as normal nerve appearance in definite conduction block sites. Nerve US can be altered also in other immune-mediated neuropathies such as CIDP, but MMN presents an highed intra-nerve variability.

Materials and Methods: Four patients with multifocal motor neuropathy treated in our Neurophysiology Unit were recruited. Clinical (MRC sum scale, single MRC value for all involved muscles) and neurophysiological data were retrospectively collected and follow up evaluation was performed. Nerve US of median, ulnar, peroneal, tibial nerves was performed and cross sectional area was measured in all abnormal sites and in definite/probable nerve conduction block sites.

Results: Four patients were evaluated: 4 males, mean age 56 (range 45-69), mean disease duration 9 years (range 5-13 years). Chronic and frequent IVIg provided in 3 patients partial efficacy with initial improvement followed by progressive axonal damage over the years. In fact, these patients (3/4) depend on periodic infusions. One patient, the one with shorted disease duration, showed a slight initial clinical and neurophysiological improvement followed by stabilization. Nerve US showed in all patients multifocal nerve enlargements in both affected and unaffected nerve segments. Table 1 summarizes patients' information while nerve ultrasound cross sectional area values are reported in table 2 and 3 respectively for lower and upper limbs.

Discussion: Follow up examination showed clinical and neurophysiological stability in some patients, while others showed a axonal damage progression despite therapy. In our case series, nerve US showed results consistent with pre-existing literature. This finding is not highly specific as it is also observed in other immune mediated neuropathies. Although nerve conduction studies remains the gold standard for its high specificity, nerve US could help increase diagnostic sensibility in showing a multifocal damage and aiding differential diagnosis.

Conclusions: We can hypothesize that the observed variability may be related not only to the different pathogenesis but to the stage and type of nerve damage and to the duration of the disease.

## A SINGLE-CENTER LONGITUDINAL AND RRETROSPECTIVE STUDY OF DYSPHAGIA IN 113 PATIENTS WITH MYOTONIC DYSTROPHY TYPE 1 (DM1)

C. R. Ferrari Aggradi[1], M. Lombardi[1], A. Zanolini[1], V. Camesasca[2], C. Cattaneo[1], J. Lops[1], V. Sansone[1]

[1]NeMO Clinical Center, Neurorehabilitation Unit, Milan University of the Studies (Milano); [2]Gastroenterology Endoscopy, ASST Niguarda Hospital (Milano)

Objectives: Pneumonia is the main cause of death in DM1 and aspiration may play an important role. Yet dysphagia is a seldom complaint, it is poorly studied in the initial stages of disease, it has a high impact on patients quality of life and information on progression is scanty in this disease. Our aim is to describe swallowing function and nutritional status of patients with DM1 at baseline and over time.

Materials: Adult patients with a DM1 genetically determined diagnosis admitted to the Nemo Clinical Center in Milan from 2013 to 2021 were included.

Methods: Dysphagia was assessed using validated questionnaires and fiberoptic endoscopic evaluation (FEES) and correlated to demographic features, nutritional status and disability.

Results: 113 adult patients with DM1 were evaluated. At baseline FEES showed that out of 113 patients (mean age: 49 years [42.50 – 57.50], mean disease duration: 16.76 years [9.56 – 23.72]; mean MIRS: 4 [3 – 4]) 27 (24%) had a normal swallowing function (Dysphagia Outcome Severity Scale (DOSS): 6-7), 81 (72%) had mild-moderate impairment (DOSS: 3-5) and 5 (4.5%) had severe impairment (DOSS: 1-2). Follow-up data available in 65 patients showed progression to a mild-moderate swallowing impairment in 8 of 16 with normal swallowing function at baseline, while only 3 of 45 (6%) with mild-moderate swallowing impairment at baseline showed progression to severe impairment.

Discussion: Dysphagia had a high prevalence in our cohort and most of our patients showed mild-moderate swallowing impairment, but with scarce awareness and possible unexpected complications. The progression from mild-moderate to severe dysphagia appeared to be slow, which was in line with the general slowly progressive course of this disease. Nevertheless, the progression from normal function to mild-moderate impairment in 50% of our patients in less than 3 years is a factor that can not be underestimated.

Conclusion: Our study brings out the crucial role of dysphagia in DM1 clinical phenotype. In addition, the progression from normal swallowing to mild-moderate dysphagia strongly suggests that regular and systematic swallowing assessments are highly recommended in this population.

Gemelli University Hospital IRCCS (Roma); [8]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia (Modena)

Amyotrophic Lateral Sclerosis (ALS) is a relentless disease, characterized by wide genetic and clinical heterogeneity which reflects its biological complexity and not fully understood pathomechanisms. Currently, the identification of significant biological indicators of the disease state and progression represents an urgent unmet need. Although ALS is typically classified as a disease involving motor neurons, increasing evidence show the contribution of different systemic players to the disease pathogenesis, including metabolism, immunity and microbiome. Microbiome is crucial for immune system functioning and it has been recognized as a critical regulator of brain physiology, therefore influencing the host susceptibility to neurodegenerative diseases, including ALS. In detail, the gut microbiota exerts its effects on the central nervous system (CNS), through a bidirectional interaction, the gut-brain axis, influencing neuronal health via production of neuroactive metabolites such as the short chain fatty acids (SCFA) and toxins and through the modulation of immune system, e.g. T cells' activity and their differentiation. In addition, the viral components of the microbiome, termed as "virome", may have a relevant role in maintaining the immune system health as well. The most prevalent element of the human virome is the torque teno virus (TTV). There is mounting evidence that TTV viremia levels are closely correlated with host immunity and it has been proposed as a biomarker for assessing the immune system's functionality. Since the microbiome composition is considered a major source of inter-individual variation in immunity, susceptibility to diseases and clinical heterogeneity, we analyzed a panel of microbiome- and inflammatory-related components as potential diagnostic and prognostic biomarkers in ALS. For the first time, we showed, through the serum level assessment of 14 cytokines, TTV viremia and 18 FFA (free fatty acids), that a set of these parameters may clearly distinguish ALS (n=100) from healthy controls (n=34). Moreover, the combination of these factors allowed to match the patients based on biological profile bringing potential for biotyping. Infact, among the ALS patients' group, the examined biological variables lead to identify four clusters of patients with a distinct biological profile, although without correspondence with clinical features such as site of onset, sex, progression rate, phenotype or C9ORF72 expansion. In addition, we found an association between 2-ethylexanoic acid level and patients' survival that was different in males and females. Our work adds new evidence to the involvement of microbiome, metabolism and immunity in ALS, offering new parameters for clinical disease phenotyping.

## GOLD COAST CRITERIA IN ALS PATIENTS: A CLINICAL PRACTICE SINGLE-CENTER EXPERIENCE

L. Ferullo[1], B. Labella[2], S. Cotti Piccinelli[3], F. Caria[4], B. Risi[4], E. Olivieri[2], L. Poli[5], A. Padovani[2], M. Filosto[3]

[1]Department of Clinical and Experimental Sciences, University of Brescia (Brescia); [2]Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Unit of Neurology, ASST Spedali Civili (Brescia); [3]Department of Clinical and Experimental Sciences, University of Brescia, NeMO-Brescia Clinical Center for Neuromuscular Diseases (Brescia); [4]NeMO-Brescia Clinical Center for Neuromuscular Diseases (Brescia); [5]Neurology, ASST Spedali Civili (Brescia)

Objectives: Revised El Escorial (rEEC) and Awaji Criteria are currently used for diagnosing and categorizing Amyotrophic Lateral Sclerosis (ALS). However, they are complex, their sensitivity is still not optimal for research purposes, and present high inter-rater variability in clinical practice. To address these points, in 2019, a new set of diagnostic criteria was proposed, namely the Gold Coast Criteria (GCC), characterized by a dichotomous diagnostic categorization, i.e., ALS or not ALS. Their reliability compared to the previous ones is debated. The aim of our study was to evaluate the sensitivity, specificity, and clinical usefulness of GCC in a practical clinical setting.

Materials: We evaluated retrospectively 131 patients diagnosed with ALS and 104 control subjects with no diagnosis of ALS at the Unit of Neurology, ASST Spedali Civili (Brescia, Italy), and NeMO-Brescia Clinical Center for Neuromuscular Disease (Brescia, Italy) between October 2003 and May 2023.

Methods: A complete clinical assessment, electrophysiological tests, neuroradiological investigations, and CSF analysis were obtained for each subject. rEEC, Awaji, and GCC at the first and last evaluations were applied.

Results: The mean age at onset was 63 and 60 years for ALS and the control group, respectively. For the ALS group, the difference between the first evaluation and the last follow-up visit was about 16 months. The mean ASLFRS-R at onset and at last evaluation was 41.78 and 27 points, respectively. The sensitivity of GCC (93.1%; 96.1%) was greater than rEEC (71.7%; 87%) and Awaji criteria (77.8%; 89.3%) both at the first visit and last follow-up. The GCC specificity (28.8%) is lower than that of the other two criteria (rEEC 45.2%; Awaji criteria 43.2%).

Discussion: Our study suggests that GCC has a greater sensitivity compared to rEEC and Awaji criteria in our population. rEEC has been found to have the highest specificity, but it might delay the diagnosis. Even if GCC's positive predictive value (62.2%) is nearly the same as previous criteria (rEEC 62.2%; Awaji criteria 63.3%), GCC has shown a negative predictive value significantly higher (77%) than rEEC (56%) and Awaji criteria (60.8%). Proving a substantially lower risk of false negative diagnoses compared to previous ones, the novel criteria could help to not delay the correct diagnosis and refer patients early to the correct treatment.

Conclusions: The reduced specificity of GCC is less likely to impact patient recruitment in clinical trials, therefore, its use might allow an earlier diagnosis of ALS and a faster enrolment.

## DRUG USE PATTERNS IN MYASTHENIA GRAVIS: A REAL-WORLD OBSERVATIONAL STUDY IN ITALY - THE CAESAR STUDY

M. Finocchietti[1], G. Crescioli[2], O. Paoletti[3], P. Brunori[4], F. Sciancalepore[5], M. Tuccori[6], A. Addis[7], A. Vannacci[2], N. Lombardi[2], U. Kirchmayer[7]

[1]Department of Epidemiology ASL Roma 1, SSR Lazio, Sapienza University of Rome (Roma); [2]Department of Neurosciences, Psychology, Drug Research and Child Health, Section of Pharmacology and Toxicology, University of Florence, Tuscan Regional Centre of Pharmacovigilance (Firenze); [3]Regional Health Agency of Tuscany, Pharmacoepidemiology Unit (Firenze); [4]Neurophysiopathology, Perugia Hospital (Perugia); [5]National Center for Disease Prevention and Health Promotion, Italian National Institute of Health (Roma); [6]Tuscan Regional Centre of Pharmacovigilance, Department of Clinical and Experimental Medicine, Unit of Pharmacology and Pharmacovigilance, University of Pisa (Firenze, Pisa); [7]Department of Epidemiology Lazio Regional Health Service (Roma)

Objectives: In the context of a comparative study of efficacy and safety of drugs used in rare neuromuscular and neurodegenerative diseases (CAESAR - call AIFA_FV_2012-13-14) we assessed the use patterns of drugs indicated for Myasthenia gravis (MG).

Materials: For each region, the following administrative healthcare data sources were considered: healthcare assistance, hospital discharge records, emergency department visits, disease specific co-payment exemptions, drug claims for reimbursed drugs for outpatient use, mortality information system.

Methods: A retrospective cohort study was conducted based on administrative healthcare data. For a cohort of MG patients, prevalent and incident use of pyridostigmine (Py) and other indicated drugs in the first year after case identification was evaluated. Prevalent combined use of major therapies (azathioprine (Az), prednisone (Pr), vitamin d (Vd)) stratifying by Py use was assessed, and a comparison between therapies at MG identification date and during the first year of follow-up was performed.

Results: We included 1,114 MG patients in 2013-2019. In the first year of follow-up, we observed prevalent and incident use of Py in 60% and 3.5% of patients, respectively, 57.1% and 4.4% for Pr, 24.7% and 3.3% for Az, and 42.5% and 8.2% for Vd. Among 668 Py prevalent users, 19.9% also used Az, Pr and Vd, while 13.2% none of these. Among 446 non-Py users, 2.9% used Az, Pr and Vd, while 58.3% none of these. An increase of combined therapies was evident only in incident Py users.

Discussion: Most MG patients use Py, often in combination with one or more drugs among Az, Pr, and Vd. Corticosteroid therapy is more frequent in new users of Py. Most non-Py users are not treated with either of these drugs. Our real-world analysis showed that the management of MG patients in clinical practice generally follows guidelines. Unexpectedly, we found a relevant number of patients who were not receiving treatment. Despite available treatment options, the impact of the disease remains high for many MG patients.

Conclusion: Our results suggest that, for some MG patients, there may be a need for treatments that combine a rapid onset of benefit with long-term and consistent disease control. These issues may be addressed by the new treatments currently being developed. To date, more studies are needed to address the heterogeneity, quality, and generalisability of the existing data, and to evaluate patterns of use, efficacy and safety of new or emerging therapies for MG.

## CARDIAC ORGANOIDS AS AN IN VITRO PARADIGM FOR MYOTONIC DYSTROPHY TYPE 1: AN INNOVATIVE APPROACH TO DISEASE MODELING

L. Fontanelli[1], A. Huang[2], A. Kostina[2], E. Schirinzi[1], A. Aguirre[2], G. Siciliano[1]

[1]Department of Clinical and Experimental Medicine, Neurology Unit, University of Pisa (Pisa); [2]Institute for Quantitative Health Science and Engineering, Division of Developmental and Stem Cell Biology, Michigan State University (Michigan-USA)

Aims: Myotonic Dystrophy type 1 (DM1) is a multisystemic disease caused by a triplet expansion of the 5' untranslated region of DMPK gene. Its pathophysiology is still debated, although it is thought that RNA toxicity plays a pivotal role in sequestering splicing factors of a multitude of genes involved in muscle contraction, cardiac conduction and central nervous system functions [1]. In recent years organoids, tissue cultures derived from induced pluripotent stem cell (iPSCs), have been able to recapitulate organ development, structure, and physiology [2]. Our aim is to generate cardiac organoids as in vitro model of DM1 to better explore disease mechanisms and as a preclinical model for testing candidate drugs.

Materials: Four induced pluripotent stem cells lines from National Institute for Neurological Disease and Stroke (NINDS) repository of four different caucasian patients (NH50153, NH50156, NH50159, NH50256) affected with myotonic dystrophy, harboring different expansion triplet numbers (CTG range: 150 – 1170). We used iPSCs of unaffected subject as control.

Methods: IPSCs were thawed and progressively transitioned them in Essential 8 medium (Thermofisher). Once the cells were ready, cardiac differentiation wee induced via transforming growth factors. Cardiac differentiation was completed in a week by sequential exposure of inhibitor of glycogen synthase kinase 3 CHIR99021 (Miltenyi Biotec), Activin A and Bone Morphogenetic Protein [3].

Results: Beating organoids of subject NH50153, NH50156 & NH50159 appeared approximately at day 7 of the differentiation protocol. We were unable to expand iPSCs of subject NH50256 (harboring 1170 CTG mutation) as they died during passages. We are performing sequential morphological analyses as well as immunohistochemistry and gene expression analyses to characterize the role of DMPK expression in organoids throughout maturation period.

Discussion: New approaches are required in order to address the limitations of current cellular and animal models. From the best of our knowledge, this is the first attempt to generate cardiac organoids from DM1 patients. We demonstrated that obtaining cardiac organoids of DM1 is feasible and allows to perform multi-dimensional and serial analyses on models directly generated from patient's genotype. This is especially important in DM1 since somatic instability plays a pivotal role in disease progression. By allowing to visualize dynamic processes happening throughout time, organoids may pave the way for more accurate disease modeling, drug screening, and personalized therapeutic approaches.

Acknowledgments: Authors would like to thank "Un Passo per Te" Foundation, for research in Neuromuscular Diseases for the scientific support and grant.

## SOD1-ALS FEATURES AND PREDICTORS OF DISEASE PROGRESSION AND SURVIVAL FROM TWO ITALIAN POPULATION-BASED REGISTRIES

A. Ghezzi[1], I. Martinelli[2], E. Zucchi[2], G. Gianferrari[2], L. Ferri[2], C. Moglia[3], U. Manera[3], L. Solero[3], R. Vasta[3], A. Canosa[3], M. Grassano[3], M. Brunetti[4], L. Mazzini[5], F. De Marchi[5], C. Simonini[2], N. Fini[2], M. Caputo[1], M. Vinceti[1], M. Pinti[6], A. Chiò[3], A. Calvo[3], J. Mandrioli[1]

Background: Uncovering distinct features and trajectories of amyotrophic lateral sclerosis (ALS) associated with SOD1 mutations (SOD1-ALS) can help with patients' counseling and stratification for trials, and timing of interventions. Our study aims to identify distinctive clinical features of SOD1-ALS focusing on genotype-phenotype correlation and on factors that may affect disease progression.

Methods: This is a retrospective observational study of a SOD1-ALS cohort from two Italian registers of Emilia Romagna and Piedmont and Valle d'Aosta regions.

Results: Among 2204 genotyped ALS patients, 2.5% carried SOD1 mutations, with a M:F ratio of 0.83. SOD1-ALS patients were younger and reported more frequently a family history of ALS or FTD. SOD1-ALS had a longer survival if compared to patients without ALS associated gene mutation, but a high variability was found across mutations and a mean survival shorter than one year was found for L39V, G42S, G73S, D91N mutations. Among SOD1-ALS, multivariate analysis showed that, besides well-known clinical prognostic factors such as late age at onset and high progression rate at diagnosis, mutations localized in exon 2 or in highly conserved gene positions, predicted a worse survival. On the contrary, among comorbidities, cancer history was independently associated to better survival.

Discussion: The prevalence of SOD1 mutations in our population was consistent with previous reports in European datasets [1]. In the context of an overall slower disease, SOD1-ALS presents a certain heterogeneity linked to the high genetic diversity dictated by the multiplicity of possible mutations sites, and to some clinical prognostic factors, among which cancer history. Recognizing the modulators of SOD1-ALS phenotypic heterogeneity may be useful for improving response to forthcoming therapies.

## ATYPICAL HIRAYAMA SYNDROME CASES WITH PROXIMAL UPPER LIMB ONSET

F. Giammello[1], A. Fortuna[2], C. Casella[1], F. Granata[3], K. Galletta[3], E. Mormina[3], V. Rizzo[4], G. Sorarù[2], A. Toscano[1]

[1]Stroke Unit, Department of Clinical and Experimental Medicine, University of Messina (Messina); [2]Neurology Clinic, Department of Neuroscience, University of Padua (Padova); [3]Neuroradiology Unit, Department of Biomedical, Dental Science and Morphological and Functional Images, University of Messina (Messina); [4]Movement Disorders Unit, Department of Clinical and Experimental Medicine, University of Messina (Messina)

Aims: To provide an insight into atypical manifestation of Hirayama disease (HD), describing two cases with insidious proximal upper limb involvement at onset.

Background: HD is a flexion-induced myelopathy, characterized by the juvenile onset of unilateral or asymmetric weakness and amyotrophy of the hand and ulnar forearm, predominantly affecting C8–T1 and most common in males in Asia [1].

Methods: Dynamic flexion magnetic resonance imaging (dfMRI) is the imaging modality of choice to diagnose HD [2]. The pathology is enhanced by flexion of the cervical spine, revealing forward migration of dura with enlargement of posterior epidural space. Herein, we present two cases of Hirayama disease with a juvenile insidious onset, atypical proximal upper limb weakness and hypotrophy with a proximal-distal progression.

Results: Case 1. A 41-year-old man reported a focal weakness and wasting of the proximal left arm, starting before the age of 18. The symptoms remained stable until the age of 38 years, when there was a progressive worsening with subsequent slow involvement of the contralateral proximal upper limb. DfMRI revealed a segmentary detachment between the posterior dural sac and the subjacent lamina at the C3-C5 level. The “snake-eye appearance” was enhanced by cervical flexion. Repeated electromyography revealed a progressive neuronopathic impairment. Case 2. A 15-year-old boy presented an insidious and progressive right proximal arm weakness for one year. After 8 months from onset, weakness spread to distal right arm muscles, and proximal hypotrophy appeared. Neurological and neurophysiological examinations highlighted right arm lower motorneurons impairment. DfMRI showed a myelopathic process in the right lateral paramedian midline between C4-C6, associated with detachment of the posterior cervical dural sac.

Discussion: The reported cases fulfil the recent Huashan diagnostic criteria for HD [1]. The prominent shifting of dural sac in C3-5 and C4-C6 segment, respectively, detected by dfMRI, may explain the unusual distribution of the disease, with the atypical involvement of the proximal upper limb at onset [3]. Case 1 experienced repeated disease relapse with an interval of stable stage. Both neurophysiological and imaging findings indicate irreversible lesions, a poor prognosis with progression of the disease, and a possible need for surgical intervention.

Conclusions: HD should be suspected in young patients presenting with slowly progressive weakness and wasting restricted to one limb at onset. While most cases involve the lower cervical myotomes, proximal upper limb involvement has been seen rarely. Nerve conduction studies and dfMRI are fundamental tools to lead to a correct diagnosis also to exclude other similar entities.

Gemelli IRCCS (Roma); [15]3rd Neurology Unit and Motor Neuron Disease Centre, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [16]ALS Center, Department of Basic Medical Sciences, Neurosciences and Sense Organs, University of Bari (Bari); [17]Department of Medical and Surgical Sciences for Children and Adults, University of Modena and Reggio Emilia (Modena)

Background: In preclinical studies the anti-inflammatory drug colchicine enhanced the expression of autophagy factors like HSPB8, the master regulator Transcription Factor EB (TFEB), the adaptor protein SQSTM1/p62 and the Microtubule- associated protein 1A/1B-light chain 3 (LC3). The concomitant induction of these proteins counteracted TDP-43 accumulation, a hallmark of ALS. Colchicine has never been tested on ALS patients.

Material and Methods: In this multicenter, randomized, double-blind trial, probable or definite ALS patients with symptoms onset within 18 months, were randomly assigned in a 1:1:1 ratio to receive colchicine 0·01 mg/kg/day, 0·005 mg/kg/day or placebo for 30 weeks. The primary outcome was the number of patients exhibiting a decrease fewer than 4 points in the ALS Functional Rating Scale-Revised (ALSFRS-R) total score from baseline to treatment end. Secondary outcomes included changes from baseline of stress granule and autophagy responses, TDP-43 and neurofilament accumulation, extracellular vesicles secretion, comparing colchicine and placebo arms. Clinical outcome measures of disease progression, survival, safety and quality of life were also collected.

Findings: Fifty-four persons were randomly assigned to colchicine or placebo. In intention-to-treat analysis, 33·3% of patients treated with colchicine 0·005 mg/kg/day versus 13·3% with placebo had a decline fewer than 4 points at ALSFRS-R in 30 weeks (95%CI 0·39 to 40·42, p=0·416). During and after treatment ALSFRS-R monthly decline slowed down only in patients treated with colchicine 0·005 mg/kg/day compared to those who received the placebo (mean difference 0·53, 95%CI: 0·07 to 0·99, during treatment; mean difference 0·46, 95% CI: 0·07 to 0·84, after treatment). Reported adverse events (AEs) were 14 (42·8% of which were severe) for placebo arm, and 34 for the colchicine arms (35·3% of which were severe). Events occurring at a greater frequency in the colchicine group were mainly gastrointestinal disorders. Based on safety, clinical and biological effects, colchicine 0·005 mg/kg/day resulted the best dosage in this study.

Discussion: For the decline in ALSFRS-R fewer than 4 points a difference of only 20% was found in the low-dose group with respect to placebo, leading to missing the primary outcome. In patients treated with colchicine 0·005 mg/kg/d, there was a trend towards a slower ALSFRS-R monthly decline during and after treatment, but we cannot

exclude heterogeneity in disease progression. Colchicine treatment was well-tolerated and provided reassuring preliminary safety findings in ALS patients.

Conclusion: Colchicine treatment was safe, but further trials are necessary to evaluate efficacy of this commercial drug in ALS.

## THE OUTPATIENT CLINIC: A NEW PERSPECTIVE TO TAKE CARE OF PEOPLE AFFECTED BY NEUROMUSCULAR DISEASE

E. Gotti[1], E. Bazzoni[1], P. Perego[1], F. Cerri[1], A. Zanolini[1], V. Sansone[1,2]

[1]Neuromuscular Omnicentre (NeMO), Serena Foundation (Milano); [2]Neurorehabilitation Unit, University of Milan (Milano)

Aim: The aim of the study is to verify whether the early outpatient care of social-welfare needs supports the patient and the clinician in the early definition of the treatment plan. We are implementing the early outpatient care model in the adult population of patients affected by neuromuscular diseases that typically occurs when an individual is usually fully engaged in working activities and is in the most active life phase with relevant social and familiar impact. In the NeMO Clinical Center there is a specialized nurse, called Nurse Coach, dedicated to take care of patients and family and who has acquired specialized skills to manage clinical and nursing aspects and to facilitate the access at home nursing cares and to socio-economics aids. During a first-time visit to the site, a newly diagnosed patient with neuromuscular disease, is not only seen by a neurologist but the initial visit includes a nurse coach and a psychologist. This allows to target the intervention early in the disease process.

Materials and Methods: Retrospective qualitative analysis of needs, aids and homecare service detected by Nurse Coach in the outpatient clinic of the NeMO Center from January 2022 to April 2023.

Results: The Nurse coach has launched a care plan in 60 patients (mainly affected by amyotrophic lateral sclerosis and myotonic dystrophy) and their caregivers (average time of this initial evaluation = 60 minutes per patient). Information on the bureaucracy of disability rights and economical aids which are the most important needs in the first stage of the disease were collected as well as the request for educational aspects to manage symptoms.

Discussion: Together with the diagnosis the family context and the economic status must be taken into consideration as soon as possible; they can affect the disease course and the possible therapeutic adherence. The nurse coach must therefore have defined skills and competences that go beyond the predetermined practical "nurse skills" to find the best solution with the families.

Conclusion: The care of patient with a neuromuscular disease and his or her family could be improved with an early multidisciplinary approach, including also social and economic aspects.

## GIVING BREATH TO MOTOR NEURONS: NON-INVASIVE MECHANICAL VENTILATION SLOWS DISEASE PROGRESSION IN AMYOTROPHIC LATERAL SCLEROSIS

M. Grassano[1], E. Koumantakis[2], U. Manera[1], A. Canosa[1], R. Vasta[1], F. Palumbo[1], G. Fuda[1], P. Salamone[1], G. Marchese[1], F. Casale[1], L. Charrier[2], G. Mora[1], C. Moglia[1], A. Calvo[1], A. Chio[1]

[1]"Rita Levi Montalcini" Department of Neuroscience, University of Turin (Torino); [2]Department of Public Health and Pediatrics, University of Turin (Torino)

Background and Objectives: Non-invasive mechanical ventilation (NIMV) improves Amyotrophic Lateral Sclerosis (ALS) quality of life and survival. However, data about its effect on disease progression are still lacking. Here, we test whether NIMV use changed the rate of functional decline among ALS patients.

Methods: In this retrospective observational study, we included 465 ALS patients followed up at the ALS Center in Turin, Italy, who underwent NIMV during the disease course. The primary outcome was the change in functional decline after NIMV initiation when adjusting for covariates. Functional decline was based on the non-respiratory items of the ALS Functional Rating Score – Revised (ALSFRS-R).

Results: A slower progression of functional decline followed NIMV initiation (mean improvement 0.13, 95%CI 0.11 to 0.16, $p<0.001$) regardless of sex, age at diagnosis, and disease duration before NIMV initiation. Indeed, the disease stage at NIMV initiation (early or advanced) did not influence the results. Respiratory support exerts its slowing effect mainly on the progression of spinal motor function.

Conclusions: We proved that NIMV influences the rate of motor progression in ALS. This result was not a consequence of the ALSFRS-R floor effect. The functional decline slowed after starting NIMV independently of the site of disease onset. Our results reinforce the importance of not delaying NIMV initiation in all ALS patients. NIMV-induced slowing of disease progression should also be accounted for when evaluating clinical trial outcomes.

Objectives: Deficits in all Social Cognition subdomains have been reported in Amyotrophic Lateral Sclerosis [1] and have been included in 2017 Strong revised criteria [2]. However, cognitive determinants of SC subdomains are largely unknown. The aim of the present study was to investigate the functional correlation between SC abilities, specifically Facial Emotion Recognition (FER) and Theory of Mind (ToM), with the other fundamental cognitive domains.

Materials: We enrolled 102 consecutive patients attending the Turin ALS Center between February 2019 and December 2022. All patients underwent a neuropsychological battery assessing fundamental cognitive domains, included SC. FER was assessed by the Ekman 60-Faces test (EK-60F), ToM was assessed by the Reading the Mind in the Eyes Test-36 faces full version, and the Story-Based Empathy Task (SET).

Method: A multiple linear regression model was conducted to correlate SC tests corrected scores as independent variables, with 8 neuropsychological tests chosen as independent variable, representative of each cognitive domain assessed. Specifically, as independent variable we included Letter Fluency test, Category Fluency Test, Trail Making Test B-A, Digit Span Backward, Wisconsin Card Sorting Test (WCST), Frontal Assessment Battery, Rey Auditory Verbal Learning Test-Delayed Recall, Rey Osterrieth Complex Figure Test-Immediate and Delayed Recall.

Result: EK-60 F test showed an overall significant correlation with the other cognitive tests (R2 adj 0.286, p 0.037), without any specific correlation. RMET-36 showed an overall moderate significant correlation (R2 adj 0.382, p 0.002), and a significant specific correlation with Wisconsin Card Sorting Test (WCST) (p 0.032). SET-GS showed an overall weak significant correlation (R2 adj 0.250, p 0.033), and also a specific significant correlation with WCST (p 0.034). SET-IA did not show an overall weak significant correlation with the other cognitive tests. SET-EA showed an overall moderate significant correlation (R2 adj 0.262, p 0.027), and a significant specific correlation with WCST (p 0.003) and TMT B-A (0.044).

Discussion: our study shows that SC subdomains have a different pattern of correlation with the other cognitive domains. Specifically, while FER does not show any specific correlation, ToM shows a specific correlation with executive functions, in line with previous results [3].

Conclusions: The relationship of ToM with other cognitive domains, especially with Executive Functions, should be further explored as it is relevant in clinical conditions with frontal involvement, where a dysexecutive syndrome may be associated with ToM deficits and/or behavioural symptoms, as we observe in ALS patients.

## EARLY ADMINISTRATION OF RITUXIMAB IMPROVES CLINICAL OUTCOME REGARDLESS OF MYASTHENIA GRAVIS SUBTYPE: A SINGLE CENTER COHORT STUDY

E. Latini, M. Maestri, M. Guida, R. Ricciardi

Department of Clinical and Experimental Medicine, Neurology Unit, University of Pisa (Pisa)

Background: Rituximab (RTX) is a chimeric monoclonal anti-CD20 antibody that had shown good effectiveness and safety in generalized Myasthenia Gravis (gMG) patients and that is currently recommended as a therapeutic option in MuSK-MG in recent consensus guidelines update. Yet, evidence indicating its most appropriate use is still scarce.

Aim and Methods: We retrospectively evaluated a cohort of gMG patients treated with RTX as an add-on therapy consecutively seen at the MG Clinic of Azienda Ospedaliero-Universitaria Pisana in order to investigate clinical predictors of better outcome after RTX infusion.

Results: Of the 36 patients included, 27 were women (75%) and antibodies against muscle specific tyrosine kinase (MuSK) were present in 18 patients (50%); mean (SD) age at treatment start was 48 (17) years. Mean (SD) MGFA composite score before RTX administration was 12,3 (8,3) and 3,5 (5,7) at last follow-up. 5 patients achieved complete stable remission and discontinued steroid therapy. We did not observe significant differences in clinical outcome and steroid sparing effect between the two MG subtypes, indeed patients who received RTX within 12 months of disease onset had a greater improvement in MGFA composite score in both groups ($p< 0.001$).

Conclusions: In our cohort of gMG patients early administration of RTX (e.g. within 12 months of disease onset) obtained better outcomes in terms of clinical improvement irrespectively of antibody status, suggesting a greater benefit of RTX earlier in the disease course also in new-onset generalized MuSK-MG. Larger prospective studies are warranted to provide further evidence.

## GENDER DIFFERENCES IN CLINICAL OUTCOMES IN MUSK-MG PATIENTS

E. Latini, M. Maestri, M. Guida, M. Caselli, A. De Rosa, R. Ricciardi

Department of Clinical and Experimental Medicine, Neurology Unit, University of Pisa (Pisa)

Background and Aim: Evidence on gender differences in Myasthenia Gravis (MG) patients showed an increased disease severity in females, especially on patient-reported outcome measures. However, studies are almost entirely based on anti-AChR positive MG patients and data is lacking regarding MuSK-MG ones. We therefore explore the potential differences in outcome measures and therapeutic approach with respect to gender in this specific subtype of MG.

Methods: We collected demographic and clinical data of 54 MuSK-MG patients out of the 202 consecutively admitted to the MG Clinic of the Azienda Ospedaliera-Universitaria Pisana with a median follow-up time of 2.3 ± 1.4 (median ± DS) years. The clinical diagnosis of MG was confirmed in all patients by a positive test for MuSK antibodies using radioimmunoassay. The Myasthenia Gravis Foundation of America (MGFA) clinical classification criteria, MG-Composite (MGC) score and the MG-Activities of Daily Living (MG-ADL) score were used to assign clinical state as outcome measures at baseline and follow-up visits, then analyzed for relationships with gender. Demographic features, comorbidities, antibodies titer and therapeutic data, including the type and dosage of standard medical therapies administered were also recorded at each evaluation and analyzed for gender influence.

Results: Our cohort comprehends 16 male patients (29.6%) and 38 (70.4%) female patients, with a median age of 49 ± 17 years. Duration of disease at first visit was di 2.6 ± 3.2 years (median ± DS) and the distribution of symptoms and clinical MGFA grade were predominantly IIb to V. There were no significant gender differences in baseline and follow-up scores, disease duration, age at disease onset, age, MGFA classification and antibodies titer. All patients improved over time when comparing baseline measures to follow-up, again without any significant gender difference. Notably, with respect to treatment, we did not observe a gender biased approach to the choice of steroid therapy and steroid-sparing agents.

Discussion and Conclusions: To date, this is the first study to investigate gender differences in clinical outcomes in MuSK-MG patients and we did not observe a gender influence on patient-reported and composite outcomes measures. Our results could reflect the distinct features of MuSK-MG. Indeed, the predominant bulbar involvement and the severity of the disease with a high tendency to frequent relapses and respiratory failure could impact on the quality-of-life scores irrespectively of gender. Further studies are needed to confirm these data and investigate how gender affects also the different immunological pathway of MuSK-MG.

## COGNITIVE FUNCTIONING IN MYASTHENIA GRAVIS: A COHORT STUDY IN A THIRD-LEVEL ITALIAN CENTER

M. Leonardi[1], A. Raggi[1], A. Fornari[1], R. Frangiamore[2], S. Bonanno[2], R. E. Mantegazza[2], C. G. Antozzi[2], L. Maggi[2], F. Vanoli[2], M. Cheli[2], E. Guastafierro[1], P. Sismondo[1], A. Marcassoli[1]

[1]Neurology, Public Health and Disability Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [2]Neurology 4 Unit, Neuroimmunology and Neuromuscolar diseases, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano)

Background: Currently there are conflicting results about the neuropsychological profiles of people with Myasthenia Gravis (MG) [1-3] while screening measures of global cognitive functioning in this population are scarcely available.

Objectives: This study aims to investigate the prevalence of individuals with MG with significant differences in performance on neuropsychological tests, compared to the general population; we will investigate the relationships between these performances and disease's clinical features, work productivity, activities of daily living, anxiety, depression, fatigue, disability, and quality of life.

Methods: 150 people with MG will be enrolled at Carlo Besta Neurological Institute in Milan. We will collect Information about socio-demographic and disease features (such as current drug therapy and antibody profile), neuropsychological tests (Brief Neuropsychological Examination-3 and Global Examination of Mental State), disability (MG-Disability), quality of life (MG-Quality of Life), work productivity (WPAI-GH), independence in daily life (MG-Activities of Daily Living), anxiety, depression (Hospital Anxiety and Depression Scale), and fatigue (Fatigue Severity Scale). Correlation analyses will be carried out between the neuropsychological performances and the other administered questionnaires. Analysis of variance models between groups of patients belonging to different clinical disease subtypes will also be implemented.

Discussion: The assessment of cognitive functioning and disease outcome's indicators such as well-being, disability, quality of life and work productivity in people with MG will allow to better understand the care, support and treatment needs of these patients, facilitating a multidimensional approach to identify tailored care pathways that will successfully respond to patient needs.

## RESPIRATORY QUOTIENT AS INDEPENDENT PREDICTOR OF PROGNOSIS IN A LARGE COHORT OF AMYOTROPHIC LATERAL SCLEROSIS PATIENTS

A. Lizio[1], J. Lops[2], V. Sansone[2], F. Cerri[2]

[1]NEuroMuscular Omnicenter (NEMO), University of Milano-Bicocca (Milano); [2]NEuroMuscular Omnicenter (NEMO), Serena Onlus Foundation (Milano)

Objective: Since a lower Respiratory Quotient (RQ) in Amyotrophic Lateral Sclerosis (ALS) patients was associated with worse functional status, lower Lean Soft Tissue Mass, higher Fat Mass %, and longer disease duration [1], which in turn are factors associated with worse survival [2,3], the aim of the study was to evaluate the prognostic role of RQ as independent predictor of survival.

Material: The RQ is the ratio of the patient's carbon dioxide production (VCO2) to the oxygen consumption (VO2), and it is obtained by indirect calorimetry (IC), a noninvasive, reliable, and valuable tool in assessing energy expenditure.

Methods: ALS patients with RQ value available at first evaluation, were retrospectively recruited at the NEMO Center (Milan) between July 2008 and November 2017. Extensive demographic and clinical features were also collected.

Results: A total of 249 ALS patients (mean age: 62yrs ± 12, bulbar/spinal ratio: 0.46) were enrolled. The decrease in RQ resulted to be significantly related to a shorter tracheostomy-free survival (p=0.0130), and this relationship was confirmed independently from age at evaluation, disease duration, ALSFRS-R total score and disease progression rate as results of backward selection method of a set of candidate confounders. An RQ ≤ 0.78 emerged as best cut-off (Contal and O'Quigley outcome-oriented approach) in discriminating short- and long-term survival (HR: 1.50 [1.11–2.02], p=0.0084). Moreover, although any significant association emerged between RQ and body composition, patients with RQ ≤ 0.78 reported a significantly lower ALSFRS-R total and subscores, seated FVC% and FEV1% compared with patients with RQ > 0.78.

Discussion: RQ level could describe the functional and respiratory condition of ALS patients and seems to independently predict survival in ALS patients. However, a prospective study will be needed to understand the relationship between respiratory involvement and nutritional aspects in defining RQ changes.

Conclusion: RQ could be used as prognostic factor in ALS to categorize patients in short- and long- term survival classes, although there is a need to more deeply investigate the RQ proportion of variance explained by both respiratory involvement and nutritional status.

## PHENOTYPIC HETEROGENEITY OF MONOGENIC AMYOTROPHIC LATERAL SCLEROSIS: THE CASE OF TARDBP MUTATION

M. Lombardi[1], F. De Marchi[1], L. Corrado[2], S. D'Alfonso[2], C. Comi[3], R. Cantello[1], L. Mazzini[1]

[1]Neurology Unit, Department of Translational Medicine, University of Eastern Piedmont (Novara);[2]Genetic Laboratory, Department of Health Sciences, University of Eastern Piedmont (Novara);[3]Neurology Unit, Department of Translational Medicine, University of Eastern Piedmont (Vercelli)

Background: Mutations in 43-kDa transactive response (TAR)-DNA-binding protein (TARDBP) are associated with 2-5% of familial ALS cases. TAR DNA-Binding Protein 43 (TDP-43) is an RNA/DNA binding protein involved in several cellular mechanisms (e.g., transcription, pre-mRNA processing, splicing). Many ALS-linked TARDBP mutations have been described in literature, but few phenotypic data of monogenic TARDBP-mutated ALS are available. This study aims to investigate the clinical genotype-phenotype heterogeneity of different mutations in TARDBP.

Material: We analyzed the clinical features of ALS patients carrying mutations in the TARDBP gene evaluated at the Tertiary ALS Center at the Maggiore della Carità University Hospital, Novara, Italy, from 2010 to 2020. Of 350 patients genotyped, 4 were carriers of TARDBP mutation.

Results: Patient 1: a 61-year-old man presented with a slowly progressive muscle weakness in the left leg first, then in the right for two years. Neurological examination showed spasticity in the lower limbs, diffuse hyperreflexia, and left Babinski's sign. No signs of lower motor neuron (MN), bulbar or cognitive impairment were evident. Genetic analysis revealed the presence of c.G1144A, p.A382T (NM_007375) missense variant in heterozygous status in exon 6 of the TARDBP gene. Patient 2: at the age of 55 a woman presented with 10 months history of progressive lower limb weakness. Neurological examination showed fasciculations with diffuse hyperreflexia. Electromyography and Motor Evoked Potentials also confirmed the involvement of both upper and lower MNs. Genetic analysis revealed the p.M539V (NM_007375) mutation in exon 6 of the TARDBP gene. Patient 3: a 66-year-old man showed a 2-year history of rapidly worsening disease till respiratory failure occurred. He presented bulbar onset with dysphonia and dysarthria. Neurological examination showed upper and lower limb hyperreflexia and spasticity. No EMG signs of lower MN involvement were observed. Genetic analysis revealed the p.G294V (NM_007375) mutation in exon 6 of the TARDBP gene. Patient 4: a 72-year-old man presented with a slow progressive history of dysarthria and dysphagia. Symptoms then proceeded with mild lower limb weakness and spasticity. No EMG signs of lower MN involvement were detected, neither sign of cognitive impairment at the neuropsychological tests. Genetic analysis revealed the p.N390S (NM_007375) mutation in exon 6 of the TARDBP gene.

Discussion: Our clinical data and those in the literature support and confirm the hypothesis that TARDBP pathogenic variants have considerable geno-phenotypic heterogeneity within the ALS spectrum, both in terms of clinical presentation at onset, prevalent phenotype, cognitive impairment, and disease progression and duration.

## A NOVEL KIF5A MUTATION LINKED TO HEREDITARY SPASTIC PARAPLEGIA AND ASSOCIATED WITH GLUTEAL CLONUS

L. Lombardo[1], E. Baroncelli[2], F. Gotta[1], E. Pedemonte[1], A. Murialdo[1], G. Zocchi[1], G. Novi[1], M. Del Sette[1]

[1]IRCCS Policlinic San Martino, University of Genoa (Genova); [2]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa (Genova)

Objectives: Hereditary spastic paraplegia (HSP) includes a heterogeneous group of genetic diseases, mainly characterized by degeneration of upper motor-neurons. HSP 10 is a rare form of autosomal dominant HSP caused by mutations within the Kinesin Family member 5A (KIF5A) gene. We report the case report of a patient with HSP 10.

Materials: A 57-year-old male was referred to our department due to progressive limb weakness and gait unsteadiness. Neurological examination showed diffuse upper motor-neuron signs, with iperreflexia and bilateral Babinski sign. Bilateral pes cavus was also present. A stereotyped rhythmic muscular contraction of gluteal muscles was triggered by sudden gluteal stretch by the examining physician, consistent with muscle clonus. Patient reported presence of slight motor impairment since childhood with progressive worsening in the adult age. A similar motor impairment pattern was also reported in patient's son.

Methods: We describe a novel complicated HSP10 phenotype in two siblings with signs and symptoms of upper motor neuron degeneration, Charcot-Marie-Tooth (CMT)-like axonal neuropathy and associated with a newly described gluteal clonus. Clinical data, genetic tests and electrophysiological features of index case and family members are reported.

Results: A genetic sequencing disclosed a novel pathogenetic mutation in the KIF5A gene (c.776T>C, p.L259P) in both patients, and electrophysiological study confirmed features of CMT-like axonal neuropathy and gluteal clonus.

Discussion: We report on a novel mutation in KIF5A gene leading to a complex form of HSP, characterized by a HSP phenotype associated with CMT2 axonal neuropathy. This mutation occurs within the N-terminal protein motor domain confirming that missense mutations involving the N-terminal motor domain mainly leads to HSP and CMT2 phenotypes, while loss of function mutations involving the C-terminal of the protein are linked with an ALS-phenotype [1]. In KIF5A-associated ALS protein aggregates accumulation within neuronal bodies might spread through an anterograde transport leading to widespread (upper and lower) motor-neuron degeneration [1-3]. Additionally, we found that index patient displayed a gluteal clonus, possibly linked to the widespread degeneration involving long motor-neuron cortico-spinal fibers. We postulate that gluteal clonus might be a previously undescribed and underreported neurological sign of cortico-spinal dysfunction and could be looked up into cases where gastrocnemius muscle clonus is found.

Conclusions: We describe a novel pathogenetic mutation in KIF5A in two family members with a complicated HSP10 phenotype with features of upper motor-neurons degeneration and CMT-like axonal neuropathy. We also describe for the first time clinical and electrophysiological characteristics of gluteal clonus.

## A CLUSTER OF ALS PATIENTS WITH ALA96GLY SOD1 MUTATION DETECTED IN A SARDINIAN VILLAGE

A. Maccabeo[1], M. Sanna[1], F. Pili[1], M. Puligheddu[1], E. Cocco[2], M. Murru[3], G. Defazio[4], A. Chiò[5], G. Borghero[1]

[1]Department of Medical Sciences and Public Health, Institute of Neurology- University Hospital D. Casula Monserrato (Cagliari); [2]Department of Medical Science and Public Health, Multiple Sclerosis Centre, University of Cagliari (Cagliari); [3]Department of Public Health, Clinical and Molecular Medicine, Multiple Sclerosis Centre, University of Cagliari (Cagliari); [4]Department of Translational Biomedicine and Neuroscience, University of Bari (Bari); [5]Rita Levi Montalcini' Department of Neuroscience, University of Turin (Torino)

Objectives: To describe clinical features of a cluster of amyotrophic lateral sclerosis (ALS) patients with Ala96Gly variant in SOD1 gene.

Cases Description: Along 2021 and 2022, three unrelated patients originally from a small village in Oristano province (Sardinia) were diagnosed with spinal-onset ALS. The first neurological examination revealed in patient 1 (female, 67 years-old) bilateral weakness and hypotrophy of lower limbs and walking instability, in patients 2 (male, 54 years-old) and 3 (male, 51 years-old) asymmetric hypotrophy and weakness of distal upper limbs muscles. All patients had hypoactive deep tendon reflexes and no bulbar functions involvement. No cognitive impairment was detected. During the follow-up period, a slow progression of limbs motor impairment was observed, without involvement of speech and swallowing. Patient 3 was diagnosed with nocturne respiratory insufficiency two years after disease onset and started non-invasive ventilation cycles. Genetic analysis for major genes responsible for ALS in Sardinia was proposed.

Results: Sequencing of coding regions of SOD1 gene identified a missense variant c.287C>G in heterozygosis in exon 4, previously described in two Sardinian patients originally from the same village. Retrospective research of our database identified other four deceased and three alive ALS patients native of the same small area and genetic analysis tested positive for the same mutation. All retrospective patients had shown a very slow progression and a long survival duration (up to 30 years), a predominance of lower motor neuron signs, late involvement of respiratory and bulbar functions and no cognitive impairment.

Discussion: With the advent of targeted gene therapies, the importance of genetic testing in ALS is increasing. Mutations in SOD1 gene have been found in 13-20% of familial ALS cases and in 1-2% of sporadic cases and up to 200 different mutations had been described to date. We describe a cluster of ALS patients with a SOD1 mutation, so far identified in a small Sardinian area only. A predominant spinal lower motor neuron involvement and a very slow progressive course are common features of this variant. Counseling for targeted gene therapy is ongoing.

Conclusion: We described a SOD1 mutation linked to slowly-progressive spinal ALS and we underline the importance of offering genetic testing to all patients early after diagnosis.

## "CROSSING" PHENOTYPE OF JUVENILE LOWER MND CASE ASSOCIATED WITH RARE SYNE-1 VARIANTS

G. Maccanti[1], F. Mari[2], S. Battistini[3], A. Carrer[2], C. Ricci[3], F. Ariani[2], N. Volpi[3], L. Monti[4], M. Alberti[4], F. Ginanneschi[3], N. De Stefano[5], A. Rossi[3], A. Renieri[2], F. Giannini[3], S. Casali[3]

[1]Department of Neuroscience, University of Siena (Siena); [2]Med Biotech Hub and Competence Center, Department of Medical Biotechnologies, University of Siena (Siena); [3]Neurology and Clinical Neurophysiology Unit, Department of Medical, Surgical and Neurological Sciences, University of Siena (Siena); [4]Unit of Diagnostic and Functional Neuroimaging, Dpt. of Neurology and Human Movement Sciences, University of Siena (Siena); [5]Clinical Neurology and Neurometabolic Unit, Department of Medical, Surgical and Neurological Sciences, University of Siena (Siena)

Introduction: Juvenile amyotrophic lateral sclerosis (JALS) is a group of MNDs, with a genetic cause in 40% of cases. Most commonly mutated genes are FUS and SOD1 associated to typical presentation and variable time course, SETX and ALS2 [1], associated to UMN phenotype and slow disease progression. We describe a patient who carried novel compound heterozygous pathogenic variants of SYNE-1 (spectrin repeat containing nuclear envelope protein-1), presenting a very atypical phenotype and slow progression.

Case Report: A 27-years-old male born to non-consanguineous marriage, with negative family history, came to our attention six years ago suffering from weakness in right upper limb (rUL). Neurological examinations showed clinical signs of LMN involvement (fasciculations, hyposthenia, amyotrophy and hypo-areflexia) restricted to rUL and, more lightly, to lLL (proximal and distal districts). He also presented fine postural tremor reported since he was eleven. Any UMN signs, nor cognitive, cerebellar, bulbar and respiratory impairment were detected. Electromiography confirmed signs of LMN damage in clinically affected limbs. Motor Evoked Potentials were normal, despite DTI sequences of brain MRI showed slight reduction of Fraction Anisotropy in pyramidal tracts. Left femoral muscle biopsy, performed because of CK value > 1000 U/ml, showed neurogenic pattern. Basal and flexion cervical MRI and CSF standard examination were negative as well as the extensive research for occult cancer. SOD1-FUS-TARDBP43-C9ORF72-VCP-SMN1/NAIP-AR-ATTR genetic analysis were negative. Next Generation Sequencing revealed c.22720G>T (p.(Ala7574Ser)) variant inherited from healthy father and c.6574C>T (p.(Leu2192Ile)) variant inherited from healthy mother in exon 126 of SYNE-1 gene. Only in the last two years mild LMN involvement of other limbs was observed with sparing of bulbar, respiratory, cerebellar functions.

Discussion: Overall data led us to a diagnosis of atypical phenotype of JALS. Mutations in SYNE-1 are commonly known to cause autosomal-recessive pure cerebellar ataxia (SCA8). Some recent studies have revealed that SYNE-1 variants lead to heterogenous and multisystemic phenotypes, not necessarily pure cerebellar, such as MNDs, brainstem dysfunctions, cognitive impairment, intellectual disability, musculoskeletal abnormalities, respiratory distress with different combinations [2]. Only three Asiatic cases are described with pure JALS associated to SYNE 1 variants[1]. To our knowledge the current patient is the first reported in Caucasian ethnicity. SYNE-1 encodes for a structural protein involved in vesicular trafficking, expressed abundantly in cerebellum but in motor neurons and brainstem also. Aberrant vesicular trafficking is one of MND possible causes [3]. Our observation would confirm the pathogenetic role of SYNE-1 variants in MNDs.

## RATE OF CHANGE IN UPPER AND LOWER MOTOR NEURON SIGNS PREDICTS SURVIVAL IN AMYOTROPHIC LATERAL SCLEROSIS

A. Maranzano[1], F. Verde[2], F. Gentile[3], E. Colombo[1], A. Wall[1], A. De Lorenzo[3], A. Doretti[1], C. Cinnante[4], C. Morelli[1], S. Messina[1], V. Silani[2], N. Ticozzi[2]

[1]Department of Neurology, Istituto Auxologico Italiano IRCCS (Milano); [2]Department of Pathophysiology and Transplantation, Dino Ferrari Center, University of Milan (Milano); [3]Neurology Residency Program, University of Milan (Milano); [4]Radiology Department, Istituto Auxologico Italiano (Milano)

Objectives: The role of upper (UMN) and lower motor neuron (LMN) involvement in amyotrophic lateral sclerosis (ALS) has been extensively studied in relation to clinical phenotype, neuropsychological involvement, and survival. Conversely, no study has explored whether the rate of change (RoC) of UMN and LMN signs from symptom onset to first clinical assessment could provide useful information related to ALS disease evolution. In this study, we investigated if RoC of UMN and LMN signs might be more informative than single quantification of UMN and LMN involvement in predicting survival.

Materials: An inpatient cohort of 1017 ALS patients, recruited at Istituto Auxologico Italiano, was retrospectively evaluated. Burden of UMN and LMN signs was assessed using the Penn Upper Motor Neuron Score (PUMNS) and Lower Motor Neuron Score (LMNS), respectively. The time interval between symptom onset and first evaluation was used to quantify the RoC of UMN and LMN scores. ENCALS survival model, survival, time from symptom onset to percutaneous endoscopic gastrostomy (PEG), and time to non-invasive ventilation (NIV) were used as outcomes.

Methods: Multinomial regression model was used to compare different measures of UMN and LMN signs among ENCALS groups. Cox regression was performed to estimate the effect of the above-mentioned variables on survival.

Results: ENCALS groups characterized by shorter survival were significantly associated with higher RoC of PUMNS and LMNS when compared to those with longer survival. Moreover, higher RoC of PUMNS and LMNS had a significant negative association with survival (RoC of PUMNS: HR= 1.33, 95% CI= [1.27-1.39], p< 0.001; RoC of LMNS: HR= 4.08, CI= [3.47-4.78], p <0.001) and were inversely associated with time to PEG (RoC of PUMNS: rho= -0.29, p= 0.010; ROC of LMNS: rho =- 0.55, p< 0.001) and time to NIV (RoC of PUMNS: rho= -0.36, p< 0.001; RoC of LMNS: rho= - 0.65, p< 0.001). Conversely, no significant associations of PUMNS or LMNS with the above-mentioned variables were observed.

Discussion: Findings from our work reveal that the RoC in UMN and LMN signs might represent a reliable clinical index to estimate disease evolution and survival in ALS patients. Indeed, these two measures provide distinct clinical information in addition to that derived from the burden of UMN and LMN signs at first evaluation.

Conclusion: By reflecting the progressing degeneration of the two distinct motor neuron subpopulations, RoC in UMN and LMN signs might offer dynamic parameters that could help clinicians to evaluate disease aggressiveness.

Aims: To investigate the molecular signature of bulbar onset ALS through integrated miRNA and proteome profiling.

Materials and Methods: We included 54 patients meeting the diagnostic criteria for ALS and 50 sex-age matched healthy controls (HC). We performed an integrated miRNA and proteome profiling in serum of a discovery cohort of 26 ALS patients and 28 HC. Serum samples were analyzed with untargeted TaqMan Human MicroRNA array cards containing 754 miRNAs. Validation of dysregulated miRNAs was performed in a second independent cohort of 28 ALS patients and 22 HC by real-time PCR using specific Taqman assays. We performed a proteomics analysis of extracellular vesicles obtained from the serum of 7 bulbar onset ALS patients, 7 spinal onset ALS patients, and 6 HC by means of a shotgun label-free platform based on the coupling of nano liquid chromatography and high-resolution tandem mass spectrometry.

Results: Discovery phase revealed four miRNAs (miR-885-5p, miR-150-5p, miR-483-5p, miR-342-3p) significantly down-regulated in bulbar onset compared to spinal onset ALS patients and HC. We did not find any differentially expressed miRNA in spinal onset ALS patients with bulbar impairment compared to spinal onset ALS patients without bulbar impairment (data not shown). These findings indicate a specific signature for bulbar onset ALS, rather than the impairment of bulbar muscles due to the progression of the disease. To validate the results of the discovery phase we analyzed the four dysregulated miRNAs in the serum of further 28 ALS patients and 22 HC by real-time PCR. A significant down-regulation of miR-150-5p and miR-483-5p in bulbar compared to spinal onset ALS patients and HC was identified, confirming the discovery phase results. Receiver Operating Characteristic curve analysis showed that serum miR-150-5p and miR483-3p could discriminate with high sensitivity and specificity the bulbar from the spinal onset ALS patients (miR-150-5p AUC=76% and miR-463-5p AUC=81%) and HC (miR-150-5p AUC=76% and miR-463-5p AUC=96%). Proteomic analysis identified three clusters of proteins indicating a distinct proteomic profile of bulbar onset ALS patients compared to spinal onset patients and HC. Integration analysis between miR-150-5p and miR-483-5p, and the selected differentially expressed proteins in bulbar onset ALS patients compared to spinal onset and HC, confirmed that distinct molecular signatures underly different biological processes.

Discussion: Our findings from integrated miRNA and proteome profiling revealed distinct molecular signatures of bulbar onset ALS.
Conclusions: We provided robust demonstration that bulbar onset ALS has a distinct molecular profile, paving the avenue for a new biology-driven classification of ALS.

## COEXISTENCE OF AMYOTROPHIC LATERAL SCLEROSIS AND AUTOIMMUNE DISEASES: THREE CASES

C. Meoni, F. Bianchi, L. Becattini, L. Fontanelli, B. Giovannini, G. Siciliano

Department of Clinical and Experimental Medicine, Neurological Clinic, University of Pisa (Pisa)

Amyotrophic Lateral Sclerosis (ALS) is a neurodegenerative disorder involving upper and lower motor neurons. Rheumatoid arthritis (RA) is a systemic autoimmune inflammatory disease characterized by chronic synovitis that may progress, leading to articular deformities and functional disability. Multiple sclerosis (MS) is a potentially disabling autoimmune disease of the central nervous system (CNS) characterized by inflammation, demyelination, gliosis, and neuronal loss. Myasthenia gravis (MG) is an autoimmune disease of the neuromuscular junction caused by antibodies against acetylcholine receptors in the postsynaptic membrane. Although the exact etiopathogenesis of ALS is partially unknown, a dysfunction of the immune system is supposed to take part in ALS pathogenesis, and several reports and nationwide registry studies have often confirmed an higher association between ALS and autoimmune diseases. Here we describe three patients affected from autoimmune diseases who also developed ALS. First case: A woman suffering from RA since the age of 13, developed, at the age of 55, fasciculations, weakness of right upper limb and, a few months later, hyposthenia in right lower limb. Brain and spine MRI were normal, while an electromyogram showed neurogenic pattern with acute denervation in all tested muscles. The neurological examination showed right limbs hyposthenia and hypotrophy with homolateral brisk reflexes, consistent with ALS. Second case: A man suffering from MS developed, after several years of clinical stability, rapidly progressive head drop, diffuse muscular hypotrophy and fasciculations. The electromyogram showed neurogenic pattern with acute denervation in all tested muscles. Brain and spine MRI were unchanged, while a high camp brain MRI disclosed the new occurrence of a T2* hypointensity in primary motor cortex, consistent with upper motor neuron burden. Third case: A man affected from MG diagnosed in 2013 came to our attention, 7 years later, for the occurrence of cramps, fasciculations and weakness in the left lower limb. Clinical, radiological, and neurophysiological

assessment were consistent with ALS, and ruled out a possible MG-relapse. Interestingly, in all the three cases above-mentioned the genetic tests for ALS resulted negative. Several studies have reported an increased risk of developing ALS in patients with autoimmune diseases, since immune dysregulation and a pro-inflammatory milieu may act as triggering factors for motor neurons' degeneration in predisposed patients, easing the possibility of forward or backward spreading of damage. Case description of these cases may help in shedding light on ALS pathogenesis.

## DATA ON SAFETY AND EFFICACY OF RISDIPLAM TREATMENT IN A SMALL APULIAN COHORT OF ADULT 5Q SPINAL MUSCULAR ATROPHY

A. G. Nanni[1], G. Milella[1], G. Piccirilli[1], M. Ucci[1], S. Idrissi[1], A. Fraddosio[1], A. Introna[1], V. Scacco[2], M. Megna[2], D. Paolicelli[1], E. D'Errico[1], I. Simone[1]

[1]Neurology Unit, Department of translational Biomedicine and Neurosciences (DiBraiN), University of Bari "Aldo Moro" (Bari); [2]Department of Translational Biomedicine and Neurosciences (DiBraiN), University of Bari (Bari)

Introduction: Risdiplam is an oral small-molecule drug recently approved for the treatment of Spinal Muscular Atrophy (SMA). It increases the functional Survival Motor Neuron (SMN) protein by modifying pre-mRNA splicing of the SMN2 gene. The aim of the study was to investigate the safety and efficacy of Risdiplam in our adult cohort of SMA patients.

Materials and Methods: The inclusion criteria were clinical and molecular diagnosis of SMA2/SMA3, SMN2 copy numbers <4, availability of clinical data, and specific motor scale assessments [Hammersmith Functional Motor Scale Expanded (HFMSE), Revised Upper Limb Module (RULM), six-minute walking test (6MWT)] at treatment baseline, after six months (T6), and one year (T12). Responders were defined as individuals showing an improvement of at least 3 points on the HMFSE, at least 2 points on the RULM score, or at least 30m on the 6MWT from baseline.

Results: We included 18 patients (9 SMA2 and 9 SMA3), with median age 41 (IQR 36-47) years at the first administration (only 4 were walkers). 13 out of 18 patients reached 12 months follow-up. HFMSE significantly increased from T0 to T6 (p=0.027) and from T0 to T12 (p=0.046). The RULM did not improved from T0 to T6, but significant improvement was observed at T12 (median values: 15.5, IQR: 8-22 vs 19, IQR: 13-25, p=0.031). No changes in the 6MWT were detected at T6 or T12 in walking patients. At T6, 10 out of 18 patients (59%) were classified as responders, and at T12, 9 out of 13 patients (69%). Among all demographic and clinical variables, the number of SMN2 copies was independently associated with clinical improvement at T6 (p=0.023) and T12 (p=0.045). No severe adverse events were reported.

Discussion: The natural history of types 2 and 3 SMA involves disease progression and continued loss of function. In patients with prolonged disease duration, early improvements are not expected. In our cohort of adult SMA patients, Risdiplam showed efficacy in improving or stabilizing motor symptoms, as demonstrated by the positive changes in HFMSE and RULM, even in a relative short follow-up.

Conclusions: Our data highlight the safety and efficacy of Risdiplam even in the first year of treatment, regardless of age, gender, functional clinical status at baseline, and SMA type. Number of SMN2 copies influence positively clinical improvement.

## 3D-STEM CELL SPINAL CORD MODEL TO STUDY THE THERAPEUTIC MECHANISMS OF RISDIPLAM-LIKE COMPOUND FOR SPINAL MUSCULAR ATROPHY

L. Ottoboni[1], A. D'Angelo[1], F. Beatrice[2], P. Rinchetti[1], I. Faravelli[1], M. Miotto[3], S. Lodato[3], M. Nizzardo[2], F. Rizzo[1], G. Comi[2], S. Corti[1]

[1]Dino Ferrari Centre, Department of Pathophysiology and Transplantation (DEPT), Neuroscience Section, University of Milan (Milano); [2]Neurology Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico (Milano); [3]Humanitas Clinical and Research Center (Milano)

Our study aimed at improving the treatment of Spinal Muscular Atrophy (SMA) by investigating the efficacy of a Risdiplam-like compound on 3-dimensional (3D) spinal cord model. SMA is a severe neurological disorder characterized by early onset and degeneration of lower motor neurons due to mutations in the SMN1 gene. To reproduce reliable human models, we generate and phenotypically characterize human spinal cord organoids from induced pluripotent stem cells (iPSCs) of SMA type 1subjects (n=3) and healthy controls (n=2). Our analysis revealed that SMA presents a pervasive cellular and molecular developmental alteration in multiple cell populations, including neural progenitors, beyond motor neurons. This was ascertained using bulk transcriptomics, single cells RNAseq, and multi-electrodes array analysis, along with immunophenotypic characterization. Treatment was started at different time points during the first 80 days of organoid development which parallels the first trimester post conception and was provided as daily therapy every two days. Our preliminary results demonstrated that 1) Risdiplam-like compound models ~ 15% of disease affected genes; 2) long-term in vitro treatment is well-tolerated; 3) ratio between full length SMN2 and Δ7 is robustly established; 4) pathological hallmarks are restored, all in all supporting the idea that SMA organoids represent a reliable model to explore drug kinetics and efficacy. Further, exploiting organoids, our study highlights the early-onset and pervasive developmental nature of SMA pathogenesis, which should be considered in therapeutic perspectives. Optimizing Risdiplam therapy for all SMA patients and developing combined therapeutic approaches is very useful and can be achieved by understanding the complex mechanisms of the drug's action. Our study contributes to the optimization of Risdiplam therapy and to the identification of complementary treatment targets for SMA patients.

## ACOUSTIC VOICE ANALYSIS AS A USEFUL PROGNOSTIC TOOL TO DISCRIMINATE DIFFERENT ALS PHENOTYPES

G. Piccirilli[1], G. Milella[1], A. Nanni[1], E. D'Errico[1], D. Paolicelli[1], S. Idrissi[1], A. Introna[1], A. Fraddosio[1], D. Sciancalepore[2], M. Fiorella[2], I. Simone[1]

[1]Neurology Unit, Department of Translational Biomedicine and Neurosciences (DiBraiN), University of Bari "Aldo Moro" (Bari); [2]Otolaryngology Unit, Department of Translational Biomedicine and Neurosciences (DiBraiN), University of Bari "Aldo Moro" (Bari)

Objectives: To evaluate the role of acoustic voice parameters as prognostic biomarker in clinical phenotypes of Amyotrophic Lateral Sclerosis (ALS) disease.

Materials and methods: We recruited thirty-six ALS patients and twenty healthy controls (HCs). Exclusion criteria included severe dysarthria, cognitive dysfunctions, hearing impairments. ALS patients were categorized into prevalent upper (pUMN) or lower (pLMN) impairment based on the median value of the Penn Upper Motor Neuron Score and the site of onset. The assessed acoustic voice parameters were Triangular Vowel Space-Area (tVSA), Alternating Motion Rates (AMR), and Sequential Motion Rates (SMR). Dysphagia severity was evaluated using the ALSFRS-r bulbar subscore and the Dysphagia Outcome and Severity Scale (DOSS). We compared the acoustic voice parameters between ALS patients and HCs, pUMN and pLMN patients, and patients with different onset types: bulbar-onset (B-ALS), spinal-onset without bulbar symptoms (S-ALS), and spinal-onset with bulbar symptoms (generalized-S-ALS) during clinical evaluation. Additionally, correlations were performed between acoustic voice parameters and clinical scales.

Results: All ALS patients showed significantly lower values of tVSA, AMR, and SMR compared to HCs ($p<0.005$). The subgroup of ALS patients with pUMN had significantly lower values of tVSA, AMR, and SMR than pLMNs. Among the acoustic parameters, tVSA showed higher accuracy in discriminating between pUMN and pLMN patients (AUC: 0.83, CI: 0.707–0.965, $p<0.001$). No differences in tVSA were observed based on the site of onset. B-ALS patients had significantly lower values of AMR and SMR compared to generalized-S-ALS, while these latter had lower values compared to S-ALS without bulbar symptoms. Furthermore, AMR and SMR positively correlated with ALSFRS-r bulbar subscore (/pa/ rs= 0.554, p= 0.001; /ta/ rs= 0.467, p= 0.005; /ka/ rs= 0.479, p=0.004; /pataka/ rs=0.427, p=0.011) and DOSS (/pa/ rs= 0.620, $p<0.001$; /ta/ rs= 0.574, $p< 0.001$; /ka/ rs= 0.614, $p< 0.001$; /pataka/ rs=0.566, $p<0.001$).

Discussion: Our study demonstrated that acoustic voice analysis can be considered a sensitive biomarker to distinguish ALS patients from HCs, and among the ALS cohort, to differentiate those with spastic and flaccid dysarthria, particularly using tVSA. Lower values of AMR and SMR were associated with higher bulbar impairment, as observed in ALS patients with B-ALS and generalized-S-ALS or in ALS patients with lower ALSFRS-r bulbar score and lower DOSS.

Conclusions: Acoustic voice analysis may serve as a useful prognostic tool to differentiate between spastic and flaccid dysarthria and assess the degree of bulbar involvement in ALS.

## FLEXIBILITY OF BRAIN DYNAMICS AS A PREDICTOR OF CLINICAL IMPAIRMENT IN AMYOTROPHIC LATERAL SCLEROSIS: A SOURCE RECONSTRUCTED MEG STUDY

A. Polverino[1], E. Trosi Lopez[2], R. Minino[2], M. Liparoti[3], A. Romano[2], F. Trojsi[4], F. Lucidi[3], L. Gollo[5], V. Jirsa[6], G. Sorrentino[2], P. Sorrentino[6]

[1]Institute of Diagnosis and Treatment Hermitage Capodimonte, University of Naples Parthenope (Napoli); [2]Department of Motor Sciences and Wellness, University of Naples Parthenope (Napoli); [3]Department of Developmental and Social Psychology, University of Rome La Sapienza (Roma); [4]Department of Advanced Medical and Surgical Science, University of Campania Luigi Vanvitelli (Napoli); [5]Turner Institute for Brain and Mental Health, School of Psychological Sciences, Monash University (Victoria-AUS); [6]Institut de Neurosciences des Systèmes, Inserm - Aix-Marseille University (Marseille-F)

Background and Objectives: Amyotrophic Lateral Sclerosis (ALS) is a multisystem disorder characterized by neurodegeneration of the whole brain. Normally, the brain dynamically reconfigures over time by large-scale bursts of activations, called neuronal avalanches [1] and defined as events starting when at least one brain region deviates from its baseline activity, and ending when all areas are back to normal activity. Conversely, neurological diseases induce stereotyped brain dynamics which, in turn, are linked to clinical impairment. Based on recent evidence showing that functional brain networks become more connected as ALS progresses [2], we hypothesized that less flexibility in brain dynamics could predict symptoms severity.

Materials: The brain activity of 42 ALS patients and 42 healthy controls was recorded by magnetoencephalography (MEG) [3]. Magnetic resonance (MR) scans were also acquired, and MEG and MRI data were used to reconstruct time series related to the regions of interest. Then, we used source-reconstructed MEG signals to quantify brain flexibility through the functional repertoire. More specifically, an avalanche pattern is the set of all brain areas recruited during the avalanche, while the functional repertoire is the set of unique avalanche patterns.

Method: The activity of brain areas was reconstructed in the classical frequency bands, and the functional repertoire was estimated to quantify spatio-temporal fluctuations of brain activity. Finally, we used the size of the functional repertoire to build a k-fold cross-validated multilinear model to predict the clinical impairment.

Results: We found a reduced functional repertoire in ALS patients compared to healthy controls, resulting in more stereotyped brain dynamics. The size of the functional repertoire correlated with clinical scores in the ALS group in both delta and theta frequency bands. Furthermore, the functional repertoire predicted both clinical staging and symptoms severity when we used a k-fold cross-validated multilinear regression model.

Discussion: In our work, we demonstrated that the pathophysiological processes of ALS reduce brain flexibility and that the smaller size of the functional repertoire predicts both disease stage and symptoms severity, even after accounting for age, education, gender, disease duration, phenotype and ECAS. This approach could provide a non-invasive tool to quantify alterations in brain dynamics in ALS and, possibly, other neurodegenerative diseases.

Conclusions: In the context of personalized medicine, our approach could serve to adapt large-scale mechanistic models to individual patients. Furthermore, neuronal avalanches can be also observed using EEG, which might allow the application of our methodology on a broader scale.

## A CASE OF LATE-ONSET NEMALINE MYOPATHY (SLONM) ASSOCIATED WITH MOTOR NEURON DISEASE: A CASUAL OR CAUSAL LINK?

R. S. Prezioso, G. Ruta, D. Totaro, F. Luisi, G. Milella, A. Fraddosio, F. Caputo

Department of Translational Biomedicine and Neurosciences (DIBRAIN), University of Bari "Aldo Moro" (Bari)

Introduction: Sporadic late-onset nemaline myopathy (SLONM) is a rare condition characterized by the presence of nemaline bodies in muscular biopsy. It can be inherited in an autosomal dominant/recessive manner and is caused by mutations in at least 12 genes, with the most common forms associated with genes encoding skeletal-muscle-α-actin (ACTA1) and nebulin (NEB). There have been occasional reports of an association between nemaline myopathy and motor neuron disease (MND), which could either be coincidental or indicate a relationship between these two conditions.

Case description: We present the case of a 52-year-old patient with a history of idiopathic juvenile arthritis since childhood. The patient had undergone left-hip prosthesis implantation, which resulted in partial relief of symptoms. Since January 2020, the patient has experienced progressive weakness in the lower limbs, which later extended to the upper limbs, accompanied by gradual respiratory fatigue. A muscular biopsy conducted in April 2022 revealed "central core primitive myopathy," and genetic testing showed a heterozygous variant of uncertain significance in the NEB gene, suggestive of Nemaline Myopathy type 2. The patient's symptoms progressively and rapidly worsened, leading to hospitalization in August 2022 due to acute restrictive respiratory failure. Nocturnal non-invasive ventilation was subsequently required. Electromyography revealed a chronic neurogenic pattern with acute denervation. Further evaluation and neurological examination revealed anserine gait, absence of bulbar signs, weak reflexes, weakness in left thigh flexion, bilateral dorsal feet flexion, spontaneous fasciculations in lower limbs. Brain MRI with Diffusion Tensor Imaging sequences showed depletion of the corticospinal tracts (CSTs), and Motor Evoked Potentials (MEPs) revealed subclinical damage of the upper motor neurons. Muscle MRI also indicated initial fibrous fatty muscle degeneration in both thighs. Based on these overlapping features, the patient was diagnosed with central core myopathy with a coexisting motor neuron disease.

Discussion: The clinical features, genetic tests, and muscular biopsy findings supported a diagnosis of SLONM. However, the rapid clinical deterioration and progressive respiratory fatigue raised concerns about the possibility of coincidental disorders. Electromyography indicated a potential overlap between end-stage disease myopathy MND. This was further supported by CST thinning on MRI and abnormal central motor conduction time, as evidenced by MEPs.

Conclusions: The relationship between skeletal muscle damage and MNDs remains unclear. It is uncertain whether there is an interplay between the conditions or if the observed association is coincidental. Further research is needed to explore the possible role of skeletal muscle degeneration in the etiopathogenesis of MND.

Aims: For patients with rare diseases, the transition phase from the pediatric care specialist center to the adult neurologist represents a complex and sensitive process involving patients in their late-childhood and adolescence age, caregivers, and health professionals, were disease-specific physical and cognitive needs, age-related changes and health system differences need careful integration and a gradual transformation. Unfortunately, in many cases this delicate moment remains subject to casualty or personal involvement and efforts of patients, families, associations, and healthcare professionals, facing the lack of a structured, dedicated, and progressive route. In present time, given the progress in therapeutic and global care of patients, life expectancy and quality of life have expanded, so that an abrupt change of direction or loss of patients once they reach young adulthood is no more acceptable.

Methods: In this framework we developed the project of a dedicated program for case management of "transition" patients with different form of neuromuscular diseases (NMD). The project involves the Neurology Unit AOUP, center for adult patients, and the Metabolic and Hereditary Diseases Unit of Meyer Hospital and Neurology and Rare Diseases Unit of IRCCS Stella Maris, both for pediatric patients. All the three are regional reference Centers for diagnosis and care of NMD. Based on the disease prevalence and number of patients followed at the Centers, we plan to include in a period of three years an estimated number of 60 NMD young patients.

Results: During the project development, the various health care professionals (neurologist, childhood neuropsychiatrist, cardiologist, pneumologist, physiotherapist, biologist, and others, to be tailored based on each case's specific needs) involved in global care of NMD patients will be identified and included in a multidisciplinary team. Patients will be evaluated firstly in the same time both by the childhood neurologist and the adult neurologist and in the pediatric Center. Subsequently, the following examinations will occur at the adult Center in Pisa.

Conclusion: Recording of diagnostic and functional parameters during this peculiar phase of our patients' life will provide a better knowledge on how to optimize global management but also on disease natural history.

## NEW CELLULAR IMAGING-BASED BIOMARKERS FOR SPG4 SUBTYPE OF HEREDITARY SPASTIC PARAPLEGIA

C. Rinaldo[1], F. Sardina[1], G. Fattorini[2], E. Cioffi[3], G. Dalla Zanna[3], F. Santorelli[4], C. Casali[3], C. Rinaldo[1]

[1]Institute of Molecular Biology and Pathology (IBPM), Consiglio Nazionale delle Ricerche (CNR) (Roma); [2]Department of Biology and Biotechnology "Charles Darwin", Sapienza University (Roma); [3]Department of Medico-Surgical Sciences and Biotechnologies, Sapienza University (Latina); [4]Molecular Medicine, IRCCS Fondazione Stella Maris (Pisa)

Aims: Microtubule defects are a common feature in several neurodegenerative disorders, including hereditary spastic paraplegia (HSP). The most frequent form of HSP is caused by mutations in the SPG4/SPAST gene, encoding the microtubule severing enzyme spastin. To date, there is no effective therapy available but spastin-enhancing therapeutic approaches are emerging [1,2] thus prognostic and predictive biomarkers are urgently required.

Materials and Methods: We have developed an automated, simple, fast and non-invasive cell imaging-based method to quantify microtubule cytoskeleton organization changes in lymphoblastoid cells (LCLs) and peripheral blood mononuclear cells (PBMCs).

Results: LCLs and PBMCs from individuals affected by SPG4-hereditary spastic paraplegia show a polarized microtubule cytoskeleton organization. In a pilot study on LCLs and PBMCs, our method discriminates SPG4-HSP from healthy donors and other HSP subtypes. In addition, it is shown that our method can detect the effects of spastin protein level changes [3].

Discussion and Conclusions: These results open the possibility to develop a test useful to recognize SPG4-hereditary spastic paraplegia subtype and evaluate the effects of spastin-enhancing drug in non-neuronal cells. We will extend these analyses to a large cohort of patients to perform clinical and molecular correlations to identify non-invasive diagnostic, prognostic and predictive biomarkers.

## PROGNOSTIC USEFULNESS OF MOTOR UNIT NUMBER INDEX (MUNIX) IN PATIENTS NEWLY DIAGNOSED WITH AMYOTROPHIC LATERAL SCLEROSIS (ALS)

B. Risi[1], S. Cotti Piccinelli[1], S. Gazzina[2], F. Caria[3], S. Damioli[3], B. Labella[4], L. Poli[5], A. Padovani[4], M. Filosto[1]

[1]NeMO-Brescia Clinical Center for Neuromuscular Diseases, University of Brescia, Department of Clinical and Experimental Sciences (Brescia); [2]Unit of Neurophysiology, ASST Spedali Civili (Brescia); [3]NeMO-Brescia Clinical Center for Neuromuscular Diseases (Brescia); [4]Unit of Neurology, ASST Spedali Civili, University of Brescia, Department of Clinical and Experimental Sciences (Brescia);[5]Unit of Neurology, ASST Spedali Civili (Brescia)

Introduction: Amyotrophic lateral sclerosis (ALS) has a highly heterogeneous clinical course, and this diversity has been brought up as a possible cause for the failure of most clinical trials to date. Motor Unit Number Index (MUNIX) is a non-invasive EMG technique that can estimate the number and size of surviving motor units (MUs). Previous studies on ALS found correlations between MUNIX and several clinical measures, such as the ALSFRS-R (1), but its potential role as a predictor of disease progression rate (DPR) [obtained as "ΔALSFRS-R (48-observed score)/disease duration (months)"] has not been evaluated so far. We aimed to investigate MUNIX's ability to predict DPR at six months.

Methods: We enrolled 24 ALS patients followed-up at two Brescia University Centers with short disease duration (<24 months from symptoms' onset); they underwent MUNIX on 5 muscles (abductor pollicis brevis, abductor digiti minimi, first dorsal interosseus, tibialis anterior, trapezius). DPR was calculated six months after baseline. Multivariable linear and simple logistic regression analyses were used to assess MUNIX parameters as predictors of DPR at six-month follow-up.

Results: MUNIX was found to predict DPR at follow-up ($\beta$=-0.228, p=0.033), along with baseline DPR and ALSFRS-R values, while no other variable considered (gender, age, bulbar site of onset, use of riluzole) showed the same ability. Precisely, patients with lower MUNIX values at baseline displayed the greatest DPRs after six months. The result was replicated considering the dichotomic category "MUNIX-Low" (derived using the sample's median as cut-off) as the independent variable and the outcome "Fast progressors" (with DPR $\geq$ 1.1) as the dependent variable.

Discussion: The application of MUNIX to a relative "early ALS" cohort (disease duration: 13 months, median) makes our results applicable to the setting of clinical trials in which patients more likely to be eligible for disease-modifying pharmacological interventions are those newly diagnosed. Our study demonstrates that the presence of few surviving MUs in the first months after the onset of symptoms reflects a rapidly evolving process.

Conclusion: Our preliminary findings pave the way for the use of MUNIX examination as a prognostic tool in early ALS, enabling patients' stratification according to their rates of future decline.

## ECULIZUMAB FOR IMMUNE CHECKPOINT INHIBITORS (ICIS)-RELATED MYASTHENIA GRAVIS

E. Rossini[1], A. Lauletta[1], P. Marchetti[2], S. Morino[1], M. Garibaldi[1], G. Antonini[1], L. Fionda[1]

[1]NESMOS Department, Sapienza University of Rome (Roma); [2]Department of Clinical and Molecular Medicine, Medical Oncology Unit, Sant'Andrea Hospital, Sapienza University (Roma)

Immune-check point inhibitors (ICIs) have been increasingly used in advanced or non-responsive tumors with promising results. Among them, Pembrolizumab is a humanized monoclonal immunoglobulin (Ig)G4 antibody directed against human cell surface receptor PD-1

(programmed cell death-1), an inhibitory signaling receptor expressed on the surface of activated T cells. Regardless of this breakthrough therapy, ICIs could cause immune-related adverse events (irAEs) or reactivate pre-existing autoimmune conditions, including Myasthenia Gravis (MG). Beyond classical therapies, complement inhibitors like Eculizumab represent a new frontier of treatment in MG, especially in patient with multiple comorbidities that cannot receive high dosage steroids and other immunosuppressive agents. Herein we report on a case of a 76-year-old male affected by generalized anti-AchR positive Myasthenia Gravis (MGFA IIb) successfully treated for 4 years with prednisone and azathioprine. He also received a diagnosis of metastatic colorectal cancer at the age of 74 unsuccessfully treated with surgery and first-line chemotherapy. For this reason, an ICI (Pembrolizumab) was started with remarkable tumor remission and azathioprine was discontinued. After the first two Pembrolizumab infusions, MG symptoms relapsed showing complete bilateral ptosis and ophthalmoplegia, fatigable dysarthria and swallowing impairment. IVIG (2 gr/kg) was started with mild clinical improvement. Therefore, a third line therapy with complement inhibitor (Eculizumab) was started. After three months therapy, MGADL and QMG improved from 15 to 9 and from 21 to 16 respectively. Neurologic irAEs related to use of ICIs are rare but often severe and can require discontinuation of ICIs. Immunomodulatory therapies, such us high dose steroids and immunosuppressants, as well as plasma exchange, are not allowed during ICIs treatment because can interfere with their efficacy. MG onset and relapse has been often described after ICIs treatment, also in association with myositis and/or myocarditis. Among MG treatments, Eculizumab is a new available drug and does not interfere with ICIs mechanism of action. Eculizumab resulted to be a good choice able to control MG symptoms without hindering Pembrolizumab action. So, are complement inhibitors suitable for ICIs-related Myasthenia Gravis?

## COMPARATIVE ANALYSIS OF PLASMA MIRNA SIGNATURES IN AMYOTROPHIC LATERAL SCLEROSIS

P. Ruffo[1,2], S. Catalano[3], V. La Bella[4], F. Conforti[1]

[1]Medical Genetics Laboratory, Department of Pharmacy, Health and Nutritional Sciences, University of Calabria (Rende-CS); [2]Neuromuscular Diseases Research Section, Laboratory of Neurogenetics, National Institute on Aging (Bethesda-USA); [3]Department of Pharmacy, Health and Nutritional Sciences, University of Calabria (Rende-CS); [4]ALS Clinical Research Centre and Laboratory of Neurochemistry, Department of Experimental Biomedicine and Clinical Neurosciences, University of Palermo (Palermo)

Background: Several studies highlight the miRNA's role in Amyotrophic Lateral Sclerosis (ALS) pathology by describing their deregulation in various biological fluids, such as plasma [1]. Furthermore, TARDBP promotes the biogenesis of miRNAs and is fundamentally involved in the pathogenesis of Amyotrophic Lateral Sclerosis (ALS). To detect potential non-invasive preclinical and clinical progression biomarkers in a TARDBP-ALS family, we assessed the expression levels of circulating microRNAs in affected patients and asymptomatic mutation carriers.

Materials and Methods: In this study, we applied qRT-PCR in 7 symptomatic patients (P), eight mutation carriers (C), and 13 healthy controls (HC) to investigate 15 tissue- and disease-specific circulating miRNAs. These are involved in targeting TARDBP or binding TDP-43 during their biogenesis/mature form [2] and are able to classify symptomatic, presymptomatic TARDBP-G376D carriers and healthy members belonging to a large ALS family [3].

Results: Five out of 15 miRNAs were significantly dysregulated between HC and P. Furthermore, 13 out of 15 miRNAs were significantly dysregulated in C; eight were deregulated exclusively in this group. We highlighted the potential of miR-132-5p, miR-132-3p, miR-124-3p, and miR-133a-3p expression levels in serum as biomarkers of preclinical progression for G376D-TARDBP-associated ALS.

Discussion: We identified miRNAs differentially expressed between clinical conditions suggesting that miRNA dysregulation may be used as an early prognostic biomarker for ALS. Interestingly, miR-574-3p, -133B, and -558-3P were identified as significantly overexpressed in C compared with HC, suggesting that the expression of this miRNA is associated with TARDBP mutation. Additionally, -124-3p was significantly deregulated in patients compared with C, which supports the correlation of miRNA-133b expression with the progression of TARDBP-associated disease.

Conclusion: This is the first study evaluating plasma miRNAs expression in a large TARDBP family of HC, C, and P samples. The results showed a specific miRNA differential expression in the symptomatic and asymptomatic mutation carriers compared to healthy controls, underlining a probable peripheral signature capable of stratifying the disease progression.

## PHENOTYPIC SPECTRUM OF THREE UNRELATED SMA ITALIAN PATIENTS WITH A COMPOUND HETEROZYGOSITY FOR A DELETION AND RARE MISSENSE MUTATION IN SMN1 GENE

A. Russo[1], D. Zoppi[1], T. Fioretti[2], R. Bencivenga[1], S. Vallone[2], V. Maiolo[2], R. Iodice[1], G. Esposito[2], L. Ruggiero[1]

[1]Department of Neuroscience and Reproductive and Odontostomatological Sciences, University of Naples Federico II (Napoli); [2]Department of Molecular Medicine and Medical Biotechnologies, University of Naples "Federico II" (Napoli)

Objective: Spinal muscular atrophy (SMA) is caused by mutation of the survival motor neuron (SMN) gene and in only the remaining 5% there is an intragenic mutation.

Materials: We analyzed the phenotypic spectrum of three unrelated SMA patients with missense mutation (exon 7 c.840C>T) in SMN1 which causes its conversion to SMN2.

Methods: For the genetic analysis we used (MLPA) and (NGS) while for the clinical evaluation the (HFMSE) and the (RULM).

Results: In our cohort twenty-four SMA patients we found three patients (2M/1F) with the deletion of exons 7 and 8 of SMN1 and a rare missense mutation (exon 7 c.840C>T). All patients had 2 copies of SMN2.

Discussion: One of two male patients with large deletion in NAIP gene, shows the most severe phenotype (SMA II) and at last neurological examination his score at HFMSE is 14 and RULM is 17. The other two patients were classified as SMA III, but their clinical severity was very different: the male's scores was 18 at the HFMSE and RULM was 24 while the female patient showed a milder phenotype and presents HFMSE score 60 and RULM 38.

Conclusions: The rare point mutation (exon 7 c.840C>T) occurs more frequently than described previously (< 3%) and there is the same phenotypic variability for patients presenting the homozygous deletion but male subjects are worse off than female ones. This could be explained by the deletion of the NAIP gene but the difference between the other male and the female remains substantially unexplained.

## VAGUS NERVE HIGH RESOLUTION ULTRASONOGRAPHIC FEATURES IN DIFFERENTIATING PATIENTS WITH AMYOTROPHIC LATERAL SCLEROSIS FROM INFLAMMATORY AND HEREDITARY NEUROPATHIES

F. Sartucci[1], T. Bocci[2], A. Filippi[3], D. Barloscio[4], M. Santin[4], L. Sagliocco[5], P. Bongioanni[6], M. Caleo[7], N. Origlia[8]

[1]Institute of Neuroscience, CNR, University of Pisa (Pisa); [2]Department of Health Sciences, "Aldo Ravelli" Center for Neurotechnology and Experimental Brain Therapeutics, University of Milan and ASST Santi Paolo e Carlo (Milano); [3]Local Health Authority Tuscany North-West, Unit of Neurology, San Luca Hospital (Lucca); [4]Clinical and Experimental Medicine, AOUP (Pisa); [5]Unit of Rehabilitation, Versilia Hospital, Local Health Authority Tuscany north-west, Versilia Hospital (Viareggio-LU); [6]Neurorehabilitation Unit, University of Pisa, AOUP (Pisa); [7]Department of Biomedical Sciences, University of Padua (Padova); [8]Neuroscience Institute, NRC (Pisa)

Background and aims: High Resolution Ultrasound (HRUS) represent an easy noninvasive tool for in vivo detection of peripheral nerve changes in several diseases. Our aim was to evaluate sonographic features of Vagus Nerve (VN) trunks in patients with Amyotrophic Lateral Sclerosis (pALS) in an attempt to assist discrimination between pALS from chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) and Charcot-Marie-Tooth disease (CMT).

Material and Methods: We scanned and measured the caliber (cross-sectional area, CSA) and perimeter of the VN in 10 consecutive pALS, in 10 pt. with CIDP and 4 pt. with CMT using HRUS imaging. Evaluation were performed by blinded raters using a Telemed Echo-wave II or an Esaote MyLabGamma device in conventional B-Mode with a 19 MHz probe.

Results: In both sides, the VN-CSA was larger in CMT and CIDP compared to pALS (7.3 and 6.4 mm2 respectively versus 4.4 mm2; p <0.001); the perimeter was also greater (9.7 and 8.9 mm versus 7.5; p <0.001). Moreover, these data provides evidence that nerve imaging are different in pALS from those with CMT and CIDP.

Discussion and Conclusion: Our findings provide evidence that VN's US CSA and perimeter in pALS differs from other neuropathies and has the potentials to differentiate between ALS and CMT or CIDP and may represent a robust diagnostic marker even in very small-sized samples. Moreover, HR HRUS represent a non-invasive easy imaging modality of screening and a possible interesting additional value with other instrumental method to disentangle the spectrum between more inflammatory or more degenerative disease variants.

## INVESTIGATION OF UNPLEASANT SENSATION PERCEPTIONS AMONG PATIENTS AFFECTED BY AMYOTROPHIC LATERAL SCLEROSIS (ALS), DURING CLINICAL TRIALS PROCEDURES

M. Sodano[1], V. Silani[1], N. Ticozzi[1], F. Tagliacarne[1], C. Amigoni[1], A. Doretti[1], G. Demirtzidis[1], E. Colombo[1], L. Ingrande[2], D. Rosa[2]

[1]Research Department of Neurosciences, IRCCS Istituto Auxologico Italiano (Milano); [2]IRCCS San Raffaele Hospital (Milano)

Introduction: ALS diagnosis is considered a traumatic life event for both the patient and their next-of-kin/carers, due to the lack of treatment for. Clinical Trials can offer pioneering treatment to reduce the impact of the disease and improve future treatments worldwide. Research protocols may involve routine diagnostic and/or therapeutic procedures which the patients may be already aware of and, therefore, expecting specific sensations. These could compromise participation or drop-out rate. Despite everything, participation in a clinical trial can guarantee continuity of care also thanks to the execution of these same procedures, through preferential access compared to other patients.

Aim: To investigate the perception of unpleasant sensations during procedures in clinical trials of ALS patients. Analysing what type of pain/discomfort frightens patients during diagnostic and/or therapeutic procedures in ALS clinical trial, including the different methods of administration of the study drug.

Methods: Descriptive phenomenological study and data will be analysed according to Sundler's method. Based on the experience of the researchers and the recommendations proposed by Sandelowski, a total of 20 interviews are estimated in order to reach the theoretical saturation per category of reference. Data collection will be carried out through in-depth semi-structured interviews recorded (13 open-ended questions after the execution of the procedures).

Expected Results: The identification of painful/unconformable procedures will help patients' retention in ALS clinical trials and improve patients' experience and mental health, while increasing adherence and reducing dropouts. Furthermore, this could enhance adherence to the clinical trial pathway, through the reduction of anxiety states generated by annoying/painful procedures. Provide data to implement

effective therapy and offer constant patients support throughout ALS specific and needed procedures. Evaluate if this support could influence adherence rate of ALS patients to conduct clinical trials as required.

Conclusion: This study could holistically evaluate the quality of care and the taking charge of patient problems by the nurses and medical team. Implementing strategies, multidisciplinary care, and assistance. This study could provide information for future studies to create an ALS Clinical Trials multiple-retention-factors adherence scale. Moreover, the study could help create and implement an ALS-specific pain scale accounting for its impact on daily activities, aiding an interdisciplinary approach of pain management. Identify the best pain management strategies and compliance techniques to address ALS, not merely in clinical trials. Provide the best individualised care for ALS patients improving their quality of life and mental state, as well as those of the caregivers.

## FOOT DROP AS PRESENTING MOTOR SYMPTOM OF CERVICAL SPONDYLOTIC MYELOPATHY

E. Sogus, G. Sorarù, M. Carecchio, F. Dainese, F. Calvi, M. Marasca, N. Ravì, V. Tuppo Rotunno

Department of Neuroscience, University of Padua (Padova)

Background and aims: Cervical spondylotic myelopathy (CSM) is a neurologic condition developing insidiously when degenerative spinal alterations cause medullary compression. Typical manifestations include sthenic and sensory deficits from the level of compression downwards, as well as upper motor neuron signs. Lower limb muscle weakness is most frequently seen in proximal areas such as the iliopsoas muscle and the quadriceps, whereas more distal muscle weakness is less frequently reported in literature. Here we present a case of CSM with foot drop as presenting motor symptom.

Case report: A 74-year-old man presented with distal upper and lower limb paraesthesia and hypoesthesia, developed over the course of seven months, and left foot drop, present for two months, causing gait instability with left steppage. The neurological examination found diffuse mild muscle weakness, mostly scoring 4/5 at the MRC scale. It also demonstrated hyperreflexia at four limbs, Hoffmann sign, Babinski sign and Achilles clonus. Initially the case was suggestive for a deficiency-related neuropathy; the patient presented an inadequate diet and lost over 10 kilos in one year following a personal mourning. Blood tests found no significant deficiency of vitamin B12 or folic acid; a brain CT scan showed no major alterations. The nerve conduction study showed normal conduction of sensory and motor nerve trunks at four limbs, including left external popliteal sciatic nerve (EPSN). The electromyographic examination documented lack of voluntary muscle activation of the left anterior tibial muscle. The patient underwent a cervical MRI which showed retrolisthesis of the C4 vertebra on C5, resulting in stenosis of the spinal canal with compressive myelopathy at that level.

Results: We presented a case of insidious onset of upper and lower limbs paraesthesia and hypoesthesia, diffuse mild muscle hyposthenia and severe left foot dorsiflexion deficit. The symptomatology seemed suggestive for a deficiency-related neuropathy; left foot drop could also have been explained by EPSN compression due to the recent weight loss caused by malnutrition. The neurological examination showed signs of upper motor neuron suffering at four limbs, and neurophysiological examinations showed no signs of abnormal nerve conduction. Spine cervical MRI found compressive myelopathy at C4-C5 level, congruous with the patient's symptomatology.

Conclusions: CSM should be suspected in slowly progressive sensitive and motor disorders. While most reported cases involve proximal lower limb motor involvement, more distal lower limb involvement can be seen rarely. Nerve conduction studies and spinal MRI are fundamental tools to lead to a correct diagnosis.

## HIGH-CONTENT SCREENING APPLIED TO MUSCLE PATHOLOGY

F. Torri[1], M. Lai[2], C. Filipponi[2], G. Vadi[1], B. Ciurli[1], M. Pistello[2], G. Siciliano[1], G. Ricci[1]

[1]Department of Clinical and Experimental Medicine, University of Pisa (Pisa); [2]Retrovirus Center, Department of Translational Research, University of Pisa (Pisa)

Introduction: Through the use of a high throughput microplate imager for high-content analysis (HCA), it is possible to acquire, analyze, and manage fluorescence, brightfield and digital phase contrast images, providing information about nuclei acids, proteins, organelles, cell metabolism and structure. It is also possible to obtain discrimination of phenotypes not only in 2D cultures but also in 3D samples of tissues and cultures, providing a machine-learning based automated analysis of the desired features. To date, the HCA system has been mostly used in physiology, pharmacology, and infectious diseases studies, but there are few data in literature about its application on muscle pathology.

Materials and Methods: We selected five frozen muscle biopsies and five myoblasts cultures lines acquired for diagnostic purpose from patients referring to the Neurology Clinic of AOU Pisan. We studied nuclei number and position with DAPI, muscle fibers and myoblasts' structure and dimension with actin and components of the cell membrane, mitochondria with Mitotracker and autophagy with LC3B by using Operetta CLS.

Results: We are obtaining preliminary results about automated detection of cells number, dimension, nuclei number and position, autophagy, and mitochondrial function. The system correctly analyses regular slices from frozen muscle biopsy samples and cell cultures. Preliminary analyses on the parameters at study reflect the expected results in correlation with histopathology and genetic diagnosis.

Conclusion: Based on the acquired results, we will take advantage of the innovative high content screening system to analyze altered gene expression of the autophagy and mitochondria pathways in myoblasts obtained from muscle biopsies of patients with late onset Pompe disease and selected interfering RNAs (shRNAs and siRNAs) will be applied to identify druggable targets.

## PLASMA GFAP INCREASE IN AMYOTROPHIC LATERAL SCLEROSIS REFLECTS A CONCOMITANT ALZHEIMER'S DISEASE PATHOLOGY

V, Vacchiano[1,2], A. Mastrangelo[1], C. Zenesini[2], S. Dellavalle[2], E. Ruggeri[2], S. Baiardi[1,2], A. Cherici[2], F. Santoro[2], S. Capellari[1,2], R. Liguori[1,2], P. Parchi[1,2]

[1]Department of Biomedical and Neuromotor Sciences, University of Bologna (Bologna); [2]IRCCS Institute of the Neurological Sciences of Bologna, AUSL of Bologna (Bologna)

Objective: Recent data show that plasma p-tau181 levels in amyotrophic lateral sclerosis (ALS) are independent from a concomitant Alzheimer's disease (AD) pathology, probably reflecting a peripheral axonal degeneration [1]. Glial fibrillary acid protein (GFAP) is an established biomarker of astrocitopathy and was found increased in AD patients. Here we aimed to study the plasmatic levels of GFAP in ALS patients and investigate their accuracy in discriminating ALS patients with an AD co-pathology.

Methods: We included 156 patients diagnosed with ALS [1] with both plasma and cerebrospinal fluid (CSF) samples available at diagnosis, and 48 age and sex-matched controls. Plasma GFAP and p-tau181 and plasma/CSF neurofilament light chain (NfL) levels were measured with the Single molecule array (Simoa) technology. CSF AD biomarkers were determined through automated chemiluminescent enzyme immunoassay. Patients were stratified according to the ATN classification [2] using in-house validated cutoffs. The CSF Aβ ratio was calculated as Aβ42/Aβ40 multiplied by ten.

Results: Plasma GFAP levels were significantly higher in ALS patients than controls ($p<0.001$). In ALS, plasma GFAP values correlated with age at sampling ($\beta=0.026$, $p<0.001$) and were higher in patients showing a concomitant frontotemporal dementia ($p=0.04$). Plasma GFAP was moderately associated with CSF Aβ ratio (rho=-0.34, $p<0.001$) and resulted associated with a poor prognosis (HR 2.46, $p<0.001$). Stratifying ALS patients according to their A and T status, we found 20 ALS patients (12.8%) showing a positive amyloid status (A+ profile), with 9 of them (5.8% of the whole ALS cohort) also having a CSF profile suggestive of a tau deposition (A+T+ profile). In the multiple-group comparison, plasma GFAP significantly differed among A+T+, A+T-, A-ALS patients and controls, with each A+ subgroup showing higher values than controls ($p<0.001$) and A- subjects ($p<0.001$ for A+T+, $p=0.02$ for A+T-). GFAP was slightly different between A-ALS patients and controls, with a trend of significance ($p=0.07$). Plasma GFAP showed the highest accuracy (AUC 0.932±0.027) among the examined plasma biomarkers in identifying ALS patients with a full-blown AD (A+T+) co-pathology ($p<0.001$ vs. p-tau181 and NfL). Interestingly, A+T+ ALS patients showed significantly lower cognitive performances, with lower total equivalent scores at Edinburgh Cognitive and Behavioural ALS Screen ($p=0.04$), at Mini Mental State Examination ($p=0.03$) and at visual memory tests ($p=0.01$).

Conclusions: ALS A+T+ patients may show a different cognitive profile; therefore, their identification might be useful in clinical practice. Plasma GFAP could serve as an accessible and high accurate biomarker of amyloid co-pathology in ALS.

## SEASONALITY IN ALS MORTALITY: A TIME-SERIES ANALYSIS USING DIFFERENT METHODS

R. Vasta[1], S. Callegaro[1], S. Cabras[1], F. Di Pede[1], F. De Mattei[1], E. Matteoni[1], M. Daviddi[1], A. Canosa[1], U. Manera[1], M. Grassano[1], A. Bombaci[1], F. Palumbo[1], F. De Marchi[2], L. Mazzini[2], C. Moglia[1], A. Calvo[1], A. Chiò[1]

[1]ALS Center, Department of Neuroscience, University of Turin (Torino); [2]ALS Center, Department of Neurology, AOU Maggiore della Carità, University of Piemonte Orientale (Novara)

Aim: Seasonal patterns in ALS mortality have been poorly studied[1]. However, identifying any periodicity would be beneficial in enhancing the surveillance of these patients. Here we analyzed the seasonality of ALS patients mortality using a large population-based cohort.

Methods: Data from the Piemonte and Valle d'Aosta ALS Register (PARALS) were used[2]. All patients who received the ALS diagnosis from 1995 to 2020 were considered. The average mortality during each Gregorian month and during each season were compared using a chi-square test. We also performed seasonal decomposition using moving averages to specifically detect periodical patterns[3].

Results: A total of 3417 patients were considered. The average number of deaths showed a seasonal variation, with lower frequencies during the late summer and early autumn months (July 8.95±3.51, 7.49%, deaths, August 9.13±2.72, 7.63%, September 8.38±3.20, 7.02%), increased thereafter and reaching a peak in December (11.25±3.64 deaths, 9.41%) and January (11.12±3.76)($p=0.06$). Accordingly, similar results were found when comparing seasons ($p = 0.07$). However, this trend was not consistent throughout the entire follow-up period. Accordingly, the seasonal decomposition did not reveal any seasonality when considering months or the canonical seasons.

Discussion. Our findings suggest that ALS mortality could be lower during the late summer months (July to September) and higher in December. However, these results are not consistent across all years and months, making it difficult to accurately predict such events.

## ADVANCED CARE PLANNING FOR MECHANICAL INVASIVE VENTILATION IN AMYOTROPHIC LATERAL SCLEROSIS IN BERGAMO PROVINCE

M. Vedovello[1], G. Negro[2], V. Dell'Era[1], V. Bonito[1], A. Negroni[3], M. Grimoldi[1], C. Conti[4], L. Novelli[4], G. Imeri[4], S. Lonni[4], F. Di Marco[4], P. Gritti[5], M. Sessa[1]

[1]Neurology Unit, Papa Giovanni XXIII Hospital (Bergamo); [2]Neurology Section, School of Medicine and Surgery, IRCCS Fondazione San Gerardo dei Tintori (Monza); [3]Neurorehabilitation Unit, Papa Giovanni XXIII Hospital (Bergamo); [4]Pneumology Unit, Papa Giovanni XXIII Hospital (Bergamo); [5]Department of Anesthesia and Critical Care Medicine, Papa Giovanni XXIII Hospital (Bergamo)

Objective: Given the often-predictable respiratory involvement in the course of motoneuron disease (MND), an early and accurate advanced care planning (ACP) for mechanical invasive ventilation is recommended. Despite this, data of the literature show low rates of ACP in MND patients. Aim of this study is to assess rate and relative results of ACP for mechanical invasive ventilation in our centre.

Materials: Medical records of MND patients attending the Papa Giovanni XXIII Hospital of Bergamo (Italy) were reviewed.

Methods: We performed a descriptive retrospective study collecting data of all the patients with a clinically and neurophysiologically established diagnosis of MND, attending our centre from the 1st of January 2019 to the 31st of December 2022. Demographic, clinical and ACP data were collected.

Results: Of 233 patients identified, 142 are male (60,94%) and 91 are female (39,06%). Patients with a diagnosis of Amyotrophic Lateral Sclerosis (ALS) were 179; 16 patients have an Upper Motoneuron Disease, 36 have a Lower Motoneuron Disease and 2 a Brown-Vialetto-Van Laere Syndrome diagnosis. Of the 233 patients 130 expressed ACP (55,79%), of whom 4 in an emergency setting, at the mean age of 67. Among 130 ACP expressed, 35 were favourable to the mechanical invasive ventilation, while 83 were against it. 12 patients were undecided All the whishes expressed in the ACP were respected except in one case. 40 patients died without ACP, of whom 15 in 2020.

Conclusions: Our rate of expressed ACP is higher than that generally reported in the literature in ALS patients. However a small number of patients died without ACP.

Discussion: The covid pandemic may have contributed to the missed ACP. Nevertheless a constant and multidisciplinary effort is mandatory to lead MND patients through the most difficult choices.

## PHOSPHORYLATED TAU IN PLASMA AS BIOMARKER OF AMYOTROPHIC LATERAL SCLEROSIS

F. Verde[1], I. Milone[1], E. Colombo[1], A. Maranzano[1], A. Dubini[2], C. Colombrita[2], F. Gentile[3], A. Doretti[1], S. Torre[1], S. Messina[1], C. Morelli[1], E. Torresani[2], B. Poletti[1], A. Priori[4], L. Maderna[1], A. Ratti[5], V. Silani[1], N. Ticozzi[1]

[1]Department of Neurology and Laboratory of Neuroscience, IRCCS Istituto Auxologico Italiano (Milano); [2]Department of Laboratory Medicine, Laboratory of Clinical Chemistry and Microbiology, IRCCS Istituto Auxologico Italiano (Milano); [3]Neurology Residency Program, University of Milan (Milano); [4]Aldo Ravelli Research Center for Neurotechnology and Experimental Neurotherapeutics, Department of Health Sciences, University of Milan (Milano); [5]Department of Medical Biotechnology and Translational Medicine, University of Milan (Milano)

Objectives: To measure plasma P-tau181 (pP-tau181), which has recently been proposed as ALS biomarker, in a cohort of deeply phenotyped patients with ALS, analyzing its relationships with clinical phenotype, neurophysiological, respiratory, and neuropsychological measures, as well as other biochemical parameters, including serum levels of NFL and GFAP.

Materials: Retrospective cohort of 29 (M = 17, F = 12) sporadic ALS (sALS) patients.

Methods: pP-tau181 was quantified using the new fully automated Lumipulse assay on the Fujirebio G600II instrument.

Results: pP-tau181 levels correlated positively with a clinical lower motor neuron (LMN) score (r = 0.3803; 95% CI, 0.004710 - 0.6619; p = 0.0418), and negatively, albeit not significantly, with a composite index of muscle strength (p = -0.3416; 95% CI, -0.6457 - 0.05589; p = 0.0811; N = 27), but not with Penn Upper Motor Neuron (UMN) Score (p > 0.05). Accordingly, pP-tau181 correlated with electromyographic indices of spinal active (r = 0.4507; 95% CI, 0.08965 - 0.7071; p = 0.0141) and chronic denervation (r = 0.3864; 95% CI, 0.01178 - 0.6659; p = 0.0384), as well as with the index of active denervation of the lumbosacral region (r = 0.4882; 95% CI, 0.1371 - 0.7303; p = 0.0072), but not with transcranial magnetic stimulation parameters of UMN dysfunction (p > 0.05 for all). pP-tau181 levels did not correlate with those in the CSF, serum NFL or GFAP, CSF/serum albumin ratio, or estimated glomerular filtration rate (p > 0.05 for all), but correlated with plasma creatine kinase levels (r = 0.4661; 95% CI, 0.1089 - 0.7167; p = 0.0108). Finally, while not being associated with neuropsychological phenotype, pP-tau181 correlated negatively with pH (r = -0.5632; 95% CI, -0.8553 - 0.0006245; p = 0.0479) and positively with partial pressure of CO2 (PaCO2; r = 0.7092; 95% CI, 0.2425 - 0.9093; p = 0.0084), HCO3- (r = 0.6667; 95% CI, 0.1651 - 0.8943; p = 0.0152) and base excess (r = 0.6611; 95% CI, 0.1555 - 0.8923; p = 0.0165; N = 13 for all) on arterial blood gas analysis.

Discussion: pP-tau181 has potential as ALS biomarker and could be associated with LMN impairment. Its raised levels might reflect pathophysiological processes (tau hyperphosphorylation and/or release) occurring in the axons of LMNs distantly from the CNS and the CSF. pP-tau181 could also be associated with respiratory dysfunction.

Conclusions: pP-tau181 might be a new biomarker of LMN and respiratory dysfunction in ALS.

## NOVEL HOMOZYGOUS OPTN MUTATION PRESENTING AS PRIMARY LATERAL SCLEROSIS

M. Vizziello[1], E. Dalla Bella[1], C. Gellera[2], V. Pensato[2], M. Consonni[1], V. Faltracco[1], M. Stanziano[3], S. Usai[1], G. Lauria Pinter[4]

[1]Third Neurology Unit and Motor Neuron Diseases Center, IRCCS Foundation "Carlo Besta" Neurological Institute (Milano); [2]Unit of Medical Genetics and Neurogenetics, IRCCS Foundation "Carlo Besta" Neurological Institute (Milano); [3]Neuroradiology Unit, Diagnostic and Technology Department, IRCCS Foundation "Carlo Besta" Neurological Institute (Milano); [4]Department Medical Biotechnology and Translational Medicine, IRCCS Foundation "Carlo Besta" Neurological Institute, University of Milan (Milano)

Aims: To describe the unusual genotypic profile of a patient diagnosed with primary lateral sclerosis (PLS).

Materials and methods: The proband underwent clinical, neurophysiological, neuroradiological and neuropsychological evaluation, and DNA collection for next generation sequencing testing.

Results: A 57-year-old man was admitted to the Motor Neuron Centre of our Institute reporting a 4 year history of subtle-onset clumsiness in his right hand with slowly progressive course. Our patient came from consanguineous parents, and his dead father had previously received a diagnosis of Parkinson's disease. The neurological examination showed mild weakness of right hand finger and wrist extensors, mild right arm spasticity, widespread increased deep tendon reflexes with extension of the reflexogenic area at upper limbs, bilateral ankle clonus, and mirror movements during voluntary upper limb activation. Motor and sensory NCS were normal, while needle EMG showed diffuse neurogenic changes in all limbs with no acute denervation potentials apart from left anterior tibialis. Motor evoked potentials revealed significant increase of central motor conduction time at the right extremities and increased cortical excitability. There was no clinical nor neurophysiological sign of bulbar muscle impairment. Cognitive and behavioral profile were normal. Brain MRI showed T2 weighted hyperintensity of the corticospinal tracts which was more evident on the left site, and SWI weighted images revealed hypointensity in the left precentral gyrus ("motor band sign"). The patient fulfilled the current consensus diagnostic criteria for definite PLS [1]. Genetic testing unraveled a novel homozygous single nucleotide deletion (c.523delG) in OPTN (optineurin) gene, which results in a premature stop codon. In silico pathogenicity prediction tools predicted it as likely disease-causing.

Discussion: OPTN gene mutations are an established, although rare, cause of amyotrophic lateral sclerosis (ALS), found both in heterozygosity and homozygosity. OPTN encodes for a protein known to be detectable as part of inclusion bodies in different neurodegenerative disorders including ALS, frontotemporal dementia and Parkinson's disease [2]. Here we describe the first case of PLS associated with a novel OPTN mutation that is predicted to be likely pathogenetic.

Conclusions: Our findings widens the genotypic-phenotypic correlation of ALS variants and suggest that OPTN mutations should be searched also in patients diagnosed with the PLS variant.

## CLINICAL, NEUROPHYSIOLOGICAL, IMAGING FEATURES AND COMPARISON WITH AMYOTROPHIC LATERAL SCLEROSIS IN A MONOCENTRIC CASE SERIES OF HIRAYAMA DISEASE

G. Zocco, S. Cabras, F. Di Pede, D. Pascariu, U. Manera, A. Canosa, R. Vasta, F. Palumbo, E. Matteoni, F. De Mattei, A. Calvo, A. Chiò, C. Moglia

ALS Center, "Rita Levi Montalcini" Department of Neuroscience, University of Turin (Torino)

Objectives: Hirayama's disease (HD) is a rare juvenile neurological disorder characterised by weakness and amyotrophy of the distal part of upper limbs. The aim of this study is to better define this clinical entity and assess whether HD should be considered a motor neuron disease or a cervical myelopathy.

Methods: We conducted a retrospective analysis of demographic, clinical, neurophysiological and neuroimaging data. Furthermore, by comparing HD and ALS patients with distal upper limb onset and available median and ulnar nerve CMAP values of abductor pollicis brevis (APB) and abductor digiti minimi (ADM), we calculated APB/ADM and ADM/APB ratios and APB-ADM amplitude difference.

Results: 7 HD patients and 18 ALS patients referring to our Centre were included. Among HD patients 5 were males; mean age at onset was 16,86 years and mean progression time was 3,3 years (SD 4.1). All HD patients showed oblique amyotrophy, while no patients showed lower limb weakness. Cold paralysis was found in 5 out 5 patients and tremor in 5 out of 6. Sensitive impairment and local sweating alterations were reported by 3 and 1 of them, respectively. MRI revealed in all of the cases forward displacement of the posterior dural sac, epidural venous plexus congestion and spinal cord atrophy. HD cases presented younger age at onset ($p<0.001$), higher stature ($p=0.021$) and longer diagnostic delay ($p=0.042$) compared to ALS patients. Finally, we analysed 3 HD and 18 ALS CMAPs, finding a statistically significant difference concerning the APB amplitude (HD=6.603 and ALS=3.186; $p=0.029$), APB/ADM ratio (HD=1.704 and ALS=0.673; $p=0.034$), ADM/APB ratio (HD=0.703 and ALS=1.992; $p=0.034$) and the APB-ADM difference (HD=2.370 and ALS=-1.531; $p=0.005$).

Discussion: In our case series typical MRI patterns have been replicated. These findings suggest that HD could be considered a flection myelopathy, due to forward dislocation of spinal cord with anterior horns' compression and microcirculatory damage. In agreement with literature, all our patients showed sparing of brachioradialis muscles. In line with a trend reported by Singh and colleagues [1], we found that, compared to ALS, HD patients tend to present higher APB/ADM ratios. These neurophysiological findings resulted consistent with the clinical detection of more severe ulnar side muscles wasting ("reverse split hand syndrome").

Conclusion: In case of young patients presenting with distal upper limb weakness, neck-flexion MRI with gadolinium should be considered mandatory, whereas in atypical cases, clinical and neurophysiological features can help in different diagnosis between HD and upper limb-confined ALS.

## A CASE OF RARE T138A SOD1 MUTATION IN A PATIENT AFFECTED BY AMYOTROPHIC LATERAL SCLEROSIS SHOWING A SLOW CLINICAL PROGRESSION

P. Zoleo[1], A. Saraceno[1], G. Annesi[2], M. Gagliardi[3], F. Pucci[1], S. Barone[1], A. Gambardella[1], P. Valentino[1]

[1]Department of Medical and Surgical Sciences, Magna Græcia University (Catanzaro); [2]Institute for Biomedical Research and Innovation, National Research Council (Cosenza); [3]Institute of Molecular Bioimaging and Physiology, National Research Council (Catanzaro)

Introduction: Amyotrophic lateral sclerosis (ALS) is currently classified as either familial or sporadic. Familial amyotrophic lateral sclerosis (FALS) constitutes 10–15% of cases. Mutations in more than forty genes have been reported to associate with ALS. The most frequent gene involved in FALS is SOD1 encoding the antioxidant enzyme Cu, Zn superoxide dismutase [1]. More than 150 different mutations have been described in SOD1 gene of ALS patients [2]. We report a very rare mutation of SOD1 gene (p. T138A) associated with slow clinical progression.

Case: A 52-years-old male, presented with a three-years history of progressive lower limb weakness and wasting. He had a family history for ALS, his mother and his uncle were affected, and died at 62 and 70-years-old respectively. Neurological examination showed difficult gait, possible without support for 100 meters, lower and distal upper limb weakness and wasting, diffuse fasciculations and positive left Babinski sign. Bulbar and cognitive functions were normal. Blood, cerebrovascular fluid examinations and motor evoked potential were unrevealing. Needle electromyography (EMG) showed widespread fasciculation, fibrillation, PSW potentials and signs of chronic partial denervation at four limbs. Nerve conduction study revealed a mild reduction of compound muscle action potential amplitude of bilateral peroneal nerve. Based on clinical and electrophysiological features, diagnosis of ALS was established and treatment with riluzole started. His Revised Amyotrophic Lateral Sclerosis Functional Rating Scale (ALSFRS-R) score was 41/48. At present, six years after onset, the patient is 57 years old, and his disability has slowly progressed. His ALSFRS-R score is 37/48. No cognitive dysfunction or bulbar impairment are noticed. A genetic analysis was performed and the T138A mutation of SOD1 gene was found. Prediction of the pathogenetic role of a T138A mutation was performed using PolyPhen-2 tool and it is classified as "probably damaging".

Discussion: In literature are described only three patients, two of which in the same family, carrying the T138A mutation, all with a slowly progressive ALS phenotype without bulbar impairment [2,3]. Our report confirms the surely T138A mutation's pathogenicity and the ALS phenotype associated with this mutation. Our case has the same clinical phenotype of the others described in literature. It is characterized by slow progression with sparing of bulbar and cognitive function. This report could help to better understand the possible role of SOD1 mutation in ALS etiopathogenesis.

Background: Oral tauroursodeoxycholic acid (TUDCA) is a drug currently tested in Amyotrophic Lateral Sclerosis (ALS). While results of phase 3 clinical trials are awaited [1,2], TUDCA is easily administered and reachable for ALS patients.

Objectives: To evaluate overall survival and safety profile in patients with ALS from Emilia Romagna Region (Italy) treated with TUDCA in a real-world setting.

Design and materials: Multicenter, propensity score–matched cohort study conducted between January 2015 and February 2022 in Emilia Romagna Region (ERR) where a population registry collects key clinical features from all specialized MND centers in the region. Since 2015 in ERR, TUDCA has been prescribed from the same specialized centers after approval from the regional rare diseases technical group. Of the 627 patients screened, 86 patients with ALS treated with TUDCA for at least three consecutive months were matched using propensity score analysis with 172 ALS patients receiving usual care. All patients were residents of Emilia Romagna Region and regularly followed till 1st February 2022.

Methods: Propensity score matching was based on age at onset, sex, phenotype, diagnostic latency, ALSFRS-R at first visit, disease progression rate at first visit, BMI at diagnosis. The exposure was oral TUDCA administration versus standard therapy. The primary study outcome was survival difference between TUDCA exposed and unexposed patients. Secondary outcomes were the rate of decline of ALSFRS-R from onset to last visit and frequency and time to support procedures.

Results: 86 patients assumed TUDCA; 64 were male (74.4%) and mean age was 58.2 years (SD 9.2). Median overall survival time was 49.6 months among TUDCA treated patients (95%CI, 41.7-93.5) and 36.2 months in controls (95%CI, 32.7-41.6), with a lower risk of death for higher dosage TUDCA-exposed patients (HR 0.56; 95% CI, 0.38−0.83; P=0.004). No differences were observed in terms of rate of ALSFRS-r decline or time to support procedures. TUDCA was well tolerated except for a minority of patients (n=7, 8.1%) who discontinued the drug.

Discussion and Conclusions: Real-world evidence studies may provide complementary information to randomized controlled trials, by observing treatment effects for a longer time and consider ALS patients at all stages of disease, without the restrictions of RCT criteria [3]. However, they are limited by their retrospective nature with missing or non-uniform information at irregular time points. This retrospective, propensity score-matched study showed that ALS patients treated with TUDCA may have a survival benefit. These findings need to be confirmed by additional prospective randomized studies.

Objectives: To evaluate the psychometrics and diagnostics of the Alternate Verbal Fluency Battery (AVFB) [1] in an Italian cohort of non-demented Parkinson's disease (PD) patients, as well as to derive disease-specific cut-offs for it.

Materials: N=192 idiopathic PD patients without dementia or further psychiatric disorders were screened with the Montreal Cognitive Assessment (MoCA) and underwent the AVFB – which includes phonemic, semantic and alternate verbal fluency (VF) tests (PVF; SVF; AVF), as well as a Composite Shifting Index (CSI) reflecting the "cost" of shifting from a single- to a double-cued VF task. Patients were on medication when tested.

Methods: Construct validity and diagnostics were assessed for each AVFB measure against the MoCA. A demographically adjusted score below the inner tolerance limit of the current Italian normative dataset [2] was addressed as the positive state. Internal reliability and factorial validity were also tested.

Results: At αadjusted=.013, MoCA scores proved to be strongly associated with PVF (r(192)=.53; p<.001), SVF (r(192)=.51; p<.001) and AVF (r(192)=.54; p<.001) scores, whilst moderately with the CSI (r(192)=.34; p<.001). The AVFB was internally consistent (Cronbach's α=.77) and underpinned by a single component (67.65% of variance explained); however, an improvement in both internal reliability (Cronbach's α=.86) and fit to its factorial structure (79.44% of variance explained) was observed when dropping the CSI. Demographically adjusted scores [1] on PVF, SVF and AVF tests accurately identified patients with a below-inner tolerance limit MoCA score (5.2%), whilst this was not true for the CSI (PVF: AUC=.91; SVF: AUC=.85; AVF: AUC=.84; CSI: AUC=.58). Disease-specific cut-offs derived on PVF, SVF and AVF adjusted scores [1] (PVF: <29.537; SVF: <38.038; AVF: <25.191) yielded overall optimal diagnostics.

Discussion: This study provides Italian practitioners and researchers with evidence on the psychometric and diagnostics soundness of the AVFB, as to its PVF, SVF and AVF tests, in non-demented PD patients. Notably, these findings support the use of the AVF as a measure of set-shifting abilities that, at variance with other, widespread tests assessing such functions (e.g., the Trail-Making Test – Part B), is not confounded by upper-limb disabilities associated with PD.

Conclusions: In conclusion, PVF, SVF and AVF tests [1] are reliable, valid and diagnostically sound instruments to detect cognitive impairment in non-demented PD patients and are therefore recommended for use in clinical practice and research.

### MOTOR AND NONMOTOR CORRELATES OF IRON DEPOSITION WITHIN THE BASAL GANGLIA AND THALAMUS IN EARLY DRUG-NAÏVE PARKINSON'S DISEASE PATIENTS

S. Aloisio, R. De Micco, N. Piramide, M. Siciliano, G. Tedeschi, F. Esposito, A. Tessitore

Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli" (Napoli)

Objective: Iron deposition using Quantitative Susceptibility Mapping (QSM) has been reported in several cortical and subcortical areas in patients with Parkinson's disease (PD), and a relationship with clinical outcomes has been proposed. We aimed at exploring the association between MRI-derived iron deposition content within the basal ganglia and thalamus, and several motor, nonmotor and neuropsychological features in a cohort of early drug-naïve PD patients.

Materials: 3T MRI images of 58 early drug-naïve PD patients (41 males, 17 females) were analyzed and compared.

Methods: QSM values were extracted from 22 subcortical deep gray matter nuclei and 16 thalamic subregions. Several PD-validated scales were performed as follows: disease severity and stage were assessed by Unified Parkinson's disease rating scale part III (UPDRS III) and modified Hoehn&Yahr (mH&Y), nonmotor symptoms severity were rated by the Nonmotor symptoms scale (NMSS), autonomic dysfunction were assessed by the Scale for Outcomes in Parkinson's disease for Autonomic symptoms (SCOPA-AUT), global cognitive functioning were assessed by the Montreal Cognitive Assessment (MoCA). Beck Depression Inventory (BDI-II), Parkinson Anxiety Scale (PAS) and Apathy Evaluation scale (AES) were also performed to determine the severity of behavioral symptoms. A partial correlation analysis

using Pearson correlation coefficient was run between MRI metrics and clinical data.

Results: Disease stage positively correlated with higher iron deposition within the bilateral dentate nuclei. UPDRS III scores positively correlated with higher iron deposition within the right substantia nigra pars compacta and left nucleus accumbens. AES scores positively correlated with higher iron deposition within the left externus globus pallidus and bilateral putamina. BDI-II scores positively correlated with higher iron deposition within the left internus globus pallidus, right red nucleus and right substantia nigra pars compacta. PAS scores positively correlated with higher iron deposition within the right substantia nigra pars compacta. SCOPA-AUT scores positively correlated with higher iron deposition within the left dentate nucleus. Higher iron content within different thalamic subregions correlated with higher burden of motor and nonmotor symptoms.

Discussion: We found that the presence of specific motor and nonmotor features is associated with increased iron deposition within different subcortical nuclei, even in the early stages of PD.

Conclusions: We hypothesize that these findings may reflect the presence of diffuse neuropathological changes, that may be associated with a more severe clinical picture at baseline and may potentially lead to more rapid worsening of motor, nonmotor and neuropsychological performances over time.

## A NOVEL PATHOGENIC MUTATION ASSOCIATED WITH EPISODIC ATAXIA

F. Ambrosio[1], S. Aramini[1], R. De Micco[1], M. Cirillo[1], F. Santorelli[2], G. Tedeschi[1], A. Tessitore[1]

[1]Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli" (Napoli); [2]Department of Neurogenetics and Metabolic Disorders, IRCCS Fondazione "Stella Maris" (Pisa)

Objective: Episodic ataxia is a clinically and genetically heterogeneous group of disorders that are characterized by recurrent spells of truncal ataxia and incoordination lasting minutes to hours. We report a potential novel genetic mutation associated with the phenomenology of episodic ataxia.

Materials: A 43-years-old man referred to our outpatient clinic for the slowly progressive onset of recurrent spells of limb weakness and gait ataxia associated with postural instability and falls, with variable duration (minutes to hours), since the age of 40 years. Episodes were anticipated and associated with anxiety. No other triggers were identified. As disease progressed, paroxysmal episodes increased in duration and frequency along with panic attacks, impacting patients' quality of life. The fear of falling forced the patient to use a wheelchair. Familiar history was positive for myocardial infarction and unspecified numbness in the lower limbs in his father. Intercritical neurological examination showed slightly wide based gait, mild limb and gait ataxia, downbeating nystagmus, slow smooth pursuit movements, mild dysarthria, with evident worsening during the paroxysmal attacks.

Methods: Brain MRI without contrast, EEG, routine blood tests, neuropsychological assessment were acquired. Moreover, we performed genetic testing for the most frequent ataxia.

Results: Brain MRI showed mild cerebellar atrophy. EEG and blood tests were unremarkable. Neuropsychological assessment revealed neurodevelopment delay during childhood. Next generation sequencing revealed a novel c.641A>G heterozygous mutation within the KCND3 gene.

Discussion: KCND3 encodes the voltage-gated potassium ion channel subfamily D member 3, involved in the transient outward K+ current. Mutations in KCND3 are associated with spinocerebellar ataxia 19/22, which has been rarely reported to present as episodic ataxia.

Conclusions: We found a potential novel pathogenic mutation linked to episodic ataxia. This confirms previous findings and expands the spectrum of spinocerebellar ataxia 19/22-related disorders.

## THE EFFECT OF CATHODAL TRANSCRANIAL DIRECT CURRENT STIMULATION IN THE TREATMENT OF LEVODOPA-INDUCED DYSKINESIAS IN PARKINSON'S DISEASE: A PRELIMINARY REPORT

B. Angeloni[1], R. Di Iorio[2], P. Sanginario[1], C. Piano[2], F. Bove[2], A. R Bentivoglio[2], P. Calabresi[2]

[1]Neurology, Catholic University of Sacred Heart (Roma); [2]Neurology, Fondazione Policlinico A. Gemelli IRCCS (Roma)

Introduction: In Parkinson's disease (PD), Levodopa is to date the most effective treatment for the management of motor symptoms. However, in a certain number of patients, prolonged treatment is associated with development of Levodopa-induced dyskinesias (LIDs). In the pathophysiology of LIDs, aberrant synaptic plasticity seems to play a key role at different levels of brain system, including the primary motor cortex (M1) [1]. Non-invasive brain stimulation (NIBS) may restore normal functioning and ameliorate clinical deficits reversing these brain plasticity abnormalities. Based on these assumptions, our study aims to demonstrate the possible effect of transcranial direct current stimulation (tDCS) in the treatment of LIDs.

Methods: We applied cathodal bilateral tDCS over M1 of PD patients with LIDs, selected according to similar age, disease duration, and levodopa equivalent daily dose (LEDD). Clinical assessment (MMSE; UPDRS I, II, III and IV; UDyRS) and neurophysiological evaluation (TMS potentiation-depotentiation paradigm) were performed before and after stimulation protocol at 3 days, 1 month and 3 months. To test depotentiation phenomenon, usually impaired in LIDs, we used a protocol already described in literature [2], in which LTP-like effect of a 20-s train of cTBS followed by 1-min contraction of the target muscle (cTBSc0) is reversed by a shorter (10-s) inhibitory form of cTBS (cTBS150). Primary endpoint was reduction in LIDs severity measured by UDyRS. Secondary endpoint was improvement in depotentiation degree measured by MEP amplitude changes.

Results: At the moment, we enrolled 8 dyskenitc PD patients (age: 63.7 ± 9.3; disease duration: 13.4 ± 8.4; LEDD: 861.9 ± 338.1). tDCS over bilateral M1 induced a reduction in LIDs of 32% at 3 days, 9% at 1 month, and 9.8% at 3 months compared with baseline. In addition, a significant change in depotentiation paradigm (p=0.01) was observed in post-tDCS recordings compared with baseline.

Conclusion: In conclusion, this preliminary report shows that, in PD patients with LIDs, cathodal bilateral tDCS over M1 induces a short-term improvement in LIDs severity associated with useful changes in synaptic plasticity.

## INCIDENCE AND RISK FACTORS FOR THE DEVELOPMENT OF POSTURAL ABNORMALITIES IN PARKINSON'S DISEASE

C. A. Artusi[1], C. Ledda[1], C. Campisi[1], D. Rinaldi[2], M. Zibetti[1], M. Rizzone[1], A. Romagnolo[1], F. Pontieri[2], M. Bozzali[1], M. Fabbri[3], L. Lopiano[1]

[1]Department of Neuroscience 'Rita Levi Montalcini', University of Turin (Torino); [2]Department of Neuroscience, Mental Health, and Sense Organs, Sapienza University of Rome (Roma); [3]Department of Neurosciences, Toulouse University Hospital (Tolouse-F)

Objective: Postural abnormalities (PA) are debilitating motor symptoms associated with Parkinson's disease (PD). However, there is limited understanding of the incidence and risk factors for PA development in PD. We aimed to evaluate the incidence of PA in the first five years of PD and identify predictors for PA development using data from the Parkinson's Progression Markers Initiative (PPMI) cohort.

Materials and Methods: The PPMI cohort comprised drug-naïve PD patients within two years of diagnosis. Among participants, we included only PD patients for whom there was at least a 4-year follow-up. Data on demographic characteristics, PA, motor impairment (by means of the MDS-sponsored Unified Parkinson's Disease Rating Scale -UPDRS- part III), physical activity (by means of the Physical Activity Scale for the Elderly -PASE- questionnaire), autonomic symptoms (with the Scales for Outcomes in Parkinson's Disease-Autonomic questionnaire -SCOPA-AUT-), and clinical phenotypes were collected. Statistical analyses included Kruskal-Wallis, Fisher exact test, and Cox regression.

Results: The analysis included 441 PD patients, of whom 10.9% had PA at baseline. Within the first five years, 23.7% of patients without PA at onset developed PA, all at the last follow-up. Comparing patients without PA, with PA at baseline, and who developed PA, we found significant differences for age ($p < 0.001$), MDS-UPDRS part III scores ($p < 0.001$), SCOPA-AUT ($p < 0.001$), PASE score ($p=0.025$), and PD phenotype ($p < 0.001$). Older age (Odds ratio [OR] per year: 1.03) and higher motor symptom severity (OR per point of MDS-UPDRS score: 1.009) were significant predictors of PA development in the multivariate analysis. Physical activity levels showed a trend towards significance as a protective factor for PA development at the univariate analysis.

Discussion: This longitudinal study provides insights into the incidence and predictors of PA in PD. Axial PA was present in a substantial proportion of PD patients within the first five years since diagnosis; on the contrary, severe axial PA remains an uncommon feature in early PD. Moreover, we found that different features can predict the onset of axial PA within 5 years since diagnosis, including a malignant phenotype, a higher burden of dysautonomic symptoms, a lower level of physical activity, an older age, and a higher severity of motor symptoms.

Conclusions: The findings highlight the importance of early monitoring and intervention in patients with older age and greater motor symptom severity at onset. The protective role of physical activity merits to be further investigated.

Objectives: Patients with Parkinson's disease (PD) manifest a complex and multidimensional impairment of speech fluency known as hypokinetic dysarthria. Deep brain stimulation of the subthalamic nucleus (STN-DBS) can further worsen speech performances in PD patients with hypokinetic dysarthria [1,2]. We have previously demonstrated that artificial intelligence can automatically and objectively detect and classify speech abnormalities in PD, with high diagnostic accuracy [1]. In this study, we examined objectively and automatically the hypokinetic dysarthria in PD patients with STN-DBS, by using specific algorithms of artificial intelligence, with classification purposes [3].

Materials: We enrolled 108 controls and 101 patients (50 with STN-DBS and 51 under the best medical treatment). The voice was clinically evaluated using the Unified Parkinson's Disease Rating Scale part-III subitem for voice (UPDRS-III-v). All PD patients were assessed ON treatment with L-Dopa.

Methods: Voice samples of the sustained emission of a vowel were collected through a smartphone from controls and the overall cohort of PD patients. Then, audio tracks underwent specific procedures of machine-learning analysis through the support vector machine (SVM) classifier. ROC curves for comparisons between controls and PD patients with L-Dopa, controls and PD patients with STN-DBS and lastly, PD patients with L-Dopa and STN-DBS were provided to calculate diagnostic accuracies. The likelihood ratio (LR) was also calculated as an objective measure for clinical-instrumental correlations.

Results: Clinically, voice impairment was greater in STN-DBS patients than in those under oral treatment. Machine-learning discriminated voices recorded from STN-DBS patients and those under oral treatments, objectively and with high accuracy. We also found significant clinical-instrumental correlations since the greater LRs, the higher UPDRS-III-v scores.

Discussion: STN-DBS further deteriorates speech performances in patients with PD by current spreading in the phonological loop network.

Conclusions: Future strategies based on current steering and closed-loop devices would be useful to reduce the negative impact of STN-DBS on hypokinetic dysarthria in PD.

## LONGITUDINAL CHANGES OF ENERGY EXPENDITURE, BODY COMPOSITION AND DIETARY HABITS IN PROGRESSIVE SUPRANUCLEAR PALSY PATIENTS

A. R. Avallone, M. Tepedino, F. Abate, M. Serio, M. Caterino, R. Erro, M. Pellecchia, P. Barone, M. Picillo

Center for Neurodegenerative Diseases (CEMAND), Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", University of Salerno (Salerno)

Objective: Recent evidence suggest that neurodegenerative diseases are associated with a wide spectrum of metabolic changes. The aim of this study is to describe longitudinal changes in energy expenditure, body composition and dietary habits in patients with Progressive Supranuclear Palsy (PSP), a rare neurodegenerative disease characterized by rigid-akinetic parkinsonism, postural instability, oculomotion dysfunction and cognitive-behavioral changes.

Materials: A total of 15 PSP patients, referred to the Center for Neurodegenerative diseases (CEMAND) of the University of Salerno, were evaluated at baseline and after a median of 7 months (interquartile range IQR=5). We assessed anthropometric parameters (weight, body mass index, waist circumference), energy expenditure, body composition and dietary intake. Disease severity was assessed with the PSP rating scale (PSP-rs) and Movement Disorder Society-Unified Parkinson's Disease Rating Scale III (MDS-UPDRS III), dysphagia severity with the corresponding PSP-rs items (i.e., dysphagia for solids, dysphagia for liquids, using cutlery), MOCA was used to evaluate global cognition and S&E scale disease disability.

Methods: Differences between paired group at baseline and follow up were performed using paired t-test or signed-rank Wilcoxon test, as appropriate.

Results: No changes were detected in anthropometric parameters nor in measured or estimated rest energy expenditure nor in total daily energy expenditure over time ($p>0.05$). Similarly, bioimpedance analysis showed no changes in fat mass and fat free mass ($p>0.05$). Dietary habits showed a reduction of daily calories ($p<0.001$), proteins ($p<0.001$), fibers ($p=0.001$), calcium ($p=0.008$), iron ($p=0.001$), zinc ($p=0.034$), vitamin E ($p=0.006$) and folate ($p=0.038$) intake compared to baseline. The PSP-rs and MDS-UPDRS III significantly increased ($p=0.001$ and $p=0.022$ respectively), as well as the severity of solid ($p=0.083$) and liquid ($p=0.046$) dysphagia and ability to use cutlery ($p=0.046$). Moreover, S&E scale and MOCA decreased ($p=0.001$ and $p=0.004$ respectively) over time.

Discussion: As expected, after a median of 7 months follow up, disease-specific motor and cognitive characteristics showed a worsening. Dietary habits presented a lower intake of daily calories, proteins, fibers, calcium, iron, zinc, vitamin E and folate. Finally, anthropometric parameters, energy expenditure and body composition remain stable in PSP patients.

Conclusions: The worsening of dysphagia associated with a global progression of disease may explain the reduction in dietary intake. We speculate changes in dietary habits, with reduction of several macronutrients in less than a year, may not be sufficient to produce significant modifications in energy expenditure and body composition, which were found to be stable.

Background: GBA mutations are known not only to increase the risk of developing Parkinson disease (PD) but also to influence the outcome. Deep brain stimulation (DBS) is considered one of the best therapeutic options for advanced PD. However, data on DBS long-term clinical outcome in GBA mutation carriers are still scarce.

Objective: To elucidate the impact of GBA variants on long-term DBS outcome.

Methods: We retrospectively collected clinical data from a multicentric Italian cohort of PD patients who underwent DBS, stratified

according to their GBA genotype (positive vs negative). We described: 1) the prevalence of GBA mutations in the DBS-PD cohort; 2) their clinical phenotype (motor and non-motor features) pre-DBS; 3) their outcomes on motor, cognition and other non-motor features after 1, 3 and (for a subset) 5 years from DBS.

Results: We included 365 subjects (244 M/144 F, age 63.4±8, age at onset 46.5±8.2, PD duration 10.4±4). GBA variants were found in 73 (20%). At pre-DBS evaluation, GBA-PD patients showed younger age, earlier age at PD onset, and a slightly shorter disease duration compared to nonGBA-PD patients. Motor, cognition and other non-motor symptoms were similar between groups, except for dyskinesias and orthostatic hypotension (more prevalent in GBA-PD). At 1-year post-DBS, both groups showed motor improvement with satisfactory control of fluctuations and dyskinesias and a significant LEDD decrease; all non-motor symptoms were also comparable. Longitudinal analysis up to 5-years post-DBS showed a prolonged motor benefit of DBS in both PD groups, except for the "on-off" phenomenon, more prevalent in GBA-PD. A deterioration of cognitive scores post-DBS was observed in both groups, with a significantly more marked worsening of GBA-PD already 3 years post-DBS. However, only 25% (8/32) of GBA-PD compared to 11% (15/140) of nonGBA-PD received a diagnosis of dementia at 5-years post-DBS. No clinically significant differences were observed in the GBA-PD group according to mutation severity prior to DBS implant and at 1-year follow-up.

Conclusion: This is the first report correlating the presence of GBA variants with DBS clinical outcomes in a large well-characterized Italian PD cohort with a relatively long follow-up. Our data indicate that GBA-PD patients have similar motor benefits from DBS as nonGBA-PD patients. Cognitive performance, although progressively worsening in both groups, shows a more rapid deterioration in GBA-PD patients, however after 5 years from DBS only a minority of patients eventually developed overt dementia.

## PROPRIOSPINAL MYOCLONUS IN ALZHEIMER'S DISEASE: A CASE REPORT

E. Bergamin, M. Del Chicca, E. Del Prete, E. Unti, F. Cignoni, L. Giampietri, F. Turco, E. Bonanni, G. Siciliano, G. Tognoni

Department of Clinical and Experimental Medicine, Neurology Unit, University of Pisa (Pisa)

Introduction: Propriospinal myoclonus (PSM) is a rare hyperkinetic movement disorder involving axial muscles, characterized by involuntary flexion movements of trunk, hips and knees that are painless, usually arrhythmic, often stimulus-sensitive and typically increase in supine position. PSM is often a functional movement disorder (FMD). The recording of polygraph and Bereitschaftpotential (BP) has been proposed to support clinical diagnosis, but sensitivity in studies varies between 25 and 80 %. To improve this sensitivity, the analysis of event-related EEG desynchronization patterns (ERD) has been proposed. Although cases of FMD have been described in patients with neurodegenerative diseases such as Parkinson's Disease, no cases of PSM have been previously described in patients with Alzheimer's Dementia (AD). Case report: A 61-year-old female patient with diagnosis of AD according to NIA-AA criteria, followed by the Neurology Clinic of University of Pisa, reported involuntary trunk movements that had begun about two months before the last evaluation. At the time of the examination, the patient, who had been on stable therapy for 9 months, presented with arrhythmic involuntary trunk movements that propagated to the shoulders, presented entrainment phenomenon, increased in clinostatism, decreased until disappearing with distraction maneuvers and during gait. The motor disorder appeared after the new onset of low back pain where the lumbar puncture was performed two years earlier. At that time, after the procedure, she presented back pain then she performed lumbar spine MRI, which was normal. The patient underwent clinical evaluation and polymiographic recording, with research for BP and ERD. The diagnosis of PSM was made according to Brown's criteria. During the polymiographic recording, 22 episodes of rhythmic movements in the abdomen and trunk were detected without corresponding changes in EEG activity; these movements presented cranio-caudal propagation from the rectus abdominis muscle. In addition, execution of voluntary movements of the upper limbs such as opening and closing of the hands determined the entrainment phenomenon and sometimes interruption of rhythmic involuntary movement. No BP was recorded, however, an ERD was found in the beta frequency prior to the motor event, supporting the electrophysiological evidence of a voluntary cortical genesis of the movement itself.

Discussion and Conclusion: Improving the diagnostic accuracy of FMD in patients with neurodegenerative diseases is one of the new challenges in the field of movement disorders. Currently, the diagnosis of functional PSM is supported by polymiographic findings with variable sensitivity, so research for additional and more sensitive neurophysiological biomarkers is needed.

## APRAXIA OF SPEECH AS AN UNUSUAL MANIFESTATION OF GAD-65 SPECTRUM DISORDER– A CASE REPORT

S. Bertino[1], D. Restivo[2], I. Arena[1], G. Falcone[1], C. Terranova[1], O. Musumeci[1]

[1]Department of Clinical and Experimental Medicine, University of Messina (Messina); [2]Department of Biomedical, Dental Sciences and Morphological and Functional Images, University of Messina (Messina)

Objectives: Apraxia of speech (AOS) is a neurological speech disorder characterized by impaired planning and programming of movements allowing phonetically and prosodically normal speech. It is observed in patients with acquired vascular lesions or neurodegenerative diseases such as primary progressive aphasias (PPA) and progressive supranuclear palsy (PSP)[1]. The glutamic acid decarboxylase 65 (GAD65)-antibody spectrum disorder encompasses a variety of neurological disorders including stiff person syndrome (SPS), cerebellar ataxia, autoimmune epilepsy, and limbic encephalitis[2]. Herein, we report apraxia of speech (AOS) as an unusual manifestation in a patient affected by a GAD65-ataxia.

Materials: We describe a case of a 41-year-old man who presented to our clinic for progressive clumsiness of gait with "rigidity" of his left leg together with swallowing and speech difficulties.

Methods: At neurologic examination the patient exhibited an ataxic gait with spasticity of his left limbs, brisk reflexes, and Babinski sign on the left. His speech was slow, effortful, halting and hypophonic. The patient underwent cerebrospinal fluid (CSF) examination and brain MRI. A neurophysiologic study consisting in electromyography (EMG) and motor evoked potentials (MEPs) was carried out. Finally, otorhinolaryngology evaluation with laryngoscopy was performed.

Results: CSF examination showed high titre of anti-GAD65. Hence, the patient was diagnosed with GAD-65-ataxia. Brain MRI showed mild atrophy of the vermis and the cerebellar hemispheres. EMG of the vastus lateralis showed continuous high frequency firing at rest bilaterally, heightened by contraction and lasting after relaxation. EMG of the thyroarytenoid muscles at rest revealed a pattern of tonic activity, without the occurrence of bursts, with MUP of normal amplitude and duration during muscle activation and normal recruitment. MEPs were unremarkable. Laryngoscopy found no structural abnormalities. The patient underwent oral steroid therapy and intravenous immunoglobulins without substantial benefit. His symptoms improved after a plasma exchange cycle. Rituximab has been administered resulting only in little improvement. He is currently assuming methotrexate with mild benefits.

Discussion: Our patient presented a mixed clinical phenotype characterized by overlapping features of SPS and GAD-65 cerebellar ataxia. The speech disorder was inconsistent with dysarthria and spasmodic dystonia for its clinical and neurophysiologic pattern[3], thus suggesting AOS as an atypical manifestation of GAD-65 ataxia.

Conclusions: Even if with a neglected pathophysiological mechanism, AOS may represent an atypical manifestation in a GAD65-spectrum disorder which, on purely clinical ground, may be easily mistaken with other speech disorders. However, laryngeal EMG may provide helpful diagnostic clues across phonation/articulation disorders.

## ASSOCIATION BETWEEN AVERAGE DAILY STEPS MEASURED THROUGH A COMMERCIAL SMARTWARTCH AND CLINICAL PARAMETERS IN PARKINSON'S DISEASE IN DIFFERENT DISEASE PHENOTYPES

E. Bianchini, G. Di Pietro, S. Galli, M. Alborghetti, D. Rinaldi, L. De Carolis, P. Pacilio, F. Pontieri

Department of Neuroscience, Mental Health and Sensory Organs (NESMOS), Sapienza University of Rome (Roma)

Objective: Commercial smartwatches could be useful for monitoring ambulatory activity in a home environment [1]. In Parkinson's disease (PD), motor impairment and reduced functional mobility are crucial aspects greatly hampering daily living independence and quality of life. However, only very few studies examined the relationship between daily steps recorded by commercial smartwatches and clinical parameters in these patients with inconsistent results [2,3].

Material and Methods: Forty-three ambulating PD patients without dementia were enrolled [28% females; age 68.7 (8.0) years; disease duration 7.3 (4.8) years; levodopa equivalent daily dose (LEDD) 616 (324) mg; median Hoehn and Yahr (H&Y) stage 2 (2-2, range 1-3)]. Average daily steps (avDS) were recorded at home through a Garmin Vivosmart 4 smartwatch for a median of 5 days (range 3-6). Data regarding motor and non-motor symptoms severity and fluctuations, presence/absence of tremor, functional mobility, quality of life, fatigue, sleep and daytime sleepiness were collected. Mann-Whitney test was used to assess difference between tremor and non-tremor patients. To assess the correlation between avDS and clinical-demographic variables, Spearman test was used.

Results: Patients took a mean 6046 (3253) daily steps. No difference in clinical-demographic and avDS between tremor and non-tremor patients were found. In the overall population, Spearman test showed a moderate positive correlation of avDS with SPPB (R=0.548; p<0.001); a weak negative correlation with MDS-UPDRS-III (R= -0.349; p=0.022), total MDS-UPDRS (R= -0.307; p=0.048), LEDD (R= -0.380; p=0.012), disease duration (R= -0.437; p=0.003), age (R= -0.431; p=0.004) and H&Y stage (R=-0.321; p=0.036). In patients with tremor (30/43, 69%), test showed a weak positive correlation of avDS with SPPB (R=0.392; p=0.032); a weak negative correlation with LEDD (R= -0.415; p=0.023), disease duration (R= -0.479; p=0.007) and age (R= -0.447; p=0.013). In patients without tremor (13/43, 31%), test showed a strong positive correlation of avDS with SPPB (R=0.842; p<0.001) and a moderate negative correlation with MDS-UPDRS-III (R= -0.629; p=0.021).

Discussion: Daily steps measured at home through a commercial smartwatch were associated with motor symptoms and functional mobility in ambulating PD patients, particularly in those without tremor. This could potentially be due to a reduced step detention performance linked to tremor or due to a more tight relationship between motor symptoms and mobility in non-tremor patients.

Conclusions: Our results suggest that mobility-related parameters measured through commercial smartwatches could add valuable and easy-to-collect information on patients status besides in-clinic evaluations, particularly in specific disease subtypes.

## RELATIONSHIP BETWEEN BRADYKINESIA AND COGNITIVE FUNCTIONS IN PATIENTS WITH ESSENTIAL TREMOR

D. Birreci[1], G. Paparella[2], L. Angelini[1], A. Di Vita[1], R. Margiotta[1], A. Cannavacciuolo[2], D. Costa[1], M. De Riggi[1], M. Passaretti[1], D. Alunni Fegatelli[3], A. Berardelli[2], M. Bologna[1]

[1]Department of Human Neurosciences, Sapienza University of Rome (Roma); [2]IRCCS Neuromed (Pozzilli-IS); [3]Department of Public Health and Infectious Diseases, Sapienza University of Rome (Roma)

Objectives: Bradykinesia in essential tremor (ET) is one of the so-called 'soft signs' configuring the diagnosis of ET-plus [1,2,3]. Cognitive disturbances may also occur in ET with a higher prevalence than in the general population [1]. Though it has been demonstrated that soft signs often occur in combination, the relationship between bradykinesia and cognitive dysfunction in ET patients has never been explored. The aims of our study is to further investigate the association between bradykinesia, as objectively assessed with kinematic analysis, and cognitive functions in ET.

Materials: 45 ET patients (23 F, mean age: 66.48±13.69). Patients underwent kinematic recordings of finger-tapping movements with an optoelectronic motion system [2,3]. A comprehensive cognitive evaluation, including the assessment of executive and visuo-constructional functions, attention, and memory, was also performed on participants.

Methods: Automatized algorithms were used for kinematic analysis, providing objective measurement of movement velocity and movement rhythm (expressed as coefficient of variation - CV, with higher values indicating a more irregular rhythm). Possible associations between kinematics and raw cognitive scores were assessed by using the Pearson correlation coefficient.

Results: We found a positive correlation between movement velocity and the Rey-Auditory Verbal Learning Test (RAVLT) immediate and delayed recall (r=0.3, p=0.04 and r=0.35, p=0.019, respectively). A negative association was found between CV and Forward Digit span scores (r=-0.3, p=0.039). Finally, CV values positively correlated with the Modified Card Sorting Test (MCST) errors (r=0.43, p=0.024).

Discussions: These results overall indicate that the lower the movement velocity and the more irregular the rhythm, the worse the performance on tests exploring memory and executive functions.

Conclusions: We here demonstrated a relationship between finger-tapping bradykinesia and memory and executive dysfunctions in ET. Our results are relevant for a better understanding of ET and ET-plus pathophysiology.

## PERIPHERAL INFLAMMATION IS ASSOCIATED WITH A WORSE PROFILE OF CSF NEURODEGENERATION MARKERS AND LONG-TERM CLINICAL OUTCOME IN IDIOPATHIC NORMAL PRESSURE HYDROCEPHALUS

J. Bissacco, C. Simonetta, D. Mascioli, A. Stefani, N. Mercuri, T. Schirinzi

Unit of Neurology, Department of Systems Medicine, Tor Vergata University of Rome (Roma)

Objectives: To disentangle the dynamics of the brain-periphery interactions in idiopathic normal pressure hydrocephalus (iNPH) by examining the correlations of peripheral immunity markers with CSF neurodegeneration-associated proteins and clinical progression severity.

Materials and Methods: We conducted a single-center longitudinal retrospective study over a 12-year-long period, enrolling 38 iNPH patients and 38 sex/age-matched controls. The leukocyte population counts (neutrophils, lymphocytes, monocytes, eosinophils, and basophils) and the neutrophil-to-lymphocyte ratio (NLR) were collected and correlated with CSF levels of amyloid-β-42, total and phosphorylated-tau in both the groups. In iNPH patients, the immune parameters and CSF biomarkers were correlated either with baseline scores of the iNPH grading scale (iNPHGS) and modified Ranking Scale (mRS) or the long-term (> 5 years) clinical outcome classified as "poor" (mRS≥5) and "positive" (mRS<5).

Results: iNPH patients had lower lymphocyte count (mean ± st.dev.: 1.89 ± 0.73 thousand/uL vs. 2.53 ± 0.80 thousand/uL, p<0.001) and higher NLR (mean ± st.dev.: 2.43 ± 1.04 vs.1.56 ± 0.47, <0.001) compared to controls. In iNPH patients, NLR directly correlated with CSF t-tau levels (r=0.50, p=0.004), even in a model adjusted for age and sex (t=2.174, p=0.039). No significant association resulted in control group. At baseline, CSF t-tau levels correlated with baseline iNPHGS cognitive subscore (t=2.43, p=0.026). At long-term follow-up, patients with "poor outcome" had higher NLR (mean ± st.dev.: 3.10 ± 1.42 vs. 2.01 ± 0.77, p=0.06) and higher CSF total-tau levels (mean ± st.dev.: 300.58 ± 114.10 pg/ml vs.175.69 ± 94.57 pg/ml, p=0.04).

Discussion: iNPH is a heterogeneous and challenging neurodegenerative condition with complex pathogenesis. While the contribution of peripheral inflammation has been ascertained in many other neurodegenerative diseases1, it needs to be adequately addressed in iNPH. Here we showed that the iNPH patients had lower lymphocyte count and higher NLR than controls, consistently with a systemic inflammatory state. Of interest, such peripheral immune changes were associated with central neurodegeneration burden and poor long-term clinical outcome. These data collectively provide novel evidence that a proinflammatory shift of the immune system might contribute to the clinical-pathological progression of iNPH, as it also occurs in other neurodegenerative diseases.

Conclusions: Increased NLR and reduced lymphocyte count emerged as the peripheral immunity signature of iNPH. Systemic inflammation was associated with a worse profile of CSF neurodegeneration markers and long-term clinical severity, suggesting a major pathogenic role with potential implications in terms of therapy or patient stratification.

## ANTI-BASAL GANGLIA ANTIBODIES (ABGA) ASSOCIATED WITH MOVEMENT DISORDERS AND PSYCHIATRIC SYMPTOMS: A CASE REPORT

F. Bonardi[1], F. De Marchi[1], C. Varrasi[1], F. Colombatto[1], L. Magistrelli[1], C. Comi[2], R. Cantello[1]

[1]Neurology Unit, Department of Translational Medicine, University of Piemonte Orientale, Maggiore della Carità University Hospital (Novara); [2]Neurology Unit, Department of Translational Medicine, University of Piemonte Orientale, S. Andrea Hospital (Vercelli)

Objective: To report the case of a 33-year-old Bangladeshi man who presented with an unusual movement disorder associated with psychiatric symptoms and anti-basal ganglia antibodies (ABGA) in serum.

Case report: The patient was a 33-year-old Bangladeshi man with aggressive behavior and gambling started two years earlier. During the same period, he also complained of constipation, epigastric pain, wheezing, and diffuse myalgias. Prior medical history was unremarkable. The patient came to our attention because of hypotension, wheezing, tachypnea, and desaturation, that were triggered by antipsychotic treatment for behavioral symptoms. He underwent orotracheal intubation as well as nasogastric tube placement for to ineffective swallowing. Neurological examination, performed after extubation, showed: hypomimia, dysarthric speech, severe sialorrhea, slowed extraocular movements with vertical gaze limitation, severe bradykinesia, diffuse muscular hypotrophy, rigidity with forced hip and knee flexion and ankle extension, dystonic posture of the hands and hyperactive deep tendon reflexes. CT scan showed bilateral calcifications in the basal ganglia, seen as paramagnetic particles on brain MRI. DATSCAN was normal. EMG showed axonal motor neuropathy at lower limbs, with diffuse denervation activity (fibrillation potentials). Cerebrospinal fluid was normal. Laboratory exams ruled out Gaucher, Niemann-Pick type C, Wilson and Lyme disease. To test autoimmune etiology, the patient underwent a panel for autoimmune encephalitis, with the positivity for ABGA in serum (research of ABGA was performed using an

immunoblotting procedure with recombinant proteins from the caudate nucleus and putamen: pyruvate kinase 60 KDa and neuron-specific enolase 40 KDa). We followed the patient over time, observing symptoms improvement: he returned to eat independently and walk without assistance. After six months, there was also an improvement in extrapyramidal symptoms. Nonetheless, behavioral symptoms, especially apathy, remained unchanged.

Discussion: Serum ABGA are commonly associated with Sydenham's chorea, and seldom found in adults. A previous study assessed the frequency of ABGA in 65 patients with adult-onset movement disorders with an unusual presentation (mainly atypical dystonia) and found 42 cases of serum ABGA positivity [1]. Dale et al. also described 20 cases of encephalitis lethargica and parkinsonism with anti-basal ganglia autoimmunity. In all reported cases, few patients had a complete recovery, showing persistence of both movement disorders and psychiatric symptoms [2]. Patients with atypical movement disorders present considerable diagnostic and therapeutic challenges to physicians, and the finding of a possible autoimmune cause in a percentage of them may help in guiding future research and therapy.

## ASSOCIATIONS BETWEEN SEX HORMONES, CLINICAL FEATURES AND MULTIMODAL BIOMARKERS IN A COHORT OF MALE PATIENTS WITH PARKINSON'S DISEASE

R. Bovenzi[1], G. Sancesario[2], M. Conti[1], M. Pierantozzi[1], A. Stefani[1], N. Mercuri[1], F. Di Giuliano[3], T. Schirinzi[1]

[1]Department of Systems Medicine, University of Tor Vergata (Roma); [2]IRCCS Fondazione Santa Lucia, European Centre for Brain Research (Roma); [3]Neuroradiology Unit, University of Tor Vergata (Roma)

Objective: Epidemiology, clinical and pathophysiological features of PD differ between females and males, suggesting a role for sex hormones [1]. At this regard there are compelling findings from animal models [2], while human-based evidence is still scarce. By integrating neurodegeneration-related CSF biomarkers and MRI-based volumetric measurement of brain structures, we can track neuropathological changes in vivo in patients. In this study, we aimed to deepen into sex-dependent mechanisms of Parkinson's disease (PD) by analyzing the relationships between sex hormones, clinical features and multimodal biomarkers in a cohort of male PD patients.

Materials: We enrolled 63 male PD patients and 56 age-matched controls afferent to the Neurology Unit of Tor Vergata University Hospital (Rome - Italy).

Methods: For each subject, demographics and anthropometrics data were recorded. A complete clinical evaluation, including motor, non-motor and cognitive scores, was coupled to lumbar puncture for CSF biomarkers assay and blood sampling for sex hormones measurement. CSF levels of total α-synuclein (αSyn), amyloid-β-42 (Aβ42), amyloid-β-40 (Aβ40), total tau (t-tau) and phosphorylated-181-p tau (p-tau) were quantified. Aβ42/p-tau, Aβ42/Aβ40 ratios were also calculated. Serum sex hormone levels, including total testosterone, estradiol, follicle-stimulating hormone (FSH) and luteinizing hormone (LH) were determined. A subgroup of 47 PD patients underwent 3T brain MRI for volumetric measurement of bilateral subcortical gray matter structures using a 3D T1-weighted MPRAGE sequence.

Results: Estradiol and testosterone levels were higher in PD patients than in controls, independently from age ($p=0.001$ and $p=0.003$, respectively). Estradiol inversely correlated with MDS-UPDRS-III ($p=0.006$) and with disease duration ($p=0.015$). Estradiol was significantly lower in patients with motor fluctuations ($17.33 \pm 11.33$ pg/ml) than in those without ($27.9 \pm 13.6$) ($p=0.016$). Testosterone was inversely associated with CSF α-syn levels ($p=0.03$) and right-globus pallidus volume ($p=0.024$). FSH and LH had a direct correlation with age (both $p<0.0001$) and an inverse correlation with Aβ42/Aβ40 ratio and cognitive scores, which were lost in the model adjusted for age.

Discussion: Higher estradiol levels were associated to milder motoric impairment, supporting a possible neuroprotective effect, especially in the earliest stages of the disease. Testosterone levels instead were directly correlated to biomarkers of neuropathological burden, suggesting a role in the males vulnerability to PD pathology. Finally, gonadotropins might mediate age-dependent phenomena of amyloidopathy and cognitive decline.

Conclusions: This study provided evidence regarding the relationship within sex hormones and both clinical features and biomarkers of disease severity, laying the foundations for a possible therapeutic role in PD.

## ANALYSIS OF ALFA-SYNUCLEIN DEPOSITION IN OLFACTORY MUCOSA AND SKIN NERVES OF TWO RELATED PATIENTS WITH THE SAME PARK18 VARIANT AND MILD PD PHENOTYPE

A. Braccia[1], A. Elia[1], G. Devigili[1], R. Lombardi[2], B. Garavaglia[3], I. Colangelo[3], M. Suerz[4], M. Spagnolo[4], S. Portaleone[5], C. De Luca[6], A. Ciullini[6], I. Dellarole[6], F. Moda[6], R. Eleopra[1]

[1]Division of Neurology 1, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [2]Division of Neurology 3, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [3]Medical Genetics and Neurogenetic Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [4]Biology, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano); [5]Otolaringology Unit, San Paolo Hospital, University of Milan (Milano); [6]Division of Neurology 5 and Neuropathology, Fondazione IRCCS Istituto Neurologico Carlo Besta (Milano)

Objectives: To describe clinical and biological findings of two related patients (mother and daughter) affected by Parkinson's disease (PD), who were found to be carriers of the same variant in exon 11 of PARK18 gene.

Materials and Methods: We performed a NGS-based genetic test to examine a panel of genes associated with PD, finding that both patients were carriers of the same mutation c.1237G>A (pGly413Arg) in the exon 11 of PARK18 gene. We used the Burghart Sniffin Sticks test for evaluation of olfactory function. We have then subjected the olfactory mucosa samples to seed amplification assay (SAA) to detect the presence of seeding activity for alpha-synuclein [1]. We investigated the presence of alpha-syn aggregates in skin sections taken from C7, thigh and distal leg, by double immunofluorescence immunohistochemical stainings [2].

Results: Our first patient is an 82-year-old woman who was diagnosed with PD at the age of 60 after the appearance of rest tremor and a long history of hypsomia. After more than 15 years since the start of treatment, she presents mild motor fluctuations without dyskinesias. Our second patient is a 50-year-old woman with a long-standing hyposmia, affected by a rigid-akinetic form of PD from the age of 46;

her actual symptoms are confined to her right hemisoma and determine a mild functional impact. For each patient, we performed an olfactory analysis and neuropathological analysis of olfactory mucosa and skin biopsy. The Burghart Sniffin Sticks test confirmed that both patients are hyposmic. SAA analysis confirmed the presence of a seeding activity for alpha-synuclein in both patients, while immunoistochemistry did not reveal alpha-synuclein deposition in skin nerves.

Discussion: The similar clinical phenomenology of our patients and the results of our analyses sustain the hypothesis that PARK18 gene could manifest as a "benign" form of PD, with a slow progression and an apparent lack of pathological alfa-synuclein accumulation in peripheric nervous system. One reason for the controversial role of this gene in previous case controls studies [3] could be the mild severity of its PD phenotype: we could consider as "healthy controls" individuals who carry the same variant and have a prodromal or non-motor prevalent form of PD (for example, with isolated hyposmia and minimal motor signs), thus underestimating the role of PARK18 gene in causing PD. Our results support the idea that the PARK18 could play a pathogenic role in determining a "benign" phenotype of PD.

## PARKINSON'S DISEASE FOLLOWING COVID-19: ONE-YEAR FOLLOW UP OF SIX REPORTED CASES

A. Calculli[1], T. Bocci[2], A. Priori[2], A. Pisani[1]

[1]IRCSS Mondino Foundation, Department of Brain and Behavioral Sciences, University of Pavia (Pavia); [2]Clinical Neurology Unit, "Azienda Socio-Sanitaria Territoriale Santi Paolo E Carlo", Department of Health Sciences, University of Milan (Milano)

Objective: Here we describe a one-year follow-up of six subjects who developed PD after COVID-19 infection.

Materials: Neurological complications may occur during SARS-CoV-2 infection, covering a wide spectrum of phenotypical manifestations. We recently described six cases of PD following COVID-19, in line with a number of post-COVID-19 PD cases reported in the literature, suggesting the possibility of a close link between infection and neurodegenerative process.

Methods: The first evaluation was performed at IRCCS Mondino Foundation Hospital, Pavia, and San Paolo University Hospital of Milan between March 2021 and June 2022. In all subjects, SARS-CoV-2 infection was confirmed by means of a RT-PCR from a nasopharyngeal swab. Subjects underwent an accurate neurological evaluation and neuroimaging studies. The one-year follow-up was performed at Mondino Foundation and San Paolo University Hospital.

Results: We described six subjects, who developed PD with an average time window after SARS-CoV-2 infection of 4-7 weeks. Apparently, no relationship with COVID-19 severity emerged, no overt structural brain abnormalities were found. DaTscan was performed in four out of the six reported cases, showing altered striatal reuptake. All subjects experienced unilateral resting tremor at onset and showed a satisfactory response to dopaminergic treatment. During follow-up clinical evaluations, performed in the past 12 months, all of the subjects exhibited a significant stable motor control, and maintained a satisfactory response to the dopaminergic therapy initially set.

Discussion: The time window of clinical presentation of PD reported, suggests that the infection might have uncovered a latent neurodegenerative substrate and made it clinically manifest. Indeed, the role of neuroinflammation in the PD pathogenesis is now well established. Inflammation is a key factor in the initiation and propagation of alpha-synuclein (α-syn) aggregates, and in addition, elevated α-syn-dependent specific T cell response may be present years before the diagnosis of motor PD. Both the clinical stability, and the good response to dopaminergic treatment observed at follow-up confirm the diagnosis of PD.

Conclusions: Immune responses to SARS-CoV-2 infection have been shown to shape the individual susceptibility to develop long-term consequences. We hypothesize that, in these subjects, COVID-19 unmasked a latent neurodegenerative process. Furthermore, the clinical course resembles idiopathic-PD, supporting the hypothesis of a close connection between inflammatory processes and neurodegeneration. Thus, the long-term follow-up of these patients is crucial to define the natural history of the disease, in order to elucidate the clinical, biochemical, imaging features of this peculiar form of PD.

## CLOZAPINE IN THE MANAGEMENT OF TARDIVE DYSTONIA: CASE SERIES AND LITERATURE REVIEW

V. Campana[1], A. Bentivoglio[2]

[1]Medical Department, Luigi Vanvitelli University (Napoli); [2]Department of Neuroscience, Catholic University of the Sacred Heart (Roma)

Tardive syndromes are iatrogenic movement disorders, characterized by involuntary repetitive body movements, caused by chronic exposure to dopamine receptor blocking agents (DRBA), mostly antipsychotics, sometimes procinetic drugs and calcium channel blockers. Tardive dystonia is an uncommon tardive syndrome, presenting with clinical features overlapping with primary dystonia, more frequent among young male patients, affecting mostly axial muscles. There are not guidelines for the treatment. Nevertheless, in a recent literature review, it is recommended the use of clozapine as a treatment and/or for drug switch. In the last two years, three patients, two male and one female, had been treated at the Movement Disorder Clinic of the Gemelli Hospital. All of them were young, treated for several years with DRBA for psychiatric conditions. DRBA treatment was ongoing when dystonia occurred, involving in all of them axial muscles and affecting neck and trunk.

## ATROPHY OF THE CAUDATE NUCLEUS AS A POSSIBLE COMMON NEUROBIOLOGICAL SUBSTRATE FOR MOTOR AND NON-MOTOR SYMPTOMS OF PARKINSON'S DISEASE

C. Campisi[1], C. Artusi[1], F. D'Agata[1], L. Serra[2], G. Morana[1], M. Rizzone[1], M. Zibetti[1], A. Romagnolo[1], C. Ledda[1], G. Imbalzano[1], E. Montanaro[1], M. Tatu[1], M. Laudadio[1], M. Coriasco[1], L. Lopiano[1], M. Bozzali[1]

[1]Department of Neuroscience "Rita Levi Montalcini", University of Turin (Torino); [2]Neuroimaging Laboratory, IRCCS Santa Lucia Foundation (Torino)

Introduction: Parkinson disease (PD) is the second most common neurodegenerative disorder, whose clinical features include motor and non-motor symptoms [1]. The relationship between motor and non-motor clinical features of PD still remains to be clarified. Recently, inertial sensors have become a useful tool for an accurate assessment of patients' motor performance through the analysis of quantitative measures.

Aim: To investigate the possible relationships and common neurobiological substrates between gait abnormalities and neuropsychological performance in patients with PD.

Methods: We recruited 51 patients with PD (mean [SD] age 60.5 [8.1]; M/F: 37/14) for a gait analysis investigation based on inertial sensor data acquisition. Evaluations were conducted under two different conditions: off-medication (12 hours from last levodopa administration) and on-medication (about 30 min after levodopa challenge). All patients underwent also an extensive neuropsychological (NPS) examination and MRI scanning at 3T, including acquisition of T1-weighted volumes. Univariate and multivariate regression analyses were first run including multidomain NPS test scores and a set of gait parameters to identify associations. T1-weighted volumes were used to run voxel-based morphometry (VBM) analyses of the grey matter (GM) tissue [2]. Then, we run a series of VBM analyses (ANOVA models) to identify associations between regional GM volumes and those cognitive and motor parameters resulted to be associated with each other. Imaging findings were accepted as significant for P values cluster-level corrected $< 0.05$. Finally, overlapping GM regions were evaluated to identify common regional patterns between NPS and motor performances.

Results: Multiple associations were identified between NPS and motor measures. Expected patterns of regional GM associations were found for NPS scores taken in isolation. VBM analyses also showed an overlapping region of GM volumes associated with both patient long-term memory scores and the sway area from gait analysis in off-medication. This region was centered on the right head of the caudate nucleus.

Discussion: This study highlights for the first time a possible common substrate for some motor and non-motor symptoms of PD. Interestingly, the head of the caudate nucleus is known to be implicated in the integration of cognitive (especially memory retrieval) and motor functions.

Conclusions: The caudate nucleus is a core structure in the pathophysiology of PD. The common substrate in the caudate nucleus between cognitive and motor features of PD opens interesting perspective for the definition of simple biomarkers of prognostic value to be used in clinical settings.

## MOOD RELATED EFFECTS OF DEEP BRAIN STIMULATION IN ADVANCED PARKINSON'S DISEASE: A RESTING-STATE FMRI INVESTIGATION

C. Campisi[1], C. Artusi[1], F. D'Agata[1], G. Giulietti[2], G. Morana[1], M. Rizzone[1], M. Zibetti[1], A. Romagnolo[1], C. Ledda[1], G. Imbalzano[1], M. Coriasco[1], M. Tatu[1], M. Laudadio[1], L. Lopiano[1], M. Bozzali[1]

[1]Department of Neuroscience "Rita Levi Montalcini", University of Turin (Torino); [2]Neuroimaging Laboratory, IRCCS Santa Lucia Foundation (Roma)

Introduction: Subthalamic deep-brain-stimulation (STN-DBS) is a widely used intervention for the treatment of advanced Parkinson disease (PD). The most important outcome of STN-DBS is improving motor symptoms and fluctuations while reducing the dose and side effects of dopaminergic therapy. Despite its great efficacy on motor symptoms, little is known on STN-DBS modulation of cognitive and neuropsychiatric symptoms. We recently identified correlations between the anatomical distribution of the volume of tissue activated (VTA) by STN-DBS and patient changes in non-motor symptoms. One of the most robust findings was an improvement of mood-depression through stimulation of an area located dorso-postero-laterally to the left STN, which we named "mood-depression-cluster" (MDC). Interestingly, MDC is anatomically crossed by the Superolateral-Medial Forebrain Bundle, which connects the midbrain to areas implicated in mood control.

Aim: To test, using resting-state functional MRI (rs-fMRI) in an independent group of PD candidates for STN-DBS, the different patterns of connectivity between the canonical VTA location and MDC.

Methods: Forty-seven patients with advanced PD eligible for STN-DBS underwent MR scanning at 3T, including rs-fMRI acquisition. rs-fMRI data were preprocessed using Conn (1) to obtain functional connectivity maps. In each subject, canonical left VTA (centered on x=-12; y=-13; z=-7) and MDC (centered on x=-15; y=-13; z=-2) were used as seed-regions to compare their patterns of connectivity with the rest of the brain. Areas of functional connectivity with seed-region were accepted as significant for P-values<0.05 (cluster-level corrected).

Results: Connectivity differences between the two seed-regions (i.e., canonical VTA and MDC) included the left nucleus accumbens septi, the left head of the putamen, the left inferior insular cortex and thalamus. These areas were significantly connected to MDC but not to canonical VTA.

Discussion: STN is regarded as the best target region for DBS in advanced PD, which induces a remarkable improvement of motor symptoms. During patients' selection for STN-DBS, severe psychiatric symptoms are considered as a contraindication. We identified a subregion nearby the left STN, whose chronic stimulation improves mood-depression. This finding is now supported by connectivity-based evidence that links MDC with a broader network related to mood control.

Conclusion: Further research on the pathophysiology of non-motor symptoms in PD and their response to neuromodulation may help improve the patient outcome of DBS. Indications for PD patient selection to DBS and stimulation programing should consider non-motor symptoms as a potential additional therapeutic target to improve patients' quality of life, in the framework of precision medicine.

## A GRN MUTATION PRESENTING AS AN ESSENTIAL TREMOR LIKE SYNDROME AND EVOLVING INTO PARKINSONISM

R. Cancilla, A. Negrotti, B. Pancaldi, M. Spallazzi, S. Romano

Department of Medicine and Surgery, University Hospital of Parma (Parma)

Background and Objectives: The GRN gene codes for progranulin (PGRN), a growth factor implicated in regulation of inflammation. Homozygous mutations in this gene are associated with neuronal ceroid lipofuscinosis 11 (CLN11), while heterozygous GRN mutations are a major cause of frontotemporal dementia (FTD). Mutations can also occur with other phenotypes such as Alzheimer's disease and atypical parkinsonian disorders (APD). Here, we present an interesting patient with an essential tremor-like syndrome evolved into the parkinsonism phenotype carrying a heterozygous GRN mutation (c.328C>T; p. Arg110).

Materials and Methods: A 70-year-old woman was referred to outpatient Department of Movement Disorders with a ten-year history of essential tremor like syndrome (postural tremor involving vocal cords, head, and hands). Her past medical history included insulin-dependent diabetes mellitus, obesity (BMI 30.44 kg/m²), hypertension, dyslipidemia, myocardial infarction. Maternal family history was positive for tremor (grandfather and uncle). She had Dopamine Transporter imaging (DAT-SCAN) and brain MRI, both negative, at presentation. She was prescribed propranolol, with benefit. In the following years, hyposmia, bilateral upper limbs rest tremor, mild right limbs bradykinesia, and right arm swing reduction appeared. A new scintigraphy was performed, with evidence of impairment of the left nigrostriatal dopaminergic pathway, for which dopaminergic therapy with ropinirole was started, with initial benefit. Given the subsequent accentuation of bilateral bradykinesia it was decided to add levodopa/carbidopa to ropinirole, with benefit. The patient was involved in the Rostock International Parkinson's Disease (ROPAD) study, which aims to better understand the overall contribution of genetics to Parkinson disease.

Results: A heterozygous mutation in GRN, c.328C>T p., (Arg110"), has been identified and classified as pathogenic (class 1) according to the indications of ACMG. Twelve years after onset, the patient had developed urinary incontinence, difficulty finding words and increased latency in responses. She underwent a comprehensive neuropsychological evaluation, showing mild single-domain non amnesic cognitive decline (sustained attention deficit, but visuo-spatial, and language domains were preserved; no psychiatric symptoms were present). Discussion: GRN mutations can occur with parkinsonism, usually after the development of the FTD phenotype and rarely as the predominant clinical manifestation. It is characterized by the rigid akinetic syndrome, insensitive to levodopa. Tremor is uncommon and may be postural, action, or occasionally at rest.

Conclusion: To our knowledge, this case study may represent the first case of an FTD-associated mutation presenting with parkinsonism preceded by essential tremor like syndrome, thus expanding the clinical spectrum of GRN-related disorders.

## ATYPICAL STIFF PERSON SYNDROME WITH ANTI-IGLON5 ANTIBODIES: A CASE REPORT

C. Castellano[1], M. Bellucci[2], F. Germano[2], C. Gemelli[1], L. Marinelli[3], A. Lechiara[4], A. Schenone[2], D. Franciotta[5], L. Benedetti[1]

[1]Department of Neurology, Hospital S. Martino (Genova); [2]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa (Genova); [3]Department of Neurophysiology, Hospital S. Martino (Genova); [4]Biology Laboratory, Hospital S. Martino (Genova); [5]Neuroimmunology Laboratory, Mondino Foundation (Pavia)

Stiff Person Syndrome (SPS) and IgLON5 disease are two apparently unrelated rare neuroimmunological disorders. The mean features of SPS are rigidity and painful spasms while the mean features of IgLON5 disease are parasomnias, bulbar symptoms, cognitive impairment, respiratory failure and IgLON5 antibodies. Herein we report a case of neuromuscular hyperexcitability overlapping with Stiff Person Syndrome associated with anti-IgLON5 antibodies positivity. An 82-year-old man presented with a 2-year history of widespread muscular fasciculations, cramps, and limb stiffness which resulted in sudden spontaneous movements in the right lower limb, unsteady gait and multiple falls. Electrodiagnostic studies (EDX), laboratory tests with an antibody panel, diagnostic imaging and lumbar puncture were performed. EDX disclosed signs of neuromuscular hyperexcitability. CSF analysis showed high concentration of tau protein and unique-to-CSF oligoclonal IgG bands. Anti-IgLON5 antibodies were positive on both serum and CSF. Brain MRI, brain PET and body CT/PET were uninformative. Lastly the patient underwent videopolysomnography (VPSG), which resulted normal. No anti-IgLON5 disease-specific "core features", previously appointed, were detected. Treatment with IV corticosteroids, followed by oral benzodiazepines prompted functional recovery, which persisted at a four-months follow-up. This case demonstrates a unique overlap between neuromuscular hyperexcitability and Stiff Person Syndrome with a so far never reported seropositivity for anti-IgLON5 antibodies. Future evaluations are necessary to confirm whether such findings could lead to a broadening of the SPS clinical and laboratory features.

## BOTULINUM TOXIN ADMINISTRATION IN PARKINSONIAN PATIENTS WITH LATERAL TRUNK FLEXION SUGGESTING EARLY PISA SYNDROME

V. Cenacchi, T. Lombardo, G. Bellavita, M. Catalan, V. Tommasini, M. Liccari, G. Mazzon, L. Antonutti, P. Manganotti

Clinical Unit of Neurology, Department of Medicine, Surgery and Health Sciences, University Hospital of Trieste ASUGI, University of Trieste (Trieste)

Aim: Pisa Syndrome (PS) is a postural disorder, occurring in about 9% of patients with Parkinson's disease (PD), defined as a lateral trunk flexion of at least 15 degrees that can be completely alleviated by passive mobilization or supine positioning [1]. We aimed at evaluating the clinical and electromyographical response to botulinum toxin (BoNT) injection in PD patients with lateral trunk flexion suggesting a probable evolution towards clinically defined PS.

Materials and Methods: 17 PD patients with trunk lateral flexion were recruited from our Movement Disorders Clinic between 2021 and

2023. A 50 UI/ml BoNT solution was injected in various points (100 UI total) of the paraspinal muscles ipsilaterally to the trunk bending side. We assessed our patients at baseline, 1 month (1m) and 3 months (3m) after BoNT injection. Lateral flexion angle was measured by software calculator Kinovea, Perpendicular Method, on planar view photographs. Clinical scales used were: Unified Parkinson Disease Rating Scale (UPDRS), Parkinson Disease Questionnaire-8 (PDQ-8), Numeric Pain Rating Scale (NPRS), Patients' Global Impression of Change scale (PGIC). An eight-channel surface electromyograph (EMG) recorded activity of paraspinal cervical (C6-C7), thoracic (T8-T10), lumbar (L2-L4) and oblique abdominal muscles bilaterally, while video recording the patient standing with and without active flexion of the trunk, sitting and laying. Data were compared using Student's t test for dependent means.

Results: Patients showed a mean lateral bending of 6.9±3.2, 5±2.4, 6.3±5.3 degrees at baseline, 1m and 3m respectively (baseline-1m p .0019, baseline-3m p .5905), PDQ-8 scores of 3.8±2.9, 3.9±3.2, 3.9±3.6 (baseline-1m p .7175, baseline-3m p .7610), back NPRS of 3.8±3.1, 2.6±2.5, 2.5±3.4 (baseline-1m p .0129, baseline-3m p .1653). 82 and 94% of the sample reported a global improvement (PGIC scores ≥3) at 1m and 3m, respectively. Qualitative EMG signal analysis showed almost uniform improvement in global paraspinal muscle activation.

Discussion: Our population differs from previous studies as we considered patients with a pre-clinic condition of PS (lateral trunk deviation lower than 15°). BoNT is known to have a beneficial effect on PS but is still not clear whether to follow the clinic (bending side, pain) or the EMG-confirmed activation [2,3]; we obtained a significant spine angle reduction when targeting the bending side, rather than the most activated side.

Conclusions: BoNT injection ipsilateral to the trunk bending side, regardless of EMG activity, resulted in our study in a reduction of the lateral flexion at 1m, partially reverted at 3m, complemented by a subjective clinical improvement.

## DYSBIOSIS OF GUT MICROBIOTA IN PARKINSON'S DISEASE AS A POTENTIAL BIOMARKER OF DISEASE SEVERITY AND PROGRESSION

R. Cerroni[1], D. Pietrucci[2], M. Conti[1], M. Pierantozzi[1], N. Mercuri[3], G. Chillemi[2], A. Stefani[1]

[1]Parkinson Centre, Department of System Medicine, University of Rome "Tor Vergata" (Roma); [2]Department for Innovation in Biological, Agro-Food and Forest Systems (DIBAF), University of Tuscia (Viterbo); [3]Department of Systems Medicine, University of Rome "Tor Vergata" (Roma)

Objective: In recent years several studies revealed dysbiosis of gut microbiota as a well-established hallmark in Parkinson's disease (PD) [1]. However, it is still unclear whether microbiota alterations, in PD, represent a pathogenetic starting point or also a consequence of disease [2]. Therefore, our aim was to investigate microbiota alterations in PD as a potential biomarker of disease severity and progression.

Materials: Microbiota compositions was studied through 16rRNA amplicon sequencing and classified to taxonomic rank through bioinformatic analysis. Stool samples were collected through pre-analytical sample processing collection tubes, to ensure storage/conservation of DNA for at least three months.

Methods: To study microbiota as a severity biomarker, we compared faecal samples collected from three groups, representative of three different times in the natural history of the disease: healthy controls (HC), PD patients at the time of diagnosis (de-novo PD), PD patients in advanced stages, defined by H&Y stage≥3 and/or LEED>900mg (advPD). A multivaristatistical analysis was performed to identify differential abundant taxa between three groups considering the effect of potential confounding factors, like lifestyle and eating habits. To study microbiota as a prognostic biomarker, we followed longitudinally 2 groups of de-novo PD: a group with dysbiosis and a group without microbiota alterations at the time of diagnosis. The two groups underwent motor, non-motor and cognitive assessment at baseline and follow-up of 2 years.

Results: For the first study we enrolled 79 HC, 30 de-novo PD and 38 advPD. We found a progressive reduction both in alfa and in beta-diversity and a progressive reduction in Lachnospiraceae, Bacteroidaceae, Prevotellaceae and Clostridiaceae families moving from HC to de-novo PD and finally to advPD, and a reverse trend in Enterobacteriaceae and Lactobacillaceae families. For the second research line we enrolled 13 dysbiotic and 11 eubiotic de-novo PD. At two years follow up, dysbiotics showed a more severe worsening of motor impairment, non-motor symptoms and in some cognitive domains compared to eubiotics. Moreover, dysbiotic patients needed more LEED respect to patients without dysbiosis.

Discussion: We showed how, moving from the early to the advanced stages of PD, gut microbiota become gradually destructured, assuming a pathologic and pro-inflammatory arrangement. Moreover, we demonstrated that the presence of dysbiosis at the diagnosis probably underlie a more severe phenotype of the disease.

Conclusion: Dysbiosis of gut microbiota represents a key to extend our knowledge on the pathogenesis of PD and it deserves the utmost attention for its potential therapeutic implications.

## PREDICTORS OF LEVODOPA-INDUCED DYSKINESIA IN PARKINSON'S DISEASE

A. T. Cimmino[1], G. Di Lazzaro[2], D. Di Giuda[3], A. Picca[4], P. Calabresi[1]

[1]Neurology Unit, Department of Neurosciences, Policlinico Universitario Fondazione Agostino Gemelli IRCCS, Catholic University of the Sacred Heart (Roma); [2]Neurology Unit, Policlinico Universitario Fondazione Agostino Gemelli IRCCS (Roma); [3]Nuclear Medicine Unit, Department of Radiological Sciences and Hematology, Section of Nuclear Medicine, Policlinico Universitario Fondazione Agostino Gemelli IRCCS, Catholic University of the Sacred Heart (Roma); [4]Medical Center of Ageing (CEMI), Policlinico Universitario Fondazione Agostino Gemelli IRCCS (Roma)

Background and Objectives: Levodopa-induced dyskinesia (LIDs) is a potential motor complication of chronic dopaminergic treatment in

patients with Parkinson's disease (PD), consisting of choreoathetoid involuntary movements associated with motor fluctuations, with a negative impact on the quality of life. The aim of this study was to determine the clinical and biological predictors of LIDs development in PD.

Materials: We retrospectively and prospectively collected data from PD patients followed up at the Movement Disorders outpatient Service, at Gemelli Hospital, Rome, Italy, between 2021 and 2023, with a diagnosis of "clinically defined PD" [1] and age between 18 and 80 years old.

Methods: All patients underwent a clinical evaluation in the best ON-medication state. Motor impairment and presence of LIDs were assessed with MDS-UPDRS parts III-IV, respectively. A minimal set of clinical and demographical data was collected (age, sex, age at disease onset, disease duration, ongoing dopaminergic therapy). A subgroup of patients underwent 123I-FP-CIT-SPECT brain imaging at diagnosis. All patients underwent venous blood sample collection and, a subgroup, lumbar puncture to collect cerebrospinal fluid (CSF). Total-alpha-synuclein (t-a-syn) levels were measured in both serum and CSF, with commercially available ELISA kits. Differences in clinical and demographical data between dyskinetic and non-dyskinetic patients were assessed with parametric and non-parametric tests as needed. Logistic regression models were employed to assess relationships between categorical and continuous variables.

Results and Discussion: A total of 104 patients were enrolled, of whom 54 underwent lumbar puncture. 123I-FP-CIT-SPECT uptake values were available for 50 patients. Longer disease duration, higher levodopa equivalent daily dose (LEDD) intake and worse MDS-UPDRS part III scores were independently associated with LIDs development, as expected [2]. With regard to biological data, no differences were found in t-a-syn levels in patients with and without LIDs, in both serum and CSF. Interestingly, the degree of putaminal dopaminergic denervation at diagnosis, measured with semiquantitative analysis of 123I-FP-CIT-SPECT uptake values, was independently associated with the development of LIDs. This association was significant also when correcting with age at disease onset, disease duration and LEDD.

Conclusion: PD patients with longer disease duration, higher LEDD intake, worse motor impairment and lower putaminal 123I-FP-CIT-SPECT uptake values are more susceptible to develop LIDs during the natural history of the disease. Conversely, t-a-syn levels did not show any relationship with the presence of LIDs. Putaminal dopaminergic denervation at diagnosis seems to represent the strongest predictor for LIDs development, independently from other modifiable and non-modifiable risk factors.

## DEEP BRAIN STIMULATION OF GLOBUS PALLIDUS INTERNUS AND SUBTHALAMIC NUCLEUS IN PARKINSON'S DISEASE: A MULTICENTER, RETROSPECTIVE STUDY OF EFFICACY AND SAFETY

D. Ciprietti[1], M. Mainardi[1], M. Pilleri[2], G. Bonato[1], L. Weis[1], V. Cianci[1], R. Biundo[1], F. Ferreri[3], M. Piacentino[4], A. Landi[5], A. Antonini[1], A. Guerra[1]

[1]Parkinson and Movement Disorders Unit, Study Center for Neurodegeneration (CESNE), Department of Neuroscience, University of Padua (Padova); [2]Service of Neurology, Villa Margherita-Santo Stefano Private Hospital (Arcugnano-VI); [3]Unit of Neurology, Unit of Clinical Neurophysiology, Department of Neuroscience, University of Padua (Padova); [4]Department of Neurosurgery, AULSS 8 Berica Ospedale San Bortolo (Vicenza); [5]Academic Neurosurgery, Department of Neurosciences, University of Padua (Padova)

Objectives: Deep Brain Stimulation (DBS) is an established therapeutic option in advanced Parkinson's Disease (PD). Literature data and recent guidelines remain inconclusive about the best choice as a target between the Subthalamic Nucleus (STN) and the Globus Pallidus internus (GPi) [1]. We aim to provide additional evidence by retrospectively evaluating outcomes in a group of patients recruited from two specialized movement disorders centers.

Materials: We retrospectively reviewed the clinical efficacy and safety outcomes of 48 DBS-implanted patients (33 STN-DBS and 15 GPi-DBS) at a short-term follow-up (<1 year from the surgery) and, for a subset of patients, long-term (2-5 years) follow-up.

Methods: To evaluate clinical efficacy, we collected MDS-UPDRS I, II, III ON-medication, III OFF-medication, IV, Levodopa Equivalent Daily Dose, Hoehn&Yahr Scores at all time-points. For clinical safety, we considered post-operative surgical complications (infections, brain lesions, ischemic strokes or hemorrhages) or the onset of severe side effects due to stimulation (suicides or other psychiatric disorders).

Results: We found no difference between STN-DBS and GPi-DBS in improving motor symptoms at short-term evaluation. However, STN-DBS achieved a more prominent reduction in oral therapy (L-DOPA Equivalent Daily Dose, p=.02). By contrast, GPi-DBS was superior in ameliorating motor fluctuations and dyskinesia (MDS-UPDRS IV, p<.001) as well as motor experiences of daily living (MDS-UPDRS II, p=.03). The greater efficacy of GPi-DBS on motor fluctuations and experiences of daily living was also present at the long-term follow-up. We observed five serious adverse events, including two suicides, all among STN-DBS patients.

Discussion: Both STN-DBS and GPi-DBS are effective in improving motor symptoms severity and complications, but GPi-DBS has a greater impact on motor fluctuations and dyskinesias [2], as well as on motor experiences of daily living.

Conclusion: These results suggest that the two targets should be considered equivalent in motor efficacy, with GPi-DBS as a valuable option in patients with prominent motor complications. The occurrence of suicides in STN-treated patients claims further attention in target selection.

## THE ROLE OF T LYMPHOCYTES SUBTYPES AS POSSIBLE POOR OUTCOME PREDICTORS IN PARKINSON'S DISEASE

F. Colombatto[1], F. Vignaroli[1], S. Gallo[1], E. Contaldi[2], R. Cantello[1], C. Comi[1], L. Magistrelli[1]

[1]Department of Neurology, University Hospital "Maggiore della Carità" (Novara); [2]Parkinson and Parkinsonism Center, ASST G. Pini, CTO (Milano)

Objectives: The aim of the present study is to evaluate, in a cohort of Parkinson's Disease (PD) naïve patients, whether peripheral

immunological parameters may correlate with long-term disease outcome.

Materials e Methods: 8 naïve idiopathic PD patients were included in the study. They were evaluated with UPDRS part III scale and a semantic fluency test, (particularly the animal fluency test). Based upon the prognostic model proposed and validated by Velseboer et al [1], we calculated the probability of an unfavorable outcome, intended as the development of dementia or postural instability (Hoehn and Yahr $\geq 3$) at 5 years from disease onset. Furthermore, we correlated this probability with lymphocyte count, cytofluorimetric T cell subsets and, through polymerase chain reaction (PCR), the expression of transcription factors involved in lymphopoiesis (such as STAT1, STAT3, STAT4, STAT6, RORC, TBX21, GATA3, NR4A2 and FOXP3). Statistical analyses were conducted using Pearson correlation coefficient (r) and t-student test.

Results: A positive correlation was found between a poor outcome and CD4+ T cells absolute count ($r = 0.62$, $p < 0.05$), while no correlation was found with CD3+ nor with CD8+. Subsequently, we evaluated CD4+ T cell subsets: T helper (Th)1 were positively correlated with a poorer outcome ($r = 0.60$, $p < 0.05$), while a negative correlation was found between Th2 and an unfavorable outcome ($r = -0.41$, $p < 0.05$). No correlation was found with Treg nor Th17, even if RORC expression had a significant correlation with the poor outcome ($r = 0.67$, $p < 0.05$). No additional correlation was found with the transcription factors analyzed.

Conclusion: Peripheral immune system plays a key role in the pathophysiology of PD both centrally and in the periphery. Particularly, patients display a pro-inflammatory phenotype characterized by increased Th1 and Th17 cells, a decrease of Th2 and dysregulation of Treg compartment. Whether it may be considered a predictor of clinical outcome has not yet been investigated. Even considering the small sample size, in the present study we identified a possible correlation between Th1 cells and poor outcome, suggesting that a greater pro-inflammatory state from the beginning may influence disease course.

## DUAL-TASK GAIT INSTABILITY AS CORE FEATURE OF PARKINSON'S DISEASE WITH MOTOR FLUCTUATIONS

L. Colombo[1], A. Pilotto[1], C. Zatti[1], A. Rizzardi[1], C. Hansen[2], M. Catania[1], R. Romijnders[2], M. Rizzetti[3], W. Maetzler[2], A. Padovani[1]

[1]Department of Clinical and Experimental Sciences, Neurology Unit, University of Brescia (Brescia); [2]Department of Neurology, Christian-Albrechts-University of Kiel (Kiel-D); [3]Parkinson's disease Rehabilitation Center, FERB European Fundation Biomedical Research, Trescore Balneario Hospital (Trescore Balneario-BG)

Introduction: State specific objective of study: Gait alterations and instability are common during the course of Parkinson disease (PD) and can threaten patents to fall and impact quality of life. Progression of gait alterations, their response to treatment and their differences between stages of the disease is still theme to debate. Motor fluctuations are a common complication of levo-dopa therapy and are characterized by clinical motor changes during the day splitted in ON and OFF phases. Aim of the study is to analyze the differences in gait patterns between PD patients with (PD-F) and without motor fluctuations (PD-N) in PD patients.

Methods: The prospective study included consecutive PD patients with and without motor fluctuations who underwent an extensive motor assessment in supervised conditions using mobile health technology (MHT). All patients with motor fluctuations were evaluated in ON condition and patients with motor dyskinesia were excluded from the analyses. The MHT assessment include gait at normal fast and motor/cognitive dual-task conditions. Differences in step time, gait phases duration, asymmetry and variability were evaluated in PD with and without motor fluctuations adjusting for the effect of age, sex and disease severity.

Results: One-hundred four PD patients entered the study, including 62 PD-N and 42 PD-F evaluated in ON conditions (mean age of 67.56 SD=8.25, mean MDS-UPDRS III of 20.67 SD=12.48, mean disease duration 8.7 years SD=12.48). In analyses adjusted for motor severity, PD-F exhibited increased double limb support and stance time and decreased swing time compared to PD-N. The differences increased from normal and fast walking conditions to dual-task walking. Asymmetry index, and gait variability was similar between PD-F and PD-N, whereas step length was decreased in PD-F in fast conditions.

Conclusion: This multicenter study using MHT showed that PD patients with motor fluctuations have a higher instability compared to PD without motor fluctuations, even when evaluated in ON conditions. The findings are highly relevant, as they might indicate a suboptimal treatment response in ON phases and underline a higher risk of falls in this specific populations. Further larger on-going analyses combining supervised and home-based unsupervised MHT assessment are important to evaluate the fluctuations of gait disturbances during the day and their impact on risk of falls and quality of life.

## VOICE CHANGES ANALYSIS IN PARKINSON'S DISEASE: PRELIMINARY RESULTS OF A MULTICENTRIC STUDY

D. Comolli[1], A. Suppa[2], G. Costantini[3], A. Saggio[3], A. Pisani[4], A. Calculli[4], C. Fazio[4], A. Barilli[1]

Introduction: Phonation is a complex activity that is altered in Parkinson's Disease (PD), causing hypokinetic dysarthria. An algorithm can analyze more than 6300 parameters in a vocal track, which can help identify different conditions not only involving the phonatory organs but also neurodegenerative diseases like PD. In this study, we aimed at investigating voice alterations in PD patients, using machine-learning techniques to extrapolate potential useful biomarkers that might help clinicians in the diagnosis of PD and disease progression.

Methods: In the preliminary phase of this multicentric clinical study, we enrolled subjects into two groups, one consisting of healthy controls (HC) and the other selecting patients diagnosed with PD according to the UK Parkinson's Disease Brain Bank diagnostic criteria. Subjects with cognitive impairment or respiratory, gastro-esophageal, auditory system, or vocal fold diseases were excluded. We collected their medical history and pharmacological conditions. UPDRS-III and H&Y scales were performed to define the disease stage. Additionally, clinical scales, including NMSS, MMSE, Hamilton depression scale and VHI were used. We recorded the patients' voices using a specific portable recording device in a quiet and comfortable

setting. The vocal track files were then uploaded to an online platform and analyzed offline.

Results: From the preliminary analysis of our center, results show that machine learning approaches can identify PD patients with high accuracy compared to HCs. Those findings confirm what was established in previous studies of the voice changes in PD, and the final phase of our research aims at strengthening those results, enrolling a wider sample, consisting in more than 150 patients. In addition, we demonstrate that voice changes in PD subjects can discriminate between early stage and mid-advanced stage patients, confirming the potential role of voice analysis as a biomarker in the recognition and stratification of the disease stage. Our preliminary findings are based on a sample from a single center in the context of a multi-center study. We also plan to perform an 18-month follow-up on a subset of patients to observe voice changes over time.

Conclusion: Preliminary data from this study are consistent with the literature and demonstrate that voice analysis allows discriminating PD subjects from HC with high accuracy. The sample dimension will be implemented, encompassing voice changes over time to better determine how to apply machine-learning analysis in clinical practice.
