Research goals. The aim of our research is to conceptualize and empirically investigate collective moral disengagement (CoMD). Our concept of CoMD is important because organizational transgressions cannot be reduced to merely individual unethical decisions, propensities, and motives (Islam, 2020). We therefore need to better understand the role of perceptions of organizational justificatory mechanisms whereby malpractices are collectively justified rendering these collective malfeasants as permissible or even desirable activities (Ashforth & Anand, 2003).

Theoretical background. Individual's propensity to morally disengage is regarded as a key driver of misbehavior (Newman et al., 2020; Ogunfowora et al., 2021). It has been studied as the personal disengagement of moral standards allowing an individual to undertake "bad" actions that damage the organization and its stakeholders (Bandura, 2002, 2016; Fida et al., 2015; Moore et al., 2012; Rice & Searle, 2022). However, as Bandura emphasized, moral disengagement is not only personal but also "operates throughout a social system in ways designed to exonerate the system as a whole" (Bandura, 2016, p. 15).

Yet, research on CoMD is rare and the concept remains underdeveloped, having mainly been studied as the perceived diffusion of personal moral disengagement within a class/school (Gini et al., 2014, 2015; Thornberg et al., 2019). Instead, we posit that CoMD is more than the perception of how widespread personal moral disengagement is within a social group, rather we contend it is the perception of how "we" as a group collectively suspend morality and justify unethical activities to benefit the organization, while also violating moral and societal standards.

We develop a measure of CoMD and examine with three empirical studies its distinctiveness from personal moral disengagement and its role in predicting unethical pro-organizational behaviors (UPB). CoMD is expected to be unidimensional (H1) and distinct from personal moral disengagement (H2). We also anticipated that while personal moral disengagement should mainly predict counterproductive work behavior (CWB), CoMD should mainly predict UPB (H3).

Methods. To validate the CoMD scale, a rigorous multi-step and multi-sample approach was followed using three distinct studies. Study 1 and 2 followed a two-wave design and were conducted in the UK. Given the importance of replication in science (Köhler & Cortina, 2019), Study 3 was conducted in Italy to determine CoMD generalizability. Study 1 sample at T1 included 301 employees (55.6% women). T2 data were collected 10 months later (199 employees, 51.8% women). Study 2 sample at T1 included 297 employees (38.7% women). T2 data were collected after five months (154 employees, 38.3% women). Study 3 included 297 employees (39.1% women).

Results. Findings supported both H1 and H2. The models including both CoMD and personal MD confirmed the distinctiveness of the two constructs (Study 1: SBΔχ 2 (1)=19.2, $p < .001$; Study 2: SBΔχ 2 (1)=36.56, $p < .001$; Study 3: SBΔχ 2 (1)=71.93, $p <.001$). H3 was also supported. In Study 1 results

showed that while CoMD was significantly associated with UPB, personal MD was significantly associated with CWB. Also, when considering UPB at T1 (in Study 2), results showed that only CoMD predicted UPB at T2 above and beyond MD and UPB at T1. Finally, the analysis of the invariance supported the generalizability of the CoMD scale across time (Study 2) and across country (Study 3).

Limitations. The first limitation of this research is that all outcomes are measured via self-reports. Also all the studies were conducted in the general working population and not in specific organizations, limiting our understanding of CoMD as a multilevel dimension.

Conclusions and Implications. As in the case of personal moral disengagement (Bandura et al., 1996; Fida et al., 2015; Moore et al., 2012), results supported the hypotheses that CoMD is unidimensional, with all the items loading onto one latent dimension (H1). Results also supported that CoMD, although correlated, is different from personal moral disengagement (H2) and that better predicts UPB (H3). Members act in accordance with, and reproduce, what they perceive to be socially established actions within their employing organization including the justification of unethical activities. Through CoMD mechanisms, organizations can foster and institutionalize ways of suspending moral control among its employees, which, when perceived as such, enable them to act conjointly in the service of organization by undertaking wrongdoing and unethical activities.

Relevance to the Congress Theme: In light of the widespread of counterproductive and deviant behavior at work we need to understand the factors facilitating the spread of them and ways to prevent them. The future is now!

Relevant UN SDGs: Good health and wellbeing; Decent work and economic growth; Peace, justice, and strong institutions

Keywords: moral disengagement, counterproductive work behavior, unethical pro-organizational behavior

Paper 2

The paradox of organizational distrust: An exploratory study of change, counterproductive work behaviour and its prevention

Rosalind Searle, Adam Smith Business School, Glasgow University; Charis Rice, Coventry University

Research goals. We explore three counterproductive work behaviour (CWB) cases examining the organizational context of "bad behaviours" and distrusting organization paradox, charting the unintended consequences following organizationally-initiated change. Drawing on socio-cognitive theory, and conservation of resources we consider the individual, behavioural and environmental (social and organizational contexts) dimensions, using our findings to improve CWB detection and prevention.

Theoretical background. Trust is the desired state between employers and their employees supported by the 'psychological contract' (Robinson, 1996). Where expectations are no longer met, trust can decline. Breaches reduce trust, leading to cynicism that extends to future employers (Pugh et al., 2003). Violations have important organizational implications reducing individuals' performance (Orvis et al., 2008), increasing CWBs (Bordia et al., 2008), and creating progressive decline (Deng et al., 2018). However, the 'distrusting organization' has not been considered.

Distrust has been regarded as accidental or unintentional (Bijlsma-Frankema et al., 2015), yet it can be a deliberate organizational strategy (Pendergrast, 2013). Workplaces institutionalize distrust signaling it in different ways to protect and control (Siebert & Czarniawska, 2020). But it requires a delicate balance between staff hyper-vigilance or disengagement and effective protective security. Navigating these distrust signals add to employees' cognitive labour, removing assumptions that things are as they appear (Schul et al., 2008). Additional labour depletes self-regulatory resources (Muraven et al., 1998), with implications for performance (Zyphur et al., 2007). Deliberately creating vigilance increases scrutiny of other's negative intentions, motives and activities (Kramer, 1999). A distrusting disposition can be advantageous in high-risk contexts (McKnight et al., 2004), where a little paranoia is prudent (Kramer, 2002). However, overtime increased suspicion can create collective debilitating paranoia (Kramer, 1994); what happens where scrutiny focuses on the organization not staff?

Change can trigger re-examination of employment relationships, with employees' treatment important in determining whether distrust replaces trust (Searle & Ball, 2004). How change is managed determines if trust can be preserved, with leaders' strategic choices and their enactment critical (Gustafsson et al., 2021). What happens in a distrusting organization? What strategies are required to avoid tipping into CWBs?

Methods. Using qualitative thematic analyses of employee and manager interviews (n=16) concerning three CWB cases in the same organization, we explore psychological (cognitive), social and organizational facets of CWBs and their roles in threats (Fida et al., 2015; Nurse et al., 2014; Rice & Searle, 2022). We map and explore the organizational and social processes and their temporal, spatial dynamics regarding individual and social aspects of CWBs (Bandura, 2016).

Results. First, we outline the distrusting organisation's clues and signals, specifically input vetting controls to reduce internal CWBs, discussing the predominant use of fear-based to externally regulate actions.

Second, we identify Human Resource Management policy changes (recruitment and selection; progression; recognition and reward (pension); organizational behaviours; and redundancy and exit) and their social exchange (Blau, 1964) and psychological contract (Deng et al., 2018) impacts. We explore sense-making and self-regulation, goal achievement and resource provisions concerns. Through mapping we explore CWB as a rational retaliation (Bordia et al., 2008), or regulatory capacity impairment (Deng et al., 2018; Thau & Mitchell, 2010). Additionally, we identify the significance of top leaders and their integrity (Kannan-Narasimhan & Lawrence, 2012) as a key tipping point. We show different outcomes for trusted and distrusted supervisors, and the impact of peer dynamics.

Using these findings, we propose prevention options. We outline the damage of breaking promises (Kiefer et al., 2022), and advocate for better review and anticipation of consequences for employee resources (Hobfoll, 1989), and accompanying strategic communication (Rice & Searle, 2022). We contend merit in segmenting employees recognizing differentiated impacts to identify those needing social and leader support. We challenge undertaking large-scale multi-psychological contact violation change in distrusting organisations given the potential to trigger deliberate retaliation (Bordia et al., 2008) and more insidious self-regulation decline (Deng et al., 2018).

Limitations. This study investigates changes in one organization with subsequent research required to test generalisability.

Conclusions – research and practical implications. The study has several practical implications. Including exploration of the paradox of distrusting organisations, and their 'balancing acts'. We show the value of inputs and process attention, delineating individual and social processes. We reveal decline trajectories noting their individual, social and leadership dimensions to help ameliorate and prevent CWBs.

Relevance to the Congress Theme. Given the emergence of pervasive CWBs in organisations, this study identifies important triggers and pathways.

Originality/Value: The paper demonstrates the interconnectedness of events and cognitive, social and behavioural dimensions. It advances conservations of resources theory and socio-cognitive theory within a 'distrusting organisation' context.

Paper 3

How and When Vicarious Interpersonal Deviance Influence Defensive Strategies

Muhammad Abdur Rahman Malik, Suleman Dawood School of Business, Lahore University of Management Sciences; Mamoona Arshad, Norwich Business School, University of East Anglia

Research goals. Interpersonal Deviance (ID) is defined as voluntary behaviors with the intent to harm a fellow employee (Robinson & Bennett, 1995). These behaviors threaten the well-being of organizational members. When an employee is not the direct target of ID, but witnesses or hears about such incidents from peers, the experience is termed as Vicarious Interpersonal Deviance. The aim of this research is to study the effects of such experiences on employees' behaviors. Using conversation of resources perspective, we highlight the defensive and aggressive-defensive strategies that employees use to minimize the negative effects of such experiences (Hobfoll et al., 2018). We also show that experiencing vicarious ID results in an increase in self-serving behaviors.

Theoretical background. Observing or hearing about ID is an uncomfortable event, which causes stress (Nesse et al., 2007) and hinders well-being (Gunia & Kim, 2016; Michalak et al., 2019; Wellen & Neale, 2006). Conservation of resources perspective terms such experiences as 'resource threatening', which motivates employees to build new resources (aggressive-defensive strategy) and / or to conserve their remaining resources (defensive strategy). While studying these strategies, most of previous research has studied behaviors targeted at others (such as helping or harming behaviors) which enable employees to protect existing and build new resources (Halbesleben & Bowler, 2007; Halbesleben & Wheeler, 2011, 2015). In the present study, we focus on self-directed behaviors that employees might use to deal with vicarious ID. We also identify an underlying mechanism that connects vicarious ID and self-directed behaviors. We suggest that employees who experience resource threatening events (i.e., vicarious ID) use communion striving as an aggressive-defensive strategy to build new resources. Communion striving is a motivational state marked with social connectivity, relationships building, and acceptance from peers (Barrick et al., 2002; Stewart & Barrick, 2004). Further, we argue that employees who experience VID are prone to exhibit self-serving behaviors as a defensive strategy to conserve their resources (Dubois et al., 2015). Finally, we propose that the effects of vicarious ID on self-serving behaviors are channeled through communion striving.

After outlining the direct and indirect effects of vicarious ID (on communion striving and self-serving behaviors, respectively,), we use conservation of resources perspective to identify two important contextual factors that strengthen the effects of vicarious ID. First, we introduce relational identification as a boundary condition for the effects of vicarious ID. Relational identification signals a state of resourcefulness, based on relationship and identification with peers (Sluss & Ashforth, 2007). We hypothesize that low relational identification – a state of low resourcefulness - aggravates the resource threatening effects of vicarious ID. Thus, employees with low relational identification experience stronger effects of vicarious ID.

We also introduce emotional contagion – the awareness of and sensitivity to the emotions and feelings of others (Boyce & Parker, 1989) – as another factor that strengthens the effects of vicarious ID. Employees who have a high level of emotional contagion are sensitive towards others' emotions. When such employees witness or hear about interpersonal deviance directed towards peers, they experience much more pain, anxiety, and resource threat than employees who are low on emotion contagion (and hence less sensitive about others' emotions). Based on these arguments, we

hypothesize that low relational identification and high susceptibility to emotional contagion is expected to positively moderate the indirect relationship between vicarious ID and self-serving behaviors (through communion striving).

Methods. Using an interval of two weeks, we collected two-wave and two-source data from various organizations. Perceptual and attitudinal measures (such as experiencing vicarious ID, emotional contagion, communion striving etc.) were captured through self-reports, whereas behavioral measures (such as self-serving behaviors) were captured through supervisors' reported data. Of the 429 distributed surveys, 380 responses were received at T1 and 346 subordinate-supervisor pairs (74.3% male subordinates, 85.8% male supervisors), completed the surveys at T2.

Results. Data supported most of the hypotheses. The indirect effect of vicarious ID on self-serving behavior (through communion striving) was positive and significant. These indirect effects of vicarious ID on self-serving behavior were much stronger for employees with low relational identification (conditional indirect effect = .03, SE =.02, 95%CI=.03, .06) and employees with high susceptibility to emotional contagion (conditional indirect effect=.11, SE =.02, 95%CI=.01, .21). Thus, data supported that employees low on relational identification and high on emotional contagion exhibited high level of self-serving behaviors when they experience vicarious ID.

Limitations. Our sample was very heterogeneous – consisting of employees at different hierarchical levels, different sectors and industries, and from different functional backgrounds. While this helps to generalize the findings to the working population, we were unable to offer a more contextualized understanding of how vicarious ID functions within the specific sector or job type.

Conclusions and Implications. The results revealed that vicarious ID is a resource threatening experience which triggers communion striving, an aggressive-defensive strategy to build new resources, which in turn invokes self-serving behaviors, a defensive strategy to protect existing resources. These direct and indirect effects are strengthened when employees have low relational identification and high emotional contagion. Thus, managers can help employees in mitigating negative effects of vicarious ID by building relational identification and by providing them emotional support to deal with such experiences.

Relevance to the Congress Theme: Witnessing vicarious ID is a common experience at work. This paper provides insights about how employees are affected by the experiences of vicarious ID, what are the outcomes of such experiences, and the factors that strengthen/weaken the effects of such experiences.

Keywords: interpersonal deviance , self-serving behaviour

Symposium S041

Enhancing creativity: The effectiveness of creativity training and the impact of digital workplace on creativity

Ut Na Sio, University of Sheffield

science_practice

What will be covered and why:

Creativity is often viewed as a foundational stage of the innovation process and is widely considered an essential skill to succeed in today and future workplaces (Bellanca & Brandt, 2010; IBM Corporation, 2010; World Economic Forum, 2018). It is also listed as a key skill in solving the sustainable development challenges outlined by the United Nations (UN General Assembly, 2015). Understandably, enhancing creativity is a prime concern for many organizations, educators, and policymakers.

A common way to enhance creativity is with creativity training programs. This approach is highly popular in organizations. According to the Eurostat's Community Innovation 2016 Survey, 44.6 % of the surveyed EU innovative enterprises engaged in innovation-related training activities. More broadly, in the countries surveyed in the UNESCO Institute for Statistics Innovation Data Collection Report (2017), the average proportion of innovative-active firms using innovation training was 44.7%. Given the popularity of creativity training, it is crucial to have an accurate picture of the effects that these programs have on creativity.

Another critical, and timely, objective in this field is to identify ways to facilitate creativity in remote work settings. As a result of the pandemic, many organizations have made a rapid and unprecedented shift to virtual work; changes that are likely to persist in the future. For example, 23% of businesses in the UK Business Insights and Conditions Survey (2022) reported using or intending to include homeworking as a permanent business. As such, understanding the impact of remote work on creativity has become an emerging research area in the field of creativity. The shift to virtual work has also greatly increased the need for technologies that enable effective group interaction — a context that facilitates idea generation, an important aspect of group creativity. According to Mckinsey Global Business Executive Survey (2020), 85% of the 800 executives surveyed say they have accelerated the implementation of technologies that facilitate group interaction and communication since the start of the pandemic. Thus, to help organizations adapt to this new way of working, it is crucial to better understand the potential challenges that arise from virtual environments for creativity, as well as how technologies can be used to facilitate group creativity.

Through four presentations, this symposium will discuss different approaches to promoting creativity. The first presentation, Dr. Ut Na Sio (University of Sheffield, UK) will focus on the traditional approach—creativity training, presenting the results of a meta-analysis examining the effectiveness of creativity training and the robustness of this body of work. This will be followed by three presentations, focusing on the impact of digital platforms and technologies on group idea generation. In the second presentation, Prof. Dermot Breslin (Rennes School of Business, France) will present the result of an empirical study examining the impact of virtual teams on student group creativity and discusses how virtual and face-to-face environments can be combined to create a hybrid environment that facilitates creativity. In the third presentation, Dr. Jonali Baruah (Tarleton State University, US) will present the findings of two experimental studies comparing the effectiveness of video-based communication with electronic brainwriting and chat-based communications on group idea generation, selection and refinement. In the last presentation, Prof.

Jared Kenworthy (University of Texas at Arlington, US) will discuss the findings of a study exploring how machine learning can be employed to analyze group idea-generation process in real-time and provide real-time feedback for enhancing group creativity.

Relevance to the Congress Theme:

Given the importance of creativity for the future of work and the surge in remote work and the demand for supporting technologies, our symposium—which focuses on the impact of creativity training and digital workplace on creativity—will provide meaningful insights on how to create a better workplace of the future that facilitates creativity.

Research/practical implications:

The findings presented in this symposium will help organizations, educators, and policymakers make more informed decisions when selecting approaches to enhance creativity. Our symposium will also provide new directions for future research and hands-on strategies to promote creativity in various work environments. As such, this symposium will be of interest to both researchers and practitioners.

Overall conclusions:

All the presentations address the challenges of facilitating creativity and provide practical implications to design more effective training and work environments to enhance creativity.

Paper 1

Do creativity training programs enhance creative thinking?

Ut Na Sio, University of Sheffield; Hugues Lortie-Forgues, Loughborough University

Research goals and why the work was worth doing

Creativity is often considered one of the top skills necessary to succeed in today's world as well as in the future workplace (Bellance & Brandt, 2010; PISA, 2022; World Economic Forum, 2018). Understandingly, enhancing creativity is a prime concern for organisations, educators, and policymakers. Numerous training programs have been developed with the aim of enhancing creativity. We undertook a meta-analysis of studies evaluating these programs to estimate their impact on creative thinking, identify factors influencing their effectiveness, and evaluate how robust the evidence surrounding creativity training effectiveness is.

Theoretical Background

A number of meta-analyses have attempted to summarize the effectiveness of creativity training programs (e.g., Ma, 2006, Scott et al., 2004). Some of these meta-analyses have been highly influential. For example, at the time of writing, Scott et al. (2004)'s meta-analysis — one of the most comprehensive in the field — has been cited more than 1400 times. Importantly, however, existing meta-analyses present a number of limitations. One has to do with the time at which they were conducted. No exhaustive meta-analysis of the field has been conducted since Scott et al. (2004)'s meta-analysis, which raises the question of whether their findings are still representative of the field. Past meta-analyses are also limited in their analytical approaches. Most did not, for example, consider the potentially large publication bias in the field or accounted for the precision and dependency of effect sizes in their analyses, features that may have biased, perhaps substantially, their conclusions. We conducted a meta-analysis of creativity training programs aimed at providing a more accurate picture of the effects that these programs have on creativity.

Methodology

We focused on studies examining the effect of creativity training on creative thinking (total: 164 independent studies [813effect sizes] conducted between 1970 and 2022). A substantial number of these were unpublished (46 independent studies, 260 effect sizes). We used robust variance estimation (RVE), a meta-analytic method that considers the uncertainty and dependency of the effect sizes (Hedges et al., 2010; Tanner-Smith & Tipton, 2014). We used a range of methods to detect and correct for publication bias and assess the robustness of existing evidence by examining the proportion of studies employing rigorous research designs.

Results

Our analyses indicated the overall effect size of creativity training was significant and positive (effect size unadjusted for publication bias = 0.52 SDs), which was similar to the estimates from previous meta-analyses (Ma, 2006: 0.77 SDs; Scott et al., 2004: 0.64 SDs). Critically, we found strong evidence of publication bias and correcting for this bias considerably reduced the effect size. We also observed a high prevalence of methodological shortcomings in creativity training studies, with little signs of improvement over time — a situation that greatly limits the usefulness of this body of work. Implications and recommendations for researchers and practitioners will be discussed during the presentation.

Limitations

Although we used different methods to identify and correct for publication bias, these methods make untestable assumptions and none of them can quantify the extent of publication bias with certainty. However, it is important to emphasize that the methods we used provided converging results, supporting the robustness of our conclusions.

Conclusions

The results of this meta-analysis, which differ substantially from past meta-analyses, provide guidance for researchers in the design of future studies evaluating the effectiveness of creativity training programs, as well as informing organisations, educators, and policymakers, about the potential impact creativity training programs can have on creative thinking.

Relevance to the Congress Theme:

Given the importance of creativity for today and future workplace, and the prevalence of creativity training to achieve this aim, our meta-analysis of creativity training fits well with the congress theme "The future is now: the changing world of work".

Relevance UN SDGs

The findings will help researchers identify methodological gaps in the current literature and inform their effort to develop theories and effective training programs.

Keywords: Creativity Training, Meta-Analysis, Publication Bias

Paper 2

The Impact of Online Teaching on Student Group Creativity

Dermot Breslin, Rennes School of Business

Research goals and why the work was worth doing

The recent Covid crisis has had a profound impact on higher education, and the development of transferable skills and competences in university students. Some argue that creativity has been a principal victim, especially as it is largely carried out through team collaboration (Amabile and Khaire, 2008; Zhou and Hoever, 2014). This study aims to understand how the shift to online learning impacts student group creativity.

Theoretical background

Recent research has shown that the shift to online learning over the past few years has negatively impacted student learning, with for example students having increased difficulties in concentrating and higher levels of stress and anxiety (Flores et al., 2021; Ilieva et al., 2021). Other research has found that following the transition to online learning, students found courses less interesting, were less motivated and online courses instilled less learning with students holding their attention less (Garris and Fleck, 2020). It is unclear how the rapid shift to online teaching has impacted students' group learning experience, with few empirical studies looking group creative processes in virtual teams (Grözinger et al., 2020; Reiter-Palmon et al., 2021). To address this gap, an experimental study was carried out to compare the creative performance of student groups in face-to-face versus virtual environments.

Design

208 participants were randomly divided into 52 groups of 4 individuals each, split between face-to-face and virtual settings. All groups completed two tests for creative or divergent thinking, the Unusual Uses Task (UUT). In UUTs participants are asked to generate as many unusual uses as possible for a common object, such as a paper cup, within a set amount of time (Baird et al., 2012). The productivity and originality of ideas generated and selected are used as measures of creative thinking. Groups completed these two consecutive UUTs, interpolated with a task designed to stimulate the process of socialization within the two different settings (i.e. face-to-face and virtual environments).

Results

Findings show that the creative fluency of student groups is significantly lower in virtual compared to face-to-face environments. Furthermore, this difference becomes even more marked as individuals begin to socialize.. The findings of this study show that by negatively impacting the fluency of the creative process in student groups, virtual interactions result in a less rich peer discussion with negative consequences for the depth of student learning within courses. Furthermore, students are constrained in their ability to develop the skills needed to be creative in group situations, with potential longer term consequences for team-working skills (Gibert et al., 2017; Lowden et al., 2011; Riebe et al., 2016). In other words, by failing to experience face-to-face teams, students cannot acquire and improve upon these important transferable skills. These deficiencies are even more pronounced when considering newly formed teams.

Conclusions – research and or practical implications

Following the pandemic many institutions have adopted hybrid forms of learning, with combinations of both face-to-face and online learning. Drawing on the findings above, we can identify some important lessons for hybrid teaching. First, the richness of the virtual environment can be enhanced to improve interpersonal communications and interactions. However, despite the richness of platforms such as Microsoft Teams, the findings of this study nonetheless point to important differences relative to face-to-face interactions. Second, virtual environments have a more profound impact on newly formed teams, as it becomes difficult to establish trusting relationships between group members (Breuer et al., 2016; Reiter-Palmon et al., 2021). This effect was seen in the findings above, where creative fluency worsened in virtual teams after individuals began to socialize. In other words, socialization processes within newly formed virtual teams have a significant and negative impact on team performance (De Guinea et al., 2012; Mesmer-Magnus, et. al., 2011). Therefore, it is recommended that the early stages of team formation occur through face-to-face interactions. This gives students the opportunity to feel socially connected (Curseu et al., 2008; Reiter-Palmon et al., 2021), and therefore build trust with other members of their team (Breuer et al., 2016; Reiter-Palmon et al., 2021).

Limitations

Future research could compare the impact of face-to-face, virtual, and hybrid teams on different types of creativity.

Relevance to the Congress Theme

Given the emerging hybrid work norm, this presentation—examining the group creative processes in virtual teams—fits well with the theme “The future is now: the changing world of work”.

Relevance UN SDGs

The findings presented would help create hybrid learning environments that enhance creativity.

Keywords: Group Creativity, Group Interaction, Virtual Team

Paper 3

Video-based team meeting as a technology for collaborative creativity: Is it better than text-based communications?

Jonali Baruah, Tarleton State University

Research goals and rationale

Organizations are increasingly becoming virtual and diverse in terms of communication and task completion. The COVID-19 pandemic further ushered in a new era of remote work, amplifying barriers to such communications. The unequal talking time, turn-taking, and technical interruptions can cause complications in video-based meetings (VM)(Issacs & Tang, 1993; Oeppen et al., 2020) which can further affect collaborative creativity. Hence, the proposed research explores the effectiveness of video-based teams and compares such teams' creativity with teams engaged in text-based communication modalities across multiple stages of creativity.

Theoretical background

Collective attention to ideas and the exchange of knowledge is the key to the process of collaborative creativity (Harvey, 2014), which can become a challenge in VM teams. In a VM meeting, four pragmatic needs that must be fulfilled are: (1) to make contact (e.g., eye gaze), (2) to allocate turns at talk, (3) to monitor understanding and audience attention, and (4) to support deixis (shared visual artifacts, physical pointing) (Daly-Jones et al., 1998). Additionally, VM can cause evaluation apprehension (Raveendhran et al., 2020) reducing knowledge-sharing and integration. Knowledge integration is the key to the creative performance of diverse expertise groups (Tiwana & Mclean, 2014).

Design/Methodology/Approach

The current investigation examines the creativity of VM through two experiments. Experiment 1 compared the creativity of VM with Electronic brainwriting (EBW) modality. The EBW modality involves silently sharing ideas using "electronic post-it notes" on a common canvas (computer screen). It allows team members to view and generate ideas simultaneously. This paradigm should promote cognitive stimulation (mutual idea sharing, facilitating the generation of more ideas) due to enhanced attention to others' ideas (Paulus & Yang, 2000) resulting in enhanced knowledge integration from diverse groups. Hence EBW was predicted to demonstrate the highest creativity than VM groups under diverse expertise conditions.

Forty-two dyads and triads (N=133) collaborated to complete an idea-generation and selection task using either VM or EBW modality. Half of the groups were diverse in their academic majors (cognitively diverse), and the other half had all members from the same major.

The 2(EBW/VM) x 2(Diverse/homogeneous)x 2(generation/selection) ANOVA revealed that EBW groups selected the most original ideas [$F(1,48)=4.91$, $p < .05$, $p\eta 2=.09$]. In contrast, the VM groups selected significantly more feasible ideas than the EBW groups. Furthermore, the diverse group generated most original ideas in EBW condition [$F(1, 48) = 4.99$, $p < .05$, $p\eta 2 = .09$]. The enhanced effectiveness of the EBW could be due to undivided attention and possibly anonymity, which gave individuals free will to evaluate ideas ignoring social norms (Cooper et al., 1998; McLeod, 1997).

Experiment 2 tested whether VM groups were more creative than electronic brainstorming (EBS) groups across multiple stages of innovation: idea-generation, selection, and refinement (evaluation). The EBS allows sharing of ideas live using an online chat portal which can eliminate evaluation apprehension when anonymity is maintained because the source is not attached to the ideas (Cooper et al., 1998; Dennis et al., 2019).

Thirty small groups of three to four members (N = 92) completed idea generation, selection and refinement tasks in either EBS or VM meeting conditions.

A 2(EBS/VM) x 3(generation/selection/refinement) ANOVA revealed that EBS condition yielded more original ideas than the VM condition. The EBS condition generated the highest number of good-quality ideas and elaboration in the refinement stage of innovation $F(2, 56) = 3.60$, $p < .0.05$, $p\eta 2 = .11$. Furthermore, participants' perceived attention partially mediated the relation between the quality of ideas in the generation and the refinement stage.

Discussion, conclusion, and implication

Experiments 1 and 2 revealed that the originality of ideas was higher in the chat-based paradigm than in the VM paradigm. Additionally, the cognitively diverse group performed better in EBW than in the VM paradigm. Finally, the EBS groups were most creative at the refinement stage of innovation, a stage that entails greater attention and deeper elaboration of ideas to make them more favorable for implementation (Baruah et al., 2021). Additionally, in both studies, anonymity possibly magnified the performance of these groups. Because anonymity can enhance attention to the task at hand (Connolly et al., 1990) and reduce inhibition (Siegel et al.,1986) and evaluation apprehension (Dennis et al., 2019) which were likely to enhance creativity in text0based communications. The findings will provide hints to practitioners to develop strategies and interventions to enhance the depth and breadth of collaborative creativity among VM groups.

Relevance to the Congress Theme

The present research seeks to address the question of the future of virtual work and how various virtual modalities can affect collaborative innovation.

Keywords: Group Idea Generation, Group Interaction, Virtual Communication Modalities

Paper 4

Developing a computer-assisted real-time feedback system for enhancing group creativity

Jared Kenworthy, University of Texas at Arlington

Research goals : We are working on the development a computer-assisted real-time feedback system for enhancing group creativity. This is important because of the difficulties of coding various idea dimensions in real-time and delivering feedback to team members.

Theoretical background : We use existing cognitive and social models of group creativity (e.g., Brown & Paulus, 2002; De Dreu et al., 2008; Nijstad & Stroebe, 2006; Paulus & Brown, 2007) to guide the development of this system.

Methodology / Approach : I will present the results of an ongoing collaboration between computer science and psychology researchers that employs Natural Language Processing (NLP) methods to examine the trajectory of semantic space used during group idea generation sessions. Specifically, we track and estimate the region of semantic space being used and the degree to which new ideas expand that space.

Results : We present a visualization of that space mapping endeavor and compare human ratings of creativity dimensions (i.e., novelty, task-relevance, and elaboration) to algorithm-based estimations of those same dimensions. A combination of algorithm-based idea novelty, relevance, and elaboration provides the best match to human-rated data.

Limitations : As yet, the sample size in the tested database is relatively limited; only about 400 ideas were tested, from a “big data” perspective, probably thousands of ideas would provide a better test of the system.

Conclusions and implications : The semantic space mapping and algorithm development projects can be used to deliver real-time feedback to human creative groups in order to optimize the collaborative creativity process. The overall goal of this research is to increase the “survival” of novel ideas and their elaboration in the collaborative ideation and subsequent decision processes.

Relevance to the Congress Theme : This work is relevant because our system is being designed for creative work teams of the future. More and more workplaces are using technology to connect people in teams and organizations. This technology would be another tool to help enhance and optimize creative processes and outputs in groups and teams.

Relevant UN SDGs : Good health and wellbeing; Quality education, Decent work and economic growth.

Keywords: Group Idea Generation, Natural Language Processing, Semantic Space

Symposium S042

New Perspectives on Workplace Stressors

Hadar Nesher Shoshan, University of Mannheim; Shani Pindek, University of Haifa

science_practice

The goal of the current symposium is to demonstrate that by investigating understudied stressors and providing new perspectives to stress, the field can gain a better understanding of what is work-related stress and help in improving the well-being of all employees as well as organizational performance (Hart & Cooper, 2002). The symposium comprises four papers, each presenting a new perspective on workplace stressors. Research on work stress has been at the forefront of organizational research for several decades and there are some work-related stressors that have been the focus of designated meta-analyses, and that are relatively well-understood (Pindek et al., 2017). Nevertheless, there are nascent approaches to what we should consider, as well as new perspectives on how well-understood stressors affect employee well-being, that we will address with the current symposium.

Two papers use a diary study methodology and a general employee population. The first paper (Authors, blind for peer review as requested by EAWOP organizers) examines a well-studied outcome of stress, that of task performance, as an antecedent of employee strain (anxiety, well-being, and physical symptoms). This is a new perspective on underperformance that puts the employees' well-being, not their contribution to the bottom line, at the center of attention. The second paper (Authors) focuses on the process of stress sensitization. Specifically, exposure to workplace incivility resulted in heightened stress response patterns to stressors in the work and home domains.

Two additional papers focus on healthcare employees, who are exposed to unique circumstances in their work environment, and thus we can expect new conceptualizations of stressors to emerge from studies that focus on this population. The third paper in the symposium (Authors) focuses on emotional workload, which is a central element of healthcare work but has not yet been properly defined or measured. This set of two studies (qualitative and quantitative) creates a classification system for objective events that are indicators of emotional workload and demonstrates its distinctiveness from operational load and emotional labor. The final paper (Authors) is a conceptual paper that describes a stressor that is unique to surgery teams: micro-coordination conflict. In this theoretical development, micro-coordination conflict is theorized to induce irritation which in turn may trigger incivility from members of the team, particularly the surgeon.

Taken together, the papers provide conceptual and empirical illustration of understudied stressors and new perspectives on the stress process. Interestingly, such perspectives can interact with each other, moving toward more integrated approaches. For example, incivility is proposed to be triggered by micro coordination conflict by the fourth paper (Authors) and to trigger sensitization processes in the second paper (Authors) demonstrating opportunities for future integration.

Overall, this symposium contributes to our growing understanding of how stress affects employees. It is extremely relevant to the conference's theme of the changing world of work because the sustainability of organizational success is reliant upon the well-being of its employees. Therefore, as researchers, we must go beyond the known stressors and stress perspectives in order to gain a more comprehensive understanding of how we can help employees and organizations thrive. This symposium is likely to be of interest to a broad range of researchers and practitioners. Considering the diversity of methods and new conceptualization, it may help spark new research ideas.

Moreover, the symposium aligns well with the United Nations Sustainable Development Goals, specifically with those concerned with employees' well-being.

Keywords: Stress, employee well-being, new perspectives

Paper 1

Underperformance As a Stressor - An Empirical Examination

Keren Grinautsky, University of Haifa; Hadar Nesher Shoshan, University of Mannheim; Shani Pindek, University of Haifa

The effects of job stressors on employee performance are widely studied and acknowledged (Gilboa et al., 2013). However, little attention has been devoted to examining what happens to the well-being of the employees after the performance was appraised, or even self-appraised, as poor (Pindek, 2020). Therefore, the goal of this study is to demonstrate that underperformance is indeed experienced as a stressor for employees, resulting in strain experiences. We will also examine an exacerbating factor for the experience of episodic underperformance as a job stressor - that of person-level job insecurity.

When viewing underperformance as a stressor, it may lead to increased anxiety, negatively impact the sense of well-being among employees (Shockley et al., 2012) and cause physical symptoms (Merrill et al., 2013). Furthermore, we expect to see differences between working individuals in the extent to which underperformance will negatively affect their strain experiences. One important factor influencing this effect is job insecurity, because when employees feel insecure regarding their job, instances that signal that they might lose their employment, such as perceiving their own performance as poor, may have a stronger effect.

Previous research showed that individuals who experience job insecurity also experience reduced well-being and physical and mental health (Jiang & Lavaysse, 2018), and in the current study we aim to show that job insecurity affects these variables not only directly, but also makes employees more vulnerable to stressors, especially those that signal job insecurity.

We test our predictions as part of one comprehensive model whereby underperformance experienced during the first half of the workday (before noon) predicts three strain indicators (anxiety, well-being, and physical symptoms) during the second half of the workday. These effects are expected to be moderated by person-level job insecurity.

Methods

Participants were full-time employees working a standard office schedule in various jobs, recruited by seminar students in a Master' program in Israel. Of the 103 employees who agreed to participate in the 5-day diary study, 88 provided enough data to be included in the multi-level analysis, with an average of 3.5 days of data (two-time points each day) per participant.

The baseline survey included a job insecurity scale (Vander Elst et al., 2014). The midday survey (sent at noon) included a measure of underperformance referring to that morning at work. The scale was comprised of the 2-item performance scale (Xanthopoulou et al., 2008), and an additional item comprised for the current study: This morning my performance was poor. and the afternoon survey (sent at 4 pm) included measures of anxiety, well-being, and physical symptoms. All measures have been validated by previous research and had good reliabilities.

Results

The results show that at the within-person level, underperformance predicted all 3 outcomes in the expected direction. Furthermore, job insecurity exacerbated the effects on the negative valenced strains (anxiety and physical symptoms) but not on the positively valenced strain (well-being).

Discussion

The main tenets of underperformance as a stressor were supported by the data. Nevertheless, there were several limitations of this study, including the small sample size and the use of only two-time points within the day, making it harder to examine mediators.

In terms of conclusions and implications, as expected, job insecurity exacerbated the negative impact of underperformance on anxiety and physical symptoms. However, there was no moderating effect of job insecurity on the relationship between underperformance and well-being among employees. This might be explained by a stronger direct effect between underperformance and well-being, which means that underperformance negatively affects the well-being of all employees regardless of their levels of job insecurity.

This work is extremely relevant to the conference's theme of the changing world of work, which focuses on sustainability over short-term profits. In the past, underperformance would have been a variable monitored for selection and termination of employment but moving forward underperformance (at least episodic underperformance) can be seen as a problem that hurts both the employee and the employer. Remedying underperformance and its effects on employees is a sustainable solution for all involved. This is in line with the UN SDGs of good health and well-being and decent work and economic growth.

Keywords: Underperformance, stress, job insecurity

Paper 2

Daily Stress Sensitization Processes associated with Workplace Incivility

Miriam Schilbach, Leibniz Institute for Resilience Research; Hadar Nesher Shoshan, University of Mannheim; Thomas Rigotti, Leibniz Institute for Resilience Research & Johannes Gutenberg-University Mainz; Anja Baethge, Medical School Hamburg; Xenia Bolschakow, Johannes Gutenberg-University Mainz

The concept of stress sensitization suggests that repeated exposure to stressors elicits increasingly strong affective responses given future stress events. This stress-related hyperreactivity represents a vital risk factor for the development of psychopathology (Post, 1992). To date, stress sensitization processes have been mainly examined in the field of clinical psychology. With this study, we apply the concept of stress sensitization to the work psychology literature and examine if and how daily experiences of workplace incivility relate to affective responses toward future home- and work-related stressors. By doing so, we explore the possibility that workplace incivility may result in vulnerability that permeates across contexts and thus, likely inhibits health and functioning in the home and the work domain.

The sensitization process is characterized by dysphoric attention (i.e., focus on the negative) and a loss of personal resources (e.g., self-esteem). This resource loss will render individuals more vulnerable when confronted with future stress events and thus, likely elicits stress-related hyperreactivity. Researchers further outline that inherent to stress sensitization lies a permeability hypothesis whereby hyperreactivity occurs not only toward a specific but to many or all types of stressors across different contexts (e.g., at work and at home). Thus, combining the concept of stress sensitization with the stress as offense to self-theory (Semmer et al., 2019), we propose that workplace incivility will result in greater affective stress responses toward private (e.g., family conflict) and other work-related stressors (i.e., hindrance stressors such as role ambiguity) through negative work reflection (i.e., dysphoric attention) and a loss of self-esteem. Hence, we propose a serial mediation model. Moreover, we suggest that social support at work may prevent incivility-induced negative work reflection and thus, disrupt the sensitization process.

To examine the proposed relationship patterns, we invited office workers to participate in a daily diary study over the course of one workweek. Participants filled out two daily surveys: One right after work, and the other before going to bed. The final sample consisted of 503 employees (N Level1 = 2056). We tested our hypotheses using multilevel moderated mediation analyses at the within-person level. Following procedures used by clinical psychology researchers and the definition of affective stress response as the tendency to react to stressors with an increase in negative affect, affective stress responses to private and work-related hindrance stressors were operationalized as negative affect under the control of the respective stressor levels.

Analyses showed that daily workplace incivility related to greater affective stress responses to private stressors in the evening via negative work reflection and lower levels of self-esteem ($\beta = .004$, 95% CI [.001, .007]). The same applied to affective stress responses toward hindrance stressors at the following workday ($\beta = .002$, 95% CI [.001, .003]). Social support had the potential to disrupt the daily sensitization process: On days when social support was high, the relationship between workplace incivility and negative work reflection was non-significant. Consequently, at high levels of social support, there was no indirect relationship between workplace incivility and affective stress responses.

Our study is mainly limited by the fact that we cannot draw any causal conclusions. This is especially the case for sensitization effects related to private stressors where we measured negative rumination, self-esteem and affective response to private stressors at the same time point (i.e., before participants went to bed).

Taken together our study supports the assumptions of stress sensitization and the stress as offense to self-theory. We showed that workplace incivility may trigger dysphoric attention and a loss of self-esteem which result in greater affective stress responses not only at work but also in the home domain. Such heightened stress response patterns have been identified as a central risk for psychopathology and hence, prevent sustainable and high levels of employee health and functioning. Accordingly, it is of vital importance to reduce workplace incivility (e.g., via raising awareness and training leaders). Moreover, on days when employees experience incivility, coworkers and supervisors should provide social support and/or employees should actively seek social support given that social support prevented stress sensitization processes to occur.

Paper 3

Explaining Situational Triggers of Incivility in Tightly Cooperating Teams: Towards a Theory of Micro-coordination Conflict

Norbert K. Semmer, University of Bern; Franziska Tschan, Université de Neuchâtel; Guido Beldi, Bern University Hospital; Ashley E. Nixon, Willamette University; Sandra Keller, Bern University Hospital

A surgeon exclaiming, "If this were an exam, you would just have failed" (Keller et al., 2016) might well be classified as a 'Difficult Surgeon' (Hallock, 2015). Such low-intensity aggressive behavior represents workplace incivility (Anderson & Pearson, 1999) and has negative effects such as risk of patient harm and reduced satisfaction and well-being (e.g., Anderson & Pearson, 1999; 2015; Cortina et al., 2017; Hershcovis, 2011; 2016).

Understanding why these behaviors occur and how they can be reduced has driven several prominent research literatures. The nursing literature has focused on personality characteristics of physicians and the hierarchical nature of medical organizations (Hallock, 2015; Lingard et al, 2002). Meanwhile, the incivility literature has focused on felt injustice/reciprocity (Anderson & Pearson, 1999; Meier & Semmer, 2013) and stressful working conditions (e.g., Bechtoldt et al., 2014; Schilpzand et al., 2016; Zhou et al., 2014) in addition to personal characteristics and power differentials (Foulk et al., 2018; Sturm & Antonakis, 2015). While these literatures can help explain the general propensity to act in an uncivil way, they cannot explain when such behavior will occur. There is a need to better understand situational triggers of these uncivil behaviors (Cochran & Elder, 2014, Lingard et al.. 2002; Mitchell et al., 2011).

Incivility is an important element of conflict behavior (Raver, 2013; Semmer, 2019), which may illuminate these situational triggers. The conflict literature distinguishes between relationship and task-based conflicts (Pinkley, 1990), with task conflicts being divided into subcategories of task outcome conflict and task process conflict (Hartwick & Barki, 2004). However, most conflict research has focused on disagreements of opinion and tend to neglect behavioral interference (Barki & Hartwick, 2001), which has a critical role in conflict (Wall & Callister, 1995).

Precisely coordinated task execution is crucial in tightly cooperating teams (Mitchell et al., 2011), such as surgical teams. These teams are characterized by movements that may have to be coordinated at the same time, or in a clear sequence, in the same speed/rhythm, with high precision, within very short time frames, often within seconds. Thus, smooth coordination is important. In recent research, Keller and colleagues (2019) observed 137 surgeries and found that 21.2% of uncivil behaviors were task-related (including disagreements but also task difficulty or missing instruments), while 72.4% results from disrupted coordination. Only 1.2% were attributed to interpersonal conflict. Thus, surgical incivility was driven by task coordination or execution issues, which is not sufficiently in the focus of the current conflict literature.

To fill this gap, we propose the concept of micro-coordination conflict (MCC), which refers to tensions that arise from poorly coordinated execution of tasks that need to be carried out by two or more team members in a well synchronized way simultaneously or in tight sequence. Teams for which MCC would be typical include teams undertaking a surgery, concert, sporting event, or preparing food at a restaurant. These conflicts may be particularly irritating given that a team member must interrupt his or her ongoing activity, s witch attention from the ongoing activity to

the trigger of the interruption, keep the ongoing activity in working memory , and then return to original task (e.g., Keller, Meier et al., 2019; Speier et al, 2003). Thus, there are three mechanisms through which MMCs are postulated to occur: goal obstruction, additional effort, and flow disruption.

With regard to goal obstruction , the interruption may make ab activity more error prone (e.g., Sevdalis et al., 2009). Particularly in the case of surgeries, this could endanger progress or even the success of the surgery, and thus induce negative emotions given the threat to the professional identity of the surgeon (Gollwitzer et al., 2013; Semmer et al., 2007). Furthermore, while the goal may still be achievable, it likely requires additional effort (Weigl et al., 2012) and a significant change to coordination (Blickensderfer et al. 2010; Weber et al., 2018), which increases fatigue, depletes resources, and tends to become aversive (Meijman & Mulder, 1998). Finally, interrupted flow experiences are aversive even when the interruption is minor and not dangerous (Weigl et al., 2018).

The irritation suggested by these three mechanisms increases the likelihood of incivility, notably when regulatory resources are limited, and specific attributions are made. Stress, culture, hierarchy, and individual differences may limit regulatory resources (Fox & Spector, 1999). Further, Keller and colleagues (2019) found that surgeons responded with incivility when they perceived others as negligent rather than lacking experience. Future theoretical development and research is needed to better understand the role and impact of MCCs on a variety of tightly coordinating teams.

Symposium S043

Organizational Practices for Ageing at Work: Internationalization and Scientific Application of the Later Life Workplace Index

Jürgen Deller, Institute for Management and Organization, Leuphana University of Lüneburg, Lüneburg, Germany; Anne Marit Wöhrmann, Federal Institute for Occupational Safety and Health (BAuA), Dortmund, Germany; Leuphana University of Lüneburg, Lüneburg, Germany

science

What will be covered and why?

Against the background of demographic change and rising regular retirement ages, it becomes increasingly important to provide work environments that enable motivated and healthy aging at work. To provide an overarching framework reflecting the characteristics of such a work environment, the Later Life Workplace Index (LLWI) was developed. Its nine dimensions include organizational climate, leadership, work design, health management, individual development, knowledge management, transition to retirement, continued employment, and health and retirement coverage. The 80-item instrument allows researchers and practitioners alike to assess the situation in organizations.

In this symposium, research findings of researchers collaborating internationally regarding the LLWI are presented. The studies are based on U.S.-American, German, Portuguese, and Israeli data. The symposium deals with validations of different language versions of the LLWI as well as the investigation of relationships of the LLWI with individual and organizational outcomes. In the first presentation, the validation of the English language version of the LLWI, which was originally developed in German language, is presented. In the second presentation, the author provides evidence for the Portuguese language version of the LLWI as well as relationships between LLWI dimensions and thriving at work. Then, insights on the associations of the LLWI dimensions with positive perceptions of older workers by managers in Israeli organizations are presented.

Finally, Beatrice van der Heijden, who has ample expertise in the field of sustainable careers, ageing and work, will reflect on the presented research in light of current developments as a discussant. She will discuss the presentations on the Later Life Workplace Index (LLWI) and reflect on the presented findings against the background of current developments within ageing and work research and practice as well as societal developments.

Relevance to the Congress Theme

The share of older workers in many OECD countries is increasing as is the share of people leaving the workforce to enter the retirement phase. Debates on expected increasing shortage of skilled labour and high pressures on social security systems has been going on for a while. Now, with the “baby boomers” in fact beginning to enter retirement, the future of the changing world of work is now. Thus, there is urgency to tackle the problems arising due to demographic change. Designing working conditions and providing a work environment that supports older workers to stay healthy and motivated is crucial to prolong working lives. The LLWI is an instrument for research and practice to assess organizational practices for older employees multidimensionally. It allows to study relationships of organizational realities for older workers with relevant outcomes on the individual and organizational level but also to directly derive recommendations for changes in specific work environments. Thus, research on the LLWI can contribute to the delivery of the desired changes in the context of “the future is now” regarding demographic change. Furthermore, with the

internationalization of the LLWI by developing different language versions and applying them in the regarding countries contributions are made to help lead the way towards the future.

Research and Practical Implications

The findings presented in this symposium have implications for research and practice alike. Amongst others, the provision of different language versions of the LLWI enables researchers from an increasing number of countries to use the LLWI or its subscales in their organizational psychological research. The LLWI covers a wide range of aspects of working conditions for older workers and with the organizational and not individual aspects being assessed it can be administered to different target groups on different levels in organizations.

The LLWI can be used by organizations to assess their current situation regarding organizational practices for older workers. Organizations can benchmark their results among peers and identify areas with need for action. Also, the findings give indications for organizations on how the provision of a work environment that is reflected by the LLWI is related to the perception of older workers in an organization by their managers. This indicates that the application of the LLWI in organizations can provide one component to create better work environments for older workers in organizations.

Overall conclusions

Overall, the presented findings underline the importance of international collaborations in the development of different language versions of instruments used in organizational research. Furthermore, they give insights into different possibilities of applications of the LLWI. Content wise, the findings emphasize the importance of well-designed work environments to beneficially enable aging at work.

Beatrice Van der Heijden

Paper 1

The Later Life Workplace Index (LLWI) - practical perspective

Jürgen Deller , Leuphana University Lüneburg; Anne Wöhrmann , Federal Institute for Occupational Safety and Health (BAuA); Julia Finsel , Leuphana University Lüneburg; Max Wilckens , Wilckens Farben GmbH

Fed by the demographic change the share of older workers among the European workforce increases rapidly. Better health status of older workers and the political ambition to relieve pension systems drive extended working lives. Consequently, organisations have to deal with increased age diversity and specific demands by older workers.

In order to summarize and describe appropriate organisational practices and working conditions for older workers nearing retirement age and beyond, we developed and operationalized the Later Life Workplace Index (LLWI). The index contains nine dimensions covering age-friendly organisational culture and leadership, as well as more specific age-friendly practices regarding work design, health management, individual development, knowledge management, transition to retirement, continued employment options and health and retirement coverage.

We operationalized and validated the index in multiple studies. The index can be assessed by 80 items in total, showing good to acceptable CFA model fit and reliabilities. The validation proofs sufficient independence from positive and negative affect, as well as discriminant validity among the index dimensions. Moreover, criterion validity proves effects on e.g. older workers' commitment towards the organisation, stress level and perceived health status. We continue the organisational study to validate the effects on organisational level outcomes as performance, illness absence and turnover.

From a practice perspective, the LLWI will allow organisations to access their own capabilities in terms of practices regarding the employment of older employees in a straightforward and low-effort manner. Organisations facing the challenge of an aging workforce either due to labour force shortages or political requirements may use the LLWI as a diagnostic tool to identify improvement opportunities for the management of older employees. By allowing for industry and regional benchmarks, the LLWI has the potential to raise awareness for later life work not only in business, but also in the political debate. Benchmark results can support the identification of best practices and thereby support the organisations' management in handling aging issues. Thereby the importance of each dimension within the entire index may differ from industry to industry, region to region, and country to country. Specific recommendations on effective practices will be the results. Within the proposed theoretical moderation model for the effect of workforce age on organisational outcomes, it is to be expected that different organisational circumstances will require certain combinations of index dimensions as moderating levers to be pulled in order to drive organisational outcomes. Individual dimensions of the index may serve researchers as a standardized and validated measure to evaluate interventions in specific research areas.

The presentation will also briefly touch upon the development of different language versions of the LLWI.

Just recently, a new standard ISO 25550 titled "Ageing societies — Guidelines for an age-inclusive workforce" has been published by the International Organization for Standardization (ISO), an independent, non-governmental international organisation with a membership of 165 national

standards bodies. The ISO 25550 standard describes guidelines for an age-inclusive workforce integrating several LLWI dimensions. Thus, successful management of an aging workforce as outlined by the LLWI will unfold internationally and develop lasting and sustainable effects.

Keywords: Later Life Workplace Index, demographic change, scale development

Paper 2

Generation management – there is more to generation management than the year of birth

Ellen-Denise Augustin, Sparkasse Harburg-Buxtehude

Research goals and why the work was worth doing

Three current trends – demographic change, digital transformation und shifting in values & needs – challenge organisations independently of industry or size. Only those organisations that review previous Human Resource approaches and adopt to the new work environment will remain successful.

Theoretical background

Twenty branches, about 660 employees and a balance sheet total of 4,6 billion Eu-ro make the Sparkasse Harburg-Buxtehude to one of the leading regional public savings bank in the South of Hamburg. As a financial institute the Sparkasse Harburg-Buxtehude provides every citizen in the region Süderelbe, the district Harburg as well as in the town Buxtehude with professional financial services. Since 2014 the percentage of employees older than 50 years rises permanently. Overall, about 47% of our employees are over the age of 50.

Given the trends, the Sparkasse Harburg-Buxtehude has started an initiative focusing on diversity management especially concentrating on the aspects “age”, “gender” and “values & needs”. The underlying assumption is that change can only be achieved and maintained if employees are right from the beginning part of the progress. Consequently, participation and open discussion at eye level are the key success factors – already symbolized in the name of the project “Wir.Sind.Sparkasse” (“We.Are.Sparkasse”).

Soon after the start of the project questions regarding older employees came up (e.g. access to training possibilities, special needs or restrictions due to age, employee satisfaction of employees older than 50 years).

Analyzing the available HR data did not show significant differences based on age. On the contrary, looking at the data of the latest employee survey older employees scored high on the categories “overall employee satisfaction”, “training & development” and “loyalty”.

Nevertheless, the - mainly subjective - assessment that older employees need more attention did not vanish looking at the obtained results. The hypothesis was formed that current instruments and data do not cover all of the relevant factors. It was decided to invest in a solid analysis before initiating measures.

Looking at best practices and scientific approaches regarding age diversity the LLWI was got to know. The top management as well as the works council decided that the LLWI should be used for getting a valid report about the status quo.

Design/Methodology/Approach/Intervention

The previously mentioned believe that participation and discussion at eye level are essential success factors were considered while implementing the LLWI. Therefore, as a first step, every employee was invited to join workshops informing about the effects of demographic change on society, industries and on the Sparkasse. A transparent and data-based presentation about the development of the age

structure of the Sparkasse demonstrated the need of action. The idea using the LLWI to get a solid basis before deciding about next steps was presented, discussed and agreed on.

As a next step, employees could apply to participate in the survey. Two groups were formed - one consisting of managers and employees of sales departments, the second including managers and employees who work in rather central units. Each group contained employees of different age groups. After putting together the final groups the survey started. The time the employees needed to respond to the inviting eMail was immediate. And the survey results were available in no time.

Limitations

At the moment the results of the LLWI are analyzed and compared to the results of the employee survey conducted in June 2022. Together with the employees who applied to work on that topic initiatives will be developed, implemented and evaluated. Current discussions showed that flexibility is key to maintain the employer of choice. A diverse workforce means on the one hand diverse skills and competencies – a great potential for organisational success. On the other hand, there are many different values & needs that had to be considered to realize the full potential of the employees and to retain them at the same time.

Research/Practical Implications

Therefore, first ideas about enlarging the scope of the LLWI – including employees of all ages – have been discussed with the Leuphana University.

Originality/Value

The final goal is to maintain the employer of choice for current and future employees in every phase of life by releasing the available potential as well as meeting individual needs and requirements – the solution to the current challenges of demographic change, digital transformation and shifting in values and needs.

Keywords: Later Life Workplace Index, demographic change, research-practice collaboration

Paper 3

Experience with the Later Life Workplace Index (LLWI) from a central bank's perspective

Werner Neumer, Deutsche Bundesbank

Research goals and why the work was worth doing

For about 10 years, the Bundesbank has been working very intensively on the question of how to cope with the challenges posed by our age structure and by demographic change in general (e.g., longer working life, retirement waves of the "baby boomers", impending loss of knowledge, "war for talent" on the labour market). The LLWI has now made it possible to assess the effectiveness of the measures we have taken so far and provided suggestions for further improvement in some areas.

Theoretical background

The Deutsche Bundesbank, the central bank of the Federal Republic of Germany, has formed part of the Eurosystem since 1999, sharing responsibility with the other national central banks and the European Central Bank for the single currency, the Euro. It has a three-tiered organisational structure with 41 locations throughout Germany. A comprehensive restructuring process starting in 2002 has created significant differences in the age structure between the tiers of the organisation and individual locations. Overall, about 50% of our 11,200 employees are over the age of 50, whilst in our branches the percentage is even 70%.

Design/Methodology/Approach/Intervention

The LLWI is based on a sample employee online survey, which keeps the administrative workload manageable. The sample survey is sufficient, as the LLWI does not record each participant's individual situation but instead the general practices within the organisation. The provision of mean value results for all participants guarantees their anonymity. At the Bundesbank, eleven tandems (managers and employees 50+) from all three tiers of the organisation as well as Bundesbank's Demographics officer participated voluntarily in the LLWI survey.

Results obtained or expected (if not available, it must be made clear when they will be)

Overall, the LLWI showed good results for the Bundesbank, particularly with regard to the dimensions of age-friendly organisational climate, age-friendly leadership, health management and individual development. These are exactly the areas of activity on which many of our previous measures were focused. For other dimensions, such as work design, knowledge management, transition to retirement and continued employment in retirement age, the results showed room for improvement.

Limitations

A central bank is home to a broad spectrum of tasks and jobs, ranging from university-educated economists or researchers to blue-collar jobs such as cash processing machine operators at our branches. That is why there is no "one size fits all" solution with regard to organisational practices – cash processing, for instance, cannot be done from home. In addition, not all LLWI dimensions are equally applicable to all organisations. For example, health and retirement coverage for the public sector in Germany is regulated by law, which rules out the option of a company pension scheme at the Bundesbank.

Research/Practical Implications

Benchmarking against other participating institutions and companies is very useful for any internal discussions with relevant stakeholders, like the Executive Board, the various business units affected, the staff representatives or the employees.

Originality/Value

The LLWI follows a holistic approach and covers all areas of activity for the design of em-ployment conditions for aging and age-diverse workforces.

Keywords: Later Life Workplace Index, demographic change, research-practice collaboration

Paper 4

Nova.PE- systematic and risk-focused know-how transfer related to the Later Life Workplace Index

Jürgen Büscher, Nova PE

Research goals and why the work was worth doing

The research goals are driven by two serious, overlapping social, respectively economic-technical changes.

From 2021 onwards, approximately one million people are going to retire in Germany each year. The huge number of future retirees results from the so-called “Baby-Boomers”. In the context of demographic change, companies must increasingly face the question of how they can secure the extensive experience and know-how of their employees.

The second change is based on the increasing speed at which digital transformation and agile work organisation are having an increasing impact.

The challenge is therefore to identify both, the experience-based, mostly tacit know-how that is critical to be successful, and to integrate the benefits in a working environment that is becoming more and more digital and agile.

Theoretical background

The Nova.PE knowledge-transfer refers directly one of the nine strategic fields of action analysed by the Later Life Workplace Index (LLWI) by Wilckens et al. (2020). The Nova.PE method is based on a concept, which was developed initially in cooperation with the Ruhr-University of Bochum to improve the demographic adaptability of companies and organisations. The main objective of this method is to identify, promote and transfer tacit knowledge of employees that are to be retired in the foreseen future

The evaluation of many hundreds of so-called knowledge transfer screening-interviews has shown that the main benefit of the transfer is based less on the classification of competencies, but in the specification of the risk relevance of the loss-critical know-how

Design/Methodology/Approach/Intervention

The systematic knowledge transfer process is built on 7 steps. The start is analysing and identifying the essential, indispensable competencies of older employees.

Step 1

In the screening interview the executive is going to assess the (risk-of lost) employee, within their business unit in terms of their competencies, which are relevant for knowledge transfer.

(high) expertise

exclusivity

strategic / future relevance

Step 2

Based on the results of the screening-interview the further temporal, methodological and organisational procedure is determined by the supervisor/ executive. He /she is the owner of the knowledge transfer, only if he expects a substantially impact, he will decide to invest resources in a transfer-process.

Step 3

In a semi-structured qualitative interview, the coach is working with the “knowledge-giver” on explication and analysis of transfer-relevant skills. The results are documented in the so-called “Tree of Know-how” and/ or "Job-Map”. The appreciation for the retiree or leaving employee is a key aspect for motivation of the knowledge-giver.

Step 4

Based on step 1-3 the executive selects and prioritize the (main-)subjects for the knowledge-transfer, he nominates the single recipients/ team members, their expectations and needs are prompted.

Step 5

On each subject a detailed transfer-plan will be worked out (learning objective, receiver focussed & active & effective) transfer methods are appointed, transformation framework and goals are set, milestones will be scheduled and contact persons will be named

Step 6

A transfer plan will be implemented by the recipient and the sender („on the job “) when appropriate amendment/adaption of the transfer-plan. Progress will be documented by the recipient.

Step 7

In the reflection- resp. final discussion the actual operational capability („learning success “) will be captured; process reliability, operational capability, conscious risks will be reflected systematically.

Results obtained or expected (if not available, it must be made clear when they will be)

A systematic view on the risk of losing (individual-tied) know-how is a success-critical factor for specific current and future aspects of work. It helps the executive to manage the requirements-matching competencies and human resources. It also enables the recipient(s) a better understanding of the implicit and experience-based side of success-critical know-how as a basis for a sustainable transformation.

Limitations

Limitations are a typically much too late “competency” -planning of the retirements of know-how critically employees and a focus of “head-count” while neglecting the “know-how & competency-count”.

Practical implications

In the evaluation of the screening interviews with executives showed us, that (depending on industry & size of company/ organisation) for a group of 5-10 percent of retirees the superiors assess a success-critically know-how and competency gap will be left, if no knowledge transfer is set.

Originality/Value

This is one of the very few methods to merge the experience-based knowledge management with sustainable transformation.

Paper 5

The Portuguese Version of the Later Life Workplace Index (LLWI): Relationships Between Organizational Practices, OFTP, and Thriving at Work

Eduardo André da Silva Oliveira, Faculty of Economics, Center for Economics and Finance at UPorto (cef.up), University of Porto, Porto, Portugal

Research goals and background

Workforces are ageing fast in most western economies (OECD, 2018) and the increasing proportion of older employees in today's workplaces raises several challenges. If the debate about organizational policies and practices for the aging workforce is to be moved forward, a better understanding of HR practices' effects needs to be developed.

Drawing on the HRM, socio-emotional selectivity theory, and thriving at work literatures, the aim of this study is twofold. First, we aim to examine the psychometric properties and validate a Portuguese version of the LLWI (Wilckens et al., 2020). The LLWI is a comprehensive set of organizational practices that encompasses nine distinct domains particularly relevant for the aging workforce. Against a context of ageing and age-diverse workforces, providing a valid, self-assessment and benchmark tool like LLWI may contribute to improve organizations' age management efforts. Second, given that age-inclusive HR practices were positively associated with both OFTP dimensions (i.e., focus on opportunities and remaining time), and with thriving at work (Oliveira, 2021), the present study intends to clarify if the organizational practices included in the LLWI have main effects on older employees OFTP, overall thriving experience, vitality levels, and learning process. Following recent calls for more investigation on the dimensionality of thriving at work (Kleine et al., 2019), it is important to understand if vitality and learning - the two dimensions of thriving at work - relate equally with contextual antecedents such as the LLWI domains. In so doing, this study hopes to increase our understanding about the extent to which organizational practices shape thriving at work from an older employees' perspective.

Design/methodology/approach

Following translation/back-translation and pilot testing procedures, cross-sectional online data was collected from a sample comprised of 329 employees aged 50 and older working at least 20 hours for one employer (with at least 30 employees) operating in Portugal. Discriminant (e.g., negative affect scale), convergent (e.g., age-inclusive HR practices), and criterion (e.g., turnover intentions scale) validity were examined following quality standards established for the translation and validation studies by the original LLWI development researchers. In addition to standard OLS regression analysis, we used Necessary Condition Analysis (NCA, Hauff et al., 2019) to disentangle which LLWI domains are sufficient and/or necessary conditions for an extended OFTP and thriving at work. Chronological age, gender, and organizational tenure were included as controls. Data analyses was performed in the R statistical computing environment.

Results

The Portuguese version of the LLWI showed good psychometric properties. LLWI domains are not necessary conditions for thriving at work, but six of them (e.g., organizational climate; knowledge management) seem to be sufficient conditions for employee thriving. Four LLWI domains (e.g., work design) can increase OFTP levels on average and all but leadership and health and retirement

coverage increase the focus on opportunities dimension of OFTP. Overall, performing NCA on the relationships between LLWI domains and both OFTP and thriving revealed a more comprehensive picture than standard regression analysis.

Limitations

Due to the cross-sectional design of the study and to the endogeneity problem, causal claims are open to debate. As such, we do not exclude that reverse/reciprocal effects may exist between, for example, LLWI domains and thriving at work, and that omitted variables might be driving the associations between constructs.

Conclusions & Implications

The current study aims to push forward the ongoing discussion about thriving at work dimensionality and to disentangle distinct relationships between focal variables (LLWI domains and thriving at work). In addition, this study will contribute to the HRM literature by showing the importance of organizational practices for the ageing workforce.

Relevance to the Congress Theme

With longer working lives becoming the norm, we expect our findings will contribute to advise organizations and HR managers to design practices that foster older employees' OFTP and thriving.

Relevant UN SDGs

This research is mainly focused, but not exclusively, on Sustainable Development Goal 3 (Ensure healthy lives and promote well-being for all at all ages) and on Sustainable Development Goal 8 (Promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all).

Keywords: OFTP, thriving at work, NCA

Paper 6

Cross-Cultural Validation of the Later Life Workplace Index (LLWI): Example of an English-Language Version

Julia Finsel , Institute for Management and Organization, Leuphana University of Lüneburg, Lüneburg, Germany; Anne Marit Wöhrmann , Federal Institute for Occupational Safety and Health (BAuA), Dortmund, Germany; Leuphana University of Lüneburg, Lüneburg, Germany; Mo Wang , Department of Management, Warrington College of Business, University of Florida, Gainesville, FL, USA; Max R. Wilckens , Institute for Management and Organization, Leuphana University of Lüneburg, Lüneburg, Germany; Jürgen Deller , Institute for Management and Organization, Leuphana University of Lüneburg, Lüneburg, Germany

Research goals

Due to demographic change and its implications for workforces worldwide, research on organizational practices that foster older employees' health, motivation, and performance has increased tremendously. However, existing measures of these organizational practices tend to use unidimensional scales, apply single-item operationalizations, or focus on specific types of practices. Thus, Wöhrmann et al. (2018) developed the Later Life Workplace Index (LLWI) to provide a multidimensional model of organizational practices for older employees. Recently, a German 80-item measure for this model was developed (Wilckens et al., 2020). Despite being based on profound qualitative and quantitative research, the applicability of the measure in countries beyond Germany is yet to be determined. Hence, the measurement is currently being translated and validated in more than ten countries across the world. This presentation illustrates the standardized validation procedure using the development of the English-language version in the U.S. as an example.

Theoretical background

The LLWI comprises nine domains, namely organizational climate, leadership, work design, health management, individual development, knowledge management, transition to retirement, continued employment, and health and retirement coverage. Each of these domains is divided into two to four indicators.

Method

The German measure was translated using a back translation procedure. The U.S. sample (N = 279) was collected via a panel provider to cover diverse organizational sizes and economic sectors. To examine measurement invariance, the U.S. sample was compared to a sample of 349 older German employees that had previously been utilized in the validation of the German version of the LLWI.

Results

The model fit of the factor structure proposed by the German measure was assessed on the domain level as well as for the overall nine-factor domain structure. For the English-language version of the LLWI, the domain-level model fit was (very) good or acceptable for all domains and showed superiority to alternative models. Internal consistency was acceptable to very good for all nine domains as well. The model fit of the overall nine-factor domain structure indicated some redundancy among the 80 items. Multigroup factor analyses comparing the U.S. sample to the German sample were conducted to further analyze the measurement invariance. For the English-language LLWI, the results confirmed configural and (partial) metric measurement invariance. The

analysis further includes the testing of convergent validity regarding conceptually similar scales, discriminant validity regarding affectivity, and criterion and incremental validity regarding individual work and health outcomes.

Limitations

The standardized validation procedure is designed cross-sectionally. Thus, we cannot infer causality regarding the observed relationships between organizational practices covered by the LLWI and older employees' outcomes. Additionally, the LLWI is a rather lengthy measure. Hence an international focus group is currently developing a short version of the LLWI.

Implications and value

So far, the LLWI provides a comprehensive German and English-language measure of organizational practices for older employees to advance research in the field of work and aging. Several other language versions are currently being validated to provide researchers from all over the world with a thorough measure. The LLWI can be used to examine the interrelations between the different domains of organizational practices and compare their relevance for older employees. Additionally, researchers can use the scales separately to focus on specific topics. Methodologically, the measure can be administered to human resource managers, (line) managers, or older employees. Thus, the LLWI measure facilitates research on a large variety of research directions and research designs.

Practitioners can use the LLWI to assess strengths and weaknesses regarding the organizational practices for their older employees. Based on the results, they can benchmark among peers and identify areas for improvement. Since the measure was developed independent of organizational size and industry, it can be utilized in a wide range of organizations.

Relevance to the Congress Theme

In light of the changing world of work and demographic change, researchers and practitioners can utilize the LLWI to formulate and implement recommendations on how to create better working conditions for an aging workforce.

Relevant UN SDGs

Based on these implications, our study also contributes to the SDG to develop decent working conditions to promote employment for everyone.

Symposium S045

Self-regulation When Confronted with Competing and Changing Goals: Insights on Well-being and Performance

Tina C. Armasu, Anita C. Keller | University of Groningen

science

What will be covered and why: Employees aim to achieve goals across various work and non-work domains. During goal pursuit, they regulate their thoughts, emotions, and behaviors to ensure they are moving towards goal achievement. The beneficial role of self-regulation for employee performance and well-being has been widely acknowledged. Self-regulation is a dynamic process involving cognitive, affective, and motivational aspects. Ensuring its success is a somewhat complex endeavor considering that between (e.g., work design, personal attributes) and within-person (e.g., disruptions, competing goals) factors may prevent workers from efficiently self-regulating to achieve their goals. Employee self-regulation may be further complicated through the unpredictable and ever-changing contextual challenges (e.g., changes due to COVID-19, competing work and non-work demands). Given that work and organizations undergo major changes frequently, it is essential to understand how employees self-regulate when faced with changing and competing goals. We argue that examining deliberate and automatic self-regulation can offer more insight into how employees navigate such challenging times. Research suggests that deliberate self-regulation plays an important role when dealing with changes in the work environment as employees invest valuable resources to modify their behaviors to maintain goal pursuit despite contextual challenges. Conversely, automatic self-regulation can occur effectively without the need for deliberate effort. The role of automatic self-regulation – particularly in an ever-changing environment – has been empirically overlooked but may also offer insight into (un)successful employee self-regulation as these processes may help employees save resources to manage other more demanding goals. This symposium aims to uncover processes underlying employee deliberate and automatic self-regulation to explore the between and within-person factors that impact deliberate and automatic self-regulation, offer insight into how employee self-regulation affects well-being and performance, and investigate employee self-regulatory experiences using quantitative and qualitative designs. In the first presentation, Roe, Shantz, and Rivkin explore how disruption to automatic self-regulation (i.e., routines) due to COVID-19 affects shifts in work meaningfulness towards other life domains in a qualitative interview study aiming to reveal and compare participants' experiences during the lockdown. This study highlights the role of disruption as a within-person hindering factor for employee self-regulation and work meaningfulness. In the second contribution, Keller, Liu, and Parker investigate the benefits of automatic self-regulation (i.e., morning routines) for performance and emotional exhaustion in a daily diary study. The study reveals that automatic self-regulation through routines is subject to gender differences as men tend to benefit more from engaging in routines. In the third contribution, Armasu and colleagues explore the relationship between deliberate and automatic self-regulation when dealing with disruptions and investigate the effect of employee automatic self-regulation (i.e., work routines) on performance at work using latent curve modelling. This study highlights the benefits of automatic self-regulation for work performance during uncertain circumstances. In the fourth contribution, Koch, Völker, and Sonnentag investigate the interaction between work and health self-regulatory goal behaviors to predict emotional states in a daily diary study. This study emphasizes employees' need to self-regulate across domains and showcases employees' challenge to navigate and pursue competing goals. Last, Chu-Hsiang (Daisy) Chang will discuss how work-related changes influence automatic and deliberate self-regulation and what practical steps can help employees deal with these challenges.

Relevance to the Congress Theme: We illustrate how changing and competing goals at work influence self-regulation and how these effects influence employee performance and well-being.

Research/Practical Implications: This symposium offers new insights into employee self-regulation in an ever-changing world of work. We contribute to the literature on self-regulation at work to unveil the effects of automatic self-regulation through routines as functional behaviors that help employees deal with disruptions. The symposium advances our understanding regarding employee self-regulation across domains by uncovering the challenges that come with striving to simultaneously manage and pursue goals in work and non-work domains. By addressing these questions using quantitative and qualitative designs, we explore the complexity behind employee self-regulation to provide theoretical and practical directions for understanding what contributes to effective self-regulation and ultimately helping employees engage in successful self-regulation at work and beyond.

discussant: Chu-Hsiang (Daisy) Chang, Michigan State University

Paper 1

"I don't feel like it's the be-all and end-all anymore": How do disruptions to self-regulatory processes affect work meaningfulness?

Amanda Roe & Wlad Rivkin | Trinity College Dublin; Amanda Shantz, University St. Gallen

Research goals and why the work was worth doing: We used the COVID-19 pandemic to explore how disruptions break self-regulatory processes and affect work meaningfulness. Accordingly, this research expands our understanding of the following research questions: How do disruptions break self-regulatory processes and thus lose work meaningfulness? Further, what happens when employees lose work meaningfulness? These are important questions because they may change how employees view their job, disrupting their performance, motivation, and commitment at work.

Theoretical background: Over the past two decades, research has provided significant insight into self-regulation (Baumeister & Heatherton, 1996; Lord et al., 2010). Self-regulation is the ability to develop, implement, and flexibly maintain planned behaviour to achieve one's goals (Carey et al., 2004). In addition, it affects individuals' ability to control their thoughts, emotions, and actions (Heatherton and Tice, 1994). Employees use self-regulatory processes to achieve work meaningfulness. Work meaningfulness refers to employees' beliefs that their work has at least one distinct purpose that they consider personally significant" (Robertson et al., 2020). Research has provided insight into how employees experience work meaningfulness and how organizations cultivate it (Lysova et al., 2019; Allan et al., 2019). However, we do not know what happens when disruptions break self-regulatory processes and the impact on work meaningfulness.

Design/Methodology/Approach/Intervention: To answer these questions, we interviewed 50 employees working from home in 2020 because of the lockdown. To explore these processes and build theory, we engaged in thematic analysis (Braun & Clarke, 2006) and case comparison methods (Kaarbo & Beasley, 1999) to unveil the similarities, differences, and patterns across the participants' experiences.

Results obtained: We draw on the meaning maintenance model to understand how disruptions break self-regulatory processes (Heine et al., 2006). Specifically, we focus on the premise that employees have a "need for meaning." According to the model, when an individual's sense of meaning is threatened, humans have an innate drive to compensate for this (Heine et al., 2006), known as the "fluid compensation" principle. Our findings support this principle. We found that the COVID-19 lockdowns disrupted employees' self-regulated processes related to work meaningfulness, that is, one or more disruptions to (a) unity with others (i.e., a sense of belonging); (b) serving others (i.e., a sense of contributing to others); (c) expressing full potential (i.e., experience a sense of achievement); and (d) developing and becoming self (i.e., a sense of being true to one's self) (Lips-Wiersma et al., 2009). For example, employees could not achieve future career accomplishments due to the changing nature of their work, disrupting their self-regulatory processes. When unable to achieve their goal of doing well at work (Carey et al., 2004), it affects their thoughts on work meaningfulness. As a result, employees began to look for meaningfulness outside the work domain, for example, by building non-work relationships.

Limitations: A limitation is that data were collected at one point in time. Follow-up interviews would be beneficial to determine the long-lasting impact of the disruption on self-regulatory processes on work meaningfulness.

Conclusions: Our study highlights employees' need for meaningfulness and applies fluid compensation to compensate for this loss. Furthermore, we introduce reflection as a key characteristic of how employees cope with disruptions that break self-regulatory processes. We found that reflection offered employees “moments of realization” (Rummel et al., 2019) that prompted individuals to take stock of their lives. Reflection came in two forms, negative backward-looking work reflection and positive forward-life reflection. Negative backward-looking reflection involves employees reviewing their choices about work. For example, employees questioned their commitment to work at the expense of other areas of their lives. This negative backward reflection initiated the loss of work meaningfulness. This highlighted employees’ “need for meaning” and instigated positive forward-life reflection. In addition, we found that employees thought about new life aspirations, which prompted shifts in meaningfulness to other life domains. Reflection aligns with research on cognitive appraisal theory (Lazarus & Folkman, 1984) because reflecting on one’s job and future life aspirations served as a cognitive re-appraisal of work meaningfulness (Lazarus & Folkman, 1984), which resulted in a reprioritization of values and beliefs around work meaningfulness.

Relevance to the Congress Theme: The prevalence of disruptions has increased threefold in the last 40 years (Wordsworth & Nilakant, 2021). For example, the 2008 Global Economic Crisis, the COVID-19 pandemic, the war in Ukraine, and the cost-of-living crisis (Wu et al., 2021). These disruptions shape the future of work because they disrupt and break self-regulation and impact work meaningfulness. This is theoretically important and has practical implications as work changes in the coming decades.

Relevant UN SDGs: This study is relevant to the UN SDGs as self-regulatory processes enhance individual growth, development, and well-being.

Keywords: disruptions, self-regulation, work meaningfulness

Paper 2

Are Morning Work Routines Relevant for Employee Well-being and Performance? A Gender Role Perspective

Anita C. Keller, University of Groningen; Sharon K. Parker, Curtin University; Yukun Liu, Zhejiang University

Research goals and why the work was worth doing: The COVID-19 pandemic has forced some workers to work remotely almost overnight, without preparation. This shift created a sudden disruption to employees' day to day work routines that usually help them to regulate how they switch from a private role to their work role. People create boundaries around different life domains and role to organize themselves and direct their attention and effort to the salient role. To easily move between different roles, employees create routines. For example, employees use the time during which they prepare their lunch for the day, commute to the office, and start their computer to emotionally and cognitively reconnect to their work and the tasks that lie ahead of them. During the early stages of the pandemic, employees tried to figure out how to be efficient at home while simultaneously learn to perform their tasks using new technology and dealing with distractions from people living in the same household.

Theoretical background: We argue that re-enacting morning work routines helps employees to transition from a private role to their work role and, as a consequence, be beneficial for well-being and performance. According to self-regulation and routine theory, routines activate relevant work goals, give a sense of direction and purpose, and can be performed without effort. As such, employees feel more energetic and engaged and as a result are more productive and satisfied with their workday. However, performing routines in the home setting may not be as effortless for everybody and might become effortful in and of itself with the various challenges presented in the working from home context. Based on social role theory, which suggests that women identify more strongly with the family role than men, we contend that gender acts as a moderator, resulting in routines being more beneficial for men than women.

Design/Methodology/Approach/Intervention: We conducted a two-week daily diary study with three assessments per day. One hundred and three remote workers in the Netherlands participated during the lockdown period in May 2020. We developed four items to capture morning work routines (e.g., "got dressed in 'work' clothes (that is, in clothes that are distinct from evening/weekend clothes") and relied on widely used measures to assess work engagement, emotional exhaustion, task proficiency, and job satisfaction.

Results obtained: Multilevel analyses revealed that engaging in routine behaviors is positively associated with daily work engagement which in turn resulted in higher task proficiency and job satisfaction. Morning work routines were also positively associated with daily emotional exhaustion. Cross-level moderation analyses further showed that the effects of morning work routines on emotional exhaustion are contingent on gender such that for men, morning work routines significantly reduced their emotional exhaustion; whereas for women, morning work routines increased their emotional exhaustion.

Limitations: Although the study has some strengths such as capturing employees during a time they tried to navigate substantial changes in their work and private life, there are also some limitations. For example, the study relied on a selected list of potentially relevant routine behaviors but did not

include an exhaustive list. In addition, the study cannot speak to differences between employees with or without children.

Conclusions: Our results suggest that morning work routines support employees to reap performance benefits, however, during massive change processes, re-establishment of routines may be costly and drain resources, at least for women. Although men were able to leverage performance and energy benefits of routines, women only benefitted in terms of performance; showcasing a complex pattern of how employees try to balance their different roles.

Relevance to the Congress Theme: The presentation contributes to the understanding of automatic self-regulation and its boundary conditions when employees are faced with changes in their environment.

Relevant UN SDGs: The paper also provides insights relevant to the UN Sustainable Development Goal of promoting employee well-being and health and understanding factors hindering or fostering gender equality.

Keywords: morning routine, automatic self-regulation, gender differences,

Paper 3

What Makes or Breaks Routines when Working from Home: Insights into Work Routines, Self-regulation, and Task Performance

Tina C. Armasu, University of Groningen; Sharon K. Parker & Caroline Knight | Curtin University; Barbara Wisse & Anita C. Keller | University of Groningen

Research goals and why the work was worth doing: Lockdowns caused by the COVID-19 pandemic forced employees to work from home with little prior experience but also prompted workers to adjust to various degrees of restrictions. Despite increasing knowledge on employees' adjustment to home office, little is known about employee self-regulation at the end of the lockdown when they transitioned from a restrictive lifestyle to having more freedom. Research investigating self-regulation mostly focused on deliberate self-regulation (e.g., planning) and overlooked automatic self-regulation (e.g., routines), but insight into both processes may be essential for explaining how employees adapt to disruptive contextual changes such as lockdowns. This study investigates the relationship between deliberate and automatic self-regulation and examines the role of automatic self-regulation through routines for individual task performance among employees working from home.

Theoretical background: We argue that beside deliberate self-regulation, employees engage in automatic self-regulation to manage lockdown-related changes. While deliberate self-regulation requires effortful behavioural adjustment that favours goal pursuit, automatic self-regulation – in the form of routines (i.e., automatic sets of consecutive actions) – is enacted without the need for awareness, thus saving precious resources. Research suggests that routines benefit employees' energy at work, stimulate their work engagement and are especially relevant during uncertain times, as they give individuals a sense of predictability and control. Thus, having routines can be beneficial which may explain why employees form routines in the first place. In this study, we explore the relationship between deliberate and automatic self-regulation (i.e., planning and routines respectively), examine the role of routines for individual task performance and investigate boundary conditions that influence the effect of routines on task performance in a sample of employees working from home during the pandemic. We argue that automatic and deliberate self-regulation go hand in hand. More specifically we suggest that with increased routine formation, the need for planning is decreased as routines becomes automatic. Conversely, as routines are disrupted due to contextual changes (i.e., easing of the lockdown), planning may increase to help workers re-establish their routines. Furthermore, we argue that due to their automaticity, and thus their efficiency, work routines can boost individual task performance as they are efficient ways to self-regulate in pursuit of goals. Finally, we consider boundary conditions that can influence routine formation namely scheduling autonomy, and distractions. More specifically, we suggest that when employees have the freedom to structure their day as they please, they can create routines that fit their lifestyle, thus increasing routine strength. We also argue that home- or work-related distractions hamper routine strength as they prevent individuals from adhering to their routines, undermining building up of routine strength.

Design/Methodology/Approach/Intervention: We used data from 182 German employees who were working from home full-time. In this longitudinal study, work from home routine strength, planning, task performance, scheduling autonomy, and distractions were measured at 6 time points resulting in 6 monthly questionnaires administered between January 2021 and June 2021. This timespan allowed us to capture effects prior and after the end of lockdown.

Results obtained: Results from latent curve analyses show that routines are disrupted when lockdown measures are relaxed, and this disruption is accompanied by increased planning. We found a significant positive effect of routine strength and of the increase in routine strength increase prior and after end of lockdown on task performance. Supporting our hypotheses, we found that scheduling autonomy benefits routine strength prior to end of lockdown and boosts the increase in routine strength before and after end of lockdown. Conversely, distractions hamper routine strength prior to end of lockdown and decrease new routine formation after lockdown.

Limitations: While we asked participants to reflect on daily routines, we measured routines monthly. Since routines are enacted daily, a daily diary design might have provided more information on within-person disruptions of routines. Moreover, our sample size was quite small for a robust latent growth model, thus a larger sample might yield more statistical power.

Conclusions: First, we advance theory on employee self-regulation by focusing on the relationship between deliberate and automatic self-regulation. Second, we explicate conditions under which self-regulation is improved or hindered by studying the effect of scheduling autonomy and distractions. Third, our spotlight on employee self-regulation after end of lockdown emphasises employees' need to also adapt to changes as they transition towards more permissive circumstances.

Relevance to the Congress Theme: Our results highlight the role of employee automatic self-regulation through routines for performance during ever-changing work circumstances.

Relevant UN SDGs: Our study contributes to the UN Sustainable Development Goal of good health and well-being by highlighting routines as self-regulatory behaviours which employees can use to optimize their resources and reach their work-related goals.

Keywords: work routine, automatic self-regulation, task performance

Paper 4

Healthy and Successful: How Health-Behaviour Goal Progress and Work-Task Progress Interact in Predicting Affective States

Theresa J. S. Koch, Sabine Sonnentag & Jette Völker | University of Mannheim

Research goals and why the work was worth doing: Health behaviours such as physical activity and healthy eating can be an essential part of everyday work life (Postema et al., 2021; Sonnentag et al., 2017) and have important consequences for employees' affective states (e.g., Calderwood, 2021; Conner et al., 2017; Reed & Buck, 2009). Hence, many worksite interventions have been developed to promote health behaviour at work (Abraham & Graham-Rowe, 2009; Maes et al., 2012). Such interventions often address self-regulatory processes – including goal striving as an essential behaviour change technique (Malik et al., 2014). However, interventions focusing on health-behaviour goal striving at work tend to overlook that making health-behaviour goal progress necessarily takes place while work tasks need to be accomplished simultaneously. Considering the resulting overlap of striving for health-behaviour goals and pursuing work-task progress, we aim to advance the understanding of their interplay in predicting affective states. These insights should help integrate health behaviour in daily work life in view of both physical (i.e., health behaviour) as well as psychological (i.e., affective states) outcomes.

Theoretical background: We build our research on the self-concordance theory (Sheldon & Elliot, 1999) by suggesting that the evaluation of one's health-behaviour goal as important predicts successful health-behaviour goal progress during the workday. Health-behaviour goal progress, in turn, should predict favourable affective states (i.e., high pride, low shame) at the end of the workday (cf., Weiss & Cropanzano, 1996). Integrating multiple-goals research (e.g., Hirschi et al., 2019; Vancouver et al., 2010), we further argue that work-task progress moderates the relation between health-behaviour goal progress and subsequent affective states.

Design/Methodology/Approach/Intervention: To test our hypotheses, we analysed daily diary data from 205 employees (1,399 days). Based on the concept of implementation intentions (Gollwitzer, 1999), participants in our sample received a daily instruction to set health-behaviour goals (i.e., increase of physical activity and decrease of unhealthy snacking behaviour). For example, a physical-activity goal could imply to take at least 10,000 steps during the workday and a healthy-eating goal could imply to eat at least three fruits when snacking at work. Our study measures (e.g., health-behaviour goal progress) referred to these day-specific health-behaviour goals.

Results obtained: Multi-level path analysis (Preacher et al., 2010) showed that goal importance positively predicted health-behaviour goal progress. Health-behaviour goal progress, in turn, positively predicted pride and negatively predicted shame at the end of the workday. We also found significant indirect relations between goal importance and pride as well as shame via health-behaviour goal progress. Moreover, the negative relation between health-behaviour goal progress and shame was stronger on days with low work-task progress. This pattern was also reflected in the conditional indirect effect between goal importance and shame via health-behaviour goal progress. However, work-task progress did not moderate the relation between health-behaviour goal progress and pride.

Limitations: Our research results are, however, subject to limitations. Specifically, we only included self-report measures, which raises concerns of common-method bias (Podsakoff et al., 2003). We

encourage future research to employ objective assessment of health-behaviour goal progress (e.g., activity trackers, photographic eating diaries) or leader ratings for work-task progress. Furthermore, as our data collection took place during the COVID-19 pandemic, we call for replications during other time periods to increase generalisability.

Conclusions: Nevertheless, our research contributes to literature on goal striving in health-behaviour at work by demonstrating the interplay of health-behaviour goal progress and work-task progress in predicting employees' affective states. Specifically, employees' main purpose at work belongs to their work tasks, so that feelings of shame following health-behaviour goal progress were even stronger when work-task progress was also low. Therefore, integrating multiple goals research can be a promising avenue for future research on health-behaviour goal striving at work. Practitioners can learn from our study that referring to personally important goals when instructing day-specific goal striving interventions promotes favourable affective states that emerge with goal progress. Importantly, health-behaviour goal progress at work thus has implications beyond increasing health behaviour, but with respect to how employees feel when leaving the workplace.

Relevance to the Congress Theme: Our research addresses the EAWOP congress theme of the changing world of work by focusing on the relevance of health behaviour in daily work life to sustain both health and well-being.

Relevant UN SDGs: Integrating health-behaviour goal progress and work-task progress further relates to the UN Sustainable Development Goal of promoting good health and well-being.

Keywords: healthy goal behaviors, affective states, work-task progress

Symposium S046

the future is now: how to enhance sustainable employability and leadership to match the changing world of work

Martine Coun & Tinka van Vuuren | Open Universiteit (The Netherlands)

science_practice

Our symposium will focus on interventions at work to enhance sustainable employability in order to be fit for the future both from both a leader and employee perspective. This subject is important because of :

Urgency : The world of work is changing due to demographic changes, the pandemic, Ukraine war and climate change.

Contribution : New digital literacy and collaboration skills of employee and leaders in the hybrid and changing work context are needed. This disruptive times might require a different kind of leadership in order to enhance sustainable employability.

Delivery : Changes in knowledge and skills, motivation, health of employees and leaders and work context are essential. We need to be fit for the future.The aim of this symposium is to get a better integration between science and practice to enhance sustainable employability. The concept of sustainability is introduced by The United Nation's Brundtland Commission (WCED, 1987) in which the importance of retaining the world's natural resources for future generations. Sustainable employability focusses on the importance of preserving employees' own resources for their future, and concerns the extent to which employees are able and willing to carry out their current and future work (Van Vuuren, 2012: Ybema, Van Vuuren & Van Dam, 2017). Sustainable employability is measured for instance with work ability, work engagement and employability. In addition, this employability assumes proactive workplace behavior on behalf of the employees and leadership definitely has to play a role in this. (Coun, 2021)

Work and organizational psychology offers many evidence-based insights about the antecedents of sustainable employability. In this symposium we want to bridge the gap from research to practice and use these insights to explore and tests interventions. It includes four presentations and an interactive discussion lead by a discussant. First, we focus on the changing role of empowering leadership on performance in hybrid work conditions and the role of professional isolation (1). Second, we present an intervention study which examines how a job crafting intervention in a municipality influence participants' willingness to continue working (2). Third, an intervention study is presented to improve the health and vitality of employees in the health care sector (3). Fourth, a study about how employers can effectively communicate the opportunity for employees to voluntarily participate in interventions is presented (4). Finally, our discussant will highlights and integrates the contributions of the four speakers. She will use her expertise as practioner to provide a general commentary on the four individual papers and will explore how the papers (in relation to each other) help to Integrate science & practice both from a leadership and employee perspective on sustainable employability interventions (5).

In this symposium we will share our research and professional experiences about this topic. We challenge work and organizational psychologists to develop interventions to enhance sustainable employability or to make people fit for the future.

Intended audience: both Academic and Practitioner

discussant: Diana Rus, Creative Peas & University of Groningen

Keywords: sustainable employability, interventions, leadership

Paper 1

The Dual Effect of Empowering Leadership on Adaptive Performance and Professional Isolation in Hybrid Work : Leads for Management interventions

Pascale Peters, Nyenrode Business Universiteit (The Netherlands), Inland Norway University of Applied Sciences; Martine Coun, Open Universiteit (The Netherlands); Maikel Nijmeyer & Rob Blomme | Nyenrode Business Universiteit, Open Universiteit (The Netherlands)

Research goals and why the work was worth doing

Organizations increasingly rely on workers' ability to adapt to fast changing conditions to enhance their sustainable performance. However, empowering leadership intended to support employees' adaptive performance is said potentially to be both enabling (via enhanced self-efficacy) and burdening (via enhanced job-induced tension). To put this dual process to the test, the research question of this study, conducted during the COVID-19 pandemic which enforced remote work and enhanced professional isolation, was as follows: 'To what extent is the relationship between empowering leadership and adaptive performance mediated by self-efficacy and job-induced tension and to what extent are these relationships moderated by professional isolation?'

Theoretical background

In this study, we built on the leadership and telework literature and focusing on the enabling and burdening process approach of empowering leadership to shed light on the underlying dual mechanism that can explain how empowering leadership relates to employees' adaptability, particularly in remote work contexts to perform sustainably. We acknowledge that the focus of work performance has shifted over the past 40 years from work roles with predefined tasks to a broader understanding of work roles within dynamic, hybrid organizational contexts. More specifically, particularly in these contexts, we consider adaptivity, reflecting employees' potential to deal with and anticipate task-related, situational, and ongoing demands, as a relevant outcome to sustain performance. The cognitive component involves recognizing changes and the mental ability to pay attention to changes. The affective component involves regulating emotions and processing negative emotions regarding changes. The behavioral component concerns the underlying behavioral repertoire and the behavioral tendencies that help the employee to proactively deal with change situations. More specifically, based on our literature synthesis, we expected the relationship between empowering leadership and adaptive performance to be positively mediated by self-efficacy and negatively by job-induced tension. Moreover, we expected professional isolation to weaken the enabling process and strengthen the burdening process.

Design/Methodology/Approach/Intervention

The study is based on survey data collected among 465 workers via social media during the COVID-19 pandemic.

Results

Preliminary analyses indicated that the enabling process is stronger than the burdening process, and that particularly the enabling process was impacted by professional isolation.

Limitations

The cross-sectional nature of the study implies that causal relationships between the variables could not be demonstrated. Moreover, this study focused on adaptive performance. However, it would be interesting to simultaneously include proficiency and proactivity as relevant outcomes of empowering leadership in future dynamic, hybrid work contexts.

Conclusions – research and or practical implications

The study provides leads for management interventions to sustain performance, particularly in hybrid and remote work contexts in which the perceived distance between employee and supervisor increases and the risk of professional isolation is high.

Keywords: empowering leadership, professional isolation and job-induced tension, sustainable performance

Paper 2

Job crafting & willingness to work longer: A longitudinal intervention study

Jeroen de Jong, Mark Tomassen & Emile van Nassau | Municipal Government of Lingewaard (The Netherlands); Hiske den Boer, Open Universiteit (The Netherlands)

Research goals and why the work was worth doing

In a job crafting intervention, employees are taught to make small adjustments in their work to accomplish better work outcomes. This study examined the impact of a job crafting intervention and proposed that a job crafting training would positively influence participants' job core dimensions and job resources and therefore have a positive impact on their willingness to continue working. In addition, it was hypothesized that job satisfaction would mediate this relationship.

Theoretical background

This intervention study was based on the Job Characteristics Model (JCM), the Job Demands-Resources (JD-R) theory, and used Wrzesniewski and Dutton's (2001) job crafting techniques.

Design/Methodology/Approach/Intervention

The study used a quasi-experimental design with a control group at a Dutch municipal organization. Older employees (N=245) participated in a job crafting training, an evaluation and completed three surveys (before the training, 1 month after and 6 months after).

Results

The results showed that the intervention had a significant increase in job resources and significant impact on participants' willingness to continue working both at time 2 and time 3. This relationship was fully mediated by job satisfaction. In addition, the results showed a significant difference between participants in managerial, professional and operational jobs.

Limitations

All participants in the job crafting intervention worked for the same local government organization, but employees from three different job categories were included to increase the generalizability of findings. In addition, only the self-assessments of the participants were measured.

Conclusions – research and or practical implications

This job crafting intervention study showed that it is possible to stimulate older employees' motivation to continue working through teaching them how to make changes to their job resources.

Keywords: job crafting interventions , satisfaction, sustainable employability

Paper 3

Time for Vitality: An empirical study into interventions at enhancing the amount of self-management among workers and their sustainable employability

Tinka van Vuuren & Judith Semeijn | Open Universiteit (The Netherlands); Beatrice van der Heijden, Radboud University (The Netherlands); Jan-Fekke Ybema, Universiteit Utrecht (The Netherlands)

Research goals and why the work was worth doing

In this study, the use and effect of 17 interventions aimed at enhancing the amount of workers' self-management is tested, and through this, the consequent effects on their sustainable employability.

Theoretical background

It is important that employees know why they have to self-manage their own health and vitality, and also want and dare to do so (Azjen, 1991; Van den Broeck et al., 2009; Van Scheppingen, 2014). This requires an attitude and culture from the employer that facilitates, informs and invites workers to manage themselves i.e. take control (Van Vuuren, Lub, & Marcelissen, 2016). We expect that employees who show more self-management on health and vitality, will be more sustainable employable as a result.

Intervention / Research method

Workers from a health care institution participated on voluntary basis in this research project (N = 997). Participants were assigned to a control group or to an intervention group. In the intervention group, participants were offered to participate in 17 different interventions. These interventions included activities aimed at, amongst others, preventing burnout, taking charge of one's career, yoga, and heart-rhythm-coherence feedback training. The control group participants were not offered these activities. Data were collected at the start (T1), in between (T2), and at the finish (T3) of the project, which took place over one year. There was substantial attrition: 191 participants filled out all three measurements, including 127 in the intervention group and 64 in the control group. To measure health and vitality, questions were asked about workers' health (BMI and general health) and about one's sustainable employability (engagement, burnout, work ability, employability and work performance). We investigated to what extent the interventions contributed to improving the participants' self-management of health and vitality. Specifically, we looked at both whether the participant was in the intervention or control group (intention to treat), and the relationship between the number of interventions that the worker was involved in and the outcome variables (dose-response relation). This was analysed by means of linear regression analysis.

Results

Results showed that the larger the number of interventions between the first and the last measurement, the higher the workers' self-management of their health and vitality in the last measurement. Furthermore, participants in the intervention group experienced slight improvements in sustainable employability i.e. general health, work ability and employability between the first and the last measurement, compared to a deterioration of these outcomes in the control group (after controlling for these outcome variables at the first measurement). These differences could only partly be explained by differences in age or educational level. However we found that participants in the intervention group on average were younger and higher educated than those in the control

group. Moreover, those in the intervention group were more likely to have a poor health situation on the first measurement, but experienced higher employability than those in the control group ($p < .05$). Classification in the intervention group appeared to not be significantly related to a higher self-management score ($p = 0.61$).

Limitations

Possibly, self-selection in assignment to the intervention or control group has played a role. We should be careful in drawing conclusions about the effects of the interventions, especially because the case organisation is in health care, which makes workers possibly also more conscious about their own health and vitality. Nevertheless, the relationship found between intervention and the change in variables under study between the first and last measurement gives an indication that these kind of interventions may contribute to improving health and vitality.

Practical implications

Interventions aimed at enhancing self-management seem to be helpful for improving the health and vitality of health care workers.

Relevance to the Congress Theme (The future is now: The changing world of work")

In addressing that people can enhance their self-management of their health and vitality with interventions at the workplace, and testing the effects on indicators of sustainable employability, we contribute to knowledge on how the world of work can be changed in a more desirable direction. With this study we also show that while workers have to deal with a changing world of work, enhancing self-management in health and vitality is possible, with outcomes that might again help in dealing with change more easily.

Keywords: Health and vitality, sustainable employability, self-management and interventions

Paper 4

How to stimulate employees to participate in vitality programs?

Pauline van Dorssen-Boog, Intrinzis (The Netherlands)

Research goals and why the work was worth doing

Vitality intervention programs can help employees to improve their well-being at work. However, this especially counts for those who participate on voluntary basis (Van Dorssen-Boog et al., 2022). This implicates that employers need to secure that intervention programs suit to employees' needs, and that employees are well informed about the opportunities to participate in interventions within their organization. This study analyses how employers can effectively communicate the opportunity for employees to voluntarily participate in a vitality intervention program.

Theoretical background

The effectiveness of vitality programs is not only a result of the content of the program, but also of the motivation of participants to develop themselves in the specific theme. If people are autonomously motivated for an intervention they will put more effort in achieving their goals (Van Dorssen-Boog, 2021). In contrast, if employers would push all employees to participate in a vitality program, this can lead to less active involvements in intervention activities, resulting in lower impacts (Deci, Olafsen & Ryan, 2017). Hence, employees need to be well informed about the opportunity to participate in vitality programs, and feel free to actually sign up (Van Vuuren, Lub & Marcelissen, 2016). This challenges employers to build a communication strategy which encourages employees to sign up for an intervention program (Nielson & Randall, 2013). For this, insights from social marketing may be helpful. The ultimate goal of social marketing is not to increase the financial benefits of the corporate, but the (sustainable) benefits for the individual or group, such as improving health and vitality (Lee & Kotler, 2016). Social marketing uses a mix of general marketing principles and techniques, such as making a good fit between the needs of the target audience on the one hand, and the product, price and place on the other hand. Moreover, the promotion of the product needs to be sufficient: a) the message should emphasize the problem and highlight the benefits of the program; b) the messenger needs to be recognized by the target audience; c) the promotion should have creative elements; d) a mix of communication channels should be used. Insights from social marketing may help employers to build an effective communication strategy for encouraging employees to participate in interventions. Such a communication strategy would be effective if employees a) sign up for interventions and b) feel that their needs for development are satisfied by the intervention.

Methodology

For this research a mix of quantitative and qualitative data was used from an intervention study in 14 Dutch healthcare organizations. Employees could voluntarily participate in a vitality event, an individual vitality check with a survey, a coaching interview, and a training self-leadership. The quantitative analysis is focused on the participation rate of interventions, and evaluation of the interventions by participants. The qualitative analysis is based on semi-structural interviews with 14 project managers who were involved with the implementation of the intervention.

Results

Most used intervention was the self-leadership training, and less used the coaching interview. Participants of all types of interventions felt that their expectation concerning the intervention was satisfied sufficiently. Travel distance influenced the decision to participate in the event or training. Price was not a threshold, since all interventions were free of charge.

The content of the promotion message was about the same for all organizations, since they got sample texts which they could use. Effective messengers were team managers and trainers via an introductory workshop. Later in the project, participants were acting as messengers by expressing their enthusiasm about the intervention. Creativity in communication through colourful postcards or a printed menu in the restaurant with the offered interventions seemed to be effective. Communication via intranet, magazines, and posters were experienced as less effective methods.

Limitations

Future research could evaluate the effectiveness of the communication strategy by asking employees how they got informed, what made them decide to participate, and whether the communication was appropriate as compared to what they priorly thought to be the benefits of the program.

Conclusions

In order to encourage employees to voluntarily participate in vitality intervention programs employers need to build a communication strategy. They need to make sure that interventions suit to the needs of employees in terms of content, price and distance, pay attention to how the message is formulated and creatively presented, as well as who brings the message.

Symposium S047

Challenge Stressors at Work: A Critical View at Stressor Classifications, Boundary Conditions, and Mechanisms

Bettina Kubicek & Roman Prem | University of Graz, Graz, Austria

science

State of the Art

The challenge stressor–hindrance stressor framework builds upon the idea that some work stressors, despite requiring effort and being associated with strain, hold the potential to promote employees' motivation and growth (Cavanaugh et al., 1998, 2000). Meta-analyses have shown that these so-called challenge stressors share, for example, positive associations with indicators of motivation, engagement, and performance (LePine et al., 2005; Crawford et al., 2010). However, in recent years it has been called into question, whether challenge stressors actually facilitate favourable work outcomes (e.g., Mazzola & Disselhorst, 2019).

New Perspectives/Contributions

This symposium focusses on challenge stressors at work. It takes a critical view on the classification of specific stressors and also investigates boundary conditions and mechanisms that could help explain, why favourable effects of challenge stressors have not been consistently found in previous research. Kubicek, Uhlig et al. show in a meta-analysis that two typical challenge stressors might have to be reclassified. Both, workload and cognitive demands, did not show the expected associations with strain, motivation, and learning. Moreover, the results suggested that many of the associations of challenge stressors with work outcomes might be moderated. Ohly and Menkhaus investigated proactive personality as a potential moderator. Using scenarios, they show that proactive personality enhances the appraisal of time pressure as challenging. This suggests that time pressure may not hold the potential for favourable effects for all but only for some employees. Baethge et al. also take a closer look at effects of time pressure and simultaneously investigate motivating and demotivating paths in a semi-longitudinal study. They show that time pressure is related to work engagement via two antagonistic mechanisms. Time pressure and work engagement are positively associated via meaning of work but also negative associated via loss of time control. Kern et al. turn the focus to interruptions and question their categorization as a typical hindrance stressor. They show that interruptions by work-related online messages can be functional. Using a diary study, they show that such interruptions are associated with employees' experienced prosocial success and that goal autonomy and goal commitment are important boundary conditions for these favourable effects of interruptions. The discussant, Norbert Semmer, will reflect and discuss these findings and take a critical view at the concept of challenge stressors at work.

Relevance to the Congress Theme

Today's changing world of work puts many challenges on employees. Typical challenge stressors such as workload and time pressure can intensify (e.g., Kubicek et al., 2014) and a more flexible organization of work can bring along cognitive demands (e.g., Prem et al., 2021). New information and communication technologies can also produce work stressors that not only promote strain but also motivation (e.g., Cascio & Montealegre, 2016). Taking a critical view at challenge stressors may help to understand how, in our changing world of work, work stressors can affect employees not only now, but also in the future.

Research/Practical Implications

The presented results further our understanding about the favourable effects of challenge stressors at work and also challenge the classification of typical challenge stressors and hindrance stressors. Practitioners should be aware of this and also keep the strenuous effects of work stressors in mind.

Overall Conclusions

The symposium will contribute to our knowledge of which work stressors hold the potential for promoting favourable work outcomes, and what boundary conditions and mechanisms play a role in these favourable effects of work stressors.

discussant: Norbert Semmer, University of Bern, Bern, Swit

Keywords: challenge stressors, favourable effects, critical view

Paper 1

Are All Challenge Stressors Beneficial for Learning? A Meta-Analytical Assessment of Differential Effects of Workload and Cognitive Demands

Bettina Kubicek & Roman Prem | University of Graz, Austria; Christian Korunka, University of Vienna, Austria; Ute Hülsheger, University of Maastricht, The Netherlands; Lars Uhlig, University of Vienna, Austria

Research Goals

Previous meta-analyses showed that challenge stressors are, though stressful, also motivating. However, their hypothesized gains related to learning are less well understood and the role of challenge stressors for learning remains controversial. Therefore, the aim of the study was to meta-analytically analyse the associations of two challenge stressors, namely workload and cognitive demands, with learning and to additionally examine the relations of these two challenge stressors with motivation and strain, to test whether they indeed show concurrent beneficial and detrimental effects.

Theoretical Background

According to the challenge–hindrance stressor framework, all challenge stressors – though being stressful – are associated with learning and motivation. In contrast to this assumption, action regulation theory posits that only cognitive demands, but not workload, are conducive to learning. Therefore, in the present meta-analysis we investigated which of the two theoretical assumptions is supported by empirical data. Furthermore, we tested whether job control, the level of a stressor, and the type of occupation may moderate the effects of these two challenge stressors on learning, motivation, and strain.

Methodology

Based on 417 independent samples collectively including 319,306 individuals, this meta-analysis tested the associations of workload and cognitive demands with learning, motivation, and strain and examined potential moderation effects.

Results

Results of a meta-analytical path model revealed that workload was negatively related to learning and motivation and positively related to strain. Cognitive demands were positively related to learning and motivation and negatively related to strain. Most of the associations of stressors with outcomes showed considerable heterogeneity, suggesting the presence of moderator variables. The detrimental effects of workload were more pronounced for care and social worker and for measures of overload. No moderations were found for country-level job control.

Limitations

Most of the studies considered in this meta-analysis had cross-sectional designs and used self-reported data, meaning that no conclusions about causality and the directions of effects can be drawn and additional concerns about common method bias may arise.

Conclusions

Taken together, the results cast doubts on whether stressors can actually be simultaneously detrimental and beneficial, as neither workload nor cognitive demands were found to have such a pattern of effects. However, the results underscore the importance of cognitive demands for good work design, as they are motivating and conducive to learning.

Relevance to the Congress Theme

The study contributes to the congress theme by providing clear evidence for the detrimental effects of workload and the importance of cognitive demands for designing jobs that help build a workforce able to deal with increasingly complex work.

Keywords: challenge stressors, learning, meta-analysis

Paper 2

Proactive Personality as a Personal Resource When Meeting Challenge and Hinderance Stressors

Sandra Ohly, University of Kassel, Germany; Carina Menkhaus, Köster GmbH, Osnabrück, Germany

Research Goals

Although proactive personality can be regarded as a personal resource, little is known about how this resource affects the appraisal of stressors, and ultimately individuals' wellbeing. Moreover, although stressors can be classified as hindering vs. challenging, recent research has question this classification, as individual appraisal might deviate. Proactive personality can be one factor explaining the appraisal and thereby this deviation.

Theoretical Background

Proactive personality refers to a dispositional individual difference in people's proclivity to take personal initiative in acting to influence their environments in a broad range of activities and situations (Bateman & Crant, 1993). People with a strong proactive personality recognize opportunities, take proactive coping strategy and action toward highly demanding environmental challenges. Challenge stressors are "work-related demands or circumstances that, although potential stressful, have associated potential gains for individuals" (Cavanaugh et al., 2000, p. 68), whereas hindering stressors do not have this potential for gain. We expect that proactive personality acts as a personal resource in secondary appraisal which will lead to higher challenge and lower hinderance appraisal.

Methodology

Hypotheses were tested in a controlled setting using scenarios manipulating the type of stressor (time pressure, role ambiguity, none) in an online sample using snowball recruitment.

Results

Results of a pilot study (N = 72) showed the stressor scenarios to be equivalent in terms of level of stressor and situational characteristics. Results of the main study (N = 297) showed that role ambiguity was appraised as more hindering overall (M = 2.90, SD = 0.87) than time pressure (M = 1.98, SD = 0.75) and the control condition (M = 1.99, SD = 0.77). In contrast to expectations, the challenge condition was not appraised as more challenging (M = 3.74, SD = 0.80) compared to the other conditions (M = 3.71, SD = 0.81 for control condition; M = 3.53, SD = 0.80 for role ambiguity). Proactive personality enhances the appraisal of time pressure as challenging, as expected.

Limitations

Although carefully constructed, the reliance on scenarios limits the external validity of findings.

Conclusions

The study supports the view that proactive personality is a personal resource that shapes the experience of stressful working conditions. Our suggest appraisal as mechanism how proactive individuals experience higher wellbeing. As practical implication, proactive personality which might be integrated more systematically in selection and recruitment efforts.

Relevance to the Congress Theme

Proactive individuals create changes in the work setting, and they might be better able to deal with future work stressors.

Keywords: challenge appraisal, time pressure, proactive personality

Paper 3

Two Sides of the Same Coin: Motivating and Demotivating Mediation Paths of Time Pressure and Their Relationship With Strain

Anja Baethge, Medical School Hamburg, Germany; Yannick Frontzkowski, Helmut-Schmidt-University, Hamburg, Germany; Ann-Kristin Menhardt, University of Bamberg, Germany; Miriam Schilbach, Leibniz Institute for Resilience Research, Mainz, Germany

Research Goals

Time pressure is commonly categorized as a challenge stressor. Accordingly, time pressure should positively relate to strain as well as motivational outcomes. However, empirical research yields heterogeneous findings regarding the motivational effect of time pressure and studies reported positive, non-significant or even negative relationships between time pressure and for example, work engagement. Previous research mostly gave quantitative explanations (i.e., referring to the level of time pressure or the duration of exposure) for these heterogeneous findings. What remains underexamined is a qualitative explanation of why time pressure (de)motivates employees. We want to take a first step in clarifying this question and offer two contradicting mediators, which may explain why time pressure consistently and positively relates to strain and simultaneously exerts motivating and demotivating effects.

Theoretical Background

Drawing on the challenge-hindrance framework, we introduce two explanatory mechanisms (i.e., a loss of time control and an increase of meaning in work) which may explain both, the consistent findings related to strain (here operationalized as irritation) as well as the diverse findings related to work engagement.

Methodology

In a prospective semi-longitudinal study with a two-week time lag we examined the mediating effect of time control and meaning between time pressure and work engagement on the one side and irritation (as a typical short/medium-term) strain indicator on the other side. The final sample consisted of 232 participants. To test our hypotheses, we used structured equation modelling.

Results

Time pressure negatively and positively related to work engagement through loss of time control and meaning in work, respectively. Further, only loss of time control mediated the time pressure-irritation relationship. Time pressure positively related to meaning in work, yet meaning in work was unrelated to employees' irritation.

Limitations

Data collection took place during the COVID-19 pandemic. Even though the first Lockdown in Germany had already phased out there still were social restrictions and companies were called to enable homebased telework. Thus, our study is mainly based on a sample working at home and this situation was new for most participants. We do not know whether our results can be generalized to quitter times.

Conclusions

Results demonstrate that time pressure likely acts motivating and demotivating at the same time, only through different paths. Hence, our study provides an explanation for the heterogeneous findings regarding the relationship between time pressure and work engagement which targets qualitative mechanisms.

Relevance to the Congress Theme

Time pressure and work engagement are known as very sensitive variables in situations of change (in situations of change usually time pressure increases, but employers wish to prevent a decrease in work engagement) and thus it is important to better understand their relationship.

Keywords: time pressure, antagonistic mediation paths

Paper 4

When Interruptions by Work-Related Online Messages Can Be Functional, Albeit Stressful: The Role of Goal Autonomy and Organizational Goal Commitment

Marcel Kern, Ruhr University Bochum, Germany; Dieter Zapf, Goethe University Frankfurt, Germany; Sandra Ohly, University of Kassel, Germany

Research Goals

We challenge the view that interruptions by work-related online messages are exclusively detrimental. Consistent with the challenge-hindrance stressor framework, we propose that interruptions involve both challenging and hindering aspects, and thus can exert positive effects on performance-related variables, while being positively associated with strain. We hypothesize that these interruptions may promote goal achievement and prosocial success, but only or especially when employees have high goal autonomy and organizational goal commitment.

Theoretical Background

Following the challenge-hindrance stressor concept, work interruptions are usually considered a hindrance stressor because they hamper the progress of work tasks (Jett & George, 2003). Research has shown that interruptions lead to a loss of concentration, as they often come at unexpected times (Mark et al., 2012). Employees are required to activate compensatory effort to process the incoming information and then resume original task performance. Thus, it is hardly surprising that research has consistently supported the strain effects of interruptions (Baethge & Rigotti, 2013). However, this view ignores the fact that interruptions by online messages may relate to important work objectives beyond a specific task. Employees need to achieve various primary and secondary goals at the same time at work and interruptions by online messages may be linked to one of these goals, e.g., a missing important information for an unfinished work task is provided. Moreover, interruptions by online messages may also serve team-related social goals (typically a secondary goal). Therefore, we believe that interruptions by online messages may be positively associated with goal accomplishment and prosocial success, but these effects should be highly dependent on one's control over goals. First, employees must have high goal autonomy to adequately respond to the interruptions. Otherwise, there will be no or negative effects on goal achievement and on prosocial success. Second, commitment to organizational goals should be high, otherwise employees will place less value on achieving the goals and thus will not benefit from coping with the interruptions, as postulated for challenge stressors. For exhaustion, we do not expect moderation effects because interruptions tax individual resources regardless.

Methodology

We conducted a ten-day diary study. Goal autonomy (Mulder et al., 2015) and organizational goal commitment (Brunstein, 1995) were each assessed with three items in a general survey. In an after-work survey at 5:00 p.m., we measured perceived interruptions using the same items as Sonnentag et al. (2016). At 8:30 p.m., goal achievement and prosocial success were assessed with an adapted version of the Grebner et al. (2010) scales and exhaustion with three items from the MBI (Büssing & Glaser, 1998). A total of 36 individuals reporting 306 days participated in the study. Hypotheses were tested using multilevel structural equation modelling. Cross-level moderations were analysed with the LMS method (Klein & Moosbrugger, 2000, see also Preacher et al., 2016).

Results

Results showed that employees experienced more prosocial success on days when they reported more interruptions. However, there was no significant relationship with goal achievement. As expected, interruptions were positively associated with exhaustion, confirming that they are stressful. Significant moderations were found for the relationship between interruptions and prosocial success by both goal autonomy and goal commitment. Contrary to expectations, however, we found no moderation effects for goal achievement. On an exploratory basis, we also tested moderations for strain and found that the positive relationship was stronger when goal autonomy and goal commitment were high.

Limitations

Despite the multilevel design with two daily surveys, we were unable to test causality. In addition, all variables were assessed using self-reports, which is known to artificially amplify relationships. However, cross-level moderation effects cannot be attributed to common-method bias (Siemsen et al., 2010). Finally, the sample size so far is somewhat smaller than would be desirable. However, despite the low statistical power, we were able to demonstrate significant results, as expected.

Conclusions

Apart from their straining effect, online messages interruptions can be associated with gains, as postulated for challenge stressors. However, these gains are dependent on access to resources, as shown by the moderating effects of goal autonomy.

Relevance to the Congress Theme

Information and communication technology messaging interruptions are becoming more common, as an increasing number of employees use mobile devices for work. Therefore, we need to know more about their functional use while preventing their negative effects.

Keywords: work interruptions, goal accomplishment, challenge stressors

Symposium S048

Interpersonal Emotion Regulation in Leadership and Teamwork

Cristian Vasquez, University of Sheffield

science

What will be covered and why (including the contribution of any discussant)

Interpersonal emotion regulation (IER) has been defined as the deliberate process of attempting to influence someone else's feelings (Niven, 2017). Although the topic of IER has only been introduced into organizational literature in around the past fifteen years (Niven et al., 2009), there is a good amount of empirical evidence showing that IER is an essential predictor of work-related outcomes, such as employees' social relationships, customer service satisfaction, and employee well-being (Troth et al., 2018). Concerning leadership and teamwork, prior empirical studies have shown that, for example, leaders who use IER build a more robust social exchange, trust and collaborative behaviour (Little et al., 2016; Madrid et al., 2018), and leaders' prosocial or egocentric motives to regulate followers' emotions also play a role in explaining leader effectiveness (Vasquez et al., 2021). However, although the existing evidence on IER indicates the relevance of this process to organizational life, several aspects of this phenomenon regarding leadership and teamwork remain obscured. For instance, we currently know little about the effects of leader IER on the compliance of their followers and on specific team processes, how team members appraise their leader's efforts to manage their feelings, or how team members' attempts to influence each other's emotions affect teamwork.

This symposium presents a collection of advanced studies seeking to understand the function of IER in leadership and teamwork. First, Naughton and colleagues explore the role of IER by distal leaders in crisis communications during the COVID-19 pandemic. Three studies (N=1197) show that distal leader affect-improving IER but not affect-worsening IER strategies influences citizens' intentions to comply with public health orders via perceived leader trustworthiness. The second and third presentations apply leader IER to teamwork. Madrid and Vasquez's results, based on a field multi-source design (N = 759 employees and 149 teams), show that leader affect-improving and -worsening IER strategies were positive and negatively related to team psychological safety, respectively, which in turn, was positively associated with team proactivity. Also in a team setting, the experimental study of Niven and colleagues seeks to shed light on the role of leader group prototypicality in shaping the impact of their IER behaviour, by influencing how team members appraise the motives of the leader. The final presentation also focuses on team members, but regarding their behaviours to regulate other members' emotions. Specifically, Vasquez and colleagues' results, based on a sample of 309 complete teams (1750 members), show that the relationship between team-level antecedent IER strategies and team relationship conflict depends on the level of disagreement between members (within-team IER variation), which in turn is associated with team performance.

Relevance to the Congress Theme

Leadership and teamwork are central topics regarding the changing world of work. As these changes occur, we need to understand better the contextual, social and interpersonal dynamics underlying these concepts. This symposium contributes to this direction by showing that IER used by leaders and team members can affect the collective behaviour of people (e.g., in terms of citizens or team members) by affecting social processes (e.g., public compliance, team psychological safety and interpersonal conflict). Furthermore, we show the role of critical contextual factors, e.g., leader

group prototypicality, in shaping the effects of IER. We strongly believe that having a nuanced knowledge of emotions' role and interpersonal regulation can be essential to understanding new leadership and teamwork configurations in this changing world.

Research/Practical Implications and Overall conclusions

The studies included in this symposium contribute to the interpersonal emotion regulation literature applied to organizations in various ways. First, they highlight the importance of IER strategies for leaders in motivating behavioral intentions in crisis communications. Second, they extend the team processes, emergent states and outcomes known to be affected by IER. Third, they provide insight into the contextual factors that shape IER. In practical terms, IER strategies represent behaviours that can be potentially modified by learning and training. Therefore, organizations and practitioners should consider IER as another intervention route to foster leader and team effectiveness. We trust that the work and discussion generated in this symposium will contribute to the emergent research on interpersonal emotion regulation at work.

Paper 1

Investigating the role of Leader Interpersonal Emotion Regulation during a Global Pandemic

Bernadette Naughton, Technological University of the Shannon: Midlands Midwest; Finian Buckley, Dublin City University; Lisa van der Werff, Dublin City University; Deirdre O'Shea, University of Limerick

Research goals and why the work was worth doing

During crises like the COVID-19 pandemic, political leaders needed to influence citizens to comply with public health measures and restrictions. These health measures (e.g., physical distancing, staying at home) had substantial negative effects on individuals lives and thus were sometimes met with defensive, non-cooperative responses. To influence citizens' compliance with public health guidance and nationally imposed restrictions, political leaders needed to effectively motivate them through their public communications. We argue that whilst negative emotions may have discouraged citizens from deviating from public health restrictions, other factors such as citizens' trust in political leaders played a role as well. We investigated whether the interpersonal emotion regulation (IER) strategies used by government leaders in ministerial briefings impacted citizens' compliance intentions via either negative affect or perceived trustworthiness.

Design & Method

Across three studies based in Western Europe, we investigated the effectiveness of IER strategies in motivating compliance with COVID-19 national restrictions amongst citizens in real ministerial speeches.

Study 1 :

The first study experimentally manipulated exposure to a single IER strategy (either affect-improving or affect-worsening) used in a real ministerial briefing to investigate its influence on participants' perceptions of leaders' trustworthiness, negative affect, and compliance intentions during COVID-19. The first author content analysed a ministerial briefing from the Taoiseach (Prime Minister) of Ireland which was broadcast on 17 th March 2020, announcing intentions to 'lock-down' the country for the first time due to rising COVID-19 cases. The first author parsed this speech into audio clips of six IER strategies, using the taxonomy developed by Niven et al. (2009). The six IER strategies identified included five affect-improving strategies, of which two were examples of positive engagement strategies (problem-focused engagement and cognitive engagement), and three were relationship–oriented strategies (validation, valuing, and distracting). One affect-worsening strategy (fear) was used.

Participants were restricted to UK residents to reduce a priori opinions regarding the leader which may have influenced responses. Participants (n=622) recruited through Prolific were randomly assigned to one of six conditions reflecting each of the six IER strategies. They were instructed to listen to an edited audio recording prefaced by a generic introduction by the Taoiseach, contextualizing COVID-19 as a pandemic, followed by a clip with one of the six IER strategies used in the ministerial briefing. After listening to the clip, participants were asked to complete a survey capturing their affective reactions to the audio clip, perceptions of the trustworthiness of the leader, and their intention to comply with the COVID-19 restrictions as a result of the audio clip.

Study 2 :

Study 2 extended Study 1 by additionally examining the simultaneous influence of affect-improving versus affect-worsening strategies in real time. We conducted a real time survey of Irish citizens' reactions to a national ministerial briefing by the Taoiseach of Ireland announcing a further two-week extension of national COVID-19 restrictions. An invitation to participate was distributed via social network platforms, e-mail to university alumni listservs, and to those indicating they were Irish residents on Prolific (n=272). Directly after the broadcast ended, participants who had signed up for the study were sent a link to the survey via email and text message, in addition to posting the survey on Prolific.

Study 3 :

In study 3, we replicated our second study but with a different government leader and with citizens of a different country (the UK). In the same manner as study 2, we focused on the impact of a full ministerial briefing broadcast and participants perceptions of the IER strategies utilized in this briefing (n=303).

Results

We consistently found that a leader's affect-improving IER strategies increased compliance intentions via perceived trustworthiness but not via reduced negative affect. Affect-worsening IER strategies demonstrated either no effect or an indirect worsening effect on compliance intentions of citizens.

Limitations

This study was limited to two nations in Western Europe.

Conclusions - Research/ Practical Implications

Our findings highlight the importance of IER strategies in ministerial briefings and perceived trustworthiness of political leaders in motivating citizens to comply with public health restrictions during a pandemic. Our studies are among the first to investigate the impact of leader extrinsic IER strategies in a distal relationship in a crisis, and the key mechanisms through which leader IER can impact follower's behavioral intentions

Relevance to the Congress Theme

The ability of national leaders to influence compliance was a pressing issue over the last few years. Although these studies specifically examined the COVID pandemic, other crises (e.g., climate change) will require similar skills from national leaders to influence citizens to change their behavior. Thus, our study is relevant for the future also.

Paper 2

Leader Interpersonal Emotion Regulation, Psychological Safety and Proactivity in Teams

Hector Madrid, Universidad Adolfo Ibáñez; Cristian Vasquez, University of Sheffield

Research goals and why the work was worth doing

Interpersonal emotion regulation (IER), namely, the strategies to elicit or change the emotional experience of interaction partners, has become a central research topic in recent years (Troth et al., 2018). Accordingly, various studies have shown that IER could benefit, or dampen, the sense of work-related well-being and job performance (Vasquez et al., 2020). Notwithstanding, most studies in this field have concentrated on the employee level of analysis, paying less attention to whether IER plays a role in collective situations, such as the case of teamwork (Madrid et al., 2019). This is a significant omission, considering that working in teams is common practice in today's organizations (Mathieu et al., 2019). Thus, in this study, we expand this body of knowledge by arguing and testing how leader IER is related to psychological safety and proactivity in teams.

Theoretical background

Niven et al.'s (2009) theoretical model proposes that IER strategies are classified into affect-improving or affect-worsening behaviors. In the first case, IER involves behaviors directed to produce positive feelings in interaction partners, for example, when discussing their positive characteristics or giving them helpful advice. In contrast, affect-worsening IER entails actions that make interaction partners experience negative feelings, such as when talking about their shortcomings or showing unfriendly toward them. We propose that when exerted by team leaders, these IER strategies should be related to team psychological safety, namely, a context described by team members' confidence in being themselves in the team environment (Edmondson, 1999). Leaders are a potent source of influence in the workplace (van Knippenberg & van Kleef, 2016), such that their motives, attitudes, goals, and behavior tend to shape team processes (Madrid et al., 2016). Based on this premise, leaders' affect-improving IER strategies would be positively related to team psychological safety because these behaviors signal interpersonal orientations that reinforce a sense of affiliation within teams. The opposite should apply to leader affect-worsening IER, which would be negatively related to team psychological safety. The latter, in turn, would be positively associated with team proactivity, which is defined as team members taking charge of making changes and improvements in the team environment (Harris & Kirkman, 2017; Parker & Collins, 2010). Team psychological safety should help express proactivity because it leads to embracing risk-taking (Frazier et al., 2017), which is necessary to challenge the teamwork status quo with new ways of doing things and face the possible resistance to change (Parker et al., 2010). Based on the above, two mediational processes are hypothesized: Leader affect-improving IER will be positively related to team proactivity by means of team psychological safety (H1), whereas leader affect-worsening emotion regulation will be negatively related to team proactivity through team psychological safety (H2).

Design & Methods

To test our hypotheses, we conducted a multisource survey study with a sample of teams of a bank organization. In this, team members provided information about the frequency of their leaders' IER behaviors and ratings of their team's psychological safety perceptions. In an independent survey, team leaders offered ratings of team-level proactive behavior within the team. Participants were 759 employees, part of 149 professional teams in the organization.

Results

Structural equation modeling analysis supported the two mediation processes proposed. Leader affect-improving IER was positively related to team psychological safety, which in turn was positively associated with team proactivity. In contrast, leader affect-worsening IER was negatively related to psychological safety, which in turn was positively related to team proactivity.

Limitations

The cross-sectional design leads to proposing and inferring causality between the variables in the model only in theoretical terms, and issues about common method variance, even controlled by using a multisource design, may be present in the model estimation.

Conclusions - Research/ Practical Implications

This study expands the literature about IER in the workplace by showing that emotion regulation plays an important role in the context of leaders and teamwork. Practitioners should bear in mind that leader IER is another intervention route to foster team effectiveness.

Relevance to the Congress Theme

In organizations, many transformations promising desirable outcomes occur in the social context of teams based on the active initiative of their members. Accordingly, our research provides meaningful knowledge of how to promote positive change in teams and organizations.

Relevant UN SDGs

This research is relevant to promote team effectiveness and, therefore, work-related well-being.

Keywords: Leadership, Interpersonal emotion regulation, Psychological safety

Paper 3

Leader Interpersonal Emotion Regulation and Group Prototypicality: A Social Identity Perspective

Karen Niven, University of Sheffield; David Holman, University of Manchester; Anna Topakas, University of Sheffield; Ashlea Troth, Griffith University

Research goals and why the work was worth doing

Leaders must manage the emotions of their team members to enhance group morale, instil motivation, calm anxieties that could distract from the team's work, and reduce simmering tensions. Hence it has been argued that effective leadership involves the deliberate influence of others' feelings (Troth et al., 2018), a process termed 'interpersonal emotion regulation' (Niven, 2017). Studies have shown that leaders' use of interpersonal emotion regulation is associated with high quality relationships with team members, team member well-being, and team citizenship and innovation behaviors (e.g., Little et al., 2016; Madrid et al., 2019; Vasquez et al., 2019).

While existing research identifies general patterns in terms of the impact of leader interpersonal emotion regulation, there has been little appreciation of whether context could shape how regulation is interpreted by team members. This omission is important because how regulation is appraised by others is likely to be the proximate driver of how effective interpersonal emotion regulation attempts are. The goal of this research is to shed light on a key set of socio-relational factors that shape the effects of leaders' attempts to manage the feelings of their team members, pertaining to leaders' group prototypicality.

Theoretical background

Our study draws on theory about the motives that drive interpersonal emotion regulation (Niven, 2016), in which a major distinction is posited between behaviors motivated by benefitting others ('prosocial') versus the person who enacted the behavior ('egoistic'). An important insight afforded by the nascent research on leader interpersonal emotion regulation is that whether leaders' motives are perceived by team members to be prosocial or egoistic is a key determinant of whether an attempt to influence others' feelings will have a positive or negative impact (Niven et al., 2019; Vasquez et al., 2021).

We further apply Hogg's (2001) social identity theory of leadership to understand how socio-relational factors influence team members' appraisals of their leader's motives. According to this theory, group prototypicality represents the extent to which a given individual is normative of the group as a whole. When a leader is highly group prototypical, group members will interpret their motives in positive terms (e.g., as serving the interests of the group), regardless of the nature of their behavior. For leaders with low group prototypicality, appraisals of their motives will conversely be dependent on the behavior itself (Platow & Van Knippenberg, 2001; Van Knippenberg & Van Knippenberg, 2005).

Design & Methods

Our study uses an experimental design, in which participants watch videos from an ostensible leader. Leader interpersonal emotion regulation behavior (affect-improving versus affect-worsening) and leader group prototypicality (high versus low) are manipulated using standardized text interspersed between the videos. Perceptions of the leader's motives, LMX and affect are captured

using validated scales. A task-based measure is used to capture effects on quality and persistence of performance.

Results expected

We will collect data by February 2023. We expect to observe an interaction between interpersonal emotion regulation behavior and leader group prototypicality. When leaders are low in group prototypicality, group members will appraise prosocial motives when leaders try to improve group emotions (e.g., using behaviors like praise, listening and positive comparisons) but egoistic motives when leaders try to worsen group feelings (e.g., using behaviors like criticism, ignoring and negative comparisons). Conversely, when leaders are high in group prototypicality, group members will appraise prosocial motives regardless of the leader's regulation behavior. In turn, appraisals of leader motives will have downstream consequences for leader-member relationships, group member affect and performance.

Limitations

Experimental research can lack in ecological validity. We will enhance the realism of our study using videos of a leader (rather than simply presenting participants with text) and by including a real performance task rather than relying on self-reported data.

Conclusions – research and/or practical implications

Greater insight into the contextual factors that shape leader interpersonal emotion regulation and how it is received by team members will provide a more nuanced understanding that is more readily applicable in practical terms for organizations and their leaders.

Relevance to congress theme

Organizational psychology is an applied discipline, but many of the insights we generate are decontextualized. We believe that the future of our discipline needs to take greater notice of the socio-relational factors that shape the processes we study, in order to be able to provide sound practical advice that allows us to change how people work for the better. The people best positioned to make a positive change for the future are leaders, and our research has implications for how they can adapt their actions in order to generate positive outcomes.

Paper 4

Interpersonal Emotion Regulation and its Diversity in Teams: Understanding its Effect on Team Relationship Conflict and Team Performance

Cristian Vasquez, University of Sheffield; Robin Martin & David Holman | University of Manchester

Research goals and why the work was worth doing

Interpersonal emotion regulation (i.e., the intentional regulation of others' affect) has been recognized as central to understanding affect dynamics in organizations (Troth et al., 2018). In the work team context, research on interpersonal emotion regulation (IER) has largely focused on its use by leaders to manage followers' emotions (Little et al., 2016; Vasquez et al., 2020). However, no previous study has investigated IER among team members (Marks, Mathieu, Zaccaro, 2001). As each member may engage in particular strategies to regulate colleagues' emotions, it is likely that they are heterogeneously distributed within a team. Thus, the main objective of this study is to explore IER diversity in teams and its effects on team relationship conflict and performance.

Theoretical background

Research on team diversity has shown the importance of conceptualizing team member variation to have a more comprehensive understanding of the impact of team phenomena on team outcomes (van Knippenberg and Mell, 2016). Grounded on the work of DeRue et al. (2010) on distributions of team self-efficacy, this research describes four general forms of team-diversity IER (i.e. shared, minority belief, bimodal, and fragmented). These team IER configurations represent different patterns of team-level agreement and disagreement which may impact the relationship of team IER and team conflict and performance.

In this study, we propose a moderated mediation model in which team IER interacts with the team IER configurations. Specifically, each configuration will show a differential effect on conflict when the average team IER is high versus low. In turn, these effects on conflict are translated into team performance. Specifically, based on Group Identity Theory (Tanis & Postmes, 2005), we argued that this effect might be particularly noticeable in the shared team IER configuration (e.g., high-level within-team agreement). When team members share their vision regarding the team, a unique social identity for the whole team is very likely (Lewis, 2011). Thus, the negative relationship between team IER and conflict will be stronger in the shared team IER configuration than in teams with non-uniform distributions, and this effect on team relationship conflict will, in turn, impact the level of team performance.

Design & Methods

The sample of 1,750 employees in 309 complete teams (i.e., teams with a hundred-percent response rate), of a multinational Latin American financial company. The average team size was 5.67 members (SD = 3.30). Using a field cross-sectional design, data were collected from two different sources. Team members reported the extent to which they engaged in IER within their teams and the perceived levels of relationship conflict. One week after, team leaders reported the levels of team performance.

Results

Results supported five Team IER configurations: shared, bimodal, solo-status low, solo-status-high, and two fragmented distributions. Moderated mediation results partially support the expected effects (using difference tests Edwards and Lambert, 2007) by showing that the mediation of team relationship conflict in the relationship between team IER and team performance was stronger in teams with the shared team IER configuration compared to the bimodal team IER configuration, and not significantly different when compared with the other non-uniform configurations (e.g., solo-status low, solo-status high, and fragmented team IER configurations).

Limitations

Although we use a multi-source strategy in which leaders provide measures of team performance, this research is limited by the use of cross-sectional design. Thus, it is not possible to infer causality between the variables.

Conclusions - Research/ Practical Implications

This contributes to having a more comprehensive understanding of the role of IER in teams, complementing the findings of prior research on leader IER (e.g., Little et al., 2016). In addition, this research contributes to the diversity literature by providing an empirical examination of diversity in a team. In practical terms, team member strategies to regulate colleagues' emotions represent behaviors that can be potentially modified by learning and training. Therefore, organizations must foster them.

Relevance to congress theme

Current transformations in work include changes in teamwork. This research provides meaningful knowledge of how to promote positive team dynamics by showing the effect of team member affect management and the role of team member diversity. This knowledge can be applied to new forms of teamwork, for example, hybrid and virtual teams.

Symposium S049

Leadership and employee well-being

Roy Sijbom & Hanneke Grutterink | University of Amsterdam

science

1. What will be covered and why

Leader behavior has a significant impact on the well-being of their employees (e.g., Montano et al., 2017). Yet, until recently the leadership literature has largely neglected research on employee health and well-being in favor of employee performance (Grant et al., 2007). This is surprising, because leaders play an important role in shaping the work environment and their behaviors are often associated with their subordinates' well-being (Arnold, 2017). The aim of this symposium is to bring together state-of-the-art insights on the role that leaders fulfil in promoting and maintaining employee well-being in the workplace.

Recent reviews and meta-analyses have identified a number of shortcomings in existing knowledge on leadership and employee well-being that limits our current understanding (Inceoglu et al., 2018; Montano et al., 2017). First, studies have predominantly focused on hedonic (usually job satisfaction), rather than eudaimonic (e.g., work engagement, thriving) and negative forms of well-being (e.g., stress, burn-out and exhaustion). Second, even though positive and negative forms of leadership differentially impact followers' well-being, we know relatively little about effects of negative forms of leadership (e.g., destructive, passive, abusive, overly critical). Third, the mechanisms underlying the relationship between specific leadership behaviors and employee well-being, as well as their boundary conditions have been underexamined. Finally, even though leaders affect employees at multiple levels of analysis (cf. Mawritz et al. 2012), few authors adopt a multi-level perspective. This symposium addresses these challenges by bringing together five studies investigating the role of leaders when it comes to creating a 'healthy' work environment.

2. Relevance to the Congress Theme

This symposium fits seamlessly within the theme of "Good health and wellbeing", one of the UN SDGs that EAWOP wishes to promote. It is vital to gain more insights into how leaders at all organizational levels can contribute to a healthy workforce. Together, the five studies presented in our symposium provide an integrative overview of current research on this topic and spark further research on the role of leadership in maintaining and developing employee health and well-being as stipulated in the UN SDGs.

3. Research/Practical Implications

In the first presentation, Jan Pletzer from the Erasmus University Rotterdam will present a meta-analysis on the relations between constructive and destructive leadership and follower well-being. In the second presentation, Svenja Sievers from Kiel University will contrast the causal effects of several forms of constructive leadership (charismatic, considerate, and directive) and mildly destructive (hypercritical or passive) leadership on follower well-being - using self-report, physiological measurements and emotion recognition software. In the third presentation, Rita Berger from Universitat de Barcelona will explain the mechanisms through which positive and negative leadership affect positive and negative forms of well-being. In the fourth presentation, Ilke Inceoglu from University of Exeter Business School will focus on critical leadership incidents and how these incidents are associated with followers' well-being. Finally, Roy Sijbom from the University of

Amsterdam will present a multi-level study about participative leadership and team commitment as psychological resources for employee well-being.

This symposium provides insights on the relationships between different types of leadership (constructive and destructive leadership styles/behaviors) and different well-being outcomes (i.e., work engagement, burnout, physiological distress and emotional reactions). Furthermore, this symposium includes a broad range of complementary methodologies each with its own strengths (meta-analysis, critical incident technique, lab experiment, and a multi-level field study). Finally, this symposium advances insight in the underlying mechanisms (i.e., including motivational, social-cognitive, relational and identification-related) and boundary conditions (i.e. team commitment, ambiguous and uncertain working conditions, group development, economic threat) of the relation between leader behavior and employee well-being.

4. Overall conclusions

Together these five studies signal the importance of leadership for employee health and well-being. Whereas active, positive forms of leadership such as constructive and participative leadership may function as psychological resources for well-being, work engagement and job satisfaction and reduce stress and burnout among employees, passive and negative forms of leadership are harmful for well-being. This symposium extends and integrates knowledge about these effects and offers insights into the mechanisms underlying the relationship between specific leadership behaviors and employee well-being, as well as their boundary conditions.

Keywords: leadership behavior; employee health and well-being;

Paper 1

The Relations of Constructive and Destructive Leadership with Follower Work Engagement and Burnout: A Pre-Registered Meta-Analysis

Jan Pletzer, Arnold Bakker & Kimberley Breevaart | Erasmus University Rotterdam

Research goals and theoretical background.

In organizational hierarchies, leaders often hold power over their followers (Krackhardt, 1990), meaning that followers are reliant on their leaders and leaders are able to enforce their will upon followers (Sturm & Antonakis, 2015). As such, leaders play a critical role in followers' work-related wellbeing (Skakon et al., 2010) and performance at work (Montano et al., 2017). One of the main aims of the current meta-analysis is to provide structure to the overwhelming leadership literature (Yukl, 2013) by testing the relations between leadership and employee wellbeing through the lens of Job Demands-Resources (JD-R) theory (Crawford et al., 2010; Demerouti et al., 2001). That is, we examine the motivational effects of constructive leadership and the health-impairing effects of destructive leadership on followers' work engagement and burnout, arguing that constructive leadership acts as a valuable job resource and destructive leadership as a hindrance job demand to followers. We also examine whether leadership relates to followers' performance via increased work engagement and decreased burnout, and provide meta-analytic effect size estimates for individual leadership styles as well as for the subcomponents of work engagement and burnout.

Methodology.

We conducted a systematic and pre-registered meta-analysis on several scientific databases, and relied on expert ratings to categorize leadership styles as either constructive or destructive. Data were coded by two individuals, resulting in agreement exceeding 95%. All discrepancies were resolved after revisiting the respective article and discussing the coding.

Results.

Based on more than 400 included studies, we find that constructive leadership behaviors relate positively to followers' work engagement (= .446, k = 253) and negatively to followers' burnout (= -.289, k = 179), whereas destructive leadership behaviors relate negatively to followers' work engagement (= -.241, k = 21) and positively to followers' burnout (= .364, k = 62). These findings demonstrate that constructive leadership behaviors have a motivating effect on followers, whereas destructive leadership behaviors have a health-impairing effect on followers. They also demonstrate that constructive leadership relates more strongly to followers' work engagement and destructive leadership more strongly to followers' burnout, both compared to the other leadership behavior and compared to the other indicator of followers' well-being. Relations were generally similar across individual constructive or destructive leadership styles, and also across the subcomponents of work engagement (i.e., vigor, dedication, and absorption). However, constructive leadership exhibited differential relations with the burnout sub-components cynicism (= -.299), emotional exhaustion (= -.253), and reduced accomplishment (= -.202), and destructive leadership correlated most strongly with emotional exhaustion (= .357), but significantly weaker with cynicism (= .197) and did not even correlate significantly with reduced accomplishment (= .040). We furthermore demonstrate that followers' work engagement partially mediates the relation of both constructive and destructive leadership with followers' job performance, whereas followers' burnout only mediates the relation of constructive, but not of destructive leadership with followers' job performance. Evidence for the

mediating role of followers' burnout is therefore substantially weaker than evidence for the mediating effect of followers' work engagement, and this finding holds across different performance outcomes (e.g., task performance, counterproductive work behavior, creativity and innovation).

Limitations.

Our findings need to be interpreted in light of the limitation that all but two of the included studies were based on correlational study designs, although we only find inconsistent evidence for the idea that effect sizes are stronger in cross-sectional compared to longitudinal or diary studies. Future research should nevertheless rely on more rigorous experimental control to alleviate endogeneity concerns. Further theoretical and practical implications as well as limitations and ideas for future research will be discussed.

Conclusion and Practical implications.

Taken together, the current results provide meta-analytic evidence for most of the core tenets of the JD-R theory in a leadership context and provide one of the first theoretically-driven overviews of the overwhelming literature on leadership in relation to follower's well-being. Organizations trying to foster employee work engagement could invest in leadership trainings based on constructive leadership behaviors, whereas organizations interested in reducing burnout and stress levels among followers should primarily focus on reducing the occurrence of destructive leadership behaviors.

Relevance to the Congress Theme.

Leadership plays a crucial role in shaping the present and future world of work, especially by relating to followers' motivation and well-being.

Keywords: Leadership; work engagement; burnout

Paper 2

How do leadership styles influence employee wellbeing under uncertain, ambiguous conditions in group setting?

Rita Berger & Paula Zamora | University of Barcelona

Research goals/why the work was worth doing

Due to volatility, uncertainty, complexity, and ambiguity in today's work environment, employees face increasing demands: new situations, unclarities and ambiguities that affect wellbeing (Reuveni & Vashdi, 2015). For achieving innovation organizations promote teamwork (Ramírez Heller et al., 2014) that can be a challenge leading to stress (Navarro et al., 2011) or be a resource for wellbeing (Di Fabio, 2017) and performance (Leuteritz et al., 2017). Leadership influences employees' wellbeing (Arnold, 2017), specifically under ambiguous conditions (Berger et al., 2019). Reviews on leadership and wellbeing call for analyzing complex mechanisms for positive and negative leadership, demands and resources, positive and negative wellbeing (Inceoglu et al., 2018). The study's goal, using the Job-Demands Resources model (JD-R) (Bakker & Demerouti, 2007), is to analyze under ambiguous and uncertain working conditions and group setting how positive and negative leadership influence wellbeing. Combining the diverse mediating working conditions uncertainty and ambiguity based on a cognitive-motivational approach and group development (GD) based on a relational and identification approach, we add information on how positive and less-researched negative leadership style increase or decrease demands and resources and wellbeing. We contribute by first, increasing the combination of mediator types including motivational, social-cognitive, relational, and identification-related mediators of leadership style and wellbeing when analyzing the working conditions, role ambiguity, unclear goals, new situations and GD. Secondly, we increase information on the seldomly analyzed identification-related mediator GD. Thirdly, we add knowledge on group level mediators that is nearly not analyzed (Inceoglu et al., 2018). Finally, using a positive and a scare researched negative leadership style (Barling & Frone, 2017) in the same model we contrast leaders' behavior on wellbeing.

Theoretical background

Using the JD-R model we combine demands and resources and examine their effect on employee wellbeing. We integrate leadership as a predictor affecting demands and resources (Schaufeli, 2015). Based on social environment model (Katz & Kahn, 1978), leaders shape employees' social environment, their perception of working conditions and their identification and relation with a team (Ashford et al., 2016) which can positively or negatively impact in followers' wellbeing. We use transformational (TFL) and the contrasting passive-avoidant leadership (PAL) (Hetland et al., 2011) of the Full Range Leadership model (Bass, 1985). The positive TFL was found to provide individual and team resources and to reduce demands (Diebig et al., 2016; Hentrich et al., 2017). Increased resources such as GD can mediate the relationship between TFL and positive outcomes such as team effectiveness (Leuteritz et al., 2017) and increase wellbeing on individual (Arnold, 2017; Inceoglu et al., 2018) and group level (Wang et al., 2011). The negative PAL is characterized by avoiding decisions (Harold & Holtz, 2015) and not providing resources (Chênevert et al., 2013). PAL is associated with perceptions of unclear guidelines (Hetland et al., 2011), creating mediators such as uncertainty and ambiguity (Skogstad et al., 2014) which as increased job demands might impair employees' wellbeing (Barling & Frone, 2017) and reduce team performance (Boies et al., 2010). Since negative forms of wellbeing have been less explored (Inceoglu et al., 2018), we analyze anxiety, a key indicator of

psychological wellbeing in occupational stress research (Nielsen et al., 2019), that previously showed a negative association with TFL and a positive one with PAL, both mediated by role ambiguity (Berger et al., 2019). Building on the JD-R we study how current job demands (new situations, unclarity of goals, role ambiguity) and team resources (GD) mediate the relationship between leadership styles (TFL, PAL) and positive and negative outcomes (team effectiveness, anxiety).

Methodology

An online survey collected data of 493 knowledge workers on TFL, PAL, new situations, unclarity of goals, role ambiguity, GD, anxiety, and team effectiveness. A multiple mediation model is proposed and tested through structural equation modelling using MPlus.

Results

The relations between TFL and PAL, anxiety and team effectiveness are partially mediated by unclear goals, role ambiguity, new situations, and GD.

Limitations

Mainly the cross-sectional data with one single questionnaire not allowing to interpret causal chains of relationships.

Conclusions

Results confirm our proposed model and extend the comprehension of the complex mechanisms between positive and negative leadership, employee wellbeing and team effectiveness. TFL reduces the analyzed demands and resulting anxiety and increases the resource GD and finally team effectiveness. PAL indicates the contrary by increasing demanding, unclear conditions and decreasing wellbeing and team effectiveness.

Relevance to the Congress Theme

These results can be used for leadership and team training to reduce unclear, ambiguous demands and to develop group resources for wellbeing and effectiveness.

Keywords: Leadership, wellbeing, Job demands-resources model

Paper 3

Participative leadership as a multilevel resource for employee well-being: A cross-level examination

Roy Sijbom & Hanneke Grutterink | University of Amsterdam

Research goals and why the work was worth doing

Accumulative evidence suggests that participative leadership behaviors are beneficial for employee well-being. Yet, two aspects have received little attention, with the risk of painting an incomplete and oversimplified picture. First, the influence of participative leadership on employee well-being has been primarily examined from an individual employee's perspective without taking the fundamental multilevel nature of participative leadership into account. We argue that beyond individual-level (within-group) differences in participative leadership perceptions, also variability between groups emerge over time. We refer to the latter as shared participative leadership perceptions - i.e. the average degree to which employees within a group perceive their direct leaders engage in participative leadership behaviors. Our study examines both individual-level participative leadership perceptions and shared participative leadership perceptions, to fully grasp its relationship with employees' well-being (i.e., job satisfaction and burnout). Second, group-level characteristics increasingly shape employees' work context. Accordingly, we examine workgroup commitment as a contextual characteristic that may function as a substitute for participative leadership in its relationship with employee well-being.

Theoretical background

Participative leadership is defined as joint decision-making or at least shared influence in decision-making by superiors and their employees. Drawing on conservation of resources theory and in line with earlier research, we suggest that participative leadership may function as a social resource for employees, thereby enhancing their well-being. Besides being a resource at the individual-level, we argue that participative leadership may also form a group-level resource by establishing a group norm that input of followers is appreciated, and that sharing information is psychologically safe. We propose that a groups' shared participative leadership perceptions increase followers' well-being beyond individual perceptions of participative leadership. Additionally, based on substitutes for leadership theory, we expect that workgroup commitment might moderate the relationship between individual perceptions of participative leadership and employee well-being, such that participative leadership will only add to employee well-being in groups with low levels of workgroup commitment.

Methodology

We tested our ideas in two survey studies with measurements spaced 3 months apart to minimize potential common method effects. Study 1 consisted of 155 employees of 48 workgroups. Study 2 consisted of 201 employees of 53 workgroups. In both studies, we tested the main effects of participative leadership (T1) (i.e., individual's perceptions of participative leadership (Level-1) and shared perceptions of participative leadership (Level-2)) on employee well-being (T2). Moreover, we tested the cross-level interaction (i.e., individual's participative leadership perceptions (Level-1) x workgroup commitment (Level 2)) on employee well-being.

Results

Common statistical benchmarks (ICC[1]; ICC[2] and r wg) showed that aggregation of individual participative leadership perceptions to shared participative leadership perceptions was empirically justified. Moreover, the important amount of variance between and within workgroups, underlined the multi-level nature of participative leadership.

Our results indicated significant relationships in the predicted directions between individuals' participative leadership perceptions (Level-1) and job satisfaction (Study 1: γ_{10} = .23, p = .041; Study 2: γ_{10} = .40, p < .001) and burnout (Study 1: γ_{10} = -.20, p = .063; Study 2: γ_{10} = -.32, p < .001). Furthermore, results showed significant positive relationships between shared participative leadership perceptions (Level-2) and both job satisfaction (Study 1: γ_{01} = .65, p < .001; Study 2:γ_{01} = .44, p = .004) and burnout (Study 1: γ_{01} = -.46, p = .004; Study 2:γ_{01} = .-39, p = .012). Finally, in both studies we showed that the interaction between individuals' participative leadership perceptions and workgroup commitment (Level 1 x Level 2) was significant and in line with our predictions for both job satisfaction and burnout.

Limitations

We used employee self-report measures. Individual-level participative leadership–employee well-being relationships are likely to be susceptible to mono-method bias and inflated correlations. However, this is less likely for cross-level main and interaction effects.

Conclusions and implications

First, our findings suggest that when it comes to employee well-being, using participative leadership behaviors is beneficial. However, in some situations, for example when workgroup commitment is relatively high, participative leadership behaviors are less beneficial compared to workgroups with low levels of commitment. Whereas organizations mainly divert to individual coaching or development trajectories to improve employee well-being, our findings point to alternative fruitful intervention routes such as team building or leadership development programs.

Relevance to the Congress Theme

Leadership plays a crucial role in shaping the present and future world of work, especially by relating to followers' motivation and well-being. As suitable leader behaviors can be trained (i.e., participative leadership behaviors), our research can make a lasting contribution to improving employee well-being (enhancing job satisfaction and reducing burnout) among employees.

Paper 4

The Causal Role of Leadership in Follower Well-Being: An Experimental Investigation

Svenja Sievers, Kiel University; Silja Bellingrath, University of Duisburg-Essen; Diana Boer, University of Koblenz-Landau; Deanne Den Hartog, University of Amsterdam; Claudia Buengeler, Kiel University

Research goals and why the work was worth doing.

Diminished employee well-being has unfavorable consequences for organizations and employees alike, and the Covid-19 pandemic has further accelerated this trend. Leadership has been put forward as an important determinant of employee well-being, as it can be both a strain and a resource. Yet there is a lack of knowledge concerning causality because correlational designs dominate the body of research on leadership and employee well-being. In addition, research has been selective regarding which leader behaviors and well-being outcomes are studied. As a result, it remains in the dark what the effects of various forms of constructive and destructive leadership on various indicators of well-being are. Does leadership causally affect follower well-being, and is constructive or destructive leadership more impactful? And are psychological and physical well-being affected similarly by leadership? This experimental laboratory study serves to investigate the causal effect of leadership on follower well-being, considering constructive and destructive forms of leading and both psychological and physical well-being.

Theoretical background. Leadership is likely to influence well-being of followers. Leaders can shape the way employees experience their social environment and appraise their own capabilities and the opportunity to gain resources. Leadership also increases or reduces resources and demands directly. Finally, leadership may be seen as an affective event at work and thereby shape well-being. When leaders employ constructive leadership such as being considerate, offering guidance or communicating an inspiring vision, this should therefore increase follower well-being (e.g., by increasing resources). In contrast, when leaders are actively destructive or passive, this should lower employee well-being by adding demands and withdrawing resources as employees need to cope with these behaviors.

Design/ Methodology/ Approach/ Intervention.

In a fully controlled computer-mediated laboratory study, we will randomly assign 647 participants to either one out of five treatment groups or a control condition. The treatments involve a series of video sequences of an actor presenting constructive (charismatic, considerate, and directive) or mildly destructive (hypercritical or passive) leadership during a mentally challenging task. We assess follower well-being before and after the treatment using survey-based measures and combine this data with continuous physiological measurements throughout the experiment. Finally, we examine followers' emotional reactions by means of automatic emotion recognition software during the task.

Results obtained or expected (if not available, it must be made clear when they will be).

We expect differences among constructive and destructive leadership behaviors in their effect on various forms of well-being. Data will be collected between October and December 2022. Results will be available at the time of the conference.

Limitations.

The standardized and validated leadership manipulation ensures high internal validity but also constrains the generalizability of the results given the virtuality and lack of actual leader-follower interactions.

Conclusions – research and or practical implications.

This study adds to prior research by illuminating the causal effect of different leader behaviors and offering insights into mechanisms underlying employee well-being consequences of different leader behaviors. By examining the whole range of leadership from constructive via passive to active destructive leadership and looking into affective, cognitive, and physical well-being, our systematic account of causal leadership effects on well-being fills blind spots and has the potential to raise awareness among practitioners regarding the well-being consequences of leadership.

Relevance to the Congress Theme.

The findings help to design effective interventions such as organizational stress and health management and leader development interventions. Our research thereby contributes to the Delivery aspect of the EAWOP Congress Theme.

Relevant UN SDGs (United Nations Sustainable Development Goals).

Employee well-being is a key aspect of sustainability (SDG3). Our research sheds light on the bright and the dark side of leadership for employee well-being and thereby demonstrates that additional strategies for sustainable people management in organizations are needed. As suitable leader behaviors can be trained, our research can make a lasting contribution to reducing sick leave and increasing the competitiveness of organizations through increasing the well-being of their workforces.

Symposium S050

Burnout Assessment Tool (BAT) advancements I: The dynamics within the BAT and its clinical validation

Jari Hakanen, Finnish Institute of Occupational Health, Finland; Angelique de Rijk, Maastricht University, The Netherlands

science

What will be covered and why?

Recently, a new burnout questionnaire has been developed to support better understanding of burnout in research and practice: the Burnout Assessment Tool (BAT; Schaufeli, Desart & De Witte, 2020). According to the BAT, burnout is a syndrome that includes four core dimensions (exhaustion, mental distancing and cognitive and emotional impairment), as well as secondary symptoms (e.g., irritability, sleeping problems, and tension headaches). An international consortium is currently using the BAT as the instrument of choice to measure burnout.

This two-part symposium presents advancements regarding I) the dynamics within the BAT and its clinical validation and II) the dynamics of burnout measured with the BAT and using longitudinal designs. This first symposium on the Burnout Assessment Tool (BAT), a recently developed instrument to assess burnout comprises five presentations from different countries focusing on temporal dynamics and predictive and clinical validity of the BAT. First, De Beer and his colleagues tested temporal relationships between the four components of burnout. Second, Popescu and Maricutoiu similarly tested temporal relationships between burnout components including also the two secondary symptoms (psychological distress and somatic symptoms). Third, Kolachec and Osin using latent state-trait models investigated to what extent burnout is stable vs. time-varying. Fourth, de Rijk and van Iperen will compare predictive validity of BAT-23, BAT-12 and their subscales for future sickness absence duration. Fifth, Schaufeli and his colleagues studied, whether the BAT is able to discriminate between those suffering and not suffering from burnout and whether similar cut-off points can be used across three European countries.

Relevance to the Congress theme

Burnout with its heavy human and economic cost is a persistent challenge for organizations in the changing world of work. These studies support the view that the BAT can provide valuable scientific and practical tool to tackle the burnout problem and in its part help to build sustainable future of work.

Research/practical implications

Insights into the dynamics of burnout components and clinical validation of the BAT instrument support better monitoring practices and will promote intervention development for preventing burnout.

Overall conclusions

Recently developed new measure to study and identify burnout, both longer (23 items) and shorter (12 items) version of the BAT, has shown to be valid instrument. These studies take a step further and shed light on the dynamics how burnout may develop over time. Moreover, the present studies also suggest that the BAT can be highly valuable practical tool in identifying different levels of risks to burnout and in predicting future sickness absenteeism.

Paper 1

Investigating the causal dynamics between the core components of the Burnout Assessment Tool with longitudinal mediation models

Leon T. De Beer, Norwegian University of Science and Technology, Norway; North-West University, South Africa; Wilmar B. Schaufeli, Utrecht University, The Netherlands; KU Leuven, Belgium; Hans De Witte, KU Leuven, Belgium

Research goals and why the work was worth doing

The research goal was to investigate the temporal relationships between the components of the Burnout Assessment Tool (BAT) to gain potential insights into how burnout may develop over time. This knowledge may broaden insight into the development of burnout in employees over time and may inform future intervention studies.

Theoretical background

Burnout is continued public health concern. The World Health Organisation has also not only recognised burnout as a work-related phenomenon but as a syndrome. The BAT is a novel instrument to identify burnout risks among employees (2020) but has already amassed a large body of psychometric literature which attests to its robust properties. Specifically, the BAT addresses many shortcomings of burnout instruments, especially the MBI which remains the gold standard. However, the longitudinal evidence for the BAT is still lacking and this study aims to contribute to not only the longitudinal evidence in the BAT project but also to the burnout literature by identifying causal pathways in which burnout may develop across time, in line with the suggested model of Schaufeli et al. (2020). Specifically, this model indicates that exhaustion leads to cognitive and emotional impairments and that this then leads to mental distance. Therefore, this study is not exploratory in nature, but follows the proposed theoretical process supposed by the BAT.

Methodology

For this study the 12-item version BAT-12 was used. Mplus 8.8 was used to test three cross-lagged panel models (CLPM) in a general sample of 1035 employees (Age M = 40.40 years; SD = 10.5; Male = 47.60%) in Belgium (Flanders). The first model was in line with our theoretical expectation that exhaustion time 1 will predict emotional and cognitive impairments at time 2 and that these will in turn predict mental distance at time 3. The second model was the reversed model, where mental distance time 1 predicts the two impairments at time two and then these exhaustion at time 3. Finally, a reciprocal model was tested where both models 1 and model 2 were combined into one. To consider the best-fitting model we considered the sample-size adjusted Bayesian information criterion (SABIC). We also used 10,000 bootstrap replications to estimate lower and upper 95% confidence intervals for the indirect effects.

Results

The results revealed that all three of the models had adequate fit to the data, that is: CFI and TLI > 0.90; RMSEA < 0.08. However, considering the SABIC values it was clear that the second (reversed) model was the worst model of the three (55327.48) and the first model the best-fitting model (55276.61). However, the third reciprocal model (55279.15) differed by only 2.54 points indicating that the evidence is positive against model 3 (>2) in favour of model 1 but not strong > 6).

In both model 1 and model 3 the stability paths over time were significant and positive, as would be expected. In line with our initial expectations, exhaustion time 1 significantly predicted both cognitive (β = 0.31) and emotional impairment (β = 0.42) at time 2, but only cognitive impairment time 2 (not emotional impairment time 2 [p = .220]) significantly predicted mental distance at time 3 (β = 0.12). Similarly, the indirect effects showed cognitive impairment time 2 to be a mediator between exhaustion time 1 and mental distance time 3 (β = 0.04, 95%CI[0.01, 0.08]), but this was not the case for emotional impairment time 2 (β = 0.03, 95%CI[-0.02, 0.07]). In the reciprocal model the only new insight was the significant path from cognitive impairment T2 to exhaustion T3, potentially revealing a feedback loop (β = 0.13).

Limitations

Even though a strength of this study was its longitudinal nature, the sample was not representative of the Belgium population and therefore careless generalisation of the results are discouraged. However, the evidence from this data did support the underlying theoretical rationale.

Conclusions – research and or practical implications

The results of this study show that the dynamics of burnout development are in line with the expectation that exhaustion leads to cognitive and emotional impairment (types of exhaustion) and that cognitive impairment leads to mental distance. These results may have important implications for the identification and intervention in burnout research.

Relevance to the Congress Theme

Burnout remains an important aspect of employee well-being in the changing world of work.

Paper 2

Temporal relationships between components the burnout syndrome: A longitudinal perspective in the case of university students

Bianca Popescu & Laurentiu Maricutoiu | Universitatea de Vest din Timisoara, Romania

Research goals. While most research studies approached burnout as a homogeneous phenomenon that needs to be explained by variables that are external to it, little is known regarding the temporal relationships between various burnout components.

Theoretical background. In the present contribution, we argue that burnout is a phenomenon that can be triggered by contextual factors (e.g., high workload, high time pressure), but it can be also self-sustained. Some burnout components contribute to the evolution of other burnout components, generating loss spirals that lead to increased burnout independent of the contextual factors. Early ideas suggested that burnout components develop in stages. For example, Leiter (1988) stated that emotional exhaustion leads to cynicism, which in turn leads to low personal accomplishment, while Lebowski (1989) argued that emotional exhaustion is the end-result of experiencing cynicism and low personal accomplishment. Although both perspectives assumed that some components of burnout contribute to the development of other burnout components, the empirical evidence to support such statements is still scarce.

In this contribution, we investigated the temporal relationships between burnout components, which we defined as the temporal relationships that can be found between burnout components (e.g., between exhaustion and mental distancing). Furthermore, to gain a more in-depth perspective, in the present contribution we used a new conceptualization of burnout (i.e., the perspective of the Burnout Assessment Tool – Schaufeli, Desart, & DeWitt, 2020). This conceptualization enlarges the operationalization of burnout, by investigating both primary burnout components (i.e., exhaustion, mental distancing, emotional impairment, cognitive impairment) and secondary burnout components (i.e., psychological distress and psychosomatic complaints).

Methodology . Participants were 354 undergraduate students (61.9% female, 57.60% studied Psychology and 42.40% studied Computer Sciences) that completed the BAT-23 weekly, for at least three out of five measurement moments (308 students had full datasets). We computed scores for the six BAT scales in the five measurement moments, and we analyzed the data using cross-lagged panel analysis. Missing data was assumed to be missing at random. Because we had four pairs of measurement moments that yielded slightly different estimations of similar relationships (e.g., the autoregressive relationships between exhaustion at different moments had different, albeit similar, values in different pairs of measurement moments). Therefore, we estimated an average parameter by constraining all relationships to be equal from one pair to another. This allowed us to focus our attention on significant relationships that were replicated in all four pairs of measurement moments.

Results . The overall cross-lagged panel model had adequate fit (CFI = .923, SRMR = .052), while the constrained model had similar values (CFI = .920, SRMR = .055). While controlling for the auto-regressive effects we found numerous significant cross-lagged relationships. Some of the significant relationships were reciprocal: past exhaustion predicted future cognitive impairment (B = .082, SE = .026, p = .002), and simultaneously past cognitive impairment predicted future exhaustion (B = .067, SE = .023, p = .004). We found similar reciprocal relationships between exhaustion and psychosomatic complaints. Interestingly, mental distance had reciprocal relationships with the two

forms of impairment (i.e., cognitive impairment and emotional impairment) but did not have any significant cross-lagged relationship with exhaustion or with the secondary burnout components. Finally, we found unidirectional relationships between past exhaustion and future psychological distress ($B = .098$, $SE = .025$, $p < .001$), and between past somatic complaints and both future forms of impairment.

Limitations. The present study has some limitations, as follows. Firstly, because the study investigated undergraduate students, its findings can be specific to this occupational group. Secondly, the study used short time lags between measurement moment (i.e., one week), and different relationships can be found by studies that use different time lags (e.g., months, or even years).

Conclusions . In conclusion, the present study found consistent evidence that supported the existence of temporal relationships between burnout components. Based on our results, we found two loss spirals that are characterized by reciprocal temporal relationships between groups of burnout components: exhaustion had reciprocal relationships with cognitive impairment and with psychosomatic complaints, while mental distancing had reciprocal relationships with both form of impairment.

Relevance to the Congress Theme: Burnout is a relevant well-being risk not only in paid jobs but also studying consists of structured, goal-oriented activities that may cause burnout and provide poor starting point for transfer to work-life.

Relevant UN SDGs:

3 - Good health and well-being

8 - Decent work and economic growth

Paper 3

Sickness absence duration of employees diagnosed with burnout in the Netherlands: predictive validity of the Burnout Assessment Tool (BAT)

Angelique de Rijk, Department of Social Medicine, Care and Public Health Research Institute, Faculty of Health, Medicine and Life Sciences, Maastricht University, the Netherlands; Wilmar Schaufeli, Research Unit Occupational & Organizational Psychology and Professional Learning, Faculty of Psychology & Educational Science, KU Leuven, Belgium; Department of Psychology, Utrecht University, Utrecht, the Netherlands; Robin Kok, Department Research and Business Development, HumanTotalCare Occupational Health Service, Utrecht, the Netherlands; Hans De Witte, Research Unit Occupational & Organizational Psychology and Professional Learning, Faculty of Psychology & Educational Science, KU Leuven, Belgium; Optentia Research Focus Area, North-West University, Vanderbijlpark, South Africa; Luuk Van Iperen, Department of Social Medicine, Care and Public Health Research Institute, Faculty of Health, Medicine and Life Sciences, Maastricht University, the Netherlands.

Research goals and why the work was worth doing

The Burnout Assessment Tool (BAT) indicates severity of burnout. In the Netherlands, occupational physicians (OPs) can officially diagnose burnout and have to offer return-to-work (RTW) guidance to employees on sick leave. In earlier research, concurrent validity of BAT-23 was found for the employee's RTW expectation. However, the predictive validity of BAT-23 for sickness absence duration (i.e., RTW) has not been studied, and understanding which subscales are most predictive could help to improve burnout treatment. Similarly, the predictive validity of the shorter BAT-12 and its subscales also requires evaluation, all the more due to its higher feasibility in practice. Therefore, this research aimed to test the predictive validity for sickness absence duration of the BAT-23 and BAT-12 and their respective four subscales. Possible confounders such as socio-demographic, job and treatment characteristics are taken into account.

Theoretical background

Theoretically, the BAT represents three aspects that are characteristic for burnout. First,

the energetic aspect that is expressed in the inability to carry out one's work properly because of chronic fatigue (Exhaustion scale). Second, the motivational aspect that is expressed by the unwillingness to perform because of mental distance towards one's job (Mental distance scale). Thirdly, the impaired functional capacity to regulate one's emotional processes (Emotional Impairment scale) and cognitive processes (Cognitive Impairment scale), expressed in sudden bursts of anger and in poor concentration respectively.

Earlier research with other burnout measures has confirmed the relation between severity of burnout and sickness absence duration. The few studies on specific burnout dimensions in relation to sickness absence duration are inconclusive. Regarding the four BAT subscales, we expect that more exhaustion requires a longer recovery period, and that strong emotional and cognitive impairments cause barriers to RTW. In comparison, mental distance is expected to show a weaker link with sickness absence duration. The relations between burnout (subscales) and sickness absence duration might depend on gender, age, type of treatment and job and organization characteristics.

Design/Methodology/Approach/Intervention

All 511 employees (47.6% male, 41.2 (10.8) years of age on average) diagnosed with a burnout at one occupational health service during February 2020-February 2021 were included and followed up until February 2023. Three sources of data were included: (1) Register data (gender, age (years), education, organization size), (2) self-reported data (date of first sickness absence day; BAT-23; job characteristics); (3) data added by the OP after each consultation (type of treatment, sickness absence percentage, RTW date). The relationship between BAT-23, BAT-12 and their subscales on the one hand and sickness absence duration on the other hand will be tested with multiple regression analysis and Cox regression analysis.

Results obtained or expected (if not available, it must be made clear when they will be)

Complete follow-up data of sickness absence is available in February 2023 (under Dutch law, a maximum of 2 years of sickness absence is possible).

Limitations

The quality of diagnosing burnout by OPs is not clear, and also employees still in the process of developing a burnout might be included. Only 21.3% of the employees reported a duration of the burnout complaints of 6 months or longer, which is one of the diagnostic criteria according to the Dutch guideline for burnout.

Conclusion research/practical implications

The research might confirm the validity of the measurement instrument. The practical implications can be large. If BAT total score predicts sickness absence duration, an employee's BAT score offer the employee, occupational physician and employer an indication of the sickness absence duration. This can be helpful for choices, e.g. regarding replacement. If there is no difference between BAT-23 and BAT-12, then this research offers additional support in favour of BAT-12. If the subscales predict sickness absence duration differently, this implies that individual scores on the subscales can be used to tailor burnout treatment and RTW guidance.

Relevance to the Congress Theme

To the best of our knowledge, the relationship between BAT and sickness absence duration has not been studied yet. There is a need for improving the diagnosis and treatment of burnout by OPs and other professionals. Knowledge about the predictive validity of BAT for sickness absence duration is needed to improve diagnosis and treatment of burnout.

Relevant UN SDGs

Knowledge on the predictive validity of BAT links to the SDG 'Good health and wellbeing'.

Keywords: Burnout, validation, sickness absence

Paper 4

Are international clinical cut-off scores for the Burnout Assessment Tool (BAT) feasible?

Hans De Witte, Research Unit Occupational & Organizational Psychology and Professional Learning, Faculty of Psychology & Educational Science, KU Leuven, Belgium Potential Research Focus Area, North-West University, Vanderbijlpark, South Africa; Janne Kaltiainen & Jari Hakanen | Finnish Institute of Occupational Health, Finland; Wilmar Schaufeli, Research Unit Occupational & Organizational Psychology and Professional Learning, Faculty of Psychology & Educational Science, KU Leuven, Belgium Department of Psychology, Utrecht University, Utrecht, the Netherlands.

Research goal and theoretical background . Clinical cut-off scores that allow to discriminate between healthy employees and those suffering from burnout are crucial for the practical use of any burnout questionnaire. To the best of our knowledge, such cut-offs are only available for the Dutch version of the MBI. However, they are outdated, dating back more than two decades. The recently developed Burnout Assessment Tool (BAT) can only make a difference in practice when validated, clinical cut-offs are available that are based on a sample of employees that suffer from severe burnout, as independently assessed by an occupational physician or psychologist. These professionals should use officially sanctioned criteria to assess severe burnout using a diagnostic interview. It is a crucial question whether these cut-offs are country specific or that different cut-offs emerge in different countries. The former would mean that similar clinical BAT cut-offs can be used across different countries, whereas the latter would mean that clinical cut-offs should be established for each country separately. This paper seeks to answer this most relevant question.

Method . Three patient samples including physician/psychologist assessed employees with severe burnout were analyzed from The Netherlands (N=334), Flanders (N=158) and Finland (N=50). Receiver Operating Characteristics (ROC)-analyses were carried out for the pooled county data as well as for each country separately. For the ROC-analyses three national representative samples of 'healthy' employees not suffering from burnout were used as reference groups: The Netherlands (N=1370), Flanders (N=1403) and Finland (N=1372). Similar analyses were carried out for the four subscales (i.e., Exhaustion, Mental Distance, Emotional Impairment and Cognitive Impairment) and the total-score of the BAT-23, the shortened BAT-12, and the ultra-short BAT-4. Two different cut-off scores were computed: (a) 'orange' for those at risk for burnout; (b) 'red' for those most likely suffering from it. Based on the clinical cut-offs that emerged from the ROC-analyses, the burnout prevalence for all three countries were estimated.

Results . Generally speaking, the area under the curve (AUC), a statistic that indicates the accuracy of the BAT, ranged between .81 and .96. Only the Mental Distance scale in the Dutch sample did not meet the criterion (> .75). This means that all versions of the BAT (including its subscales) are able to distinguish between healthy employees and employees suffering from burnout. Despite minor changes between countries, similar 'orange' and 'red' cut-offs with appropriate specificity and sensitivity could be established for all three national samples. The prevalence of burnout differs somewhat depending on the BAT-version, but estimates are in a similar range. In the Netherland, Flanders and Finland about 15%, 10%, and 13% are at risk for burnout, whereas 12%, 8% and 7% are likely to suffer from burnout disorder, respectively.

Limitation . Although the occupational physicians and psychologists who classified employees as suffering from burnout used specific diagnostic guidelines, it was not possible to test the inter-rater reliability of their classification.

Conclusion. The BAT is able to discriminate between those suffering and not suffering from burnout. Similar cut-off scores can be used across counties to identify those at risk for burnout and those who most likely suffer from burnout disorder. The fact that similar cut-offs can be produced clearly adds to the practical use of the BAT internationally. The 'red' cut-offs of the BAT-23 (including its subscales) can be best used to identify the most severe cases in a clinical treatment setting, whereas the 'orange' cut-offs of the BAT-12 (or BAT-4) can be best use for screening employees in organizations who are at risk for burnout.

Relevance to the congress theme . Undoubtably, burnout will remain an important issue in todays and tomorrow's changing world of work because job demands will continue to increase as a result of globalization, flexibilization, 24/7 economy, and shortage of labor. Hence, clinically valid cut-offs are crucially important to identify those who are at risk for burnout or suffering from it in order to implement targeted interventions to prevent and reduce burnout

UN SDG. The topic of burnout ties in with goals #3 'good health and well-being' and #8 'decent work and economic growth'.

Symposium S051

Shock around the clock: Examining career shocks across career stages

Jos Akkermans, Vrije Universiteit Amsterdam; Annabelle Hofer, University of Cologne; Daniel Spurk; Karen Pak, Tilburg University

science

What will be covered and why?

This symposium focuses on advancing the scholarly knowledge of career shocks, disruptive events that trigger deliberate career reflection (Akkermans et al., 2018). Research in this area has gained significant momentum in light of ongoing societal developments, such as the COVID-19 pandemic and #thegreatresignation (see, e.g., Akkermans et al., 2020), which have shown that careers are far from predictable. Indeed, emerging empirical findings show that career shocks play a critical role in people's work, such as person-job fit (Pak et al., 2021) and thriving (Mansur & Felix, 2021), and career, such as career transitions (Seibert et al., 2013; Wordsworth et al., 2021) and outcomes (Hofer et al., 2021; Kraimer et al., 2020). However, research is still developing, and further insights are needed to advance our knowledge in this area. More specifically, Akkermans et al. (2021) argued that, among others, we need a valid measurement instrument and more empirical insights into the role of career stages and contextual factors. In reply, this symposium presents four studies that start offering such insights.

The four studies all contribute to advancing methodological and contextual insights into the role of career shocks across different career stages. The first study showcases a quantitative study on medical students' stress and career decisions. Focusing on COVID-19 as a career shock, the study shows that career shocks can already impact career decisions at an early stage in people's careers. The second study focuses on how career shocks influence people's work and career experiences. They also examine the pivotal role of social support in dealing with such shocks. The third study zooms in on yet another career stage as it looks at the role of work-life career shocks and parents' return to work after having their first child. Finally, the fourth study presents the development and validation of a measurement instrument for assessing career shocks. The study could offer a concrete tool for future research in the area of career shocks. After the four presentations, an expert discussant will reflect on the four studies in this symposium, specifically paying attention to their novel contributions to the existing literature. The discussant has been an influential scholar in career shocks research.

Relevance to the congress theme

EAWOP 2023 focuses on the changing world of work. Our symposium fits this theme excellently, as career shocks are becoming more prominent and important for people navigating their work and careers. Indeed, given the increasing complexity and ambiguity of careers, people likely encounter more sudden disruptions now than ever. As such, understanding how disruptive events impact people's work and career processes and outcomes is timely and relevant.

Research and practical implications

Akkermans et al. (2021) called for more empirical research in the area of career shocks to ensure methodological rigor and a better understanding of mechanisms and boundary conditions. Our symposium contributes to answering this call by presenting a set of empirical studies uncovering several critical mechanisms and boundary conditions, such as stress appraisals (Study 1), social

support at work (Study 2), and identity processes (Study 3). Moreover, the symposium presents the validation of a measurement instrument (Study 4) that can trigger more research in this area. A valid measurement tool and more accurate insights into mechanisms and boundary conditions also contribute to practice. For example, educators, HR professionals, and career counselors can gain tailored insights into the specific factors they need to intervene on to help workers deal with career shocks.

Overall conclusions

This symposium shows that, across career stages, career shocks impact work and career outcomes. Moreover, the studies show how individual appraisals and contextual support mechanisms are pivotal in dealing with such shocks. In all, the symposium helps advance empirical knowledge of career shocks.

discussant: Scott Seibert, Rutgers University

Paper 1

Challenge or threat? Investigating the impact of the COVID-19 pandemic on medical students' career development through the lens of transactional stres

Daan Fris, University of Amsterdam; Anne De Pagter & Matthijs De Hoog | Erasmus Medical Center Rotterdam; Annelies Van Vianen & Edwin Van Hooft | University of Amsterdam

Research goals

Career shocks can trigger career transitions, influence career decisions, and cause stress (Akkermans et al., 2020; Akkermans et al., 2018). The COVID-19 pandemic is such a career shock which might have impacted the career decision-making process of medical students. Although the pandemic can be regarded as a negative career shock (generally resulting in negative outcomes), Akkermans et al. (2020) suggest that negative career shocks might have favorable effects on career outcomes as well. The present study aims to uncover when and why the pandemic as a career shock may have positive or negative consequences for students' career decision-making process. We propose an Appraisal-Coping Career Shock Model (ACCSM) to specify the cognitive and behavioral mechanisms that ultimately lead to positive or negative career outcomes.

Theoretical background

Transactional Stress Theory (Lazarus & Folkman, 1984) argues that people appraise events that have consequences for their interests and goals as challenging or threatening. These challenge and threat appraisals inspire, respectively, more or less effective ways of coping with the event, which subsequently affect levels of stress. Our ACCSM proposes that depending on their core self-evaluations (CSE), students appraise the pandemic as threatening to or as challenging for their career, which determines whether they engage in proactive or avoidant career behaviors. We specifically expect that challenge appraisals are associated with proactive career behaviors (PCB; e.g., networking), while threat appraisals are associated with avoidant career behaviors (ACB; e.g., procrastination) . In this study, we apply our model to career decision-making stress (CDMS) as a career outcome and propose that PCB and ACB relate negatively and positively to CDMS, respectively.

Methods

In June 2021, medical master's students (N = 2293) were invited to fill in a first questionnaire, of which 507 responded. This T1 questionnaire included the CSE scale and control variables (i.e., age, gender, and CDMS). Eight months later 279 students responded to the second questionnaire. This T2 questionnaire included the appraisal scales, the career behaviors scales, and the CDMS scale.

Results

Hypotheses were tested using path modeling. We controlled for CDMS (T1) in our analyses. Results showed that CSE and threat appraisal are negatively related. In turn, threat appraisal is positively related to ACB which are positively related to CDMS. Explorative analyses suggested that the positive relation between threat appraisal and CDMS is fully mediated by ACB. Results did not support relations between CSE, challenge appraisal, PCB, and CDMS.

Limitations

A limitation of this study is that the appraisal, career behaviors, and CDMS scales were measured at the same time point. This limits the extent to which we can draw conclusions about the directionality of the relationships. It should be noted though, that the two-wave survey design allowed us to control for prior CDMS, strengthening our conclusions.

Conclusion

We found evidence for the ACB-path but not for the PCB-path. The pandemic might have caused uncertainty about the future causing proactive career behaviors to be ineffective in reducing career decision-making stress. Besides, PCB might aid in identifying possible career obstacles resulting in increased CDMS.

Relevance to the Congress theme

The pandemic has severely impacted the health and careers of medical students as well as healthcare workers in general. To ensure a healthy workforce in the future, it is of critical importance that medical students make a career choice fitting with their personal interests, values, and competencies.

Relevant UN SDGs

This study contributes to the third and fourth SDGs from the UN. Optimizing students' career choices not only keeps them healthy but contributes to the quality of healthcare as well. Besides, part of high-quality education is providing adequate career guidance. This study offers several suggestions for medical schools to provide career guidance in the event of career shocks.

Paper 2

Social support, career meaning, and its outcomes in the context of the COVID-19 pandemic: Examining the role of career shocks

Janine Bosak; Sergio Madero, Tecnológico De Monterrey; Sushanta Mishra , Indian Institute of Management; Martina Gianecchini, University of Padova; Silvia Bagdadli , Bocconi University; Mami Taniguchi , Waseda University; Richard Cotton, University of Victoria; Evgenia Lysova, Vrije Universiteit Amsterdam; Émilie Lapointe, BI Norwegian Business School; Pamela Suzanne, Universidad de San Andres; Eric Michel, Northern Illinois University; Jon Briscoe, Northern Illinois University

Research goals and theoretical background

Employees' work and careers have in many cases been turned inside out during the Covid-19 pandemic as work shifted from the office to the home. The collective impact is comprised of multiple career shocks (Akkermans et al., 2018; Seibert et al., 2013), that have implications for the future of work. Consistent with the Job-Demands Resources (JD-R) model (Bakker et al., 2003), we investigate how work-related career shocks experienced during the COVID-19 pandemic serve as a boundary condition of the social support-career meaning relationship. In times of change, research suggests social support in the workplace is a key resource which helps employees adapt (Jolly et al., 2020).

One way that social support in the workplace can assist employees is through the construction of career meaning. Career meaning combines work experience, career goals, and social interaction into purpose (Shuck & Rose, 2013). Employees develop work meaning when others recognize the value of their work (Wrzesniewski et al., 2003). Consistent with the JD-R model (Bakker et al., 2003), we anticipate that during the aforementioned work-related career shocks in the COVID-19 pandemic which serve as job demands, people would seek meaning and that work relationships would be one key resource for developing such meaning. What's more, as a result of experiencing meaning, people may have a lower degree of burnout, experience increased well-being, career optimism, and employability. Therefore:

H1: The relationship between coworker career support and career meaning is moderated by work-related career shocks such that the relationship is stronger for employees who experienced more work-related career shocks during the COVID-19 pandemic.

H2: The relationship between coworker psychosocial support and career meaning is moderated by work-related career shocks such that the relationship is stronger for employees who experienced more work-related career shocks during the COVID-19 pandemic.

H3: The relationship between perceived supervisor support and career meaning is moderated by work-related career shocks such that the relationship is stronger for employees who experienced more work-related career shocks during the COVID-19 pandemic.

H4a-d : Career meaning is positively associated with (H4a) burnout, (H4b) well-being, (H4c) career optimism, and (H4d) perceived employability.

Design and methodology

We tested the hypotheses utilizing data drawn from 2,832 respondents resided in 18 countries worldwide and working full-time in managerial and professional occupations from the 2020-2021 5C

Career Barometer survey. We measured three types of social support (i.e., co-worker career support (three-items; Higgins, 2004), co-worker psychosocial support (four-items; Higgins, 2004), perceived supervisor support (four-items; Eisenberger et al., 1986)). Employees also reported on work-related career shocks experienced during the COVID-19 pandemic (Burton et al., 2010), career meaning (four-items from Steger et al., 2012), burnout (five-items from Maslach & Jackson, 1986), wellbeing (five-items; Topp et al., 2015), career optimism (three-items; McIlveen et al., 2013), and perceived employability (four-items; De Cuyper et al., 2014).

Results

Using Mplus 8.6 (Muthen & Muthen, 2021), CFA results suggested that the eight-factor model fits the data well ($\chi 2$ = 9,029.24, df = 953, $p < .01$, CFI = .95, TLI = .95, SRMR = .04, RMSEA = .04). Results supported H1 ($\beta = .15$, $p < .05$). H2 was not supported ($\beta = -.09$, n.s .). Conversely, H3 was supported ($\beta = -.18$, $p < .01$). Finally, our results suggest career meaning decreases burnout (H4a: $\beta = -.44$, $p < .01$) and leads to increased wellbeing (H4b: $\beta = .46$, $p < .01$), career optimism (H4c: $\beta = .47$, $p < .01$), and perceived employability (H4d: $\beta = .28$, $p < .01$), supporting Hypotheses 4a-4d.

Limitations

One of the limitations of the study is its cross-sectional data.

Conclusions and implications

Our results extend research studying the role of social context in shaping individual career-related and well-being outcomes (e.g. Allen et al., 2004; McArdle et al., 2007; Spurk et al., 2015). We find that receiving support from coworkers alone may not be enough for employees to experience career meaning and have other benefits in such contexts as the Covid-19 pandemic. Rather disrupting events (i.e. career shocks) are needed to stimulate the process of meaning creation in this context (Akkermans et al., 2020). Moreover, the results extend research on career shocks (e.g. Akkermans et al., 2018). We show that work-related career shocks serve as important boundary conditions shaping the effect of social support variables on career meaning.

Relevance to the conference theme and the UN SDGs

The paper addresses the future of work by studying career-related implications of COVID-19 and SDGs #3 and #8.

Keywords: Social support, career meaning, career shocks

Paper 3

Back to work after our first baby: How disruptive identity transformation affects dual earners' perceptions of the return to work

Paulien D'Huyvetter; Jos Akkermans, Vrije Universiteit Amsterdam; Marijke Verbruggen & Elisabeth Abraham | KU Leuven

Research goals

The transition to parenthood has received considerable research attention and is viewed as a major life event for couples. Less is known about how dual-earner parents experience the return to work after a first child. Going back to work may be a complex, disruptive event for new dual-earner parents, not only because it involves identity transformations and adaptation to changed roles (Lee et al., 2005), but also because the experiences of mothers and fathers are likely to be different and intertwined at the same time. With this study, we aim to gain more insight into these challenges by exploring the return to work as a potential career shock (Akkermans et al., 2018) for new dual-earner parents.

Theoretical background

Research addressing the impact of return to work after childbirth has mostly looked at labor market reentry for mothers. Overall, this research suggests that having children may function as a career shock for women associated with, for instance, career penalties (e.g., lower income), adjustment challenges (e.g., identity and efficacy challenges; Ladge & Greenberg, 2015), and adverse effects on mothers' well-being (Grether & Wiese, 2016). Although this research offers us valuable insights into the impact of reentry for mothers, it only depicts part of the reality for dual-earner couples. One shortcoming is that research insufficiently addresses the impact of reentry for men, who may face specific challenges in navigating their identities as new fathers and employees (Humberd et al., 2015). Another shortcoming is the limited understanding of how partners influence each other after an important event like the return to work. In line with this criticism, a recent framework by Crawford et al. (2019) calls for more research on dual-earner couples' responses to career and life shock events. This framework proposes that partners' individual sensemaking of a shock shapes intensity perceptions between partners, a process characterized by complex dyadic negotiations and identity processes.

Building on Crawford et al. (2019), this study explores how identity derailment – i.e., the feeling that one's identity has been disrupted by b-ecoming a working parent – affects shock intensity perceptions regarding the return to work. As presented in Figure 1, we expect that each partner's identity derailment will impact their own and their partner's shock intensity perceptions. Moreover, we expect that perceived work-related partner support will moderate the individual effects. Finally, we explore gender differences in these relationships because identity transformations, shock intensities, and the need for partner support may substantially differ between mothers and fathers.

Methodology

In December 2019 and January 2020, we collected data via a standardized questionnaire amongst 212 Flemish first-time parents, i.e., 106 dual-earner couples. Data will be analyzed using the Actor-

Partner-Interdependence Model, which allows for the estimation of both individual and partner effects (Cook & Kenny, 2005). Results have not yet been obtained but are expected in January 2023.

Limitations

Our study relies on cross-sectional data. Therefore, we cannot make inferences about the direction of potential causal effects. In addition, we used retrospective measurements for identity derailment and shock intensity perceptions, which may be sensitive to recall bias.

Conclusions: Implications and relevance for the future of work

This study extends existing research by concentrating on a subpart of the transition to parenthood, which is typically studied as a phase of the transition rather than a potential shock event for parents. Moreover, in OECD countries dual-earner couples are the most common household type today, many as full-time earners with children, and their prevalence could still increase in the future (OECD Family Database, 2022). With an eye on ensuring decent work and gender equality, our research may stimulate organizations to pay attention to the complexities of the return to work for an important group in society, e.g., by providing adapted support, mentoring, or flexibility during resocialization at work. Moreover, an in-depth understanding of gender differences and the interlinkage between dual-earner partners may guide policymaking on parental leave, flexible work arrangements, and more.

Relevant UN SDGs

This research contributes to several SDGs. Most notably, it connects with decent work and gender equality. To a somewhat lesser extent, the study also connects with good health and well-being.

Paper 4

Development and validation of the Career Shocks Questionnaire

Jos Akkermans, Vrije Universiteit Amsterdam; Daniel Spurk, University of Bern; Andreas Hirschi, University of Bern; Annabelle Hofer, University of Cologne

Research goals and theoretical background

Career shocks are disruptive events that trigger deliberate career reflection (Akkermans et al., 2018). Although research on career shocks is on the rise (see Akkermans et al., 2021), a validated measurement instrument still lacks. The emerging empirical research confirms that these shocks play a pivotal role in people's career decisions (e.g., Seibert et al., 2013), career transitions (e.g., Rummel et al., 2021), and work and career outcomes (e.g., Blokker et al., 2019; Hofer et al., 2021; Kraimer et al., 2019). However, quantitative research has thus far mainly used Seibert et al.'s (2013) scale. While this is a good starting point, this measure conflates the shock event with its career impact and refers to specific pre-defined shocks (see Akkermans et al., 2021). Therefore, the field needs a more valid measurement instrument that can be used independently from specific shocks. Our project aims to do this by developing and validating the Career Shocks Questionnaire.

Design and methodology

We carefully reviewed the available conceptual and empirical work on career shocks in the first step of the research process. Based on this review, we created an initial over-inclusive item set of 20 items. We then proceeded with an expert check by 17 scholars knowledgeable about the topic of career shocks. Their feedback allowed us to delete several unclear items and reformulate some others. Furthermore, based on their feedback, we decided to have separate questions for positive and negative shocks, as it would be difficult to test any effects if these were combined. This led us to include 15 items for positive shocks and 15 items for negative shocks – the same items but with positive vs. negative terms – for the exploratory factor analysis. After these analyses and potential changes to the items, we will proceed with a second data collection to conduct CFA. Afterward, we aim to finalize the career shocks questionnaire and conduct a third independent data collection consisting of two measurement waves. This final dataset will serve to conduct additional validity checks, such as predictive, discriminant, and incremental validity (e.g., compared to Seibert et al.'s scale and existing measures for chance events).

Results obtained and expected

The initial expert check allowed us to improve the clarity of the items and reduce the number of items. We are currently analyzing the first data to see if the career shocks questionnaire items will form one overall dimension for positive career shocks and another for negative career shocks. We expect to finalize the EFA in October 2022. Next, we will collect data for the CFA, which we expect to complete before the end of 2022. Finally, we will collect data to conduct the additional validity checks mentioned earlier, which we aim to finalize in Q1 2023. Overall, we expect to have a final career shocks questionnaire well before the EAWOP conference takes place.

Limitations

We decided to create a generic measurement instrument for career shocks because lists of specific events are never exhaustive and, from a conceptual perspective, do not form a coherent scale (e.g., being laid off and losing a loved one are entirely different events). As such, a generic questionnaire

allows respondents to make their assessment of disruptive events that triggered them to reconsider their career investments. Though we will include an open-ended question to assess those specific events, a potential limitation of this approach is that the items do not lend themselves well for diagnosis or intervention purposes. That said, we also plan to test more tailored items, e.g., where we replace terms such as „a disruptive event" with „the recent reorganization."

Conclusions and implications

The career shocks questionnaire will allow scholars to use this validated instrument to assess career shocks in future quantitative research on career shocks. We expect the final questionnaire to be relatively short, with four items for positive and four for negative shocks. As such, it will be easy to implement in larger survey research.

Relevance to the conference theme and the UN SDGs

The changing world of work likely features many disruptions in people's work and careers. As such, a valid method for assessing career shocks will significantly contribute to scholarly work and practical interventions moving forward. Our research also connects with several SDGs, notably good health and well-being and decent work.

Keywords: Career shocks, measurement instrument, validation

Symposium S052

Emerging technologies and AI in organizations: Implications for job design and employee well-being

Pascale Le Blanc, Eindhoven University of Technology; Maria Peeters, Utrecht University

science_practice

What will be covered and why?

Influential trends, such as robotization, big data, and Artificial Intelligence not only play a major economic role, but they also have a profound impact on the way we live and work (Özdemir & Hekim, 2018). As technological innovations succeed one another at high speed and their applications are becoming increasingly versatile, the efficient functioning and survival of organizations requires the ability to continuously align work processes with the flow of digital innovations (Nylén & Holmström, 2015). Insight into the consequences of working with new technologies for job quality and employee well-being can be translated into guidelines for designing and implementing emerging technologies in a human-centered instead of a technology-centered way. In this way, a stimulating and healthy work environment in the midst of this ongoing technological revolution can be ensured. In this symposium, 5 empirical studies that focus on the implications of emerging (technological) changes for job design and employee well-being are presented.

In the first contribution, Hosseini and colleagues present the results of a daily diary study among logistics warehouse employees and their supervisors about the extent to which working with (new) technologies affects their job characteristics and well-being at work (i.e., exhaustion).

In the second contribution, Schneider and colleagues address the problem of the opaqueness of Machine Learning-based systems. Using existing ML use cases in the railway domain, they take on the challenge of providing new insights in designing explainable AI within an overarching design framework for socio-technical integration.

In the third contribution, Fraboni and colleagues emphasize the psychological and organizational aspects of industrial Human-Robot Collaboration. They present the development of a toolkit targeted at expanding guidelines for safety, efficiency, and acceptance of Human-Robot Collaboration HRC in the manufacturing sector.

In the fourth contribution, González-Romá and colleagues clarify the influence of job digitalization (i.e., the extent to which digital technologies are used by employees to perform their jobs) on overall perceptions of organizational fairness, and positive affect in a 3-wave study among 158 Spanish employees.

Finally, in the fifth contribution Sijbom and colleagues expand the focus by exploring the consequences of general changes at work (including, but not limited to technological ones) for the learning behaviour of employees. Results of two studies among representative samples of Dutch employees showed that changes at work generally foster employee learning and that supervisors' role in employee formal and informal learning is relatively large.

Research/practical implications

This symposium provides insights into (changing) job characteristics and employee well-being in workplaces where new technologies have recently been introduced. It contributes to knowledge about a more human-centered design and implementation of new technologies at work.

Overall conclusions

The results of the studies in this symposium help us to better understand the complexities of implementing emerging technologies and AI in organizations and suggest ways to foster its functional consequences, reduce its dysfunctional ones and consequently improve employee well-being and performance.

Intended audience

This symposium is interesting for both academics and practitioners

Keywords: emerging technologies, job design, well-being

Paper 1

Technologization in the warehouse: a diary study among logistics employees

Ziagul Hosseini, Pascale Le Blanc & Evangelia Demerouti | Eindhoven University of Technology

Research goals: The goal of this research is to (1) explore the relationship between physical workload, work pace and exhaustion, and (2) examine whether and how autonomy and participation in decision making buffer these relationships.

Theoretical background: Place your order now and get it delivered the same day.' That is what most webshops offer to their customers when they buy a product. The logistics sector, which is responsible for the warehousing, packaging and distribution of products, is challenged to pick and pack orders fast, and deliver them on time. Warehousing companies opt to make use of labour-saving technological innovations, such as automated picking and packing tools, to meet customers' (high) expectations. However, technologies can positively and negatively affect job characteristics, with unintended consequences on employees' job content, experience of meaningful work, wellbeing and performance. For example, technologies may make work-related tasks more complex and stressful due to information overload. However, when technologies help out, assist with, and take over the dull, dirty, and dangerous tasks, employees can focus on more challenging and meaningful tasks (Parker & Grote, 2020), such as coordinating and solving technical breakdowns (Smids et al., 2020).Taking the Job Demands-Control model (Karasek, 1979) as our theoretical basis, we investigated which job characteristics play an important role in working with technologies and their relation to employees' wellbeing. In other words, we wanted to know to what extent (new) technologies affect warehouse employees' job characteristics and their work-related outcomes.

Design/Methodology: We conducted a daily diary study among seventy-one warehouse employees in three Dutch warehousing companies. Using short daily surveys, we asked questions on, among other things, physical workload, work pace, work autonomy, participation in decision making and exhaustion (on a five-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree), or 1 (never) to 5 (always)). Warehouse employees filled out these (online and on paper) short diary surveys at the end of their workday for five consecutive days. Multilevel regression analyses were performed using MLwiN. We recognised two levels in the regression equations. All day-level variables were person-mean centred and the person-level variable was grand-mean centred. The dependent variable was day-level exhaustion, the independent variables were day-level physical workload and day-level work pace, and we had two moderators namely day-level work autonomy and person-level participation in decision making.

Results: Our results show that autonomy and participation in decision making buffer the positive relationship between physical workload, work pace and exhaustion. In other words, an increase in physicalworkload leads to more exhaustion in case of low autonomy and low participation in decision making. We also found that an increase in work pace leads to more exhaustion in case of low autonomy and low participation.

Limitations: A limitation of this study could be that the data is self-reported. However, taking multiple measures over five days could reduce the common method bias effects.

Conclusions: Extensive research into psychosocial aspects of (new) technology implementation may uncover ways in which warehouses can establish sustainable workplaces in the new technological era. Specifically, we explored whether and how (new) technologies impact the nature of work or the

conditions under which work is performed. This knowledge can guide companies to introduce and implement technologies to benefit the organization and their employees' wellbeing in a sustainable manner.

Relevance to the congress theme:This research fits the congress theme 'the future is now: the changing world of work' since logistics warehousing are going through this technological transition whereby employees' workplace and tasks are changing due to the deployment of new technologies.

Relevant UN SDGs: This research focuses on what impact new technologies has on warehouse employees in order to ensure that they can keep performing their job in a good health while warehousing companies can create workplaces that foster innovation to keep pace with the high demands and help drive the logistics sector forward. Good health and wellbeing; decent work and economic growth

Keywords: technology, sustainable workplaces, well-being

Paper 2

Designing explainable ML-based systems for collaborative work in the railways: First insights

Lena Schneider, ETH Zurich; Daniel Boos, Swiss Federal Railways; Gudela Grote, ETH Zurich

Research Goals

This study addresses the challenge of designing explainable AI within an overarching design framework for socio-technical integration based on the recently proposed concept

of networks of accountability. The results will provide first insights into the effects of AI on human factors in safety critical domains and the different stakeholders involved

Theoretical Background.

The opaqueness of machine-learning (ML) based systems is a key barrier to fully benefitting from these technologies. To advance research and practice on explainable AI, there needs to be a much clearer understanding of who the users are (e.g., system developers, employees working with the system, individuals affected by decisions made by the system) and what purposes the explanations aim to fulfil (e.g., technology acceptance, learning, collaboration).

Explainability is tightly linked to questions of shifting control and accountability in these systems. Control is an essential prerequisite for accountability; if it is lacking actors have to explain and justify actions they had no choice over. As ML-based systems may autonomously expand and alter their knowledge base and the way that knowledge is used for predictions and decision-making, humans interacting with the system have less influence and control increasingly resides in the AI itself, while the accountability remains with humans. The resulting control-accountability gap is not an entirely new phenomenon, as traditional automation already severely restricts human control. The opaqueness and dynamism of AI significantly adds to this gap, rendering efforts at human-centred design aimed at adequately matching control and accountability of actors through socio-technical integration particularly challenging. Control and accountability cannot be matched at the level of the individual human user anymore. Rather, all stakeholders involved in the development and use of AI need to be part of "networks of accountability" (Slota et al., 2021, p. 11). To date, no full account exists of what such networks entail for the development and use of systems based on AI-technologies. Accordingly, some general characteristics and functions of such networks need to be laid out before explainability requirements for different stakeholders and for successful negotiations of accountability among these stakeholders can be defined. Our study does this by building on a conceptual framework developed by Grote et al. (2022). In industries characterized by high safety standards and strict regulation, such as the railway industry, a potential loss of human control is particularly relevant and the gap between control and accountability is a limiting factor for the use of ML systems. Moreover, in many cases ML systems will be an integral part of work processes and coordination activities between individuals and teams within and between different occupations. Based on different professional backgrounds and roles along with different degrees of required control and accountability, explainability requirements may vary substantially, but need to be jointly met to allow effective collaboration.

Design/Methodology.

Using existing ML use cases in the railway domain, which will be collected from the literature as well as through qualitative interviews, we will develop a taxonomy regarding types of users, types of

collaborative use, distribution of control and accountability among users, and other relevant stakeholders. Issues concerning accountability and explainability of AI will be identified with the critical incident technique. We will conduct a document analysis on the most advanced internal AI projects collected by the network group for AI at the Swiss Federal Railways (SFR). Topic coding will be used to develop a taxonomy which will define requirements for the establishment of networks of accountability and the curation of accountability negotiations.

Results.

First results based on the qualitative interviews are expected by Spring 2023.

Limitations.

While the use of ML-based systems is gaining more and more interest and companies are planning to implement them, few industry sectors are actually using these systems which means the available use cases will be limited. Furthermore, while the qualitative interviews will provide first insights, the generalizability of our findings will be limited.

Conclusions.

This study will advance our understanding of the requirements to design explainable AI based systems and identify key characteristics and functions of networks of accountability. Potential application areas for our findings range from predictive maintenance (i.e., wheelset inspection) over rail traffic management systems (i.e., for re-dispatching), and assisted and driverless train operations to rolling stock planning and personnel deployment planning.

Relevance to the Congress Theme.

AI is an integral part of the future of work. ML systems are being integrated in work in more and more organizations and are going to change the way we work considerably.

Paper 3

Development of a Toolkit for Improving Workers' Well-being in Collaborative Robotics – An Experts' Survey

Federico Fraboni, University of Bologna; Erwin Rauch, Free University of Bolzano; Luca Pietrantoni, Hannah Brendel & Gabriele Puzzo | University of Bologna; Luca Gualtieri, Free University of Bolzano

Research Goals

Collaborative robotics profoundly affects workers' conditions by driving many work environments towards radical changes, particularly in the manufacturing sector. However, the psychological and organisational factors affecting workers' experience and the quality of human-robot collaboration are often underestimated or neglected. The present contribution emphasises the psychological and organisational aspects of industrial HRC. It presents the development process of a toolkit targeting collaborative workstation designers, which aims to provide operational support in increasing workers' safety, performance and well-being through cognitive ergonomics and organisational factors.

Theoretical Background

Previous authors argued that addressing psychological and organisational factors in HRC is crucial for the operator's well-being and production performance. However, current research primarily focuses on technical aspects (Torvald et al., 2017; Gualtieri et al., 2021). Literature suggests the importance of addressing factors such as perceived enjoyment (Elprama et al., 2016), perceived stress (Hancock et al., 2008), cognitive workload (Kalakoski, 2020) and acceptance (Bröhl et al., 2016) to improve workers' conditions in HRC.

Previous authors conducted a systematic literature review to develop guidelines addressing cognitive ergonomics and organisational factors when designing collaborative workstations (Gualtieri et al., 2022). After reviewing the content and main results, each article was labelled according to four categories: (i) workstation layout and elements, (ii) robot system features, (iii) robot system performance, and (iv) organisational measures. Their effectiveness was evaluated through a preliminary laboratory case study where participants interacted with a collaborative robotic system. Results show improved operator experience and efficiency by manipulating the system features and interaction patterns according to the proposed design guidelines.

Methodology

The toolkit development started with a systematic literature review of papers published between 2020 and 2022. The goal was to identify which workstation characteristics and HRC patterns could affect workers' perceived enjoyment, stress, cognitive workload and acceptance. A total of 615 documents were found. Duplicates and articles on healthcare robots, social robotics, mobile/teleoperated robots, and exoskeletons were excluded, leaving a total of 186 articles. After a further screening of the content, 93 works were selected to improve and expand the guidelines.

Afterwards, an online survey was developed. The survey targets experts in different disciplines: design; safety; system integration; human factors and ergonomics, work and organisational psychology.

The survey was administered to around 50 participants who were asked to comment on the guidelines. Participants reported their opinions on the guideline's clarity and relevance. Participants have been prompted to suggest one or more practical solutions for implementing the guideline and an assessment method or KPI to evaluate its effectiveness. Lastly, participants reported possible challenges and barriers in implementing the proposed solutions regarding organisational capabilities.

Expected Results

Results will be available around the first quarter of 2023 and will be used to improve the set of guidelines in terms of clarity and relevance. Furthermore, the results will be used to develop a toolkit containing practical solutions for guideline implementation and KPIs to assess their effectiveness in the organisation. Future steps will aim to evaluate the quality and effectiveness of the developed toolkit in two experimental studies.

Limitations

The study's main limitations are self-selection bias, common method bias, and questionnaire fatigue.

Research/Practical Implications

Theoretical implications relate to expanding guidelines for safety, efficiency and acceptance of HRC in the manufacturing sectors. Practitioners could also use results to overcome practical barriers and develop more comfortable, safe, and efficient collaborative workstations. The present study can contribute to the high-level goals of Industry 4.0 in terms of social and economic sustainability.

Relevance to the Congress Theme

The present work focuses on how Work and Organisational Psychology can contribute to steering technological advancements in modern manufacturing environments, highlighting the importance of workers' well-being. To our knowledge, our toolkit will be the first one aiming at supporting professionals with no expertise in organisational psychology to account for human factors, cognitive ergonomics and organisational elements when implementing robotic technologies.

Relevance to UN SDG

The present work is relevant for the UN SDG n° 8, "decent work and economic growth", and n° 9 ", Industry, Innovation and Infrastructure".

Keywords: collaborative robotics, toolkit, well-being

Paper 4

The influence of job digitalization on overall organizational fairness and positive affect at work

Vicente González-Romá, University of Valencia; Marija Davcheva, University of Valencia; Agustín Molina, University of Valencia; Ana Hernández, University of Valencia; Inés Tomás, University of Valencia

Research goals and why the work was worth doing

The goal of this study is to clarify the influence of job digitalization (i.e., the extent to which digital technologies are used by employees to perform their jobs) on overall perceptions of organizational fairness, and an indicator of subjective wellbeing at work (positive affect). Job digitalization is a growing phenomenon that is rapidly changing the way employees work in organizations (Cascio & Montealegre, 2016). However, insufficient attention is being given to how digitalization is changing jobs and employee experiences (Barley, 2015; Cascio & Montealegre, 2016; Parker & Grote, 2022). This omission is worrisome if we want to maximize the potential positive influences of job digitalization and minimize its potential negative ones (Coovert & Thompson, 2014). We focused on organizational fairness because it can channel the influence of job digitalization on employee wellbeing.

Theoretical background

Based on theories about work design (Hackman and Oldham, 1976; Morgeson & Humphrey, 2006; Parker & Grote, 2022), and organizational fairness (Colquitt & Zipay, 2015), we posited that job autonomy mediates the influence of job digitalization on overall fairness, which in turn has a positive influence on positive affect.

Methodology

We collected data from a sample composed of 158 employees who responded to a questionnaire at three different time points separated by three months. Job digitalization was measured at Time 1, job autonomy at Time 2, and overall organizational fairness and positive affect at work at Time 3. Our research model was fitted to data by means of Mplus.

Results

The proposed model showed a good fit to data (RMSEA = .065; CFI = .96; SRMR = .076). Job digitalization was positively related to job autonomy (.40, $p < .01$), which in turn was positively related to overall organizational fairness (.41, $p < .01$), which in turn was positively related to positive affect (.37, $p < .01$). The indirect effect of job digitalization on overall fairness via job autonomy was positive (.16) and statistically significant (bootstrapped 95% CI = .07; .27). The indirect effect of job digitalization on positive affect via job autonomy and overall fairness was positive (.06) and statistically significant (bootstrapped 95% CI = .02; .12).

Limitations

The main limitation of our study is that all the data were collected through self-reported questionnaires and from the same source (employees). This might have inflated the correlations among the study variables due to common-method variance. To minimize its impact, measurement occasions were separated by a 3-month period.

Conclusions

Our results show some of the mechanisms through which job digitalization is related to subsequent overall organizational fairness and positive affect. Identifying this mediation chain helps us to improve our understanding about the influence of job digitalization on employee work outcomes. From a practical perspective, our results suggest that to harvest the functional benefits of digitalization, digital technologies should be implemented in a way that fosters employee autonomy.

Relevance to the Congress Theme

Digital technologies are changing the world of work. To a certain extent, this study helps clarify how and why job digitalization impacts on a key job characteristic (job autonomy), an important employee judgement (overall organizational fairness), and a relevant indicator of employee subjective wellbeing (positive affect).

Relevant UN SDGs

Paper 5

Change at work and employee learning: the moderating role of supervisor support

Roy Sijbom, University of Amsterdam; Roy Peijen, Paul Preenen & Jessie Koen | Dutch Organization for Applied Scientific Research (TNO)

Research goals

The goal of this research is to (1) explore the relationship between change at work and employee learning, and (2) examine whether and how supervisor support affects these relationships.

Theoretical background.

Due to labor market developments such as digitalization and technological innovations, changes at work have become increasingly common. Such changes incorporate, for example, changes in technology, in the way jobs are done, in the products/services to be made or provided, and/or in the contact with customers, patients, students, or passengers. It is essential that employees continuously develop new knowledge, skills and abilities to cope with these ongoing changes: such lifelong learning not only allows them to execute their changing job tasks and to remain employable, but also contributes to the performance and competitiveness of the organization.

According to the Work Design Growth Model (WDGM), changing job tasks and characteristics can promote employee learning. For example, technological changes at work might require new skills needed to work with new technologies, and new work relationships may expose employees to other ways of working, different feedback, and new knowledge. Using the WDGM as a theoretical lens, we argue that change at work is positively related to employee learning, both formal (participating in a course or training) and informal (learning from tasks and people at work). Furthermore, we propose that the relationship between change at work and employee learning can be better understood by paying attention to the role of supervisor support for learning: high levels of support may be a stimulating resource for employee learning, which might be especially fruitful for low levels of change at work.

Design/Methodology.

We used self-report survey data from a large subsample of employed workers who participated in the Netherlands Working Conditions Survey (NWCS) for Employees from TNO in 2018 (n=62,602) and 2020 (n = 58,012). Change at work was captured by creating an index of the number of structural changes at work that employees reported (i.e., change in technology, such as machines or ICT; in the way jobs are done, in the products/services to be made or provided, and/or in the contact with customers, patients, students, or passengers), with a higher score indicating a higher number of changes. We assessed both formal (dichotomous variable; participating in a course/training) and informal learning (continuous variable; learning from tasks and colleagues at work). Supervisor support was assessed by asking participants to indicate the extent to which their supervisor stimulated their development of knowledge, skills and abilities.

Results.

Change at work was positively related to formal and informal learning. For formal learning, this relationship was curvilinear: the positive relationship between changes at work and formal learning became especially pronounced when employees reported multiple changes at work. Supervisor

support was positively related to formal and informal learning, and weakened the curvilinear relationship between change at work and formal learning: only under high levels of supervisor support, learning depended less on the amount of change at work. For informal learning, the moderating role of supervisor support was slightly different: only under low levels of supervisor support, informal learning depended more on change at work.

Limitations.

The cross-sectional nature of the data does not allow for causal inferences. Furthermore, our measure of formal learning only provided information on whether employees participated in formal training, but did not take into account whether they completed the training and whether they were able to use it at work.

Conclusions.

This study shows that changes at work generally foster employee learning. The reported curvilinear effect for formal learning signals a tipping point or acceleration point at which changes at work seem to 'force' employees to participate in learning activities. Additionally, supervisors' role in employee formal and informal learning seemed relatively large: the more supervisor support, the higher the chance that employees participated in formal learning and the more likely they were to report that they had learned from their tasks and colleagues (informal learning). Supervisor support also outweighed the effect of change at work for learning: for employees who experienced high supervisor support, learning depended less on change at work. For informal learning, however, it was not the experience of supervisor support that made the difference, but the lack thereof.

Relevance to the congress theme.

Ongoing change at work is common for contemporary organizations. These changes also require new skills and competencies from employees to remain sustainably employable.

Relevant UN SDGs.

Good health and wellbeing; Quality education; decent work and economic growth

Keywords: change at work, employee learning, supervisor support

Symposium S053

Affect at Work: New Conceptual Developments

Hector Madrid, Universidad Adolfo Ibáñez, Chile

science

What will be covered and why? Affect is a pivotal psychological process in organizations (Barsade et al., 2003; Elfenbein, 2007). The extant research in this field of inquiry has shown that, for example, the experience of emotions and moods participate in employee motivation, stress, performance, and well-being in the workplace (Totterdell & Niven, 2012). However, despite the weight of studies conducted over the last two decades, research on affect at work is far from complete due to the constant introduction of new research questions, topics, and constructs of interest. Thus, this symposium presents a collection of conceptual papers aimed to address issues about affect linked to cognition, well-being, and teamwork in organizations.

In the first paper, Ibaceta develops a theoretical framework to describe the antecedents of mind-wandering in the workplace. The latter denotes the cognitive process of being immersed in the inner world and thoughts, which can promote creativity at work. The second paper of Escaffi builds a model to describe and understand the role of autonomy to take breaks in the workplace for affective well-being and work performance in service jobs. The third paper presented by Vasquez proposes a taxonomy for interpersonal emotion regulation in the context of teamwork, founded in multi-level theory and group composition models theories. Finally, Perez presents a theoretical review to build the basics of a conceptual model of group-level affect in virtual teams and how shared affective experiences in the context of virtuality influences teamwork effectiveness.

Relevance to the Congress Theme . The affective experience is a core component of psychological well-being, and the latter is essential to a better future. Furthermore, in the context of intense changes in the world of work, the correlates of affect studied here, expressed in creativity, work performance, and teamwork, should be deeply understood for effective practice in the present and future of organizations.

Research/Practical Implications . The papers presented in this symposium contribute to continuing and expanding research on affect in organizations by the conceptual elaboration of underexplored psychological processes and social dynamics related to affect at work. As such, these works have the potential to inform and nurture novel research initiatives in work and organizational psychology.

Overall conclusions . The symposium contributes to the work and organizational psychology

by the elaboration of novel research questions and conceptual developments of affect at work.

Paper 1

Affect and Mind-Wandering at Work

Miguel Ibaceta, University of Manchester, UK

Theoretical background. Mind-wandering refers to the shift of attention from events in the external environment to internal, self-generated thoughts (Smallwood & Schooler, 2015). Traditionally, mind-wandering has been considered counterproductive behavior in organizational psychology since it involves diminished attention to the tasks at hand (Robinson & Bennett, 1995). However, recent studies have argued and supported that mind-wandering may have under-appreciated benefits because it leads to creativity in the workplace (Baer et al., 2021). Given this positive side, determining which factors drive mind-wandering emerges as a relevant research problem (Dane, 2018). Thus, this conceptual paper develops a framework to understand where mind-wandering comes from, focusing on affect and job characteristics in the work context.

General psychology research has shown that affect plays a role in the emergence of spontaneous thoughts (Poerio et al., 2013; Smallwood et al., 2009). When individuals experience negative feelings linked to, for example, anxiety and depression, their minds are prone to drift from the external world toward their intrapersonal realm. The explanation for these effects proposes that mind-wandering is a "way of escape" from stressful environmental conditions to obtain mental recovery. Thus, integrating the job demands-resources model and the affect-as-information hypothesis (Bakker et al., 2014; Madrid &Patterson, 2019; Martin & Stoner, 1996), I argue that it might be the case that employee mind-wandering emerges from job stressors, such as workload, time pressure, and problem-solving demands. Specifically, negative affect informs individuals that potential threats to well-being (i.e., demands) are present in the work environment, increasing the likelihood of mentally escaping from them, which is functional to psychological recovery and, therefore, better future performance. Furthermore, I expand the above argumentation, proposing that spontaneous thoughts might also steam from positive affect, like enthusiasm and inspiration, associated with job resources, such as autonomy and task variety. In such a case, positive feelings cue the presence of environmental conditions involving possible psychological rewards, which facilitates spontaneous thoughts to engage in problem-problem solving. Together, mind-wandering evolving from job demands and resources, by means of negative and positive affect, would lead to performance outcomes depending on deep thinking processes, like creativity.

New Perspectives/Contributions. Mind-wandering has just recently been recognized as a relevant phenomenon to understanding psychological processes at work, such that relevant theory and research are still scant in work and organizational psychology. Thus, the model presented here is a novel research endeavor to expand and continue with this stream of research.

Conclusions. Given that mind-wandering could benefit work outcomes, the description of its etiological factors is valuable and needed for theory and practice in organizations. In the latter case, interventions in, for example, job design might help to manage the impact of mind-wandering in the workplace. This work is one of the first efforts to describe and understand the affective antecedents of mind-wandering at work by integrating research on general psychology and organizational psychology applied to the workplace.

Relevance to the Congress Theme . Affect and mind-wandering are potent drivers of creativity and innovation, which are essential ingredients for building change and a better future.

Relevant UN SDGs. Good health and well-being

Keywords: affect, mind-wandering

Paper 2

Break Autonomy, Affective Well-being and Service Performance

Maximiliano Escaffi-Schwarz, Universidad Adolfo Ibáñez, Chile

Theoretical background . Deciding when to take breaks should increase affective well-being because it lets employees effectively manage their energy levels and reduce the stress that may come from unwanted interruptions. However, why break autonomy is related to the affective experiences at work has not been theoretically elaborated enough in work and organizational psychology. Thus, here, I present a model of break autonomy considering the direct and combined effects of break activity and timing autonomy on affective well-being and, thereby, job performance. In this model, I focus on affective well-being because it contains in a single construct other common conceptualizations of break outcomes, such as vitality, energy, positive affect, and fatigue. Furthermore, customer satisfaction is utilized as the performance criterion in the model, given that service jobs are highly sensitive to the experience of well-being linked to intense interpersonal interactions.

Past empirical research on breaks has suggested breaks perceived as chores (i.e., low activity autonomy) or interruptions (i.e., low break autonomy) can have negative consequences, such as reduced well-being (Boucsein & Thum, 1997; Trougakos et al., 2014). Thus, breaks should be most effective in protecting well-being when taken in a timely way (Feyer & Williamson, 1995). Accordingly, having break timing autonomy will help keep low-activated negative affective experiences at bay and allow workers to feel more energetic after the break. Alternatively, a lack of break timing autonomy can turn breaks into interruptions. The latter makes it more difficult for workers to re-engage in work tasks after the break and increase experiences of stress. Therefore, workers with high levels of break timing autonomy should report higher levels of high-activated positive affect and lower levels of high and low-activated negative affect. Deciding what to do during breaks should also be related to affective well-being because it protects breaks from being perceived as chores and allows workers to engage in their preferred activities. Specifically, workers who are unable to decide what to do during breaks have to exert extra effort to engage in those activities, which results in higher levels of fatigue (Trougakos et al., 2014). Additionally, when there is a congruency between job demands and rest activities, break effectiveness is maximized (Dababneh et al., 2001) because workers can target their recovery efforts toward specific needs (Venz et al., 2019). All of this should be experienced as higher levels of activated and deactivated forms of positive affect.

In turn, affective well-being resulting from breaks should be related, in the context of service jobs, with higher levels of customer satisfaction after the break. Specifically, workers who experience positive affect during a break display more positive emotions after the break (Trougakos et al., 2008). Customers who interact with employees who display positive affect usually perceive workers as more helpful and friendly, resulting in higher levels of satisfaction with the interaction (Holman, 2016; Tsai & Huang, 2002). In contrast, workers who experience negative affect during the break will have to fake positive affective displays to meet display rules in service organizations (Hochschild, 1983). Nevertheless, some customers can detect these inauthentic emotional displays, which would violate the expectations of a service encounter, thus leading to lower levels of satisfaction (Holman, 2016). Moreover, when self-regulation processes fail, employee negative affect might leak out, violating customers' expectations. Combining the above points, I propose that break timing and activity

autonomy should be indirectly related to customer satisfaction via the experiences of affective well-being.

New perspectives/Contributions . This research contributes to current conceptualizations of breaks' boundary conditions and their specific effects on employee affective well-being. Specifically, studies on break usually focus on break activity autonomy (Trougakos et al., 2014; Venz et al., 2019) but do not consider whether workers proactively engaged in the break.

Conclusions . This conceptual development expands the emerging research on breaks and affect at work, focusing on service performance. In practical terms, practical implications derived from this knowledge will inform organizations to promote employee well-being and job performance. This work is one of the first conceptual developments aimed at disentangling the role played by break timing and activity autonomy for affective well-being and job performance.

Relevance to the Congress Theme . During the pandemic, many workers have been left mentally exhausted. One of the many ways to address this exhaustion is through better work breaks, but only if these breaks are taken when and how they are needed. Therein lies the relevance of this study to the congress theme: workers are in need of better work environments that help them restore and improve their well-being, and autonomous work breaks are one way of doing this.

Relevant UN SDGs. Good health and well-being

Keywords: affect, breaks, well-being

Paper 3

Interpersonal Affect Regulation in Groups and Teams

Cristian Vasquez, University of Sheffield, UK

Theoretical background

In the past years, researchers have proposed several mechanisms by which group members may influence the affective experiences of other members (Collins et al., 2013; Marks et al., 2001). Most of the works have appeal to emotional contagion – the automatic process by which affect is quickly transmitted among group members – as the main mechanism through which team members influence others' affect (Ashkanasy & Humphrey, 2011; Collins et al., 2013). However, individuals are not simply passive receivers of others' affect; they are agents instead. They can strategically modify others' affect to match situations' requirements. Interpersonal Affect Regulation (IAR) has been defined as individuals' deliberate attempts to regulate someone else's affect (Niven et al., 2009).

This conceptual paper presents a theoretical elaboration of the concept of IAR in work groups and teams. Following the multilevel structure that IAR may adopt in group contexts, for example, multiple individuals engaging in actions to regulate other members' affect within the group, we examine previous evidence in IAR at different levels of analysis (i.e., individual, dyadic, team). Regarding the individual and dyadic level of analysis, previous evidence has shown how social ties and feedback mechanisms influence IAR between group members. Thus, members may engage in particular strategies to regulate the feelings of their colleagues who have a distinctive relationship. In terms of the group-level of analysis, we use Chan's (1998) composition model framework to examine several alternative ways of conceptualizing a group-level IAR (e.g. additive, direct consensus, referent shift, and dispersion models).

In a group additive model of IAR the greater the number of IAR behaviors shown by group members on average, the more the group level IAR. A direct consensus model of IAR involves there being an agreement between group members on the extent, frequency, or choice of strategies that members use to regulate others' emotions. Thus, the meaning of the group-level is in the consensus among members. A referent shift model of IAR adds nuances to the consideration of this agreement, claiming that a group-level phenomenon has meaning only if a shift in the referent prior to the consensus assessment is made. This shared perception of a group-level reality means that members agree on the extent to which the group-as-a-whole regulates its own affective states. The dispersion model of IAR obtains its meaning from the variation or heterogeneity that can be observed among group members. Specifically, as members may vary in terms of the strategies that they use to regulate colleagues' emotions and the frequency with which they engage in these actions, it is important to analyze this effect as well.

New Perspectives/Contributions

This research contributes to the contemporary theory of interpersonal affect regulation (Troth et al., 2018), and group emotions (Collins et al., 2013) by having a more refined understanding of the role voluntary actions that group members may engage in to actively influence other members' affect. This theoretical elaboration examines a key missing piece to understanding affective dynamics in groups and teams. Additionally, this research contributes to multilevel theory applied to organizational behavior (e.g., Ashkanasy & Dorris, 2017) by studying interpersonal affect regulation considering different levels of analysis (i.e., individual, dyadic, team).

Conclusions

The theoretical development performed in this research will contribute to future scientific inquiries by outlining the importance of IAR as a key psychological mechanism to understand group affect, and by specifying the extension and boundaries of a conceptualization of this construct in the group context. This may facilitate more comprehensive research questions and appropriate methods to assess such behaviors. For example, regarding a hypothetical research question: Do group members engage more frequently in AIR with their friends within the group vs other members? The focus might be on understanding dyadic effects within groups. Thus, multi-level models may be the most appropriate to analyze individuals nested in dyads, and nested in teams.

Relevance to the Congress

Theme Teamwork is the future for many organizations. The theoretical elaboration advanced in this article will contribute to the new world of work by enabling researchers to have a fine-grain knowledge of interpersonal behaviors within complex social contexts, such as groups and teams. Thus, having a more precise understanding of teamwork will likely increase the development of tailored initiatives to improve employee experience at work.

Paper 4

Affect and Team Virtuality

Ignacio Perez, University of Sheffield, UK

Theoretical background . Research about work groups has shown that shared affective experiences among team members play an important role in team effectiveness, expressed in, for example, information processing, motivation, and interpersonal behavior. However, most of this research is based on studies with face-to-face (FtF) teams, such that the function of affect in virtual teams is still underdeveloped. This paper presents a review of research to build the basics for a theoretical elaboration about affect and virtuality at work to contribute to this field of inquiry.

Emotional contagion, that is, "the transfer of emotion from one person to another" (Menges & Kilduff, 2015, p. 867), has been the most studied mechanism that allows team members to develop shared affective experiences. Several automatic and conscious processes have been accounted for to explain this transfer of emotions. From the automatic processes, mimicry is relevant as people copy the facial expressions, voice intonation, and body movements of their interaction partners (Barsade & Knight, 2015; Hatfield et al., 1993), which in turn leads to the mimicker to feel the emotions of their interaction partner based on primitive afferent feedback (Elfenbein, 2014). Regarding conscious processes, explicit expressions of emotions and sensemaking have been proposed. Emotional expressions are an important source of information, and team members will likely consider other members' emotions to adapt their feelings to specific situations (Van Kleef, 2009). Similarly, sensemaking is the process by which team members arrive at collective interpretations – or appraisals – of events through interactions and conversations (Hareli & Rafaeli, 2008), which in turn makes them more likely to have similar emotional reactions to those events (Lazarus, 2001).

The media by which team members interact and its characteristics could be influential in facilitating or hindering several of the mechanisms mentioned above. Media Synchronicity Theory (MST; Dennis & Valacich, 1999; Dennis et al., 2008) is one of the recent developments that have systematized the physical attributes – or capabilities – of different types of media, considering both FtF and information and communication technologies (ICTs), such as video calls, chats, and emails. MST argues that media differ in their capabilities to support the transmission or processing of information (Dennis et al., 2008). Usually, the transmission of information requires media that support quick delivery of messages (transmission velocity), multiple communications and participants (parallelism), and the use of verbal and non-verbal communications (natural symbols). On the other hand, information processing is better supported by media that allows to review the information multiple times (reprocessability), refine messages before sending them (rehearsability), and that relies on text and numbers (digital symbols). While there is clarity on the relevance of transmission capabilities for emotional contagion (e.g., by allowing the mimicry of facial expressions or by facilitating the quick exchanges needed for sensemaking), less is known about the impact that processing capabilities could have on affective convergence. For example, Cheshin et al. (2011) found that emotional contagion happens in virtual teams that only communicate through text-based ICTs, which dampens the automatic mimicry of facial expressions or body movements. However, to do so, members rely on the interpretation of communicational behaviors, such that, for example, flexibility is seen as a reflection of happiness and resoluteness of anger.

Cheshin and colleagues' study offers important insights into understanding the impact of ICTs on affect in teams. Nevertheless, the dichotomy of virtual vs. FtF teams has been questioned as most

teams will have some degree of virtuality; that is, most teams will combine, to some extent, the use of FtF and ICT-mediated interactions (Gilson et al., 2015). In this context, we are still lacking theoretical works that help us to understand the impact of processing capabilities when used as a complement of transmission features rather than as a replacement.

New Perspectives/Contributions . This work will expand the literature on affect in work teams by examining how different media capabilities are related to the development of shared affective experiences within teams. Especial attention will be given to the impact that combining both processing and transmission capabilities can have on the development of affect in teams. This is of particular relevance as, after the COVID-19 pandemic, team members rely more on hybrid modalities of work communicating through a combination of ICTs and FtF than ever before.

Conclusions . This research will provide the basics for building a theoretical framework to understand how affective processes evolve in a virtuality context. In practical terms, this knowledge will help practitioners by giving them more fine-tuned guidelines to manage the use of multiple interaction media within teams beyond the dichotomy of virtual vs. traditional teams. This work represents one of the first attempts to understand the relationship between teams' virtuality and affective processes based on the conceptualization of media capabilities.

Relevance to the Congress Theme . Due to the many changes that the COVID-19 pandemic brought, team members are relying more than ever on ICTs to support their interactions. Understanding how the use of this type of media can impact the development of affective experiences within teams is crucial for researchers and practitioners to help teams in their development of positive interpersonal relationships, effective work processes, and thus contribute to the overall well-being of workers.

Relevant UN SDGs . Good health and well-being

Symposium S054

Process and effect evaluation of interventions at different levels across organisations: Case studies from the H-WORK project

Marco De Angelis, University of Bologna

science_practice

What will be covered and why: The symposium aims to present the main evidence-based findings of the Mental Health and Workplace Stress Intervention, which was carried out as part of the H- WORK project (De Angelis et al., 2020). The EU-funded project aimed to test and validate interventions at different levels of the organisation (individual, group, leader, organisation; Day & Nielsen, 2017), particularly in public health and SMEs, which are considered critical work environments for mental health. In occupational health and work and organisational psychology, a limited number of studies consider relevant aspects of the intervention, such as the underlying mechanisms that determine effectiveness (Liu et al., 2019). In other words, there is still a lack of studies that use a realist approach to assess the mechanisms involved in interventions that promote well-being (Nielsen & Miraglia, 2017). The four contributions will provide valuable insights into how contextual factors and implementation mechanisms play a role in the overall effectiveness of interventions by applying the principle of realist evaluation

The first presentation will outline how mindfulness-based interventions influenced participants' emotional styles at an individual level. The intervention targets personal skills to better cope with stressful events, and training transfer and peer and supervisor support are critical mechanisms fundamental to achieving positive changes in mental health outcomes. The second presentation provides evidence of a group-level digital intervention to promote communication through social network visualisation and team coaching. The digital-based intervention offers real-time data on group dynamics and increases team awareness and reflexivity. In this study, a positive evaluation and experience with the digital tool are considered crucial for training transfer and the effectiveness of the intervention at the team level. Thirdly, the authors will present the results of the efficacy of the mental health intervention at the leadership level in Czech SMEs. The intervention, which involves managers and their employees, aims to raise awareness of the possible negative consequences of remote working. In this new work scenario, managerial commitment, individual readiness for change and job (in)security can promote positive change. The fourth presentation explores the effectiveness of e-coaching interventions for managers and employees to deal with the challenges the participants faced during the acquisition phase.

Relevance to the Congress Theme: Changing work environments are a constant in today's world. The pandemic has made the need to address mental health in the workplace even more apparent. At the same time, it has become even more urgent to provide employees, teams and managers with practical and evidence-based guidance on adequately dealing with the emotional and barely manageable consequences of such changes (WHO, 2022). It has recently been highlighted that managers lack knowledge and organisational measures to deal with the adverse effects of mental health in the workplace (EU-OSHA, 2019), or they rarely implement mental health promotion and occupational stress programs (Martin et al. 2020). The symposium explores the topic of mental health and wellbeing in the workplace by examining relevant aspects such as job insecurity and employees' attitudes towards the interventions they have participated in, group processes and leadership styles, and highly complex organisational scenarios such as mergers and acquisitions.

Research/Practical Implications: Understanding the contextual aspects and mechanisms that facilitate the implementation of different interventions targeting the different levels of the organisation allows practitioners and researchers to understand what works, for whom and in what circumstances. The results provide evidence-based knowledge about the effectiveness of these interventions, i.e., whether or not the interventions bring about the desired change, which promisingly facilitates the transfer of this knowledge and these interventions to other work environments. Indeed, another exciting aspect is the diversity of the organisational contexts studied. On the one hand, a public healthcare organisation, on the other hand, small and medium-sized enterprises from different sectors (IT, retail cloud services), thus providing practical guidance to multiple stakeholders.

Overall conclusions: This symposium will provide an overview of different interventions to promote well-being and mental health at different levels of the organisation (i.e., individual, group, and leadership). A realistic evaluation approach emphasises how contextual aspects in the workplace trigger the mechanisms associated with intervention outcomes that explain why, how and with whom the interventions had the desired impact in the different organisations involved in the European project.

Keywords: Multilevel interventions; Realist evaluation; Mental Health

Paper 1

The impact of mindfulness-based individual level interventions on the Emotional Style of participants: A process evaluation study

Marisa Salanova, Department of Social Psychology, WANT Research Team, Universitat Jaume l, Spain; Siw Tone Innstrand, Department of Psychology, Norwegian University of Science and Technology, Norway; Karina Nielsen, Sheffield University Management School, University of Sheffield; Kristýna Krejčová, 2Department of Psychology, Faculty of Management and Economics, Czech University of Life Sciences, Prague, Czech Republic; Josefina Peláez Zuberbühler, Department of Social Psychology, WANT Research Team, Universitat Jaume l, Spain

Research goals: This study is part of the European project H-WORK, which aims to promote employee mental health and well-being in small and medium enterprises (SMEs) and public organisations through the design, implementation, and evaluation of multilevel interventions (De Angelis et al., 2020). Specifically, this study aims to examine the effects of different phases of three Mindfulness-Based Interventions (MBI) on participants' emotional styles. The individual-level intervention was conducted in four SMEs in Spain and the Czech Republic.

Theoretical background: Promotion of well-being and optimal mindset of employees belongs among the most fundamental and still current challenges for work psychology. This area has become even more urgent due to the Covid-19 pandemic and connected restrictions (Evanoff et al., 2022). One of the recent fast-spreading methods for improving the population's well-being is MBI (Carmody & Baer, 2008). However, little attention has been paid to MBI as a tool to promote healthy and positive outcomes rather than to reduce adverse outcomes (Coo & Salanova, 2018). One potential positive outcome is the Emotional Style of the participants, which is susceptible to changes (Kesebir et al., 2019). The construct of healthy emotionality is based on neuroscientific studies of emotions developed over the last three decades (Davidson & Begley, 2012), which identify six critical dimensions of emotional life: Attention, Self-Awareness, Outlook, Resilience, Social Intuition and Sensitivity to Context. In addition, the present study follows the theoretical approach of Realist Evaluation (Nielsen & Abildgaard, 2013), which strives to include elements from the Context and the implementation process (Mechanisms) associated with the expected Outcomes.

Design/methodology: Employees in four SMEs (one global retail company in the Czech Republic, N = 48; a mobile device management system developer company in the Czech Republic, N = 37; a Spanish IT company, N = 66; and a business performance consulting company in Spain, N = 28) participated in different Mindfulness-based interventions: 1) a 3 group sessions Positive Stress Management Program that aimed to develop a set of skills to proactively manage stressful situations (Coo & Salanova, 2018); 2) a Healthy Emotionality Program (Davidson & Begley, 2012), which consists of a digital platform and follow up group sessions with practical training on the six critical dimensions of emotional life; and 3) a group 8-week training in Mindfulness-Based Cognitive Therapy focused on increasing mindfulness and self-compassion and decreasing stress, anxiety, rumination and depressive symptoms (Williams & Penman, 2011; Frostadottir & Dorjee, 2019). For the evaluation, quantitative measures are collected at different points in time, covering contextual factors, mechanisms and outcomes. The data will be analysed using Structural Equation Modelling with PROCESS in SPSS to test for mediation and moderation effects.

Expected results: We expect that the baseline levels of employee Readiness for Change (Context measure) before starting the interventions will prompt participants to Transfer the Training

(Mechanism) acquired to their daily work, which in turn will increase participants' Emotional Style and Well-being (Outcomes) levels after the interventions. Peer support and Leader Support will act as moderators in the interaction between Readiness for Change and Training Transfer, and Work Demands will serve as a moderator in the interaction between Training Transfer and Outcomes. The intervention program, intervention site, country, and participation in other interventions will be used as control variables to compare our study sample.

Limitations: A limitation of the study is that data collection for follow-up intervention time (6 months after finishing interventions) will not be gathered before the presentation. Thus, we cannot present the results for the whole research model at this stage. However, we analyse and include baseline, process evaluation and post-interventions results for the presentation.

Practical Implications: Implementing these individual-level Mindfulness-based interventions in different organisations will allow for cross-countries scientific comparison on what conditions and mechanisms lead to the desired outcomes, for whom and under which circumstances.

Relevance to the congress theme : Findings might be of interest to the Congress theme because of the novelty of our study in incorporating digital versions of interventions, thus creating excellent opportunities for organisations to ensure continued working from home and maintaining productivity and well-being.

Relevance to UN SDGs: Results might contribute to UN SDGs 3 (Good Health and Well-Being) and 8 (Decent Work and Economic Growth), given that the ultimate goal of our study is to promote healthy, resilient, and productive employees and organisations, to be able to emerge even more robust and thrive in adverse situations, such as economic crisis or critical internal changes (Salanova, 2021).

Keywords: Mindfulness-based interventions; Emotional Style; Well-being

Paper 2

A realist evaluation of a group-level digital intervention to promote communication via social network visualisation and team coaching: Longitudinal m

Davide Giusino, Department of Psychology, University of Bologna, Italy; Cristian Vasquez Guerra, Institute of Work Psychology, Sheffield University Management School, University of Sheffield, United Kingdom; Siw Tone Innstrand, Department of Psychology, Norwegian University of Science and Technology, Trondheim, Norway; Marit Christensen, Department of Psychology, Norwegian University of Science and Technology, Trondheim, Norway; Vince Pelzer, Department of Work and Organizational Psychology, University of Amsterdam, The Netherlands; Rudolf Kubik, QED Group a.s., Prague, Czech Republic; Judith Schmitt, Department of Managerial Psychology and Sociology, Faculty of Business Administration, Prague University of Economics and Business, Czech Republic; Edoardo Pische, Department of Education Studies, University of Bologna, Italy

Research goals and why the work was worth doing: Perform a realist evaluation of a digital-based team coaching intervention to promote communication via social network visualisation. Context, working mechanisms, and attitudes should be considered when evaluating interventions (Nielsen & Randall, 2013; Roodbari et al., 2021) as they may influence intervention outcomes, facilitate, or hinder the effectiveness, and explain the success or failure of an intervention.

Theoretical background: Interventions are effective when trainees have support from colleagues and managers to use acquired skills and knowledge (Holton III et al., 1997). In turn, they must transfer new skills and knowledge to the workplace and implement action plans (Grohmann & Kauffeld, 2013). The digital-based intervention (Bahbouh, 2012) aims to promote desired over current dynamics through action plan development. Its success implies a team effort, acceptance, and usability of deployed digital tools. Therefore, we hypothesised that if recipients perceive peer and manager support to apply developed action plans to everyday work, they are more likely to transfer and implement the action plans jointly define during the intervention. In turn, they will show improved team performance, teamwork, coordination, and less interpersonal workplace conflict. Also, a moderation effect is hypothesised, such that relationships will be stronger for those higher in acceptance and usability at the immediate end of the intervention and those higher in team performance, teamwork, and coordination, and lower in interpersonal workplace conflict at pre-intervention.

Design/Methodology/Approach/Intervention: The intervention was delivered in a large Italian public healthcare institution and a medium Czech retail enterprise. In Italy, seven teams from 3 hospital areas were involved, each including 6 to 13 healthcare workers (N = 62) who received 4 group sessions in 2-month intervals via a videoconferencing platform. The first session was scheduled for 3 hours, and the remaining three sessions for 2 hours. In the Czech Republic, 15 teams from 5 departments were involved, including 6 to 16 members (N = 107) who received three online group sessions in 3-month intervals. Depending on team size, the first session was scheduled for 3 hours and the remaining 2 for 1.5/2 hours. We collected survey-based psychometric measures at five-time points. At T1, pre-intervention proximal outcome measures were collected for team performance (support, autonomy and reflexivity), interpersonal conflict at work, teamwork and coordination. At T2, measures of contextual factors such as peer and supervisor support were collected. At T3, attitudes towards the digital intervention were measured, e.g., acceptance and usability. At T4, measures of working mechanisms were collected, e.g., training transfer and implementation. At T5,

proximal measurements were taken post-intervention, as at T1. All measurements were quantitative and included Likert scales.

Expected results: We will use Mplus to test a Context-Mechanisms-Outcomes configuration (Nielsen & Miraglia, 2017), that is, a longitudinal structural equation model in which, by 2023, we expect to find peer and manager support as critical factors positively predicting training transfer and implementation which, in turn, will positively predict team performance, teamwork, and coordination and negatively predict interpersonal workplace conflict. These mechanisms will be moderated by higher/lower levels of acceptance and usability of the digital tool. Results will be compared across the intervention sites.

Limitations: The high turnover of participants across intervention sessions may have caused answers to questionnaires not to be fully informed. The small sample size limits statistical power; therefore the generalisability remains limited to digital team communication interventions in Italian public healthcare and Czech retail.

Research and practical implications: Findings may support previous research in that intervention context influences working mechanisms, with peer and manager support being able to facilitate transfer and implementation and those being able to translate into proximal outcomes, thus helping to understand how the intervention brings about changes. Managers may design the context in which digital group-level interventions occur to provide recipients with social support and opportunities to transfer and implement what has been learned and developed through training.

Relevance to the congress theme: Results might be relevant to "The Future is Now: The Changing World of Work" as the study encompasses novel ways of delivering workplace interventions.

Relevant UN SDGs: Results might be relevant to UN SDGs "3: Good Health and Well-Being", "8: Decent Work and Economic Growth", and "9: Industry, Innovation and Infrastructure" since good communications is a cornerstone of healthy teamwork and contribute to high team performance at work (Marlow et al., 2018).

Paper 3

An evaluation of the effectiveness of leader-level intervention Mental Health Awareness Training on mental health in Czech SMEs

Ivana Šípová, Department of Psychology, Faculty of Arts, Charles University, Prague, Czech Republic; Siw Tone Innstrand, Department of Psychology, Norwegian University of Science and Technology, Trondheim, Norway; Karina Nielsen, Sheffield University Management School, University of Sheffield, United Kingdom; Judith Schmitt, Prague University of Economics and Business, Prague, Czech Republic ; Dorota Lofajová, QED Group A.S., Prague, Czech Republic

Research goals and why the work was worth doing. The study aims to evaluate the effect of mental health awareness training for managers on employees' appraisal of the mental health climate, considering the moderating role of leadership commitment, employee participation, readiness for change and job insecurity.

Theoretical background. The research seeks to analyse the effect of a leader-level intervention on mental health during the Covid-19 pandemic. Pandemic restrictions have entirely changed work habits. Most workers have moved from offices to their homes which caused new challenges and demands on several aspects of work (Žiedelis, 2022). One of the most affected is mental health. Online work settings make well-being issues less visible as online interaction focuses mainly on task topics (Molino et al., 2020). Continual changes, lack of predictability in workload, and unclear boundaries between work and personal life contribute to poor mental health (Helliwell et al., 2021). As people work from home, managers do not meet them daily to check their mental health in personal contact.

This demands managers to be more aware of how their employees feel. For this reason, there is an increased need to develop the competence to talk about mental health topics openly, safely and confidentially (Corrigan, 2014). Mental health awareness training helps managers to identify the early signs and symptoms of common mental health conditions, talk about mental health issues and prevent well-being-related problems (Dimoff et al., 2016; 2019).

Methodology. The pre-post field research design was implemented to investigate the effect of mental health awareness training on the well-being of employees. The intervention was delivered based on the results of a needs analysis carried out upfront, which indicated a lack of competency in talking about mental health issues openly, safely and confidentially.

In total, 60 managers (26 and 34) from two different SMEs attended the online training. Managers and their subordinates completed the mental health baseline questionnaire at two-time points- before the interventions had started and one year after the interventions had started.

Expected results. Data collection is in progress, and results will be available in the coming weeks. We expect that if there is a high leadership commitment, high participation from the employees, increased readiness for change and low job insecurity, then the employees will participate voluntarily in the sessions, will feel optimistic about the content, and have a high intention to transfer the knowledge and skills into their daily work life. As a result, the employees will be better able to care about their mental health and be more resilient due to increased psychological capital and self-compassion, which, in turn, will foster a mentally healthy work climate. Data will be analysed using Structural Equation Modelling to test the moderation effects of leadership commitment, participation, readiness for change and job insecurity on training effectiveness.

Limitations. At the time of the presentations, pre- and post-intervention data will be available even though the research will still be in progress. The research's field character might decrease the study's external validity.

Conclusions. There is a need for knowledge on preventing well-being-related problems in a changing world with more remote work and mental health issues. The present study adds to this need by exploring the effect of mental health awareness training. The practical contribution of this research is to provide specific recommendations on creating mental health awareness for leaders through training interventions and thus promote employee wellbeing.

Relevance to the congress theme. The presented study meets the congress topic as mental health is currently highly vulnerable and significantly impacts well-being and employee productivity.

Relevance to UN SDGs: Results might be relevant to UN SDGs “3: Good Health and Well-Being”, “8: Decent Work and Economic Growth”, and “8: Decent work and Economic Growth”.

Paper 4

Guiding through turbulent times: Positive Leadership Coaching during Merger and Acquisition

Judith Schmitt, Prague University of Economics and Business, Prague, Czech Republic; Daniela Pauknerova, Department of Managerial Psychology and Sociology, Faculty of Business Administration, Prague, University of Economics and Business, Prague, Czech Republic; Cristian Vasquez Guerra, Institute of Work Psychology, Sheffield University Management School, University of Sheffield, United Kingdom

Research goals : This study examines how positive leadership coaching (PLC) supports employees and managers to cope with the challenges induced by M&As. Using a qualitative approach, we aim for a detailed understanding of the subject's experiences; the perceived challenges generated by the M&A and to analyse how exactly they reflect the coaching's support mechanisms to cope with those challenges. Our research provides evidence on the effectiveness of coaching in the context of M&A and advising organisations undergoing M&As, on how coaching should be organised to maximise its effect.

Theoretical background: Mergers and acquisitions (M&As) are common procedures in the business world, often associated with a negative impact on employee well-being. The M&A procedure may create difficulties, such as layoffs, job insecurity, reorganisation, or change in business culture (Dick et al., 2006; Seo & Hill, 2005). In addition, M&A has been associated with employee anxiety, feelings of ambiguity, lower productivity, lower self-esteem, and mental and physical illness (Mangundjaya &Fachruddin, 2012; Rosa et al., 2017; Smollan, 2015; Wang et al., 2012).

Over the years, this phenomenon triggered intense research on different mechanisms organisations may implement to support employees during M&A processes, such as leadership support or job redesign (Seo & Hill, 2005). Previous studies show a positive correlation between coaching and successful change management by promoting solution-focused thinking and self-efficacy (Grant, 2014). Yet, little is known about how coaching interventions help employees manage change in the M&A context (Bickerich et al., 2018).

Design/Methodology: The single-case study was conducted in a globally operating marketing company based in the Czech Republic with approximately 300 employees. A larger, UK-based corporate organisation acquired the Czech SME. PLC was implemented to facilitate well-being and empowerment, support managers to lead by example, and enhance personal and professional development. The coaching concepts drawn on were positive leadership (Malinga et al., 2019) and Whitmore's GROW model (2013), applied as individual case coaching (Grant & Greene, 2004). The coaching was part of the H-Work project, which offers multilevel interventions to organisations to promote mental health and well-being. We conducted 11 semi-structured interviews with PLC participants as part of an overarching study to evaluate the interventions' effectiveness. The purposive sample consisted of seven managers and four employees, all of whom stayed in the organisation after the acquisition. The data analysis was carried out by all researchers independently, who then discussed and merged the results. Deductively, we developed three main categories for the themes "acquisition", "Coaching," and "Leadership," with a total of 27 codes.

Results obtained or expected: We got preliminary findings creating a clear picture of the challenges the participants faced caused by the acquisition. In particular, they were dealing with changes due to the organisation's restructuring, the evolution of corporate identity, and the high fluctuation. Besides

a high satisfaction with the coaching, our findings point to a strong efficacy in helping employees cope with the acquisition process's challenges. In particular, we discovered that the participants benefited from an improved self-awareness regarding their needs and goals and empowerment to advocate for their interests. Further, this helped several participants evaluate their future, especially those considering leaving the organisation, which became aware of reasons to stay. Thus, we see an apparent effect on avoiding turnover. The analysis is still ongoing, and we expect to identify crucial factors relevant to the effectiveness of the coaching intervention in this context.

Limitations: The main limitation of this study is that it is a single case study. As every M&A process is different, this limits the transferability to other M&A cases. Also, the interventions took place amid the COVID-19 pandemic, thus, the acquisition wasn't the only cause of employee disruption. A second limitation is that the coaching was part of a package of multi-level interventions offered; Many interviewees participated in other interventions as well, so the effects can't be attributed to coaching explicitly.

Relevance to Congress Theme "The Future is Now: the changing world of work": M&A processes are one facet of today's changing world of work. This research underlines the importance of designing change processes emphasising the well-being of those affected.

Relevance to UN SDGs: As this research presents relevant findings about promoting well-being in the workplace during M&A processes, it contributes to goals 3, "good health and well-being", and 8 ", decent work and economic growth", of the SDGs.

Symposium S055

Regret in Careers: Examining its sources, implications, and responses

Alexandra Budjanovcanin, King's College London; Bettina Wiese, RWTH Aachen

science

Introduction

Decisions are a mundanely routine feature of life and where there are choices to be made there will be scope to regret. Although individuals confront choices almost daily in their working lives, and the consequences of regretted decisions taken during one's career must be lived, it is an area of the research landscape that remains sparsely studied (Byington , Felps and Baruch, 2019). This symposium therefore explores career regret - the feeling of wishing to undo a past decision made in one's career – and illuminates its sources, implications, and responses, broadening our knowledge of this ubiquitous cognitive emotion. Specifically, through three empirical studies that encompass both qualitative and diary study designs, the symposium conveys the variety of ways in which regret is impacting individuals' careers and working lives, individuals' responses to experiencing career regret and both the positive and negative consequences of this emotion – for people and for organisations.

The first paper highlights how changes to global norms around parental leave have caused fathers to seek to take advantage of this practice. Yet, despite this good news story about greater equality in parental leave taking, the study shows that some fathers end up regretting their decision to utilise this HR practice, which may threaten its future adoption. Importantly, this diary study, amongst 146 German fathers, highlights that line managers in particular play a role in lessening parental leave regret and points specifically to practices that convey both supervisory and organizational family-support.

The second paper examines occupation-specific regret and its effect on performance through a 45-person qualitative study in the UK. Unsurprisingly, occupational regret is linked to detrimental consequences including withdrawal behaviours, which impacts on individual performance and has implications for organisations. However, the interviews revealed that a subset of individuals – those with a strong work ethic – reported no effect on their performance, highlighting a psychological paradox (a wish to withdraw from work caused by regret and a simultaneous wish to maximise effort because of their work ethic). The study draws attention to the personal costs of this paradox - emotional labour and exhaustion - and the findings highlight the divergent outcomes for organisations and individuals.

The final paper shifts focus to examining how individuals respond to their career missteps, allowing them to potentially avoid career regret. Through 72 interviews with a range of professionals in the Netherlands, this qualitative study coins the term 'career repair' in identifying the variety of processes that can occur to respond differently to regretted decisions. Specifically, the study identifies several clear and practical strategies, including restoring (re-aligning career with personal values), extending (broadening boundaries), transitioning (changing organization/team) and negotiating ((re-) negotiation of conditions) that can lead to either career recovery or career growth. This study brings the concept of regret full circle in providing a constructive approach to dealing with this cognitive emotion in the context of one's career.

In seeking to clarify the (practical and theoretical) relevance of illuminating the nomological network of career regret in this symposium, we will draw on the expertise of the discussant Dr Ricardo Rodrigues, whose scholarly work focuses on careers. Dr Rodrigues' knowledge of the careers

research landscape, and specifically career orientations, choice and regret (e.g., Rodrigues et al., 2013), will facilitate in contextualising the insights from the symposium to the broader careers and organisational literature.

Relevance to Congress Theme

In order to compete and collaborate in the changing world of work, individuals need to be positively psychologically adjusted to their careers. With ever-present changes occurring, decisions made by individuals today may become regretted tomorrow and as such, greater understanding of this emotion can help individuals to feel better equipped to navigate their working lives.

Implications

The contribution to research of this symposium lies mainly in the way it illuminates this less understood experience in the work context. Identifying its nomological network is important because of its detrimental individual and organisational implications for individuals in the workplace. Practical implications relate to individual actions (linked to career repair) organisational policy (linked to support-related practices) and government policy (linked to ensuring better career guidance for individuals choosing their occupation).

Overall conclusions

Despite its ubiquity, there is a relative dearth of studies that examine this experience in people's working lives. For better adjusted employees and greater career wellbeing, we propose the further study of career regret.

discussant: Ricardo Rodrigues, King's College London

Keywords: Regret career decisions

Paper 1

Fathers' daily regrets of being on parental leave: The roles of perceived family-support by the supervisor and the organisation

Anna Stertz & Bettina Wiese | RWTH Aachen University

Aim: Today, many fathers want to be actively involved in the care and development of their children. After childbirth, a parental leave offers employed fathers the opportunity to immerse in parenting and concentrate on family life for a certain period. In Germany, the number of fathers taking parental leave is increasing, but with a portion of around 40%, leave-taking fathers still represent a minority. Some studies have shown that a family-supportive work environment has an impact on fathers' decision to take parental leave. In our study, we go beyond the question of what role organizational influences play in fathers' decision whether to take a parental leave or not. We propose that to better understand involved fatherhood from an organizational perspective, it is important to also investigate how fathers evaluate their work-family decisions. For a deeper insight into fathers' post-decisional experiences, the concept of regret might be particularly well suited. In this study, therefore, we examine whether fathers who decided to take parental leave might regret this decision depending on how they perceive their social work environment.

Theoretical Background: This research combines theoretical strands and concepts from the fields of organizational support and decision making. We focus on informal organizational family-support and post-decisional regrets. Regarding organizational influences, we concentrate on fathers' perceptions of two forms of informal organizational support, that is, the family-supportiveness of (a) their organization as a whole and (b) of their supervisor. Perceived organizational family-support has been defined as employees' perception of the assistance available from their organizations regarding their family demands, perceived supervisory family-support as the extent to which the supervisor is perceived to be flexible and understanding regarding employees' family demands (Jahn et al., 2003). Regrets have been defined as a negatively toned experience resulting from "imagining that our current situation would have been better, if only we had decided differently" (Zeelenberg &Pieters, 2007, p. 3). In this research, we focus on fathers' being-on-leave regret and define it as the belief that it would have been better to have decided against parental leave and not to be on leave at the very moment. There is evidence that perceived organizational support can mitigate different forms of strain (cf. Rhoades & Eisenberger, 2002). Consequently, the level of strain—reflected in our study in the intensity of fathers' being-on-leave regret—is assumed to be lower among fathers who do perceive their organization and their supervisor as family-supportive in contrast to those fathers who feel not supported.

Methodology: Data were gathered in a standardized diary study involving fathers currently on parental leave. The study consisted of a pre-diary questionnaire and a diary part with daily questionnaires to be completed on five consecutive evenings within one week (i.e., from Monday to Friday). Perceptions of organizational and supervisory family-support were assessed in the pre-diary questionnaire; fathers' daily regret of being-on-parental leave were repeatedly assessed in each diary questionnaire.

The analyses are based on data from N = 146 German fathers (Mean age: 35.6 years , SD = 4.9). Half of them (50.0%) were first-time fathers, and nearly half of the participants were on parental leave for the first time during the study.

Results: Multilevel analyses showed that if the supervisor was perceived as family-supportive, fathers regretted less being on parental leave. Perceiving one's organization as family-supportive, in contrast, did not influence fathers' being-on-leave regrets.

Limitations: Fathers' use of parental leave and the lengths of leave vary across countries depending on legal frameworks and gender-specific norms. Accordingly, future research should investigate the role of a family-supportive work environment for fathers' regrets of being on parental leave in contexts other than the German one.

Conclusions/Relevance to the Congress Theme/Relevant UN SDGs: Fatherhood has changed and many fathers today strive for being much more integrated into family live than fathers in previous generations. The change in fatherhood ideals is also reflected in the changing world of work. In many countries, the number of men taking parental leave and temporarily interrupting their careers for family reasons is on the rise. Fathers' use of parental leave can foster gender equality by increasing fathers' participation in childcare and housework and, in turn, facilitating mothers' participation in paid work (Huerta et al., 2014; Tamm, 2019). However, at the same time, many fathers are still hesitant about taking parental leave. This study highlights the critical role of supervisors. It is the supervisor's understanding that helps to prevent the young fathers from regretting having taken time for the family in this important phase of their life.

Keywords: Fathers regret support

Paper 2

Regret's consequences: the role of work ethic and emotional labour in the performance of regretful workers

Alexandra Budjanovcanin, King's College London; Chris Woodrow, Henley Business School

Research Goals

The present study focuses on the consequences of occupational regret, which is argued to be increasing because individuals have greater access than ever to information about potential career paths and therefore far greater awareness of foregone alternative paths to feel regretful about (Obodaru, 2017). The consequences of occupational regret may be detrimental for employees as well as the organisations that employ regretful workers. The goals of this study are therefore to explore the outcomes of occupational regret, addressing the following question:

What are the individual and work-based consequences of occupational regret?

Theoretical Background

Regret is "the emotion we experience when realizing or imagining that our current situation would have been better, if only we had decided differently" (Zeelenberg and Pieters, 2007: 3). Within career-related research, it is notable by its absence (Byington, Felps and Baruch, 2018). Amongst the few studies examining occupational regret's consequences, Wrzesniewski, Tosti and Landman's unpublished, quantitative study of nurses, although not directly measuring performance, found evidence for "linkages between regret and likely precursors to poor performance, including absenteeism" (2006: 24). Another study by Budjanovcanin, Rodrigues and Guest (2019) focused on occupational commitment and professional quitting intentions, highlighted an association with these important work-related attitudes – albeit cross-sectionally. These studies hint at some of the individual-, organisation- and occupation- level consequences of occupational regret but are far from forming a complete picture. In the light of this paucity of findings, the present study focuses on how individual performance is affected by occupational regret and the consequences for both people and organisations.

Design/Methodology/Approach/Intervention

Interviews were conducted with 45 people at various stages of career, who self-identified as having career regret. The sample involved interviews with: 27 women, 18 men; high school to PhD educated; predominantly British (64%); ages ranging from 26 to 66.

Findings

The findings suggest that occupational regret has differential effects on performance for different types of individual. Broadly, our data revealed two categories of individual; those for whom occupational regret was detrimental to their performance, and those whose performance was not affected by their regret, but who suffered personal consequences of maintaining their performance in the face of regret instead.

The first group, in line with expectations, discussed how regret detrimentally impacts their engagement with work highlighting a reduction of work effort or hours invested in work, greater lateness and absenteeism and a decline in discretionary efforts - in other words psychological/behavioural withdrawal resulted from feeling regret about one's career choice. These

findings align with a broader literature on regret (e.g. Savitsky, Medvec, and Gilovich, 1997) and highlights the cost to organisations, as well as the customers or clients they serve.

The second, smaller group was of individuals who were characterised by a strong work ethic. These individuals didn't believe that their regret affected their performance at work, precisely because of their strong work ethic. However, the occupational regret and high work ethic combined led to a psychological paradox created by two contradictory elements (Smith and Lewis, 2011): both wanting and not wanting to engage with their work. This contradiction emerged from trying to stay true to multiple values – the value of diligence (underpinned by their strong work ethic) and the value of authenticity (driven by their wish to find a fulfilling career).

The resultant desire to simultaneously minimise and maximise their work effort led to personal costs including emotional labour, which was used as strategy to manage the paradox. Individuals described the emotional labour associated with hiding one's regret from colleagues; almost unanimously, participants outlined the toll taken by having to 'act' enthusiastically about their work whilst at work. This was compounded for individuals working in client facing sectors and roles (e.g. healthcare and teaching). Specifically, there was a negative impact on wellbeing from the additional emotional labour required to 'perform' for their clients or customers.

Limitations

Qualitative research is often retrospective in nature - however, the study interviewed individuals reflecting on both past and current occupational regret. Whilst the sample included a diverse range of interviewees, there is a bias towards more educated and professional individuals, which could be broadened out in future.

Conclusions/Relevance to the Congress Theme/UN SDGs

This study illuminates the nuanced way in which regret affects performance-related outcomes at different levels and highlights the vulnerabilities in worker wellbeing caused by this emotion, especially amongst those with a strong work ethic. Given the large role work plays in our lives, these findings are important for the UN SDG of good health and wellbeing. Empirically, it helps to build a picture of the mechanisms through which performance in the workplace is potentially threatened by occupational regret – directly or indirectly - and in a changing world of work, may become more relevant as individuals seek to leave less meaningful occupational avenues.

Keywords: Regret career performance

Paper 3

Finding the Beauty in Your Career Missteps: Exploring How Individuals Deal With Their Career Missteps and Prevent Career Regret

Claire Schulze Schleithoff, Vrije Universiteit Amsterdam; Konstantin Korotov, ESMT Berlin; Svetlana Khapova & Evgenia Lysova | Vrije Universiteit Amsterdam

Research goals

Our study aims to shed light on career decisions that do not lead to the expected outcomes and are, thus, perceived as missteps and how individuals deal with them. To tackle this, we address the following research question:

How do individuals deal with their career missteps and prevent experiences of career regret?

In so doing, we aim to extend current knowledge on individuals' career decision-making in the contemporary career context (e.g., Gati & Kulcsár, 2021). Specifically, we contribute to prior calls to help individuals to make better career decisions which are not solely based on rationality and logic (Gati, 1996; Gati & Kulcsár, 2021). Additonally, we aim to contribute important theoretical knowledge for career regret development (e.g., Sullivan et al., 2007).

Theoretical background

Although, career research is fairly well established and topics such as career-decision making (e.g., Gati et al., 2019), career success (e.g., Heslin, 2005) and employability (e.g., Forrier et al., 2015) have attracted various scholars in the past (Akkermans & Kubasch, 2017), the "dark side of contemporary careers" (Baruch & Vardi, 2016, p. 355) has only been addressed to a limited extend so far. In particular, to date we lack important knowledge on career failure, career error, as well as career regret (Byington et al., 2019; Sullivan et al., 2007). While contemporary careers are characterized by self-management, deliberate decision-making, and an agentic career perspective (e.g., Arthur et al., 2005; Sullivan & Baruch, 2009), we need to acknowledge that not all career decisions lead to the desired outcomes and can, thus, be perceived as missteps later on. We conceptualize career regret is a constant negative feeling (Schulze Schleithoff et al., 2022), while career missteps are perceived as not optimal decisions (c.f., Gati & Kulcsár, 2021) since they do not lead to the expected outcomes.

However, insights on individuals' reactions to their career setbacks and failures (Baruch & Sullivan, 2022; Byington et al., 2019) as well as how they experience career regret (Sullivan et al., 2007) remains limited. This is surprising, since individuals are more frequently confronted with alternative career paths and consequently create possible selves leading to regretful thoughts about forgone opportunities (Obodaru, 2012, 2017) and occupational choice regret (Budjanovcanin et al., 2019). Hence, many of them experience career decision-making as difficult and stressful as they aim to avoid regret (Argyropoulou et al., 2007; Gati & Kulcsar, 2021). Thereby, the lack of insights on career missteps and career regret limits a comprehensive understanding of individual's decision making in the contemporary career context (Baruch & Vardi, 2016; Sullivan & Al Aris, 2021).

Design/Methodology/Approach/Intervention

We draw on qualitative data collected on a sample of professionals (N=72) and used the analysis techniques of grounded theory (Gioia et al., 2013; Strauss & Corbin, 1990). When looking at the emergent findings, we turned to the concept of repair, which we found in research about social

relationships (e.g., Dindia & Baxter, 1987) or customer relationships (e.g., Xie & Peng, 2009). This prior research helped us to see the interviewee's efforts as an example of conducting repair in relation to their careers. Thus, we introduce career repair as new term to the career literature.

Findings

We saw that not every career misstep results in a regret. More specifically, the majority of our participants actively engage in career repair and value or rationalize their career missteps later on as they offer them valuable learning opportunities. We found four career repair strategies, namely (1) restoring ((re-) aligning career with personal values), (2) extending (broadening boundaries), (3) transitioning (changing organization/team), and (4) negotiating ((re-) negotiation of conditions). This leads to either career recovery or career growth. Consequently, career repair helps individuals to learn from their career missteps and to engage in a career learning circle. Based on these findings we developed a process model on career repair. The data further showed that successful career repair (regardless of the strategy) avoids career regret.

Limitations

Since this study is based on perceptions of a group of individuals, who were all reflective towards their careers and highly educated, the outcomes are not generalizable to every working individual.

Conclusions/Relevance to the Congress Theme/UN SDGs

In this paper, we emphasize that individuals deal with their career missteps by employing career repair which helps to prevent career regret. Our insights provide important theoretical and practical implications which help to foster individual's health and well-being (SDG 3).

Symposium S056

Reducing judgmental bias and adverse impact in recruitment and selection

Annemarie Hiemstra, Erasmus University Rotterdam

science_practice

What will be covered and why: Systematic differences in unemployment rates show that underrepresented groups on the labour market, such as older and ethnic minority job seekers, are less successful in finding work than majority applicants with a comparable education level (OECD, 2016; Dagevos & Gijsberts, 2007). This is partly due to judgmental biases in recruitment and selection (Derous et al., 2017). This symposium brings together researchers from seven institutions in five countries, across Europe and the United States, involved in innovative research on reducing judgmental bias and adverse impact in recruitment and selection. They will present their work in three presentations followed by a discussion led by dr. Nikolaou.

Building on the dual-process theory, previous research showed that screening tools in the early selection stage, like resume screening (Derous & Ryan, 2019), are vulnerable to bias. Similarly, social media screening for selection might be prone to bias. Recent research indeed showed initial evidence for bias against older applicants during LinkedIn screening (Krings et al., 2021). Schellaert, Derous, and Oostrom are among the first to empirically investigate the role of recruiters' stereotypes (i.e., warmth and competence) of younger and older applicants on their job suitability ratings. Furthermore, Odijk, Hiemstra, Franx, and Born investigate an intervention aimed at reducing the influence of HR professionals' judgmental bias in CV screening of ethnically diverse applicants, namely via a standardized application form that was developed to increase equal opportunities among job seekers. They compare the effectiveness of this standardized application form with job suitability ratings of the same applicants via a traditional resume.

The studies by Schellaert et al. and Odijk et al. focus on judgmental bias that may lead to adverse impact for underrepresented applicants at the earliest selection stage (i.e., cybervetting and resume screening). Different stages of a selection process can vary widely from each other in selection ratio and selection measures used. It is not uncommon to use the same methods for assessing adverse impact across stages. Deciding which adverse impact metric(s) to apply can be difficult, confusing, and time consuming for researchers and organizations alike. Hence, Walker Nottingham, Rupp, and Iliescu provide evidence-based guidance, using a Monte Carlo simulation, that can help in choosing the best adverse impact metrics to use to understand how various demographic subgroups fare at various stages of selection processes.

Based on the three presentations in this symposium, dr. Nikolaou will reflect on the latest developments in personnel selection research aimed at reducing inequalities. Dr. Nikolaou is Professor of Organisational Behaviour, Director of the MSc in Human Resources Management at Athens University of Economics and Business, Greece and Editor-in-Chief of the peer-reviewed journal International Journal of Selection & Assessment . His research interests focus mostly on employee recruitment, selection and assessment and more recently on the use of social media and serious games/gamification. He maintains active links with the industry through Human Resource consulting projects and executive training. He is the co-founder of the European Network of Selection Researchers (ENESER).

Relevance to the Congress Theme: The urgency to reduce social inequalities (SDG goal) is expressed by the congress theme (The future is now!) and this symposium supports evidence-informed actions that aim to contribute to achieving this SDG goal in the context of recruitment and selection.

Research/Practical Implications: Given the global aging, diversifying work population and shortages on the labor market (United Nations, 2019) it is highly relevant to use unbiased selection tools. This symposium shows that LinkedIn screening is prone to age bias. As HR professionals tend to categorize less when more personalized information is available, a well-developed profile can help older applicants through the LinkedIn screening phase. Furthermore, structuring the rating process, particularly in the bias-prone resume screening phase, can help to reduce the influence of individual differences in ratings and hence ensure a more equal treatment of all applicants. This is important to prevent both over- and underprediction of (minority) applicants' job suitability. Lastly, our simulations and visualizations provide insight into how utilizing different metrics at various stages in a selection process can affect whether a selection procedure is determined to have adverse impact.

Overall conclusions: This symposium shows what recent empirical evidence is available to reduce inequalities in recruitment and selection. This symposium helps practitioners to make evidence-informed decisions to create an inclusive selection procedure and to assess the potential adverse impact in an optimal way.

Paper 1

LinkedIn as screening tool: Prone to bias?

Maaike Schellaert, Ghent University; Janneke Oostrom, VU Amsterdam; Eva Derous, Ghent University

Research Goals. Social media, in particular LinkedIn, are widely used among HR professionals to screen job applicants and make initial hiring decisions (i.e., cybervetting). However, due to the limited information available on LinkedIn profiles, LinkedIn screening might be vulnerable to bias against underrepresented groups, including older applicants. Despite the societal importance to retain older workers in the workforce, studies on potential bias in LinkedIn screening and strategies to reduce age-related differences are limited.

We aimed to address this gap in the literature and examined age bias in LinkedIn screening. Further, we considered the role of two contingencies: recruiters' stereotypes and applicants' recommendations.

Theoretical Background. Building on the dual-process theory, previous research showed that initial screening tools, like resume screening (Derous & Ryan, 2019), are vulnerable to bias. Similarly, LinkedIn screening might be prone to bias. Recent research indeed showed initial evidence for bias against older applicants during LinkedIn screening (Krings et al., 2021). Therefore, we expected lower job suitability ratings for older compared to equally-qualified younger applicants during LinkedIn screening (H1). Due to the lack of personalizing information on LinkedIn, bias can be affected by recruiters' stereotypes about older workers' warmth and competence. However, it is unclear whether recruiters' explicit stereotypes can affect age bias during cybervetting. Since warmth/competence perceptions are related to hiring outcomes, we expected that positive attitudes about older workers' warmth (H2a) and competence (H2b) mitigate age bias. Further, LinkedIn-specific elements, like recommendations received from colleagues/supervisors, can provide personalized information and signal applicants' warmth and competence, which could affect social judgments. Therefore we expected that recommendations signaling applicants' warmth (H3a) and competence (H3b) mitigate age bias.

Methodology. An experimental study among 372 HR professionals/recruiters (M age =35.85y, SD age =11.65y; 73.1% women; 51.5% university degree), using a 2 (age: <30y vs. >50y) by 2 (recommendations' warmth: neutral vs. high) by 2 (recommendations' competence: neutral vs. high) within-subjects factorial design was conducted. Prior to the main analyses, we conducted three pilot studies (N total = 216) in order to develop study materials.

Results. Preliminary analyses showed that manipulations were successful. Based on the correlation table and previous research (De Meijer et al., 2007), we controlled for recruiting experience. First, a repeated measures ANCOVA showed a main effect for age (H1 supported). Job suitability ratings were higher for younger than older applicants based on their LinkedIn profile. Second, results showed no significant interaction effect between applicants' age and recruiters' warmth stereotypes (H2a unsupported), but a significant interaction effect of applicants' age and recruiters' competence stereotypes (H2b supported). When recruiters have more positive stereotypes about older workers' competence, the negative relationship between the applicants' age and job suitability ratings is weaker. Third, there was no significant interaction effect of applicants' age with recommendations'

warmth (H3a unsupported), however the interaction effect of applicants' age with recommendations' competence was significant (H3b supported).

Limitations. First, fictious LinkedIn profiles were evaluated; future research could use real LinkedIn profiles to increase ecological validity. Second, the within-subjects nature of our randomized experimental design is realistic and controls for participants' characteristics (i.e., real HR professionals/recruiters), but might potentially inflate hiring discrimination scores (Bal et al., 2011). Follow-up studies could use a between-subjects design to replicate findings. Third, we used male applicants with 30 and 50 years as age boundaries. Further research could consider female applicants and other age categories to investigate the intersectionality between age and gender.

Conclusions – Research and or Practical Implications. Given the global aging population and shortages on the labor market (United Nations, 2019) it is highly relevant to use unbiased selection tools. Nevertheless, thorough research on cybervetting and bias is limited. Our results showed that LinkedIn screening is prone to age bias, with recruiters' positive stereotypes about older workers' competence and applicants' competence recommendations mitigating this effect. As HR professionals tend to categorize less when more personalized information is available, a well-developed profile can help older applicants through the LinkedIn screening phase (Chiang & Suen, 2015; van Dijck, 2013). Additionally, organizations could organize trainings for recruiters to create awareness about the potential biases and advise them how to screen profiles.

Relevance to the Congress Theme. Fairness during personnel selection is increasingly important, especially given increased retirement ages and a switch to more technology-based hiring practices.

Relevant UN SDGs. The topic is related to the SDG 'Reduced Inequalities'.

Keywords: cybervetting; older workers; stereotypes

Paper 2

Equal opportunities in selection – The effectiveness of an intervention to reduce judgmental bias against diverse applicants in resume screening

Janice Odijk, Annemarie Hiemstra & Marise Ph. Born | Erasmus University Rotterdam

Goal and theoretical background. Systematic differences in unemployment rates show that minorities with a non-Western migration background are less successful in finding work than majority applicants with a comparable education level (OECD, 2016; Dagevos & Gijsberts, 2007). This is partly due to judgmental biases in recruitment and selection (Derous et al., 2017). An overwhelming number of studies show that people with a non-Western name or background are less likely to be selected during the selection process (Baert et al., 2017). Traditional CV screening has particularly been found to be very susceptible to judgmental bias as selection methods (Derous & Ryan, 2019). In this study, we investigate an intervention aimed at reducing the influence of HR professionals' judgmental bias in CV screening of diverse applicants, namely via a standardized application form.

Method . Applicant participants (89 Dutch, 7 Western and 31 non-Western backgrounds; N = 127) participated in an application simulation, in which they were instructed to apply for a non-existent vacancy for a retail management traineeship at a large Dutch company. The HR participants (N = 112) were actual professionals who assessed CVs or structured competency-based responses of 10 applicants. A 2 (CV format, within-subjects) x 2 (ethnicity, between-subjects) mixed design was used to test the effect of the intervention. The order of presentation of the CVs and forms was randomly shuffled (counterbalancing) to avoid order effects in the assessments. Prior to the experiment, the experimental materials (vacancies, standardized application form and questionnaires) were developed and piloted. The standardized application form was based on an intervention that was developed for the Dutch Ministry of Social Affairs and Employment (Huijs et al., 2021).

The assessment form used by HR participants to score the candidates contained items related to job suitability (3 items; Derous et al., 2009), perceived candidate fit as measured by perceived similarity (Person-Person fit, 4 items; Howard & Ferris, 1996) and likeability (2 items, Good & Rudman, 2009). Approximately two weeks after submitting the assessments, each HR professional completed a questionnaire about individual characteristics. This included demographic characteristics, External and Internal Motivation to Respond Without Prejudice (10 items; Plant & Devine, 1998) and Social Dominance Orientation (14 items; Pratto et al., 1994).

Results. Analyses showed no significant difference in job suitability ratings between Western applicants and non-Western applicants when applying with a traditional resume (M = 3.51; M = 3.65 respectively) nor when applying with the standardized application form (M = 2.92, M = 2.94). It was remarkable that the job suitability ratings were consistently lower in the condition in which the standardized application form was rated. Interrater reliabilities for the various rater groups were good for the standardized form (between 0.90 – 0.94), but variable for the traditional resume (between 0.45 – 0.91). Correlational analyses showed a significant relation between individual differences dimensions and job suitability ratings, but only in the traditional resume condition (e.g., perceived similarity: r = .45, p <.001; r = .15, p = .27). Further analyses are currently being conducted and will be presented. First results suggest that in the traditional resume condition a

higher perceived similarity positively moderated the job suitability score for minority applicants, while this effect was not found in the standardized application form condition.

Implications, limitations, and conclusion. We tested the effectiveness of an intervention to reduce judgmental bias against ethnic minority applicants by using a structured application form compared to a traditional resume. No difference in job suitability ratings were found between minority and majority applicants. The relation of job suitability ratings with HR professionals' individual difference variables, however, were significant in the traditional resume condition and absent in the structured application form condition. Furthermore, interrater reliabilities were lower in the traditional resume condition. Based on these results we conclude that structuring the application process, particularly in the bias-prone early selection stage, can help to reduce the influence of individual differences in ratings and hence ensure a more equal treatment of all applicants. This is important to prevent both over- and underprediction of (minority) applicants' job suitability.

Relevance to Congress theme and UN SDGs. The urgency to reduce social inequalities (SDG goal) is expressed by the congress theme and this presentation provides an evidence-informed intervention to contribute to achieving this goal in the context of recruitment and selection.

Keywords: bias; resume screening; intervention

Paper 3

Adverse impact statistics across selection stages: A Monte Carlo simulation

Dragos Iliescu, University of Bucharest; Deborah Rupp & Anna Walker Nottingham | George Mason University

Research goals and why the work was worth doing. Adverse impact is the statistical result that occurs when organizations (often unintentionally) select individuals from a legally protected demographic subgroup at a significantly lower rate than a comparison group. Several adverse impact metrics are used by researchers, organizations, plaintiffs, expert witnesses, and the courts to determine if differences in selection rates across demographic subgroups are statistically and/or practically significant. The use of these various metrics can make a difference in terms of both the strength/rigor of the inferences made based on the results, and whether adverse impact is viewed as being present. In this paper, we explore the implications of using differing adverse impact metrics, under various selection conditions, which often exist (and vary) across the stages of a selection process.

Theoretical background. Even though different stages of a selection process can vary widely from each other in number of applicants assessed, selection measures used, selection rate, etc., it is not uncommon to use the same methods for assessing adverse impact across stages. Deciding which adverse impact metric(s) to apply can be difficult, confusing, and time consuming for researchers and organizations alike. Hence, evidence-based guidance is needed that suggests the best adverse impact metrics to use to understand how various demographic subgroups fare at various stages of selection processes.

Design/Methodology/Approach/Intervention. Specifically, we utilized a Monte Carlo simulation to evaluate various adverse impact statistics. We varied overall sample size, overall selection ratio, proportion of minority group members, and minority selection ratio to simulate different contexts throughout the stages of the selection process (see Table 1 for our parameter levels). Iterating through each combination of parameter levels produced 6096 configurations that each contained 1000 runs so that we could evaluate each metric's sensitivity to 'calling' adverse impact in a variety of contexts. Then, we computed data visualizations to better understand how various adverse impact metrics behave under varying circumstances mirroring typical selection stages. First, we created a data visualization in which overall sample size was held constant and all other parameters (overall selection ratio, minority selection ratio, proportion of minority group members) were allowed to vary. This chart enabled us to evaluate the overall effect of sample size on each hurdle's sensitivity to 'call' adverse impact. Second, we simulated the characteristics of a typical multiple hurdle selection process.

Results. The data visualization chart with all parameters held constant except for sample size displays the metrics and their sensitivity (S) to call adverse impact across sample sizes. From most sensitive to least sensitive, the shortfall 80 , shortfall 85, impact ratio, Phi coefficient, h-statistic 20 , and h-statistic 50 display almost uniform sensitivities across sample size. The Z-test and LMP display increasing sensitivity as sample size increases.

Limitations, implications and conclusions. Our simulations and visualizations provide insight into how utilizing different metrics at various stages in a selection process can affect whether a selection procedure is determined to have adverse impact. When other parameters were allowed to vary,

sample size greatly affected the sensitivity of the Z-test and LMP, but not the shortfall statistic, impact ratio, phi coefficient, or h-statistic. Consequently, as sample size decreased, especially to under 50 applicants, the Z-test and LMP showed much less sensitivity to concluding adverse impact, even when a selection method may be 'truly' adversely affecting a certain subgroup.

Relevance to the Congress Theme. The theme of adverse impact and of fairness specifically is becomes even more critical than it was already in light of our interest in the changing nature of work – which is also the Congress theme.

Relevant UN SDGs. The topic is connected to SDGs 8 (Decent Work and Economic Growth), 9 (Industry, Innovation and Infrastructure), and 10 (Reduced Inequalities).

Keywords: adverse impact; selection; monte carlo simulation

Symposium S057

The role of leisure crafting in people's (working) lives

Paraskevas Petrou, Erasmus University Rotterdam, The Netherlands

science

What will be covered and why

Leisure crafting is often defined as the proactive pursuit of leisure activities targeted at goal setting, learning and development, and human connection. Unlike in casual leisure, leisure crafters take up high-commitment and long-term challenges in their free time, which may help them grow as individuals. Recently, literature has revealed that leisure crafting has benefits for individuals, both at their work and outside their work. The goal of the present symposium is to showcase this relatively new, yet growing, research area and bring together researchers who are currently investigating the benefits of leisure crafting. Notably, all four contributions adopt a work-life interplay perspective and suggest that leisure crafting plays a prominent role within work-life balance. Different contributions of this symposium highlight different directions in which work-life balance may unfold. The first contribution (Manzanares, Martínez-Corts, Hernández, Demerouti, & Medina) reveals that on weeks when employees craft their jobs, they also display leisure crafting, which enhances not only their own wellbeing but also the wellbeing of their partners. The second contribution (Abdel Hadi & Häusser) proposes leisure crafting as a mechanism that may potentially transform suboptimal levels of job control (too high or too low control) into need satisfaction at work. Similarly, the third contribution (Chen) uncovers leisure crafting as a mechanism that transforms employees' homesickness into creativity at work. Finally, the last contribution (Petrou & de Vries) proposes and validates a leisure crafting intervention that leads to work-related benefits (e.g., work engagement and creativity) and context-free benefits (e.g., meaning and self-efficacy).

Relevance to the congress theme

The changing world of work has led to drastically new working conditions. Jobs become increasingly flexible; "nine-to-five" jobs are becoming an exception and employees are expected to be proactive, creative and entrepreneurial and to reinvent themselves in this revolutionary new world. The notion of leisure crafting, by definition, shows employees to be more than just workers. Leisure crafters proactively pursue what is meaningful to them and this is not only at work but it can also be outside work. As such, they cross boundaries and navigate their way throughout multiple life domains. Especially in the post-COVID-19 times, boundaries between such life domains are blurred. A potential risk of blurred boundaries is that employees neglect their authentic selves and identities outside work (e.g., because they overwork). A potential opportunity of these blurred boundaries is that by engaging in leisure crafting, employees may not only benefit their lives and wellbeing overall but also these experienced benefits may carry over to other life domains (e.g., at their work).

Research/practical implications

In work-life literature, there are alternative views about how life domains interact with other. For example, one life domain may compensate for the inefficiencies of another domain (i.e., compensation perspective), but also one domain may further enhance or boost another domain (i.e., spillover perspective). Arguably, the studies of this symposium highlight that both of these perspectives can be true. While contribution 2 and 3 suggest that leisure crafting compensates for suboptimal personal states (e.g., homesickness) or working conditions (e.g., job control), contribution 1 suggests a positive spillover effect from work to leisure, while contributions 2, 3 and 4 suggest a

positive spillover effect from leisure to work. As suggested by contribution 4, future research should keep developing and optimizing leisure crafting interventions that can be used by employees and practitioners to attain higher quality of (working) life.

Overall conclusions

Leisure crafting may be triggered by both context-free states and work-related states and it may have both context-free and work-related benefits for individuals. The present studies validate this assumption by using longitudinal survey methodology of different time intervals as well as intervention methodology.

discussant: Jessica de Bloom, University of Groningen, The N

Paper 1

Crafting Behaviors and Employees' and Partners' Well-being: The Mediating Role of Leisure Crafting

Inés Martínez-Corts, Sandra Manzanares & Francisco J. Medina | University of Seville, Spain; Evangelia Demerouti, Eindhoven University of Technology, The Netherlands; Ana Hernández, University of Valencia, Spain

science

Research goals and why the work was worth doing

The importance of employees' well-being for organizations is increasing, due to its impact on organizational performance and competitiveness and on society. This is especially relevant if we consider that employees' well-being might be transferred to other people in their close environment (for example, to their partners), thus multiplying its effects. In this study, we address job crafting and leisure crafting as proactive behaviors that build a pool of useful resources for work and nonwork domains and enhance employees' and their partners' well-being.

Theoretical background

Based on the COR theory, the Work-Home Resources (W-HR) model explains how resources are interconnected across work and non-work domains. Employees develop different personal resources to foster goal achievement. These personal resources are relevant because organizational resources are generally scarce. Then, through a gain spiral, these personal resources generate new resources that spillover from the work domain to the nonwork domain. The relationship between job crafting and leisure crafting is suggested to be based on a positive spillover process of motivation, efforts, and outcomes between work and nonwork domains.

Design/Methodology/Approach/Intervention

A quantitative longitudinal study using weekly online questionnaires (for four weeks) was conducted among 50 participants and their partners.

Results obtained or expected (if not available, it must be made clear when they will be)

Multilevel analyses provided empirical support for a three-path sequential mediation model: Weekly expansion-oriented job crafting related to weekly leisure crafting, which related to employees' weekly well-being, which related to partners' weekly well-being. Leisure crafting played a key role as a mediating mechanism.

Limitations

The methodology used does not allow us to establish any causal relationships between our main variables. We encourage the use of longitudinal diary studies with a large and heterogeneous sample and several data points per day, in order to analyze the link between work, leisure time, and personal relationships over time, where antecedents precede the mediators and mediators precede the outcomes.

Conclusions – research and or practical implications

This study demonstrates that the work and leisure domains can be integrated rather than segmented to increase employees' well-being. This is one of the first studies to show the relationship between weekly expansion-oriented job crafting and leisure crafting behaviors and to empirically

demonstrate the benefits of weekly leisure crafting for the weekly well-being of employees and their partners.

Relevance to the Congress Theme

As work and organizational psychologists, we are unique professionals in understanding how individuals relate with contextual and personal resources and the benefits that resources have not only to avoid pain but also to enhance wellbeing. By understanding these psychological mechanisms we can design tools such as job crafting and leisure crafting interventions to increase personal resources, help individuals deal with demands in different life domains and increase their wellbeing.

Relevant UN SDGs

The present study proposes two mechanisms (job crafting and leisure crafting) that help employees improve their work and non-work domains, and enhance their own health (i.e., wellbeing) as well as the health of their partners. As such, the research is aligned with de “Good health and wellbeing”, and “Decent work and economic growth” Sustainable Development Goals.

Keywords: leisure crafting, job crafting, wellbeing

Paper 2

Relationships between optimal job control, psychological need satisfaction, and leisure crafting

Sascha Abdel Hadi & Jan A. Häusser | Justus-Liebig-University Giessen, Germany

science

Research goals

A central goal of this study is to examine how (optimal) job control is related to the satisfaction of basic psychological needs, assuming a curvilinear relationship between job control and need satisfaction. We expect that both too low as well as too high levels of job control decrease opportunities for psychological need satisfaction at work, whereas moderate levels of control should be positively associated with it. In addition, we propose that leisure crafting is initiated by unfavourable (too low or too high) levels of job control to compensate for insufficient psychological need satisfaction at work, by providing opportunities for need satisfaction during leisure time.

In a four-wave longitudinal study, we aim to test the curvilinear relationship between job control and psychological need satisfaction, which in turn should be negatively related to leisure crafting, ultimately restoring need satisfaction. To test the assumption of curvilinear relationships between job control and need satisfaction, we adapted optimized measures (too much/too little rating scales) of job control to capture its full range.

Theoretical background

Previous research based on Self-Determination Theory supports the assumption that job control (i.e., the ability to make own decisions at work) is crucial for the satisfaction of basic psychological needs. Basic psychological needs refer to the need for autonomy, the need for competence, and the need for relatedness. However, theoretical considerations and empirical studies suggest that there might be a tipping point with regard to the effects of job control beyond which its (positive) effects turn negative. Thus, both too high and too low levels of job control may pose a threat to need satisfaction, and satisfaction of psychological needs should occur at moderate levels of job control.

Furthermore, we assume that leisure crafting can serve as a strategy for need fortification. Leisure crafting is defined as the proactive pursuit to engage in leisure activities targeted at goal setting, human connection, learning, and personal development. Prior research has found that, on the one hand, leisure crafting is affected by job control (in combination with job demands and home control) and that, on the other hand, it satisfies psychological needs.

Methods

We are currently conducting a longitudinal study with four measurement waves to examine whether unfavorable levels of job control (Time 1) undermine need satisfaction (Time 2), which in turn increases leisure crafting (Time 3), which should ultimately be related to fortification of these needs (Time 4). Our surveys include measures with regard to (optimal) job control, as well as measures to capture need satisfaction and leisure crafting. Data collection is conducted through an international online panel provider. We aim to collect data of at least 300 participants over the course of all four times of measurement.

Results and Conclusions

As the study is still ongoing we are not able to provide final results by the time of the abstract submission. However, data collection will be completed in time so that the results will be presented within the session.

Our research adds to theorizing on job control as a work-related resource by increasing knowledge with regard to possible curvilinear relationships and need satisfaction. Applying a new measure to capture optimal levels of control contributes to a deeper understanding of non-linear effects of job control. Furthermore, by testing whether unfavorable levels of job control initiates leisure crafting, we increase the understanding of how employees might compensate for unsatisfied psychological needs at work through crafting leisure.

Limitations

Although we will model time-lagged effects, we cannot fully exclude the possibility of reversed effects or third variable influences.

Relevance to the Congress Theme and to UN SDG's

Our research fits well with the congress theme of EAWOP '23 "The future is now: the changing world of work" and the UND SDG'S ("Good health and wellbeing" and "Decent work and economic growth") as it increases knowledge on how to improve flexible working conditions through optimal levels of job control. Furthermore, it aims to identify strategies (i.e., leisure crafting) that workers use to compensate for unfavourable levels of job control.

Keywords: leisure crafting, job control, need satisfaction

Paper 3

Expatriates' homesickness and creativity: The mediating role of online leisure crafting moderated by technology self-efficacy and COVID-19 stress

I-Shuo Chen, Anglia Ruskin University, UK

Research goals and why the work was worth doing

Our primary aim was to investigate whether homesickness benefits expatriates' creativity at work through online leisure crafting. Investigating this issue enables not just us to broaden existing knowledge regarding homesickness in the literature but also the managers of multinational enterprises to promote better work behaviors for expatriates who experience homesickness during the pandemic. We took creativity at work as the studied work behavior since it is critical for the long-term development of companies.

Theoretical background

We adopted conservation of resources theory as the theoretical underpinning. By viewing homesickness as a sign of the need for resources, we posited that although homesickness hinders creativity at work directly, it indirectly benefits creativity at work through online leisure crafting. We also claimed that as a personal resource, technology self-efficacy may motivate individuals to perform online leisure crafting. It is conceivable that compared to those low in technology self-efficacy, homesick individuals who have high technology self-efficacy may be more likely to invest resources in online leisure crafting. Furthermore, we claimed that, due to its resource depletion nature, COVID-19 stress may lead individuals to reduce creativity at work. It is also conceivable that compared to those low in COVID-19 stress, those high in COVID-19 stress may not be in a better position to invest the resources they acquired through performing online leisure crafting in work creativity.

Methodology

By studying a group of Taiwanese expatriates using a three-wave design (N= 485), we measured homesickness and technology self-efficacy at Time 1, online leisure crafting and COVID-19 stress at Time 2, and manager-rated creativity at Time 3.

Results

We not just provided empirical evidence to support existing studies' finding that homesickness may reduce creativity at work, but also showed that homesickness contributed to creativity at work through online leisure crafting. We revealed that expatriates' technology self-efficacy amplified the positive impact of homesickness on their online leisure crafting. We showed that expatriates' COVID-19 stress nullified the positive impact of online leisure crafting on their creativity at work.

Limitations

First, all respondents had the same nationality. Our results may not be generalizable to non-Taiwanese expatriates. Second, this study does not consider the role of manager- or organizational-level variables in the model. Third, future research may use quantifiable creativity as an outcome measure to retest our hypotheses.

Conclusions

We explored the positive role of homesickness in creativity, while providing empirical evidence to support the conventional view of homesickness in the literature. We proposed that online leisure crafting is a mechanism homesick individuals use to obtain resources that in turn benefit their creativity at work. The test of the moderating role of COVID-19 stress in this study allows us to discover what may affect the effect of online leisure crafting on individuals' behaviors. We opened a budding debate by proposing that different levels of COVID-19 stress may alter the impact of online leisure crafting on individuals' subsequent behaviors.

Relevance to the Congress Theme

The Congress theme is The Future is Now: the changing world of work. The world of work has been largely impacted by the COVID-19 pandemic. We investigated the role of expatriates' homesickness due to the pandemic in their online leisure crafting and subsequently creativity at work. We also took into account the role of COVID-19 stress in the model. This study is hence relevance to the Theme of the Congress.

Relevant UN SDGs

This study reflects and contributes to one of the sustainable development goals of the United Nations. According to Goal 3: Good health and wellbeing, it is essential to ensure and promote the wellbeing for individuals, regardless of age, for sustainable development. Homesickness has long been viewed as a detrimental factor for individuals' wellbeing and health. However, we proposed that homesickness motivates individuals (e.g., expatriates) to acquire resources (e.g., through online leisure crafting). This to a certain extent contributes to their wellbeing and health due to resources acquisition. To promote the wellbeing for homesick expatriates, we suggest that the managers encourage them to perform online leisure crafting.

Keywords: leisure crafting, homesickness, creativity

Paper 4

Context-free and work-related benefits of leisure crafting: An online intervention and a survey study

Paraskevas Petrou, Erasmus University Rotterdam; Juriena de Vries, Leiden University, The Netherlands

science

Research goals and why the work was worth doing

Recent literature has addressed leisure crafting (i.e., proactive pursuit of leisure activities targeted at goal-setting, human connection, and personal development) as a behavior that may help employees attain both context-free and work-related benefits. However, there is a paucity of leisure crafting interventions aiming at training participants to display leisure crafting and, thereby, attain such benefits. The current study aims at designing and validating a leisure crafting intervention among working individuals and, thus, provide concrete tools that employees may use in order to not simply survive but also to thrive in multiple life domains.

Theoretical background

The theoretical rationale for our expectations is two-fold. First, we draw on theoretical frameworks suggesting that active leisure behaviour leads to multiple benefits by enhancing positive emotions and strengths-use, by helping people form their identity and by fulfilling needs that cannot be otherwise met. Second, our expectations are built on work-life spillover theoretical frameworks. Accordingly, the positive experiences and personal resources that individuals build during their leisure time do not cease to exist but, rather, they are carried over when individuals cross boundaries towards different life domains (i.e., work).

Design

Study 1 was a 4-week randomized controlled trial among 257 respondents working in several occupational sectors in The Netherlands. It compared an online leisure crafting intervention group against a control group, on context-free outcomes (i.e., meaning in life, need satisfaction, self-efficacy and context-free creativity) and work-related outcomes (i.e., work engagement, seeking challenges, and employee creativity). Study 2 was a cross-sectional survey study among 195 employees in The Netherlands. It aimed at replicating findings from Study 1 and, additionally, assessing correlations between self-reported leisure crafting and other-rated subjective wellbeing and context-free creativity.

Findings

Analyses from Study 1 revealed that the intervention group experienced a greater increase in meaning, self-efficacy, work engagement and employee creativity (results for need satisfaction were significant but not robust). Study 2 replicated these effects and additionally revealed positive links between leisure crafting and other-ratings of subjective well-being and context-free creativity.

Limitations

Study 1 was conducted among a sample where younger females where overrepresented and about half of the sample comprised working students. Future research should replicate our intervention among a more representative sample that does not include students.

Conclusions

Leisure crafting seems to be an effective strategy that helps employees achieve multiple work-related and non-work-related benefits. These benefits are validated by a variety of methodologies including an actual leisure crafting intervention (Study 1) and self-reported leisure crafting correlations (Study 2) and they still hold true even when outcomes are other-rated (Study 2).

Relevance to the congress theme

The changing world of work has been a central instigator and inspiration for our research. Our studies suggest that employees are not passive recipients of their (work) life conditions. Rather, they are active agents who cross life domain boundaries and may use one domain (i.e., leisure) to boost another domain (i.e., work). This is especially important in the post-COVID-19 times, where working from home creates blurred boundaries between life domains. Our research suggests that leisure crafting may be a way to not only minimize potential risks of these blurred boundaries but also to capitalize on potentially positive (spillover) effects that one domain may have on the other.

Relevant UN SDGs

By helping employees achieve work-related benefits (e.g., work engagement) as well as context-free benefits (e.g., self-efficacy and wellbeing), leisure crafting is arguably relevant for the UN SDG “Good health and wellbeing”. Furthermore, leisure crafting implies that individuals are more than simply the role of a worker. In fact, they have additional identities that span outside their work or their families. This helps individuals build meaning and authenticity that exists not only in their free time but is also carried over to their working lives. This connects to the “decent work” end of the “decent work and economic growth” UN SDG.

Keywords: leisure crafting, intervention, quality of life

Symposium S059

Do you see what I see? Exploring the antecedents and outcomes of congruence of perspectives at work.

Emilia KEEGAN, University of Toulouse Capitole

science

Content

Congruence in perception also referred to as perceptual difference, perceptual fit, perceptual congruence, and perceptual similarity, refers to alignment of perceptions of different parties. There are many reasons why different individuals in the same organisation, or even on the same team, may have differing perceptions of the same phenomenon, including different experiences, personalities, skills, and values (Harrison et. al, 2002). The difference in perception between team leaders and members has been illustrated in relation to work performance, communication, subordinates' roles, and organisational support (e.g., Hsiung et. al, 2009; Li et. al, 2015; White et. al, 1985). Such incongruence between hierarchical levels matters because research suggests that it is related to team performance, team-positive behaviours, and employee health and satisfaction (e.g., Gibson et al., 2009; Matta et al., 2015; Baer et al., 2021). The present symposium aims to bring together new research on (in)congruence.

The researchers contributing to this symposium use different theoretical frameworks (e.g., person-fit environment, complacency theory, justice enactment, and social exchange theory) and different approaches of analysis (e.g., DNDD approach, latent change score model, polynomial regression, and response surface approaches); promising to spark new debates. Specifically, our presenters provide insight into (1) the congruence between the psychological needs of employees, which refer to what employees want from work, and the promises made by their managers (Paper 1), (2) entrepreneur-employee socioeconomic wealth congruence effects on employee task performance and OCB, and the moderating effect of leader-member exchange on such congruence effects (Paper 2), (3) employee-work group, and employee-leader change in trust congruence over time and its impact on well-being and helping, as moderated by task interdependence (Paper 3) and, (4) antecedents of congruence in employees' justice perceptions and managers' justice enactment perceptions (Paper 4).

Paper 1 finds that a deviation from promises of supplies for employees leads to negative affect. This highlights the crucial need for psychological contracts and the need for alignment between promises and needs supply. Paper 2 finds that congruence on entrepreneur-employee socioeconomic wealth congruence is related to negative outcomes, namely decreased performance behaviours. They draw on complacency theory to explain this counterintuitive finding. Paper 3 finds a higher level of positive change in trust congruence to be linked to positive outcomes, with this relationship being moderated by task interdependence. Finally, the contribution by Paper 4 finds support for the hypothesized role of three antecedents of congruence; goal clarity, continuous feedback, and supervisor credibility, each of which can reduce incongruences in justice between managers and employees. All papers presented in this symposium thus present empirical contributions focused on the topic of congruence.

Research & Practical Implications

By including both potential negative effects of congruence and positive effects of congruence, the symposium highlights the complexity of the role of alignment of perspectives for both researchers

and practitioners. Similarly, including both work on outcomes and antecedents allows for a more holistic comprehension, which is particularly important for practitioners wishing to improve congruence dynamics. Our collective results also begin to show that congruence can be changed with time and so training, communication methods, and other actions can be put in place to achieve this.

Relevance to the Congress Theme

In line with this year's theme, "The Future is Now: the changing world of work" this symposium highlights the role of congruence in the workplace, both theoretically and practically. The work included in this symposium will showcase methods for analysing multistakeholder perception data (polynomial regression and latent change score models). Through the inclusion of employee well-being outcomes, our session contributes to the good health and well-being category. Our focus on team dynamics, performance team outcomes, and the overall impact on the company's bottom line of congruence effects speak to decent work and economic growth also.

Conclusions

This symposium will conclude by delivering an agenda for future research and practical insights. These results can help companies choose actions in order to better align perceptions and to reflect on which level and type of tension will push performance. This 90-minute symposium will be an interactive dialogue between presenters and audience members. The presentations will be 15 min each, after which we will summarise key insights and identify important directions for future research (5 minutes). The remainder of the time (20 min), will be dedicated to an interactive discussion between the audience and the presenters.

Keywords: congruence, multistakeholder perception, team performance

Paper 1

Multi-stakeholder view of Trust Congruence: Does change in trust congruence impact team effectiveness?

Emilia Keegan, University of Toulouse Capitole; Yannick Griep, Radboud University; Marion Fortin, University of Toulouse Capitole

Research goals and why the work was worth doing:

A crucial component of ongoing cooperative relationships is mutual trust. Trust can play a significant role in determining productivity for individuals, teams, and the organisation in organisational contexts (Anderson & Weitz, 1989; Smith & Barclay, 1997; Dirks & Ferrin, 2001, 2002; Kramer & Tyler, 1996; Rousseau et al., 1998). We know that perceptions of team trust lie in the eye of the beholder (Carter & Mossholder, 2015) and that misalignment or incongruence can be detrimental causing diminished effects on positive outcomes (Baer et al., 2021). Beyond looking at baseline trust congruence, practitioners and researchers need to understand the impact of change in trust congruence over time. Therefore, the aim of this study is to examine whether and when a change in trust congruence between employees and their team members or team managers over time predicts well-being and helping behaviour.

Theoretical background:

Individuals who work together have varying experiences, skills, values, and personalities (Harrison et al., 2002) and thus can have differing perceptions of trust in their team. This incongruence can occur between team members as it can occur between managers and teams (Bass & Yammarino, 1991; Van Velsor et al., 1993; Tafvelin et al., 2017). Research on perception between managers and teams on various salient team concepts (e.g., goal accomplishment, constructive conflict, power distance preferences, organisational support) and various team outcomes found that levels of congruence led to positive team outcomes, above and beyond the baseline level of the team process being measured (Gibson et al., 2009, Cole et al., 2013, Bashshur et al., 2011).

More specifically, a study on trust congruence has found that when cognitive and affective trust congruence between supervisor and work group increase over time, both extra-role behaviour and group performance increased (Carter & Mossholder, 2015). Amongst the theoretical reasoning given for the positive effects of congruence and the negative effects of incongruence are; collective cognition, social exchange theory, relational uncertainty, and cognitive dissonance.

We hypothesise that a positive change in trust congruence over time between employees and (1) managers and (2) team members, will lead to increased helping and well-being. Furthermore, we expect task interdependence to moderate the effect of change in trust congruence over time because task interdependence leads to members frequently interacting, communicating, and information sharing (Kozlowski et al., 1999; Thompson, 1967), leading to more opportunities to find a common purpose and common understanding. Therefore, we expect that when task interdependence is higher, the positive effects of change in congruence over time will be stronger.

Methodology:

Overall we collected matching data for 122 teams (T1 1559 members and 137 managers, T2 1393 members and 122 managers) in a repeated-measurement design, separated by a time lag of four to six months. To model change in congruence between (1) an individual employee and their team

members, and (2) an individual employee and their team manager in trust, we used a latent change score model (see Cheung, 2009; McArdle, 2009).

Results obtained:

Our results show that an increase in trust congruence over time between an employee and their team members is positively and significantly related to well-being and helping at T2. Task interdependence at T1 moderated this relationship, further strengthening the already positive effects of trust congruence. These effects are present above and beyond baseline levels of trust and initial levels of trust congruence. Unexpectedly, an increase in trust congruence over time between an employee and team manager, was not significantly related to wellbeing at T2, whereas it was positively and significantly related to helping behaviour at T2. This relationship was again moderated by task interdependence, as hypothesised. These effects are present above and beyond baseline levels of trust and initial levels of trust congruence.

Limitations:

A measurement design with two-time points does not allow us to fully investigate more complex temporal developments.

Research & Practical Implications:

Our results highlight the importance of considering change and directionality in change of trust congruence beyond absolute levels of trust congruence and the explanatory value of taking a multistakeholder perspective on congruence. This understanding is important for organisations wishing to improve their team functioning.

Originality & Value:

To the best of our knowledge, this is the first study to investigate the evolving effects of two types of trust congruence in the same design, member-to-team and member-to-manager. In addition, we introduce a structural moderator (task interdependence).

Keywords: trust congruence, latent change, well-being

Paper 2

Do You See What I See? The Performance Effects of Congruence Between Entrepreneur-Employee Socioemotional Wealth

Min Carter, Southern Illinois University; James Vardaman, Memphis University; Benjamin McLarty, Mississippi State University

Research goals and why the work was worth doing:

As the most common organisational form in the world, family businesses often face the dilemma of pursuing financial wealth or maintaining socioemotional wealth (SEW) (Gomez-Mejia et al., 2018). Whereas prioritising SEW (e.g., family prominence) shifts the firm's focus to actions that promote the image and reputation of the organisation to external stakeholders (Gomez-Mejia et al., 2017), motivating performance behaviors of employees, a key internal stakeholder, in alignment with these goals can be challenging. After all, employee performance collectively contributes to firm performance, a key indicator of finacial wealth. Thus, the goal of this research is to examine the complexity of this dilemma among the two key internal stakeholders, employees and entrepreneur-supervisors (entrepreneurs thereafter) who directly manage their employees. Specifically, we examine entrepreneur-employee SEW congruence effects on employee task performance and OCB, and the moderating effect of leader-member exchange (LMX) on such congruence effects.

Theoretical background:

SEW is defined as non-financial endowments that meet the family's affective needs (Gomez-Mejia et al., 2018). A specific form of SEW, family prominence (Debicki et al., 2016), reflects the goals to preserve and enhance the recognition/reputation of the family in the eyes of external stakeholders (e.g., community, suppliers). The desire to preserve family prominence often requires firms to shift their focus externally and stay small, especially if they seek to maintain their family essence by maintaining control and involvement in the business (Carr et al., 2011), which presents challenges for motivating employee performance. Although some perspectives submit aligning the importance of SEW by entrepreneurs-employees should foster behaviors (e.g., Joshi et al., 2003), complacency theory suggests that SEW alignment may create a state of equilibrium, or an "all is well" feeling (Raup, 1925), that reduces the salience of engaging in valuable performance efforts.

We theorize that SEW-prominence alignment between entrepreneurs and employees may create a sense of self-contentment and attentional inertia that makes performance behaviors less salient. Conversely, incongruence should create tensions and increase the salience of these behaviors, thus cultivating performance behaviors. We further propose that high-quality LMX can enhance these effects, as entrepreneurs and employees with better relationships should communicate and understand their differences and agreements more clearly which alleviates employees' complacency mindset.

Hypothesis 1: The more aligned entrepreneur-employee SEW-prominence importance perceptions, the lower (a) task performance and (b) OCB.

Hypothesis 2: LMX moderates the congruence effect of entrepreneur-employee SEW-prominence importance perceptions on (a) task performance and (b) OCB, such that the congruence effects are stronger when LMX is lower than when it is higher.

Design/Methodology/Approach/Intervention :

We included family firms from various industries including retail, services, construction, agriculture, finance, and manufacturing with the vast majority (82%) being small organizations (i.e., ≤ 50 employees). We collected employees' demographics and contact information for their entrepreneur-supervisors in Survey 1. Two weeks later, employees assessed SEW-prominence importance (Debicki et al., 2016) and LMX (Liden & Maslyn, 1998) in Survey 2, and entrepreneurs assessed SEW-prominence importance and their employees' task performance (Alper et al., 2000) and OCB (Kluemper et al., 2013) in Survey 3. Our final sample consists of 159 entrepreneur-employee dyads. We control for employee gender, age, race, dyadic tenure, and family membership status.

We used polynomial regression and response surface approaches to test congruence effects (H1) (Edwards & Cable, 2009) and followed the principles of moderated regression (Cohen et al., 2003) to test moderated congruence effects (H2).

Results obtained:

Supporting H1, the response surface along the incongruence line is curved upward for task performance (curvature = .21, p = .011; slope = -.31, p = .045) and for OCB (curvature = .24, p = .029; slope = .001, ns), indicating that performance behaviors decrease as entrepreneur-employee SEW scores become more aligned but increases as the scores diverge in either direction. For H2, the five product terms collectively account for significant incremental variance in OCB (ΔR2 = .08, p = .016) but not in in task performance (ΔR2 = .05, ns) over and above the polynomial regression terms. Thus, H2b is supported but not H2a.

Limitations:

Our study focuses on smaller entrepreneurial family firms; caution should be taken when generalizing results to larger family-owned organizations. We only collected perceptual data.

Research/Practical Implications:

Our findings inform the effects of the entrepreneur-employee relational dynamics involving the dilemma, a "paradox of fit" in family-owned ventures. Although counterintuitive, the interplay between entrepreneur-employee and a focus on SEW creates a unique situation where SEW congruence has a significant downside on performance. Our research further provides evidence that high-quality LMX can buffer undesirable congruence effects on OCB, underscoring the importance of social exchange between entrepreneurs and employees.

Originality/Value:

This research is original, not previously presented or published, and not under concurrent consideration elsewhere.

Keywords: socioemotional wealth, performance, congruence

Paper 3

What makes employees and managers see eye to eye concerning organizational justice? Predicting congruence in the pay-setting context

Eib Constanze, Uppsala University; Magnus Sverke, Johnny Hellgren & Helena Falkenberg | Stockholm University

Research goals and why the work was worth doing:

The aim of this study is to investigate predictors of congruence in employees' justice perceptions and managers' justice enactment perceptions. Using pay-setting as context, we hypothesize that goal clarity, continuous feedback, and supervisory credibility are predictors of congruence in justice perceptions (distributive, procedural, interpersonal and informational justice). With this, we make a theoretical contribution to the organizational justice literature by investigating predictors that may facilitate congruence in justice perceptions.

Moreover, the literature on congruence as an outcome is generally scarce in any field of organizational behavior. One of the reasons for this lack of studies has to do with the methodological difficulties to predict congruence. In this paper, we use a recently published strategy to analyze congruence and, with this, we add to the very scarce literature of congruence-as-outcome.

Theoretical background:

A large number of studies show that employees' justice perceptions are positively associated with organizational commitment, citizenship behaviors, and task performance. Only recently has the literature started to also consider justice enactment, or a manager's adherence to justice rules and principles. Rooted in social exchange theory, perceived and enacted justice supposedly refer to the same phenomenon but empirical studies report correlations from non-significant to moderately high. This is a puzzle essential to solve for the justice literature at large. While some may claim that it is employees' justice perceptions of managers' behaviors that matter, this line of thought would render justice enactment or what managers think they do in terms of justice futile. In contrast, recognizing that both – what employees perceive their manager does and what managers perceive they do – are subjective evaluations from different perspectives may provide fruitful avenues to study how to improve justice and fairness at workplaces. One of these avenues is to look at which managerial actions can facilitate congruence in justice perceptions.

Methodology:

Data stem from an industrial company operating in Sweden. Analyses were based on 124 pay-setting managers, who had at least two employees who provided data (N=535). Based on sufficient agreement indices, scores were aggregated for employees who had the same manager.

We followed the directional and nondirectional difference (DNDD) approach, as suggested by Bednall and Zhang (2020), which attempts to overcome limitations of prior approaches to estimate congruence as outcome variable.

Results obtained:

Generally, managers' justice enactment perceptions had a higher mean (i.e., directional difference) than corresponding employees' justice perceptions. The directional difference in justice perceptions was reduced for distributive ($b = -.37$, $p < .05$) and informational justice ($b = -.28$, $p < .05$) but not for

procedural and interpersonal justice with higher levels of goal clarity as perceived by employees. Thus, with increasing levels of goal clarity, congruence between managers and employees regarding distributive justice and informational justice increased. With higher levels of continuous feedback as perceived by employees, the directional difference was reduced for all four justice dimensions ($b = -.33–.53$, $p < .001$). Similarly, with higher levels of supervisor credibility as perceived by employees, the directional difference was significant for all four justice dimensions ($b = -.37–.63$, $p < .001$), In addition, supervisor credibility was negatively associated with shared variability in distributive justice ($b = -.12$, $p < .05$), which suggests that with higher levels of supervisor credibility, the response pattern between managers and employees diverged more.

Limitations:

Data were cross-sectional and were aggregated by manager but stem from two different sources. The method used to predict congruence is a newly published approach.

Research & Practical Implications:

We focused on concrete managerial actions in the context of pay setting as predictors of justice congruence. Generally, results revealed that the three chosen predictors (goal clarity, continuous feedback, supervisor credibility) reduced the mean value difference in justice between managers and employees. This is an important result, because the differing views of managers and employees in pay-setting discussions are widely known and problematized. When managers provide clear goals, give continuous feedback to their employees, and are seen as credible and competent in assessing performance, these differing perspectives may be overcome and justice congruence can be facilitated.

Originality & Value:

This is, to our knowledge, the first study to predict congruence in justice perceptions from the perspectives of pay-setting managers and their employees.

Keywords: Organizational justice; justice enactment; pay-setting

Paper 4

Needs-Supplies Fit and Psychological Contract Fulfillment: Competing Versus Complementary Predictors of Work Outcomes

Lisa Schurer Lambert, lisa.schurer.lambert@okstate.edu; Anders Friis Marstand, Durham University; Jeffrey Edwards, University of North Carolina

Research goals and why the work was worth doing:

Much research has examined how employees evaluate their work experience against various standards. One standard involves the psychological needs of the employee, which refer to what employees want from work. Psychological needs are central to various streams of research, most notably needs-supplies fit (Edwards, 1991; Kristof-Brown, Zimmerman, & Johnson, 2005), and the person-environment fit theory of stress (French, Caplan, & Van Harrison, 1982), and discrepancy theories of job satisfaction (Dawis & Lofquist, 1984; Locke, 1969). This research is based on the premise that, when psychological needs are fulfilled by work experiences, the employee experiences positive outcomes. Another standard concerns beliefs held by the employees about the promises made by the employer, which form the core of psychological contract research (Rousseau, 1995). To the extent these promises are fulfilled, positive outcomes are expected to result. Research on needs-supplies fit and psychological contract fulfillment both attempt to explain how employees respond to work experiences. Where these streams of research differ concerns the standards held by employees, with psychological needs underlying needs-supplies fit and perceived promises emphasized by psychological contract fulfillment. Because these streams of research have developed independently, little attention has been devoted to comparing them, which leaves important questions unanswered. For instance, are psychological needs or perceived promises more influential as evaluative standards? When explaining outcomes, are needs-supplies fit and psychological contract fulfillment redundant, or do each provide unique insight? How might integrating psychological needs and perceived promises enhance our understanding of how employees respond to work experiences?

Theoretical background:

This study addresses these questions by presenting a conceptual and empirical integration of needs-supplies fit and psychological contract fulfillment. We develop three perspectives regarding the relationships of needs-supplies fit and psychological contract fulfillment with affective outcomes associated with work. The first perspective argues that needs-supplies fit is the primary predictor of work-related affect, based on research that positions psychological needs as the most salient standard held by employees. The second perspective treats psychological contract fulfillment as the core predictor of work affect, drawing from theories that characterize perceived promises as the foremost standard by which employees evaluate their work experiences. The third perspective is integrative, whereby employees compare what they receive at work against psychological needs as well as perceived promises, which operate as related but distinct standards of evaluation. This approach to hypothesis development draws from the principle of strong inference (Platt, 1964), which argues that scientific progress is enhanced when alternative hypotheses are pitted against one another. As outcomes, we use two dimensions of work-related affect, which include job satisfaction and affective organizational commitment.

Methodology:

Data were collected from 366 employees in five manufacturing organizations in Denmark who held jobs in various functions (e.g., production, project management, sales and marketing, research and development). Respondents completed three-item measures of supplies ("How much do you have in your job?"), needs ("How much would you like to have in your job?"), and promises ("How much has your employer promised you?") in reference to variety, security, autonomy, pay, and authority. Outcome measures included job satisfaction and organization commitment.

We tested our hypotheses using an expanded version polynomial regression and response surface methodology (Edwards, 2002) based on the following equation:

$$Z = b0 + b1S + b2N + b3P + b4S2 + b5SN + b6N2 + b7SP + b8P2 + e$$

where S, N, and P represent supplies, needs, and promises, and Z signifies the outcome (job satisfaction or organizational commitment). Tests of needs-supplies fit focused on the terms S, N, S2, SN, and N2, and psychological contract fulfillment involves the terms S, P, S2, SP, and P2.

Results obtained:

Results for needs-supplies fit suggest that supplies themselves are related to affective outcomes, irrespective of psychological needs. In contrast, deviations of supplies from promises were associated with negative affect, which increased when supplies differed from promises in either direction. These results challenge the core assumptions of needs-supplies fit research and highlight the crucial role of psychological contract fulfillment.

Limitations:

We acknowledge that our study has limitations, such as relying on self-report data, although this method of data collection is appropriate due to the psychological nature of the constructs involved.

Research & Practical Implications:

Having said this, we believe our findings underscore the importance of considering multiple standards when attempting to explain how employees respond to experiences at work. We discuss future directions, theoretical and methodological work in the domain of congruence research.

Originality & Value:

Our study demonstrates the extension of polynomial regression and response surface methodology to accommodate multiple standards against which experiences are evaluated.

Keywords: Needs-Supplies Fit, Psychological Contract, polynomial regression.

Symposium S060

Job Insecurity – symposium 3. How do subjective and objective insecurity associate with health, proactive work behaviour and career-related outcomes?

Claudia Bernhard-Oettel & Magnus Sverke | Stockholm University, Sweden

science_practice

What will be covered and why?

This third symposium on job insecurity extends the perspectives provided Jiang & De Witte in symposium 1 and symposium 2. In this third symposium, we focus on new evidence concerning subjective perceptions of job insecurity and objective circumstances that imply different degrees of insecurity (e.g., employment contract, degree of labor market participation, national safety networks) and discuss how these link to health, proactive work behaviors and career prospects in today's world of working.

This symposium brings together five contributions that take different approaches (diary study, group comparisons, meta-analysis, trajectory analysis, multi-country and longitudinal study of reciprocity), focus on outcomes of relevance for both employees and organizations (e.g., health, proactive work behaviour, career-related outcomes), and build on evidence from different countries and labour markets (Germany, Sweden, New Zealand, Belgium, the UK, and the US).

In the first paper, Klug and Drobnic study trajectories of labour market attachment (permanent vs. temporary employment) using German panel data from 2008 to 2019 to investigate predictors and health consequences of more stable vs. unstable career trajectories. Low education and motherhood appeared as risk factors for less stable trajectories, and trajectories of lower attachment associated with lower life satisfaction and higher depressiveness over time. Second, Bernhard-Oettel and Müller compare how young vs. older Swedish employees (re)starting their career with temporary agency work experience their job and career insecurity and differ in job and career satisfaction. Preliminary results did not support the hypotheses that younger workers perceive less insecurity and are more satisfied with temporary jobs. Third, Van Hootegem, Näswall, Selenko, Shoss and De Witte investigate how associations between job insecurity and safety networks differ across countries (UK, US, Belgium) and study reciprocal relationships between job insecurity and safety networks in Belgium. Preliminary results indicate that better safety networks decrease job insecurity and buffer its negative effects. Fourth, in a diary study Näswall and Van Hootegem follow daily fluctuations of job insecurity and proactive work behaviour at the intra-individual level. In line with the hypothesis short-term fluctuations were found. Quantitative job insecurity related to lower proactive behaviour in resource seeking, qualitative job insecurity related to lower levels in seeking challenges. Finally, Sverke, Pienaar, Richter, Hellgren, Näswall and Låstad report results of a meta-analysis of job insecurity and career-related outcomes (e.g., career management, learning, employability, mobility). Preliminary findings are mixed and may signal different consequences of job insecurity for career and learning inside and outside of the organization.

Relevance to the Congress Theme

Restricted possibilities for labour market participation, temporary employment and contextual factors related to a national safety network are all of relevance to better understand and mitigate negative effects of employment uncertainty and job insecurity. In a time with a growing inflation and economic turmoil, employment uncertainty and job insecurity that may threaten the individual's economic situation and affect their work-related behaviors and career prospects are important

factors to study to build a sustainable future and good health for the working population. This ties well into the congress theme since the future is already shaped by circumstances of today. Likewise, the symposium also has relevance for the UN goals regarding “decent work” and “good health”.

Research and practical implications

The symposium gives a deeper understanding of how employment uncertainty and job insecurity and their consequences are experienced in different and potentially vulnerable groups in the labour market, and highlights the implications for a variety of national contexts and across different time frames. Altogether, this enables a better understanding of what needs to be done for individuals, in organizations, and at the societal level to mitigate negative effects for proactivity, health and individual career prospects.

Overall conclusions

The various presentations in this symposium highlight the importance of studying subjective and objective indicators of job and employment insecurity in a rather complex manner. By covering various forms of uncertainty (attachment to the labor market, temporary agency work, and perceived job insecurity), focusing on various outcomes that directly relate to career development (e.g., career management, employability) or indirectly fuel a successful career (e.g., health and proactive work behaviour), this symposium provides a rich perspective to add knowledge about job insecurity and uncertain employment and their relevance for health, proactive work behavior and career outcomes.

Keywords: Job insecurity, Employment, Career

Paper 1

Who is secure in the long run? On trajectories of labor market attachment, their socio-demographic predictors, and consequences for mental well-being

Katharina Klug & Sonja Drobnič | University of Bremen, Germany

Research goals and why the work was worth doing

Throughout Europe, the flexibilization of labor markets has made employment more volatile for many workers, while the risk of instability is unequal: Temporary jobs and unemployment are more common among those in weaker labor market positions, namely people with lower education, women and especially mothers reconciling employment with childcare. As for health consequences, unemployment is evidently a risk, but research has been inconclusive regarding temporary employment. We argue that timing and duration play a role: Throughout their career, people may move in and out of more or less stable jobs, thus accumulating differing degrees of labor market attachment. The aim of this study was to identify such long-term trajectories of labor market attachment and investigate their relationships with sociodemographic predictors (education, gender, parenthood) and mental well-being (life satisfaction, depressiveness).

Theoretical background

Labor market attachment is defined as a person's proximity to the labor force. The concept refers to the formal employment status, ranked on a spectrum from "fully attached" (i.e. employed) via less stable, temporary jobs to "completely detached" (i.e. inactive). Previous research suggests that most adults still experience long-term high labor market attachment, but a substantial number also follow less stable trajectories. Conservation of Resources Theory serves to explain the relationships between trajectories of labor market attachment, predictors, and outcomes: First, continuous labor market attachment secures access to resources. We therefore expect the threat or lack of resources implied by less stable, low or declining attachment to impair well-being. Second, accumulating resources tends to be more difficult for people with fewer resources to begin with. We therefore expect people in weaker labor market positions, namely those with lower education, women and especially mothers to experience less stable trajectories.

Methodology

Our analyses are based on a sample of N = 3208 employees from the German Family Panel, covering 12 years from 2008 to 2019. Labor market attachment was operationalized as the formal employment status (1 = permanent employment, 2 = temporary employment; 3 = not employed), and we calculated latent class growth analyses to identify trajectories. We investigated relationships with predictors and outcomes via multinomial and linear regression, respectively.

Results

We identified five distinct trajectories: 1) persistent high attachment (67%), characterized by continuous permanent employment, 2) persistent low attachment (8%), characterized by continuous non-employment, 3) decreasing attachment (8%), characterized by initially permanent employment, followed by temporary employment, 4) early increasing attachment (14%), characterized by initially temporary employment, quickly followed by permanent employment, and 5) late increasing attachment (4%), characterized by long-term non-employment, followed by a slow transition to permanent employment. Relative to persistent high attachment, low education and motherhood

appeared as risk factors for each of the less stable trajectories. Persistent low attachment predicted lower life satisfaction at T12 compared to persistent high attachment, as well as higher depressiveness. Decreasing attachment predicted lower life satisfaction and late increasing attachment predicted higher depressiveness.

Limitations

We cannot rule out that the sample may have been selective regarding initial labor market attachment, nor can the design account for the mobility dynamics underlying the trajectories. Similarly, trajectory differences in outcomes at the end of the observation period do not account for the process of change in well-being over time.

Conclusions

The results provide a nuanced understanding of when and for whom low or less stable labor market attachment becomes a risk to well-being: Analyzing trajectories uncovers qualitative differences in patterns of accumulated labor market attachment. This approach better reflects the notion of employment stability as long-term access to employment than a snapshot at a specific point in time. Accounting for both sociodemographic predictors and health outcomes, the findings illustrate the implications of labor market attachment for health inequalities. Future research is needed to test the generalizability of our findings and delve deeper into the change processes underlying employment trajectories and their relationship with mental well-being.

Relevance to the Congress Theme

Our findings reflect broader trends of changing employment relations, which have been unfolding for decades and will likely persist. Equal access to long-term stable employment and the economic security it provides is a key issue to ensure sustainable and healthy work for everyone.

Paper 2

(Re)Starting a career: Job and career insecurity and their importance for well-being in older vs. young temporary agency workers in Sweden

Claudia Bernhard-Oettel & Franziska Müller | Stockholm University, Sweden

Research goals and why the work was worth doing

As much as 25% of all young workers in Sweden enter the labour market via a temporary agency, and to growing extent, even older workers redirect or restart their careers via temporary agency work (TAW). It is often assumed that young – in contrast to older - workers seek flexibility and thus react differently to different aspects of insecurity (with respect to job, career, finances) that working in a temporary agency may entail. In this study, we therefore test and compare how younger and older temporary agency workers' demographic backgrounds, contractual arrangements, vulnerability factors, contractual motives and career stages relate to their insecurity perceptions. Furthermore, we test how insecurity relates to well-being and satisfaction in both groups.

Theoretical background

By nature, TAW entails switching clients on a regular basis, thus offering opportunities to gather work experience, build a CV and test different employers. For young workers with little experience TAW may provide a pathway into the labour market, and for older workers, TAW may be a useful means to restart or redirect their careers.

For the group of young workers, it is often assumed that they value flexibility and choose temporary work to higher extent than older workers do, and thus perceive less of- or react less to - the different aspects of financial, job and career insecurity. Theoretically, this assumption may be based on the fact that young workers still have lower income responsibilities and thus are less dependent on a particular job and income. Additionally, having been in the labour market only for a short time, they may not yet have had many scaring' experiences (e.g. unemployment, lay offs) Also, the group of young workers may be considered more resourceful with more recent and perhaps also higher education. However, whether this assumed difference between younger and older workers entering TAW holds true has not been studied in detail.

Design/Methodology/Approach/Intervention

Data was collected in during December 2021 to February 2022 in three temporary agencies in Sweden (N = 238). Mean age for younger TAWs (M = 25,7 years) significantly differed from the mean age (M=43,8 years) in the older group. After missing analysis and factor analyses to establish the quality of the data and measurement instruments, we ran some first preliminary regression analyses for both groups to (1) compare level of insecurity perceptions, (2) examine predictors for job insecurity, career insecurity and financial insecurity in young and older temporary agency workers and to (3) test how the three different types of insecurities related to well-being, job and career satisfaction.

Results

Preliminary findings from first analyses show no significant mean differences in perceived job insecurity, financial insecurity and career insecurity between younger and older temporary agency workers. Few significant relations were found between individual background and contract

arrangements and insecurity perceptions. Instead, vulnerability factors (unemployment experience, financial household responsibility), contract motives and perceived career stage were significantly, but differently related to the studied insecurity perceptions. Moreover, we found that the three tested insecurity perceptions were related to well-being, job and career satisfaction in different ways in both groups of temporary agency workers.

Limitations

This is a cross-sectional study in a specific sample of Swedish temporary agency workers which restricts generalizability of the findings.

Conclusions – research and or practical implications/Originality/Value

Many young workers work via temporary agencies in their early career, but at growing rate also older workers may use temporary agency work as a pathway to restart or redirect their career. The results of this comparative study suggest that both groups perceive insecurity related to their job, finances and career future, but the magnitude of these perceptions and their relations to well-being and satisfaction did not differ. The idea that younger workers at the beginning of their careers do not feel as insecure as older workers, or do not react upon insecurity is not supported. Starting and re-starting a career seems to be perceived similarly, independently of age.

Relevance to the Congress Theme

(Re)starting a career is an activity of today that paves the way into a desirable future – an individual's work of tomorrow.

Paper 3

The role of social safety net in job insecurity reactions: a multi-country and longitudinal test of reciprocal and moderating relationships

Anahí Van Hootegem, KU Leuven, Belgium; Hans De Witte, KU Leuven, Belgium; Mindy Shoss, University of Central Florida, USA; Eva Selenko, Loughborough University, UK; Katharina Näswall, University of Canterbury, New Zealand

Research goals and why the work was worth doing

The social safety net refers to economic or social support provided by the government to maintain a good standard of living for vulnerable individuals or families. In the current volatile organisational and economic landscape, these explicit provisions can be seen as resources that may buffer and protect employees from economic, such as experiencing job insecurity. Several studies have shown the relevance of the social safety net in job insecurity reactions (e.g., Debus et al., 2012), usually operationalizing countries as proxy's for the access to a social safety net. However, no prior research has considered perceptions of one's social safety net, which may be useful in capturing the large range of differences across countries. Moreover, perceptions of social protection have been shown to be an important indicator to explain variance in psychological variables (e.g., Schmalor & Heine, 2022). In addition to testing the moderating role of social safety net, this study also wants to examine whether social safety net functions as a predictor or a consequence of job insecurity perceptions.

Theoretical background

This study builds on principles of Lazarus and Folkman's appraisal theory of stress to reason that social safety net may function as an antecedent of job insecurity. Individuals who experience a strong safety net could appraise an insecure job situation as less threatening, and consequently, experience less job insecurity. At the same time, we build on sociological and political literature to argue that individuals coping with job insecurity may be more likely to attribute their economically precarious position to inefficacy of the government. Previous research has shown that distrust in political institutions is associated with negative assessments of social protection (Haugsgjerd & Kumlin, 2020). In this sense, job insecurity may be associated with lower evaluations of one's social safety net. Lastly, social safety net may function as a moderator, in which higher perceptions may aid in providing a higher sense of control over one's situation, thereby becoming less prone to experiencing strong negative reactions. This study uses job satisfaction, life satisfaction, trust in one's organisation, and trust in government as outcome variables.

Methodology

We employ two different datasets to test our hypotheses. First, we use multiple-country cross-sectional data to test the moderating role of social safety net perceptions across three countries (i.e., UK, US, Belgium). Second, we use longitudinal data among Belgian employees to test reciprocal pathways in the relationships between job insecurity and social safety net, as well as to test the moderating role of social safety net across time. Analyses were conducted by means of structural equation modelling using Mplus statistical software.

Results

We first tested the moderating role of social safety net across three countries using a multiple-group analysis. The preliminary results demonstrated that social safety net functioned as a moderator for

job satisfaction in the UK, life satisfaction in the UK and the US, and trust in one's organisation in the UK. All significant interactions pointed towards a buffering effect of social safety net, as expected. The longitudinal cross-lagged panel analysis – based on an all-Belgian sample – tested the direction of the relationship between job insecurity and social safety net and provided support for a negative relationship that flows from social safety net to job insecurity, and not for the other way around. This indicates that higher perceptions of one's social protection are associated with lower job insecurity perceptions across time. The longitudinal analyses did not provide support for the moderating role of social safety net perceptions.

Limitations

Our study focussed only on three specific countries, while many other country differences may exist. Moreover, we focussed only on perceptions, whereas it may be valuable to include a combination of objective and subjective indicators.

Conclusions – research and or practical implications

The present study contributes to the job insecurity literature by focussing on perceptions of a macro-level indicator, thereby acknowledging the broader context within which job insecurity unfolds. In addition, we focus on a broad level of outcomes, and apply a comprehensive approach in examining social safety net by considering its role as an antecedent, consequence, and moderator.

Relevance to the congress theme

To understand job insecurity reactions in a changing world of work it is important to consider the influence of the broader context.

Relevant UN SDGs

This research aligned with SDG 8 "Decent work and economic growth" and SDG 16 "Peace, justice and strong social institutions".

Paper 4

Within-person fluctuations of job insecurity and proactive work behaviours: A diary study

Katharina Näswall & Katharina Näswall | University of Canterbury, New Zealand; Anahí Van Hootegem, KU Leuven, Belgium

Research goals and why the work was worth doing

Previous research consistently associates job insecurity with negative consequences for employees and organisations, but less is known about the impact of changes in job insecurity perceptions within person over a short period of time. The current study uses daily diary study design to investigate whether fluctuations in job insecurity are observable in a New Zealand sample of employees over a 10-day period. It is expected that job insecurity will vary within person and that this variation will relate to variation in the job crafting behaviours.

Theoretical background

The limited research on job insecurity and job crafting have had mixed findings. Some research suggests the uncertainty surrounding job insecurity motivates people to engage in proactive behaviour (i.e., job crafting) that subsequently reduces uncertainty. Other research suggests job insecurity negatively affects proactive behaviour because the insecurity may result in threat perceptions that trigger behaviours like withdrawal from work. This study aimed to address these conflicting findings by investigating whether job insecurity directly influences job crafting behaviours. Additionally, as previous research suggests self-efficacious individuals have greater confidence in their abilities to overcome a job insecure situation, and that self-efficacy is a predictor of proactive behaviour and job crafting, self-efficacy was included as a moderator in the job insecurity-job crafting relationship.

There is also very little evidence about whether job insecurity experiences fluctuate in the short term. To address this, a 10-day diary study design was used to investigate daily levels of job insecurity.

Design/Methodology/Approach/Intervention

Participants in this study were 56 full-time workers from a range of industries in New Zealand. Ages ranged from 20 to 66 years old, with an average age of 33.52. 73.2% of participants identified as female and 26.8% identified as male. Organisational tenure ranged from less than a year to 26 years, with an average tenure of 4.07 years.

Participants completed diary surveys for 10 working days. A baseline survey captured person-level qualitative and quantitative job insecurity, self-reported job crafting behaviours (resource seeking and support seeking), and self-efficacy. For the daily surveys the measures were adapted to reflect job insecurity and job crafting on that day.

Results

Short-term within-person fluctuations in job crafting behaviour and job insecurity perceptions were observed over the 10-day study period. Participants with higher job insecurity engaged in less job crafting behaviour compared to participants with lower job insecurity. Specifically, the results found that higher levels of quantitative job insecurity predicted lower levels of seeking resources. Additionally, higher levels of qualitative job insecurity predicted lower levels of overall job crafting

and seeking challenges. Self-efficacy did not moderate any of the relationships between the two types of job insecurity and three job crafting outcomes.

Limitations

The study was conducted over a relatively short period of time, and it may be that the daily intervals were too short to identify fluctuations. Future research might extend the intervals to weekly to understand the nature of fluctuations better. It may also be useful to control for the opportunities employees have to engage in job crafting, as this may vary between different roles.

Conclusions – research and or practical implications

The results have important implications as organisations can take action to increase positive outcomes and reduce withdrawal behaviour. Because job crafting is associated with positive outcomes, and this study found that job crafting can fluctuate daily, organisations should support employees in their job crafting behaviour and train them in how to craft their jobs on a day-to-day basis. This study also found differences between quantitative and qualitative job insecurity. The former impacted seeking resources and the latter impacted seeking challenges and overall job crafting behaviour. Therefore, organisations should identify what type of job insecurity employees are experiencing so they can adapt their job crafting training based on the type of job insecurity experienced. Due to the fluctuations in job insecurity perceptions, organisations should regularly monitor employees job insecurity and behaviour to identify any changes early, allowing them to intervene at the right time.

Relevance to the Congress Theme

Job insecurity is a very salient part of the changing world of work – for many people, work will change from secure to more insecure, but it may also be that job insecurity perceptions fluctuate for individuals. Understanding the behavioural responses to these changes will help organisations implement supportive structures to enable proactive behaviours despite uncertainty.

Paper 5

Moving on up now? A meta-analysis of the associations between job insecurity and career, learning, employability, and mobility outcomes

Magnus Sverke, Stockholm University, Sweden; Lena Låstad, Stockholm University, Sweden; Katharina Näswall, University of Canterbury, New Zealand; Johnny Hellgren, Stockholm University, Sweden; Anne Richter, Karolinska Institutet, Sweden; Jacobus Pienaar, Stockholm University, Sweden

Research goals and why the work was worth doing

While the literature regarding job insecurity and work-related and health-related outcomes has blossomed over the last approximately 40 years (as covered in several reviews and meta-analyses), studies investigating how job insecurity relates to career-related attitudes and behaviors remain scarce. We aim to contribute to this literature by providing, to our knowledge, the first meta-analysis of job insecurity and career-related outcomes, including career management (career planning, networking, perceived career opportunities, career satisfaction, and career commitment), learning (proactive skills development and willingness to participate in training), employability, and mobility (job search behaviors, organizational turnover intention, occupational turnover intention, and actual turnover). A further aim of the study is to explore the potential moderating role of study design (cross-sectional vs. longitudinal studies) and type of job insecurity measure (cognitive, affective, or mixed) in the associations between job insecurity and such outcomes.

Theoretical background

Job insecurity represents the subjective experience of risking to lose one's employment. A range of studies, including several reviews and meta-analyses, have shown that job insecurity may result in impaired health and well-being, negative attitudes towards the job and the organization, and work-related behavior such as poorer job performance and a higher willingness to quit one's job. Previous research also suggests that employees may engage in active career management, learning, and attempts to enhance their employability to try to counteract their vulnerability in the labor market (as evidenced by high levels of perceived job insecurity). Job insecurity may also, ultimately, be related to career mobility, such as job search behaviors and turnover. The global economic outlook points to a future increase in precarious forms of employment (short-term, part-time contracts) but also precariousness (uncertainty of job futures and stabilities).

Methodology

Literature searches were conducted in established databases (PsycINFO, Web of Science and EBSCO) to identify peer-reviewed articles written in English and published in scientific journals 1980–2020. A total of 180 independent studies (covering 218 samples, 58 countries and with N =72,094 individuals) could be included. We used Hunter and Schmidt's (2017) meta-analysis method to calculate the meta-analytic mean correlations and the variability of associations between job insecurity and career-related outcomes.

Results

Preliminary results of main effects show that job insecurity was negatively related to career satisfaction and career opportunity, but not significantly associated with career planning, networking behaviors, and career commitment. In terms of learning, job insecurity was negatively related to

proactive skills development but unrelated to the willingness to participate in training. Job insecurity was negatively related to (external) employability. Regarding mobility, job insecurity evidenced positive associations with job search behaviors and organizational turnover intention, whereas the confidence intervals for occupational turnover intention and actual turnover included zero. The possible moderation effects of study design (cross-sectional vs. longitudinal) and job insecurity measure (affective, cognitive, mixed) will be tested before the congress.

Limitations

Any meta-analysis depends on the quality of the included studies. The forthcoming moderator analyses regarding study design (cross-sectional vs. longitudinal), as well as type of job insecurity measure (affective, cognitive, mixed), may shed additional light on the associations between job insecurity and career-related outcomes.

Conclusions

The present meta-analysis of job insecurity and career-related outcomes suggests that job insecurity may result in poorer career opportunities, less learning, lower employability, and a higher inclination to leave the organization. It is therefore vital to counteract experiences of job insecurity. The findings may assist individuals in planning their career management and learning, but also organizations in supporting employee employability and managing turnover.

Relevance to the Congress Theme

Job insecurity is a prevalent attribute of the changing world of work. By investigating how this experience relates to career-related outcomes, we contribute to the understanding of the implications of employment uncertainty.

Relevant UN SDGs

Good health and well-being

Decent work and economic growth

Keywords: Job insecurity, career, meta-analysis

Symposium S061

Understanding and Breaking the Self-Maintaining Cycle of Gender Inequality in Organizations

Jenny Veldman, NYU Abu Dhabi; Levke Henningsen, University of Exeter

science

What will be covered and why ？ Despite great efforts, women are still underrepresented in traditionally male-dominated careers, such as in the military, in STEM (science, technology, engineering, mathematics) fields, and in high-level leadership positions. This symposium, with presenters from three different countries (i.e., the Netherlands, United Kingdom, and United Arab Emirates), addresses the complex, self-maintaining cycle of gender inequality in organizations and aims to provide implications for individual careers, and decision-makers in organizations. Specifically, the symposium consists of four reports of empirical research that focus on women's experiences with and coping responses to different forms of stigmatization at work. Talk 1 takes a self-selection perspective by addressing psychological processes – such as work-life conflict, fear of backlash, identity threat, and leadership self-efficacy – that can help explain gender differences in career aspirations. Talk 2 focuses on incivility as a subtle form of stigmatization at work and reveals how this increasingly prevalent form of subtle mistreatment negatively affects female employees' career and work attitudes. Talk 3 focuses on workplace cultures with strong masculinity norms as a covert form of gender bias, leading women to distance themselves from other women to gain status in such workplace cultures. The final talk 4 reflects on the challenges and opportunities in creating an inclusive workplace. A future research agenda is proposed which aims at stimulating new research streams to enhance our understanding of processes and practices to foster inclusion.

Relevance to the Congress Theme ： The world of work is changing and the workforce becomes increasingly diverse. With these changes come new possibilities and challenges for organizations to perform at their best by including and providing chances for all their employees. For example, women are increasingly entering industries and positions that have been historically occupied by men (Catalyst, 2020), yet they remain substantially underrepresented in those domains. In line with the EAWOP Congress Theme "The Future is Now", this symposium aims at providing a better understanding of (a) some of the main challenges that women (and members of traditionally underrepresented groups more generally) face in majority-male industries and positions, (b) how they cope with them, (c) what effects these challenges have on targets' work- and career-related outcomes, and (d) how practices of inclusion (e.g., inclusive leadership, inclusive HR management) can become means of support. These insights will support our understanding of how to attract and retain a diverse workforce and develop towards a sustainable and healthy workforce in the future that may tackle society's major challenges.

Research/Practical Implications ： The overall symposium shows the importance of addressing the complex and self-maintaining cycle of gender inequality in organizations: It shows several ways in which women experience subtle forms of stigmatization, such as through lack of fit (Talk 1), incivility (Talk 2), and workplace culture (Talk 3). Talks 1 and 2 demonstrate that these subtle forms of stigmatization negatively affect women's career-related attitudes, for example through processes of low belonging and perceived discrimination (Talk 2) and lower leadership self-efficacy, fear of backlash, and anticipated work-life conflict (Talk 1). Talk 3 shows that women distance themselves from other women to try and gain status in organizations in which they experience such subtle forms of stigmatization – an identity-management strategy that maintains gender inequality by legitimating these subtle forms of stigmatization that often seem neutral at surface. Talk 4 provides insight into the complex and self-maintaining cycle of gender inequality by discussing paradoxes in inclusion

research and how we can move this research field forward. This talk also provides practical tools on how this cycle can be broken by organizational practices that foster inclusion.

Overall conclusions ： All four research reports address the persisting challenges of women's career advancement to prestigious occupations and high-level leadership roles, and provide practical implications on how to break the complex and self-maintaining cycle of gender inequality at work through practices of inclusion.

Keywords: Managing diversity, Gender balance, Equal opportunities

Paper 1

Career Aspirations: Why Do Women and Men Differ?

Tanja Hentschel, University of Amsterdam

Research goals: Despite equal levels of education and research demonstrating that women have equal leadership skills to men, women are underrepresented in leadership positions. On the one hand, much research shows how biases of hiring or promotion committees can prevent women from being selected for high-ranking organizational positions. On the other hand, women may also choose not to pursue high-ranking organizational positions – and we currently know little about reasons for their potentially lower career aspirations. Such knowledge, however, may inform organizational policies targeted at advancing the careers of women. Thus, this research aims to understand if and why women have lower career aspirations than men.

Theoretical background: Building on Lack of Fit (Heilman, 1983), Role Incongruity (Eagly & Karau, 2002) and Backlash Theory (Rudman & Phelan, 2008), four mechanisms may be relevant in explaining women's versus men's career aspirations. First, due to a lack of fit between how women perceive themselves and how they stereotypically perceive leaders, women may perceive themselves as having lower leadership self-efficacy compared with men. Second, because of these same lack of fit perceptions, women may anticipate higher levels of identity threat in leadership positions (e.g., they may anticipate lower levels of belongingness). Third, because leaders are often perceived to work overtime and women tend to have more household and family responsibilities compared to men, women may anticipate higher levels of work-life conflict . Finally, people have normative expectations about which behavior they appreciate in men and women and they socially penalize or sanction people who violate these expectations. Women might be aware of the norm that career ambition is less accepted for their gender and experience higher levels of fear of backlash for being ambitious. These four processes – that is, women's lower levels of leadership self-efficacy, and higher levels of identity threat, anticipated work-life conflict and fear of backlash – are likely to limit career aspirations.

Methodology: A time-lagged field study with three times of measurement (about 1-2 weeks apart) and almost 400 participants was conducted in the Netherlands. Gender (as well as self-ratings on gender stereotypical characteristics) was measured at time 1, leadership self-efficacy and fear-of-backlash at time 2, and career aspirations, anticipated work-life conflict, and identity threat at time 3. Participant age and whether participants worked in a male-dominated (or female-dominated) surroundings was controlled for in the analyses.

Results: PROCESS model 4 (mediation model) was used with gender as the predictor, leadership self-efficacy, identity threat, work-life conflict, and fear of backlash as parallel mediators and career aspirations as an outcome. Results showed that women had lower career aspirations than men. Female gender was negatively related to leadership self-efficacy and positively related to anticipated work-life conflict and fear of backlash. However, gender was unrelated to identity threat. In addition, leadership self-efficacy was positively related to career aspirations while work-life conflict and fear of backlash were negatively related to career aspirations (identity threat was unrelated). The indirect effect of gender on career aspirations was, however, only significant for the mediator leadership self-efficacy.

Limitations: Despite limiting common-method bias with partly separating the measurement of variables, no causality can be inferred. In addition, other variables not measured in this study may mediate the relationship between gender and career aspirations. All ratings were done by the same person and common-source bias might be an issue. Future studies should replicate these findings using experiments to infer causality and include ratings by supervisors or colleagues to limit common-source bias.

Implications: Knowledge about the psychological processes influencing men's and women's career aspirations can help organizations and policymakers to design interventions. For example, designing organizational surroundings to show achievements of women and having visible female leaders may heighten other women's leadership self-efficacy. In addition, creating a gender-inclusive culture in which career aspirations of all people are accepted and appreciated, may limit women's fear of backlash.

Relevance to the Congress Theme ： When considering desirable changes in the future, this research helps to better understand the factors that might hold women back from choosing leadership careers. The research further offers practical implications that can help organizations to implement policies aiming at gender equality.

Relevant UN SDGs ： This work is relevant to the UN SGD goal of gender equality. More women in high-level leadership positions is one of the UNs sustainable development goals and hopefully what the future of work will look like.

Keywords: gender stereotypes, leadership, career aspirations

Paper 2

Experienced Incivility at Work: Effects of Perceived Belongingness and Gender Discrimination in Female-Dominated and Male-Dominated Work Teams

Levke Henningsen, University of Exeter; Colette Van Laar, University of Leuven; Tara Reich, King's College London; Jamie L. Gloor, University of St.Gallen

Research goals and why the work was worth doing: Overt workplace discrimination has become largely unacceptable; however, scholars have identified modern, covert forms of discrimination that sustain inequalities at work and beyond. Previous research addressing selective incivility as a modern form of discrimination revealed that low-status groups (e.g., women in male-dominated work domains) are at higher risk to experience uncivil behavior at work than high-status groups (e.g., men; e.g., Cortina et al., 2013). The present study addresses the concept of selective incivility (Cortina, 2008) and aims to advance the understanding of the psychological mechanisms through which experiences of uncivil acts at the workplace affect women's career-related attitudes.

Theoretical background: Despite previous evidence on more frequent incivility experiences among low-status (e.g., women) compared to high-status group members (e.g., men) in male-dominated work domains, the existing literature reveals theoretical gaps that limit our current understanding of the outcomes, psychological mechanisms, and moderators of experienced workplace incivility for these groups. To better understand how incivility experiences at work contribute to gender inequality in careers, we bridge selective incivility (Cortina, 2008), social power (Sidanius & Pratto, 1992), and attribution (Jones et al., 1972; Weiner, 1974) theories to study the psychological mechanisms (i.e., belongingness at work; attributions of incivility to gender discrimination) through which experiences of uncivil behavior predict women's career-related attitudes. Further, we considered contextual factors (e.g., gender of initiators, gender distribution in the work team) as moderators of the proposed relationships.

Design/Methodology/Approach: We conducted a time-lagged online survey with three measurement occasions (with time lags of four weeks each) among 276 female employees from German-speaking countries and a variety of sectors (e.g., finance, transportation, engineering). At timepoint 1, the survey included measures of participants' demographics, work situation, experiences of workplace incivility (predictor), gender of initiators of uncivil behaviors, and the gender distribution in the work team (moderators). At timepoint two, participants were asked to indicate their perceived belongingness, and their perceived gender discrimination at work (mediators). At timepoint 3, participants filled in questions regarding their work- and career-related attitudes (i.e., career withdrawal intentions; job turnover intentions).

Results obtained or expected: Multi-group path analyses revealed associations between experienced incivility and women's lower sense of belongingness as well as stronger perceptions of gender discrimination at work. More precisely, in male-dominated work teams, perceptions of gender discrimination mediated the effects between women's experiences with uncivil workplace behavior and higher job- and career withdrawal intentions. In female-dominated teams, women's perceptions of a lower belongingness at work mediated the effects between experienced workplace incivility and the career outcomes. Furthermore, in female-dominated teams, women were more likely to perceive gender discrimination from male than from female initiators of uncivil behaviors.

Limitations: Although longitudinal research designs provide strengths, there are some limitations. For example, despite separating the measurements of study variables across three time-lagged surveys to address common-method bias, we cannot claim causal effects. Furthermore, data from different time lags came from the same sources and therefore, common-source bias might have affected our study results. Future studies are encouraged to investigate ratings of team members to limit this bias.

Conclusions – Research/Practical Implications : The study contributes to previous research while also offering practical insights on the factors that shape women's career-related attitudes. For example, the current study contributes to previous research efforts by showing that low-intensity forms of mistreatment at work (e.g., interrupting, or questioning the expertise of a team member) affect women's career-related attitudes, mainly through stronger perceptions of gender discrimination in male-dominated teams, but through feelings of lower belongingness at work in female-dominated teams. The study further highlights the importance of the context in which uncivil behavior takes place as it affects the way in which individuals make sense of their experiences. It therefore offers implications that take away the pressures from victims of incivility and puts the focus on the context that requires different organizational strategies, such as awareness trainings.

Relevance to the Congress Theme ： Although there have been considerable changes in the labor market with more women entering traditionally male-dominated careers, women are still underrepresented in many of these career fields. This research aims at providing a better understanding on how subtle barriers could be dismantled to facilitate women's equal workplace participation.

Relevant UN SDGs ： This work addresses subtle forms of gender discrimination that can sustain inequalities at work and beyond. Therefore, the research is most relevant to the UN SGD goal of gender equality but also addresses the goal of good health and wellbeing.

Keywords: incivility, career, gender

Paper 3

Current and Emerging Paradoxes in Inclusion Research: A Focused Review and Future Research Agenda

Brooke Gazdag, Deanne N. den Hartog, Corine Boon, Tanja Hentschel & Emma M. Op den Kamp | University of Amsterdam

Theoretical background. In today's ever increasingly diverse and globally connected world, employees are inevitably confronted with questions and challenges around how to manage and harness the power of diversity. Inclusion has been positioned as the missing puzzle piece that allows people to be outwardly and openly valued for their unique qualities and to feel that they, too, belong in the organization and team (e.g., Nishii, 2013; Roberson, 2006; Shore, Randel, Chung, Dean, Holcombe Ehrhart & Singh, 2011). Beyond the context of diversity, inclusion, or specifically inclusive leadership or inclusive HR management, creates a climate of psychological safety (Carmeli, Reiter-Palmon & Ziv, 2010; Nembhard & Edmondson, 2006), and facilitates learning from failure (Hirak, Peng, Carmeli & Schaubroeck, 2012). It also enhances team performance via creating a team identity (Mitchell, Boyle, Parker, Giles, Chiang & Joyce, 2015). Although still in its nascent stages of development (Janssens & Steyaert, 2020), the burgeoning research on inclusion demonstrates its increasing relevance, not just for the study of diversity, but also as a concept and practice that incorporates many aspects of organizational life.

New Perspectives/Contributions. However, existing work on inclusion tends to narrowly focus on a single aspect or perspective, which neglects the paradoxical nature of inclusion. Scholars often depict inclusion from a structuralist perspective in that the actions of one entity, that is the organization, team, or leader, impact the intended includee and their subjective experience, as opposed to the agentic perspective, which argues that individual includees are able actors that also in part shape their own outcomes and pathways. In addition, current inclusion research takes primarily a social approach, often neglecting inclusion or exclusion for functional reasons. We believe that the reliance on an understanding of inclusion from a structuralist and/or social perspective unnecessarily narrows the scope of inclusion research and theory (e.g., Janssens & Steyaert, 2020), and thereby stunts potential growth to reach the popularity and ubiquity of diversity research.

Conclusions – research and or practical implications. Using a two part approach (Parmigiani & King, 2019), we both synthesize existing research and highlight two existing paradoxes in inclusion research and three emerging paradoxes. First, in Part I, we conduct a focused review of the inclusion literature and organize and summarize the literature using a paradox framework to make explicit two paradoxes in existing inclusion research: (1) Inclusion is the responsibility of both organizations/teams/leaders and individuals and (2) Inclusion is both social and functional. Based on our review, in Part II, we extend our framework to include three additional paradoxes emerging in the field: (1) Members of underrepresented groups both need to be included and their resources need to be respected and protected, (2) Inclusion is based on individual subjective perception and objective measures or practices, (3) Everyone needs inclusion and everyone has different needs. In doing so, we attempt to redirect (Cronin & George, 2020), add to (e.g., Adamson, Kelan, Lewis, Śliwa & Rumens, 2020; Tyler, 2018), and ultimately "shed light (not just heat)" (Hollenbeck, 2008, p. 20-21) on the conceptualization and operationalization of inclusion. Taken together, our paradox framework answers calls to focus more on processes and practices that foster inclusion (Nkomo, Bell, Roberts, Joshi & Thatcher, 2019) and ultimately, by taking this approach seeks to avoid unintended consequences of well-intended inclusion initiatives (Leslie, 2019). In bringing the paradoxical nature

of inclusion to the fore we hope to stimulate new streams of future research that both challenge and accelerate the nascent field of inclusion research.

Relevance to the Congress Theme. The concept of inclusion is evolving as our way of working evolves. How inclusion is practiced in organizations must take a process approach and activate all the relevant populations and incorporate their voices. In other words, in order to manage the competition and collaborate effectively with diverse others, future workers will need to develop a competence for managing the paradoxes inherent in inclusion.

Relevant UN SDGs. This work is relevant to three UN SDGs. First, for Goal 5: Gender equality, organizations, teams, and leaders who master inclusion can effectively attract and retain talent from all genders. Second, Goal 3: Good health and wellbeing and Goal 8: Decent work and economic growth together support a holistic approach to work-life and inclusion can achieve these goals by embracing individual needs and establishing systems that adapt and evolve with employee needs.

Keywords: inclusion, diversity, paradox

Paper 4

Masculinity Contest Workplace Cultures Lead to Self-Group Distancing in Women

Jenny Veldman & Andrea Vial | New York University Abu Dhabi

Theoretical Background & Research Goals: Women are increasingly entering industries that have been historically occupied by men (Catalyst, 2020), although they remain substantially underrepresented in those domains. In part due to the preponderance of men, these organizational contexts are often characterized by a "masculinity contest culture" (MCC; Berdahl et al., 2018)—a workplace environment that encourages the enactment of (negative) stereotypically masculine behaviors and attitudes, leading to a workplace culture where employees frequently adopt a "dog eat dog" mindset, avoid showing weakness at all costs, strive to display endurance, strength, and a single-minded focus on work, and engage in cut-throat competition with others (Berdahl et al., 2018). Although masculinity contest workplace cultures do not explicitly refer to gender (Cheryan & Markus, 2020), they place women at a disadvantage by rewarding male-typed behaviors incongruent with gender prescriptions for women to be communal (Prentice & Carranza, 2002). The traits that make up the "ideal worker" in these contexts align well with the highly-assertive elements of male norms, including negative agency traits like aggression and dominance. Women, who have been traditionally taught to be modest, kind, and cooperative (Prentice & Carranza, 2002) may find it challenging to navigate MCC environments, and may experience their gender group membership as a liability in these contexts. We theorize that, in order to gain status in MCCs, women try to create a distance between themselves and their gender ingroup or to dissociate themselves from it—a phenomenon known as self-group distancing (Van Veelen et al., 2020).

Methodology & Results: Four pre-registered studies examined how women create a distance between themselves and their ingroup in order to gain status in workplace cultures with a masculinity contest culture. Experiments 1 (n = 358) and 2 (n = 816) showed that the female (vs. male) social identity is devalued in a strong (vs. weak) MCC workplace, which partly explains women's (vs. men's) lower sense of personal status in strong MCCs. Experiment 3 (n = 1687) showed that women (and not men) were more likely to distance themselves from their gender group in a virtual workplace characterized by a strong (vs. weak) MCC, both affectively (self-report) and behaviorally (i.e., to conceal their gender). Field Study 4 (n = 612) demonstrated this process in a representative sample of men and women employed in industries with strong and weak MCCs.

Limitations : All studies were pre-registered before data collection and were high-powered for the analyses. Our methods are diverse. We used experimental methods (Studies 1-3) that gave strong internal validity and insight into the causal process. A limitation of these studies is that convenience samples from an online recruitment pool were used. This enabled us to collect large samples, but it constrains generalizability. To account for this limitation, we also collected correlational field data (Study 4) among a representative sample of employees across a range of industries with the highly respected market research company Ipsos.

Conclusions /Implications: Together, the studies demonstrate that women distance themselves from other women to gain status in workplaces with strong masculinity contest cultures. The research presented here sheds light on the antecedents and psychological function of self-group distancing, a strategy that perpetuates the legitimation of masculinity norms in the workplace. Previous research has shown that self-group distancing occurs in direct response to a personal experience of gender bias (Derks et al., 2011a, 2011b). However, we demonstrate how merely being

immersed in a cultural context that devalues the ingroup leads to self-group distancing. This distinction between first-hand experiences of gender bias and a more subtle workplace climate that glorifies male behavior as the "default" (Berdahl et al., 2018; Cheryan & Markus, 2020) is practically meaningful because blatant forms of discrimination are becoming largely unacceptable in modern-day organizations and women increasingly face discrimination in more subtle and covert forms that are harder to recognize as bias (Ellemers & Barreto, 2015), but which have important social identity consequences.

Relevance to the Congress Theme ： With the workforce getting increasingly diverse, it is crucial to understand how members of underrepresented groups (such as women in majority-male industries) cope with the challenges they face and how these coping strategies can perpetuate gender inequality.

Relevant UN SDGs: The present work is relevant to the UN SDG of gender equality. This research focuses on an identity management strategy that women use to navigate masculine contexts. By focusing on how women cope with challenges they face in masculine contexts, the present work provides critical insight into understanding the often-subtle ways in which gender inequalities are maintained from women's perspective–and ultimately also how we can challenge persistent gender inequality by changing organizational cultures.

Keywords: masculine workplace cultures, identity management, women

Symposium S062

Do it Yourself – Multilevel Perspectives on Job Crafting in the Workplace

Elisa Lopper, Humboldt-Universität zu Berlin

science

What will be covered and why: Job crafting describes employee-initiated changes to the job to better fit their skills, preferences, and abilities (Tims & Bakker, 2010; Wrzeniewski & Dutton, 2001). There is numerous evidence that job crafting is positive for employees as well organisations (e.g., increases in work engagement or performance). The changing world of work challenges employees to adapt to uncertain and dynamic situations. Also, the COVID-19 pandemic has required mechanisms of adaptation. Job crafting enables employees to deal with such demanding situations, as it can fluctuate within employees within short periods of time (e.g., daily). Therefore, is important to have deeper insights into between- and within-person variations of job crafting and their effects. In this symposium, we discuss three studies with different multilevel approaches of job crafting. The focus is on the experiences of employees in the workplace. The first paper (Mülder et al.) introduce the new construct job crafting preparation to refine how employees cognitively prepare for job crafting. Furthermore, the authors investigate cross-lagged relationships between job crafting preparations and job crafting during a workweek on between- and within-person levels. This helps to better understand cognitive processes that play a role before, during and after job crafting. The second paper (Lopper et al.) examine within-person relationships between job crafting, work engagement and performance on a weekly basis. Over and above unidirectional associations between the study variables, the authors reveal a more dynamic approach. Using a weekly diary study, they investigate within-person gain cycles between job crafting, work engagement and performance from one week to the next. The third paper addresses the COVID-19 pandemic. Lehmann et al. focus on job crafting and its changes during the COVID-19 pandemic to examine how employees adjust their work under societal and work-related challenges due to the pandemic crisis. Especially, in their longitudinal panel study they differentiate between employees with and without mental health issues to address the high prevalence of employees with mental health issues. Additionally, the authors investigate the role of job resources on changes of job crafting.

Relevance to the Congress Theme : In the changing world of work organizations benefit from proactive employees. The future of work makes it is almost impossible for organizations to create jobs that fit all. Job crafting describes changes to aspects of one's work to make the job to better fit itself. That is, employees adjust proactively aspects of their work which has numerous positive effects for employees and employers. Especially, in a changing world of work, job crafting plays an important role to adapt to uncertainty and dynamic situations. The different papers of this symposium cover newest developments of between- and within-person level job crafting in the workplace.

Research/Practical Implications : The three studies provide different multilevel approaches of job crafting, demonstrating that there are different results by separating between- and within-person level. Furthermore, there are change differences in job crafting depending on the mental health status of employees. Thus, future research should focus the multilevel perspective on job crafting with varying time intervals. From a practical point of view, the studies demonstrate that it is important to consider the multilevel approach of job crafting by developing job crafting interventions in organisations.

Overall conclusion : Overall, the research in this symposium confirmed that job crafting fluctuates within different time periods and enables employees to deal with changing situations. As the future of work faces new challenges for employees and organisations, employees' self-initiated changes to aspects at work becomes more important. In the changing world of work, not only employees benefit by using job crafting, but also organisations stay competitive.

Paper 1

Cognitive processes before showing job crafting behaviour – Introduction of the concept job crafting preparation and time-continuous relations to job

Lina Marie Mülder, Johannes Gutenberg-University Mainz; Thomas Rigotti, Johannes Gutenberg-University Mainz/Leibniz-Institute for Resilience Research Mainz; Wiebke Plückhahn, Johannes Gutenberg-University Mainz

Research Goal: Flatter hierarchies in organizations, the growth in mobile work, as well as dynamic adaptations to the organization of work go along with increased demands for self-management of employees. Employees need to take the initiative to fit their job characteristics to their personal needs. Such proactive behaviour of self-initiated bottom-up job design is known as job crafting. By introducing the new construct of job crafting preparation, we aim to refine how employees cognitively prepare for job crafting. Improving our understanding of the process of job crafting can help to tailor job crafting interventions and refine our knowledge on how employees determine which job crafting behaviour is the most suitable and healthy in the long run.

Theoretical background: Job Crafting is a set of employees' self-initiated adaptations of their job characteristics. Drawing on the wise proactivity model and given that human actions require analysing the situation, evaluation, and execution processes, we introduce the construct job crafting preparation. We understand job crafting preparation as the cognitive processes happening before job crafting behaviour, which involves the dimensions of conducting job analysis (external analysis; e.g., examining working conditions that help to perform tasks), internal analysis (e.g., reflecting own actions at work), job evaluation (e.g., do job characteristics match individual needs), and the planning of job design solutions (e.g., knowing how own actions can improve working conditions) to set goals and perform appropriate and adequate crafting. First, we introduce the construct job crafting preparation and illustrate how employees use job crafting preparation based on a multi-study validation (cross-sectional and weekly diary sample). Second, as short-term effects might play an important role in considering cognitive processes, we give insights on how it is related to actual job crafting behaviour and well-being outcomes, using time-continuous analysis on a daily diary basis over one week.

Design/Approach: We collected daily diary data from 93 employees over five consecutive workdays in spring 2021 who worked at least 10 hours a week from home. As continuous time models give the opportunity to specify differing underlying processes for how constructs change from one time to the next, and to test for reciprocal relationships. Therefore, a continuous time cross-lagged panel model implemented in the R package ctsem was performed to detect the cross-lagged relations between job crafting preparation and job crafting during a workweek on within- and on between-person level. First, we determine the optimal time lag of strongest lagged effects in both directions. We will report specific effects that occur after one, two, three, and four days.

Results : On the between-person level, no significant effects from job crafting preparation on job crafting and vice versa were detected. The effects are the strongest after the second day. However, we found significant negative reciprocal effects from job crafting to job crafting preparation on the within-person level. Job crafting negatively predicted subsequent job crafting preparation, and this effect reached its maximum after one day, and was still present after four days. Job crafting preparation on the other hand showed no lagged effects on job crafting behaviour. The results provide additional insights into short-term job crafting behaviour, as sooner studies showed a

positive relationship between the two variables over five weeks on the within and the between levels.

Limitations: The data was collected during the COVID-19 crisis, where many participants worked from home, which resulted in the sample overrepresenting white-collar workers.

Conclusion: Our study indicates that over the workweek, job crafting impacts job crafting preparation stronger than the other way around. However, analyses with the four dimensions of job crafting preparation and job crafting are necessary to refine conclusions regarding reciprocal relationships. Additionally, different time intervals as over several weeks should be considered in the future.

Relevance to the Congress Theme: The construct of job crafting preparation is directly related to the changing world of work, as it underlies the individual cognitive process that employees do before, during, and after adjustments to their own work (e.g., job crafting). Investigating the dynamic relations is a first step to supporting employees in managing the given expectations to take the initiative and craft their jobs.

Relevant UN SDGs : “Good health and wellbeing” and “Decent work and economic growth”

Paper 2

Weekly Reciprocal Relationships between Job Crafting, Work Engagement, and Performance – a Within-person Approach

Elisa Lopper & Annekatrin Hoppe | Humboldt-Universität zu Berlin; Sandra Nitz, University Koblenz-Landau; Dorota Reis, Saarland University; Marvin Milius, University Koblenz-Landau

Research goal: Following principles of conservation of resources theory (COR; Hobfoll, 1989), we aimed to investigate whether job crafting outcomes, like work engagement and performance, can simultaneously be antecedents of job crafting (i.e., reciprocal relationships). Thereby, we focused on effects within employees on a weekly basis. More specifically, we aimed to explore whether positive cycles evolved between job crafting, work engagement and performance within employees from one week to the next.

Theoretical background : Job crafting as a form of proactive behavior at work describes self-initiated changes to one`s job (Tims & Bakker, 2010; Wrzesniewski & Dutton, 2001). According to COR (Hobfoll, 1989), job crafting enables employees to create a resourceful work environment, which enhances work engagement and offers employees the opportunity to do their job well (i.e., performance). Through this initial resource reservoir, employees can build further resources that finally tend to form resource caravans (Hobfoll, 2002). That is, due to an increase in work engagement and performance – triggered by job crafting – the mobilization of further resources, for example by job crafting, can be facilitated. Indeed, engaged and high-performing employees are likely to use job crafting, as they can be motivated to fulfill (further) work goals (Xanthopoulou et al., 2009). For this, employees need resources that they can get by job crafting. To conclude, job crafting, work engagement and performance tend to be reciprocally related and evolve on gain cycles. Gain cycles can be seen as reciprocal relationships between constructs that relate to each other over time (Salanova et al., 2011). As employees have to deal with dynamic situations in the workplace, for instance, job crafting can fluctuate within an employee over short periods of time (e.g., weekly; Petrou et al., 2017). Given these fluctuations, it is important to know whether job crafting induce short-term resource gain cycles with work engagement and performance.

Design/Approach: 175 teachers in Germany participated in the diary study, completing questionnaires once a week over a period of six weeks. Data were analyzed with a random intercept cross-lagged panel model (RI-CLPM) that differentiates between stable trait-like between-person and state-like within-person components.

Results: Results revealed that, between persons and within weeks, job crafting, work engagement, and performance are related to each other. Across weeks, on average, job crafting predicted work engagement and performance at the within-person level in the next week. Inversely, work engagement, on average, predicted job crafting in the next week. Although job crafting predicted performance in the next week, there was no reverse effect of performance on job crafting. Finally, work engagement and performance were reciprocally related from one week to the next, although the effects varied greatly in magnitude and direction.

Limitations: The generalizability of our results is limited as we used a homogenous sample consisting of teachers. Furthermore, performance was assessed with a specific form of teacher's performance, such that it is hard to compare our results with previous research as well there might have been a misfit between the study variables regarding their level of specificity.

Conclusion: Overall, job crafting, work engagement, and performance are related to each other between teachers. Further, our results indicate that weekly teachers' job crafting plays an important role as it predicts both work engagement and performance in the following week. In addition, work engagement, predicted by job crafting in the last week, can in turn predict job crafting in the next week, indicating a positive cycle between both variables. That is, by using job crafting teachers enhance their motivational state that they maintain (or increase) by changing aspects at work proactively. Having a better understanding of the mechanisms by which these variables are linked helps to prepare more effective interventions.

Relevance to the Congress Theme: Job crafting is able to fluctuate within short-time periods (Petrou et al., 2012) and has positive effects on employees (e.g., work engagement). These short-term adjustments are significant in a changing world of work, in which employees have to deal with dynamic, demanding situations.

Relevant UN SDGs: "Good health and wellbeing", "Quality education", "Decent work and economic growth"

Keywords: Job crafting, Within-person effects, Gain cycles

Paper 3

Changes in job crafting during the COVID-19 pandemic in employees with and without mental health issues: The role of job resources

Anja Lehmann, Georg F. Bauer & Philipp Kerksieck | University of Zurich

Research goals: The aim of this study was to investigate changes in job crafting during COVID-19 among employees with and without mental health issues (MHIs). Furthermore, this study aimed to explore the role of job resources with regard to these changes.

Theoretical background: MHIs were highly prevalent in society long before the COVID-19 pandemic. The COVID-19 pandemic has further increased mental health pressure across the population. Due to limited personal resources, employees with MHIs might be less able to craft their jobs during the COVID-19 pandemic. This is important since work-related proactive efforts at the individual level (job crafting) have been identified as beneficial to various work-related parameters. On the other hand, the psychosocial working conditions, particularly job resources, might have a buffering effect on a deterioration of job crafting among this group of employees.

Design: We have analyzed longitudinal panel data of five waves between 2018 (pre-pandemic baseline) and 2021 from employees in Switzerland, Germany and Austria (N = 597). Furthermore, N = 150 employees with (sub-)clinical depression or anxiety were identified.

Results: The multilevel growth models showed that employees with MHIs rather experienced a decrease in job crafting throughout the COVID-19 pandemic compared to employees without a MHI. However, job resources buffered the decrease of job crafting among this group of people.

Limitations: Other mental health issues (e.g., alcohol addiction) were not considered in the study. Moreover, our study was limited by self-reported information.

Conclusions: This research illustrated change differences in job crafting among employees with and without MHIs throughout the pandemic crisis. The psychosocial working conditions, particularly job resources, can prevent a decrease in job crafting among employees with MHIs and thus a potential deterioration of their working situation. Therefore, strengthening job resources is particularly important for this group of persons.

Relevance to the Congress Theme: This research fits to the congress theme “The Future is Now: the changing world of work” as it addresses societal and work-related challenges due to the pandemic crisis. Beyond that, the high prevalence of MHIs indicates that mental health should be a stronger focus in research and practice. To prevent further social inequalities, we need knowledge about how workplaces should be designed to support employees with MHIs. Job crafting as a concept eliciting well-known positive effects on work-related outcomes needs to be elaborated in the context of MHIs.

Relevant UN SDGs: (3) “Good health and well-being”, (8) “Decent work and economic growth” and (10) “Reduced inequalities”.

Symposium S063

Understanding the Temporal Dynamics of Employee Wellbeing in a Changing World of Work

Anne Casper, Department of Psychology, University of Mannheim, Germany; Jesse Vullinghs, Work and Organizational Psychology, Vrije Universiteit Brussel, Belgium

science_practice

What will be covered and why: Many workplace phenomena are dynamic and continuously undergoing change, especially in a world that is continuously changing.The COVID-19 pandemic has caused changes in the lives of many. The pandemic has barely passed, and the next world-changing events such as war, the oil-and-gas crisis, and climate-change are already at our doorstep. These larger-scale events also impact employees' work lives. However, changes in employees' work life have been apparent for a while, for example via the rise of technology (e.g., internet availability). These large-scale events (e.g., a pandemic) and changing trends (e.g., technology) manifest in how employees experience their daily work. To adapt effectively to these changes in terms of practices and policies, we need to better understand the temporal processes that unfold in employees' workplaces and with respect to their well-being.

Researchers are increasingly paying attention to these dynamics of change in the workplace related to employee wellbeing. Initially, with longitudinal studies examining timeframes of several months. More recently, interest is shifting from the stable aspects of employee wellbeing to day-to-day changes. Whereas interest in these temporal dynamics is rising, the COVID-19 pandemic revealed gaps in our understanding of these dynamics. Wellbeing theories inform about the consequences of adverse events for wellbeing but are vague about how these responses evolve over time. For example, how does the safety climate change during enforced remote work? How do resilience and burnout interact when facing acute stressors? How does burnout develop and change over time? And, are existing conceptualizations suitable to answer these questions? Answers to these questions contributes to the literature on employee wellbeing and to an appropriate societal response to the changing nature of work. This symposium highlights the temporal dynamics of employee wellbeing with the aim to advance the temporal specificity of wellbeing theories and improve the practical applicability of research results on this topic.

In the first paper, Mäkikangas et al . use a person-centered approach to examine how psychosocial safety climate (PSC) evolves over time during remote work. Results show that psychological safety climate deteriorated during enforced remote work and that subgroups of employees experienced different patterns of decrease over time. These results suggest a need for interventions to improve PSC, especially during stressful times. In the second paper, Fleuren et al. present a 30-day diary study examining how burnout affects employees' resilience in response to acute stressors. Thus, they identify a proximal mechanism that may explain burnout's negative effects on health, well-being, and performance. In the third paper, Vullinghs et al. use a 35-week daily-diary study to examine teacher wellbeing pre- and post- COVID-19 lockdown. Results reveal the limited temporal specificity of existing wellbeing theories and highlight its relevance for the ecological validity of these theories. In the fourth study, Sagmeister et al. develop a temporal network conceptualization of burnout. By acknowledging the dynamic and developmental nature of burnout, this study offers a fundamentally different conceptualization of burnout to advance a more dynamic and person-centered approach to employee burnout research, prevention, and treatment. Lastly, Prof. Dr. Thomas Rigotti will serve as a discussant on this symposium. Relying on his extensive experience in employee well-being research, he will address strengths and limitations of the individual papers and highlight their potential to stimulate future research on the temporal dynamics of employee well-being.

Implications: This symposium will stimulate critical discussion among scholars about the temporal specificity of existing wellbeing theory and draw attention to the temporal dynamics in employee wellbeing in the face of a changing world of work. Beyond new empirical insights, also several novel methodological and conceptual advancements that will aid in the future study and understanding of the temporal dynamics in employee wellbeing will be presented. The results and methods advanced in the studies of this symposium will also enhance potential implications for practitioners interested in employee-wellbeing.

Overall conclusions. Employee wellbeing is dynamic, and especially in the changing world of work, these dynamics need to be understood to enable employees, leaders, and policymakers to manage them appropriately. Novel empirical findings, conceptualizations, and methods are presented in this symposium that advance your understanding of the temporal dynamics in employee wellbeing and how these can be studied. Existing wellbeing theories are informative in the face of crisis, but particularly their ecological validity and practical utility can be improved by enhancing their temporal specificity.

discussant: Thomas Rigotti, Leibniz Institute for Resilien

Paper 1

Development of psychosocial safety climate during enforced remote work: a longitudinal person-centered approach

Anne Mäkikangas, Jaana-Piia Mäkiniemi & Kirsi Sjöblom | Work Research Centre, Tampere University, Finland

Research goals: There is an urgent need to better understand what factors contribute to healthy multilocational work, which is predicted to present an increasingly pervasive model. The study therefore set out primarily to investigate the development of psychosocial safety climate (PSC), referring to shared perceptions of the extent to which psychological health and safety are prioritized in organizations during enforced remote work occasioned by COVID-19. Second, the implications of the PSC for remote work preferences in the future, the clarity of the new hybrid work practices, and experienced job-related well-being were investigated.

Theoretical background: Psychosocial safety climate (PSC) refers to shared perceptions regarding policies, practices and procedures regarding how psychological health and safety are prioritized and protected in organizations (Dollard & Bakker, 2010). It comprises four content domains: 1) management commitment: is management committed to preventing stress at the workplace? 2) management priority: does management prioritize psychological well-being over productivity? 3) communication: are the employees' concerns regarding psychological well-being listened to, and is information about psychological safety and well-being brought to their attention? and 4) participation: are all levels of the organization involved in preventing stress? (Hall, Dollard, & Coward, 2010). Psychosocial safety climate is seen as an antecedent and moderator of work conditions: it complements and extends the Job Demands-Resources theory (JD-R; Bakker & Demerouti, 2017). A recent organizational intervention aiming at improving PSC was successful although the COVID-19 pandemic started during the intervention (Dollard & Bailey, 2021). However, there is no evidence for how PSC developed during COVID-19 without interventions, whether there were differences between employees' experiences of PSC and its development, and whether the development of PSC had vital consequences for the new work practices and well-being.

Methodology: The participants were 351 Finnish higher education employees who completed five well-being surveys. Data collection began in April 2020, soon after the large-scale shift to COVID-induced remote work, and continued through November/December 2021, covering altogether a 20-month period. Participants completed the psychosocial safety climate questionnaire (PSC; Dollard, 2019) at each of the five measurement times. Latent profile analysis (LPA) was used to investigate PSC profiles. Differences between profiles were examined with the BCH method using the auxiliary command in Mplus (Asparouhov & Muthén, 2014). Analyses were performed using Mplus (version 8.8).

Results: The results revealed four distinct PSC profiles: 1) Low and linearly decreasing PSC (23%), 2) Very low and fluctuating PSC (6%), 3) Average decreasing PSC (44%), and 4) High and initially increasing PSC (27%). Participants belonging to profile 4 showed a more marked preference for remote work in the future than did participants in profile 1 at T5. The PCS profiles also differed in the clarity of the new work practices at T5, that is, these were evaluated at the highest level in profiles 3 and 4. Moreover, emotional exhaustion increased and work engagement decreased among the participants belonging to profiles 1 and 2, that is the profiles where PSC was found to be at a low level.

Limitations: As regards the generalizability of these results, our sample was limited to higher education employees. Moreover, the initial (T1) response rate was 38%, which would suggest initial selective attrition. Furthermore, the data did not include information on the level of PSC before COVID-19.

Conclusions and implications: A notable finding is that PSC decreased among all participants during the enforced remote work. Different PSC profiles were also evident, suggesting varying remote work experiences. PSC had important consequences for remote work preferences, clarity of the new work practices, and well-being. In practice this means that organizations need to design interventions to improve PSC, especially during stressful times.

Relevance to the congress theme: Investigation of psychosocial safety climate in the new era of work is much needed and aligns well with the theme of the congress. There is a need to better understand multilocational knowledge work from the perspective of the health-promoting organizational climate as flexible working arrangements will likely increase in the future.

Relevant UN SDGs : The study will mainly and mostly facilitate the development of sustainable employment. Investigation of psychosocial safety climate is rooted in positive organizational psychology – an approach urgently needed to create socially sustainable work now and in the future.

Keywords: Psychosocial safety climate, longitudinal person-centred approach, enforced remote work

Paper 2

Troubles on Troubled Minds: An Intensive Longitudinal Diary Study on the Role of Burnout in Resilience in face of Acute Stressors

Bram Fleuren, Annika Nübold, Sjir Uitdewilligen, Philippe Verduyn, and Ute Hülsheger | Department of Work and Social Psychology, Faculty of Psychology and Neuroscience, Maastricht University, The Netherlands

Research goals. Burnout is a work-related state of exhaustion that manifests as reduced cognitive and emotional regulation, extreme tiredness, and mental distance to work. Burnout is known to negatively affect employees' health, well-being, and performance considerably and in various ways and to occur at increasing rates in the general working population. Importantly, studies that documented these undesirable effects of burnout typically look at distal and general outcomes (e.g., well-being, performance, and health in general), while much less is known about how burnout shapes immediate responses to stressors. As elaborated below, the present study argues that as burnout might represent a state of diminished regulatory abilities it could impact workers' resilience when facing stressful events. This study aims to examine how burnout shapes workers' resilience using an intensive longitudinal daily diary study design. It uniquely considers how workers' levels of stressor-specific worrying, positive and negative affect, and work engagement are impacted on the day of a stressful event and what the recovery trajectories on the subsequent days looks like. By comparing workers with high and low burnout scores, this study offers fine-grained analysis of how burnout can proximally produce its known adverse distal outcomes. Moreover, the study provides an innovative longitudinal illustration of studying process resilience as demonstrated.

Theoretical background. Theoretical work on burnout suggests that it includes a decreased ability to regulate cognitive and emotional processes. This decreased ability could theoretically reflect the notion that people with higher burnout scores have adverse distal work-related outcomes because they have a lowered resilience. Resilience can namely be defined as the ability to withstand adversity and bounce back from difficult (life) events. Translating this general definition of resilience to resilience as a process, resilience can be observed by considering workers' responses to an event on relevant proximal outcomes. By doing so across multiple narrowly spaced time points the regulatory resilience process can then effectively be observed and be compared across individuals with higher and lower burnout scores. Following the line of reasoning that burnout makes workers less resilient, it is to be expected that workers with comparatively higher burnout scores show more profound immediate reactions to and slower recovery from being exposed to a stressful event.

Methodology. The study consists of a 30-day diary study among an international sample of 410 employees. All variables in the study (i.e., burnout, work engagement, positive and negative affect, COVID-19 related worrying, and the COVID-19 event) were measured through self-reports that were previously validated if possible.

Results. Multilevel analyses with cross-level interactions between individual-level burnout and day-level stressor occurrence reveal that employees high in burnout score significantly higher on negative affect and lower on positive affect and work engagement on the day the stressor occurred. Additionally, discontinuous random coefficient growth modeling with burnout-time parameter interactions shows that employees high in burnout sustain higher levels of COVID-19 worrying, but their negative and positive affect return to pre-event levels in the post-event days.

Limitations. The study has some limitations. The first is the relatively narrow scope of the immediate outcomes considered. On other potentially stressor-relevant proximal outcomes, additional relevant patterns might emerge. Second, the COVID-19 event used as stressor is not perfectly comparable among participants given variations in severity, actual closeness, and international difference in infection rates. Finally, the power of the study is limited as only 66 events have been reported by participants, which might have resulted in under detection of effects.

Conclusions. This study's findings shed new light on how burnout affects employees' resilience in response to acute stressors. Hereby they potentially identify a key proximal mechanism by which burnout's negative distal effects on health, well-being and performance emerge.

Relevance to the conference theme and SDGs. This study fits with the conference theme as it offers a novel dynamic approach to studying burnout related individual differences in resilience. The changing world of work requires dynamic approaches that consider change over time and both resilience and burnout become more important in rapidly changing workplaces. By understanding these phenomena better, the SDGs of decent work and health and well-being can be more easily attained.

Keywords: Process Resilience, Burnout, Dynamic Recovery

Paper 3

Temporal Dynamics of the COVID-19 Lockdown Impact on Employees' Wellbeing

Jesse Vullinghs, Vrije Universiteit Brussel & STRASS Research; Tim Vantilborgh, Vrije Universiteit Brussel; C Drive, Max Planck Institute for Human Development; M Geijer, STRASS Research

Research goals. The aim of this study is to examine the temporal characteristics (i.e., direction, duration, rate of change, and shapes) of the COVID-19 lockdown effect on employee wellbeing. Although the Job-Demands-Resources (JDR) model is informative about employees' initial responses to the lockdown as a work-stressor (i.e., demands increase and job resources and employee wellbeing decrease), wellbeing theories are conflicting in their predictions of the temporal dynamics that follow this initial response; does the effect of the lockdown increase over time (i.e., JDR/COR-theory) or does the effect dissipate over time (i.e., Set-point theory)? At what rate do these changes occur? And thus, what are the time courses of these effects?

Theoretical background. JDR theory builds on Conservation of Resources (COR) theory, which states that individuals are motivated to obtain, retain, foster and protect resources that they value (Hobfoll, 1989). In the context of the COVID-19 lockdown, COR/JDR theory would suggest that the COVID-19 lockdown triggers a loss cycle , meaning that perceptions of job demands and burnout increase gradually over time, while perceptions of job resources gradually decrease over time. Alternatively, Set-point theory (Headey & Wearing, 1989) proposes that employees have a baseline in their work experience. While events cause employees to deviate from their baseline, people generally adapt and return to their baseline over time. This suggests that the COVID-19 lockdown effects are temporary and dissipate over time as employees return to their baseline. Interestingly, the temporal patterns implied by COR/JDR theory, and Set-point theory appear to be conflicting. Moreover, both theories remain vague about the effect duration and rate of change .

Methodology. We investigate these temporal effects in a sample of Dutch educational staff (N = 118, 42% men and 58% women) through daily surveys over 35 weeks. Data collection has continued, and we plan to redo the analysis before the EAWOP conference in the dataset of 50+ weeks of data. We used Hierarchical Bayesian Continuous Time Dynamic Modeling to analyze the data and model the impact and temporal characteristics of the COVID-19 lockdown effect. To illustrate the relative impact of the COVID-19 lockdown on employee wellbeing, we contrast its effects with that of a positive event, namely vacations.

Results. Our preliminary results show that job demands increased (i.e., work-to-life spillover), job resources (i.e., social support) increased, and while employees experienced an increase in cynicism, they simultaneously felt less exhausted, and their professional efficacy was unaffected. Our results, however, suggest that the lockdown effects on employee wellbeing worsen over time: work-to-life spillover (job demands) further increased in the weeks following the lockdown; the increase in social support from the workplace (job resources) dissipated rapidly, suggesting employees rapidly deplete their resources. Moreover, employee cynicism also increased over time. Our results align mostly with a gradual change effect (i.e., COR theory), when focusing on a timeframe of five weeks after the lockdown. However, the gradual change effect may shift into a dissipation effect as the observational timeframe widens, which we will assess in our additional data.

Limitations. The preliminary analysis only included 5 weeks of data after the first lockdown and including more weeks of observations might impact on the results, as the effect of the lockdown

impact changes over time. Therefore, we will re-run the analysis on the additional data that we already collected. Another limitation is that our sample is comprised of secondary-school teachers and employees in other professions might have had experienced the lockdown differently (e.g., not as a stressor).

Conclusions. The immediate effect of the COVID-19 lockdown on employee wellbeing may appear amendable—the magnitude of effects did not appear to differ substantially from that of vacations—but this picture changes when one takes the duration and rates of change of effects into account. This draws attention to the time courses of effects, and that (implicitly) assuming that effects are stable over time can lead to false conclusions. As such, our study underscores the importance of improving the temporal specificity of our wellbeing theories. The results of our study provide fertile ground for such conceptual development.

Relevance to the conference theme and SDGs. This study fits with the conference theme as it illustrates a novel method to measure and analyze the changing world of work. Moreover, it draws attention to the dynamic nature of employee wellbeing and how our current wellbeing theories can be improved to be more informative about the changing world of work. Our study contributes to the SDGs good health and wellbeing and to decent work and economic growth.

Keywords: Employee wellbeing, Time courses of effects, Temporal Dynamics

Paper 4

Capturing burnout dynamics: A systematic review to identify symptoms relevant to the development of burnout

Valentina Sagmeister, Sara de Gieter, Jesse Vullinghs, Safâa Achnak & Tim Vantilborgh | Vrije Universiteit Brussel, Belgium

Research goals and why the work was worth doing. In this study we aim to identify burnout symptoms relevant to conceptualising this phenomenon from a dynamic network perspective. Results will be used to formulate hypotheses on the role of these symptoms in the development of burnout and on the dynamics between the identified burnout symptoms. Using this perspective will contribute to our understanding of burnout as a dynamic and idiosyncratic phenomenon.

Theoretical background. Burnout continues to have a strong, negative impact on society, which we should urgently attend to. Decades of research using a latent variable approach, i.e., burnout as an unobservable entity that can only be measured through its symptoms (de Vet et al., 2011), have given us important insights into risk factors, correlates, and consequences of burnout. Nonetheless, this research has not yet led to successful person-centred care, with burnout rates continuing to be high and long recovery periods for individuals with burnout (van Dam, 2021). Inspired by research on other psychopathologies (Fried, 2017; Cramer et al., 2010), researchers are proposing an alternative conceptualization of burnout, namely as a dynamic network of interacting symptoms (Sagmeister et al., 2022). In this approach, burnout symptoms have an active role by forming a network of causally related factors that interact over time, giving rise to burnout. Currently, there are no tools available to appropriately measure burnout as a dynamic network, since latent measures typically omit symptoms to avoid undesired overlap between psychopathologies, e.g., between burnout and depression (Schonfeld et al., 2018) or anxiety (Koutsimani et al., 2019).

Methodology. We searched three databases (Web of Knowledge, PsycINFO, and PubMed) for peer-reviewed articles that investigated 'burnout symptoms' in adult working populations with a qualitative, quantitative, or mixed-method methodology. We used the r package 'litsearchr' to develop our search query and to remove duplicates. We imported resulting papers into Zotero to preliminary screen the abstracts and titles, and then into 'asreview' (a software using active-learning AI techniques), to select articles for in-depth screening. For the screening process, five reviewers followed a predefined screening manual to identify relevant symptoms, considering content and quality of the studies.

Results : We are currently in the title and abstract screening phase. Results are expected to be ready in November 2022, after which we will start writing the paper. The results of this project will be ready to present well in time before the EAWOP 2023 conference.

Limitations. Many studies on burnout use cross-sectional data. Therefore, for those studies we will not be able to make deductions about the dynamics between symptoms. However, we will use the symptoms identified in this study to conduct future studies with an intensive longitudinal research design to identify those dynamics.

Conclusions – research and or practical implications/Originality/Value. With this study, we provide a comprehensive overview of symptoms associated with burnout and lay the foundation for developing a tool to measure burnout as a network of symptoms. By comparing symptoms in various stages of burnout development, we highlight the necessity to consider burnout from a dynamic

perspective. Advancing our understanding of this approach may lead to stronger and more adequate research methodology, e.g., more researchers may consider a more dynamic perspective on other work phenomena in their work. In practice, tools based on the dynamic approach may lead to more unambiguous diagnostic guidelines, while still considering a person's unique context. This may lay the foundation for person-centred interventions, which can contribute to treatment success and more long-term health behaviour changes (Visvikis-Siest et al., 2020; Goetz et al., 2018).

Relevance to the Congress Theme. We need to challenge the current conceptualization of burnout and consequently, how we measure burnout in our research (and) practice. The dynamic network approach of burnout may offer possibilities to accommodate more easily the constantly changing world of work and the diverse needs of individuals.

Relevant UN SDGs . This project contributes to the 'Good Health and Well-Being' and 'Decent Work and Economic Growth' UN SDGs, since it improves our understanding of burnout development in the working population.

Keywords: Burnout, Employee Well-being, Temporal Dynamics

Symposium S064

Brave new world of work? Challenges and opportunities in hybrid work settings

Christiane Stempel, FernUniversität Hagen

science

Aim and relevance

The topic of our international symposium are the challenges and opportunities of hybrid work settings in Austria, Switzerland, and Germany. Accelerated by the Corona pandemic, we have experienced a tremendous shift in the way we work together. The aim of our symposium is to investigate and discuss the implications of these changes from different perspectives.

Arabella Mühl and colleagues take a closer look at a major challenge people face when working remotely in teams: How to feel related to your co-workers when working apart? Drawing on a diary study among 795 remote workers, the researchers investigate the role of task-related clarity for the need for relatedness. The results not only demonstrate the complexity concerning the antecedents of relatedness satisfaction, but also suggest two practical learnings: first, organizations ought to increase role clarity to foster relatedness satisfaction; second, when fluctuations in clarity cannot be avoided, teams should intensify their team collaboration to circumvent loss of relatedness.

Magdalena Maatescu and colleagues focus on the organizational perspective, investigating the impact of working from home on the identification with the organization. Based on an empirical study, the researchers found that neither extend of home office nor the satisfaction with office design impacts the identification with the organization, but the frequency of contact within the organization does. Because identification is positively related to individual and team level performance potential, these results provide clear implications for organizations about what to emphasize when designing collaboration in hybrid teams.

Christiane Stempel and Sina-Dorit Groenewold shift the focus to the leader role and leaders working conditions in hybrid teams. Drawing on a qualitative approach, they identified various challenges leaders face in the increasingly digitalized work settings. However, the 33 leaders also reported a number of advantages. Furthermore, the analysis of the interviews suggests that leaders are more conscious about tangible aspects like technical or ergonomic equipment than psychological work design. Hence, it would be important to incorporate psychological work design in leadership development programs to address the challenges of hybrid work.

Finally, Hartmut Schulze and Andreas Urech take an external perspective on hybrid work settings, asking production workers how they perceive the increased flexibility for office workers, whether they feel appreciated and informed, and what opportunities for improvement they see. The group interviews reveal what kind of appreciation was considered especially valuable for the workers and how recognition can buffer short-term strain. Injustice was seen as a major problem and several problems were described regarding the cooperation between people on site and working from home. The participating workers developed ideas for improvement in four different areas of action.

Relevance to congress theme: All studies address emerging issues in hybrid work settings and therefore reflect not only a current but also a future development of work. The research in this symposium brings together perspectives from individuals, teams, leaders, and the organization itself. Additionally, we discuss an important social aspect because not all employees have equally access to remote working possibilities.

Research/practical implications: The insights from the studies not only contribute to broaden theoretical knowledge on hybrid work settings but also provide specific orientation for healthy and productive work design in practice. Mühl and colleagues as well Maatescu and colleagues point out specific aspects that need to be considered when designing successful collaboration in hybrid teams. Stempel and Gronewold underline the importance to implement work design in leadership programs in order to address the new challenges faced in digital leadership. The research by Schulze reveals challenges of flexibilized work for production as compared to office workers and offers specific possibilities for improvement.

Conclusions: The research presented in this symposium contributes by offering different perspectives on challenges and opportunities in hybrid work settings. Two studies investigate how we can improve collaboration among people who do not work in the same place. The study on the working conditions and role of leaders indicates steps that need to be taken to prepare leaders for the future developments in hybrid work settings. The perception of production workers on site on the topic of flexibilized work completes the picture by taking potential injustices between employee groups into account.

Keywords: Hybrid Work, working conditions, well-being

Paper 1

Feeling related when working apart: The inconsistent effect of lack of clarity on remote workers

Arabella Mühl, Christian Korunka, Eva Straus & Julia Schöllbauer | University of Vienna

Theory: Self-determination theory (Ryan & Deci, 2000) identifies the need for relatedness as a universial basic psychological need that is an important determinant of motivation, performance, and wellbeing. The need for relatedness refers to the innate desire to feel connected and part of a group or team and may be satisfied by maintaining close relationships and engaging in meaningful interactions with others. Need satisfaction, however, is strongly influenced by contextual factors, such as a lack of task clarity. This may be particularly true for remote workers because a lack of clarity regarding one's work tasks may emphasize their isolation. Remote workers who experience a lack of clarity may feel that colleagues or supervisors are failing to provide them with relevant information. We aimed to further understand the complex antecedents of relatedness satisfaction and to shed light on daily processes in remote work contexts. Based on Uncertainty Management Theory (Kramer, 2004) we argue that a lack of task-related clarity may also increase daily feelings of relatedness because it fosters team interactions, which is positively related to relatedness satisfaction. Consequently, we hypothesized an inconsistent mediation. We assumed that daily lack of task-related clarity would directly negatively affect daily relatedness satisfaction, while it would indirectly increase relatedness feelings via coordination with colleagues and supervisors.

Method: We conducted a daily diary study among 795 remote workers. We observed a direct negative relationship between lack of task clarity and satisfaction of the need for relatedness. Moreover, lack of task clarity was positively associated with coordinating with others, i.e., with increasing lack of clarity individuals increasingly coordinated with colleagues and supervisors. Coordinating with others, in turn, predicted satisfaction of the need for relatedness.

Results: The relationship between coordinating with others and the satisfaction of the need for relatedness was positive. Contrary to the direct effect on relatedness satisfaction and in accordance with our hypotheses, there was a positive indirect positive relationship between lack of task clarity and the satisfaction of the need for relatedness via coordinating with others. The total effect of lack of clarity on relatedness satisfaction was significant and negative.

Conclusions: Our results indicate that remote workers rely on others when they experience a lack of clarity regarding their work tasks, which in turn increases their feelings of relatedness. Moreover, we found empirical evidence for the hypothesized inconsistent effect of lack of clarity on relatedness satisfaction.

Theoretical & Practical Implications: Our results highlight the relevance of studying the antecedents of relatedness satisfaction and suggest that a lack of clarity, as an antecedent of relatedness satisfaction, has been neglected in research so far and needs to be studied further to understand its complex consequences. Particularly the circumstances under which remote workers increase coordination efforts warrant investigation. Nevertheless, practical implications arise. Organizations ought to increase clarity to avoid negative consequences for relatedness satisfaction. However, when fluctuations in clarity cannot be avoided, organizations should foster communication and collaboration to circumvent these consequences.

Limitations: Limitations of this study primarily pertain to the generalizability of our findings. Participants reported high levels of clarity. Our findings, thus, may only apply for individuals with a

basic level of clarity. Moreover, data was collected in March/April of 2020 during a time in which many employees unexpectedly shifted to full-time remote work, which may have affected our results. We aimed to reduce this unwanted influence by excluding participants without prior remote work experience.

Relevance for conference Theme: Remote work as a form of flexible work that allows or requires employees to work from locations other than their organization's premise, such as their own homes, has been increasingly implemented in the last years. Empirical research has identified various challenges and both positive and negative effects on work-related outcomes (for reviews see De Croon et al., 2005; De Menezes & Kelliher, 2011). Our study identifies a lack of clarity as a challenge and chance for remote workers' relatedness satisfaction, and in extension health and motivation, and, thus, contributes to the understanding of changing work conditions.

UN Sustainable Development Goals: Our research contributes to the achievement of the two sustainable development goals of good health and wellbeing and decent work . We identify relevant antecedents of relatedness satisfaction, which, in turn, is strongly associated with health, wellbeing, and motivation. We further and strengthen our understanding of daily challenges at work, particularly for remote workers. These findings allow us to shed light on how work places and daily work processes should be designed to enhance wellbeing.

Keywords: task clarity, relatedness, remote work

Paper 2

Working anywhere and Identification with the organization and the team. Results from an empirical study.

Dharneeka Jeyam, Andreas Urech, Hartmut Schulz & Magdalena Mateescu | FHNW University of Applied Sciences and Arts Northwestern

Research Goals

The dramatic rise in the number of employees working from home due to the corona-pandemic led to the need to reevaluate the effects of working anytime, anywhere. Positive effects on motivation, work-domain balance or productivity are well known, as are adverse effects such as social isolation, loneliness, and lack of informal communication (Gajendrah & Harrison, 2007). Less known is the effect of working from home on organizational identification. Our empirical contribution deals precisely with this context.

Theoretical backround

Previous research on mobile-flexible work shows that a large part of communication is mediated by technology which for years has been seen as not well equipped to convey a sense of identification (Wiesenfeld, Raghuram, Garud, 1998). Therefore, organizational identification is expected to decrease with an increase in time spent away from the office, e.g., in the home office. In contrast, organizational identification is expected to strengthen with the increase in the on-site presence (Millward, Haslam, & Postmes, 2007; Albert, Ashforth, & Dutton, 2000). Physical co-presence and higher percentages of face-to-face interactions are considered pivotal for the emergence of organizational identification (Millward, Haslam, Postmes, 2007).

Method

We present a empirical study (N = 252; mean age= 48.05, 177 female) in which we deepened our understanding of the effect of the amount of time spent in the home office on identification with the organization, the department, and the team, while also considering the influence of the frequency of contact and satisfaction with the office design. The employed Structural Equation Model considers the consequences of working from home, contact, and identification on teams and individual performance potential.

Results

The results of our empirical study show that the extent of the home office has no impact on identification. What significantly matters is the frequency of contact within the organization. A further predictor of team identification was satisfaction with the office design. While satisfaction with the office design did not influence identification with the organization, it was found to play a role in the choice of the work location. A positively perceived atmosphere of the room could positively affect the frequency of work on site. While working from home had no influence on individual or team performance potential, we found positive relations between identification and individual and team performance potential. The results confirm previous findings, which found that the frequency and quality of contact are crucial for successfully working from anywhere in virtual teams (Maznevski & Chudoba, 2000).

Conclusion and Limitations

In conclusion, our studie generates a series of practical implications. (1) Given the importance of contact for team identification, organizations need to advise teams on how to design their 'contact phases'. (2) The negative relation between the office design frequency of work from home might be essential to consider when looking for incentives in 'return to office' policies. (3) Measures to improve performance can profit from strengthening the identification with the team and the organization. Thus, it is essential to make sure employees who mainly work on-site understand that working from does not necessarily indicate a low amount of identification.

One limitation of the study is that we conducted the research in only one organization, a University of education. This limits the generalizability. Further studies must prove the transferability to other fields.

Relevance to congress theme

The study deals with the impact of remote working for the identification with the organization. This topic reflects a major challenge companies and organizations currently face. Against the background of a massive shortage of skilled workers and increasing flexibility of work place and time, identification with the organization is crucial for organizational strategies for the future.

Relevant UN SDGs

The topic of the study primarily targets SDG 3 of the UN named "good health and well-being" as well as SDG 8 on "decent work and economic growth", because it investigates the conditions that foster organizational identification.

Keywords: organizational identification, remote work, performance potential

Paper 3

Digital Leadership: Challenges and Resources for Leading Hybrid

Christiane Stempel & Sina-Dorit Groenewold | FernUniversität Hagen

Research goals: Accelerated by the Corona pandemic, more people work in tele- or hybrid work settings. This development is not only accompanied by massive changes in the way people work together, but also entails new challenges and opportunities for leaders. To design healthy work environments and prepare leaders for the changing world of work it is necessary to investigate how leaders of hybrid teams understand their role and which leadership aspects they consider most relevant. Furthermore, this research takes a closer look at the working conditions that facilitate or hinder adequate digital leadership.

Theory: Drawing on the conservation of resources theory and the job demands resources model, it is assumed that personal and structural resources foster the establishment of successful digital leadership behaviors and a health-promoting hybrid work environment. In contrast, a lack of resources or excessive (new) demands might cause strain and obstructs leadership in hybrid teams.

Method: A qualitative approach was chosen to conduct an in-depth analysis of leadership in hybrid work settings. Semi-structured expert interviews with 33 direct leaders who work in hybrid teams were conducted. Leaders were asked about their hybrid work situation, perceptions regarding (changes of) their leadership role, and fostering/hindering work characteristics. The deductive categorization of work characteristics is based on the Questionnaire of Psychosocial Work Risk Assessment (FGBU) that covers the whole range of job demands and resources as outlined by the Joint German Occupational Health and Safety Strategy. Inductive categories were developed based on the transcribed material. Data was analyzed with qualitative content analysis.

Results: On the one hand, first findings suggest that leaders do not perceive significant changes in their role as leaders due to hybrid work settings. On the other hand, they report various challenges they face ranging from formal and informal communication and team cohesion to feedback culture and technical infrastructure. At the same time, leaders perceive several advantages of hybrid working for themselves and their followers such as more work flexibility and autonomy, reduced commuting, and better life-domain balance. When asked about working conditions, the most prominent topic mentioned was the technical and ergonomic equipment. Initial analysis indicates that leadership tasks regarding psychosocial work conditions, like work content, work organization, and social factors, seem less present and less reflected upon among leaders. More detailed results will be available at the beginning of next year.

Limitations : Even though the sample reflects a variety of occupations and is gender balanced (17 female, 16 male leaders), self-selection biases and the sample size limit the generalizability of the results. The interviews are based on a structured interview guideline but were conducted by four different interviewers.

Conclusions: The findings have implications for research and practice. Past research on leadership neglected structural aspects. It seems necessary to investigate the demands and resources of leaders as a prerequisite for adequate leadership. Here, the specific demands and resources associated with hybrid work settings seem a promising avenue for future research. In terms of practical implication, it seems necessary to include work design in leadership development programs, taking into account the special demands that are associated with hybrid work environments. Furthermore, it would be

important that leaders reflect on their role modelling, e.g., in terms of extended availability behaviors.

Relevance to congress theme: The study addresses leadership in hybrid work settings and therefore reflects not only a current but also a future development of work. To investigate personal and structural factors that enable constructive leadership in these new work settings, it is crucial to design healthy work environments and prepare leaders accordingly.

Relevant UN SDGs: The topic of the study primarily targets SDG 3 of the UN named “good health and well-being”. Addressing structural working conditions in hybrid work settings and developing adequate leadership programs help to ensure sustainable occupational health and safety. SDG 5 on “gender equality” and SDG 8 on “decent work and economic growth” are also topics that emerge in the interviews with the leaders and are important to consider when designing the hybrid work settings of the future.

Keywords: Hybrid Work, Expert interviews, Working Conditions

Paper 4

Experiences of production workers whose job profile does not allow home office. Results of an interview study at an energy producer.

Hartmut Schulze & Andreas Urech | FHNW University of Applied Sciences and Arts Northwestern

Research Goals

The aim of this interview study was to better understand the situation of production employees at different sites of an international energy producer in Switzerland during and shortly after the lockdowns in the wake of the Corona pandemic. Key research questions were how employees perceive the flexibilization of office staff in relation to their own situation, how they feel valued and informed, and what opportunities there are for improvement.

Theoretical background and qualitative interview study

In the debate about mobile-flexible work and home office, the perspective of employees in production areas whose presence on site is mandatory is often overlooked. Against the backdrop of organizational justice, however, it is obvious that those companies face major challenges, which have both “white” and “blue collar” workers. They want to introduce policies for their office employees on the one hand and do not want to neglect their blue-collar workers on the other.

Method

In order to answer these questions, a qualitative approach was chosen by means of data collection through qualitative, semi-structured interviews with employees. The survey was conducted in group interviews. The group interviews were based on a guideline consisting of open, narrative-generating questions and detailed follow-up questions. The group interviews with 67 production employees at 6 locations in Switzerland were conducted anonymously and the results were recorded based on an interview protocol. The analysis was carried out by coding the interview transcripts. The evaluations were carried out using the MAXQDA tool.

Results

The first key result was that most respondents take it for granted that their work with machines and systems cannot be done in a home office. They do not directly compare their work with that from the office. In the interviews, the positive value of working in production became very clear. The production employees interviewed particularly valued seeing the team on site and being able to leave the house. During the pandemic and the two lockdowns, this provided a welcome distraction as well as a way to compensate for the otherwise present Corona problem. Working on-site in production can thus be understood as a psychological resource.

However, negative experiences with on-site work during the pandemic were also reported. In particular, the employees interviewed stated that they lacked recognition and appreciation for their performance in maintaining production during the pandemic and the associated risk of infection. The work climate also suffered during the pandemic measures.

In terms of perceived appreciation, production employees, compared to those working in home office, expressed slightly lower appreciation on average. The positive and negative aspects mentioned in the interviews explain the impression of somewhat lower appreciation and will be

presented in the presentation. The interviews also showed that the feeling of being appreciated can buffer stresses that occur in the short term.

Conclusion and limitations

At the end of the group interviews, four areas for improvement were identified. These are improvement of working conditions, more appreciation for maintaining production, improvement of "factory-office" cooperation, and the transfer of flexibility aspects to production. In the topic of more appreciation, employees' wish for financial appreciation (e.g. bonus, benefits, discounts) but also for appreciation through attention (e.g. e-mail account, words of thanks) is found. This also includes transparent communication within the company. With regard to production processes, employees want to have technological tools at their disposal that provide them with the necessary information on an ad-hoc basis and regardless of location. When it comes to overarching information such as strategic corporate decisions, employees also want a tool that enables them to call up this information promptly as needed.

One limitation of the study is that we conducted the research in only one organization. This is at least partially compensated for by the fact that we were able to include production staff in both the German- and French-speaking parts of Switzerland and thus quite different cultural backgrounds.

Relevance to congress theme and relevant UN SDGs

In the study, the UN SDGs reduced inequalities and peace, justice and strong institutions are addressed. White and blue collar workers can be recognized as two different subgroups with different mindsets and cultures. Working from home further widens the gap between these groups. Therefore, the topic matches to the mentioned UN SDGs. Furthermore, the topic matches to the EAWOP Topic Area 19) Work patterns and conditions.

Keywords: blue-collar, flexibilized work, interview study

Symposium S065

Promoting mental health in the workplace: From needs analysis to multilevel interventions in the H-WORK project

Marit Christensen & Siw Tone Innstrand | Norwegian University of Science and Technology

science

What will be covered and why

Mental health problems are an increasing challenge in worklife as stress, depression and anxiety are the top three causes of illness among European workers and one of the leading causes to sick leave. For the future this is imposing a major burden on individuals, society, and the economy. To promote good mental health in the workplace we need knowledge about the implementation strategies of effective interventions. This symposium presents research from the H-work project, which aims to design, implement, and validate effective multilevel assessment and intervention toolkits to promote mental health in SMEs and public workplaces.

The H-work project builds upon four theoretical pillars: the multilevel appraoch (IGLO-model - Individual, Group, Leader, and Organisation), a participatory bottom-up approach, the JD-R model and application of digital technologies. This implies that we include all stakeholders in a participatory approach to the needs analysis, explore needs at different levels of the organization, and focus on both the health impairment and health promoting processes of mental health. To adapt to the challenges of a changing worklife, application of digital technologies is tested and offered. This symposium aims to present results on how: a) to conduct needs analysis targeting multilevel interventions for improving mental health, b) to adapt the needs analysis and action planning to online and hybrid settings, and show two practical examples of implementation of team level interventions in c) a school setting in Northern Italy, and d) a public organization in the Netherlands. By doing so we show the importance of a participatory approach to securing a fit between the needs analysis and the implementation of the organisational intervention. By presenting results from process evalution of the intervention process we provide knowledge on what works, for whom, and under which circumstances.

This symposium consists of four presentations. Presentation 1 aims to give an overview of the development, application and utility of the H-WORK tool for needs assessment (HAT) for improving mental health and well-being and show how they inform the choice of interventions at multiple levels within the organisation (Christensen, et al.). Presentation 2 considers the opportunities and challenges of conducting mental health needs analysis and action planning in an on-line and hybrid setting (Axtell et al.). Presentation 3: describes the selection, implementation, and evaluation of a team-level intervention carried out in an educational institution (Paganin, et al.). Presentation 4 develops, implements, and evaluates the effectiveness of a brief team development intervention focused on improving team functioning and well-being in a large public organization (van den Heuvel, et al.). Together, these presentations suggests that the HAT function well as a participatory, multilevel tool for needs assessment for mental health and well-being in SME's and public organisations. In line with the changing world and new ways of working, digital solutions for conducting needs analyses show both opportunities and challenges. The evaluation of the implementation process reveals new insights on how the needs analyses aligns with the interventions. Further, the results show how the context, processes, and working mechanisms (e.g., organisational support, training transfer, acceptance, digital system usability) might affect the outcome of the intervention.

Relevance to the Congress Theme

The present symposium aligns with the congress theme by offering knowledge and presenting tools for developing, implementing, and evaluating organizational interventions which show us how to act now to secure a sustainable, mentally healthy workplace for the future.

Research/Practical Implications

The symposium offers a new theoretical approach on how to develop, implement and evaluate participatory multilevel organisational interventions. For research this will contribute to a more in-depth understanding on how the working mechanisms are triggered by the organizational context and leads to a positive mental health outcome. For the practices this will offer knowledge and tools on how to promote mental health in SME's and public workplaces. Overall, the results from the H-work project contribute to the SDG number 3 by offering knowledge on how to ensure healthy lives and promote well-being in working life.

Overall conclusions

To secure a mentally healthy workforce for the future we need to act now. The results from the H-work project underline the need for a participatory and multilevel approach, and a focus on both promoting good mental health and preventing mental illness. In line with a changing worklife and the need for digital solutions we offer new and innovative tools which show promising results.

Keywords: organisational interventions, mental health, multilevel

Paper 1

Needs analyses for targeting multilevel organizational interventions to improve mental health and well-being – the H-WORK needs assessment tool (HAT)

Marit Christensen, Norwegian University of Science and Technology; Marco De Angelis , University of Bologna; Karina Nielsen, University of Sheffield; Carolyn Axtell, University Sheffield; Anne Iversen, Norwegian University of Science and Technology; Karoline Grødal, Arbeidstilsynet; Siw Tone Innstrand, Norwegian University of Science and Technology

Research goals

The objective of this presentation is to give an overview of the development, application and utility of the H-WORK tool for needs assessment (HAT) for improving mental health and well-being and show how they inform the choice of interventions at multiple levels within the organisation.

Standardized questionnaires for mapping the psychosocial working conditions in organisations is often used in organizations, however, it neither consider individuals' appraisals of working conditions nor the specific context of the workplace (Nielsen, Abildgaard & Daniels. 2014). The H-work needs assessment tool is taking a comprehensive approach in order to understand the needs of an organization with the aim of improving mental health and well-being.

Theoretical background

The conceptual background of the needs assessment tool builds on three pillars. First, it builds upon the IGLO model (Individual, Group, Leader, Organisational; Nielsen, et al., 2018) to tackle mental health and wellbeing at multiple levels in the organisations. Research has shown that organisational interventions with a multilevel approach (individual, group, leader, organisational) to mental health and well-being seems to be more effective than interventions only targeting one level (LaMontagne et al, 2014, Nielsen et al, 2018). Second, it is based on the Job-Demands-Resources theory (JD-R; Bakker & Demerouti, 2014) targeting both demands and resources in the work environment to facilitate a health reducing processes and health promoting processes. Examining both positive and negative dimensions of well-being is increasingly recognized as important for understanding effects of workplace change more comprehensively (Mäkikangas et al., 2016; Page & Vella-Brodrick, 2009). Third and finally, it follows a bottom-up and participatory approach where the employees themselves have an active part. A participatory approach throughout the intervention process is essential for successful implementation (Nielsen & Randall, 2012).

Design and methodology

HAT consists of (i) focus group interview, (ii) semi structured interviews, (iii) contextual measure, and (iv) a plan for a stakeholder meeting and action plan. A summary of these needs analyses makes the basis for a stakeholder meeting, which is a participatory process including representatives for all stakeholders within the organisation. The purpose of the stakeholder meeting is to prioritize which needs the stakeholders would like to preserve and improve and then to develop and decide upon an action plan and choice of multilevel organisational interventions for improving mental health and well-being. The needs analyses have been conducted in six intervention sites representing SMEs and public workplaces in different sectors around Europe. In addition, we have conducted a meta process evaluation by interviewing the researchers conducting the needs analyses in these six interventions sites about the process.

Results

The preliminary results from the needs analyses and prioritization of areas to preserve and improve, reflected that these aspects differed naturally across organizations as they are all unique, with different perceived demands and resources. Based on these results different interventions were suggested at different levels as a result of the discussions in the stakeholder meeting. In total 26 interventions were planned to be implemented, most of these on the individual level, followed by group and leader level. Least interventions were suggested on the organizational level.

Limitations

Due to the COVID-19 pandemic we had to conduct many of the interviews and stakeholder meeting through digital platforms. The digital approach might have influenced the communication and openness throughout the process of the needs analyses.

Conclusions – research and or practical implications

Using IGLO as a guiding principle, the results showed that the choice the sites made of interventions was at multiple levels within the organisation. The results also shows that the participatory bottom-up approach secured that the employees were able to state there needs and that it was included in the decision made at the stakeholder meeting and further informed the choice of interventions. We can therefore conclude that the H-WORK needs assessment tool works for identifying the needs within organisations and informing the choice of interventions at multiple levels for improving and promoting mental health at work.

Relevance to the congress theme

This study adds to the importance of understanding how the everchanging context of today, tomorrow and the future triggers the mechanisms which eventually leads to mental health and well-being at work. We add to this perspective by using a participatory perspective in order to understand the needs for interventions for mental health.

Relevant UN SDG

HAT has the objective of contributing to good mental health and well-being among employees in small and medium-sized enterprises who cannot afford to hire expensive consultants. In this way HAT can contribute to balance social inequalities.

Keywords: IGLO-model, needs analysis, organizational interventions

Paper 2

Adapting the Process of Mental Health Needs Analysis and Action Planning to Online & Hybrid Settings: Lessons Learned During Covid-19

Marit Christensen, Norwegian University of Science and Technology; Josefina Peláez Zuberbühler, Universitat Jaume l; Susana Llorens Gambau, Universitat Jaume l; Beate Muschalla , Technische Universitaet Braunschweig; Ivana Šípová, Charles University; Martin Tušl, University of Zurich; Greta Mazzetti, University of Bologna; Marco De Angelis, University of Bologna; Machteld van den Heuvel, University of Amsterdam; Vince Pelzer, University of Amsterdam; Siw Tone Innstrand, Norwegian University of Science and Technology; Cristian Vasquez, University of Sheffield

Research Goals: This paper considers the opportunities and challenges of conducting mental health needs analysis and action planning in online and hybrid settings. It also seeks to understand how these opportunities and challenges inform process adaptations within the context of increased remote work within organisations.

During the Covid-19 pandemic, social distancing restrictions across Europe disrupted the usual face-to-face operations of many organisations. Working from home increased dramatically and will likely continue as many workers desire the flexibility this work arrangement allows. However, high levels of remote and hybrid working can create challenges for collecting information about employee needs.

Theoretical Background: Research on mental health needs analysis argues that active engagement and participation among stakeholders within organisations is required to better understand the situation and align the interventions with the organisational context and objectives (von Thiele Schwartz et al, 2021). Therefore, the use of engaging data gathering methods (such as interviews, focus groups and group-based workshops) may be required to fully appreciate the mental health needs and to plan actions to prevent risks and promote wellbeing at work. However, it can be challenging to use such methods when employees are not collocated.

Whilst technology-mediated communication and online video meeting tools offer the possibility to gather information from workers spread across different locations these methods do not have the same 'naturalness' and social cue availability of face-to-face communication (Kock, 2005) which can result in misunderstandings, impaired relationship building and increased cognitive load (Axtell, et al, 2004; Reidl, 2022). Conducting these activities on-line may be particularly difficult for sensitive topics like mental health, where the ability to build relationships as well as to see social cues and facial expressions may be especially important. However, there is limited academic research on the suitability of video calls for conducting information gathering exercises on such topics within organisations, and still less on the use of hybrid methods. This is a gap that the current research seeks to address.

Method: Data collection occurred as part of a large H2020 project (H-Work) focused on implementing mental health interventions in SME's and Public organisations. Due to Covid-19 restrictions, methods for needs analysis and action planning had to be quickly adapted from the expected face-to-face methods to either fully online or hybrid (with some participants face-to-face and others online). The methods used for needs analysis and action planning included dyadic/on-to-one interviews and group exercises/meetings using online meeting platforms.

Data for this current paper derives from nine focus group interviews with the project interventionists about their experiences of conducting needs analysis and action planning across ten intervention sites in five European countries. Questions were asked about the opportunities and challenges experienced, how challenges were dealt with, and lessons learned. Interviews were transcribed and analysed in NVivo using template analysis.

Findings: Two opportunities and five challenges were identified. Opportunities related to time efficiency gains and increased openness, but these opportunities almost exclusively appeared during the dyadic 'one-to-one' activities conducted rather than group activities. The challenges were: problems with relationship building, conveying non-verbal and emotional cues, knowledge and information sharing, cognitive load, and technical difficulties. Mostly, these challenges occurred when conducting group activities or when trying to develop relationships with the wider organisation.

The extent to which these opportunities and challenges were experienced also differed depending on different contingencies operating in the individual, project, organisational, or wider omnibus contexts. Knowledge of these contingencies can inform improvements to the process, to enhance the likelihood of opportunities and reduce the challenges. Several mitigating actions were put in place to try and deal with the challenges identified. For example, to help mitigate difficulties with information exchange and cognitive load, engaging materials were developed to send in advance.

Limitations: Data was collected during the pandemic when activities were moved online with little preparation. Therefore, some of the challenges identified may be less prevalent in future circumstances, although still likely relevant given increasing hybrid working.

Conclusions: The opportunities provided by online methods may mean that the benefits outweigh the negatives for dyadic/one-to-one activities during mental health needs analysis. However, there are challenges related to group activities that require mitigating actions and adaptations.

Relevance to Congress theme: The changing world of work involves increased prevalence of online/hybrid working. This paper contributes to an understanding of ways of dealing with the challenges associated with these new ways of working.

UN SDG: Good health & wellbeing

Paper 3

Promoting mental health in the school setting: from needs analysis to a team-level intervention

Giulia Paganin, Dina Guglielmi, Edoardo Pische, Alessandra Albani & Greta Mazzetti | University of Bologna

Research goals

The contribution aims to describe the selection, implementation, and evaluation of a team-level intervention carried out in an educational institution in Northern Italy as part of the EU-H2020 European project H-WORK. The added value of this implementation process lies in the link between needs analysis results and the plan and implementation of a digital-based intervention in the educational context, using a participatory approach and carrying out a process and effect evaluation.

Theoretical background and research question

Following a multilevel approach based on an integration between the IGLO model (Day & Nielsen, 2017) and the JD-R model (Schaufeli, 2017), job demands, and resources can be identified at four organisational levels (individual, group, leader, and organisation), negatively or positively impacting job well-being. A needs analysis process was conducted through interviews, focus groups and questionnaires. Based on the findings, workers were involved in a participative and bottom-up decision-making process that highlighted the need to address collaboration and communication in teamwork. For this reason, Sociomapping digital-based intervention was selected and adapted to the needs and constraints of the intervention site.

Sociomapping is a group-level intervention that, by analysing and working on interpersonal relationships, aims to increase cooperation and communication levels among colleagues, to enhance group performance and work climate. Sociomapping is theoretically built on the JD-R model and the Equilibrium Theory. In particular, the latter postulates that group members strive to preserve a balance between task-oriented and socio-emotional needs.

Design/Methodology/Approach/Intervention

The intervention site is an educational institution in Northern Italy, managing schools of different grades in four locations: 3 Nursery Schools, 4 Preschools, 2 Primary Schools and 1 Middle School.

A participatory needs analysis was carried out to screen workers' mental health with a contextualised approach. We conducted 12 interviews with senior and middle managers and two focus groups involving 12 employees (educators, teachers and administrative staff) to gather workers' mental health needs at the four IGLO levels. The research team discussed the findings with relevant stakeholders. Based on the needs analysis, the Sociomapping intervention was identified as a suitable intervention strategy. We conducted four sessions (one hour each) using a videoconferencing platform. Seven editions were conducted with 76 participants (100% female). During the intervention, participants were asked to complete questionnaires aimed at building Sociomap visualisations representing communication patterns within each team. These were then compared with maps showing ideal communication flows perceived by participants as necessary to work properly. The sessions aim to reduce the gap between current and desired team communication by discussing the communicative situation and developing an action plan to achieve the desired communication structure.

Longitudinal data collection is ongoing. The collected data will be analysed using ANOVA repeated measure.

Results expected

By adopting a realist evaluation framework (Nielsen & Abildgaard, 2013), we expect to be able to determine the effect of meaningful implementation aspects, such as context, processes, and working mechanisms (e.g., organisational support, training transfer, acceptance, digital system usability) of the intervention.

Limitations

Limited participant number and homogeneity of the sample working in the educational sector and completely composed of females.

Conclusions - research and or practical implications

Research implications are twofold, as the present contribution aims to advance the knowledge about (1) effective interventions to promote mental health and (2) the effectiveness of digital-based solutions to implement workplace mental health interventions.

The Sociomapping digital-based intervention can guide educational managers in designing, developing, and implementing multilevel intervention strategies to promote the mental health of people working within the school setting.

Relevance to the Congress Theme

The increasing complexity of the world of work and the unexpected challenges brought by the Covid-19 pandemic has made it even more imperative to analyse and tailor interventions for well-being promotion and stress risk prevention. Needs analysis and a participatory approach are crucial to implement interventions tailored to the workers' needs and to increase the chances of their effectiveness. Moreover, to gather more accurate and valuable information, it is essential to evaluate the implementation process, not only the effectiveness of the intervention itself.

Relevant UN SDGs: SDG 3-Ensure healthy lives and promote well-being for all at all ages.

Paper 4

The strengths-based team crafting intervention for project teams: development, implementation and initial results

Machteld van den Heuvel, Edwin van Hooft, Roy Sijbom & Vince Pelzer | University of Amsterdam

Research goals

The aim of the overall study is to improve well-being in a large public organization using an elaborate multilevel needs analysis, leading to tailored interventions at the group and leader-level (Di Angelis et al., 2020). Based on the insights from the needs analysis, we designed a team-intervention (and a leader-intervention) focused on improving well-being.

Theoretical background

Recent studies emphasized the importance of intervening at multiple levels in organizations to improve work-related well-being (De Angelis et al., 2020). Previously, emphasis has mainly been on the individual-level, while the group-level (teams) is underrepresented in intervention research (Van Woerkom, 2021). This is a shortcoming as teamwork and team social interactions are important sources of well-being (Mazetti et al., 2021). In this study, we aim to develop a multilevel intervention approach to improve well-being. Based on a multilevel needs analysis, our intervention approach focused on 1) the team-level (project teams) and 2) the leader-level (project managers; leadership micro-coaching intervention). In this presentation we focus on the team-intervention. To develop the intervention, we combined literature on team-interventions (Lacerenza et al., 2018) with insights from strengths-based interventions and job crafting approaches (Van den Heuvel et al., 2019). We expect that the strengths-based team crafting intervention will improve team and well-being outcomes (i.e. affective well-being, team crafting behaviors, strengths-use and knowledge, team reflexivity and team support).

Methods

In the first phase, the needs analysis used focus groups, interviews and a context measure with employees, line managers, project managers, senior leaders and HR representatives within a public organization in the Netherlands, to assess well-being related factors. The strengths-based team crafting intervention was designed as part of the recommendations from this needs analysis. The intervention consists of a day of team development activities, including team exercises and discussions, e.g. reflecting on team-cooperation, strengths-use and the team's purpose. The team draws up a team crafting action plan and after approximately 4 to 5 weeks, they meet again to evaluate progress. To analyze the data, we plan to use a mixed-methods approach, combining quantitative pre-post measures of team and well-being outcomes and thematic analyses of qualitative data from open-ended questions.

Results

The needs analysis showed positive findings regarding the availability of well-being resources as well as high levels of work commitment. Areas for development were awareness of organization-level resources, lack of autonomy and high workload. Results pointed towards a need to focus on well-being in the project-teams. Specifically, there was a need to discuss well-being and team-related processes that support well-being. Due to the organizational matrix-structure, the project managers seemed less equipped to deal with well-being issues in project-teams. Taken together, these findings

informed the design of the interventions. We have currently worked with six teams (N=50) and we aim to work with at least 4 more teams before starting the data analyses on the relevant outcomes mentioned. Final results are expected around July 2023.

Limitations

The matrix-structure of the organization has resulted in multiple team membership for most employees. This complicates and potentially limits the implementation and effectiveness of the intervention (Margolis, 2020). Team composition changes and employee turnover pose another challenge for the intervention's potential to transfer to daily work life in the longer term. The interval between the first session and the follow-up was not the same for each team due to scheduling issues. Small sample size may result in limited power for the quantitative analyses.

Conclusions

The evidence-informed strengths-based team crafting intervention may potentially be a relatively brief way to facilitate awareness of well-being-issues in otherwise highly content-focused project teams. The intervention is designed to stimulate positive behaviors and team processes to support well-being. Further analyses should focus on the impact of the leader-level intervention in combination with the team-level intervention.

Relevance to the Congress Theme

The study's context is the post-covid workplace where teams are struggling to collaborate effectively in a changed work-setting. The study focuses on how to optimize team-processes (and leadership) to ensure well-being in this changed environment.

Relevant UNSDGs

This study contributes to the development of the workplace as a source of human health & wellbeing (UNSDG 2 & 5), since the intervention aims to optimize team processes to create an optimal work environment for employees and the team as a whole.

Keywords: well-being, team crafting, intervention

Symposium S067

Workplace learning

Ellis S. Emanuel, University of Amsterdam

science

What will be covered and why?

The nature of work constantly changes due to technological innovations and globalization. To cope with these changes, it is essential that employees continuously engage in workplace learning. Workplace learning can be defined as the multiple ways through which employees learn in organizations (Jacobs & Park, 2009; Sadeghi, 2020). Workplace learning ensures that employees can frequently update and improve their competencies and employability (Van der Heijden et al., 2009), but also helps organizations to gain competitive advantage (Vaughan, 2008).

While already quite a lot is known about workplace learning, new developments and advancements also warrant new directions for research. For example, research has shown that knowledge sharing can facilitate workplace learning (e.g. Mura et al., 2016), yet we still know little about the dynamic processes underlying knowledge sharing. This requires a shift from a static to a more dynamic perspective on workplace learning. Also, competence and expertise are seen as valuable resources of employees (Paloniemi, 2006). However, we still know relatively little about employees' abilities to flexibly deal with new experiences and newly needed expertise. This symposium addresses these, more dynamic, processes and abilities regarding workplace learning by discussing (1) individual differences in employees' abilities to learn and (2) how and when employees share knowledge.

First, Frie and colleagues introduce 'Flexpertise' as an individual ability that determines workplace learning in a dynamic context. Flexpertise refers to the adaptive ability by which workers are able to meet new expertise needs within and across the boundaries of their working contexts and expertise domains. The researchers clarify when and how an individual's flexpertise can be fostered and discuss an agenda for future research.

Second, Hadiono and Okay-Somerville stress the importance of an employee's ability to learn from a different yet complementary perspective. They shed light on the construct of 'learning agility': dealing with new experiences flexibly and rapidly by trying new behavior and making quick adjustments in order to realize new learning when one does not know exactly what to do. Results show how some dimensions of personality are positively associated with learning agility in the workplace, regardless of organizational climate.

Third, Emanuel and colleagues argue that workplace learning, or more specifically, knowledge sharing, is an interpersonal dynamic process that fluctuates from day to day. Using a multilevel diary design, they focus on how supervisor and co-worker support within the organization may facilitate knowledge sharing. The results of their diary study confirm the importance of daily social support for knowledge sharing.

Fourth, Rinker and colleagues build further on the topic of knowledge exchange and uncover how another interpersonal process, namely social comparison, is involved in employees' decisions with whom to exchange knowledge. The results of their study show that social comparisons impact knowledge sharing and knowledge hiding and that this is moderated by age differences.

Following the presentations, Professor Dr. Beatrice van der Heijden, who is a renowned expert in the field of employability, expertise development, age stereotypes, and sustainable careers, will integrate the key takeaways from the presentations and will lead a stimulating discussion.

Relevance to congress theme

In a world in which work is changing rapidly, it is important that employees learn and develop new competencies. The four papers presented in this symposium address this by stressing the relevance of taking into account the individual abilities of employees when designing interventions and by discussing the importance of knowledge sharing for learning.

Research/Practical implications

The implications are twofold. First, the studies aim to understand individual differences and underlying processes related to knowledge sharing and acquiring new expertise. Second, from a practitioner's point of view, emphasis is put on bridging the theory with relevant HRM practices such as recruiting and creating learning climates. The knowledge presented here helps organizations to develop employee learning abilities (e.g., by focusing on highly agile learners and the need to shift their focus from expertise to flexpertise), as well as create a climate in which knowledge can optimally be exchanged.

Overall conclusions

The goal of this symposium is to gain a better understanding of the individual and contextual factors that influence workplace learning. The four papers aim to do this by adopting a dynamic rather than static perspective both in operationalization and research designs. In particular, the papers highlight how certain individual (e.g., learning agility, flexibility in learning) and contextual factors (e.g., organizational climate, social support) impact workplace learning.

discussant: Beatrice I. J. M. Van der Heijden, Radboud University Nijmegen

Keywords: knowledge sharing, flexpertise, learning agility

Paper 1

Fostering flexpertise through workplace learning: An empirical study using Group Model Building

Lonneke S. Frie & Ellen Sjoer | The Hague University of Applied Sciences; Hubert P.L.M. Korzilius & Beatrice I. J. M. Van der Heijden | Radboud University Nijmegen

Research goals

Flexpertise concerns the adaptive ability by which workers are able to meet new expertise needs within and across the boundaries of their working contexts and expertise domains (Van der Heijden, 1998). This ability is required given the volatile working contexts and expertise domains in which workers (collaboratively) function, and the shifting needs and expectations of their surrounding stakeholders (Frie et al., 2019; Grenier & Kehrhahn, 2008). However, meeting new expertise needs is by no means an easy process and not necessarily aspired and mastered by each worker (Van der Heijden, 2005). Research has shown that workers may develop inflexibility in their thinking, acting and motivation throughout their career (Dane, 2010; Feltovich et al., 1997), which can hamper the interplay of adaptation processes they need to manifest (Authors, manuscript under resubmission). On the long run, this may imply that an individual's employability becomes at stake when they are not able to reactively or proactively respond to shifting expertise needs (Van der Heijde & Van der Heijden, 2006; Van der Heijden, 2002). Thus far, we have a limited understanding of what individual workers and their stakeholders can do to (re)ignite the required interplay of adaptation processes. This dynamic system includes the redevelopment of expertise at the workplace in which workers develop new expertise within and across their domain boundaries (Grenier & Kehrhahn, 2008; Gruber & Harteis, 2018; Wallin et al., 2019). Therefore, in this study, we aim to empirically investigate the validity of a newly developed so-called dynamic model of flexpertise at the workplace.

Theoretical background

The dynamic model of flexpertise at the workplace that is based upon an integrative review of research regarding flexible forms of expertise (Authors, manuscript under resubmission), captures the interrelatedness of six clusters of adaptation processes that workers need to manifest in order to meet new expertise needs on an ongoing basis. These adaptation processes involve intra-individual adaptations over time, as well as social interactions with surrounding stakeholders. We use this model as our underlying theoretical foundation to increase our understanding of when and how adaptation processes can be hampered or impaired, and which individual factors and interventions may increase the effectiveness of these processes.

Methodology

By deploying a Group Model Building (GMB) process (Vennix, 1996), we aim to collect opinions of HR/D professionals regarding when and how in the dynamic model of flexpertise the individual's adaptive ability can be fostered. Through a structured group decision-making process, we collect their perspectives to fill lacunas in our understanding, and use their perspectives to build consensus on the leverage points and interventions to foster flexpertise at the workplace.

Results expected

Data collection will take place during Q4 2022. Data analysis will be done in Q1 2023.

Limitations

The quality of the output of the GMB sessions will be highly dependent upon the experience of the participants regarding the flexpertise phenomenon and their understanding of system dynamics. By following the guidelines for GMB (Rouwette et al., 2011; Scott et al., 2016) and by making use of extensively evaluated workshop scripts (Scriptapedia, 2022), we safeguard the quality of the output of the GMB sessions.

Conclusions

This research project is expected to set avenues for future research involving a dynamic perspective on expertise and employability development (Fugate et al., 2021). Such a perspective takes into account that, over time, workers need to engage in multiple exchanges with their surrounding contexts, and in doing so to build up flexpertise in order to safeguard their career sustainability (De Vos et al., 2020).

Relevance to the congress theme

This study will further our understanding of how an individual can sustain their position as a worker with valuable and recognized expertise throughout one's career. This may require that organizations shift their focus from expertise to flexpertise development (Authors, under review). More specifically, our newly developed dynamic model of flexpertise is expected to provide the grounding for designing interventions that help to protect and enhance workers' career sustainability throughout the life-span.

Relevance UN SDGs

The SDGs (UN, 2015) require sustainability transitions that necessitate workers to operate in multi-disciplinary teams, to develop innovative solutions, and to collaborate with stakeholders who have different expectations regarding the workers' expertise and contributions to practice (Belda-Miquel et al., 2020; Martins et al., 2019; Van Mierlo & Beers, 2020). This may necessitate that organizations need to upskill and reskill their workforce (WEF, 2020), which is easier said than done since it concerns adaptive and maladaptive processes of workers. As such, we would like to conclude that using our dynamic model for fostering flexpertise at the workplace will specifically help to realize the SDG 8 'Decent work and economic growth'.

Keywords: flexpertise, adaptative ability, dynamic perspective

Paper 2

The Interaction of Individual Differences and Motivational Climate using Trait Activation Theory

Belgin Okay-Somerville, Alvin Hadiono | University of Glasgow

The recent pandemic calls for large-scale organisational and work arrangement changes, in which managers and employees must adapt and maintain high performance within such context (CIPD, 2020). Being agile, innovative and able to consider multiple scenarios in these uncertain times, dealing with complexity and managing paradoxes have been long noted as some of the "in-demand skills" to have during such times of change (Oxford Economics, 2012).

This study investigates the construct of learning agility, i.e., the ability to deal with new experiences flexibly and rapidly by trying new behaviour and making quick adjustments so new learning will be realised when one does not know exactly what to do (Burke, 2016). Firstly coined by Eichinger & Lombardo (2000), learning agility is positively related to employees' performance during changing organisational contexts (Bedford, 2011), the potential for advancement (Miklos, Herb & Forbringer, 2013), being identified as high potential (Dries, Vantilborgh & Pepermans, 2012) as well as to leadership success (De Meuse, 2017). As a relatively new construct, the practitioner's interest in learning agility has been growing rapidly in the last decade beyond robust empirical substantiation (De Meuse, 2015). While the organisational implications of learning agility have been looked at in several research (De Meuse, 2017), our understanding of "who" demonstrates learning agility and "how" individual differences interact within the environment is still relatively scarce.

Responding to the call for empirical research on the role of context (DeRue, Ashford & Myers, 2012), the present study aims to understand the individual differences (i.e., personality and goal orientation) associated with learning agility in the workplace and the organisational climates that facilitate/hinder this relationship. Utilising Trait Activation Theory, we examined organisational motivational climate as a boundary condition within which the impact of individual differences on learning agility is strengthened or weakened. Agile learners might have a deeper appreciation of social realities around them and pay more attention to how those climates affect their behaviours (Hoff & Burke, 2017). In terms of value/originality of this study, it contributes towards a contextualised understanding of learning agility and achievement goal theory in the organisational context, as much of its supporting research was conducted in educational, sports and physical activity settings (Roberts, 2012).

This study is conducted within the context of Indonesia, Asia Pacific's third and South East Asia's most populous country and biggest economy. Using data from 1499 "high-potential employees" from 18 different organisations in Indonesia, the study employed Structural Equation Modelling to test a model of learning agility where personality (HEXACO) and learning goal orientation (mastery and performance orientations) were direct predictors and perceived organisational mastery vs performance learning climate was the moderator of these relationships.

The results show that Extraversion, Openness to Experience, and Conscientiousness are positively associated with learning agility, while Emotionality, Honesty-Humility and Agreeableness are negatively associated. Both goal orientations are also found to be significantly associated with learning agility. An examination of the interaction effects shows that the mastery climate facilitated learning agility due to Honesty-Humility, and Emotionality, while the performance climate facilitated learning agility due to Agreeableness. Unfortunately, no significant climate interaction is observed in relation to goal orientations. Further discussions regarding the valence of the personality-climate relationships and interactions were then elaborated using the lens of social adroitness in the context

of "high-potential employees" identification in the workplace (Ashton & Lee, 2007; 2005; Markey & Markey, 2006; Ashton, Lee and Son, 2000).

Intended for both academics and practitioners alike, the implications of this study are two-fold. Beyond using more updated and rigorous models of personality (i.e., HEXACO) and motivation than extant research, this study tries to extend the understanding of learning agility by taking trait activation and achievement goal theories into account, emphasising the role of motivational climates. From a practitioner's point of view (Rotolo et al., 2018), consistent conceptualisation, measurement and reporting back to the industry are important to prevent learning agility from becoming another management 'fad'. This study tries to do that by carrying forward Hoff & Burke's (2017) latest line of research and bridging the theory with managerial implications, i.e., relevant HRM practices on recruiting, developing highly agile learners and establishing a conducive learning climate.

Learning agile employees are 1.2x more capable of responding to a competitive environment, 3.2x more prepared to anticipate and react to nature and speed of change and eventually 4.6x more engaged with their organisations ("Global Leadership Forecast 2018," 2018). This research is foreseeable to be aligned with Goal 9 of the UN's SDG (Building resilience infrastructure, promoting inclusive and sustainable industrialisation and fostering innovation) as well as with the congress theme of "The Changing World of Work," as it primarily investigates individuals' experimentation and adaptive behaviour in order to keep learning and innovating during shifting organisational contexts and priorities (Harvey & De Meuse, 2021).

Keywords: learning agility, individual differences, organizational climate

Paper 3

Knowledge sharing at work: The role of daily work-based social support, learning goal orientation and task interdependence

Ellis S. Emanuel & Matthijs Baas | University of Amsterdam; Jessie Koen, University of Amsterdam/TNO; Roy B.L. Sijbom, University of Amsterdam

Research goals

Knowledge sharing is a key source of competitive advantage in many industries (De Vries et al., 2006; Wang & Noe, 2009). Most research on knowledge sharing, however, examines differences in knowledge sharing between employees, implying that knowledge sharing is stable over a longer period of time and ignoring what causes individuals to share knowledge on one day, while sharing little to none on the next day. In this study we aim to unpack if daily fluctuations in employee knowledge sharing depend on daily work-based social support from one's supervisor and co-workers. In addition, we look at the moderating role of learning goal orientation and task interdependence.

Theoretical background

According to Social Exchange Theory (SET), employees continually have to consider if the benefits of sharing information outweigh the costs. Research shows that employees are more likely and better able to share knowledge if their environment invites them to. Knowledge exchange between employees is, on average, higher when employees feel supported and encouraged by their supervisor and co-workers (Cabrera et al., 2006; Kulkarni et al., 2006; Wang & Noe, 2009). The extent to which an employee engages in knowledge sharing can fluctuate from day to day. While social exchange theory explains how individuals exchange resources (e.g., reciprocity; Blau, 1964), the theory is less clear about fluctuations in exchanges over time. Typical leader behaviors, such as offering a challenging assignment or social support, may be more present (or more positive) on some days compared to other days affecting employees' knowledge sharing behavior to a greater or lesser extent. The same goes for the behavior of co-workers; the amount of perceived support from co-workers can differ per day, and receiving support on one day does not guarantee support on other days.

First, we expect positive relationships between daily supervisor support and daily knowledge sharing and between daily co-worker support and daily knowledge sharing. Second, we expect these positive relationships to be weaker for employees with higher levels of learning goal orientation compared to employees with lower levels of learning goal orientation. Finally, we expect these positive relationships to be weaker when task interdependence is high rather than low.

Methodology

A ten-day diary study was conducted among a sample of employed workers in the United Kingdom (n = 111) that were recruited via the online participant recruitment tool 'Prolific'. Participants filled out a daily survey at the end of each workday for a period of 10 consecutive work days, leading to a total of 829 measurement occasions. We performed multilevel analyses using Linear Mixed Models in IBM SPSS 26, with the repeated measures at day-level (n = 829 study occasions) and the individual participants at person-level (N = 111 participants).

Results

Our findings show support for the positive relationships between daily perceived supervisor support and daily knowledge sharing and daily perceived co-worker support and daily knowledge sharing. A significant interaction effect was found for learning goal orientation and daily co-worker support on daily knowledge sharing. The relationship between daily co-worker support and daily knowledge sharing appeared -contrary to what we had hypothesized- stronger for employees with higher levels of learning goal orientation compared to employees with lower levels of learning goal orientation. Results showed no significant interaction effect of learning goal orientation and daily supervisor support on daily knowledge sharing. Also, we did not find support for any effect of task interdependence.

Limitations

First, the results of this study are correlational in nature and therefore it is not possible to make any claims about causality. Second, the use of mere self-reports potentially increased the risk of common method variance.

Conclusions

In summary, this study emphasizes the importance of both supervisor and co-worker support for knowledge sharing in the workplace -regardless of employees' level of learning goal orientation and the degree of task interdependence. Especially employees with higher levels of learning goal orientation are likely to respond with knowledge sharing to the interest and support from co-workers mainly.

Relevance to the Congress Theme

By looking at drivers of employees' knowledge sharing on a daily basis, this study is a first step in shedding more light on the daily process underlying social exchange and collaboration in the workplace. In an ever changing world of work, it is extremely important that organizations focus on the sharing of knowledge within their organizations.

Relevant UN SDGs

Pursuing the UN SDG 'Decent work and economic growth' requires, in an ever-changing world of work, adaptability of both organizations and employees when it comes to the interpretation of jobs and tasks. Knowledge sharing can and should play a role in alleviating this required adaptability.

Keywords: knowledge sharing, social support, daily fluctuations

Paper 4

Do you pose a Challenge or a Hindrance to me? A Dual Pathway Model of Upward Social Comparison and Employees' Knowledge Exchange Behaviors

Laura Rinker, University of Hohenheim; Anne Burmeister, Erasmus University Rotterdam; Fabiola H. Gerpott, WHU – Otto Beisheim School of Management; Ulrike Fasbender, University of Hohenheim

Research goals and why the work was worth doing: Workplace learning, for instance in the form of knowledge exchange, is essential to organizational success. In particular, knowledge exchange between younger and older employees has generated increased research interest (Dietz et al., 2022). Knowledge exchange nurtures both older employees' efforts to keep up with new knowledge as well as younger employees' acquisition of specific organizational and job-related knowledge, which has been generated through experience and tenure. Because knowledge exchange requires employees to invest time and effort, they must choose with whom to exchange knowledge. Our study aims to shed light on the interpersonal processes involved in this decision, which have received little research attention so far. Thus, we consider upward social comparisons (i.e., employees' relative comparisons with colleagues who they perceive to be better than themselves; Buunk & Gibbons, 2007) as a decisive factor for (de-) motivating employees to engage in knowledge exchange (Reh et al., 2018).

Additionally, we consider the context of interactions between age-diverse colleagues, because different literature streams suggest opposite predictions regarding the hindering or facilitating influences that age differences between colleagues may exert on the mechanisms linking employees' social comparisons with their knowledge exchange behaviors (Fasbender & Gerpott, 2022).

Theoretical background: Our study integrates social comparison theory (Festinger, 1954) with the challenge-hindrance stress model (Cavanaugh et al., 2000). We conceptualize social comparisons as a work-related stressor (Greenberg et al., 2007) and propose that its stress appraisal shapes how employees engage in knowledge exchange. Accordingly, social comparisons can be appraised either as a demand involving potential gains (i.e., challenge appraisal) or as a demand that obstructs one's goal achievement (i.e., hindrance appraisal). We propose that appraising a social comparison as a challenge prompts an approach response, promoting knowledge exchange. In contrast, appraisal as a hindrance triggers an avoidance response, reinforcing behaviors inhibiting knowledge exchange. Because the perception of a stressor as a challenge or hindrance is not mutually exclusive, we expect that both pathways can occur simultaneously.

Yet, we suggest that this stress appraisal is shaped by the characteristics of the social comparison target (i.e., the colleague an employee compares oneself to). Drawing on Festinger's (1954) theory of social comparison, we argue that an age difference weakens the links between social comparisons and challenge and hindrance appraisals as people prefer to compare themselves to similar others. We assume that the age difference between an employee and their social comparison target thus also influences downstream knowledge exchange behaviors.

Research methodology: We conducted an online experiment using a 2×3 between-subjects design in which we manipulated the factors social comparison (upward vs. lateral) and age difference (older vs. same age vs. younger comparison target) by providing participants (N = 206) with randomly assigned bogus performance feedback on a cognitive ability test. We pre-registered our hypotheses

at the Open Science Framework (https://osf.io/26qxc/?view_only=889ab88b83d84c1882eb49accf0ed391). To test our hypotheses, we utilized path analyses in Mplus 8.4. To investigate the indirect and conditional indirect paths, we simulated Monte Carlo confidence intervals for the indirect and conditional indirect paths in R.

Results obtained: Our findings show support for the proposed avoidance pathway, suggesting that upward social comparisons are negatively linked to knowledge sharing and positively linked to knowledge hiding via hindrance appraisal. As hypothesized, the age difference between participants and their social comparison target buffered these relationships such that the negative effect of hindrance appraisal on knowledge sharing and the positive effect of hindrance appraisal on knowledge hiding were weaker. We did not find support for the approach pathway via challenge appraisal.

Limitations: First, we were not able to capture the entire age spectrum in our sample, which may raise concerns regarding its representativeness and the generalizability of the results, especially to older age groups. Second, despite our experimental approach, we relied on the use of self-ratings to obtain the data, which may introduce common-method-bias.

Conclusions: In summary, our study highlights the benefits that age diversity can entail in terms of knowledge exchange as one type of workplace learning. At the same time, it cautions against the possible negative effects of social comparison.

Relevance to the Congress theme: Our study speaks particularly to the facets contribution and urgency embedded in the congress theme. By combining the topics of social comparison and knowledge exchange, our study examines how employees deal with competition and collaboration. Second, by exploring how age differences between colleagues shape interpersonal processes, our study addresses the urgency of the ongoing demographic change.

Symposium S068

Leadership and well-being in turbulent times

Judith Volmer & Philipp E. Otto | University of Bamberg, Germany

science_practice

What will be covered and why (including the contribution of any discussant)

Leadership is a highly complex task that has become even more demanding due to continuously changing work environments, digitization, and current crises (e.g. the COVID-19 pandemic). This symposium provides researchers and practitioners alike with knowledge on how to create and sustain leaders‘ and employees‘ well-being in these turbulent times. The first paper (Güntner et al.) focuses on a multisource, longitudinal field study with three measurement points on leaders‘ well-being, their encoding capabilities, and their consequences on employees‘ well-being. The second paper (Otto & Volmer) examines in a treatment and waiting group design with 34 leaders from diverse companies the effectiveness of virtual executive coaching on affective, strategic, and behavioral changes. Third, the paper by Sedefoglu and Ohly investigates in an experimental study whether feedback framed to come from an AI can increase a leader’s empathetic (virtual) communication in comparison with feedback from a human supervisor. Findings will add to the congress theme by focusing on the topic of human-computer interactions. The fourth paper constitutes a meta-analysis of the relationship between different leadership concepts and various operationalizations of employees‘ resilience, including studies of the last 20 years of research. Findings will shed light on how employees‘ resilience can be fostered.

Relevance of the Congress Theme

Coping with changes in the workplace, driving innovation, and understanding human-computer interaction is central to economic development. Several developmental goals are addressed in this symposium (e.g., “good health and well-being”, “decent work and economic growth”, and “leadership development”). Leaders shape the innovation of work and their own well-being and that of their followers can be considered a key driver to enable sustainable change. Central influences here need to be better understood and put into relation to each other.

Research/Practical Implications

The symposium investigates the question of how leaders can foster health at work from different angles with different methodological approaches. By combining the individual papers in the proposed symposium, the audience will better understand which cognitive, affective, and behavioral outcomes result from various leadership approaches. The symposium will also discuss critically how leadership research can be advanced theoretically and methodologically in the future. Practitioners will learn about best-practice strategies to create and maintain a healthy and sustainable workplace.

Overall conclusions

The proposed symposium provides insights into various opportunities to foster health at work in turbulent times. Leader well-being is as important as follower well-being, which are strongly interdependent. Ongoing turbulences provide novel opportunities for organizations to support leaders using (virtual) coaching and supporting tools. Besides the positive outcomes of leadership interventions, also potential drawbacks will be discussed. Positive as well as negative effects of changes in work need to be better understood together with success enabling moderators.

Keywords: digital leadership, well-being, human-computer interaction

Paper 1

Encoding the Room and Follower Needs: Understanding the Effects of Leader Well-Being on Follower Well-Being

Amelie V. Güntner & Martin Kleinmann | University of Zuerich, Switzerland; Pia V. Ingold, University of Copenhagen, Denmark

Research goals and why the work was worth doing

Organizations are challenged by continuously changing environments and vast technological advancements, knowledge, and globalization. Dealing with these challenges requires a productive yet healthy workforce, including leaders and followers alike. Although it is an increasingly prevalent assumption that leader well-being may positively affect their leadership skills and, in turn, follower well-being, to date, more empirical evidence supporting this view is required (Inceoglu et al., 2018). Specifically, extant literature primarily focused on leaders' behavioral skills while neglecting cognitive skills crucial for leaders' ability to accurately perceive situational demands in interactions with their followers, thereby allowing them to respond effectively to followers (Gottfredson & Reina, 2020).

Theoretical background

The present research links theoretical frameworks explaining well-being as a resource (e.g., conservation of resources theory; Hobfoll, 1989; broaden and build theory; Fredrickson, 2004) with theory on the relevance of individuals' situation construal (i.e, perception; Funder, 2016), to develop and test a serial mediation model of leader well-being. First, we propose that leaders with better well-being are a source of social support for followers, thereby directly benefiting follower well-being. Furthermore, leader well-being supposedly broadens their scope of attention and cognition, such as their situation construal accuracy. Situation construal accuracy can be defined as leaders' capability to encode (i.e, perceive) situational demands accurately to identify which leadership behavior is required from them in a given situation (Funder, 2016). In contrast, leaders with poor well-being may lack the resources to perceive situational demands accurately. Hence, we propose that better leader-well being increases leaders' situation construal accuracy. Thinking of situational demands in terms of the needs followers express to their leaders, research has acknowledged the critical role leaders play in followers' need fulfillment (e.g., Van Quaquebeke & Felps, 2018). Leaders with better well-being likely are better at accurately perceiving and responding to their followers' needs, which should result in higher need fulfillment as perceived by followers. That is, we expect leaders' situation construal accuracy to lead to an increase in followers' need fulfillment. Furthermore, given that the fulfillment of individuals' basic needs (i.e., need for autonomy, competence, and relatedness; Deci & Ryan, 2000) plays a key role in human functioning, including well-being (Patrick et al., 2007), we further assume that followers' need fulfillment increases their well-being.

Design/Methodology/Approach/Intervention

We tested our serial mediation model in a longitudinal field study with experienced leaders (N = 275) and their followers (N = 723). We asked leaders to report on their well-being (T1), and we asked their followers to rate their leader's situation construal accuracy (T1) and to report their need fulfillment (T2) and personal well-being (T3).

Results obtained

Results showed that, first, leader well-being was positively, but not significantly related to follower well-being. Second, we found that leader well-being was significantly positively related to their situation construal accuracy as perceived by their followers. Third, results revealed that leader situation construal accuracy was significantly positively related to followers' need fulfillment. Followers reported higher need fulfillment when they attributed their leaders the capability to perceive situational demands accurately. Fourth, followers' need fulfillment was significantly positively related to their self-reported well-being. Lastly, results supported the proposed indirect effect of leader well-being on follower well-being. Specifically, in line with our assumptions, results indicated that this indirect effect was serially mediated by leader situation construal accuracy and follower need fulfillment.

Limitations

Although our study results may be interpreted in a temporal direction due to the longitudinal design, no causal inferences can be drawn due to potential endogeneity threats. The longitudinal design is suitable to account for simultaneity or reverse causality, but omitted causes may still influence the study results.

Conclusions – research and or practical implications

The present study contributes to research on leadership and well-being by illuminating the underlying mechanisms through which leaders' well-being influences the well-being of their followers. Our findings point at leader well-being as a resource that increases leaders' situation construal accuracy, thereby highlighting the relevance of leaders' cognitive skills in explaining the positive effects of leadership. We hope that our findings on the indirect, positive effects of leaders' well-being on their followers will inspire future research in the important realm of leader well-being, both regarding its effects on others, but also regarding its antecedents.

Relevance to the Congress Theme: The Future is Now: the changing world of work

Our findings contribute to a better understanding of how leaders can use their resources to strengthen the well-being of their followers, thereby helping them navigate through the changing world of work.

Relevant UN SDGs

Our research contributes to the SDGs of the UN, specifically to the goal of focusing on "good health and well-being" by offering evidence-based recommendations for policy and practice on well-being.

Keywords: leader well-being, enoding, well-being

Paper 2

Leadership coaching effectiveness: Evaluating affective, strategic, and behavioral changes in SMEs

Philipp E. Otto & Volmer Judith | University of Bamberg, Germany

A rapidly changing world requires quick adaptation to secure sustainable development. Here especially new forms of leadership need to be developed to cope with the novel work requirements. Coaching is the standard form for fostering self-organized change. Bavarian SMEs are used as a case study to evaluate coaching effectiveness in relation to work satisfaction and other concepts covering affective, strategic, and behavioral components. Theoretical background

Diverse studies illustrate the effects coaching has and consider various variables. Coaching increases individually reported well-being (i.e., Kraiger et al. 1993, Jones et al. 2016), where also specific effects on workplace well-being or work satisfaction are reported (Grant et al., 2009, Burt & Talati, 2017, Athanasopoulou et al., 2018). Positive effects are also reported for attitudes, coping, skills, and performance (see Theeboom et al. 2014). These are to be confirmed for leaders in small and medium enterprises. Potential moderators for longer-term coaching effects on reported work satisfaction and performance are self-esteem (Rosenberg 1965), career engagement (Hirschi et al. 2014), career resources (Hirschi et al. 2019), self-efficacy (Rigotti et al. 2008), resilience (Soucek et al. 2015), psychological safety (Edmonson 1999), leader-member-exchange (Liden & Maslyn 1998), attitudes (Schaufeli et al. 2006), personality (Rammstedt & John 2005), and working alliance (Wilmer et al. 2008). Furthermore, a combined evaluation over time could help to find dependencies and to isolate critical influences.

Design/Methodology/Approach/Intervention

Scientific coaching is offered for SME in Bavaria as part of an applied research project. In total 34 participants take part (29.4% females, 64.7 with coaching experience, and an average age of 43 years) equally divided into a treatment and a waiting group. Coachings are implemented as virtual one-to-one sessions with 5 monthly repetitions. The coaching of the waiting group begins after the coaching of the treatment group to distinguish the coaching effects over time. Before the start of the first coaching, demographics, personality, affective, strategic, and behavioral scales are retrieved. Furthermore, presumably less stable components are retrieved monthly and more stable components every six months over the whole duration of the project (5/2022 till 11/2023). Further details concerning the various measures and their retrieval frequency are provided in study's pre-registration at https://osf.io/rbta7/ The completeness of the data concerning the repeatedly requested questionnaires is 99% (as of 10/2022).

Results obtained or expected (2/2023)

Upon completion, the coaching effectiveness for SME leaders is to be documented on various scales. The repeated measures allow to infer causal relationships between personality, strategic, affective, and behavioral factors. First results indicate that the subscale "focused realization" of resilience (Soucek et al. 2015) increases through coaching and influences the affective work evaluation (here especially the item "absorption" from the work engagement scale of Schaufeli et al.). Also working alliance (Wilmer et al. 2008) strengthens over the coaching sessions and might be an important differentiating factor for coaching success.

Limitations

Given the size and specificity of the sample, the generalizability of the results is limited. Dependencies and changes over time could only inform future studies, but might provide valuable insights concerning the measurement of coaching effectiveness.

Conclusions – research and or practical implications

A better understanding of how coaching is effective could inform theory and practice alike. Which factors are influencing coaching results in what way over time could be an important source of information to understand how coaching becomes effective. Possibly more important though is that it could help design scientifically grounded coaching leading to a higher acceptance of coaching practice over the long term.

Relevance to the Congress Theme: The Future is Now: the changing world of work

The project represents a research application for a more systematic understanding of behavioral change and possible coping strategies for future work requirements. In this regard it fosters the imminent change in one of the key innovative drivers of the society: leaders of SMEs.

Relevant UN SDGs

SMEs are driving innovation and are central for economic development. This includes general growth, poverty reduction, improved health, as well as general wellbeing. SMEs usually feel more responsible for their employees and as partners in the respective goal attainment. Further developing the resources and capabilities of SME leaders helps to secure sustainable growth in the future. This builds on scientific knowledge transfer to achieve higher level education.

Keywords: leadership coaching, evaluation, executives

Paper 3

Can AI make leaders more empathetic? An experimental investigation on leadership communication and the influence of AI

Didem Sedefoglu & Sandra Ohly | University of Kassel, Germany

Research goals and why the work was worth doing

In the contemporary business environment, a significant proportion of interactions between leaders and followers take place electronically. Communicating effectively in a virtual setting is particularly challenging for leaders because the physical distance from followers increases the difficulty of building relationships and trust (Marlow et al., 2017; Tuschner et al, 2022). Previous research suggests that leaders can create positive relationships with their followers using empathy – the ability to view things from another person's point of view and understand their feelings (Holt & Marques, 2012). With this study, we aim to examine whether feedback framed to come from an AI can increase leaders' empathetic (virtual) communication compared to feedback from a human expert.

Theoretical background

Empathetic communication is one of the central concepts of motivating language theory, which suggests that communicating support for followers' feelings has positive effects on followers (Mayfield & Mayfield, 2018). Prior studies have linked empathy with perceived communication competence (Redmond, 1985) LMX (Mahsud, Yukl & Prussia, 2009), and job satisfaction (Kock et al., 2019). Although, there is evidence empathy can generally be trained (Teding, Berkhout & Malauff) most studies that examine improvements in empathetic communication through AI focus on healthcare professionals and student samples (e.g. Wambsganss et al., 2021).

Early research on the use of algorithms in decision-making revealed that individuals often discount advice from algorithms across different scenarios, even with knowledge of their superior performance – a tendency called algorithm aversion (Mahmud et al., 2022). Despite the accumulating evidence in favor of the concept, recent research found that individuals may also react the opposite way – under some circumstances, they may rely more strongly on algorithmic than human instructions, which researchers refer to as algorithm appreciation (Logg et al., 2019). While it is known that algorithms can generally increase the efficiency of workflows by offering fast and standardized results (Dietvorst et al., 2015; Duggan et al., 2020) it remains ambiguous whether leaders will dismiss or accept input and feedback from an AI regarding their empathy. On these grounds, we explore the effects of AI-based feedback on supervisors' empathetic communication.

Design/Methodology/Approach/Intervention

To gain insights into the effectiveness of recommendations of an AI, we conducted an online experiment in which participants were randomly assigned to either feedback from a human or an AI. Participants were recruited via LoopsterPanel (German survey panel). In the experiment, the participants were introduced to a vignette that assigned them the role of a manager and described a fictional organizational situation, in which they got the task to write an e-mail to one of their subordinates. After finishing the task, all participants received the same feedback which advised them to be more empathic – in one condition, the feedback was framed to come from an AI and in the other from an expert. Subsequently, the participants got the opportunity to rewrite their emails.

Attention checks were included to ensure that participants read and understood their task. In the analysis, we will compare both conditions in terms of empathy improvement, including control variables such as demographics and prior use of AI.

Results obtained or expected (if not available, it must be made clear when they will be)

We expect that feedback from an AI will positively impact the use of empathy, but feedback from a human expert will be more effective. We collected data in January 2023 and will obtain the results until the conference.

Limitations

The external validity of our findings might be limited due to the experimental vignette approach of our study.

Conclusions – research and or practical implications

We contribute to research by showing whether AI can be useful to improve leadership communication in the workplace. The findings will provide important insights for leadership and communication management scholars, human resources practitioners, and organizational leaders. Further studies could focus on whether AI has indeed the potential of increasing the use of empathetic communication in the field, e.g. by introducing an intervention at a real organization.

Relevance to the Congress Theme

Our research adds to the congress theme by focusing on the topic of human-computer interactions and the use of technological advances to improve communications at work, which has and will increasingly become an integral part of workplaces of the future.

Relevant UN SDGs

Good Health and Wellbeing (SDG X).

Paper 4

Leadership and Resilience – First insights from a meta-analysis

Miriam Arnold, Leibniz Institute for Resilience Research Mainz, Germany; Hannah Schäfer, Johannes Gutenberg University Mainz, Germany; Eva-Maria Schulte, Technische Universität Braunschweig, Germany; Thomas Rigotti, Leibniz Institute for Resilience Research and Johannes Gutenberg University Mainz, Germany

Research goals and why the work was worth doing

Research on workplace resilience is an ever-growing literature. In reaction to stressors, organizations aim for a resilient workforce which can cope with changes in the work environment. One aspect in the work environment which can contribute to resilience is leadership.

Theoretical background

Despite the wealth of primary studies linking different leadership concepts with various operationalizations of employees' resilience, up to date, there is no systematic integration of the results. Existing meta-analytical or review papers in this stream of research either focus on one specific leadership style or only mention leadership as one of multiple resilience promoting factors.

This paucity concerning a systematic integration of empirical evidence is of concern because these scattered results make it difficult to infer which leadership styles are especially suited to foster workplace resilience. A thorough meta-analysis of this relationship allows relevant practical implications for organizations based on empirical evidence.

Design/Methodology/Approach/Intervention

In conducting the literature search, we follow the PRISMA protocol. After defining the search string, relevant databases, inclusion and exclusion criteria, two independent raters decide on the inclusion or exclusion of primary studies. In the further process, relationships between various leadership styles and behaviors and resilience will be analyzed. Currently, we prepare the preregistration of the meta-analysis.

Results obtained or expected (if not available, it must be made clear when they will be)

Results of the meta-analysis are not yet available since we only started with the selection process of primary studies. However, results of the meta-analytical search will be available at the EAWOP conference.

Limitations

We expect that a majority of relevant primary studies will be cross-sectional and conducted as self-report surveys. This poses the risk of common method bias inflating the studied relationship. Another critical aspect is the proliferation of both, the leadership and the resilience literature. In both fields, a multitude of different operationalizations and definitions exist, thus making it difficult to meaningfully merge them for the meta-analysis. This also leads to the limitation that the number of primary studies for specific leadership concepts or specific operationalizations of resilience might be very small, thus limiting the strength of empirical evidence for these aspects.

Conclusions – research and or practical implications

This project contributes to the literature by organizing the available literature on the relationship between leadership and resilience. The meta-analysis will cover approximately 20 years of research

on the relationship between leadership and resilience. It is a first attempt to systematically summarize empirical findings on resilience and leadership. There is a high demand for training and workshops, especially in leadership development. Therefore, the question of how leaders can support, and influence employees' resilience is of high practical relevance. The topic of resilience for personnel development has even gained increased attention during the pandemic and the dynamic changes this brought to the organization of work. To answer these practical questions with strong empirical evidence, the field is in urgent need of a meta-analysis on the relationship between leadership and resilience.

Relevance to the Congress Theme

Workplace resilience can be seen as an integral aspect of coping with changes in the workplace and beyond. Especially in crises such as the COVID-19 pandemic or the trouble of the power supply industry resilience becomes relevant. However, also coping with daily hassles at work requires resilient strategies.

Relevant UN SDGs

This study can be located at the intersection of sustainable development goal 3 ‘good health and well-being’ and goal 8 ‘decent work and economic growth’. We posit that the working environment, which is (amongst others) shaped by the leader is a relevant aspect pertaining to the health of employees.

Keywords: leadership, resilience, meta-analysis

Symposium S069

Sustainable careers across age, time, and life domains

Claire Leeming & Ieva Urbanaviciute | University of Lausanne

science

What will be covered and why. This symposium includes four presentations that address different elements of the sustainable career framework using various samples and methodological approaches. The first presentation adopts a meta-analytical approach to investigate the impact of key stakeholders in different life domains (private and work) on career sustainability in terms of health, happiness and productivity. Results show that supervisors, coworkers, and spouses (or cohabiting partners) influence the development of sustainable careers of focal individuals,thereby confirming the important role of significant others in enhancing one's capacity to sustain employment. The second presentation uses 7 years of longitudinal data and growth mixture modelling to investigate trajectories of within-person change of work-leisure goal interference and the subsequent impact on well-being, while also accounting for the impact of career adaptability. Results show clear trajectories of work-leisure goal interference, with those in the low interference group displaying higher well-being, with career adaptability acting as protective resource against high levels of interference. The third presentation adopts a more contextual approach and investigates the effect of short-time work compensation schemes on career sustainability through career insecurity. While the results for this presentation are not yet available, the authors expect to find that short-time work compensation schemes, in comparison to redundancy, are more favorable for career sustainability. The fourth presentation investigates future time perspective profiles of younger and older workers and their relation with goal orientation and training motivation, with continued learning being a key element in the maintenance of sustainable careers. Results show that different future time perspective profiles are identified in older and younger workers and that depending on the profile different relationships are found in goal orientations and training motivations, suggesting that future time perspective, in addition to age is an important consideration in the design of Human resource policies and practices. The combination of these four studies makes a holistic contribution to our understanding of what contributes to sustainable careers on an individual and contextual level, as well as across time. Our discussant will conclude the symposium by providing some summarizing insights across the presentations and offer some reflections on questions raised by the symposium and suggestions for further exploration. He will also respond to questions.

Relevance to the congress theme. The topic of sustainable careers is highly relevant for the congress theme of "The Future is Now: the changing world of work". The world of work has already changed due to influences linked to globalization, the climate crisis, the migration crisis, more flexible social and labor market structures, and technological evolution. The world of work will continue to change, becoming increasingly characterized by a de-standardization of career paths, more frequent career transitions, increased vulnerability for some groups, and the desire to have meaningful careers. In this perspective, the sustainable career framework offers a helpful paradigm for understanding how individuals maintain careers that are characterized by health, happiness, growth, and productivity while taking into account the impact of individual and contextual factors, as well as time and processes of dynamic adjustment.

Research / practical implications. On a theoretical level, all these presentations contribute to theory development of the sustainable career framework. Given the recency of the framework, our results help us to understand the factors that contribute to sustainable careers. The collection of presentations in this symposium also show how different methodological approaches can be used

while investigating sustainable careers. Our results have implications for individuals, career guidance counsellors and practitioners, as well as for organizations and HR policies and practices.

Overall conclusions. Overall, this symposium shows the importance of considering different life domains in combination with individual factors while adopting a temporal perspective to understand sustainable career development. We show the importance of key stakeholders in different contexts; the role of protective resources such as career adaptability; the necessity to consider the institutional context and HR policies, and the requirement to consider different factors for different age groups.

Paper 1

A Meta-analysis of Health, Happiness, and Productivity Crossover

Ngoc Nhu Y "Chloe" Nguyen, Vrije Universiteit Amsterdam; Cort. W. Rudolph, Saint Louis University; Svetlana. N. Khapova & Jos Akkermans | Vrije Universiteit Amsterdam

Research Gaps and Goals. Sustaining careers in which individuals are healthy, happy, and productive has become a salient concern for individuals and organizations in today's context of rapidly changing and unpredictable work environments. This has led to the scholarly emphasis on the preservation of career sustainability. Research in this regard has explored multiple individual and contextual factors that could contribute to establishing sustainable careers. However, the ongoing discussion has left out an important aspect - the influence of key people such as spouses, supervisors, and coworkers, who share a great part of their lives with the individuals. We argue that it is critical to consider stakeholders and their interpersonal effects because individuals' careers might be undermined when partners experience unfair treatment at work or adverse health symptoms. Therefore, the aim of this paper is to investigate the relations between stakeholders and individuals' health, happiness, and productivity.

Theoretical Background. The process that occurs when the experience of stress and strains of one person leads to stress and strains being experienced by another person is defined as crossover (Bolger et al., 1989). Scholars have discovered negative crossover (e.g., depression, job burnout, time theft) and positive crossover (e.g., work engagement, job crafting) between spouses, coworkers, and leaders and followers. These existing findings on crossover have led us to expect that stakeholders might exert their influence on individuals' health, happiness, and productivity via the crossover process. Therefore, in this paper, based on previous crossover findings, we examined the associations between a set of stakeholders' variables (i.e., personal resources, job demands, job resources, work-family conflict, family-work conflict, work-family enrichment, family stressors, marital satisfaction, spousal commitment to employee's organization, life satisfaction, career sustainability indicators) and individuals' health, happiness, and productivity.

Methods. Using a dataset of 96 published and unpublished primary studies, we performed zero-order correlation meta-analysis and meta-analytic path analysis to test the proposed hypotheses in R. The main analysis was followed by the test of publication bias using the triangulation method and moderator analysis, including subgroup analysis and meta-regression, to detect possible moderators (i.e., dyadic relationship, age, relationship length, and number of children).

Results. Stakeholders' personal resources, work-domain variables (i.e., job demands and resources), cross-domain variables (i.e., work-family and family-work conflict, work-family enrichment), family-domain variables (i.e., family stressors, marital satisfaction, spousal commitment to employee's organization), life satisfaction, occupational health, happiness, and productivity were related to the development of individuals' sustainable careers. Age and relationship length did not affect the intensity of the crossover process. The number of children weakly moderated crossover. Among different types of dyadic relationship, organization members (i.e., supervisors and coworkers) has a greater effect on the crossover of happiness than spouses.

Limitations. First, the small number of primary studies per relationship may make second-order sampling error a problem in our study. Second, our meta-regression analyses are likely to have low statistical power, undermining our ability to obtain accurate and significant findings. Third, our

study's generalizability might be negatively affected because of the large percentage of cross-sectional studies (i.e., 73%) in our dataset. As such, the causal conclusions in this paper should be carefully interpreted.

Conclusions. The most important finding of this meta-analysis lies in the dependence of individuals' health, happiness, and productivity on the presence of a sustainable climate in which supervisors, coworkers, and spouses (or cohabiting partners) of the focal individuals are flourishing instead of being dysfunctional, thereby confirming the important role of significant others in enhancing one's capacity to sustain employment. Evidence in this paper suggests that career sustainability management practices should be designed to include stakeholders for a successful delivery. This means organizations should look beyond the work context and take other domains such as family and various stakeholders into consideration.

Relevance to the Congress Theme. The fast-changing and unpredictable world of work threatens individuals' employability. Thus, to ensure continued employment, it is important to not only maintain a good level of health, happiness, and productivity but to sustain them over time. This makes the notion of sustainable careers more salient to individuals, organizations, and society as a whole. By studying career sustainability, we address the changing world of work and provide more insights into how to promote individuals' capacity to run long in their careers.

Relevant UN SDGs. Our study emphasizes the promotion of occupational health, happiness at work, and productivity, thereby contributing the UN Sustainable Development Goals of Good Health and Wellbeing.

Keywords: crossover, stakeholders, well-being

Paper 2

Trajectories of work-leisure goal interference and sustainable careers

Claire Leeming, Jérôme Rossier & Ieva Urbanaviciute | University of Lausanne

Research goals and why the work was worth doing. This research investigates the trajectories of within person change in work-leisure goal interference over time, adopting a sustainable careers perspective. In recent years, increasing attention has been given to the role of non-professional factors in career development. One approach, the sustainable career framework, suggests that individual, temporal, and contextual factors (e.g., influencing factors from other life domains) should be considered in the development and maintenance of sustainable careers, as evidenced by health, happiness, and productivity. Given the recency of this framework, there is a need for longitudinal research in this area. Similarly, to date, most research on work-life issues has adopted cross-sectional approaches or diary studies, and the longitudinal studies that do exist tend to have limited measurement points over a shorter time frame. In addition, work-life research has mostly focused on the family domain, to the exclusion of other domains, such as leisure.

Theoretical background. The sustainable career framework is focused on the individual, who is considered as the central, career-oriented stakeholder. However, it adopts a systemic and dynamic approach to explain the multiple factors (context and stakeholders) and changes over time which can influence the sustainable aspect of the career. The framework suggests that on a context level, one needs to consider the impact that other life domains may have on sustainable career development. In this study, we consider how trajectories of work-leisure goal interference relate to indicators of sustainable careers. The sustainable career framework also highlights the importance of individual proactivity and ability, and to this end we also investigated the role of career adaptability in the experience of work-leisure goal interference. Taken together, we sought to answer the following research questions, 1) can we observe distinct trajectories of within-person change in work-leisure goal interference? 2) what impact does career adaptability have on these trajectories? and 3) are trajectories of work-leisure goal interference related to indicators of sustainable careers, notably in terms of well-being?

Method . To address our research questions, we used 7 years of longitudinal data from the “Career Paths” panel survey based on seven yearly measurement points. The survey was carried out within the framework of the Swiss National Centre of Competence in Research—Overcoming Vulnerabilities: Life Course Perspectives (LIVES) and includes a large sample of professionally active adults that is representative of the German- and French-speaking population in Switzerland. Our analytic sample consisted of 1225 participants (50.2% women, mean age at T1 = 42.41, SD = 8.43). Growth mixture modelling was used to analyze the data.

Results . Our findings revealed the following trajectories characterizing within-person change in work-leisure goal interference over time: “stable high interference” (58.8% of the sample), “stable low interference” (22.6%), “gradually increasing interference” (9.4%), “gradually decreasing interference” (9.2%). Those with higher career adaptability resources were less likely to experience a persistently high work-leisure goal interference. Furthermore, outcome analyses showed that workers with persistently low or decreasing work-leisure goal interference reported the highest well-being at the end of the study. Notably, most outcome indicators (except life satisfaction) also showed some temporal dynamics (i.e., T1-T7),with the most marked decrease in job satisfaction and an increase in life stress among workers experiencing an increasing trajectory of goal interference.

Limitations . Our analyses are specifically focused on work-leisure goal interference and do not cover other work-life goal aspects.

Conclusion . Trajectories of stable low and decreasing work-leisure goal interference were the most favourable in terms of employee well-being and sustainable career development. Career adaptability seems to be an important resource for balancing work and non-work goals.

Relevance . The changing world of work takes a toll on the work-life interface, posing numerous risks for employee well-being and career sustainability. Adopting a novel methodological approach, our findings show the potential long-term implications of goal support vs. interference on selected outcomes, which highlights the current study's relevance to the congress theme and UN SDG 3 (Good health and well-being)

Keywords: work-life interference, sustainable careers, well-being

Paper 3

The Effects of Short-Time Work on Career Sustainability: The Lesser Evil Option?

Charlotte Rodriguez Conde, KU Leuven and UC Louvain; Hans De Witte, KU Leuven ; Florence Stinglhamber, UC Louvain; Nele De Cuyper, KU Leuven

Research goals and why the work was worth doing . Short-Time Work (STW) compensation schemes ("temporary unemployment" in Belgium, or "furlough" in the UK) are public programs that allow companies facing a temporary reduction in demand to suspend the execution of employment contracts while providing employees with unemployment benefits (EC, 2020). During the COVID-19 pandemic, European employers made unprecedented use of STW. Such job-retention policies remain topical in the current economic climate: one may expect a severe recession in Europe due to the energy crisis and hence a renewed increase in the use of STW. Surprisingly, scholars have paid limited attention to the impact of STW on careers so far (Stuart et al., 2021; Zheng et al., 2022). Yet, there is a need to examine how this alternative to redundancy relates to career development in the longer run: both redundancy and STW are disruptive events for employees but redundancy is perhaps even more so. Filling this gap, this study (1) investigates how STW compared with no change in employment conditions potentially undermines career sustainability after more than one year, (2) via perceptions of career insecurity. To examine to what extent STW represents a lesser evil option, (3) the effects of STW on career insecurity and career sustainability are compared with the effects of a job loss.

Theoretical background. Sustainable careers refer to sequences of work experiences that are characterized by continuity over time in terms of health, satisfaction, and productivity (De Vos et al., 2020). Based on the Conservation of Resources theory (Hobfoll, 1989), we hypothesize that STW and redundancy (vs no change in employment conditions) are negatively associated with three types of indicators characterizing career sustainability: well-being, career satisfaction, and work engagement. Our argument is that sustainability and continuity require the constant generation and preservation of resources (Pak et al., 2020), whereas STW and redundancy rather signal a threat to resources.

More concretely, we expect these relationships to be mediated by career insecurity and four of its dimensions: worries about career opportunities, unemployment, undesired transitions, and work-nonwork interactions (Spurk et al., 2022). Indeed, by highlighting uncertainty in the job market and the resulting scarcity of resources, STW and redundancy reveal the likelihood that one's career might develop in an unwanted manner (Spurk & Straube, 2020). In addition,these experiences are likely to challenge the role played by work as a meaning framework and cause a shift in life priorities (e.g. Mandeville et al., 2019), which may emphasize concerns regarding the way work interacts with other life domains. Career insecurity and the related feelings of lack of control over resources may, in turn, negatively affect well-being, career satisfaction, and work engagement (Spurk et al., 2022).

Consistently with the view that STW is a lesser evil option, we finally assume that STW is associated with lower levels of career insecurity, leading to higher levels of well-being, career satisfaction, and work engagement, in comparison with redundancy. As a matter of fact, STW implicitly means that one represents a valuable asset, less likely to be affected by the unfavorable job market than dismissed workers.

Design and Methodology. We will test our hypotheses using a cross-sectional design and SEM. The sample (N=600) will consist of three groups of workers with different employment statuses during

the pandemic: STW, redundancy, no change in employment conditions. Data will be collected on Prolific.

Results Expected. Data collection will start in November—after the approval of the Ethical Committee.

Limitations. This research counts three main limitations, which will be partly addressed in a follow-up study involving new data collection. First , cross-sectional associations based on data collected after the shock provide limited evidence for causal inference. Second, the sample might include workers exposed to different implementations of STW, affecting career sustainability in a way that is difficult to assess. Third, our model tends to disregard individuals' adaptability, by focusing on losses of resources exclusively.

Implications. While job-retention policies tend to be seen as a lesser evil in the face of adversity, this research explores for the first time to what extent they make employees less vulnerable in the job market than redundancy. In that respect, it contributes to the existing literature on career sustainability by showing a concrete example of the influence of the institutional context on career development.

Relevance to the Congress Theme. In a European society threatened by repetitive economic recessions, this study on a job-retention policy fuels the Market-led VS State-led restructuring debate and paves the way for further reflections on how to better preserve career sustainability.

Paper 4

Career Sustainability of Young and Older Workers: Future Time Perspective Profiles and their Relationship with Goal Orientation and Training Motivatio

Isabel Raemdonck, UCLouvain (BE); Ruth Kanfer, Georgia Tech – School of Psychology; Michaël Parmentier, UCLouvain (BE)

Research gaps and goals. The current changes in retirement policies that raise the legal retirement age to 65 (OECD, 2019) imply a need for the promotion of sustainable careers that enable workers to extend their working lives through actions that take a developmental approach (van der Heijden et al., 2020). This is valid for the careers of both young as well as older workers. A sustainable career is only possible if workers themselves have the tendency to think in terms of the future (the psychological time). When their future time is perceived as open, workers see many opportunities in front of them. Different researchers (see review Henry et al., 2017; Kooij et al., 2018) showed that Future Time Perspective (FTP) is more limited in older workers compared to younger workers as older workers become increasingly aware that their time is running out. Other researchers such as Carstensen and Lang (1996) demonstrated that an open FTP is associated with the pursuit of goals related to growth and development. Pursuing goals related to knowledge acquisition and training motivation are both key factors in developing a sustainable career. It is therefore important to explore the relation between FTP, goal orientation and training motivation in both young and older workers. Our main objective is to examine if different profiles of FTP exist in young and older workers and if there are differences in goal orientation and training motivation depending on the FTP profile.

Research questions:

Do distinct profiles of FTP emerge in the data among young and older workers?

To what extent do young and older workers display similar profiles?

What are the differences across profiles in terms of goal orientation and in training motivation?

Theoretical background. Profiles of Future time perspective: In the literature, two conceptualizations of FTP exist (Betts, 2013). The concept is analyzed on the life level, which is called 'General Future Time Perspective' (GFTP, Carstensen & Lang, 1996), and on the work level, which is named 'Occupational Future Time Perspective' (OFTP, Zacher & Frese, 2009). Older workers, for example, might see OFTP as limited but still have an open GFTP because many opportunities still await once they will retire. Other older workers might perceive both OFTP and GFTP as limited. Different goal orientations (GO) are distinguished: performance approach, performance avoidance, learning approach, and learning avoidance approach. Training motivation is operationalized as training intention and perceived utility for a leadership training and software training. Based on de Lange et al. (2010) and Kooij and Zacher (2016), we expect different relationships with GO and training motivation depending on the FTP profile. Especially, cumulating both high OFTP and high GFTP should be associated with the highest levels on learning GO and training motivation.

Method. A sample of 630 workers, of which 363 young workers (< 35 years old) and 267 older workers (>50 years old), completed a self-report online questionnaire including demographics, GFTP (Carstensen & Lang, 1996), OFTP (Zacher & Frese, 2009), goal orientation (Janssen & Van Yperen, 2004) and training motivation. Group-specific latent profile analyses were performed among young

and older workers separately. Differences in goal orientations and in training motivation between profiles were then examined using the BCH option in M plus.

Results. A 3-profile solution was identified in the junior sample, and a 5-profile solution in the senior sample. Among young workers, overall differences in goal orientations between juniors' profiles were found for learning approach and learning avoidance. Differences were also found for intentions to participate in leadership training and for perceived utility of leadership and of software training. Among older workers, significant differences between profiles were only found for learning approach, with the profile cumulating both GFTP and OFTP exhibiting the highest scores. However, more significant differences were systematically found for training intentions and perceived utility, as profiles exhibiting high GFTP or high OFTP (or both) reported higher intentions and perceived utility compared to profiles with lower GFTP and OFTP scores.

Conclusion. Based on the FTP profiles, we conclude that older workers are a heterogeneous group. We should therefore adopt HR measures for sustainable careers to the FTP profile one belongs.

Limitations. Replications with adequate power and within-person longitudinal studies are necessary.

Relevance to congress theme. In the changing world of work sustainable careers become increasingly important for all ages.

Relevant UN SDG. goal 8 promote sustainable work for all

Keywords: Future time perspective profiles, goal orientation, training motivation

Symposium S070

Working time organisation for a sustainable working life

Anne Marit Wöhrmann, Federal Institute for Occupational Safety and Health (BAuA), Dortmund, Germany; Leuphana University of Lüneburg, Germany

science

What will be covered and why

Working time organisation determines employees' time for recovery and private life. These in turn are crucial aspects for employees' work ability and work motivation and, thus, for a sustainable working life. Keeping employees in the workforce healthy and motivated becomes increasingly important in times of demographic change as well as current and future crises. In this symposium, empirical findings on how working time should be organized to enable sustainable working lives are presented.

The first presentation takes on a systems perspective on working time organisation in the context of shift work and recovery in the health care sector. A series of studies including semi-structured interviews, actigraph measurements, and a recovery intervention give insights into how multiple levels within an organisation need to be involved to create sustainable working times. The following three presentations address the role of different aspects of working time organisation for employees' exhaustion taking on different methodological approaches. The second presentation of the symposium gives insights into an intervention study conducted in seven organisations. In this study, employees' availability for work outside regular working hours was redesigned to reduce their exhaustion. The following presentations deal with working time organisation during the work day. Findings from an employee survey, that is representative of the German workforce, reveal the extent of work break violations in terms of skipping and shortening of breaks as well as their relation with employees' exhaustion. Afterwards, findings from a five wave longitudinal study shed light on idle time at work, defined as a period during which employees cannot work on their core tasks for reasons beyond their control. The authors investigate effects of idle time on employees' exhaustion and engagement considering other working conditions. In the final presentation of the symposium, a study based on nearly 8000 older employees is presented in which the role of different aspects of working time organization for the relationships between work demands and older employees' expected ability and motivation to work until regular retirement age is explored.

Relevance to the Congress Theme

Investigating the role of working time organization for sustainable working lives is at the core of the congress theme "The future is now: The changing world of work". The current times create an increasing need to keep employees healthy and motivated in the workforce. Every employee is affected by their working time organization which is therefore key to address. Also, working time organization and with it recovery opportunities are affected by changes in technology and altered needs in times of different crises. Thus, there is an urgency to ensure occupational safety and health with regard to working time to ensure sustainable working lives. Findings presented in the symposium can contribute to this, amongst others, by demonstrating possibilities for interventions on different levels. In terms of delivery, it will be important to communicate the findings in political contexts as well as to make them accessible for practice.

Research/Practical Implications

The research presented in this symposium gives insights into the impact of working time organization for sustainable working lives, more specifically, on employees' recovery, exhaustion, and motivation. Thus, amongst others the findings extent research on work design and recovery. For practice, in the symposium different possibilities for a sustainable working time organization addressing different levels are demonstrated. They range from individual level recovery interventions to recommendations for shift scheduling on an organizational level as well as regulatory needs with regard to extended availability and work breaks. The findings also point out the need for employers to be mindful of contextual working conditions when organizing their employees' working time.

Overall conclusions

The findings presented in the symposium underline the important role of working time organisation with respect to employees' recovery, exhaustion, as well as motivation, and thus, sustainable working lives. Amongst others, recommendations with regard to shift scheduling, extended availability, and work breaks can be drawn from the studies presented. As the world of work is changing, it is important to continue to monitor trends with regard to working time organization and to be prepared to tackle arising challenges with interventions on individual, organisational, and societal levels.

Keywords: working time, sustainable working life, mixed-method

Paper 1

Work hours and recovery – a systems perspective on future challenges and solutions for a sustainable working life

Anna Dahlgren, Department of Clinical Neuroscience, Karolinska Institutet, Solna, Sweden

Aim

This research aims to understand I) which factors in the health care system promote or hindered sustainable work hours and recovery, both before and during the Covid-19 pandemic; II) the effects of interventions supporting recovery; and III) how different shifts arrangements affect recovery, cognition and health.

Theoretical Background

Work stress or demanding work hours do not need to have a negative impact on health and well-being if the employee achieves recovery (Geurts and Sonnentag, 2006). Recovery can take the form of either sleep or recovery behaviors that enable psychophysiological deactivation. Shift work is often associated with impaired recovery due to interference with circadian rhythms and homeostatic processes for sleep. Fatigue and sleep deprivation have been linked to several negative outcomes such as poor health, reduced cognitive executive function, impaired emotion regulation and increased risk of accidents. Thus, the organization of work hours and promotion of recovery during and between shifts are of importance for production as well as employee well-being and safety.

Design and methods

The studies adopted a mixed methods approach. Semi-structured interviews with HR-representatives, ward managers, scheduling assistants and employees were conducted and subjected to a thematic analysis. To examine the effects of different shifts, participants were followed with diaries and actigraphs for one week and analyzed using ANOVA. An intervention involving a group-administered recovery program supporting recovery in relation to shift work and work-related stress was evaluated in a RCT (99 participants in the intervention group, 108 participants in the control group). Measurements were obtained using questionnaires, diaries and actigraphs before the intervention, and one and six months afterwards. Participants were either recruited via the introduction programs for newly graduated nurses or via HR-departments. Data were analyzed with longitudinal analysis of mean response profiles, using the mixed model procedure.

Results

Interviews revealed several factors for achieving sustainable work hours within the context of participatory scheduling. Amongst others, it was observed how ward managers and scheduling assistants sought to ensure sustainable working hours by weighing the balance between production and staffing needs, individual preferences, and protection of health and safety. Interviews also highlighted how HR representatives managed the interplay between work hours, staffing and recovery during the pandemic. During this time, high demands for patient care were met by the frequent scheduling of overtime work double shifts and irregular shift patterns, as well as interrupted vacations. This resulted in nurses experiencing insufficient recovery.

Analysis of actigraphy data showed that quick returns (QR; < 11h between shifts), had an especially negative impact on recovery, with participants losing an average of 1h sleep per QR. Moreover, they reported more fatigue and increased risk of making mistakes. However, QRs also facilitated taking reports from patients and planning work, as these tasks were more often rated as 'very easy' following a QR compared to other shift combinations. Thus, QRs seem to benefit continuity in work processes, but may do so at the expense of recovery and safety.

The results from the intervention study, supporting newly graduated nurses' strategies for recovery in relation to work related stress and irregular working hours, showed that participants used the strategies in the recovery program. Moreover, there was a preventive effect on somatic symptoms for the intervention group as well as less burn-out and fatigue symptoms, increased sleep quality and less thoughts about work during free time.

Limitations

The presented studies have all been conducted in Sweden and may not be generalizable to other national contexts.

Conclusions

Improvements to the scheduling process should involve managers, scheduling assistants and employees, while simultaneously organizations should work towards sufficient staffing. Quick returns should be minimized. Future work scheduling interventions should consider contextual factors and work processes. As well as improving work schedules, organizations can support individual employees through interventions that support their strategies for recovery in relation to irregular work hours and work-related stress. In sum, sustainable work hours and recovery needs to be addressed at multiple levels within the organization.

Relevance to the Congress Theme

This research I relevant to the congress theme "the future is now" as it contributes to knowledge about future challenges and directions for interventions supporting sustainable work hours and recovery in health care. This is of importance as health care faces several challenges due to demographic changes, lack of nurses and high turnover of staff.

Relevant UN SDGs:

Our findings suggest that a systems view is needed to create a sustainable work environment in the health care setting. This could help fulfill the SDGs good health and wellbeing and decent work and economic growth.

Keywords: work hours, recovery, interventions

Paper 2

Redesigning extended availability – An intervention study

Jan Dettmers, FernUniversität in Hagen, Germany

Background

Studies that investigated the effects of availability for work (extended availability) outside regular working hours found that extended availability is associated with impaired well-being. However, the identified mean effects are rather small and longitudinal studies that distinguished between within- and between-person effects find considerable between-person variance in the effects. Based on these results, a variety of boundary conditions and specific characteristics of availability have been identified that may increase or decrease the detrimental effect. Building on these results we developed an intervention to systematically redesign extended availability demands in order to reduce the negative effects of availability while simultaneously preserving its potential positive flexibility gains for the employees.

Intervention

The starting point of the intervention was a survey to systematically analyze the demands for extended availability and the design characteristics of the experienced extended availability that moderate its effects on well-being. After the survey a workshop was conducted to feedback the survey results to the participants, to inform about the optimal design of availability and to compare this with the specific design of the currently realized availability. After that, participants were asked to propose redesign measure to improve the current design of availability, i.e. reducing the expectations of supervisors, customers or co-workers or to optimize the boundary conditions, i.e. increase the own control on calls or to optimize flexibility gains for the workers. Finally, an implementation plan for employees, supervisors and management was adopted to realize the proposed redesign measures.

Method

To evaluate this intervention, we conducted a study within 7 organizations. 181 employees participated in a pre-post longitudinal study. We measured exhaustion, availability demands. and the design characteristics predictability of calls, control of calls, availability regulation, technical equipment adequacy, flexibility gains, and legitimacy of availability before and six months after the design workshop. We conducted repeated measurements ANOVA with workshop participation and time independent variables and exhaustion and the availability characteristics as outcomes. Furthermore, we used path analyzes to analyze parallel changes of availability characteristics and exhaustion.

Results

The ANOVA results revealed that the participation at the design workshop was associated with changed in the design of extended availability. Workshop participation was associated with a decrease of availability expectations and reported calls to work outside regular working hours. Furthermore, workshop participation was associated with and increase in flexibility gains and the perceived legitimacy of extended availability. Independently, of the workshop participation we found that changes in the availability design characteristics between t1 and t2 were associated with changes in exhaustion.

Limitation

The intervention aimed at finding and implementing structural changes in the design of extended availability rather than individual strategies to cope with availability. Therefore, the intervention effects should not only have affected the workshop participants. Due to organization constraints it was not possible to clearly distinguish survey participants that were affected by changes and those that were not affected. In the current study we only use the workshop participation as the separator between intervention and control group which is not optimal top analyze the effect of the intervention. Furthermore, the results could have been affected by a significant number of dropouts between t1 and t2. Finally, the reported relationship between intervention, design criteria and outcomes are mainly correlation of parallel changes. Therefore, we have to be careful to draw on causal relationships.

Discussion

The results support assumption of prior studies that characteristics of extended availability may vary and the characteristics may moderate to the effects of extended availability on impaired well-being. Other that prior cross-sectional studies this study demonstrated in a longitudinal design, that changes in characteristics of extended availability may be associated with changes in impaired well-being. Furthermore, this study demonstrated that the design of the extended availability on a specific work place can be changed my systematic intervention to optimize the design of extended availability. For workplaces that highly rely on employee flexibility and availability also outside regular working hours, organization should systematically analyze the specific design of the extended availability and find derive measures to optimize the availability design in a way that is non-detrimental.

Relevance to the Congress Theme

Our research topic is especially relevant to the congress theme “the future is now”, because we have to expect a further development of information and communication tools and increasing demands for flexibilization. In this new and future works of work, we have to find design solutions for healthy workplaces.

Relevant UN SDGs

Our findings could help fulfill the SDGs good health, wellbeing and decent work in an increasingly flexible world of work.

Keywords: availability, intervention, flexibility

Paper 3

Work break violations and employees' exhaustion

Laura Vieten, Anne Marit Wöhrmann, Alexandra Michel & Johannes Wendsche | Federal Institute for Occupational Safety and Health (BAuA), Dresden, Germany

Research goals and why the work was worth doing

Work breaks are an important opportunity for at-work recovery. Previous studies have found that work breaks are related to reduced fatigue and improved health. However, many studies focused on specific occupational groups. Thus, there is little knowledge about the prevalence and health effects of work breaks across occupational groups, which would be needed to identify implementation gaps and to better understand work breaks' potential for health protection in general. Furthermore, many previous studies examined different work break characteristics (e.g., frequent break skipping and work break duration) in isolation, although they may be correlated. Hence, the single and combined relations between different work break characteristics and employee health are still masked. Therefore, this study contributes to literature by using data from a nationally representative study of the German working population and examining three organizational work break characteristics, namely skipping work breaks, interruption of work breaks, and duration of the meal break. This study aims, first, to investigate the distribution of these work break characteristics among German employees in general and different employee groups, and, second, to examine their relationships to employees' exhaustion.

Theoretical background

According to the effort-recovery model (Meijman & Mulder, 1998), fulfilling work tasks requires effort and hence causes load reactions such as fatigue or an accelerated heart rate. Recovery is needed to mitigate these load reactions and prevent their accumulation, which could result to chronic reactions such as prolonged fatigue or exhaustion in the long term. Since work breaks are an important recovery opportunity, we hypothesize a positive relationship between frequent skipping and frequent interruption of work breaks and employees' exhaustion as well as a negative relationship between the duration of employees' meal breaks and their exhaustion.

Methodology

Data from the BAuA-Working Time Survey 2017, a nationally representative study of the German workforce were used. We restricted the sample to full-time dependent employees aged 18 to 65 years, resulting in a final sample of 5979 participants (63% male, average age: 48.34 years). The distribution of the three work break characteristics was examined calculating percentage shares, mean values, and standard deviations. To test the relationships between work break characteristics and employees' exhaustion logistic regression analyses were used. We used three exhaustion complaints as dependent variables: (1) general tiredness, faintness, or fatigue, (2) physical exhaustion, and (3) emotional exhaustion.

Results

We found that 29% of the employees reported frequent skipping of their work breaks, and 16% reported frequent interruptions. Meal breaks lasted about 35 minutes on average. There were significant positive relationships between frequent skipping of work breaks and all three exhaustion

complaints and between frequent interruptions of work breaks also. The duration of the meal break had a significant negative relationship with physical exhaustion.

Limitations

Limitations are, for example, a limited generalizability to other countries due to the German sample or the fact that no further work break characteristics, such as activities during work breaks or recovery experiences, were examined. Besides, there are some methodological limitations due to the cross-sectional and self-reported nature of the data.

Conclusions

Although German legislation mandate work breaks, our data indicate that many employees frequently skip their breaks and experience break interruptions. In line with previous research and the assumptions of the effort-recovery-model, we found that the three examined work break characteristics, especially skipped and interrupted work breaks relate to employees' exhaustion. Thus, employers and employees should try to avoid skipping and interruptions of work breaks.

Relevance to the Congress Theme

This study's topic is relevant to the congress theme "The Future is Now: the changing world of work", since against the background of an increasingly flexible world of work and increasing performance and time pressure, employees' recovery and thus also the organization of their work breaks plays a vital role.

Relevant UN SDGs

Our study reveals that work break organization relates to employees' exhaustion and thus health. Hence, study results might help to fulfill the UN SDGs of good health and well-being (goal 3) and of decent work (goal 8).

Keywords: occupational health, recovery, rest breaks

Paper 4

Idle time – demand or resource?

Martin Zeschke & Hannes Zacher | Wilhelm Wundt Institute of Psychology, Leipzig University, Germany; Laura Venz, Leuphana University Lüneburg, Germany

Research goals and why the work was worth doing

Idle time at work is a period during which employees cannot work on their core tasks for reasons beyond their control. For example, they have no costumers, are finished with their work but cannot clock out, or have to wait for feedback from others. Idle time is a frequent experience at work and was shown to have detrimental effects on employees.

We argue that idle time is a complex situation that unfolds different (negative but also positive) consequences, depending on the individual work circumstances. For example, job demands and job autonomy (as a job resource) may influence how employees experience idle time. Moreover, the effects of idle time may differ when working from home or not, which has become an increasingly important work circumstance in recent years.

The goal of this study is two-fold. First, we aim at identifying general effects of idle time on employees over time, considering exhaustion and engagement as negative and positive outcomes. Second, we want to identify under what circumstances (moderators), when (within-person level), and for whom (between-person level) the different effects of idle time show.

Theoretical background

We use the job demands resources model to research whether idle time is more of a demand, a resource, or both by studying exhaustion and engagement as outcomes. Additionally, we test moderators in these relationships, namely job resources (autonomy), job demands, and remote work, to understand under which circumstances idle time might function as a resource rather than a demand.

Methodology

We conducted a 5-wave longitudinal study over the course of one year (October 2020 – October 2021) with over 1,000 employees at T1. Participants were at least 18 years old and worked 20h/week or more. We conducted a hierarchical mixed model multiple linear regression to analyze the data.

Results

We found that idle time was common for employees and that it had negative effects on them: It was associated with higher emotional exhaustion and lower emotional engagement. We found a crossover interaction effect of work demands on the relationship between idle time and emotional engagement, such that the negative relationship was stronger when demands were low and turned positive when demands were high (between level). Autonomy unexpectedly strengthened the negative relationship between idle time and emotional engagement, such that the relationship was stronger when autonomy was high and weaker when autonomy was low (within and between level). We found no moderating effects of remote work (both with a binary predictor (no vs. yes) or with days/week) and no moderating effects on exhaustion.

Limitations

We used self-reports relating to periods of three months which may lead to common-source and hind-sight bias. We did not focus on the antecedents of idle time, which makes it difficult to prevent idle time from occurring. We did not assess whether employees worked from home voluntarily, which may influence whether the effects of remote work are beneficial or not.

Conclusions – research and or practical implications

Our research shows that idle time has uniformly detrimental effects for employees, clearly placing it as a job demand that should be prevented. The negative effects of idle time may be buffered by demands and strengthened by autonomy, which has implications for work design. We found no effects of remote work on the relationship between idle time and the outcomes, which could be further investigated in future studies, for example on a daily level.

Relevance to the congress theme

This research contributes to answering the question how we want to work in the future with focus on individuals and their work day. In an increasingly flexible working world, it is important to know how idle time affects employees and companies in order to prevent negative effects.

Relevant UN SDGs

This research contributes to UN SDGs “good health and well-being” and “decent work and economic growth”. Because idle time was shown to have detrimental effects for employee engagement and well-being, idle time is detrimental to said goals. People are active beings who want to engage with their environment and actively contribute to society. During idle time, this is not possible for many. Simultaneously, idle time is not only an individual problem. Companies lose money when paying employees to be idle and should help employees to prevent it or to make use of it. It may be time to take a proactive approach to managing idle time: allowing employees to engage in activities other than their actual job duties or to take time off work.

Keywords: idle time, demands, resources

Paper 5

The role of working time conditions for the relationship between job demands and retirement

Anne Marit Wöhrmann, Alexandra Michel & Julia Fähnrich | Federal Institute for Occupational Safety and Health (BAuA), Dortmund, Germany

Research goals and why the work was worth doing

Early retirement can have numerous disadvantages for employees, organizations and society. Creating suitable working conditions to maintain employees' willing-ness and ability to work until regular retirement age thus appears increasingly im-portant.

Working conditions should not be too demanding, as previous research has shown, that high job demands might contribute to early retirement. However, certain job demands – for example physical demands as heavy lifting and carrying, or psy-chological demands as high work intensity – may be inherent to a job due to its characteristics and the job tasks that need to be accomplished. This is why they cannot be easily adapted to employees' needs.

In this case, organizational framework conditions under which the work is con-ducted may be especially important. A central framework condition is the working time regime as it determines how long and at which times employees are exposed to possibly adverse working conditions. Hence, the goal of this study was to shed light on how physical job demands and psychological job demands are related to the an-ticipation of being able to retire at regular retirement age and the willingness to do so. Primarily, we were interested in how this relationship differs under different working time conditions.

Theoretical background

According to conservation of resources theory (COR theory; Hobfoll, 1989) employees loose resources when coping with high physical and psychological job demands. This resource loss intensifies, when they are simultaneously confronted with working time demands. For that reason, we assume that these job demands are negatively related to the anticipation of being able to retire at regular retirement age (vs. early retirement) and the willingness to do so. Furthermore, we hypothesize that demanding working time conditions – more specifically, excessive working hours, frequent changes in working hours and night shift work – as a moderator strengthen this negative relationship. According to COR theory, providing resources might compensate for resource losses. This is why we expect that designing resource-friendly working time conditions, more specifically work time control, might buffer the assumed negative relationships.

Design/Methodology

We used data from the BAuA Working Time Survey 2015 – a representative employee survey. The sample included 7859 German employees aged 50 to 65 years. Around 61 % of these employees anticipated that they were not willing and 69 % anticipated that they were not able to work until regular retirement age. We conducted hierarchical logistic regression analyses to examine main and interaction effects of job demands and working time characteristics. For this purpose, we computed one model each for the willingness and for the ability to remain employed until regular retirement age.

Results

Physical job demands were related to the anticipated ability, but not to the willingness, to remain employed until regular retirement age. Work intensity was negatively related to both dependent variables. Night shift work strengthened the negative relationship between physical job demands and both dependent variables, and frequent changes in working hours strengthened the negative relationship between work intensity and the anticipated ability to work until regular retirement age. The remaining moderation effects were non-significant.

Conclusions for research

We identified risk factors for early retirement that might arise from an unfavorable combination of job demands and working time conditions. From our results, it can be concluded that physical job demands and work intensity increase the risk of early retirement, especially when they occur in combination with night shift work or frequent changes in working hours. Contrary to expectations, work time control did not have a buffering effect.

Relevance to the Congress Theme

Our research topic is especially relevant to the congress theme “the future is now”, because due to demographic change the proportion of older employees is expected to grow enormously in the following years. An early exit from the work force might thus have severe consequences, for instance the overburdening of welfare systems, loss of know-how in companies or old age poverty. This is why there is a need for action to prevent early retirement by designing working (time) conditions that better meet the aging employees’ needs. Our research contributes to the understanding of how the choice of suitable work design measures can help keep older employees in the workforce.

Relevant UN SDGs

Our findings suggest that early retirement could be avoided by providing adequate working conditions. This could help fulfill the SDGs no poverty , reduced inequalities , good health and wellbeing and decent work and economic growth .

Keywords: working time, retirement, job demands

Symposium S071

Team features and processes supporting innovation

Nicola Cangialosi, Università degli Studi di Firenze

science

What will be covered and why

Most of the research on workplace innovation has traditionally focused on personal aspects, uncovering several individual-level antecedents and inhibitors. Nevertheless, much of innovative ideas at work are carried out by teams, and teamwork, in general, has been a growing feature of present organizations (Bell et al., 2018). Modern organizations increasingly rely on their teams to increase their levels of innovation by entrusting them with the resolution of difficult problems or the development of new procedures and products. Hence, understanding what factors affect innovation in teams is very important for organizational and managerial research and practice. For this reason, researchers are bringing increasing attention to team characteristics and processes that lead to innovation. The goal of this scientific symposium is to showcase cutting-edge team research on innovation.

This symposium consists of four distinct empirical studies that examine the new topics within the team realm and extend our understanding of the antecedents of innovation.

The first study "Uncovering the potential of team faultlines to boost team innovation: Relationship between team faultline strength, team innovation and social learning" examines the relationship between team faultline strength and team innovation, and the mediating role of social learning in such a relationship.

The second study "Voice climate, perceived team support, individual voice, and innovation: a cross-level study" examines the role of voice climate, perceived team support, Individual Voice, and innovation drawing from social exchange theory and change and innovation perspectives. This study proposes a model that investigates both individual and team level mechanisms leading to innovative behaviors.

The third study "Consideration of Future Consequences and Innovative Work Behaviour: a multilevel view" presents a multilevel model cross-level hypothesis which proposes that the Consideration of Future Consequences impact Innovative Work Behavior, both at the individual and at the team level of analysis.

The fourth study "Team personality composition for innovation, a fsQCA approach for building innovative teams" examines the role of different personality traits in teams for innovation. By employing fuzzy set qualitative comparative analysis this presentation will explore optimal configurations of personalities for promoting team innovation.

Relevance to the Congress Theme

The relevance of this symposium is due to the role of innovation in the dynamics of the future of the world of work. Indeed, the world of work is changing shaped by powerful forces, so that organizations can keep pace and proactively intervene in an ever-changing environment is key to being able to constantly innovate. For this reason, innovation is a fundamental characteristic for shaping the future of the world of work.

Research/Practical Implications

This symposium offers several implications, from a research perspective it provides several perspectives to advance our knowledge of the team-level characteristics that can influence the innovation process. From a practical point of view, it offers guidance to organizations, leaders or HR professionals who aim to strengthen employee-driven innovation by highlighting specific team features.

Overall conclusions

The belief that the work of teams naturally produces more, and better ideas is a common misconception (Coursey et al., 2018). Research has repeatedly shown that teams produce fewer and worst new ideas, when compared to a similar number of non-interacting individuals (Mullen et al., 1991). Contextually, when teams are appropriately composed and successfully managed, they can push individuals to accomplish more than they can on their own (Bell et al., 2018). For this reason, finding ways to best design and lead teams is paramount for organizational studies and although great progress has been made over the past years, there is still much to understand.

Keywords: Team, Innovation

Paper 1

Uncovering the potential of team faultlines to boost team innovation: Relationship between team faultline strength, team innovation and social learning

Marco Pena Jimenez, Université Paris Nanterre

science

Research goals

In a growingly diverse world of work, team faultlines, or the symbolic dividing lines which create homogenous subgroups within the same group based on their attributes (e.g., social, informational) (Lau & Murnighan, 1998), has become a key research line to seize the opportunities of teams to foster innovation. While numerous studies have shown the negative effects of team faultlines on team outcomes (e.g., team performance, creativity), considering the social nature of innovation, other more nuanced effects of team faultlines must not be overlooked through examining different team processes such as social learning (e.g., Liu et al., 2021; Mitchell et al., 2022). In this regard, the research goals were the following: 1) to examine the relationship between team faultline strength and team innovation, and 2) to evaluate the mediating role of social learning in such a relationship.

Theoretical background

Social Distance Theory (SDT; Brewer et al., 1993) posits that different subgroups can coexist within a group, where team members from a subgroup experience a psychological distance from team members from other subgroups. That is, SDT theorizes two underlying aspects of a group dynamic (i.e., within-subgroup, inter-subgroup) that can help to reveal different facets of team faultlines. Regarding goal 1, several studies have shown that team faultline strength is positively associated with task and relationship conflict, and negatively related to team cohesion and performance (Thatcher & Patel, 2012). In accordance with SDT, and from an inter-subgroup view, faultlines strength may create inter-subgroup frictions, thus negatively impacting team innovative behaviour (i.e., teams generating, promoting and implementing new ideas; Amabile & Pratt, 2016). As regards goal 2, recent studies have also shed light on the complex relationship between faultlines strength and innovative-related behaviours at a team level, and more precisely how social learning behaviours (i.e., sharing information, knowledge acquisition) mediate this relationship (e.g., Chen et al., 2019; Liu et al., 2021). According to SDT, and from a within-group angle, team faultlines may positively relate to social learning since members from the same subgroup can learn from others (e.g., leaders, colleagues), which in turn may positively impact team innovation.

Design/Methodology/Approach/Intervention

Based on the above, a cross-sectional study was carried out in 73 teams (N = 2096) from the Italian Airforce. By using a cluster-based approach (Meyer & Glenz, 2013), this study explores the relationship between informational faultlines strength (through three attributes: team tenure, organizational tenure, age) and team innovation through social learning.

Results

The current findings revealed that faultlines strength, in the form of informational-based faultlines, was negatively and directly related to team innovative work behaviour. In addition, this study showed the positive indirect relationship between team faultlines strength and team innovative behaviour via social learning.

Limitations

The present work is not exempt from some limitations. First, the present study focused on faultlines related to informational differences, further studies might therefore consider exploring other attributes (e.g., education, expertise). Second, team faultlines were measured through a strength approach, organizational scholars are thus encouraged to study other approaches (e.g., distance, temporal alignment). Last, considering the study design, no causality can be inferred.

Conclusions – research and or practical implications

Current findings have two main practical implications. On the one hand, organizations might consider acknowledging the value of informational or work experience differences (e.g., organizational and team tenure), rather than other demographic characteristics (e.g., sex, race). On the other hand, HR and leadership strategies enabling social learning (e.g., promoting information sharing, feedback seeking) seem to be able to counterbalance the detrimental effects of faultline strength.

Relevance to the Congress Theme

As regards its relevance to the congress theme, considering that organizations are increasingly changing and diverse environments, this study provides new insights to unlock the potential of team faultlines to develop innovation via social learning, thus benefiting from team diversity in the workplace.

Relevant UN SDGs

This study responds to the call of the UN SD goal 8 (decent work and economic growth), and more specifically, creating supportive environments to foster creativity and innovation in the workplace.

Keywords: faultline strength, social learning, team innovation

Paper 3

Consideration of Future Consequences and Innovative Work Behaviour: a multilevel view.

Jan Schmutz, University of Zurich; Mirko Antino & Alejandro Diaz Guerra-Romero | Universidad Complutense de Madrid

science

Research goal and why the work was worth doing:

This research aims to test a multilevel model cross-level hypothesis which proposes that the Consideration of Future Consequences might impact Innovative Work Behavior, both at the individual and at the team level of analysis. This approach extends previous research on team composition and innovation, as well as, on individual level of innovation.

Theoretical background:

The Consideration of Future Consequences (CFC: the extent to which individuals consider, and are influenced by, the potential immediate and distant outcomes of their current behaviour), is an individual characteristic with relationships with several behavioural domains (health, finance, work, etc.). Within the work domain, literature shows that having higher levels of CFC leads to a better quality of job performance and job safety, reduces intergroup conflict and increases Organizational Citizenship Behaviours (OCBs). However, to date, no research has investigated how team members' CFC differences could impact group-level outcomes, like group-level Innovative Work Behaviour (IWB). Then, analysing this issue from an Equity Theory point of view, we predicted that, although having higher levels of CFC will foster individual IWB in the short and mid-term, the intra-group CFC variance will have a negative impact on group-level IWB in the long-term, since these high CFC team members will scale back the effort they put in IWB as they perceive that it is not accompanied by their less innovative co-workers.

Design/Methodology:

We are collecting data from a public Hospital in Switzerland, with multilevel data structure (i.e.: professionals, units, hospitals) over three time waves. Multilevel models were used to test level 1 (individual level CFC – individual level IWB) besides level 2 (team level CFC differential - team level IWB) relationships. Data collection is still ongoing and will be ended in 2022.

Results Obtained:

Preliminary results obtained through a subsample show a positive relationship between individual level of CFC and individual level of IWB ($r = .23$, $p < .05$). We will present results differentiating short and mid-term time intervals (data are currently not available for the third wave), in order to understand differential effects according to different time frames.

Conclusions:

Preliminary results support our hypothesis at level 1, but do not support our hypothesis at level 2: CFC influence individual-level outcomes, while group-level CFC differences do not seem to impact team-level outcomes (Hypothesis 2 was tested using the same time frame as for Hypothesis 1 - long term effect will be tested once data collection ends).

Limitations:

This research is not free from limitations. The main limitation is that we are currently showing preliminary results for a subsample and only with two waves of collection. The second limitation is the specific time frame that was chosen (4 weeks interval between each measurement), this will be discussed according to the results.

Relevance to the Congress Theme:

For scholars, this study extends prior research in Innovation literature, showing an individual characteristic – not considered until today in the specialized literature - which fosters individual-level IWB. At the same time, it advances our knowledge of team composition in terms of individual differences, investigating how having partners with similar or dissimilar levels in certain traits – CFC, in our case – could impact group-level outcomes. For HR practitioners, especially those in the healthcare sector, it highlights the importance of considering CFC and teams' CFC composition in understanding individual and team-level IWB.

Relevant UN SDGs:

This research might be framed in the 8 th objective of the 2030 agenda (decent work and economic growth) as it generates knowledge about individuals and teams' performance, especially considering Innovative Work Behavior as an outcome.

Keywords: Consideration of Future Consequence, Innovative Work Behaviour

Paper 4

Team personality composition for innovation, a fsQCA approach for building innovative teams

Nicola Cangialosi & Carlo Odoardi | Università degli Studi di Firenze

science

Research goals

The present study sets up to analyze the personality composition of teams and its link to team innovation. The research goal is to identify specific combinations of the five personality traits conducive to team innovation and to highlight substitutive and/or synergistic mechanisms thanks to the use of the fuzzy-set qualitative comparative analysis (fsQCA). The obtained results offer a contribution to the literature by delivering a finer-grained perspective capable of addressing the synergistic effects of personality characteristics in teams.

Theoretical background

Organizations are increasingly relying on team-based work systems to increase their levels of innovation (Mohrman, et al., 1995), consequently, both researchers and practitioners have strived to find ways to design innovative teams by identifying the factors that promote team innovation (West, 2002). Including the right mix of people in the team is critical to the team's success and its ability to innovate (Mathieu et al., 2014), yet little is known about how to effectively build innovative teams (Chatzi et al. 2020) and only a few studies have examined the relationships between personality composition in teams and innovation (e.g., Den Hartog et al., 2020). Personality represents the structures and propensities that reflect the unique patterns of an individual's thoughts, emotions, and behaviors (Funder, 2001). Historically, the most used model to describe an individual's personality is that of the Big Five (McCrae & Costa, 1987), including openness, conscientiousness, extraversion, agreeableness, and neuroticism as key traits (LePine, et al., 2011). Team personality composition represents the aggregation in team-level indices of the average of everyone's personality trait scores (e.g., Barrick et al., 1998). Thus, team personality composition is a concept where the different personality traits are combined so that different team members contribute to the team with their different and unique personalities (Kozlowski & Klein, 2000). The elevation of personality traits in teams has received considerable attention as a predictor of team innovation (Chatzi et al., 2020) and previous research suggests that teams composed of members with different levels of each of the five personality dimensions have the potential to exhibit high team innovation (e.g., Robert et al.,2004). Specifically, while some studies suggest that composing teams of individuals high on extraversion or openness to experience may incentive high levels of innovation (Driskell et al., 1987), others have stressed the importance of assembling teams composed primarily of individuals low on conscientiousness (Moynihan & Peterson, 2004). Nevertheless, other research advises that agreeableness and neuroticism may also be relevant when composing teams that have the potential to produce creative ideas (Goncalo & Staw, 2006). The results mentioned above are based on studies focusing on single personality characteristics, but teams are necessarily made up of a blend of all five traits. In this regard, the effects of group trait configurations, or joint effects between traits, have so far been unexplored although such analytical approaches seem necessary for further advances in the field. The present research aims at filling this gap by examining specific configurations of personality traits in teams that are associated with team innovation.

Design/Methodology/Approach/Intervention

The research question is addressed through a two-wave self-report survey of 69 teams and 379 employees of two Italian manufacturing company by adopting a fuzzy-set qualitative comparative analysis (fsQCA).

Results

Results reveal five compatible configurations of team personality composition leading to high levels of team innovation.

Limitations

All data were collected with self-reporting measures which may lead to the common method bias in observed relationships. However, for dealing with this issue, the study adopted the statistical recommendations of Podsakoff et al. (2012).

Conclusions – research and or practical implications

This research is one of the first to empirically test the relationship between team personality composition for team innovation using a configurational approach. By doing so it contributes to the literature by advancing the notion that innovative endeavors are determined by the holistic effects of different interdependent configurations of personality within teams. Additionally, presented results offer guidance for managers and organizations that aim to strengthen team-driven innovation by offering different recipes of team personality composition.

Relevance to the Congress Theme

This work is relevant to the theme of the congress "the Future is Now: the changing world of work" as it offers specific ways to implement innovative teams, and these are key factors in the ability of organizations to adapt to the continuously changing world of work.

Relevant UN SDGs

This study is relevant to the UN SD goal 8 aiming at generating awareness about teams' innovation as means to both decent work and economic growth.

Keywords: Team personality composition, innovation, fsQCA

Symposium S072

A matter of trust: Collaborating with Artificial Intelligence at Work

Anna-Sophie Ulfert-Blank & Sonja Rispens | Eindhoven University of Technology

science

Over recent years, artificial intelligence (AI) has become increasingly competent, reliable, and autonomous. By assisting employees in decision-making tasks or by taking over dirty or dangerous work, the implementation of AI systems is transforming work across industries (Parker & Grote, 2020). Although human-AI work collaboration is promising, transitioning to a wider implementation of AI brings challenges (Berkers et al., 2019; Ulfert, et al. 2022). Recent studies show that employees have ambivalent reactions toward AI: some people are reluctant to rely on and accept decisions made by AI, whereas others rely too much on the system, decreasing their situation awareness (Kaplan et al., 2021). For human-AI work collaboration to become a success, it is pivotal that human workers perceive the system as trustworthy and develop trust towards it (Langer et al., 2022; Ulfert & Georganta, 2020). Building on theories of organizational and team trust as well as trust in technology, the papers presented in this symposium shed light on the distinct factors that affect the development of trust towards AI-systems in the work setting.

This symposium hosts four empirical studies that investigate trust and trust development in human-AI collaboration at work. The first study, by Kares and colleagues, examines human-AI collaboration in personnel selection. Specifically, it investigates the question of whether moving towards more hybrid human-automated decision support systems can be beneficial for trust development. The second empirical study, by Hunsicker and Langer, explores people's preferences regarding the trade-off between transparency and accuracy of AI systems and their trust in the system. The last two contributions move towards trust in human-AI team settings. Erengin and colleagues focus on how an individual's beliefs about the reliability, dependability, and competences of an AI agent depend on a third, human, party. Georganta and Kaut investigate interpersonal and team trust, comparing human-AI and all human teams when working on different task types.

Together, the findings of these studies suggest that, overall, people are inclined to have more trust in fellow humans than in AI systems. This may be particularly the case when the AI system functions highly autonomously. Hybrid systems - with both humans and AI systems involved in task processing - are likely to increase employees' trust. However, this effect may depend on the task and social contexts. The implications of this novel research will be discussed by Sonja Rispens, who is an expert on collaboration processes at work, including human-AI collaborations. She will invite the audience to engage in the discussion of the theoretical, methodological, and practical implications of these studies in light of current organizational change.

Relevance to the conference theme : The world of work is changing; technological innovations such as AI are expected to play a larger role in many if not all, work processes. Understanding what constitutes effective human-AI collaboration is pivotal to safeguarding high-quality work for human workers and aiding the promise of augmented performance.

Research/Practical Implications :

To develop and design effective AI systems and human-AI collaboration, it is important to gain a better understanding of how human-AI collaboration differs from more traditional collaboration settings. The findings of this symposium aim to contribute to the literature by highlighting the significant role of trust for effective collaboration. Further, it investigates the impact of the AI's and

the user's characteristics, the task and social context, and performance outcomes on trust. The line of research presented in this symposium will ultimately provide insights for the development and implementation of AI-systems in work processes such that the quality of work remains high.

To enable effective human-AI collaboration, we propose to consider both the system's as well as the user's characteristics when implementing AI systems at work.

discussant: Sonja Rispens, Eindhoven University of Technology

Paper 1

Trust in Hybrid Human-Automated Decision-Support

Felix Kares, Markus Langer, Clea Protzel, Richard Bergs & Cornelius J. König | Saarland University

Research goals and why the work was worth doing: Although there is extensive research on trust in, both, human and automated support, little is known about trust in an automated system and a human decision-maker working together. We explore these kind of hybrid collaborations as they reflect a likely implementation of automated systems in future high-risk decision-making processes such as personnel selection given that ethical guidelines (e.g., the European Commission's Ethics Guidelines for Trustworthy AI, 2019) and proposed legislation (AI Act, 2021) call for keeping humans in the loop.

Theoretical background: Automated decision support (DS) systems are realizations of mechanical combination of data that can increase the validity of job performance prediction compared to holistic data combination methods (Kuncel et al., 2013), even if scientific evidence regarding validity automated DS is just emerging (Hickman et al., 2021). Although there is potential for high perceived trustworthiness for automated decision-support, people might not necessarily perceive automated systems as capable of high-quality personnel selection (Langer, König, & Busch, 2021). We hypothesize that depending on whether the task is more suited for automation or humans, the respective agent is perceived more favorably. Additionally, hybrid DS might combine the positive aspects of both agents and achieve favorable attitudes in both contexts.

Methodology: We conducted two experiments where participants received a preselection of applicants from a DS. The task context was personnel selection (Study 1, N 1 =170), a task presumed to be more suited for humans, and the selection of employees to receive a bonus payment (Study 2, N 2 =154), presumed to be more suited for automation. The preselection was produced either by a human, an automated, or a hybrid human-system DS. Participants then had to decide whether they accept the preselection and had to rate trustworthiness and trust towards the decision-support. We additionally examined a possible trust violation by presenting one group of participants a preselection that included predominantly male candidates, thus reflecting possible unfair bias. This resulted in a 3 (DS type: human, automated, hybrid)×2 (gender balance: predominantly male, balanced) between-subjects design.

Results: The main findings of our studies are that (a) hybrid DS led to higher trust and trustworthiness perceptions than automated support and was on-par with human DS, (b) the impact of trust violations did not differ based on DS type, and (c) the context of application alone did not elicit different perceptions between DS types. We also did not find a greater difference in trust and trustworthiness of balanced compared to unbalanced preselections for human relative to automated DS.

Limitations: First, our experiments only involved a simulation of selection tasks, the selection situation may thus not be perceived as involving any risk for our participants. The higher risks in real decisions could affect how HR managers perceive different types of DS, for example when it comes to the perceived ability of support or importance of the task. Second, the dynamic nature of trust is not reflected in our studies because participants only completed a single round of a selection process. We were thus only able to evaluate initial trust in DS. Attitudes could change after repeated

interactions and in cases where decision-makers have to live with the consequences of decision-support.

Conclusions – research and or practical implications: Our studies demonstrate that, whereas fully-automated decisions involve possible negative reactions, the level of trust in hybrid DS, consisting of a human and a system closely collaborating, may be no different than the level of trust in human-only support. To implement DS that benefits from the possible advantages of automated systems without having to fear possible negative reactions by important stakeholders, organizations could therefore consider human oversight for high-risk decisions instead of implementing full automation.

Relevance to the Congress Theme: The world of work is changing, automation is becoming more ubiquitous and with it the calls for regulation to ensure accountability for and trust in automated outcomes. A likely implementation of this is human oversight in the form of increasing interactions between humans and systems, thus creating hybrid DS systems.

Relevant UN SDGs: By keeping a human in the loop, we believe that our work can contribute to the sustainable development goal of furthering technological innovation. The acceptance of human system interaction will be crucial to ensure a future in which automation can be introduced in a responsible way that minimizes adverse impacts.

Paper 2

Unexplainable accuracy or explainable faultiness? Investigating the accuracy-transparency trade-off of AI-based systems

Tim Hunsicker & Markus Langer | Saarland University

Research goals and why the work was worth doing: The choice between different algorithmic approaches underlying AI-based systems is accompanied by the fact that the approaches yielding the most accurate outputs are often the least transparent and the most transparent ones are the least accurate. Therefore, when choosing between approaches in everyday use contexts, there is an accuracy-transparency trade-off. The aim of this study was to shed light on the decision-making and weighing process considering this trade-off from a psychological perspective.

Theoretical background: When choosing between different AI-based systems, the decision can be influenced, for instance, by information about system performance, by the role of the person who chooses the system within the decision process in terms of accountability and the context of application. Since AI-based systems and their properties can be described in various ways, we expected that the choice of a system, which involves trade-offs between performance and transparency, may be influenced by framing effects. Specifically, the performance of systems could either be framed as accuracy rate or as error rate. In the context of the accuracy-transparency trade-off, different framing effects could occur: goal framing could influence system choice, because system performance information is weighted more strongly when it is displayed as error rate compared to when it is presented as accuracy (Levin et al., 1998). At the same time, attribute framing suggests that there may be a higher perceived competence and ultimately a higher level of trust when system performance is framed positively (ibid.). Transparency, in terms of the understandability of a particular model or explanations of how its decisions are arrived at, provides clarity and can be a facilitating key factor for accountability (Lepri et al., 2018). So, we expected, that participants are more likely to make a system choice with a preference for transparency when they are required to be accountable for their decision. We additionally explore the hypothesis that the context of application (e.g., medicine, in management) may affect the choice between system transparency and performance.

Methodology: In a between-participants online study (N = 383), we investigated whether framing of the prediction performance of these systems (positive framing as accuracy rate vs. negative framing as error rate), accountability (decision-makers were informed that they need to explain their decision vs. that they do not need to) and the context of use (medicine, personnel selection, finance, law) affect the choice between different versions of systems underlying the accuracy-transparency trade-off. Additionally, we examined whether the experimental manipulations and the system choice affected trustworthiness and trust perceptions.

Results: Contrary to the assumptions, framing and accountability showed no significant effect on system choice. The use context affected system choice. As predicted, there was a preference for high performance and low transparency in medical contexts. Furthermore, the results supported the assumed relationship between system choice and different trustworthiness facets as well as the stronger perceptions of system trustworthiness and trust in the positive framing condition.

Limitations: Participants were recruited via Prolific and there was no real interaction with a system. Furthermore, it remains unclear whether the accountability manipulation worked as intended or

whether the unexpected results are due to participants understanding accountability differently than intended (accountability for system choice vs. accountability for subsequent system decisions).

Conclusions – research and or practical implications: Results showed that the context of use is critical for human preferences regarding system accuracy and transparency. This highlights the importance of applying context-specific and user-centered approaches to realize AI-based systems that are supposed to be used in the real world. Additionally, framing effects can influence system perceptions. This finding is important as it emphasizes the necessity to be careful when designing communication about system properties. For practice, our findings indicate that it is possible to influence perceived trustworthiness and trust in AI-based systems with minimal effort (e.g., without changing the system properties) just by reframing the description of the system properties.

Relevance to the Congress Theme: The present work contributes to the emerging topic of Artificial Intelligence and Human-machine-systems within the field of technology.

Relevant UN SDGs: On the one hand, our work aims for technological progress as described in the SDG regarding industry, innovation and infrastructure. On the other hand, the developments of AI and the efficient use of technology and AI-based systems contribute to the SDG of responsible consumption and production.

Paper 3

Do you trust me enough to trust the AI? Examining third-party influence on cognitive trust towards an AI team member

Türkü Erengin, Roman Briker & Simon B. De Jong | Maastricht University

Goals

With recent improvements, Artificial Intelligence (AI) has moved from being merely a tool to acting more as a capable team member. Yet, to fully utilize AI's potential as a team member, it is imperative that human team members trust their AI colleagues. In line with other studies on trust in technology, we particularly focus on cognitive trust (CT) (i.e., an individual's beliefs about a trustee's reliability, dependability, and competence). Existing research has revealed various antecedents of human trust in AI, mainly focusing on the characteristics of the human trustor (e.g., propensity to trust, experience with AI, personality traits) and the AI trustee (e.g., reliability, transparency, and tangibility). Although these insights are important, we argue that a limitation was the limited dyadic focus on the AI and its direct user, treating human-AI relationships as occurring in social isolation.

Theory

The main aim of this study is to expand contemporary theoretical and empirical insights on how employees develop CT in their AI team members by taking a triadic perspective to assess third-party influences on this relationship. For this novel perspective on the human-AI teams, we integrate Heider's Balance Theory (1958) with a focus on the importance of "balance" within a triad (i.e., consistency between the attitudes of others and oneself). In particular, we build and test the hypotheses that; (A) human team member's CT in AI positively affects the focal employee's CT in AI; and (B) that the focal employee's CT in the human team member positively strengthens this relationship.

Design

We test these hypotheses in a mixed experimental design with a sample of 364 observations of 182 working individuals across Europe, North America, and Australia. Participants were presented with an online vignette and asked to envision a situation where they were starting a new team project as consultants and were required to work with both a human team member and an AI team member, having similar positions and responsibilities. Utilizing common conceptualizations of CT, we experimentally manipulated the CT of human team member towards the AI as a within-subjects factor and the focal employee´s (i.e., participant's) CT toward their human team member as a between-subjects factor. We measured the dependent variable using subjective ratings of a focal employee's CT towards the AI at two points in time.

Results

Analyses obtained from multilevel modeling supported our hypotheses. Particularly, a human team member's CT to AI was positively related to the focal employee's CT in the AI. Importantly, this positive relationship was strengthened such that it was stronger when the focal employee's CT towards the human team member was higher, and weaker when it was lower. Results from two additional, incentivized experiments to further test our predictions will be available in late 2022.

Limitations

In line with prior research, we focused on one form of trust (i.e., CT), yet future research could explore other types of trust. Also, future research could investigate bigger teams with different numbers of human and AI members and utilize different experimental designs or datasets from non-Western cultures.

Conclusion

Overall, the present study provides new insights into the previously ignored role of the social context on trust in AI, providing initial evidence on the key role of human third-party stakeholders. We also showcase how classic theory on balance in triads can be extended toward human-AI interactions and expand contemporary research by going from a dyadic to a triadic team setting. Our research also has practical implications for organizations and teams that plan to include AI team members. We recommend organizations be aware of the importance of third parties and how they might shape the trust evaluations of employees towards AI. Therefore, to create a positive impact on human-AI trust, organizations should develop new ways of increasing AI readiness and other exposures to AI. Such efforts are crucial for employees to evaluate AI as a colleague rather than a tool and foster positive attitudes toward it as a team member.

Relevance to the conference theme

Combining the trust and human-AI interaction literatures with a classical social psychology theory results in a new perspective and understanding of the underlying mechanisms of human-AI teams. With organizations' increased interest in technology, AI's new role as a team member is a highly relevant subject that requires more attention from researchers.

Relevance to SDGs

Tackling human-AI interaction is imperative to promote new ways of sustained and productive employment, making this study an important step in contributing to the UN's SDGs.

Keywords: Trust, Human-AI Team, Artificial Intelligence

Paper 4

Disentangling Trust in Human-AI Teams: Does the type of task matter?

Eleni Georganta & Mira Kaut | Technical University of Munich

Even though trust is an essential mechanism for effective collaboration between humans and Artificial Intelligence (AI), our understanding of trust towards AI as teammates and human-AI teams, and how this might differ from trust towards human teammates and human-only teams is limited. At the same time, it remains unclear whether specific circumstances might shape these relationships. The goal of the present study is to investigate differences in trust towards a teammate (interpersonal trust) and trust towards the team as a whole (team trust) when having an AI compared to a human teammate. Given that task type impacts the relationships between team inputs and outcomes, we also explore whether the relationships between team composition (human vs. AI teammate) with interpersonal and team trust might change depending on task type (social or administrative). We integrate work on trust in human teams and trust in autonomous technologies while considering possible boundary conditions of trust in human-AI teams.

Theoretical Background

Similar to human teams, we expect that interpersonal trust towards an AI teammate (cognitive and affective) and team trust - the shared psychological state towards the human-AI team - contribute to successful collaboration and team effectiveness. However, previous evidence has shown that humans have difficulties trusting intelligent technologies, even when AI systems have the same roles as humans. Consequently, we expect interpersonal and team trust to be lower when having an AI than a human teammate. Due to previous experiences and expectations, one might feel less familiar with an AI than a human teammate, resulting in lower levels of trust. At the same time, we argue that differences in interpersonal and team trust might change depending on the type of task that the teammate (AI or human) is executing. Specifically, we expect that differences in interpersonal trust and team trust are weaker when the teammate is executing an administrative than a social task. Although no clear guidelines on whether a specific task should be executed by a machine or a human exist, AI systems have mostly been assigned to administrative responsibilities. Consequently, we believe that when an AI teammate executes an administrative rather than a social task, the human-AI collaboration is perceived as more familiar; thus, differences in trust towards an AI than a human teammate are weaker.

Methodology

Using a mixed-subjects design, 106 participants were randomly assigned to one of two conditions (human-AI or human-only teams). Participants were informed that they were members of a medical team that either consisted of a human and an AI teammate or two human teammates (between-subjects factor). In both conditions, participants were presented with two online scenarios describing either an administrative or a social task that the team was executing (within-subject factor). The order of the scenarios was counterbalanced. After each scenario, participants completed an online questionnaire assessing interpersonal trust and team trust. In the last questionnaire, demographics were assessed.

Results

In contrast to expectations, task type did not moderate the differences in interpersonal and team trust when having an AI than a human teammate. For both social and administrative tasks, interpersonal trust (cognitive and affective) was lower when having an AI than a human teammate. Interestingly, team trust was lower in human-AI than in human-only teams only for the administrative task; no differences were found for the social task. Having human teammates in addition to an AI teammate might have been perceived as an important equalizer for the team to be able to respond to its social responsibilities. Another possible explanation is that the social capacities of the AI teammate might have been positively surprising, leading to acknowledging that the human-AI team as a whole can perform successfully a social task.

Limitations

We only investigated the perception of one individual and not of a complete team and explored the proposed relationships within a fictional scenario that did not require actual teamwork. Participants might have also experienced difficulties imagining an AI as a teammate.

Conclusions

We found that trust is lower towards an AI than a human teammate, no matter the type of team task executed. Our findings may inspire future human-AI research and help understand possible challenges when introducing AI teammates.

Relevance to the Congress Theme

Considering the relatively unknown nature of trust in human-AI teams and the limited research at hand, our work can contribute to supporting organizational success in the human-AI age.

Relevant UN SDGs

We adopt a human-centered approach and provide initial evidence to ethically support interpersonal relationships between human and AI teammates.

Symposium S073

New directions in work design research: Understanding mechanisms between work characteristics and their antecedents in the changing world of work

Katharina Klug, University of Bremen, Germany; Anne Casper, University of Mannheim, Germany

science

What will be covered and why

There is ample evidence on what constitutes good work: among other things, having a variety of engaging, meaningful tasks, high autonomy, and manageable demands. However, while the literature has accumulated evidence on how work should be designed to foster employee motivation, performance, and well-being, poorly designed work persists – yet it is unclear why: Despite the longstanding tradition of research on work design, evidence about the antecedents of essential work characteristics is still scarce. Additionally, long-term trends like the digital transformation and immediate disruptions like the Covid-19 pandemic put pressure on organizations to adapt, which profoundly impacts employees' working conditions. To varying degrees, employees are exposed to fast-paced changes and intensifying workloads, while not all of them have the necessary resources to cope with their demands. So when and why do good or bad working conditions come about? How can organizations mitigate repercussions of the transformation of work for their employees' work? The goal of this symposium is to advance research on the mechanisms of work design. To this end, we present a collection of studies focusing on different pertinent work characteristics (e.g., task variety, autonomy), on different levels (e.g., at the organizational or unit level), and using different methodologies (e.g., experimental studies, qualitative approaches, and survey studies).

Starting at the organizational level, Handke, O'Neill, McLarnon and Kauffeld ask whether introducing telework can improve working conditions or whether good working conditions enable engagement in telework. In a quasi-experimental field study, they take a closer look at the causal relationships between part-time telework and essential work characteristics such as autonomy and interruptions. At the unit level, three studies address leaders as essential organizational actors who design work for their employees: Van den Broeck, Sarmah, Germeys and Proost draw on the theory of planned behavior to investigate leaders' intentions and behavior to provide autonomy for their employees. They use a mixed-methods design, consisting of a qualitative inquiry and a survey study, to develop and validate a questionnaire to measure leaders' attitudes, perceived control, and subjective norms as predictors of leaders' autonomy-providing intentions and behavior. Casper, Klug, Andrei and Parker investigate leaders' efforts to improve employees' work design in terms of enriching tasks and solving organizational problems based on principles of work design. Drawing on the job demands-resources model, they test whether time pressure leads to poorer work design decisions via increased cognitive load and reduced perspective-taking in a scenario-based online experiment. Klug, Casper, Andrei and Parker draw on the same experimental paradigm to investigate workload and autonomy as situational antecedents of leaders' work design decisions, as well as strain-based and motivational intervening mechanisms. Tackling the individual level, Scharp and van Zoonen focus on interruptions and ways to help employees mitigate their negative effects. They evaluate the effectiveness of an intervention to reduce exhaustion by decreasing attentional residue in a daily diary design.

Relevance to the congress theme

Work design has long been and will continue to be one of the essential building blocks for research and practice in work and organizational psychology: As organizations adapt to everchanging environments and an uncertain future, employees experience the consequences (both positive and negative) in their immediate work environment – for example, as employers introduce telework, as immediate supervisors translate organizational strategies into everyday tasks, or as the increased use of information and communication technologies increases interruptions during the workday. Therefore, the present symposium addresses a highly important topic at the core of the conference theme.

Research and practical implications

Collectively, the contributions highlight that work characteristics are not fixed entities once a job or task is created. Instead, work design is a process which unfolds in the everyday practice and decisions of executives, managers and individual employees. To arrive at a comprehensive understanding of these dynamics of work design, the symposium offers fruitful avenues for more research into the antecedents and moderators of work characteristics at the different interrelated levels. The resulting evidence can enable organizations to take a proactive role in creating the future of work, from creating structural resources to improving leaders' and employees' everyday practices.

Overall conclusions

In conclusion, the symposium highlights how work design research and practice can benefit from shifting the focus from employee reactions to antecedents and moderators of work characteristics at different levels.

Paper 1

What Goes Around Comes Around – The Relationship between Part-time Telework and Work Design

Lisa Handke & Simone Kauffeld | Technical University Braunschweig, Germany; Matthew McLarnon, Mount Royal University, Canada; Thomas O'Neill, University of Calgary, Canada

Research goals and why the work was worth doing

Part-time telework (PTT), which allows employees to spend some of their work hours to work away from their central workplace, is clearly emerging as an expectation of many employees. Effective organizational PTT programs can allow employees to redesign their work, such as by giving them the freedom to choose where and when to perform their tasks, or enabling them to work in an environment with no interruptions from their colleagues (e.g., Grant et al., 2013).

However, although the effectiveness of PTT theoretically functions through improvements to employees' work characteristics, we still lack evidence that supports this mechanism. Specifically, prior research largely relies on cross-sectional designs that measure telework and work characteristics at the same time. These designs are thus inherently confounded, as they may include that PTT improves job autonomy (and other work characteristics), but the alternative, reversed relation could be just as likely. Accordingly, we have yet to determine whether PTT is an effective measure of work (re-)design or whether it is not employees with an optimal work design that engage in PTT to begin with (or a combination of both).

The present study aims to shed light on this "chicken and the egg" issue through using a quasi-experimental research design that captures actual changes in work characteristics through PTT while simultaneously considering the effect of pre-intervention work characteristics on PTT engagement. As such, our study not only offers important insights regarding the relation of PTT to work (re-)design but also promotes a better understanding of the preexisting conditions necessary for employees to engage in PTT in the first place.

Theoretical Background

The actual effects of organizational levers of work redesign (such as PTT policies) on employees' work characteristics not only occur on more local levels but also demonstrate a certain degree of circularity (e.g., Clegg & Spencer, 2007; Parker et al., 2017). That is, even though work redesign may be initiated at the organizational level (i.e., by introducing a PTT policy), the actual changes will depend on whether employees have the opportunity and motivation to actually engage in PTT. At the same time, employees' opportunity and motivation to enact changes to their work is simultaneously influenced by how their work is designed in the first place. For instance, while higher levels of autonomy give employees the opportunity to craft their jobs, the motivation to do so typically arises as employees are faced with job demands that they would like to reduce (e.g., Tims & Bakker, 2010).

Accordingly, we argue that PTT affords employees the flexibility to improve their work design – particularly with regards to characteristics reflective of employees' workflow and work environment (e.g., autonomy, time pressure). At the same time, we assume that these very same work characteristics will also impact employees' PTT engagement.

Design/Methodology/Approach/Intervention

Employing a quasi-experimental research design, we collected data on perceived autonomy, demanding work conditions, workflow interruptions, and time pressure from 699 white-collar workers at a German car manufacturer pre and post the introduction of an organizational PTT program. We used latent change score modelling to analyze how PTT engagement relates to changes in employees' work characteristics as well as how pre-intervention work characteristics influences the likelihood of PTT engagement.

Results obtained

Our analyses show that PTT engagement lead to a reduction in all three job demands (demanding work conditions, workflow interruptions, and time pressure), yet not to an increase in autonomy. Conversely, autonomy and workflow interruptions (yet not demanding work conditions and time pressure) predicted engagement in PTT.

Limitations

Data was collected in a single company and before the Covid-19 pandemic, which may limit its generalizability. Moreover, teleworkers and non-teleworkers were also not independent from one another, meaning that PTT may have indirectly also affected the non-teleworkers.

Conclusions

Our results show that the factors that drive PTT are not necessarily those that result from it, with high autonomy acting as a main driver, and a reduction in job demands (e.g., workflow interruptions) being the main consequence. This suggests that organizational PTT policies can improve job demands but that these benefits may only be reaped by a select group of employees.

Relevance to the Congress Theme

We believe that the insights from these findings can inform future research and practical interventions aimed at improving individual work design and should encourage scholars to develop a more sophisticated understanding on how HRM practices such as PTT translate into more proximal processes of work redesign.

Paper 2

When do managers provide autonomy to their subordinates? Insights from a theory of planned behavior (TPB) based model

Anja Van den Broeck, Karin Proost, Filip Germeys & Pallavi Sarmah | KU Leuven, Belgium

Research goals and why the work was worth doing

Autonomy at work refers to "the extent to which a job allows freedom, independence, and discretion to schedule work, make decisions, and choose the methods used to perform tasks" (Morgeson & Humphrey, 2006, p. 1324). Decades of research has shown that providing autonomy to employees facilitates numerous positive outcomes such as increased employee motivation, work-engagement, job satisfaction, and wellbeing (Parker, Morgeson et al., 2017). However, many jobs continue to provide limited autonomy (Holman, 2013). To explore why such autonomy-deficient jobs continue to exist, researchers investigated various antecedents that could influence the creation of work (Parker, Van den Broeck et al., 2017). In doing so, they highlighted that managers are among the key stakeholders who may directly influence their subordinates' work (Parker, Van den Broeck et al., 2017). Yet, research tapping into the role of managers as designers of the work of employees is still scant and there has been little focus on examining the underlying decision-making processes that shape such managers job design endeavors. As such, the extant literature lacks in explained variance and requires a comprehensive examination that (1) explores a wider range of antecedents, and (2) highlights the processes by which such factors may relate to managers' work design behaviors like granting autonomy.

Theoretical Background

We aim to advance our understanding of managers' job design behaviors by relying on the theory of planned behavior (TPB; Ajzen, 1991), which is a socio-psychological theory that allows an in-depth examination of a wide range of personal (e.g., individual's attitude), social (e.g., subjective norms) and non-volitional (perceived control) determinants of intended behavior. TPB facilitates the defining and measuring of such factors by contextualizing them specifically to the behavior in question while also highlighting their relationship with a particular behavior via intention. Additionally, it also allows us to dig deeper and explore the underlying beliefs that explain how such factors relate to variances in behavior. As such, TPB is well-suited for examining how antecedents such as managers' attitudes, perceived behavioral control, subjective norms, and the underlying beliefs thereof, relate to their job design behavior, and to their intentions and actions to provide autonomy in particular.

Design/Methodology/Approach/Intervention

First, we started off by conducting a qualitative enquiry to elicit managers' salient beliefs about their attitudes, behavioral control, and subjective norms about giving autonomy to subordinates. Second, we used these insights to develop a questionnaire that allowed us to test the assumptions of TPB towards managers' autonomy providing behavior. Finally, we administered the questionnaire on another sample of managers to test our hypotheses.

Results obtained

Findings of our qualitative inquiry inform the work design literature that, managers' hold salient beliefs that giving autonomy to their subordinates has many positive (e.g., better productivity) and negative consequences (e.g., managers losing control). They also highlight that while some factors

may facilitate managers' to give autonomy (e.g., managers' own autonomy), others my hinder them in doing so (e.g., conflicts and unhealthy rivalry in the workplace). Results of the survey highlighted that (a) managers' beliefs about the consequences of granting autonomy, and their evaluation of whether or not those consequences were favorable, were positively related to their attitude towards giving autonomy, (b) the more managers believed that they had powerful facilitators (and less hindering factors) that enabled them to give autonomy, the more likely they were to perceive having control over providing autonomy to their subordinates, and (c) when managers believed that important people (both within and outside of their organization) favored giving autonomy, they were more likely to think it is normative for them to give autonomy as well. Managers' perceived control was the strongest predictor of managers' intention to give autonomy, followed by managers' attitude and subjective norms.

Limitations

Future research may aim to expand this line of work towards other job characteristics and examine managers' actual job design behavior in real life.

Conclusions

This study showed that in line the tenets of TPB, managers' attitude, perceived control, and subjective norms— as shaped by their underlying beliefs— relate to managers' intention to provide autonomy, and consequently also their autonomy providing behavior.

Relevance to the Congress Theme

We believe that the insights from our study may help managers to design better work for their employees in the future, which is important in face of new technology, digitalization and crises.

Relevant UN SDGs

Paper 3

Work-design decisions under time pressure: An experimental approach

Anne Casper, University of Mannheim, Germany; Katharina Klug, University of Bremen, Germany; Sharon Parker & Daniela Andrei | Curtin University, Australia

Research goals and why the work was worth doing

The goal of the present study was to examine how stressful working conditions may impair work-design decisions. Work-design decisions refer to decisions on how to design a job as a whole as well as to solving work-related problems based on principles of work design (Parker et al., 2019). Specifically, including different tasks when designing a job results in varied rather than monotonous jobs and therefore represents an enriched work-design decision. Similarly, solving a work-related problem such as low productivity by making changes in work organization refers to problem-solving by work design principles. While past research has established how work should be designed in order to maximize employee well-being, motivation, and performance, much less is known about how work is designed by decision-makers in organizations. In the present study, we argue that stressful working conditions such as time pressure impair enriched work-design decisions. We integrate the literature on job stress and the nascent literature on work-design decisions by examining how time pressure influences work-design decisions in an experimental setting.

Theoretical background

Based on the job-demands resources model, we hypothesized that time pressure leads to poorer work-design decisions via increased cognitive load and impaired perspective-taking. Time pressure depletes energetic resources, therefore resulting in increased cognitive load and impaired ability to take the perspective of others. Increased cognitive load and impaired perspective taking, in turn, will result in poorer work design decisions. Specifically, we hypothesized that time pressure results in poorer work-design decisions when designing a new job (Hypothesis 1) and in choosing fewer work-design based strategies when solving work-related problems (Hypothesis 2). Moreover, we hypothesized that increased cognitive load (Hypothesis 3a) and reduced perspective-taking (Hypothesis 3b) mediate the relationships.

Design/Methodology/Approach/Intervention

We conducted an online experiment with a student sample (major: psychology) and scenario-based work-design tasks. Students were randomly assigned to a time-pressure or no-time-pressure group. All students had to do twelve tasks. The four work-design tasks were embedded between eight distractor tasks of similar design but different content. The time-pressure group had to do the tasks as quickly as possible and should not take longer than twelve minutes. They saw a running timer on each survey page that indicated the remaining time. The no-time-pressure group did not have a time limit. After the tasks, participants answered items measuring time pressure for the manipulation check as well as the mediating variables.

Results obtained or expected (if not available, it must be made clear when they will be)

The time-pressure group reported more time pressure than the no-time-pressure group ($t(98) = 11.4$, $p < .001$, $d = 2.3$), thus the manipulation check was successful. Analyses of variance showed that the time-pressure group designed less enriching jobs ($F(1, 83) = 7.35$, $p = .008$, $\eta^2 = .08$) and chose less work-design focused strategies for dealing with work problems ($F(1, 90) = 7.38$, $p = .008$,

η^2 = .08) than the no-time-pressure group. The time-pressure group reported more cognitive load than the no-time-pressure group, but the difference failed to reach significance ($F(1, 98) = 3.47$, $p = .065$, $\eta^2 = .03$). The time-pressure group did not report impaired perspective-taking compared to the no-time-pressure group ($F(1, 98) = 0.799$, $p = .373$, $\eta^2 = .01$).

Limitations

The main limitation of our study is low ecological validity of the experiment and our use of a student sample. However, students majoring in psychology may likely hold managerial positions in the future and are therefore a relevant population when studying work design decisions. Nevertheless, Future studies should replicate our results in a field study with managers, directly assessing work-design decisions.

Conclusions – research and or practical implications

Our research shows that work-design decision can be impaired when they are made under time pressure, suggesting that managers' own working conditions may influence the work-design decisions they make for their employees. For practice, our results imply that managers should not make work design decisions under time pressure but rather take their time when making these decisions. Specifically, managers may want to allocate specific time slots for their leadership tasks. Organizations should ensure that managers have sufficient time for their 'leadership tasks' such as distributing tasks and managing their employees.

Relevance to the Congress Theme

In rapidly changing working conditions, managers have an important role in designing the work for their employees. The current study addresses this topic by examining decision-making with regard to work design.

Relevant UN SDGs

Well-designed work is an important factor for health and well-being. Focusing on how decisions regarding employees' working conditions are made contributes to the UN SDG of "Good health and well-being".

Keywords: work design decisions, quantitative demands, perspective-taking

Paper 4

When do we design good work for others? An experimental approach to situational antecedents of individual work design decisions

Katharina Klug, University of Bremen, Germany; Sharon Parker, Curtin University, Australia; Daniela Andrei, Curtin University, Australia; Anne Casper, University of Mannheim, Germany

Research goals and why the work was worth doing

It is well documented what constitutes good work design based on how job characteristics relate to employee outcomes. However, research on antecedents of job characteristics is scarce. Defining and allocating tasks, leaders frequently make decisions with repercussions for their employees' work design, for example in terms of task variety, workload, or autonomy. Leader behavior thus emerges as an important work design antecedent on the meso- and microlevel, but little is known about how leaders make these decisions. The goal of this research was to investigate leaders' own working conditions as situational antecedents of their work design decisions in an experimental setting. We focus on workload and autonomy as antecedents and argue that less favorable working conditions for leaders will lead to poorer decisions about their employees' work design.

Theoretical background

Drawing on the Job Demands-Resources (JD-R) Model, organizing work can be construed as part of leaders' job performance. Accordingly, high demands would impair work design decisions via strain, whereas resources would improve work design decisions via motivation. Broaden-and-Build Theory would suggest that positive affect resulting from a high level of resources should broaden leaders' thought-action repertoire, whereas negative affect resulting from high demands would narrow this repertoire. Leaders in a positive affective state would take a more holistic approach and make more favorable work design decisions. This study is based on two operationalizations of work design behavior: 1) designing jobs by allocating tasks (enriching task allocation) and 2) applying principles of work design in solving organizational problems (enriching work strategy selection). We expect 1) workload to predict less enriching task allocation and less enriching work strategy selection, and 2) autonomy to predict more enriching task allocation and more enriching work strategy selection. We also expect 3) strain and negative affect to mediate negative effects of workload, and 4) engagement and positive affect to mediate positive effects of autonomy.

Design

We designed two online experiments in which students (majority: business) take the perspective of a department leader in organizational scenarios. Five scenarios assess work design decisions as described above. In Study 1, participants are randomly assigned to a low workload condition with a generous time limit to complete the work design scenarios, versus a high workload condition where they complete the work design scenarios, plus ten distractor tasks in the same time limit. Study 2 consists of a low autonomy condition where the work design scenarios are presented in random order with a specific time limit per scenario, and a high autonomy condition where participants choose the order of the scenarios and receive an overall time limit for all scenarios.

Expected results

Two pilot studies served to test the design: Pilot 1 (N = 61) tested the workload manipulation and found a large difference in perceived workload between the two groups as expected (F (1, 59) =

49.57, $p < .001$, $\eta 2 = .46$). Pilot 2 (N = 38) tested the autonomy manipulation and found moderate to large differences in perceived scheduling autonomy ($F (1, 36) = 70.36$, $p < .001$, $\eta 2 = .66$) and decision-making autonomy ($F (1, 36) = 4.63$, $p < .05$, $\eta 2 = .11$). The design thus seems suitable to test the hypotheses. The main data collection has started in February 23, so that first results will be available by the time of the conference.

Limitations

The external validity of this study may be limited due to the student sample. On the other hand, many students may later take leader positions without being specifically trained in work design. Assessing their decisions as "naïve" work designers is thus of practical relevance. Further replication with leader samples will still be required, as well as field studies to investigate work design decisions in organizational settings.

Conclusions – research and practical implications

Our studies contribute to the emergent literature on individual work design behavior and underline the importance of investigating the antecedents of work design decisions: Antecedents in leaders' work environments, such their own workload and autonomy, can play an important role in shaping the work environment of their employees. This implies for organizations that their leaders should be equipped with adequate resources to design good work for others.

Relevance to the Congress Theme

In rapidly changing environments, organizations have to adapt quickly. Leaders are key actors on the team level, implementing organizational strategies and at the same time reacting to immediate problems. Their everyday decisions about how to organize work thus play an important role in shaping employees' experience of the changing world of work.

Paper 5

Managing Daily Work Intrusions and Exhaustion: A Ready-to-Resume Field-Experiment

Yuri Scharp, Tilburg University, Netherlands; Ward van Zoonen, Erasmus University Rotterdam, Netherlands

Research goals and why the work was worth doing

"Hey, do you have a minute?" is a question most of us hear at least a few times a day. This question exemplifies a work intrusion, which refers to an unexpected encounter initiated by other people that completely and temporarily halts an ongoing task. Such intrusions have proliferated as a consequence of the vast adoption of information-communication technologies in society. Indeed, we are more 'connected' than ever before. Unsurprisingly, work intrusions are described as "ubiquitous in organizational life." An office worker is interrupted approximately every 3 to 11 minutes. We may conclude that an uninterrupted workday is a rare luxury. The prevalence of such intrusions is not without consequence. They demand the expenditure of self-regulatory resources. Thoughts about the preceding task persist while working on the interrupting task (i.e., attention residue) and this lingering activation depletes energetic resources (i.e., exhaustion). However, eliminating intrusions is impractical. They often represent a vital part of organizational functioning. Hence, rather than trying to root out the sources of these intrusions, the present study aims to elucidate how organizations and employees may mitigate the negative implications of work intrusions (i.e., attention residue and exhaustion).

Theoretical Background

We draw on the tenets of attention residue and self-regulation theory to formulate our hypotheses. The literature on self-regulation suggests that devoting cognitive energy to focus attention on one task while mentally lingering on another drains important and finite cognitive resources. Specifically, having two tasks–the interrupted and interrupting task–mentally activated concurrently creates an additional cognitive load that exhausts regulatory resources. Hence, we expect frequent intrusions to promote attention residue and, therefore, increase exhaustion. In contrast, the duration of intrusions may limit attention residue and, therefore, the expenditure of regulatory resources. Namely, the memory for goals theory posits that the moment an individual starts a new task, the activation of the preceding task starts to decay (Altmann and Trafton, 2007). Thus, intrusions that last longer should relate to less attention residue and exhaustion than brief intrusions. However, we posit that a writing exercise may disrupt these processes by freeing regulatory resources. Specifically, we posit that participants who record details regarding the progress on the interrupted task will decrease lingering thoughts (attention residue) and limit the expenditure related to these thoughts (exhaustion).

Design/Methodology/Approach/Intervention

We conducted a daily diary study among 50 employees working in the Dutch branch of a global technology consulting company (n = 200 days). Participants were randomly assigned to the intervention (n = 25) and control group (n = 25). The participants occupied a diverse set of roles, including customer success (34.0%), human resources (20.0%), technology and innovation (18.0%), global finance (12.0%), and product engineering (10.0%). We conducted multilevel analyses and controlled for the autoregressive effects of attention residue and exhaustion. Therefore, the coefficients represent unique daily changes in attention residue and exhaustion.

Results obtained

As expected, on days when intrusions were more frequent, participants experienced more attention residue and exhaustion (level-1). In addition, the ready-to-resume intervention decreased overall attention residue (level-2 association) and partially inhibited the daily association between attention residue and exhaustion as hypothesized (cross-level interaction). However, in contrast to our expectations, the duration of intrusions was not related to attention residue or exhaustion (level-1). Another unexpected finding was the positive effects of the ready-to-resume intervention on overall exhaustion (level-2). Limitations

Data collection was conducted in a single company, which may limit generalizability. Hence, future research may replicate in different settings to establish external validity.

Conclusions

Our findings advance our understanding of interruptions in several ways. First, the findings suggest that the frequency of interruptions is more important for attention residue than their duration. Second, the findings suggest that writing plans may mitigate the effects of exhaustion. Thus, writing down progress on tasks appears to disrupt health-impairing processes. Therefore, integration of writing plans through organizational ICTs such as Google docs or Outlook may represent a fruitful avenue for organizations. Importantly, the findings complement cross-sectional findings and research conducted in laboratory settings (Leroy & Glomb, 2018). Nonetheless, future research should investigate how to limit the direct association of the intervention with exhaustion.

Relevance to the Congress Theme

Technologies have made work intrusions a typical feature of most workplaces. While eliminating intrusions in the future is improbable, we can develop evidence-based strategies to navigate this landscape. Our research pinpoints what changes are desirable and how organizations may help employees achieve these changes.

Symposium S075

Crafting Jobs and Beyond: How Crafting Is Linked with Changes Across Contexts

Arianna Costantini, University of Trento

science

What will be covered and why:

By crafting their job, employees shape their work experiences to fit their needs better. To date, much research in work and organizational psychology has investigated how employees' efforts to shape their jobs can impact work-related outcomes. More recently, research has started to pay attention to how these proactive efforts can unfold and have consequences beyond organizational boundaries and the work domain. Indeed, the positive and negative implications of crafting may have ripple effects beyond the job itself, that is, on aspects of people's experiences that go beyond the primary aim of redesigning the job and extend over the workday, across different contexts and domains. However, our knowledge of the processes and mechanisms through which crafting may exert its influences beyond the (current) job is still scarce, and we have yet to form a precise understanding of how these proactive behaviors may be involved in shaping individuals' choices and experiences of well-being across domains and contexts.

This symposium aims to provide new insights into how crafting drives changes across work experiences and domains, stretching beyond the workday and work-related outcomes. To do so, we present a collection of four empirical works conducted across Europe – i.e., in the Netherlands, Italy, Germany, and Switzerland – with a variety of longitudinal designs.

We begin by zooming into how job crafting can set in motion a process leading to voluntary job change. Addressing the timely topic of the "great resignation", the first contribution presents a two-wave longitudinal study on the role of job crafting in the voluntary job change process. This study proposes job crafting as a mechanism influencing intentions to quit and actual job changes and investigates the role of employees' career need for challenges as a boundary condition influencing voluntary job change. The second contribution examines the role of daily job crafting in influencing psycho-physiological states at the end of the day. Assuming job crafting as a process promoting adjustment and hence better regulation of one's energies, this 10-day diary study examines whether job crafting can boost the positive effects of morning personal resources on better physiological and psychological functioning when the day is over. The third contribution switches the focus to off-job crafting and presents a daily diary study investigating how different demands impact employees' need for competence satisfaction at the end of the workday, eventually influencing how individuals craft for mastery during their off-job time. Finally, further extending the study of crafting processes across life domains, the fourth contribution adopts ecological momentary assessment to investigate how crafting aimed at satisfying psychological needs develops daily over weekdays and weekends and how these proactive efforts are related to daily work-life balance.

Relevance to the Congress Theme:

Drawing on the key role of agentic change to shape and alter actions and circumstances, this symposium contributes to our understanding of the processes and outcomes of different proactive changes that extend beyond the (current) job experience. By examining the role of different types of employees' crafting as mechanisms of change, this symposium expands our knowledge of how crafting efforts are involved in shaping changes beyond current organizational boundaries and the

work domain, providing indications on which proactive changes may be desirable to promote health and well-being and how.

Research/Practical Implications:

The contributions in this symposium extend the proactivity literature by depicting a nuanced perspective of how different forms of crafting efforts are involved in shaping employees' choices, psycho-physiological well-being, and the interplay between work and personal aspects. As such, the studies offer practical implications on how organizations and individuals can leverage proactivity to achieve positive outcomes and drive the changes they desire to achieve in optimal ways.

Overall conclusions:

Employees' proactive efforts to change the circumstances and experience better fit and higher need satisfaction are key ingredients of different change processes. When considering voluntary job change, job crafting can lead to quitting intentions, but the way in which employees craft their jobs (approach- or avoidance-oriented) influences whether they will follow up with enacting their intentions or not. At the day level, approach-oriented job crafting seems to be important for employees to adjust the work conditions and make room for the expression of their personal resources such that they can positively regulate psycho-physiological states. Finally, proactive efforts expressing employees' agency can be determined by the types of demands employees encounter at work and can have consequences for their daily work-life balance.

Keywords: Job crafting; Proactivity; Self-regulation.

Paper 1

From Job Crafting to Job Quitting? Exploring the Role of Crafting Strategies and Career Needs in the Voluntary Job Change Process.

Tom L. Junker, Center of Excellence for Positive Organizational Psychology. Erasmus University Rotterdam, The Netherlands; Arnold B. Bakker, Center of Excellence for Positive Organizational Psychology. Erasmus University Rotterdam, The Netherlands / Department of Industrial Psychology and People Management, University of Johannesburg, South Africa.; Marjan J. Gorgievski, Center of Excellence for Positive Organizational Psychology. Erasmus University Rotterdam, The Netherlands

Research aims and theoretical background:

Job crafting is frequently mentioned in the debate on the "great resignation" that many organizations are currently witnessing. This term has been used in the popular press to refer to the growing number of employees who voluntarily quit their job, in order to find more meaningful work (Klotz, 2021). Instead of quitting their jobs directly, employees may try to initiate small changes in the characteristics of their work (i.e., job crafting), in order to achieve a better fit with their needs, values, and abilities. Yet, it is also conceivable that job crafting sets a voluntary job change process in motion. This scenario may occur when job crafting attempts remain unsuccessful or when employees use job crafting strategically to enhance their employability, in preparation for future job changes. The aim of the present study is to bring more clarity to the puzzling role of job crafting in the voluntary job change process by examining the relationships of this behavior with (a) quit intentions and (b) actual voluntary job changes.

We clarify this empirical puzzle in three ways. First, we investigate the role of different behavioral strategies in terms of approach-oriented and avoidance-oriented job crafting. According to meta-analyses (Rudolph et al., 2017), avoidance-oriented job crafting aimed at reducing job demands is positively associated with quit intentions, while relationships with approach-oriented job crafting aimed at seeking job resources and challenges are mixed. Approach-oriented job crafting has been linked to higher quit intensions in some studies (e.g., Bruning & Campion, 2018) and to reduced quit intensions in other studies (e.g., Debus et al., 2020). Here, we revisit these relationships longitudinally, while prior studies were restricted to cross-sectional data.

Second, we further clarify the relationships between approach-oriented job crafting and quit intentions by drawing from career needs perspectives (Sullivan & Baruch, 2009). Specifically, we hypothesize that employees with a high career need for challenge are more likely to use approach-oriented job crafting strategically, in preparation for future job changes. Hence, we expect that relationships between approach-oriented job crafting and quit intentions are more likely to turn positive for employees with a high (vs. low) career need for challenge.

Third, we investigate how job crafting moderates the relationship between quit intentions and actual voluntary job changes. Approach-oriented job crafting helps employees to acquire new resources and to stay attached to their job, especially when they experience though times (Wang et al., 2018). In contrast, avoidance-oriented job crafting is a withdrawal strategy that is less likely to create the necessary changes that help employees to stay attached to their job. Thus, we expect that approach-oriented job crafting (but not avoidance-oriented job crafting) weakens the link between quit intentions and actual voluntary job changes.

Method and results:

Data were collected from 575 employees of a large public organization in the Netherlands with two measurement moments three months apart. Results indicated that approach and avoidance-oriented job crafting were positively associated with quit intentions at both time points. As predicted, need for challenge strengthened the relationship between approach-oriented job crafting and quit intentions, but did not moderate relationships between avoidance-oriented job crafting and quit intentions. Finally, approach-oriented job crafting weakened the relationship between quit intentions and actual voluntary job changes, such that employees who engaged in approach-oriented job crafting were less likely to act on their quit intentions (i.e., remained in their current job).

Conclusion, limitations and future directions:

The present study portrays a more nuanced perspective on the role of job crafting in the voluntary job change process. While approach-oriented job crafting may engender more thoughts about job quitting among employees with a high need for challenge, engagement in this proactive behavior may simultaneously keep employees attached to their current job. In contrast, avoidance-oriented job crafting is unlikely to create the necessary changes to prevent voluntary job changes. Given that the data of this study were collected pre-COVID, replications may be necessary to ensure generalizability to the post-pandemic context.

Relevance to the Congress theme:

In the future of work, employees are increasingly operating as active crafters of their careers, while organizations are struggling to retain talent. This study addresses these developments by investigating the role of job crafting in the voluntary job change process.

Relevant UN SDGs:

The study would be relevant for the UN SDGs: “Good health and well-being” and “Decent work and economic growth”.

Keywords: Job crafting; Need for challenge; Job change

Paper 2

Off to a Good Start? How Job Crafting Moderates the Influence of Morning Personal Resources on Evening Psycho-Physiological States.

Arianna Costantini, Michela Vignoli & Lorenzo Avanzi | Department of Psychology and Cognitive Science, University of Trento

Research goals and why the work was worth doing:

A sizable body of research investigated how employees' job crafting relates to work-related positive and negative outcomes. Despite research recognizing that work proactivity can influence experiences in different domains, we have yet to fully understand how proactive behaviors may be involved in changes in daily psychological and physiological states at the end of the day. The current research addresses this question using a 10-day diary study with three measurement points per day. To better understand the role of proactivity for optimal human functioning, this research examines how approach-oriented job crafting alters the relation between personal resources and daily psychological (burnout, fatigue) and physiological (heart rate, blood pressure) states. Understanding how the enactment of job crafting can impact individuals' health and well-being is paramount given the centrality of proactive behaviors in the future of work.

Theoretical background:

We draw on coping theory (Lazarus & Folkman, 1984) and the process of allostasis (McEwen, 1998) to examine how daily job crafting moderates the influence of morning personal resources on evening psychological and physiological responses. In our model, we propose that daily personal resources – individual differences improving the ability to manage stressful events and shown to be tied to lesser distress and better health outcomes – promote allostasis by providing a positive psychological state at the onset of the day. Moreover, we examine job crafting as a manifestation of approach-oriented coping processes unfolding at work to promote a balance in job characteristics through change, hence promoting adjustment and boosting the effects of personal resources to improve further the adaptation of the individual to the circumstances of life, eventually influencing health and well-being.

Design/Methodology/Approach:

We used daily diary data (preliminary data n = 217 observations) collected from full-time employees. Participants filled out an initial online survey measuring demographics, dispositional, and control variables. Approximately 2 weeks later, participants filled in three daily surveys for 10 consecutive workdays: the first, measuring personal resources, had to be completed in the morning before going to work, the second measured job crafting at the end of the workday, and the third survey assessed psychological and physiological states in the evening at bedtime. In our multilevel regression analyses, demographics and baseline physiological parameters (Level 2) were controlled for and were grand-mean centered. Within-person predictors (i.e., personal resources and job crafting) and daily control variables (i.e., number of working hours and whether employees worked remotely during the day) were group-mean centered.

Results:

Data collection is still in progress; the following findings are provisional.

Results showed that self-efficacy in the morning was negatively associated with diastolic pressure only on days when people sought fewer resources. Self-efficacy was also associated with increased heart rate in the evening only on days when people sought fewer challenges at work. A higher state of recovery was associated with increased systolic pressure in the evening only when people sought fewer challenges at work. Higher self-efficacy and optimism were related to lower burnout only on days when employees increased their resources more often. Similarly, higher self-efficacy resulted in lower fatigue at the end of the workday only when employees also sought challenges at work more often.

Limitations:

The sample size for the preliminary findings is small (n = 25 employees), so the results should be interpreted with caution. We are currently collecting more data and expect to have a larger sample size for the time of the Congress, which will also allow us to have more power and test all the paths in a single overall model.

Conclusions:

The present study suggests that job crafting contributes differently to psychological and physiological states at the end of the day. For physiological conditions, the lack of proactive behaviors at work prevents the realization of the gains of personal resources in terms of improved physiological states. For psychological states, it is the higher occurrence of proactivity that is linked to less negative states.

Relevance to the Congress Theme:

The strong focus on proactivity calls for a deeper understanding of its implications for employees' health and well-being. This study addresses these aspects by investigating how job crafting interacts with personal resources and influences daily psycho-physiological states.

Relevant UN SDGs:

This research contributes to the UN SDGs: "Good health and well-being" and "Decent work and economic growth".

Keywords: Job crafting; Personal resources; Heart rate.

Paper 3

Do employees search for challenges outside work when hindered at work?

Svenja Leimbach, Thomas Rigotti, Miriam Schilbach & Hendrik Isenbart | Johannes Gutenberg-University Mainz; Institute for Psychology – Work, Organizational, and Businesspsychology

Research goals and why the work was worth doing:

Extant research shows that job stressors impair recovery (e.g., Sonnentag, 2018; Steed et al., 2021). When looking at differential effects of challenge versus hindrance stressors however, a meta-analysis has shown that when controlling for challenge stressors and job resources, hindrance stressors were positively related to the recovery experience of mastery (Bennett et al., 2018). To better understand this finding, we aimed to uncover its underlying mechanism. This could contribute to advance and refine interventions which aim at facilitating mastery.

Theoretical background:

Recovery does not simply happen to individuals. Instead, employees can proactively shape their environment to fulfill their needs. We focused on crafting as we were interested in what individuals actively do. Such crafting efforts are aimed to resolve perceived needs discrepancies (De Bloom et al., 2020). In general, stressors can cause such needs discrepancies. However, with regard to mastery this should only be true for hindrance stressors. Challenge stressors typically represent the opportunity to personally grow and to experience mastery; whereas hindrance stressors block goal attainment and do not offer the chance for personal development (e.g., Lepine et al., 2005). Hence, hindrance stressors should be related to more crafting for mastery due to a low satisfaction of the need for competence. Challenge stressors however should be unrelated to or even reduce crafting for mastery as they already fulfill the need for competence.

Design/ Methodology:

In order to investigate the proposed relations between work stressors and crafting for mastery via need satisfaction of competence, we conducted a daily diary study. We assessed job complexity (i.e., challenge stressor) and illegitimate tasks (i.e., hindrance stressors) as well as current need satisfaction of competence after work, and crafting for mastery during the evening, before going to bed. We analyzed our hypotheses with path models including job complexity and illegitimate tasks as predictors, need satisfaction of competence as mediator, and crafting for mastery as outcome. They were modeled simultaneously on the day- and person-level using latent aggregation.

Results:

The final sample included 70 employees (204 occasions) who indicated to work more than 20 hours per week. Path analyses revealed that only illegitimate tasks were negatively related to need satisfaction of competence on the day-level. That is, on days when individuals experienced more illegitimate tasks, they reported lower need satisfaction of competence. No relationships emerged between the stressors and crafting for mastery. Moreover, need satisfaction of competence was unrelated to crafting for mastery at the day-level. At the person-level need satisfaction of competence positively related to crafting for mastery. Across levels of analyses, no significant indirect effects were found.

Limitations:

Due to the study design, we cannot draw firm causal conclusions. Further, we did not control for job resources which might have influenced the relations.

Conclusions:

We did not find evidence for the hypothesized indirect effects from hindrance stressors to crafting for mastery via need satisfaction of competence. At the day-level, need satisfaction of competence at the end of the workday did not reduce the following crafting for mastery; not indicating an “enough is enough” mechanism in the short-term, and thus not supporting our assumption. At the person-level, need satisfaction of competence was positively related to crafting for mastery which may point at a gain spiral.

Relevance to the Congress Theme:

This study contributes to the understanding of the interplay of work and home. In particular, it advances the knowledge on how job stressors relate to employees’ off-job recovery.

United Nations Sustainable Development Goals (UN SDGs):

Good health and well-being.

Keywords: Challenge hindrance stressors; Recovery; Diary study.

Paper 4

Need-based crafting and work-life balance during the day

Nanxi Yan, University of Groningen; Jessica de Bloom, University of Groningen / Tampere University; Philipp Kerksieck, University of Zurich; Merly Kosenkranius, University of Groningen

Research goals:

The relationship between work and non-work life—work-life balance—has been a topic of interest in both public discourse and academic research in recent decades (Kelliher et al., 2019). Work-life balance can be defined as employees' attitude toward their life situation-specifically their satisfaction with balance between different areas of life, different roles, and goals (Syrek et al., 2011). One essential antecedent to work-life balance is psychological needs satisfaction, e.g., autonomy, belonging, and competence (Warner & Hausdorf, 2009). In addition to the top-down approach—providing employees with a need supportive environment, employees can also proactively engage in needs-based crafting (i.e., proactive self-management of need-based experiences, de Bloom et al., 2020). Needs-based crafting has the potential to help employees obtain health and wellness outcomes. Current research mainly examined the relationship between crafting and work-life balance at the trait level (Kerksieck et al., 2022; Sturges, 2012) but very little is known regarding how this relationship unfolds within the day. An enhanced understanding of need-based crafting trajectories and how it relates to work-life balance at the day level can provide new, fine-grained insights into individuals' crafting behavior in their natural environment.

Theoretical background:

The theoretical backdrop of this study is the needs-based crafting model (de Bloom et al., 2020) which proposes that individuals crafting efforts satisfy their psychological needs: detachment, relaxation, autonomy, mastery, meaning, and affiliation (DRAMMA) across life domains is related to beneficial health and well-being outcomes. Crafting efforts have been categorized into approach-focused (i.e., expansion-oriented, aiming at approaching or adding desirable aspects) and avoidance-focused (i.e., contraction-oriented, aiming at avoiding or reducing negative aspects) crafting which provides a more nuanced understanding of crafting behavior and aligns with recent meta-analyses on crafting (Zhang & Parker, 2019).

Methodology:

We collected ecological momentary assessment (EMA) data for four measurement days, two weekdays and two weekend days in Spring 2021. Participants worked at least 24 hours per week, had no planned holidays nor shift work during measurement days/weeks. 110 employees completed at least one EMA survey (in total, we collected 2,358 observations nested in 396 days). The average age of participants was 40.4 years (SD =14.2), 44.5% were female, 70% received higher education, 53.6% lived in Germany, followed by 29.1% in the Netherlands. On average, they worked 39.5 hours per week (SD =8.2) with 70.9% had a permanent contract. The measures we used including needs-based crafting, work-life balance, energy, work engagement.

Results:

Using the NLME library in R, we specified growth curve models to investigate change trajectories of needs-based crafting across the day and the role of day-level work-life balance as a predictor of change in the needs-based crafting trajectory. Our preliminary analyses confirmed that needs-based

crafting followed an inverted U-shaped trajectory during weekend day and U shape during weekday. Work-life balance contributed to these change trajectories that people with high work-life balance also crafted more. We present the complete results during the conference.

Limitations:

The study limitations including the use of self-report measures raising concerns about common method biases. Also, there might be some between and within-level third variables cannot be ruled out (e.g., life events, yesterday's negative emotions) in this study.

Conclusions:

Taken together, this research of crafting and work-life balance at the day level contributes to the understanding of the micro-temporal process of this relationship; and it also contributes to research on boundary crossing (Ashforth et al., 2000) between life domains that employees' crafting efforts fluctuates from time to time, and from one domain to the other. In terms of practical implications, briefly speaking, the research findings can inform organizations' work design and policy making (e.g., providing crafting support, awareness, etc.).

Relevance to the Congress Theme and UN SDGs:

Need-based crafting, as a self-management skill, is an important toolkit for employees to become more prepared and resilient in today's ever-changing work and non-work life. It is related to UN SDGs: "Good health and well-being" and "Decent work and economic growth".

Keywords: Need-based crafting; Work-life balance; Ecological momentary assessment.

Symposium S125

Ensuring the health and well-being of health care workers after the pandemic: reflections and comparative research on protective factors

Silvia Platania, University of Catania, Italy

science_practice

The situation caused by the COVID-19 pandemic required healthcare workers to operate on an emergency status to ensure care and safe measures for people who had been exposed to the virus and to limit the spread of this infection. In addition to these initial problems, additional psychological difficulties arose related to the fear of becoming infected and infecting relatives, and a general sense of helplessness towards patients' losses. The COVID-19 emergency exposed healthcare workers to multiple challenges and threats over time, causing symptoms of anxiety, exhaustion and stress, and even the development of depression, as confirmed by some findings on Chinese, Turkish and Spanish healthcare workers. As reported by Chen and colleagues, more than 40 percent of healthcare workers reported experiencing anxiety symptoms; more than 46 percent reported depression, 32 percent insomnia and 69 percent high levels of stress.

According to Folkman and Lazarus, the greater the stress perceived by the subject, the greater the possibility of manifesting symptomatic states that cause a lower ability to manage the situation, experienced as excessive and lower perception of one's own management skills. As previous researchers investigating healthcare workers engaged in the SARS and MERS pandemics reported, acute distress levels are associated with other psychopathological symptoms, such as anxiety, depression and secondary traumatic stress. The occurrence of post-traumatic symptoms combined with stressful situations is inclined to negatively impact on employee satisfaction and promote a decline in coping skills.

The theoretical reflections presented so far lead us to stimulate the debate on what is one of the main themes of the conference and which is fully inserted within what is one of the main themes of 2030 Agenda for Sustainable Development „Good health and wellbeing „. The workers who most suffered the burden and stress deriving from the pandemic were health care workers. the four contributions that will be presented within the symposium will allow to identify both different theoretical points of reflection on what is the perception of the safety and psychosocial climate by health organizations, and to identify the protective factors that the worker is able to field in the face of emergency situations. Furthermore, important points for reflection will emerge on the practical interventions that can be implemented to promote the well-being of workers.

For this purpose, therefore, the symposium will include the presentation of four empirical research contributions. The first contribution entitled „The effect of dispositional resilience on the relationship between professional quality of life and psychological distress factors of healthcare workers during the pandemic: a three-wave longitudinal study" will address the issue of dispositional resilience as a fundamental protection factor in longitudinal key; in the second study „The effect of Psychosocial safety climate on psychological distress of healthcare workers during the pandemic: a multilevel analysis", the effect of the psychosocial climate of safety will be addressed by comparing the perception both at individual and group level; in the third study „The effect of psychological stressors on Job Satisfaction of Healthcare Workers during COVID-19: the mediation role of psychological capital", the mediating effect of psychological capital between stressors and job satisfaction will be discussed; finally, in the fourth study „Safety Climate and Service Access during COVID-19: a

preliminary study in healthcare sector", the overview will conclude with the analysis of the safety climate through a qualitative analysis.

Keywords: well being; protective factors; climate

Paper 1

The effect of dispositional resilience on the relationship between professional quality of life and psychological distress factors of healthcare workers

Martina Morando & Silvia Platania |University of Catania, Italy; Anna Paolillo & Vittorio Edoardo Scuderi | Kingston University, London; Stefania Gruttadauria, University of Catania, Italy

Research goals

The situation related to the COVID-19 pandemic forced healthcare workers to operate under emergency conditions to ensure treatment and safety measures for people who had contracted the virus and to limit the spread of infection. Since the beginning of the pandemic in Italy, medical staff had to cope with long, exhausting and stressful shifts and heavy workloads. In the first weeks of the pandemic, they also needed clear intervention protocols, adequate tools and the necessary personal protective equipment (PPE). As shown by other research since 2020, Italy has been and continues to be one of the most afflicted nations in terms of overload of hospital patients and difficulties in managing shifts due to staff shortages. This has resulted in high psychological stress, high health risks for healthcare workers and a generally reduced professional quality of life. Against this background, the aim of the present research is to examine the trend of stress, anxiety, depression and resilience levels and the effects on professional quality of life in Italian healthcare workers who worked on the front line during the first, second and third waves of the pandemic.

Theoretical background

In the current healthcare environment, job stress indicators is an important public health problem. Work-related and personal aspects could have an impact on the quality of life of healthcare workers. The current epidemic of COVID-19 stresses health care workers (HCWs) around the world and has impacted on the nature of their work and the quality of their personal and professional lives. Therefore, it is necessary to pay attention to and examine their professional quality of life. For this purpose, most studies (including our study) employ the Professional Quality of Life scale, which is used as a screening tool for the positive and negative aspects of working in the helping professions. This instrument allows us at the same time to analyse compassion satisfaction and compassion fatigue. For Stamm (2010), compassion satisfaction is the job-related satisfaction from helping or caring behaviour at work. While compassion satisfaction comes from positive interactions with patients, compassion fatigue comes from negative interactions, which result in the caregiver being worried about the trauma experienced by the patient and increase the emotional arousal or avoidance behaviour associated with the patient. In conceptualising ProQOL, Stamm (2010) embodies the previous behaviours and cognitions in the construct of secondary traumatic stress, suggesting that it reflects feelings of fear arising from the described sources. A secondary component of compassion fatigue according to Stamm's (2010) conceptualisation is burnout, as indicated by perceptions of exhaustion, hostility and depression. Several studies reported that frontline healthcare workers had higher secondary trauma scores than non-frontline healthcare workers (Kang et al., 2020; Lu et al., 2020). Resilience appears to play a mediating role in certain psychological dynamics variables (Wagnild & Young, 1993). Few research considered the relationship between resilience, Burnout and psychological distress as interacting variables.

Method

Participants and procedure

The research design of the study was established from the outset in three waves. In wave one, 478 people were recruited and they agreed to complete a survey on google platform. The same participants were then invited to a follow-up eight months later (wave two), where 92% of the original pool of participants agreed to participate (n = 440). Finally, during wave three, which also occurred eight months later wave two, the number of participants who responded to the survey dropped to 86% (n = 411; 52% men; Mage = 38; SDage = 8.1). The measures used were as follows: DASS-21 (Depression, anxiety and stress scale; Henry & Crawford, 2005); Professional Quality of Life Scale (ProQoL, for measuring compassion satisfaction, secondary traumatic stress, burnout) (Stamm, 2005); Dispositional Resilience Scale (Kobasa et al., 1982; it. Picardi et al., 2012).

Results

Results indicated that in all three waves there is a significant increase in the effect of resilience on burnout: specifically, the effect of all three psychological distress decreases from the first to the third wave on Burnout. The effect of resilience on Burnout is significantly stronger in the third wave. In relation to secondary traumatic stress, progressively higher scores are found in the three waves, demonstrating a greater perception of workload and greater difficulty in managing the emotionality associated with the patient's perceived stress. This trend can also be seen in the resilience mediator effect, where despite the significant effect, an increase in stress and depression is found in the three waves. Finally, with regard to burnout, an increase can be observed in the comparison between the first and second wave, but a significant decrease during the third wave. Indeed, the effect of resilience on Burnout is significantly stronger in the third wave.

Practical implications

Our findings are aligned to the existing literature on the fundamental role played by resilience and they underline the importance to invest on intervention strategies and programmes aimed at developing resilience in healthcare workers; however, it also underlines the importance to provide to provide prevention and assistance to health care workers with regards to job demands and unsustainable stressors. In terms of sustainable development goals, this work is part of good health and wellbeing.

Paper 2

The effect of Psychosocial safety climate on psychological distress of healthcare workers during the pandemic: a multilevel analysis

Silvia Platania, University of Catania, Italy; Vittorio Edoardo Scuderi, Kingston University, London; Marcello Boccadamo & Martina Morando | University of Catania, Italy

Research goals

During the Covid-19 emergency, exceptional precautionary actions were taken with different effects on the population and workers involved. Work demands and workloads of healthcare workers have increased along with deteriorating physical and psychological well-being, and fear of being infected and passing the virus on to family and friends (Liu et al., 2020). These the critical conditions are increased by the obligation to wear personal protective equipment which, although essential, have caused and still cause inconvenience and some difficulties in breathing. Several studies have shown that a perceived lack of security leads to lower levels of personal well-being, less involvement, greater anxiety levels and an increased tendency to become a workaholic. The commitment has been defined as a positive motivational state that promotes a strong commitment of individual to work and, in turn, promotes positive outcomes for workers and businesses. In addition, there are discrepancies in perceptions of safety between nurses and doctors has been shown to affect different levels of psychosocial well-being during communication disease outbreaks. In response to this health crisis, the psychological assistance of health professionals they should be an essential part of the fight against the COVID-19 pandemic because of them vulnerability. The main objective of the study was to investigate the perception of a psychosocial safety climate and the effect on engagement and psychological stress in a sample of healthcare workers. Furthermore, we wanted to investigate the mediating effect of workaholism at both individual and group level.

Theoretical background

Several studies have shown that infectious diseases caused long-term and persistent psychopathological consequences in health workers (Tam et al., 2003; Lee et al., 2007). For example, previous evidence of the 2002--2004 severe acute respiratory syndrome (SARS) epidemic and the 2015 Middle East respiratory syndrome (MERS) epidemic showed that frontline health workers reported a lack of support. workplace and higher levels of psychological distress, anxiety, depression, and increased risk of developing long-term Post Traumatic Stress Disorder (PTSD).

Frontline health workers have found an unexpected increase in workload in a context of uncertainty, helplessness, alienation and isolation, making them more vulnerable to infection than other health workers or other categories of workers, they tend to report a higher prevalence of adverse psychological outcomes such as psychological distress. In addition, an excessive workload can intensify the work rate and pressure to meet all the job demands of health care workers, which, in turn, would increase the tendency to overwork and compulsively.

Several protective factors can help healthcare professionals cope emergency, during outbreaks or in other critical situations. The purpose of these protective factors was to provide essential resources, promote a climate of psychosocial security (PSC), and mitigate the negative effects of work (Yulita, Idris & Dollard, 2020). PSC is defined as shared employee perceptions of " policies, practices and procedures for the protection of health and psychological safety of workers " (Dollard & Bakker, 2010, p. 580). Among these protective factors are the practice of physical exercise, clarity in

communication, the availability of personnel protective equipment, the need for adequate rest and practical and psychological support.

Method

Participants and procedure

The study involved 945 healthcare workers (physicians 42.3%, nurses 39.2%, healthcare assistants 18.5%) at the forefront of the battle against COVID-19 during the pandemic (males were 41.5% of the total sample), belonging to 9 organisations and organised into 21 working groups. Each group consisted of members from a distinct division of the organisation who were assigned to the same head of department. Participants were recruited through convenience sampling, and companies were contacted via written correspondence; once the approval from the HR department was given, a link to the survey was published in the companies' social media groups (i.e., LinkedIn, Twitter) and they were also approached in workgroups via written correspondence (e.g., email or invitation by letter to participate). The measures used were as follows: Psychosocial Safety Climate (PSC-12) (Hall, Dollard & Coward, 2010); Utrecht Work Engagement Scale (UWES-9) (Schaufeli and Bakker, 2003); Dutch Work Addiction Scale (DUWAS) (Balducci et al., 2019); Kessler 10 Psychological Distress Scale (K10) (Kessler et al., 2010).

Results

The results indicate that a climate of psychosocial safety in health workers leads to a decrease in engagement through the mediation of compulsive work. This probably happens because inadequate work resources could lead to counterproductive and negative behaviors and reactions. One of the main connotations that characterized the COVID-19 pandemic concerns the great pressure of health institutions on workers, the requests for work have increased and the number of available resources has decreased. The mediating effect of compulsive work in the relationship between psychosocial safety and involvement could be due to a climate that does not guarantee or preserve the psychological health and safety of health workers. Compulsive work due to the state of emergency can cause tension, anger and irritation, leading to a reduction in all positive engagement-related behaviors such as happiness and enthusiasm.

Practical implications

The results show the importance of the role that working compulsively plays as a mediator, as it can undermine the psychosocial safety climate causing workers to become detached from their work. In these frenetic times of insufficient readiness for a global pandemic, we need to understand whether healthcare organisations are prepared to support workers in their time of need, or whether all the burden is placed solely on these workers. Our research unlocks the possibility of investigating the negative effects of a poor psychosocial safety climate and compulsive work on effective employee engagement in various work environments, not only in the healthcare sector.

Paper 3

The effect of psychological stressors on Job Satisfaction of Healthcare Workers during COVID-19: the mediation role of psychological capital

Pasquale Caponnetto, Giuseppe Santisi & Claudio Maggio | University of Catania, Italy

Research goals

The covid 19 pandemic has had a major impact on the lives, working and otherwise, of frontline health workers. New challenges have affected their lifestyles, increasing their levels of anxiety, irritability, and loneliness. Evidence shows that psychological capital (PsyCap) was a strong protective factor against these stressors. The purpose of this study was to analyze the job satisfaction of health care workers and the protective role of Psycap. Therefore, we set out to investigate the negative correlation between anxiety, stress vulnerability, loneliness, and irritability with job satisfaction; furthermore, it is consequential, considering the literature, the negative correlation between Psycap and these 4 stressors, and the protective role and positive correlation between Psycap and job satisfaction.

Theoretical background

Frontline health workers have had to cope with an emergency condition that has led them to have new rhythms, new protocols, awareness of exposing themselves and their loved ones to a higher risk of infection, in addition to the fatigue resulting from the workload.

Under conditions such as fatigue, increased workload and high psychological stress, the perception of the quality of their work life deteriorated. Since the beginning of the pandemic, numerous publications and authors have reported that anxiety, depression, and stress are prevalent among frontline health workers. However, a very limited number of studies examine the extent and ways in which the job satisfaction construct has been affected. Among the published research, however, the findings are very clear: health care workers worldwide are largely dissatisfied with their work situation in the context of the COVID-19 pandemic (Zhang et al.). In addition, several studies reveal that the physical and psychological symptoms of anxiety and depression lead to poor work performance and significantly increase the risk of accidents (Da Silva, Dale). The impact of anxiety on job performance is significant and affects work at both the individual and organizational levels. At the individual employee level, it leads to impaired job performance, accidents, and sick leave. At the organizational level, there are impacts on productivity, staff morale, accidents, absenteeism, and staff turnover (Haslam). Job satisfaction, defined by Mousazadeh as an employee's accomplishment resulting from his or her work, producing a positive emotional response that is achieved as a result of self-assessment of one's experience at work, is known to have a positive effect on levels of self-esteem and self-efficacy and, consequently, on work behaviors. The analysis of job satisfaction of health care workers is a crucial factor for both health care workers and health care management. In conducting our study, we found that there was limited literature on the topic of health worker satisfaction during the emergency phase in Italy (Ramaci et al.). Therefore, the purpose of our study was to assess levels of job satisfaction among healthcare workers, investigating both specific antecedent factors (more traditional and more situation-specific) and the impact that psychological capital plays in preserving and promoting higher levels of job satisfaction. The present study will then be used to implement targeted health promotion interventions among health care workers.

Method

Participants and procedure

The convenience sampling technique was used in this study, which is a method where the selection of participants is based on their ready availability, and we enrolled participants from the health workers population. Five-hundreds and twenty-seven health care workers on the front line of the battle against COVID-19 during the pandemic were enrolled in this study (physicians 35.2%, nurses 48.1%, health care assistants 16.7%; females were 71.7% of the total sample). Participants were from different areas in Italy (North, 36%; Central, 23%; South, 41%). The measures used were as follows: SVS (Stress Vulnerability Scale; Miller and Smith, 1985); GAD-7 (General Anxiety Disorder; Spitzer, 2006) scale in both the English and French versions; UCLA Loneliness Scale (de Grace, 1993); Brief Irritability Test scale (Holtzman, 2015); CPC-12 (Compound PsyCap Scale; Lorenz, 2016); JSS (job satisfaction scale; Platania, 2022).

Results

Results indicated that psychological stress-related factors had a considerable impact on job satisfaction. All four of the predictors (Stress Vulnerability, Anxiety Symptoms, Loneliness and Irritability) examined were found to particularly decrease job satisfaction. Amongst other things, it is interesting to note the more pronounced result of Loneliness, whose impact on job satisfaction was significantly greater than the other factors analyzed.

The aspect of Loneliness in health professionals was also investigated in other studies and seems to be a particularly important finding for studies concerned with professionals who work in the environment of a health crisis.

Another objective of our study was to test the indirect effect of psychological capital, as a personal resource to be drawn on in response to the psychological stress arising from the situation. Our study shows how Psychological Capital could diminish the effects of psychological stressors on job satisfaction. Our results are consistent with previous studies that demonstrated that Psychological Capital could alleviate the role in work-related circumstances.

Practical implications

The results suggest how, in a pandemic situation, involving frontline health workers, the effect of psychological capital could reduce the psychological stress arising from the work situation experienced and this implies that job satisfaction is not diminished. It is therefore necessary to develop psychological interventions that assist healthcare personnel in acquiring important resources such as resilience, optimism, self-efficacy, etc., that are useful for facing moments of crisis such as the COVID-19 pandemic. In conclusion, we believe that our research contributed to recent efforts to uncover the mediating role of psychological capital in the relationship between psychological stress and job satisfaction among frontline health professionals since the outbreak of the global COVID-19 epidemic.

In addition, these findings encourage the development of human resource management practices such as programs that aim to increase the performance and health of the psychological capital of frontline health workers.

Relevant SDGs

In terms of sustainable development goals, this work is part of good health and wellbeing.

Paper 4

Safety Climate and Service Access during COVID-19: a preliminary study in healthcare sector

Vittorio Edoardo Scuderi, Kingston University, London; Ally Memon, Northumbria University, Newcastle; Anna Paolillo, Kingston University, London

Background : It has been apparent during the COVID-19 pandemic that there has been a hesitancy amongst the public (users) in accessing healthcare provision, typically in secondary and acute healthcare establishments, such as pharmacies and emergency care services. At the same time and especially at the peak of the pandemic, healthcare professionals across the world had to either refrain from physical working in hospital and community care environments or to deal with entirely new ways of working in novel risk averse environments, where safety is of paramount concern. For both employees and users, perceptions of safety climate and risk have radically altered during pandemic, as shown from the existing research in the last two years, and it appears to continue to do so in the post-COVID era, where the disease is far from disappearing yet. Despite the last 40 years of research on safety at work has often focused on safety climate as an antecedent of safety performance, this relationship has been scarcely investigated in the healthcare sector. More specifically, existing research in healthcare organisations has primarily focused on safety-related injuries, demonstrating what has already found in other settings, that better safety cultures and climates lead to less patients' injuries (defined as those injuries attributable to healthcare systems and professionals' mistakes, such as infections and medication errors). This research represents an innovative attempt to spotlight the users/patients' perspective; similar to the impact of safety climate on healthcare employees, users also perceive the atmosphere in which an organisation supports its employees to serve patients. Hence, the aim of this study is to examine possible spill over effects from the organisation and employees' safety climate to the users' safety perception of the same organisation/service provider, which could ultimately impact the delivery and usability of healthcare services. Investigating safety climate perceptions from the perspectives of both employees and users provides richness to this enquiry since both those stakeholders are key change agents in determining performance and creating value in public service organisations.

Method: This study applied a qualitative research design by interviewing two samples of 17 healthcare professionals and 23 healthcare users in the following departments: mental health and social care, cardiology, maternity, and critical care, respectively. Both samples were interviewed using semi-structured interviewing technique to gather primary data about their perceptions of their organisation (for employees) / last service accessed (for users) with regards to priority given to safety, together with employees/users' individual motivation to perform safely and their actual behaviours in terms of measures personally taken to reduce the risk of accidents and incidents when at work / accessing the service. Then, the interviews were transcribed and analysed using thematic analysis to identify possible recurring themes and patterns and enable one to gain insight and understanding of the phenomena in question. Data were analysed using AntConc qualitative data analysis software.

Findings : Findings have shown that professionals and users' perception of safety in the healthcare sector has increasingly become a priority after the spread of the SARS-CoV-2. Regarding healthcare professionals, safety procedures, protocols and practices have increased along with training sessions aimed at reducing the risks of infection faced by both professionals and users. At the same time, healthcare users perceived good levels of safety when they had to use private or public healthcare services such as NHS or general practitioners. This was due to both displayed instructions and verbal

guidance provided by healthcare institutions and professionals to reduce the risk of infection; at the same time, users underlined their own motivation to follow those guidelines and to correctly use the measures (i.e., masks, hand sanitisers and social distancing) to safeguard their health and prevent the risks of transmission. Despite the above, some additional themes have emerged; specifically, some users reported that, during the peaks and between waves of the pandemic, the delay in planning interventions for severe or mild conditions posed a risk to their safety. Specifically, the main words used were “unsafe/risk”, “short-staffed”, and “appointments after months”, hence the main perceived concern was related to “treat people in time”. Therefore, the rigour applied by healthcare professionals in implementing safety policies and practices and the importance given to such procedures (e.g.,“… it was pretty much really safe, and just because of how they conduct…they still stick with those restrictions…even during the hospital visit, even if it was like high cases of Covid when I was attending the hospital back then, but still they really monitored my conditions…I was happy, honestly, with everything”) appear to promote users' compliance with safety procedures and their perception of being safe when accessing the service, although it did seem to pose some concerns with regards to their long-term health conditions, but non COVID-related.

Conclusions/Practical implications: This study shows that if patients feel that their healthcare provider attempts to maintain excellent safety levels and provides employees with measures and systems for a safe service delivery, then patients will feel safe to access and use the service. This has important implications for the organisation as well, since it helps highlighting how promoting a safe environment for workers, (in this case in terms of giving priority to minimising the risk of contracting the COVID-19 disease at work), can have positive repercussions on the users’ perceptions of safety when accessing the service. From a practitioner’s perspective, through the development of a positive safety climate among employees, there appears to be the added benefit of the behaviours and interpretation of events that occur among users too. A positive safety culture may be therefore enforced not only by having the workforce as the main goal, but also considering the service users, with positive repercussions for the whole organisation.

Relevant SDGs: In terms of sustainable development goals, this work is part of good health and wellbeing.

Symposium S077

Sustainable Careers in Times of Change

Madeleine Haenggli, University Carlos III de Madrid / University of Bern; Jos Akkermans, Vrije Universiteit Amsterdam

science

What will be covered and why

Research on sustainable careers has gained considerable momentum in recent years. Sustainable careers are characterized by happiness, health, and productivity indicators and focus on the interplay between person, context, and time requiring different research approaches to gain insights (De Vos et al., 2020; Van der Heijden et al., 2020). The contributions in this symposium use a variety of methodological and theoretical approaches to examine different aspects of sustainable career development in times of change.

The first contribution investigates international graduates' employability development during the school-to-work transition. The two-wave qualitative study applies a sustainable career perspective and emphasizes that the balance and alignment between three characteristics (happiness, satisfaction, productivity) is key to attaining a sustainable career. The second study presents a longitudinal quantitative intervention study targeting proactive motivation states as theoretical key predictors of career self-management behaviors. This study provides insights into how and by what means proactive career self-management behaviors can be systematically promoted to facilitate sustainable career development. The third contribution is a qualitative exploration of different processes that arise from the desire to realize an intra-organizational change. Taking a dynamic approach to understanding contemporary careers, the study provides insights into which pathways arise from this desire, whether people succeed in realizing the desired change, why people act (or fail to act) on this desire, and how this is influenced by their context. The final contribution presents a study on career self-management as a predictor of wellbeing trajectories during organizational restructuring. This longitudinal quantitative study provides insight into how these trajectories develop over time and differ between people and when during organizational change processes, career self-management is most critical for these trajectories.

The symposium will end with our discussant opening a discussion on sustainable careers integrating the four contributions. The discussant is an expert in the area of sustainable careers, as evidenced by being an author of numerous publications on sustainable careers' individual, job-related, and organizational determinants.

Relevance to the congress theme and SDGs

The papers in the proposed symposium explore topics and research methods that are directly relevant to the congress' theme. Nowadays, individuals experience various career changes throughout their working lives, starting in an early phase during the school-to-work transition and continuing through both voluntary and involuntary change. Effectively managing these changes can contribute to long-term career success and enable sustainable career development. In addition, the focus in the future of work is increasingly on the employees' responsibility to create their sustainable career development. The symposium connects with the UN SDGs focusing on decent work and wellbeing.

Research/practical implications

Using a variety of longitudinal methodological approaches (e.g., intervention, qualitative studies), this symposium offers theoretical and empirical advances in the sustainable career development framework for managing change in one's career. Furthermore, it provides valuable insights into research on sustainable careers by including different career development factors.

Overall conclusions

Our symposium explores sustainable careers throughout the lifespan using different methodological approaches and longitudinal research designs. Taking into consideration the dimensions of person, context, and time, the findings provide insight into how individuals achieve their career goals and maintain sustainable career development. Moreover, the symposium enriches the research on sustainable career development by highlighting different samples and perspectives. As such, the symposium provides insights into international students facing a double transition (educational and cultural). Furthermore, the symposium explores employees who need to proactively manage their careers to achieve career goals and adapt to changing organizational circumstances. Moreover, it deals with how these behaviors can be fostered and what this means for their well-being. Finally, different forms of stable careers, career inaction, and intra-organizational careers are included. Accordingly, our symposium offers new insights for a better understanding of the dynamic nature of the work world and should inspire future empirical research and theory.

discussant: Beatrice van der Heijden, Radboud University Nijmegen

Keywords: Sustainable Careers, Career Development

Paper 1

Tackling Tricky Transitions: A Two-Wave Qualitative Study on International Graduates' Employability Development During the School-To-Work Transition

Di Dong, Svetlana Khapova & Jos Akkermans | Vrije Universiteit Amsterdam

Research goals and why the work was worth doing

Our goal is to investigate international graduates' employability development during the school-to-work transition (STWT). We focused specifically on international students as they likely face unique enablers and obstacles during this critical transition. With this qualitative study, we aim to more fully comprehend the role that cultures play in STWT in both the home and the study countries. Furthermore, by viewing it through the lens of sustainable careers (De Vos et al., 2020), it helps us better understand how graduates' context, time, and agency interplay to shape their early-career happiness, wellbeing, and productivity, allowing them to develop and lay the groundwork for future career development.

Theoretical background

This research applies the sustainable career perspective as a theoretical framework (De Vos et al., 2020; Van der Heijden et al., 2020), it emphasizes that the balance and alignment between three characteristics (happiness, satisfaction, productivity) is key to attaining a sustainable career. Moreover, the trend of career development is a lifelong succession, STWT as a starting point is important for emerging adults (see, e.g., Akkermans et al., 2021), especially international mobile graduates as a stepping-stone to advance their career development. Thus, it provides a unique angle to better understand the perception of this group during STWT.

Design/methodology/approach/intervention

The study adopts a two-wave qualitative research approach to inductively gather insights into international, specifically Chinese graduates' perceptions of employability and early career development. To obtain a profound understanding and preserve consistency in the result, interviewees were interviewed twice: approximately 6 months before graduation (when studying abroad) and 6 months after (when working in Europe and China). In total, we conducted 50 semi-structured interviews (25 participants who completed two interviews).

Results obtained or expected

Preliminary findings point toward two groups of graduates' career paths, which align with their initial career expectations and vision prior to graduation. Specifically, the group that planned to work in China successfully found jobs there, whereas the other group ended up working in the Netherlands as expected. Hence, their primary career goals and destinations were relatively stable across a 1-year period. Second, we uncovered what we term a " double transition ," referring to the STWT alongside a cultural transition. We found that the graduates who returned to China continued to retain the mentality they acculturated from western culture and perceived various aspects of a sustainable career. Finally, we preliminarily identified three patterns that reveal disparities in career-related orientations: proactive, indifferent, and passive orientations, which are influenced by international experiences and multicultural worldviews.

Limitations

First, we tracked Chinese graduates who received their degrees from Dutch universities one year later, therefore, did not investigate other European countries. It is necessary to research whether the perceptions and understandings will remain the same in other European countries. Second, the professional areas of the graduates were not specified. Because of the variations in organizations, positions, and personal objectives throughout the course of a career, it could be useful and adequate to investigate different industries in the future.

Research/practical implications

The study contributes to the STWT and sustainable career literature in two ways. First, we apply a career perspective to international mobile graduates and look beyond the educational or cultural transition. Specifically, we create a better understanding of how international mobility experience may be instrumental for the double transition, especially for their career establishment. Second, through a sustainable career lens, as contemporary careers are more unpredictable, our findings on international graduates provide insights into how individuals achieve their long-term career goals from a sustainable career perspective.

Relevance to the congress theme

This group of recent graduates acculturated with bicultural and multicultural backgrounds, equipped with new competencies and skills, could contribute to many professionals and promote more collaborations worldwide, thus in line with the congress theme, they also play an essential role in presenting and delivering the changes in the future, that is to say, our participants are the future of work.

Relevant UN SDGs

The research first replies to the UN SDGs: Achieving full and productive employability for young people and tied to international employment expansion and accelerating economic development globally. Second, our study group complements the strengthening of the international partnership for sustainable development by mobilizing, sharing, and exchanging their knowledge, expertise, and skills to support the accomplishment of individual sustainable development goals in the countries where they work.

Keywords: International Mobility, School To Work Transition, Sustainable Career Development

Paper 2

The Effect of Online Interventions Focusing on Different Aspects of Career Self-Management Motivation

Dawa Schläpfer, Francisco Wilhelm & Andreas Hirschi | University of Bern

Research goals and why the work was worth doing

The present study aims to provide new scientific knowledge on the promotability of Career self-management (CSM) behaviors through the systematic development and evaluation of career interventions. This study goes beyond previous studies by systematically manipulating proactive motivation states as theoretical key predictors of CSM behaviors. In this regard, three electronic proactive motivation interventions were developed.

Theoretical background

Consistent with Parker et al.`s (2010) model of proactive motivation, we propose that individual differences in the degree of engagement in proactive CSM behaviors arise through activating a person`s career-related motivation and that proactive motivation acts as the primary proximal predictor of CSM behaviors. Following Pinder`s (2008) definition of work-related motivation, we define CSM motivation as a set of energetic forces that originate from personal and contextual factors that drive the selection, intensity, and persistence of CSM behaviors. Thus, each intervention to promote one of three motivational states (i.e., can do, reason to, energized to) consist of personal and environmental factors.

Design/methodology/approach/intervention

To investigate whether the interventions can increase the three motivational states, a pilot study with a between-subjects design, consisting of three different intervention groups and an active control group, was conducted. Wang et al.`s (2022) indicate that at least two of the three motivational states should be activated to enhance engagement in proactive behaviors. Thus, for the main intervention study, using a repeated measures design, the newly recruited employees will complete several weekly assessments for three consecutive weeks. To deal with possible order effects of the interventions, we will use a complete counterbalancing design. We will conduct post-tests three weeks (Follow-up 1) and six weeks (Follow-up 2) after the final intervention week. This research design will allow us to (a) examine how the effects develop during the weekly intervention period and (b) to what extent the effects are sustainable over several weeks after the interventions.

Results obtained or expected

Preliminary findings of the pilot study show promising results for two of the three online interventions. Contrast analyses revealed that, while controlling for age, work experience, organizational tenure, and salary, the can do intervention significantly increased CSM self-efficacy $t(502) = 0.414$, $p = .048$, compared to all other conditions. The reason to intervention did significantly increase identified regulation $t(502) = 0.863$, $p = .049$, career goal clarity $t(502) = 0.726$, $p = .016$, and career goal commitment $t(502) = 0.61$, $p = .040$ compared to all other conditions. However, the intervention did not significantly increase intrinsic motivation $t(502) = 0.524$, $p = .244$, and self-transcendent career meaningfulness $t(502) = -0.305$, $p = .351$ compared to the other conditions. The energized to intervention showed no significant increase in high positive affect $t(502) = -0.359$, $p = .295$, and low positive affect $t(502) = -0.451$, $p = .155$

compared to the other conditions. We expect that the interventions focusing on motivational aspects of CSM may result in improved CSM behaviors, and more distal outcomes such as occupational wellbeing and career/job satisfaction.

Limitations

A common factor across all three interventions is that the method of expressive writing was used shorter than other studies used expressive writing (e.g., King, 2001; Lanaj et al., 2019), which might limit its effectiveness. Another limitation of the study was the use of a panel provider which might result different participants, and thus results, compared to self-selected intervention samples.

Research/practical implications

First, although recent research has broadly acknowledged the importance of CSM, how and by what means proactive CSM behaviors can be systematically promoted remains an important open research question (Hall et al., 2018). The study provides a theory-based online intervention that provides an integrative understanding of the nature of CSM behaviors. Second, the interventions assist adults in lifelong CSM, and empower employees to master their career-related challenges autonomously, enabling them to access and effectively use the full range of resources within themselves and their environment. Lastly, the three electronic proactive motivation interventions provide a deeper insight into the effectiveness of online interventions and create a more accessible, cost- and time-effective alternative to traditional face-to-face interventions.

Relevance to the Congress Theme

This research contributes to the congress themes “training and development” and “wellbeing” by studying how people can get motivated for lifelong career self-management within a changing work environment.

Relevant UN SDGs

The research contributes to the UN Sustainable Development Goals ‘good health and wellbeing’ and ‘decent work and economic growth’ by providing more insight into the career self-management process which could help employees build sustainable careers.

Keywords: Career Self-Management, Proactive Motivation, Sustainable Career Development

Paper 3

Desiring a Career Change: What's Next?

Roosmarij Clercx, University of Antwerp; Sofie Jacobs, Antwerp Management School; Ans de Vos, University of Antwerp / Antwerp Management School

Research goals and why the work was worth doing

Time and dynamics are core elements of careers (Akkermans et al., 2021; De Vos et al., 2021; Mayrhofer & Gunz, 2022). However, career transitions are mostly approached from a static perspective and therefore fail to capture how processes such as career decisions emerge and evolve over time (Fouad, 2021; George et al., 2022). Taking a dynamic perspective is important because it will enable us to understand why careers remain stable (Rodrigues & Guest, 2010) and why people fail to realize their desires (Verbruggen & De Vos, 2020). In addition, due to the focus on agency, the context in which careers develop is neglected (e.g. De Vos et al. 2021). The aim of this paper is to gain more insight in the different pathways that arise from the desire to realize an intra-organizational change, why people act (or fail to act) on this desire and how this is influenced by their context.

Theoretical background

The theory of career inaction explains the decision process of people that fail to act on their desire for a career change (Verbruggen & De Vos, 2020). The process consists of three phases (1) awareness (2) inaction and (3) recall phase. When people become aware of their desire for change, several inertia-enhancing mechanisms (i.e., short-term costs, fear, and high cognitive demands) make it more difficult to act on this desire. The mechanisms are more likely when the desire for change is vague, when it is perceived as a big step or when the timeframe to realize the change is long. In addition, experiencing high job embeddedness and norms of staying within the social context, also increases the inertia mechanisms.

In this research we focus on intra-organizational mobility. Due to the appearance of new types of careers (e.g., boundaryless and protean career Defillippi & Arthur, 1994; Hall, 2004) that emphasize individual agency, organizational careers have received less attention (Mayrhofer et al., 2020). However, organizations expect individuals to take more responsibility for their careers (De Vos & Cambré, 2017). It is interesting to study career inaction in this context as the responsibility to realize the desire for change is a key element of its definition (Verbruggen & De Vos, 2020). At the same time, there is critique on overemphasizing agency in careers (De Vos et al., 2021; Forrier et al., 2009). Therefore, we take both agency and structure into account by studying the decision-making process of individuals within their context.

Design/methodology/approach/intervention

We use a longitudinal qualitative research design in which we follow 30 employees who expressed a desire to make an intra-organizational change within two organizations that stimulate internal mobility but emphasize personal agency. During the timeframe of one year, we interview the employees three times, separated by six months. In the first interview, we first discuss the previous career and their desire for change in detail. The second interview looks back on their experiences in the past months and looks forward to the next months.

Results obtained or expected

At the moment, the second wave of interviews is being collected. The result of the ongoing analyses will be presented at the conference.

Limitations

The scope of the study is limited to 30 individuals within two organizations, which limits the generalizability of the study. Second, since the timeframe to realize the desire for change might vary (Verbruggen & De Vos, 2020), the timeframe of one year might be insufficient for some people to realize their desire.

Research/practical implications

We contribute to the literature in the following ways. First, we contribute by giving a prominent place to time in our study (Akkermans et al., 2021; De Vos et al., 2021; Fouad, 2021) and therefore contribute to theories that are inherently dynamic, such as the theory of career inaction (Verbruggen & De Vos, 2020). Second, we study poorly understood phenomena such as different forms of stable careers, career inaction (Verbruggen & De Vos, 2020) and intra-organizational careers (Baruch & Sullivan, 2022). Lastly, we contribute by considering both agency and structure in the career-decision making process (De Vos et al., 2021; Forrier et al., 2009).

Relevance to the congress theme

This research contributes to the congress theme by studying how people make career decisions and shape their career within a changing work environment.

Relevant UN SDG's

Lastly, the research contributes to the UN Sustainable Development Goal 'wellbeing' and 'decent work' by providing more insight in the career decision-making process which could help employees in pursuing their career desires and building sustainable careers and organizations in shaping their HR policies.

Keywords: Intra-Organizational Mobility, Career Inaction, Career-Decision Making

Paper 4

Facilitating Adaptation to Organizational Change Using Employees' Career Self-Management

Madeleine Haenggli, University Carlos III de Madrid / University of Bern; Sjir Uitdewilligen, Maastricht University; Ramón Rico, University Carlos III de Madrid

Research goals and why the work was worth doing

Organizational change research has mainly focused on the business and strategic aspects, neglecting employee-related factors and wellbeing outcomes (Trenerry et al., 2021). Particularly, there is a lack of knowledge about how employees' career self-management (CSM) behaviors can facilitate adaptation to organizational change and ensure sustainable career development and wellbeing. Furthermore, the literature lacks an understanding of the mechanisms driving these effects and potential boundary conditions. To redress these gaps, this study examines when and under which circumstances organizational change has positive versus negative effects on sustainable career development and employee wellbeing. Specifically, we investigate the role of employee CSM on employees' wellbeing, expecting positive relations between CSM and wellbeing outcomes over time.

Theoretical background

Work plays a vital role in employees' wellbeing. Nowadays, work not only provides sustenance and livelihood but serves as an essential source of meaning, personal fulfillment, enrichment, happiness, and satisfaction, which can be seen as principal elements of perceived wellbeing (Diener et al., 2018). However, recent changes in how we organize work profoundly affect employee wellbeing (Pereira & Romero, 2017), evoking fear of job loss and uncertainty about personal career development (Akkermans et al., 2021). Such significant events that occur in an individual's professional life can significantly impact their career paths (Hirschi, 2010), threatening sustainable career development (Akkermans et al., 2021) and, thus, wellbeing (Luhmann et al., 2012). Against this background, it is increasingly important to foster CSM as a vehicle to ensure wellbeing in our society (Hirschi et al., 2020). CSM is defined as "a process by which individuals develop, implement, and monitor career goals and strategies" (Greenhaus et al., 2010, p. 12) and is thus a powerful contributor to employees' wellbeing, serving both their own goals and those of the broader society and economy (Lent, 2018).

Design/methodology/approach/intervention

Data was collected during organizational restructuring at a large company in Switzerland at four measurement time points with time lags of 8 weeks between each survey. The final sample consists of 308 employees. Specifically, we investigate how trajectories of wellbeing outcomes develop from the begging of the organizational change over time, how individual differences influence these trajectories in prevention and promotion focus, and when during organizational change CSM may be more beneficial for these trajectories.

Results obtained or expected

The idea is that CSM buffers organizational change, as employees conduct CSM behaviors to better deal with changes, leading to more sustainable career development and, thus, increased wellbeing. Also, the frequency of CSM behaviors depends on employees' career focus (prevention vs. promotion focus). Employees with a promotion focus show more career-related activities, whereas those with a prevention focus maintain the same level over time.

Limitations

We exclusively relied on self-reports and cannot claim causality based on our time-lagged data.

Research/practical implications

This study is an important step forward, exploring employee CSM behaviors, sustainable career development, and wellbeing during organizational change and over time. This study identifies employee populations that are particularly vulnerable when faced with change and provides insights into factors that help employees adjust to organizational changes. Furthermore, we integrate critical theories and insights from (sustainable) career literature to provide the most inclusive model of factors that help individuals during a potentially disruptive period in their lives.

Relevance to the Congress Theme

As voluntary and involuntary changes in current work settings occur more frequently, our study contributes to the congress theme in several ways. First, the study provides important insights into how people cope with unexpected work events and what helps them to adapt successfully to maintain sustainable career development and wellbeing. Second, the study investigates the active role of employees in supporting a successful adaptation to organizational changes. Third, insights may become groundbreaking for organizations, policymakers, and career counselors to help individuals to pursue sustainable and healthy careers. Moreover, the study contributes to a better understanding of the impact of organizational change on employees' wellbeing, advancing a crucial research area.

Relevant UN SDGs

The study is in line with the following UN SDGs: Investigating what fosters individuals in dealing successfully with contemporary career dynamics and increasing their wellbeing levels as a result. Furthermore, our study provides insights into embracing the active role of employees in times of uncertainty, contributing to working conditions improvement.

Keywords: Career Self-Management, Organizational Change, Sustainable Career Development

Symposium S078

Harnessing the "Power of Us": The Importance of Social Identity in Pandemic, Emergency and Disaster Responders

Stefan Schilling, University of Oxford

science_practice

Pandemic, Disaster, and Emergency workers (e.g., firefighters, police officers, paramedics, healthcare workers, and disaster relief personnel) perform in a unique organizational context. For most, responding to extreme events is not their primary role and many have received only limited training for such eventualities (even dedicated disaster relief agencies such as the German Technische Hilfswerk (THW) or the Israeli Homefront command consist predominantly of volunteers or reservists with different day jobs). Yet, when they are called upon to respond, such personnel are routinely expected to operate in highly chaotic, unexpected, urgent, and dangerous situations, with their work having a wide-reaching impact on people's survival and livelihood, and the reduction of damage to local infrastructure. Given the high-risk environment and their unique responsibilities, such personnel often share a strong identification with their immediate team, and performance requires strict adherence to corresponding professional values, norms, and standard operating procedures of their organization. While identification between the organization and the team provides valuable resources for dealing with adverse experiences and can mitigate against negative mental health outcomes, strong identification with the team and differentiation from outgroups can have detrimental effects on collaboration across professional boundaries and can hinder effective disaster and emergency response. The inherent multi-sectorial complexity of most disasters, which requires effective interoperability, operational communication, and coordination across multi-disciplinary and multi-agency networks often highlight the limits of teams and organizations with strong group membership.

This symposium highlights the importance of the group and associated social identity processes for understanding the functioning of emergency services and the implications of the work on their employees. The present work provides both empirical evidence and practically innovative approaches to how social identity can be harnessed to improve mental health, interprofessional teamwork, and rescue operations. First, Neela Mühlemann will set the scene of the symposium by exploring the importance of firefighters' occupational identity for their well-being during active duty and after retiring from the fire service. Stefan Schilling will then present qualitative and quantitative evidence from the NHS COVID Teams study showing how social identification with their immediate team impacted healthcare workers working on COVID wards. The presentation will show that social identification with other ward members, social support as well as proximity with co-workers help to prevent ill-mental health above and beyond the preventative effect of training and preparation measures. Louise Davidson will move into the operational space, addressing how blue light personnel's occupational identities can create conflict and reduce joint teamwork. Simultaneously, harnessing and embracing a common superordinate identity as Pandemic Multi-Agency Response Teams (PMARTs) can be used to enhance multi-agency working. Finally, Tal Levy Diamenshtien will showcase – using her own experience in search & rescue operations – a practical innovation developed by the Israeli Disaster Response Unit, which utilizes a shared social bond between first responders and affected population to aid in the search and rescue effort and support the subsequent recovery and bereavement process. Finally, Prof. Alex Haslam, will pull the affective and functional threads together by discussing the impact of the presented empirical and practical contributions for future research.

By discussing how social identity processes within and between emergency services impact individual health, operational performance and multi-agency teamwork, the symposium is addressing several of the EAWOP 2023 themes, e.g.,

- how social identification can contribute to improved mental health and well-being by mediating stressors

- how social group membership can be utilized to increase collaborative working in an inter-professional environment

- showcase innovative practices to integrate affected populations in the S&R efforts and aid in their grieving process.

We conclude that the social identity approach is an appropriate theoretical lens to investigate the work in disaster and emergency services. Due to the nature of their work, social identities are central to the sense of self of personnel in these organizations and are an important source of social support, a sense of belonging, and guidance in facing adversity at work. The present work highlights the importance of identification processes across multiple emergency service organizations (e.g., police, fire, rescue service, etc.) and contributes to our understanding of the impact of intra- and intergroup dynamics in the contexts of emergency and disaster response.

discussant: Alex Haslam, University of Queensland

Paper 1

Firefighters' occupational identity: A cure and curse for their health and well-being

Neela Mühlemann, University of Greenwich

Research goals and why the work was worth doing: The work of first responders to emergencies (e.g., firefighters, police officers and other member of the emergency services) is threating, dangerous, and demanding. Work in these high-risk occupations are considered to be stressful and linked to a range of adverse psychological outcomes, for example depression and anxiety. The purpose of the present research was to provide insights into the role of firefighters' occupational identities in preventing or promoting ill-mental health.

Theoretical background : Because firefighting is an occupation that can be characterized by teamwork, camaraderie, and strong identification, there is likely a shift from the personal towards the social (group) level of identity. Thus, the social identity approach is appropriate in an analysis of firefighters' health. This theoretical approach makes the fundamental point that social group membership (e.g., being part of a work or occupational unit or team) can provide valuable resources to cope with adversity. At the same time, if an important identity is lost, it can have detrimental effects on individuals' health. The core research question that the study aims to address is: How can variables of social connectedness be managed to foster individual resilience of firefighters to deal with adverse experiences at work and in retirement and how group-based resources can prevent them from ill-mental health.

Design/Methodology/Approach/Intervention : Qualitative data from 20 in-depth, semi-structured interviews were conducted with retired firefighters. Participants reflected on their work as firefighters and discussed the importance of their occupational identity for their life in retirement.

Results: Thematic analysis indicate that firefighter identity very central to firefighters' sense of who they are and provides valuable resources for coping with adverse experiences at work. However, retirement is experienced as identity loss associated with missing a sense of meaning in life among retired firefighters and left them socially isolated in retirement.

Limitations : The number of participants was rather small, and findings of the qualitative study based on only twenty interviews.

Conclusions – research and or practical implications : Thus, we conclude that the occupational identity plays an important role for firefighters during their work life and beyond in retirement. The centrality of their strong sense of belonging to the occupation and the fire service has important implications for their mental health and well-being. By managing this important occupational identity and the associated group dynamics, fire services and their leaders can help their employees to sustain good health despite the adversities they experience in their work and the aftermath.

Relevance to the Congress Theme : The change from working to retired life can be considered as a major challenge. What the future hold for firefighters after leaving the Fire Service depends on their ability to manage the identity transition. The research demonstrates that identity management is key for a bright future and good health in retirement.

Relevant UN SDGs : The research contributes to our understanding and the promotion of good health and wellbeing.

Keywords: Firefighters, Social Identity, Well-Being

Paper 2

"Built out of the horror of what we were seeing" – Teamwork, Social Identity and Social Support as predictors of menta health outcomes in interprofess

Stefan Schilling, University of Oxford; Nik Steffens, University of Queensland; Neela Mühlemann, University of Greenwich

Research Goals and why the work was worth doing: We aim to examine how non-technical factors for healthcare delivery (e.g., teamwork, preparedness, communication, shared mental models), social identification and social support by family and colleagues' impact on the mental health of interprofessional healthcare staff working on COVID-19 wards. Given the increase of deployed personnel during COVID, and the fact that individual augmentees in other occupational contexts repeatedly report higher rates of negative mental health outcomes (Cucciare, Mengeling, Han, Torner, & Sadler, 2020; Ursano et al., 2017), it is important to assess the enduring effects on staff members least prepared for – or experienced in – emergency and critical care environments.

Theoretical Background: The multi-symptom pathology of SARS COV-2 required the quick integration of personnel from different disciplines, with varying degrees of intensive or acute care experience and little or no preparation or training, into COVID-19 wards. While recent studies highlight negative mental health outcomes in Health Care workers during the COVID-19 pandemic – with one recent UK study reporting that 39.5% of ICU personnel exhibited signs of probable PTSD and up to 80% struggled with stress, anxiety and exhaustion (Greenberg et al., 2020; Neil Greenberg, 2020) – little is known about the impact of different levels of occupational experience, preparedness, and training on such mental health outcomes. Furthermore, despite pre-pandemic evidence of the beneficial impact of social factors (e.g., social support, social identification with the team, and teamwork) on mental health of healthcare personnel, little research has focused on such factors during COVID work. Considering these difficulties, this ESRC funded and NIHR adopted research aims to understand the impact of preparedness, training, teamwork, social identity, and social support during long-term high stress work on frontline personnel from different care pathways and professions.

Design/ Methodology: The study will present some qualitative interview data from Phase 1 and quantitative data from Phase 2 of the NHS COVID TEAMS Study, which surveyed 458 permanent and deployed NHS Healthcare personnel from 18 NHS trusts working in wards treating Covid patients (e.g., ITU, respiratory HDU, COVID rehab unit). The survey contained standardised measures (GHQ-12 (Goldberg & Hillier, 1979), PCL-C 6 (Lang & Stein, 2005) to test prevalence of PTSD, NHS Burnout Scale, DRRI-2 Social Support Scale (Affairs et al., 2016; Vogt et al., 2013) and the 4 item Social-Identification Scale (Doosje et al., 1995; Drury et al., 2015; Veelen et al., 2015). Additionally, the survey tested for teamwork, preparedness and COVID work stressors and experiences.

Results obtained or expected: Results from linear regression analysis show that deployment had no significant effect on mental health outcomes, whereas social identification with other ward members, social support (from both family and colleagues) as well as proximity with co-workers helped to prevent negative mental health outcomes in IP personnel above and beyond technical trainings and preparation measures. The findings indicate that technical trainings preparing personnel on Covid-wards could prevent ill-mental health (PTSD, Burnout) to some extent, but group dynamics within the teams played a crucial role in helping them to deal with adversity at work.

Limitations: The data was limited to cross-sectional data of UK personnel deployed during COVID and as such may not be generalizable to other healthcare systems.

Conclusion: The results show that beyond training personnel for technical and non-technical skills factors social identification with the team, proximity to co-workers and social support significantly reduce negative mental health outcomes. This suggests that healthcare services need to invest more into developing identification with the work-team, provide for more opportunities for social exchange and enhance social support. The research project has relevance for the nation-wide response to future pandemics as well as to localised emergency and disaster relief efforts requiring ad-hoc fluid teamwork.

Relevance to Congress theme: This research expands upon preliminary work conducted on individual health outcomes during the initial stages of the COVID-19 pandemic, by systematically analysing the enduring impact of teamwork, social identification, and social support upon psychological outcomes of medical staff at the front line of the COVID response. By addressing the impact of social identification in healthcare personnel the study is highly relevant to practitioners by emphasising not only the need for training and preparedness of healthcare staff, but also highlight the importance of team integration to increase interprofessional collaboration and teamwork.

Relevant UN SDGs: This research contributes to UN SDGs 3 and 11. By providing recommendations for the training and professional development of healthcare staff, and the organisational structure within hospitals, we hope to support the development of resilient and effective hospitals and healthcare providers. By supporting the health and well-being of healthcare staff, this research is not only relevant to ensure healthy lives by providing effective patient care, but it also informs how to structure, lead, and manage rapidly amalgamated healthcare staff in future disaster, pandemic, and emergency situations.

Keywords: Healthcare Workers, Covid-19, Social Identity

Paper 3

A social identity perspective on interoperability in the emergency services in the UK: Understanding how police officers, firefighters, and paramedics

Louise Davidson, University of Sussex and the UK Health Security Agency

Research goals: Incident inquiries and reports highlight the need for better understanding of multi-agency emergency response, specifically the social interactions that take place in the process of dealing with major incidents. With this in mind, we sought to understand, from a psychological point of view, how multi-agency response teams operate and the possible role of shared identity in facilitating effective multi-agency working. More specifically, the aims of this study were to identify:

Was there any evidence of a shared identity between responders?

What factors facilitated or challenged effective multi-agency working?

If there was a sense of shared identity, was this linked to any of the factors that facilitated or challenged effective multi-agency working?

Theoretical background: Previous research shows there are persistent challenges with multi-agency response centring on problems of communication and coordination. To better understand this challenge, the Social Identity Approach provides an important psychological framework for analysing relations within and between groups which can be used to understand why challenges in multi-agency response occur, and what can be done to prevent them re-occurring in the future. According to this approach, as well as defining themselves, and behaving in terms of their personal identity as individuals, people can, and often do, define themselves and behave in terms of their social identity, as members of social groups. Subsequently, this sense of shared social identity can improve joint working.

Methods: Semi-structured interviews were conducted with 14 responders from the police, fire, and ambulance service in the UK who were involved in the Pandemic Multi-Agency Response Teams (PAMRT) during the initial months of the COVID-19 pandemic. These teams responded to suspected COVID-19 deaths in the community. Interviews were transcribed and analysed using thematic analysis.

Results: Results show that responders appeared to share the pre-existing superordinate identity of all being members of the blue-light service . This identity was made salient as a result of responders experiencing positive contact with each other. Responders also shared the situational superordinate identity of PMART which was both created and made salient through positive contact with each other, as well as responders sharing difficult experiences. Results show that these factors that are linked to responders' social identity, also worked to facilitate multi-agency working. At the same time though, structural factors, such as inequalities in building access and different shift patterns increased the salience of sub-group identities in ways that created conflict between these identities, as well as operational challenges for joint working.

Conclusions: There was evidence of a sense of shared social identity between responders in the multi-agency teams and this sense of shared identity was linked to factors that facilitated joint working. Yet, factors that appeared to create challenges for joint working were present when salient or sub-group norms were salient or conflicting with each other. These findings point to the relevance

of the Social Identity Approach to the analysis of multi-agency working during emergency response, and to ways in which insights from this approach can inform efforts to improve this in the future.

Relevance to congress theme: This research contributes to the development of new competencies when it comes to multi-agency emergency response. Applying social identity processes to multi-agency response provides both researchers and practitioners a greater understanding into why challenges in joint working persist. This research not only gives us an insight into this, but it also provides specific practitioner recommendations to make this work accessible to the emergency services and to facilitate changes in collaboration between the services to happen. Through this research, we aim to open emergency responders' eyes and minds to a different way of thinking about collaboration in the hope that change will happen, joint working will be improved, and ultimately lives will be saved.

Relevant UN SDGs: This research contributes to UN SDGs 3 and 16. By providing recommendations for improved joint working in the emergency services, we hope to help build effective and accountable emergency services who serve the public. If we can improve the way that responders are able to work together and prevent the persistent challenges reoccurring then this can help save lives as well as helping minimise the extent of harm faced by individuals who are casualties in major incidents. Whilst conducted in the UK, we believe this research has transferrable lessons which can be utilised by responders across the world.

Keywords: Emergency Responders, Covid-19, Social Identity

Symposium S080

The implications of incivility on employee well-being, personal life, and work outcomes

Paolo Yaranon, University of Limerick

science

What will be covered and why : In today's competitive world, the growing interdependency of jobs and people has made organisations rely on positive exchanges between employees to foster effectiveness and productivity. Indeed, work is a social endeavour. However, a greater part of work stressors is socially related (Sonnentag & Frese, 2013). Mild and ambiguous deviant behaviours, such as incivility, are prevalent in the workplace (e.g., Sliter et al., 2013). Although there is compelling evidence to suggest that uncivil behaviours can have adverse effects on employee well-being and that incivility can originate from individuals across all levels in the workplace, our understanding of the differential impact of experiencing incivility from colleagues and people external to the organisation (e.g., customers) is lacking. Furthermore, the increase in the use of digital technology for communication, such as e-mails, has increased the ambiguity of interpersonal interactions. Uncivil exchanges can also happen online, but the impact on well-being and how it can spill outside work is yet to be investigated. In this symposium, we present four studies related to these gaps in the literature. The first paper (Argote & González-Morales) is a bibliometric review which provides a summary of empirical research to date on workplace incivility. The second paper (Yaranon et al.) investigates the differential impact of insider versus outsider sources of incivility on employee well-being and how individual differences in personal resources can potentially mitigate its adverse effects. The third and fourth papers look at incivility exhibited online via e-mails. In a two-sample study, Bernuzzi et al. explore whether uncivil e-mails from colleagues directly and indirectly (through techno-distress invasion) relate to work-to-private life conflict and emotional exhaustion. Finally, Sommovigo et al. experimentally examine the mediating mechanisms and the boundary conditions associated with how and when a single episode of e-mail incivility may trigger the intention from the recipient to reciprocate with an uncivil e-mail.

Relevance to the Congress Theme : Workplace incivility is a social stressor. The studies indicate that this deviant behaviour can happen in person or via online communication. Therefore, this symposium relates to the conference theme as it focuses on issues related to the changing nature of work, communications, and interpersonal relationships at work.

Research/Practical Implications : Combined, the four studies in this symposium provide evidence that incivility is a significant issue in the workplace and has implications for scholars and practitioners. First, it provides a picture of the current landscape of incivility literature, which should guide scholars in future investigations. Second, it offers novel evidence by adopting a comprehensive approach that considers different sources of incivility and their differential impact. Third, it provides new insights into an emerging topic, cyber incivility. Thus, it helps us understand the mechanisms by which incivility can penetrate personal life and shows interactional injustice as a key process that explains why and how incivility can proliferate at work. Based on the issues emerging from this symposium, organisations and practitioners must develop the necessary steps and interventions that aim to curtail the propagation of incivility in the workplace.

Overall Conclusions : The research in this symposium indicates that, although characteristically mild, these deviant behaviours can have negative implications on employee well-being, personal life, and work outcomes. Therefore, organisations should not underestimate the impact incivility can do and emphasise the significance of respect and professionalism at work.

Intended Audience : Academic, Practitioners

Keywords: incivility sources, e-mail incivility, well-being

Paper 1

Workplace Incivility: A Bibliometric Review

Nohelia Argote & M. Gloria González-Morales | Claremont Graduate University

Research Goals and Why the Work was Worth Doing : Workplace incivility is defined as a low-intensity deviant workplace behaviour with ambiguous intent to harm (Andersson & Pearson, 1999). Using a bibliometric review approach, the primary contribution of this study is providing scholars with a better understanding of workplace incivility research and directions for the field to move forward our understanding of this important phenomenon.

Theoretical Background : This paper analyses more than 20 years of scientific research on workplace incivility using a bibliometric approach to create an overview of the field, determine relationships among different concepts, identify primary authors, and explore the intellectual structure of the field. Both reviews and meta-analyses are great tools to summarize previous research (e.g., Cortina et al., 2017; Chris et al., 2022), but bibliometric reviews provide an additional holistic picture of the field without having to focus solely on specific studies that demonstrate exact relationships between constructs (Raghuram et al., 2010). Bibliometric analysis is a widely accepted and rigorous method for analyzing extensive amounts of scientific studies (Donthu et al., 2021) that we use to answer the following research questions: (1) What is the current structure of the workplace incivility field? (2) What are the theoretically and practically relevant future directions for research in the workplace incivility field? (3) Who are the key contributors to the workplace incivility field?

Methodology : We used VOSviewer, a free software, to construct and visualize bibliometric networks (Van Eck & Waltman, 2010). Study 1 involves a bibliographic coupling analysis, study 2 is a co-word analysis, and study 3 is a co-author analysis. Bibliometrics methods are quantitative in nature, and they allow researchers to provide descriptions and evaluations of scientific fields; they allow transparency and structure not afforded by other traditional types of reviews (Zupic & Čater, 2015) and when collecting primary documents for reviews bibliometric methods aid in avoiding subjective bias (Anand et al., 2020).

Results : The bibliometric coupling analysis allowed us to determine the structure of the current workplace incivility field. We determined that the field primarily focuses on the antecedents and outcomes of experienced incivility. We can also see other kinds of incivility explored (e.g., witnessed and enacted incivility). The coupling analysis also shows that first respondents and service workers are a primary area of interest. Regarding this area, one of the main focus areas is customer incivility and how it affects employees. We also identified an emergent area of study: cyber-incivility, defined as incivility through electronic forms of communication such as e-mail.

The co-word analysis results aligned with the major themes found in the coupling analysis: keywords were related to contributing factors and outcomes of workplace incivility and cyber-incivility as an emergent area study.

Lastly, co-authorship analysis identified the major contributor in the field, Lilia Cortina, conducting the first quantitative empirical studies on workplace incivility and introducing the selective incivility theory. Other primary contributors to the field, are women academics, such as Dana Kabat-Farr, and Vicki J. Magley, among others.

Limitations : A bibliometric analysis uses the number of citations that two publications have in common as a semantic measure between them. A limitation of this analysis is that it is impossible to determine why a publication is cited multiple times based exclusively on this procedure.

Conclusions : This study provides new insights into research trends. The three opportunities for future research are (1) exploring enacted incivility and victimization mechanisms further, (2) exploring workplace incivility at the team and organizational level, and (3) further exploring interventions that counteract incivility.

Relevance to the Congress Theme : This study contributes to the congress topic “The Future is Now: the changing world of work” as it provides new directions in the field of workplace incivility related to the changing nature of work towards remote and hybrid modes, in which cyber-incivility may occur and needs to be studied in terms of virtual challenges and opportunities.

Relevant UN SDGs : Workplace incivility is a prevalent problem in organizations and institutions that affects the health and well-being of workers around the world, especially those with unprivileged identities (i.e., selective incivility theory), contributing to inequality and lack of decent work. The study of workplace incivility is related to the following UN SDGs: Good health and well-being; Decent work and economic growth; Gender equality; Reduced inequalities. Overall, the study aligns with the Peace, justice, and strong institutions goal.

Audience : Scholars

Keywords: Bibliometric Analysis, Incivility, Bibliometric Coupling

Paper 2

The Effects of Insider and Outsider Sources of Incivility on Teachers' Well-being. Can Personal Resources Mitigate the Impact?

Paolo Yaranon, University of Limerick; Janine Bosak, Dublin City University; Deirdre O'Shea, University of Limerick

Research Goals : Workplace incivility refers to mild and discourteous behaviour, to which the clarity of its intention to harm another person can be vague (Andersson & Pearson, 1999). However, due to the instigator's low intensity and unclear intent, the harmful effects of workplace incivility are often overlooked compared to other forms of workplace mistreatment. Therefore, the goals of the present study are two-fold. First, it aims to examine how incivility experienced from colleagues (i.e., insider incivility) versus people outside of the organisation (i.e., outsider incivility) differentially relates to burnout. Doing so represents a significant step forward within the incivility literature as it will provide a deeper understanding of the distinct impact of these sources. Furthermore, investigating each source alone cannot address the many nuances of how incivility can impact employee well-being. Second, it also aims to advance our understanding of how individual differences in personal resources can influence the effects of incivility on employee well-being. Specifically, we investigate how personal resources (i.e., resilience and self-efficacy) can potentially minimise the positive relationship between experienced incivility from organisational insiders versus outsiders on burnout.

Theoretical Background : Drawing on the Job-Demands Resources Model (JD-R; Demerouti et al ., 2001) and Conservation of Resources Theory (Hobfoll, 1989), we propose that employees appraise these uncivil exchanges as job demands and stressors to their well-being. As such, episodes of uncivil interactions are stressful events which can harm well-being and lead to burnout symptoms such as feeling emotionally overwhelmed, detachment from others at work, or reduced personal accomplishment (i.e., health impairment process). Moreover, we also propose that self-efficacy and resilience can potentially alleviate the effects of experienced incivility from insider and outsider sources on well-being.

Design : Using a lagged design, we distributed and collected surveys online separated by two weeks from 205 primary, secondary, and special education teachers in Ireland. We measured insider incivility (i.e., perceived incivility from colleagues), outsider incivility (i.e., perceived incivility from students' parents), trait self-efficacy, and trait resilience at time 1. In addition, we assessed burnout at time 2.

Results : Path analyses indicated that both insider and outsider sources of incivility predicted burnout. However, both self-efficacy and resilience were not effective buffers. Although we found a significant interaction between insider incivility and resilience in predicting burnout, findings showed that the positive relationship between insider incivility and burnout was stronger at high levels of resilience. At the same time, it was weaker for low levels of resilience. These findings were contrary to our predictions and previous investigations.

Limitations : The study utilised self-report measures that retrospectively asked participants about areas such as experienced incivility from their colleagues, the parents of their students and their well-being during the past working week.

Conclusion : In the context of the present study, it showed that experiencing incivility, regardless of the source, was positively related to burnout. Although incivility from students' parents (i.e., outsider

sources) impacts well-being, teachers may be accustomed to these uncivil behaviours and consider such interactions part of their job. Additionally, parents do not influence the day-to-day work of teachers, unlike their colleagues. Considering that teachers work closely with their fellow teachers (i.e., insider sources), it makes sense that incivility from them impacts their well-being and disrupts the workplace norms of respect and professionalism. As for the potential moderating roles of personal resources, neither self-efficacy nor resilience were effective buffers on the relationship between experienced incivility and burnout. This further suggests that personal resources alone are not enough to tackle the adverse effects of incivility on well-being.

Relevance to the Congress Theme : The present study adds to the topic of communication and relationships by identifying the distinct effects of experienced incivility from colleagues and people outside the organisation on employee well-being. Hence, it should assist practitioners in changing the work landscape by finding effective ways to minimise workplace incivility and improve interpersonal relations among workers.

Relevant UN SDGs : Good health and well-being

Audience : Both scholars and practitioners

Keywords: Incivility Sources, Personal Resources, Burnout

Paper 3

Exploring the costs of co-workers email incivility on employees' wellbeing and personal life: A two-sample study

Chiara Bernuzzi, University of Pavia; Deirdre O'Shea, University of Limerick; Ilaria Setti, University of Pavia; Valentina Sommovigo, Sapienza, University of Rome

Research goals : This research aimed to explore whether co-worker email incivility would be directly and indirectly (via techno-distress invasion) related to work-to-private life conflict and emotional exhaustion among affected employees. By pursuing this objective, this research contributes to the existing literature on cyber-incivility and technostress.

Theoretical background : Email represents a crucial and ubiquitous form of communication in the workplace (McCarthy et al., 2019). Evidence showed that employees spent up to 28% of their working week addressing e-mail-related issues and 6.3 hours per day communicating via email (Aljawarneh et al., 2020). This is expected to increase due to the ever-increasing adoption of remote working arrangements following the COVID-19 pandemic. While the use of email represents a faster and more effective way to communicate in the workplace, it can be a "double-edged sword" as it may pave the way to email incivility (i.e., behaviours that violate workplace norms of mutual respect exhibited in email-mediated interactions; Lim & Teo, 2009). Although the literature on this topic is still in its infancy, there is evidence that email incivility can trigger negative emotions (Zhou et al., 2022) and sleep problems (Yuan et al., 2020). Email incivility can also be associated with negative job-related outcomes, such as greater employees' distress at work and at home (Park et al., 2018), and work withdrawal (Park &Haun, 2018). Given the increased use of email for job-related communications and the costs associated with email incivility, further scientific knowledge on this topic is essential to effectively counteract its potentially harmful effects.

Design : Two studies were conducted with 199 Italian (Study 1) and 330 English (Study 2) workers. Research participants completed online questionnaires that measured prior experiences of email incivility from co-workers, techno-distress invasion, work-to-private life conflict, emotional exhaustion, average weekly working hours, and socio-demographic variables.

Results : In both studies, employees who reported co-worker email incivility were more likely to experience work-to-private life conflict and emotional exhaustion. These relationships were partially mediated by techno-distress invasion so that employees who experienced co-worker email incivility were likely to perceive that their personal life was invaded by technologies and then develop higher levels of work-to-private life conflict and emotional exhaustion.

Limitations : This cross-sectional study used self-report measures only. Data to compare e-mail incivility with in-person incivility were not collected.

Conclusions : Unlike most previous studies that focused on email incivility from supervisors, this study adds to the literature on incivility by concentrating on co-worker email incivility and showing its detrimental effects not only on employees' well-being but also on their personal life. Moreover, even if the previous literature confirms the crossover effect of cyber-incivility on spouses' work withdrawal (Park & Haun, 2018), this research helps understand through which mechanisms receiving an uncivil email from a co-worker may spill over to the personal life domain. This suggests that organizations should provide their employees with training about time and email management as well as adopting family-friendly practices by recognizing the "right to disconnect" Organizations

should also set ‘‘netiquette’’ codes to provide their employees with rules about writing emails in a civil tone, facilitating positive interpersonal online-based interactions. Organizations should consider inform their managers about the costs associated with email incivility so that they can act as role models for civil email communications at work. Additionally, training programs that increase employees’ awareness of the tendency to misinterpret online-based communications and knowledge of the harmful effects of incivility may also represent helpful interventions to mitigate incivility in the workplace.

Relevance to the Congress Theme : Interpersonal interactions via email are becoming increasingly common to the extent that the rising number of emails sent and received per day is forecast to grow to over 376 billion by the year-end 2025 (The Radicati Group, 2021). This may represent a fertile ground for the rise of email incivility episodes at work. Therefore, by demonstrating for the first time that co-worker email incivility is related to techno-distress invasion and then to work-to-private life conflict and emotional exhaustion among affected employees, this study enriches the scientific literature on the topic and encourages practitioners to adopt work-related intervention aimed to reduce the incidence of this kind of rudeness.

Relevant UN SDGs : Good health and wellbeing.

Keywords: email incivility, emotional exhaustion, techno-invasion

Paper 4

Explaining target-specific reactions to email incivility from colleagues: An experimental examination of mediating and moderating factors

Valentina Sommovigo, Sapienza, University of Rome; Deirdre O'Shea, University of Limerick; Francesco Montani, University of Bologna-Rimini; Ilaria Setti, University of Pavia; Monica Magrone, University of Bologna-Rimini; Chiara Bernuzzi, University of Pavia

Research goals : In recent years, email incivility (i.e., uncivil behaviours exhibited in email-mediated interactions) has become an ever-increasing concern in the workplace as most employees refer to experiencing rude email communications at work. However, despite the progress achieved in this research field, research has disregarded whether, how, and when a single episode of email incivility may trigger the intentions of an email recipient to reciprocate with uncivil online communications. Shedding light into how and when employees negatively react to email incivility is nonetheless crucial to formulate preventive measures that help companies reduce the likelihood of downward spirals of interpersonal behaviours. This study aims to experimentally examine the mediating processes – i.e., justice perceptions – and moderating conditions – i.e., individual values and goals – associated with the influence of the incidence of email incivility from a colleague on target-specific email uncivil reactions.

Theoretical background : Based on social exchange theory, we theorize a two-stage moderated mediation model in which interpersonal justice mediates, and individual uncertainty avoidance values and compassionate goals buffer, a negative indirect relationship between the incidence of email incivility from a colleague on target-specific email uncivil reactions. Precisely, we argue that respondents to uncivil email would cognitively interpret the email-mediated interaction as interpersonally unjust and, thereby, would be motivated to reciprocate by engaging in email incivility toward the sender of the rude email. However, holding high uncertainty avoidance values would help people reappraise the meaning of email incivility, preventing the emergence of negative justice perceptions. Moreover, holding compassionate goals would enable “victims” of email incivility to maintain a sense of interpersonal safeness and connection that prevents the likelihood of reciprocated uncivil reactions to interpersonal injustice.

Design : A total of 199 Italian (Study 1) and 330 English (Study 2) research participants completed questionnaires that included an experimental task manipulating email incivility levels through imaginative emails to create three conditions (civil, neutral, uncivil email). In both studies, interpersonal justice perceptions, uncertainty avoidance cultural values, and sender-directed email incivility intentions were analysed. In Study 2, we also collected data on employees’ compassionate goals.

Results : In both studies, the manipulation check confirmed the effectiveness of our experimental manipulation. Respondents in the uncivil (versus civil) email condition were likely to reported higher engagement in email incivility toward the sender of the rude email through the mediating role of interpersonal justice perceptions. However, this relationship was stronger for employees who had high scores on the individual-level cultural dimension of uncertainty avoidance (Studies 1 and 2). Moreover, even a single episode of email incivility motivated uncivil reactions toward the colleague-sender of the rude email (Study 2), especially when the employee-recipient of the email had high uncertainty avoidance levels and, simultaneously, low compassionate goals (Study 2).

Limitations : This cross-sectional study relied only on self-report measures.

Conclusions : The present findings contribute to extend prior research on email incivility, which had primarily focused on the direct impact of supervisor uncivil emails on subordinates' reactions. Our findings highlight co-worker email incivility as a specific form of uncivil behaviour leading to reciprocated email-mediated incivility intentions and discloses interactional injustice as a key process explaining why and how such a downward spiral of negative interpersonal behaviours arises. Moreover, our results shed new light on the boundary conditions associated with these negative effects by showing that the ambiguous intent of email incivility may be differently interpreted based on individual-level cultural values, and that compassionate employees are less likely to reciprocate email incivility. From a practical standpoint, organizations should set clear norms concerning acceptable and unacceptable emails. The topics of email incivility should be incorporated into formal training programs to make employees aware of potential misperceptions/biases in online communication. Online etiquette training may be useful to educate workers about the proper ways to interact through ICTs, while compassion meditation could have the potential to reduce employees' uncivil reactions.

Relevance to the Congress Theme : This study extends the topic of communication and relationships by disclosing how and when a specific incidence of email incivility from a colleague would lead to more target-specific uncivil reactions to colleagues as entities.

Relevant UN SDGs : Good health and wellbeing.

Audience : Both practitioners and academics

Keywords: email incivility, uncertainty avoidance, compassionate goals

Symposium S082

The State of Work and Organizational Psychology: Critical Investigations of our Scientific Field and Practice: PART I

Matthijs Bal, University of Lincoln

science

What will be covered and why (including the contribution of any discussant)

THIS IS PART 1 OF A DUAL-SYMPOSIUM CONSISTING OF 2 PARTS, IN TOTAL 7 PRESENTATIONS AND A DISCUSSANT.

Is Work and Organizational Psychology in crisis? Previously, scholars have drawn the attention to the important issues that we face as a scientific discipline, such as the relevance of our work (Bal et al., 2019; Highhouse et al., 2020). There are multiple indicators that we desperately need to pay attention to the research we conduct in our field (e.g., Bal & Dóci, 2018), but also to the way we organize as academic field and as universities more broadly (Bal et al., 2019). As academics, we are often struggling to maintain ourselves and our positions in academia, facing the burnout crisis and the rapid rise of precarious employment in academia. This 2-part symposium brings these important topics together, and presents a wide range of new perspectives on our field, including an assessment of the responsibilities we have as academics to build a sustainable system, the need to decolonize our curriculum in order to make WOP truly global, a discussion of the role of social class in our profession as work psychologists, the need to organize our conferences differently, a study of the publication patterns and authorship inequality in WOP over the last 60 years, and finally, an empirical study on the state of WOP in Italy. The symposium contributions answer questions about how we can enact upon our responsibilities as academics, how we can be more responsible educators, how we can be more critical of our own positions in our field, and how we can better organize conferences in our field.

Jointly, these presentations offer a wide perspective on the state of our field, elucidating the nature of our field as problematic such that there are a variety of aspects to our work which need to be improved substantially. This includes the way we organize our publication system, our professional values, and the ways we organize our institutions such that not only high-quality research and teaching can be conducted, but also such that our well-being as academics is protected.

The presentations all give insights into the problems faced by our WOP system, and all offer ways out of the current situation. Thereby, the 2-part symposium not only offers insights into the problems we face as a field, but also showcase the future of our field, and the ways we can collectively improve our field, and make it more sustainable for our colleagues and students.

Finally, the discussant Yvonne van Rossenberg (Radboud University Nijmegen, the Netherlands), has the experience to put the presentations into perspective, and will provide specific reflections upon the policy implications of the set of presentations in the dual-symposium. Van Rossenberg has a wide interest in the state of WOP research, and has ample experience in researching the state of the field, and evaluating hegemonic practices in the field.

Relevance to the Congress Theme

The symposium has great relevance for the theme of the conference. While sessions and presentations at the EAWOP conference often focus on the content of our work, we tend to forget about the structures and institutions that we have developed to make our research and teaching

possible. The current symposium is crucial as it draws the attention to the system we are in, and thus how we can change our own institutions for a more sustainable future. Moreover, if we are able to change our own institutions, we can also show the ways through which the world of work can be changed, and how organizations may engage in change processes for a more sustainable future.

Research/Practical Implications

The symposium will have important implications for both research and practice. First, the contributions show how we can study our own field, why it is important, and why self-reflection and reflexivity is crucial in maintaining (the relevance of) our field. Moreover, the various presentations show the ways future research in WOP and about WOP can be conducted. Finally, the session has important practical implications, in the ways through we can maintain our system and how we can organize the WOP field, and organize sessions at conferences. We will discuss policy implications in particular, and with special focus on the

Overall conclusions

This symposium aims to highlight the various problems that we face as a scientific discipline in both the ways we conduct our research and maintain our publication system, but also how we uphold our professional values and teach our students. Overall, the symposium offers anyone in the field an engaging session in which we debate the state of our field and how we can make our field more sustainable for the future.

Keywords: State of WOP, Critical Reflections

Paper 1

The recommendations for sustainable future of Work and Organizational Psychology are worth it: initial evidence for the of FoWOP measurement in academ

Amalia Perez-Nebra, University of Zaragoza; Solange Alfinito, University of Brasilia; Edgar Reyes Júnior (in Memoriam), University of Brasilia

Research goals and why the work was worth doing : Although the recommendations for sustainable future of Work and Organizational Psychology (FoWOP) (Bal et al., 2019) had a great impact, there was no measurement of how much those practices are worth. This work aims to propose and show evidence of the validity of a scale to measure post-graduate students' perceptions of their supervisors' FoWOP practices.

Theoretical background: Post-graduate students could be considered as entry careers into academia. Students' perception of their supervisors' academic practices influences their behaviour in many ways: as models to follow, the learning process and achievement, and to support /disapprove them/us. The perception of employee RHM Practices field showed similar results and has categorized three main conceptualizations to employee perceptions of RH practices (Van Beurden et al., 2021): exchange, communication, and occupational health. The former category provides a framework for understanding the quality of exchange. The second describes how the practices can contribute to achieving performance. The last category of theoretical perspective focuses on explaining employee wellbeing. The integrated perspective to explore the practices improves the operationalization of students' perception of FoWOP practices and was used.

Methodology: We conducted a systematic, multi-study scale development. Using the Manifesto 10 recommendations for a sustainable future for the field of Work and Organizational Psychology, we generated items and conducted an expert panel (N=5) and one survey (N = 70; 25 tutors).

Results obtained or expected: Face and content validity were examined through a jury of experts who evaluated clarity and appropriateness of each item. To verify the internal validity a preliminary exploratory factor analysis was conducted and showed 3 emerging factors: Exchange (e.g., he/she gives me regular feedback on the work I did and shows me how I should do things), Communication (e.g., he/she is accessible - the communication is easy) and Health (e.g., engages in open dialogue with me to find sustainable ways of learning, wellbeing, health, and development). The average were quite high. The validity of construct and criterion were examined through correlation analysis with the relative growth of the supervisor citation (i.e., the percentage of growth/decrease between 2021 and 2020 using the Scholar Google metric). The Health dimension is the most positive related to citation growth.

Limitations: A cross-sectional study design, one post-graduation program in Brazil and sample size are the main limitations of the study.

Conclusions – research and or practical implications: The present study proposes an instrument to measure the degree of FoWOP practices within the academic context and also the relationship with external validity (citation growth index) suggesting that FoWOP practices facilitate a win-win HRM perspective.

Relevance to the Congress Theme: FoWOP practices represent the first instrument that measures FoWOP recommendations, and it may contribute to a positive and sustainable necessary change in academic work.

Relevant UN SDGs: Good health and wellbeing; decent work and economic growth; Quality education

Keywords: Manifesto, FoWOP

Paper 2

Reengineering HE Education through Decolonization: A Postcolonial perspective

John Mendy, University of Lincoln

Research background

In 'The future of work' Gratton (2011) examined 5 economic, technological, demographic, individualistic, energy and societal forces that will reshape the future world of work. Eleven years on, her predicted changes on individuals' adaptability skills, networking capability and the prioritization of life have been overtaken by greater consumerism and the decolonization debates in HE. Likewise, the extent to which her recommendations for organizations' leaders to be transparent and authentic, to develop partnerships, to network, to be socially interconnected and to enhance flexible working, teams have still not highlighted why the anticipated high-performance capability of institutions such as Universities has still not been fully achieved through reengineering initiatives (e.g. decolonization). This study focuses on the urgency to address such a gap by examining and problematizing not only UK-wide but also global HE institutions' sudden push to decolonize their curricula by modifying the contents, methodologies and personnel required to deliver quality education for the workplace of the future.

Research goals and why the work was worth doing

Who defines and what framework(s) do we use in charting the quality education for the future.

What type(s) of education is/are required in workplaces of the future.

Whom and what purpose does the decolonization agenda serve.

Theoretical anchor

The theoretical anchor for this presentation is postcolonial theory partly because I seek to problematize and situate its variety of narratives to understand issues of inequality within the decolonization of higher education worldwide. Postcolonial theory arose as a chronological sequence from colonization but, more fundamentally, it captures the significant resistance impact of the experiences of millions of people across the Americas, Africa and Asia and over a 400-year time span. It forms part of an increasing body of critical debates and analytical frames that seek to capture the differences, nuances and reverberations of colonial trajectories in various countries, continents and societal spheres. This set of theoretical engagements highlight the criticality with which academics, researchers and practitioners in the Social Sciences surface the socio-cultural, the economic and political legacy of colonialism and conquest and the impact of human and territorial subjugation, exploitation and control. From here postcolonial theoretical analysis and discourse was created to help study the deep underlying power relations of people interactions, cultures, histories and organizational and national dynamics.

Although the theory accommodates different approaches, from the anthropological that highlights understanding and knowledge of the colonial colonizer-colonized interactions to the narrative that highlights the experiences and stories of those who were colonized to a deeper appraisal of the socio-economic, political and cultural structural interactions that have maintained and nurtured the colonial and even neo-colonial discourses and narratives over the centuries. It is the latter approach that resonates with the interdisciplinarity of the theoretical selection and its justification given its

ability to describing and appraising incidents/cases of an historic, anthropological, scientific, political, geographic, philosophical, sociological and philosophy nature. By extension, other scholars have used the theory and its inherent approach to investigate and understand complex issues around ideology, gender and sexuality issues and religion.

Design/Methodology/Approach

The study's methodological design is based on an initial examination of a cross section of what Universities in the UK have been doing to decolonize their teaching, learning, research contents. The aim is to develop an epistemology on the future of higher education to ascertain its capacity to provide a toolkit that meets the challenges related to Gratton's and FoWOP's future of work agenda. To do so, the narratives of participants will be used for verifiability, for discussing ethical, philosophical and morality issues that may have constrained what participants perceive as good quality and liberalising forms of education in a post-colonial world of work and education. Additionally, the narrative accounts are used to understand and develop knowledge on what really captures the individual, collective, national and international identities of educators, researchers, policy makers and beneficiaries of the decolonization of education. This is taken from the following:

a) The processes via which implementers of a decolonized educational programme acquire socio-economic, cultural and political knowledge of those onto whom the decolonization programme is being implemented for.

b) How changes to the education programme are being conducted as part of a reengineering discourse and their impacts on implementers and recipients.

This design was chosen because it provides intellectually safe spaces for people, who would otherwise not have the opportunity, to converse openly and freely on matters of significant future impact. By so doing, they project their voices, perspectives and opinions, thereby articulating/producing their own socio-economic, political, philosophical and cultural discourses. This produces a more balanced, yet nuanced presentation that highlights the varieties of structural, processual and human power dynamics that would have been negated in the traditional bi-polar, binary implementer (in a position of powerful 'colonizer') and recipient (in a position of non-powerful 'colonized') relation (see Said's (1978) discourse analysis in his seminal work 'Orientalism' and Bhabha's (2012) cultural hybridity and its potency for socio-political change).

Preliminary Results

The initial results highlight the following categories:

Universities that show commitment to decolonizing their curriculum by mentioning it in their strategy or curriculum.

Universities that decolonize their curriculum by making amendments to various modules' reading lists without amending their contemporary or future pedagogic contents.

Universities whose imperial and colonial infrastructures in terms of institutional and knowledge development processes remain intact.

Universities that conduct training and development for students, academic and administration staff

Universities that choose not to do anything in relation to decolonizing their infrastructures or contents

Universities that consult minoritized and marginalized communities that may have been adversely impacted by curricula that were received from colonial past.

Relevance to Congress

This study on decolonization within the HE context is significantly relevant research and fits the theme of the congress.

Relevance to UN SDGs

This study is relevant to tackling issues of lack of inclusion, poor attainments and poor achievements that may have been the outcomes of a non-decolonized teaching, learning, research infrastructure of HE institutions. Future work will entail an expansion of the study to other HE institutions within and beyond Europe and to develop a toolkit for actualizing a greater democratization of HEI spaces, contents, methodologies and infrastructures.

Keywords: Higher Education, Decolonizing, Curriculum

Paper 3

Observations on (un-)conferencing: How science fails to communicate knowledge

Johanna Degen, University of Flensburg; Franziska Koessler, Humboldt-Universität zu Berlin; Francesco Tomassi, University of Verona

The aim of this study is to a) understand the effectiveness of scientific communication at conferences, b) map and evaluate conference organizers' measures for innovation and successful communication of research, and c) analyze the scholarly reactions to such measures and their effectiveness.

In the globally growing neoliberal ideology, sciences too underlay quantitative aims, measuring researchers against numbers: the worth equals many papers placed well and the number of talks given. Such quantitative measures and newer scientific traditions of publishing limit the communication of research and knowledge to specific forms, monotone in style and confined in scope. This leads to growing scientific fatigue – talks and papers seem redundant and the communication of knowledge is impended.

Contemporary attempts of conference organizers at breaking such logics aim for post-qualitative ways of research, including new ways of communication. Besides remaining in the margins and located largely in neighbouring fields, such attempts include labelling events as “unconferences”, including buzzwords such as “un-keynote” and presentations called “a virtual salon”. Observing such conferences we can learn, besides single and pleasurable exceptions, one awaits the new, artistic or innovative in vain. Covered behind fancy wording the repetitive style is sometimes even accelerated, with prolonged pre-recorded monologues, not seldom enough followed by the audience asking: Can you summarize in short, what you try to say?

The data collection was conducted by three researchers as ethnographic participatory observation studies and interviews during seven conferences during the years 2021 and 2022. We collected both the organizer's theorization and visions, logged presentations following a standardized protocol, and conducted problem-centered interviews. Moreover, we logged planned interventions, such as a “bell of boredom” and kept protocol of effects on group dynamics and styles of presentation. The data is analysed using discourse analysis.

the preliminary results demonstrate that organizers emphasize strongly new orders of communicating scientific knowledge and research, urging for creativity and innovation. Such attempts are built up in the calls for contribution, the offered formats of presentation, wording, and the digital architecture of conference websites, e.g. by building online surroundings for data sharing and games. The researcher's realization instead holds largely on to traditional presentation styles, overwriting new formats against the formal guidelines and visions. At the same time, growing fatigue from attending such contributions is expressed by the audience, verbally in the interviews, and visible by body-language, e.g. groaning or writing emails, making explicit that communication at the conferences is failing. Such situations are reportedly demotivating for both attendances and contributors.

This study is limited due to the case study design, stretching between the field of work- and organizational and social psychology.

While un-conferencing is much needed, the implementation still leaks behind. Tradition is holding a grasp around science, and more seems needed than a changed label. What does it take to break tradition and year-long conditioning? In this presentation, we will give examples of successful un-conferencing and post-qualitative ways of communicating knowledge, followed by a discussion, on how we envision communication in the future to avoid scientific fatigue.

Study and results are directly related to the EAWOP congress theme and questions on how to communicate eminent new knowledge and how to constitute contemporary work- and organizational sciences in a changing world and future, including effective knowledge transfer. It moreover shares positive blueprints of successful knowledge transfer and communication of significant scientific work and results, securing knowledge flow for the future, alongside concrete examples.

Successful communication of scientific work and knowledge is applicable to most of the UN SDGs, as it regards WOPs scientific communication in general.

Symposium S083

The State of Work and Organizational Psychology: Critical Investigations of our Scientific Field and Practice: PART II

Matthijs Bal, University of Lincoln

Science

THIS IS PART II OF A DUAL-SYMPOSIUM CONSISTING OF 2 PARTS, IN TOTAL 7 PRESENTATIONS AND A DISCUSSANT.

What will be covered and why (including the contribution of any discussant)

Is Work and Organizational Psychology in crisis? Previously, scholars have drawn the attention to the important issues that we face as a scientific discipline, such as the relevance of our work (Bal et al., 2019; Highhouse et al., 2020). There are multiple indicators that we desperately need to pay attention to the research we conduct in our field (e.g., Bal & Dóci, 2018), but also to the way we organize as academic field and as universities more broadly (Bal et al., 2019). As academics, we are often struggling to maintain ourselves and our positions in academia, facing the burnout crisis and the rapid rise of precarious employment in academia. This 2-part symposium brings these important topics together, and presents a wide range of new perspectives on our field, including an assessment of the responsibilities we have as academics to build a sustainable system, the need to decolonize our curriculum in order to make WOP truly global, a discussion of the role of social class in our profession as work psychologists, the need to organize our conferences differently, a study of the publication patterns and authorship inequality in WOP over the last 60 years, and finally, an empirical study on the state of WOP in Italy. The symposium contributions answer questions about how we can enact upon our responsibilities as academics, how we can be more responsible educators, how we can be more critical of our own positions in our field, and how we can better organize conferences in our field.

Jointly, these presentations offer a wide perspective on the state of our field, elucidating the nature of our field as problematic such that there are a variety of aspects to our work which need to be improved substantially. This includes the way we organize our publication system, our professional values, and the ways we organize our institutions such that not only high-quality research and teaching can be conducted, but also such that our well-being as academics is protected.

The presentations all give insights into the problems faced by our WOP system, and all offer ways out of the current situation. Thereby, the 2-part symposium not only offers insights into the problems we face as a field, but also showcase the future of our field, and the ways we can collectively improve our field, and make it more sustainable for our colleagues and students.

Finally, the discussant Yvonne van Rossenberg (Radboud University Nijmegen, the Netherlands), has the experience to put the presentations into perspective, and will provide specific reflections upon the policy implications of the set of presentations in the dual-symposium. Van Rossenberg has a wide interest in the state of WOP research, and has ample experience in researching the state of the field, and evaluating hegemonic practices in the field.

Relevance to the Congress Theme

The symposium has great relevance for the theme of the conference. While sessions and presentations at the EAWOP conference often focus on the content of our work, we tend to forget about the structures and institutions that we have developed to make our research and teaching

possible. The current symposium is crucial as it draws the attention to the system we are in, and thus how we can change our own institutions for a more sustainable future. Moreover, if we are able to change our own institutions, we can also show the ways through which the world of work can be changed, and how organizations may engage in change processes for a more sustainable future.

Research/Practical Implications

The symposium will have important implications for both research and practice. First, the contributions show how we can study our own field, why it is important, and why self-reflection and reflexivity is crucial in maintaining (the relevance of) our field. Moreover, the various presentations show the ways future research in WOP and about WOP can be conducted. Finally, the session has important practical implications, in the ways through we can maintain our system and how we can organize the WOP field, and organize sessions at conferences. We will discuss policy implications in particular, and with special focus on the

Overall conclusions

This symposium aims to highlight the various problems that we face as a scientific discipline in both the ways we conduct our research and maintain our publication system, but also how we uphold our professional values and teach our students. Overall, the symposium offers anyone in the field an engaging session in which we debate the state of our field and how we can make our field more sustainable for the future.

Paper 1

Six decades of organizational research: Authorship inequality, elite dominance, and the inevitable rise of eminent scholars

Mehmet Orhan, EM Normandie Business School; Yvonne van Rossenberg, Radboud University Nijmegen

Research goals and why the work was worth doing: Ideally, the academic publication process should be meritocratic and, at the same time, fair and accessible to diverse groups of scholars. Yet, many scholarly disciplines are far from this ideal state, as many voices are believed to be underrepresented. To explore the extent and nature of authorship inequality in organizational research, we examined 60 years of publication trends in Industrial-Organizational Psychology (IOP), Management (MNGT), and Human Resource Management (HRM).

Theoretical background: Drawing on the economic theory of income inequlity and Mertonian scientific norms, the impact of authorship inequality on scientific progress is discussed.

Design/Methodology/Approach/Intervention: Analyzing over 55,000 publications in 42 top journals of these fields, we reviewed authorship inequalities in the last six decades.

Results obtained: Based on the publication records of more than 3,000 of the most prolific researchers, we identify a stronger dominance of a small cluster of researchers in IOP compared to MNGT and HRM. Analysis shows the most prolific IOP researchers publish a significantly larger number of articles than those in other fields. Besides this excessive number of publications, the super-elite of IOP are found to be dominating more journals, as we observe a higher frequency of the same authors appearing on the top-10 most productive list in IOP than in the other two fields.

Limitations: Our analyses were based on top-tier journal publications. Considering the wide range of scientific communication options, authorship inequality might be overstated in top journals.

Conclusions – research and or practical implications: We conclude by discussing the impact of inequality and dominance of a scholarly elite and provide recommendations for future practice and policy.

Relevance to the Congress Theme : 4 – Diversity and inclusion – Equal opportunities

Relevant UN SDGs: Reduced inequalities. Reducing inequalities in societies is one of the primary goals of UN.

Keywords: underrepresentation, hyperproduction, scientific elites

Paper 2

On Reproduction of Form in WOP Research

Matthijs Bal, University of Lincoln

Theoretical Background

Why do we as academics collectively (and individually) produce so many papers? Why are so many papers published in our field and top journals so boring to read? In this paper, we set out to analyze academic research practices in WOP research drawing on the construct of Reproduction of Form. Reproduction of form is the reproduction of the authoritative ideological discourse, while the meaning attached to individual terms grows ambiguous (hypernormalization), is paradoxical and, eventually, devoid of meaning. Based on work of the Russian-born anthropologist Yurchak (2005), reproduction of form was the mechanism used by the Soviet Union after the death of Stalin to control public discourse in society. All communication by the Soviet government (newspaper, cultural symbols, propaganda) perfectly reproduced discourse from the Stalin era, in order to maintain stability and ideological rule over society. However, over time, this discourse became increasingly meaningless. Drawing upon Yurchak's work, we identify reproduction of form in contemporary academic research, whereby we observe how papers and academic research are reproductive in their form, and what ideological meanings this has, and what paradoxes emerge out of this hyper-reproduction of academic research.

We identify three dimensions of reproduction of form, at the level of form, content, and ideology. We proceed by analyzing the authoritative discourse underpinning these elements, their constative dimension. In so doing, we describe the performative and constative dimensions of these paradoxes, and connect the ideological and the practical level of reproduction of form.

New Perspectives/Contributions

Our use of Reproduction of Form to understand the contemporary WOP publication system is entirely new. While reproduction of form is often prescribed by journals and editors themselves (e.g., through the requirement to shape submissions to a journal in a particular style), this is associated with an increasing uniformity in how journal papers look like and what they describe. One primary consequence is the lack of pluralism in WOP, which is accentuated through the continuous stylistic reproduction within academic papers. The content-dimension takes this reproduction of form one step further, by analyzing the 'theoretical contribution' that is proclaimed as the primary requirement to get published in WOP. However, analyzing what is expected reveals that contributions should be incremental enough to fit with the journal, and are implicitly expected to reproduce the more hidden, and ideological assumptions under research. Thereby, hegemonic theorizing within journals dictates authors to comply with the ideological underpinnings of journals and the work published in journals, ultimately stifling scientific progress.

Finally, the systemic dimensions underpinning reproduction of form further support ideological status-quo. While authoritative discourse in academia proclaims that publishing is a fair competition and that academia is a collective and collaborative space, in reality, academia and the publishing process is dominated by a small group of elite scholars who take up an unfair amount of space in journals. Consequently, this exacerbates the status-quo as elite scholars, who have priority access to journals, tend to defend the ideological status-quo and disincentive critique on hegemonic practice within WOP. This leaves the young and early career scholar in a position of dependence on the elite,

as the early career scholar has fewer chances to publish original work (deviating from the prescribed norms) in journals, and thus to develop an academic career. Increasingly, the road for early career scholars is to comply with the system, collaborate with elite scholars, thereby being allowed access to the system.

Conclusions

We conclude the paper with identifying different ways of dealing with the reproduction of form. We advocate for pluralism, elite scholars to publish less, renewal of the publication system, and open review processes, whereby publishing becomes less dependent upon the approval of the elite into the restricted space of top-tier journals. We identify problematization, resistance, imagination and transformation as four subsequent steps that may help academics to escape the current system, and to contribute to a healthier and more sustainable publication system.

Relevance to Conference theme

The conference theme relates to the future of our field, and the future is bleak. This paper shows how our field has stifled scientific progress. Therefore, it is of great importance to understand how Reproduction of Form unfolds in WOP, such that we can actually create a more sustainable field of WOP that has real meaning.

UN SDGs

This paper is about equality in society, and the chances for academia and scientific research to contribute to this.

Keywords: Reproduction of Form, Academia, Research

Paper 3

Investigating the Italian academic movement toward future directions of Work and Organizational Psychology

Mara Gorli, Marta Piria, Sara Petrilli, Silvia Gilardi, Laura Galuppo & Chiara Corvino | Università Cattolica di Milano; Daniela Converso, Università di Torino; Andreina Bruno, Università di Genova; Angelo Benozzo, Università della Valle d'Aosta; Luca Vecchio, Università Bicocca di Milano; Silvio Ripamonti; Francesco Tommasi, Università di Verona

Introduction and conceptual background

As scholars of work and organizational psychology, we are all aware that contemporary workplaces and organizations are radically changing, bringing about new challenges for people and their relationship with work. Our discipline responds to such challenges by taking different positions concerning organizational research and interventions. Various approaches are supported by different and separate theoretical positions which affect the way of conducting research. This echoes in the organization and evaluation of the academic system. Mutually, academics and the academic system itself perpetuate the same ideological tenets.

This work aims to explore the way the Italian academic community of Work and Organizational Psychology (WOP) is adapting to new emerging contents and research objects, and to the contemporary conditions for conducting research and education in the university system.

Theoretical background

According to Bal and Doci (2018), the influence of neoliberalism is being felt not only in the workplace but also in how we do research and produce knowledge in our discipline. Current trends in how the academic activity is evaluated, in how research gets financed, and in how academic career tracks are constructed, have also transformed the nature of work and organizational psychologists operating in universities.

The risk is to acritically assume two out of the three tenets of neoliberalism: individualism and instrumentality (Harvey, 2005).

Perhaps as a reaction, some movements and some published Manifesto-works are appearing both in the psychologists' communities and within the organization scholars' groups, calling for a (more) sustainable future for the discipline and the communities (Bal et al., 2019; Korica 2022; Benozzo et al 2021; Kudina et al 2022).

Research goals and why the work was worth doing

Based on this reading of the context, the study we present aims to explore the research choices and practices adopted by scholars in the WOP sector in Italy, and their expectations and ways of envisaging the future. This study aims to contribute to the debate about the prevalent issues being investigated in WOP; the theoretical frameworks used to interpret the relationship between individuals and organizations; the space dedicated to macro-level societal issues such as inclusion and social inequalities.

Methodology

The work is based on two phases and different methodologies. In a first phase, we examined the scientific production of WOP scholars in the last ten years (2011- 2021), considering 1.941 “research products” (papers, book chapters etc) appearing within the Scopus database. The analysis digs into the kind and dimension of publication growth, the numerosity of co-authors and the typologies of journals chosen. Through the T-LAB software, we have analyzed and mapped the topics, interests, methodologies and contexts of the WOP community.

A second phase, a qualitative inquiry through explorative interviews, has been conducted into the community of researchers and professors in the Italian WOP sector for understanding approaches and evolutions of research objects, investments and publication choices during the academic career.

Thirty in-depth interviews were performed and then examined using thematic analysis.

Results obtained or expected

The research illustrates the results, which reveal the contradictions and divergences regarding assumptions, critical views, and objects of investigation within WOP.

The results help understand the scientific development of the discipline in Italy in relation to the more actual economic, social and political challenges, and the way they are tackled.

Furthermore, the analysis outlines some aspects of how neoliberalism is shaping the Italian WOP community members' work and offers interesting critical thoughts for debating and reflecting on the future of WOP.

Limitations

The study is directed to different geographical positioning of WOP scholars. For the scope and dimension of this study, we could not investigate the single contextual specificities of territories and institutional local investments, which are surely interesting to analyze for future works.

Conclusions – research and or practical implications:

The present study proposes a picture of an evolving field that deserves wide consideration for two reasons: it affects both the applied contribution of psychologists in helping organizations and workers cope with the current trends; and it sheds light on the state of the internal academic field as one broad organization whose workers (the scholars) themselves deserve care and critical attention for more sustainable working conditions.

Relevance to the Congress Theme

The future of WOP must be interrogated by taking into consideration both local perspectives, and more macro scenarios. The Italian context offers an interesting analysis of how specific, situated and contextual considerations may impact the evolution of the WOP discipline. At a macro scenario, the broad WOP community may benefit by considering multiple perspectives through which to understand and look at the future of the sector.

Symposium S084

What happens at work, stays at work…? How and when work experiences spill over into recovery time

Rosine Rutten & Ute Hülsheger | Maastricht University

science

In this symposium, we present five empirical papers that look into the relationship between experiences at work and experiences after work. As work is becoming more complex and the boundaries between work and life increasingly blur, it is important to understand the specific challenges of the modern work-life interface. Therefore, all five contributions focus on when and how employee recovery is affected by work factors, and together build on a shared understanding of how the impact of work on employee well-being can be successfully managed. The presented work hereby contributes to research on recovery, by 1) identifying work-related antecedents of recovery and well-being, 2) examining cognitive mechanisms through which work affects employees during their free time, and 3) providing insights that guide practical interventions aimed at improving work-life balance and recovery.

Julia Iser and her colleagues will present their work on supportive supervisor behaviors that could benefit employees' daily recovery from work. They conducted a daily diary study with a subordinate sample over the course of two workweeks (N = 171) that examined daily fluctuations in workload and supervisor work- and non-work support as predictors of vitality and recovery experiences. With this contribution, they add to the recovery literature by identifying daily work-related antecedents to recovery experiences during free time. Practically, they show how supervisors can positively influence their employees' recovery.

Rosine Rutten and colleagues posit that it is important to not only take past workday demands into account when examining recovery processes, but also consider upcoming work demands. In a typical workweek, workdays follow each other closely, with recovery from past demands and anticipation of future demands likely overlapping and accumulating. In a daily diary study (N = 166), they therefore examined the conjoint influence of past and future challenge and hindrance demands on evening fatigue, and the role of work prospection (i.e., future-oriented work-related thinking) in this relationship. They contribute to the recovery literature by drawing attention to the temporal context in which the stressor-strain reaction occurs.

Johannes Wendsche and his team take stock of and extend evidence on the link between unfinished work tasks and three types of work-related thoughts (detachment, negative rumination, and problem-solving pondering) during internal and external recovery periods. They will present four studies, including a meta-analysis, two cross-sectional studies, and a longitudinal study, which all focused on the extent to which unfinished tasks sparked work-related thoughts during free time and how this affected recovery. Furthermore, they investigated whether personal and organizational resources buffer any detrimental effects. Their work adds to the recovery literature by shedding light on the consequences of unfinished tasks for after work cognitive activity.

Anja Morstatt and colleagues investigate day-specific crafting patterns across life domains (i.e., work and private life), and more specifically, whether and how anticipating both high work and life demands, as well as crafting opportunities, may impact crafting efforts and subsequent recovery experiences. The study they will present employed an ecological momentary assessment methodology, with participants (N = 415) reporting on their experiences six times a day on six

working days across two weeks (10922 observations in total). They hereby provide new insights on how people navigate individual life challenges on a daily basis, both at work and at home.

Dana Unger and her colleagues propose that strict boundaries between work and private life helps employees detach from their work during their free time. In an experimental field study (N = 237), they investigated whether actively creating boundaries would positively affect recovery and work performance through increased detachment. Not only does this study advance the literature on boundary management by shedding light on the processes taking place during the transition from the work domain to the home domain, it also offers practitioners evidence-based information on the effectiveness of a low-cost intervention aimed at improving both recovery and work performance.

Together, these contributions demonstrate that research on recovery is far from parched and that various streams of research are motivated to support a harmonious and healthy work-life interface. The studies employ various research methods (i.e., experience sampling, experimental, meta-analytic, cross-sectional, and longitudinal designs) and integrate different theoretical perspectives. Together, they have the potential to further exploration and integration of recovery research and provide insights for evidence-based management practices for organizations and practitioners.

Intended audience: Academics and Practitioners.

Keywords: recovery, work-related thinking, boundary crafting

Paper 1

A work-home resources perspective on recovery experiences: The role of supervisor work and non-work support, workload, and subordinates' vitality

Julia Iser, Sabine Sonnentag, Hadar Nesher Shoshan | University of Mannheim

Research goals: The goal of our study is to identify supportive supervisor behaviors that could benefit employees' daily recovery from work. For that purpose, we examine supervisor nonwork support (i.e., supportive behaviors that help subordinates manage work and nonwork roles) and supervisor work support (i.e., support aimed at the work domain such as helping with work tasks) as predictors of recovery. Former research has mostly focused on identifying negative antecedents of recovery, such as work stressors. Our aim is to simultaneously look at resources (i.e., supervisor support) and demands (i.e., workload) as predictors of recovery experiences.

Theoretical background and hypothesis: Drawing on the work-home resources (W-HR) model (ten Brummelhuis & Bakker, 2012), we propose that work resources (i.e, supervisor nonwork support and supervisor work support) positively predict recovery experiences at home, while work demands (i.e., workload) negatively predict recovery. The W-HR model suggests that the associations between resources and demands with home outcomes are mediated by personal resources. Therefore, we examine employees' vitality (i.e., their energetic state) after work as underlying mechanism. In addition, we propose that the association of supervisor nonwork support, supervisor work support, and workload with recovery experiences is stronger on days when people work from home. Because people work in the home domain and lack segmentation between work and home, work demands and resources should have stronger effects on home outcomes (i.e., recovery experiences).

Design: We conducted a daily diary study with a subordinate sample over the course of two work weeks (171 employees, 871 days). After filling in an entry survey, participants completed daily surveys after work and before going to bed. We only included days in our analysis when employees had (virtual or face-to-face) contact with their supervisor.

Results: Multilevel path models revealed that supervisor work support was positively related and workload was negatively related to subordinates' vitality after work, vitality positively predicted recovery experiences, and the indirect effects of supervisor work support and workload on recovery experiences via vitality were significant. Working from home did not moderate the associations of supervisor work support and workload with recovery experiences. We found no support for the indirect effect of supervisor nonwork support on recovery experiences via vitality. However, supervisor nonwork support was positively related to subordinates' detachment, relaxation, and control on working-from-home days but there were no significant relationships on working-at-the-office days.

Limitations: Our study is not without limitations. First, we measured supervisor support from the subordinates' point of view and did not include supervisors as respondents in our sample. However, as the subjective perception of support should be especially relevant to influence employees' psychological experiences, we decided to focus on subordinates. Second, we measured both the predictors and vitality in the end-of-work survey. Nevertheless, because the predictors retrospectively assess factors at work, whereas vitality indicates how employees felt while filling in the survey, predictors and mediators are conceptually separated in time.

Implications: In conclusion, our study contributes to the recovery literature by identifying supervisor supportive behaviors as daily antecedents of employees' recovery experiences. Supervisor support can positively influence recovery from work either directly (on working-from-home days) or by fostering personal resources. We show that both supporting employees' with their work tasks and helping them manage their nonwork roles is associated with successful recovery from work. This knowledge can also be useful in practice: Supervisors can help their subordinates to recover from work by showing work and nonwork supportive behaviors.

Relevance to the congress theme: The congress theme "The future is now: the changing world of work" is reflected in our study because we are examining the moderating effect of daily working from home. The pandemic has greatly changed employees' daily work situations with more people than ever regularly working from home. Social interactions with supervisors during work time are therefore qualitatively different from pre-pandemic times. We capture the changing world of work by taking new perspectives on work and home into account.

Relevant UN SDGs: Our study contributes to the UN Sustainable Development Goal of health and well-being. By examining predictors of recovery from work, we seek to identify factors that can promote employees' well-being on a day-to-day basis.

Keywords: supervisor support, recovery experiences, working from home

Paper 2

I saw, I foresaw, and… I felt drained? How past and future work demands conjointly influence evening fatigue via work prospection

Rosine Rutten, Ute Hülsheger & Fred Zijlstra | Maastricht University

Research goals: While past empirical work stress research has mostly focused on the effects of past work stressors on employee well-being and recovery (e.g., Guthier et al., 2020), stress researchers in both work and non-work domains agree that stressors can affect employee well-being before, during, and after they are imposed (Verkuil et al., 2009; Casper & Sonnentag, 2019; Hülsheger et al., 2022). However, this has thus far been solely examined in a piecemeal fashion, with studies focusing on either past stressors or the anticipation of future stressors. More realistically, stressor-strain reactions occur in a temporal context (Rosen et al., 2020). In a typical workweek, workdays follow each other closely, with recovery from past demands and anticipation of future demands likely overlapping and accumulating. In the current study, we therefore consider both past and future work demands simultaneously. This enables us to partition variance in employee well-being stemming from either past or future work demands, and test whether mental representations of demands (i.e., work prospection) act as the mechanism through which work demands can affect well-being during free time.

Theoretical background: Drawing on cognitive activation theory of stress (CATS; Ursin & Eriksen, 2004; Meurs & Perrewé, 2011), we propose that both past day and next day work demands can drain employees' evening energetic resources (i.e., fatigue). CATS argues that it is not the stimulus itself that elicits the stress response, but an individual's appraisal that is based on both past experiences and future expectations that translates a stimulus into a stressful experience. We directly test this proposition by suggesting that work prospection – future-oriented thinking about work (Rutten et al., 2022) – acts as the appraisal process. More specifically, while past workday demands can directly affect evening fatigue due to depletion following effort expenditure (Meijman & Mulder, 1996), future work demands can only indirectly affect fatigue. We argue that both certain (e.g., planned meetings) and uncertain (i.e., unexpected interruptions, others' actions) elements of future work demands feed into the mental representations people have or actively construct about them. Furthermore, we expect that the effects of challenge demands will be more pronounced. Challenge demands are inherently more strongly linked to goals, and past findings showed that it is more difficult to detach from challenge demands than from hindrance demands (Bennett et al., 2018).

Design: We conducted a 14-day diary study on a working population (N = 166). Participants completed an intake survey, followed by daily after work and before bedtime surveys (2443 observations). We measured challenge and hindrance demands in the after work survey, and work prospection and fatigue in the evening survey.

Results: Multilevel analyses showed that both past day and next day challenge demands were positively related to work prospection in the evening, while we did not find these effects for hindrance stressors. In turn, work prospection was positively related to fatigue in the evening. Past work day challenge stressors were also directly and positively related to fatigue in the evening, in line with our expectations. These results are preliminary, but thus far partly confirm our hypotheses and show that especially challenge demands – both past and future – may spark work-related thoughts during free time, which in turn drains further energy.

Limitations: First, we assumed certain work demands as being challenging or hindering, but did not assess whether participants appraised them as such. Second, we measured work prospection and fatigue in the same survey. However, we ask for momentary fatigue and work prospection during the past evening, conceptually separating the measurements. Moreover, participants may have refrained from responding when demands that day were particularly high, which may have deflated our results.

Conclusions/implications: Our study shows that it is important to take into account both past and future work demands when considering the work demand – stress relationship. While employees are already tired after their workday, next day demands can cause them to think about work and instigate the stress response, drawing on their energy levels even further. Moreover, while challenge demands are typically seen as the more favorable type of work demand, our findings show that they can have detrimental effects on well-being.

Relevance to Congress Theme: Work is becoming more complex and employees are faced with high demands that require them to be proactive. Our study shows that employees do in fact think about their upcoming workday during their free time, which affects their fatigue levels. This can eventually impact workers' health.

Relevant UN SDGs: Our work contributes to the UN Sustainable Development Goal of health and well-being.

Keywords: work prospection, work demands, employee well-being

Paper 3

Unfinished tasks and work-related thoughts during recovery periods: The role of recovery resources

Johannes Wendsche, Federal Institute for Occupational Safety and Health, Department of Work and Health, Dresden, Germany; Annika Schulz, Ina Schöllgen & Andrea Lohmann-Haislah | Federal Institute for Occupational Safety and Health, Department of Work and Health, Berlin, Germany; Susanne Liebermann, FH Westküste University of Applied Sciences; Hiltraut Paridon, SRH Gera University of Applied Sciences; Oliver Weigelt, University of Leipzig

Research goals and why the work was worth doing : Research on how unfinished tasks as a work-related stressor may impair recovery has gained traction in recent years. Drawing on this line of research we set out to take stock of and extend evidence on links between unfinished tasks and three conceptualizations of work-related thoughts (WRT; low psychological detachment, affective rumination/negative work-reflection, and problem-solving pondering) during internal and external recovery periods. Furthermore, we consider leverage points for intervention and explore how personal (i.e. recovery competence) and organizational (i.e. organizational recovery climate) recovery resources shape these relationships.

Theoretical background : Recovery theories suggest that work stressors negatively affect cognitive recovery from work. This research has drawn on different conceptualizations of work-related rumination (i.e., different measures of WRT) – making integration across studies challenging. Many studies have focused on external recovery periods such as evenings or weekends. Based on more specific propositions from cognitive and motivational psychology, we study how unfinished work tasks relate to different aspects of WRT during internal (i.e., work breaks) and external (i.e., evenings) recovery periods. In addition, we extend these theoretical approaches and hypothesize that personal and organizational recovery resources, such as high recovery competence and a strong organizational recovery climate, are not only associated with lower WRT but also mitigate the detrimental effects of unfinished tasks.

Methods : In Study 1, we meta-analyzed relationships between unfinished tasks and WRT (k = 10, N between = 1208; N within = 8833). We collected further cross-sectional data in Study 2 and 3 (Ns = 154/164) on relationships between unfinished tasks, organizational recovery climate, recovery competence, and detachment in the evening and during work breaks (only Study 3). In Study 4 (N = 309), we collected longitudinal data over three waves (each 6 months apart) and considered, in addition to the variables in Study 3, negative work reflection and problem-solving pondering during work breaks and evenings as WRT outcomes. We analyzed data from Study 2-4 with structural equation modeling including latent interactions. In Study 4, we used latent difference score modeling to examine lagged between-person relationships and within-person change effects between unfinished tasks and WRT measures in combination.

Results : In Study 1, we found positive relationships (ρ s) between unfinished tasks and WRT (detachment, affective rumination, problem-solving pondering) both at the between-person (-.39, .45, .33) and the within-person-level (-.22, .43, .32). After including our data from Study 2-4, between-person-relationships emerged as independent from WRT conceptualization (-.35, .35, .36). In Study 2, we found a negative relationship between unfinished tasks and evening detachment that was no longer significant when adjusting for the positive relationship between recovery competence and detachment. In Study 3, we found a similar pattern for detachment during breaks but unfinished

tasks were not significantly related to evening detachment. Organizational recovery climate had neither direct nor moderating effects in Study 2 nor 3, and recovery competence did not moderate relationships between unfinished tasks and detachment. In Study 4, our results revealed positive person-level relationships between unfinished tasks and all WRT aspects six months later. Change-to-change relationships were widely not significant. However, a six-month change in unfinished tasks related positively to problem-solving pondering during breaks and evenings after that time. In line with results from Study 2 and 3, higher recovery competence related to less WRT six months later, independent from WRT conceptualization and recovery period, but interactions with unfinished tasks did not emerge. Moreover, we found some partial support for the protective role of a high organizational recovery climate when considering the relationships between changes in unfinished tasks and detachment and problem-solving pondering during breaks.

Limitations : Due to the limited sample, moderator testing had to be dropped in Study 1. Study 2 and 3 are cross-sectional and hence mute on causality. In Study 4, the long intervals between assessments might have affected our results.

Conclusions : Our study results show that unfinished tasks are positively and recovery competence is negatively related to different aspects of WRT measures during work breaks and evenings, especially when considering their more chronic and stable emergence. Perceived organizational recovery climate is largely not predictive of WRT and does not account for reactivity to unfinished work tasks in this regard.

Relevance to congress theme : About 30% of all European workers state that they have at least sometimes not enough time to get their job done. Thus, unfinished tasks at work are highly prevalent. Since a meta-analysis revealed that WRT relate to lower health and wellbeing, reducing unfinished tasks and increasing employees' recovery competence are relevant from a practical perspective.

Keywords: unfinished tasks, detachment, rumination

Paper 4

Anticipatory processes as predictors for day-specific crafting patterns across life domains and its consequence for the recovery process

Anja Morstatt, University of Zürich; Jessica de Bloom, University of Groningen; Georg Bauer & Philipp Kerksieck | University of Zürich

Research goals, why the work was worth doing and theoretical background : Crafting is considered a proactive strategy that enables employees to address their individual life challenges (de Bloom et al., 2020). In our study, we will address cognitive processes to explain why employees engage in crafting and how they reflect about their work and private life afterwards depending on the crafting effort taken. Specifically, we would like to transfer the idea of an anticipatory phase from coping research (Folkman & Lazarus, 1985; Lazarus & Folkman, 1984) to the crafting concept. In the context of stress and traditional coping research, anticipation has been discussed and investigated as an activating mechanism (Brosschot et al., 2005; Casper et al., 2017; Monat et al., 1972), but little is known about anticipatory processes when focusing on proactive crafting behaviors. We will consider anticipation in two ways: First, in a positive light, we will address whether employees anticipate daily crafting opportunities (e.g., timewise) and how this relates to their crafting efforts towards needs satisfaction (e.g., the need for mastery). Second, we will also address whether employees anticipate stressful life characteristics (e.g., high workload, high demands outside of work), which might lead employees to craft for needs satisfaction as a compensation. Further, we assess how these are then related to relevant health and performance indicators, e.g., job performance, or recovery, both in terms of recovery experiences and reflective processes at the end of the day. This is important because a more positive reflection of the work-domain is beneficial for the recovery processes of employees (Bono et al., 2013; Casper et al., 2018; Meier et al., 2016). Lastly, we will also investigate whether specific person characteristics, e.g., in general thinking more positive about stress and its outcomes (Stress Mindset; Crum et al., 2013) could explain differences in the intensity in which employees engage in daily crafting depending on their anticipation.

Design/Methodology/Approach/Intervention : We have collected intensive longitudinal data via an ecological momentary assessment study from May to July 2022. German-speaking employees from Germany, Austria, and Switzerland were surveyed six times per day on six measurement days (Mondays, Wednesdays, Fridays; schedule adapted to part-time workers) across two work weeks. We received survey responses from N = 415 participants (total of 10922 measurement). On average, participants filled out 26 of the 36 possible measurements (SD = 8.622). The final N will depend on further data cleaning. The data will be analyzed using multilevel structural equation modeling to account for the nested structure of such data (Schwartz & Stone, 1998).

Results obtained or expected: Results are currently unavailable and will be presented at the conference.

Limitations: Our study focused specifically on crafting behaviors across days and repeatedly asked participants to rate their extent of crafting multiple times per day. The measurement by itself might have led to self-reflective processes and measurement reactivity, altering the natural behavior of participants over the course of the study participation (French & Sutton, 2010). Additionally, this study will also focus on demand anticipation. Study participation was voluntary, which is why participants might have decided to not respond to survey invitations on working days with high demands, leading to a selective sample. Both limitations will be examined during data analysis.

Conclusions – research and practical implications: We add knowledge to the processes that possibly trigger crafting efforts and shed light on the general frequency and intensity of crafting efforts during the course of a workday. Further, we relate day specific crafting patterns across life domains with recovery from work, bridging the two research fields. This knowledge could direct future research to investigate suitable interventions e.g., incorporating anticipation exercises to motivate crafting behaviors.

Relevance to the Congress Theme: In a rapidly changing world, employees are faced more than ever with complex life challenges. Crafting is a suitable strategy to address such challenges and offers employees opportunities to act where top-down work design strategies might not be sufficient. In our study, we further bridge the field to recovery from work, which also becomes more important when life including work becomes more complex and demanding. Therefore, we conclude that to investigate the future of work, crafting and recovery should be focus topics.

Relevant UN SDGs: The study would be highly relevant for the UN SDG: “Good Health and Well-being”.

Keywords: recovery, work-life balance, job crafting

Paper 5

Creating Boundaries for the Better: An Intervention to Study how Boundary Creation Behaviors Relate to Well-Being and Work Performance

Dana Unger, UiT The Arctic University of Norway; Wladislaw Rivkin, Trinity College Dublin; Laura Venz, Leuphana University Lüneburg; Fabiola Gerpott, WHU Otto Beisheim School of Management

Research goals and why the work was worth doing: During the COVID-19 pandemic, many media outlets were happy to advise their audience to create boundaries between work and home. Drawing on boundary theory (Ashforth et al., 2000) and recovery research (Sonnentag & Fritz, 2015), we have indeed good reasons to assume that boundary creation behaviors might be beneficial for recovery and work performance. However, much-needed empirical evidence for this assumption is lacking. We contribute this evidence by shifting the research attention from how employees manage their boundaries while being in one domain to examining the actual transition between domains (see Cobb et al., 2022). In a field intervention study, we investigate whether boundary creation behaviors have a beneficial impact on recovery (i.e., detachment and energy states) and work performance.

Theoretical background: We define boundary creation behaviors as the enactment of strategies to actively draw a line between the end of one's working day and the beginning of one's free time. We integrate boundary theory with the stressor-detachment model to develop a conceptual framework that links boundary creation behaviors at the end of work with employees' recovery at home, same- and next-day energy states, and next-day work performance. Ashforth and colleagues' boundary theory (2000) postulates that individuals create boundaries between various spheres such as work and home. We argue that on days on which employees actively engage in boundary creation behaviors, they can draw firm lines between work and private life increasing the likelihood of detachment (i.e., being mentally away from work; Sonnentag & Fritz, 2015). Detachment should, in turn, improve employees' energy states on the same day (i.e., evening) and the next morning, which should have a positive effect on next-day work performance.

Design/Methodology/Approach/Intervention: We ran an intervention study across two subsequent workdays with 237 full-time workers in the United Kingdom who were recruited by Prolific Academic. We randomly assigned these participants to one of three conditions: Seventy-three people were in the boundary creation condition in which we asked them to deliberately create a boundary between work and free time (e.g., turn off all work-related equipment, clean their workspace, engage in a relaxing activity), 78 people were in the active control group in which we asked them to write down three good things that happened at work that day, and 86 people were in the passive control group (i.e., no intervention). The outcomes evening detachment, evening and next-morning energy states, and next-day work performance were measured on the same evening and the next day respectively.

Results obtained: Participants in the intervention group who actively engaged in boundary creation behaviors subsequently reported higher detachment in comparison to the active and passive control groups. Furthermore, we found indirect effects of active boundary creation behaviors on same- and next-day energy states as well as higher next-day work performance via detachment.

Limitations: First, we did not analyze whether some boundary creation behaviors are more beneficial than others. Second, we did not consider participants' personal preference for segmented (vs. integrated) work-to-home boundaries which might buffer the effect of the boundary creation intervention on detachment with its downstream consequences for energy states and work

performance. Finally, our research design does not allow us to study the role of time in the context of boundary creation behaviors. For instance, the effectiveness of these behaviors might rise with increasing levels of routinization.

Conclusions – research and or practical implications: We advance the literature on boundary management by shedding light on the processes taking place during the transition from the work domain to the home domain. Our field study informs evidence-based management decisions about the effectiveness of a low-cost intervention that has the potential to improve recovery and work performance to achieve organizational sustainability.

Relevance to the Congress Theme: With technological advancements and the emergence of hybrid work practices for larger parts of the working population, the work and leisure domains are becoming ever more blended. With physical boundaries ceasing to exist for telecommuters, employees must draw work-home boundaries themselves. We contribute to shaping the future of work by outlining how to facilitate this process.

Relevant UN SDGs: Our research advances the pursuit of Sustainable Development Goal “Good health and wellbeing”.

Keywords: boundary management, well-being, intervention

Symposium S085

Bionics and Robotics at Work: Consequences for Workers' Social Perception and Work Experience

Bertolt Meyer, TU Chemnitz

science

Labour within the contemporary world of work, still described with terms like Industry 4.0, Automation 4.0, or Work 4.0, is characterized by constantly advancing digitization and automation processes. Along with these processes, the use of (social) robotics and embodied digital technologies (EDTs) for restoring or extending the capabilities of their users is increasingly shifting into focus. These changes require investigating the the consequences of the shift towards hybrid societies characterized by increasing human-machine interaction. How are working and living environments changing through the use of such technologies? What opportunities and risks are associated with these developments for the working individual and the workforce as a whole? How must bionic instruments, technical assistance systems, and robotics be designed to offer the utmost acceptance while simultaneously providing the best performance and mitigating unwanted side effects?

The symposium, which originates from the Collaborative Research Center 1410 "Hybrid Societies" at TU Chemnitz, reflects those questions mirroring the conference's central theme and will address three significant developments regarding future work settings. The presented research approaches these questions from different angles and reports the first results of various studies focussing on the usage of bionic devices, human-robot interaction, and the specific use of social robotics in working environments. Further research questions will also be discussed and embedded in the context of current developments. Overall, the symposium comes with a two-fold thematic focus.

The first part of the symposium presents research regarding the use of bionic devices and their effects on social perception and feelings toward the users of such technologies. The initial presentation will focus on how the usage of bionic devices will influence social perception and behavior toward their users. The presented study addresses the user experience and the broader perspective of users of bionic devices for the first time, while also pointing out current difficulties when studying the phenomena due to the small number of eligible participants. The second contribution addresses this problem by presenting an augmented reality environment capable of simulating the use of bionic devices and thus enables experimental research regarding the effects of bionic devices on the self-and other perception.The presented system allows users to control a simulated EDT device, which makes experiments on perception more accessible and and allows to study users with no prior experiences regarding EDTs. To widen the scope of the symposium from restorative bionic devices to augmenting ones, the third speaker will present specific aspects on the comprehensive user experience of occupational exoskeletons from a design practice and research perspective. The presentation will highlight the meaning of "close-to-body" interaction for the users and the relation between the exoskeleton´s characteristics and users´ self-perception, and provide implications for design approaches of those devices..

The second part of the symposium will address topics apart from merging humans with technology and will focus on human-robot interaction against the background of the emerging use of robotics in various settings. With a focus on feelings and possible fears induced by robot coworkers, the fourth contributor will investigate how sociodigital self-comparisons with a robot influence the perception of threat and job insecurity. The final presentation will continue the outlook on human-robot interaction. It will widen the perspective while focusing on a specific but increasingly important aspect, the effects of social robots' perceived gender. The presented research will shed light on how

gender attributions may influence ascriptions, feelings, and behavior, such as the willingness to cooperate, towards social robots.

A concluding discussion opens the space for comments, identifies future research topics, and finally wraps up and reflects on the contributions to emphasize the relevance of well-designed EDTs for inclusive working environments, good working conditions, and thus for employees well-being.

Keywords: Robotics, Bionics

Paper 1

The Impact of Bionic Prostheses on Social-Perception from the Users' Perspective

Maximilian Bretschneider, Bertolt Meyer & Frank Asbrock | TU Chemnitz

Goals: Bionics can have a profound effect on the social perception of their users such that they are perceived differently in terms of warmth, competence, and morality (Bretschneider et al., 2022; Mandl et al., 2022; Meyer & Asbrock, 2018). Therefore, using restorative bionics will likely affect attitudes and behaviors toward their users. However, the user perspective still needs to be studied. The present study aims to gain more profound insights into how restorative bionic devices influence users' self-perceptions. We aim to shed light on the influence of using such technologies on the user's self-perception, meta-perception, and everyday experiences in social interactions. To realize these insights, we conducted an exploratory qualitative study.

Theoretical background: Recent studies (Bretschneider et al., 2022; Mandl et al., 2022; Meyer & Asbrock, 2018) address how others perceive users of bionic prostheses. This research is primarily based on the Stereotype Content Model (SCM; Fiske et al., 2002). The SCM proposes two fundamental dimensions, Warmth and Competence, across which others perceive groups and individuals. Additionally, the perception of warmth and competence elicits specific emotional and behavioral reactions (Cuddy et al., 2008). People with physical disabilities are typically perceived as warm and incompetent evoking pity and active facilitation as emotional and behavioral correlates (Asbrock, 2010; Fiske et al., 2020; Meyer & Asbrock, 2018). Users of bionic prostheses reclaim perceived competence while still being perceived as warm as people with physical disabilities (Meyer & Asbrock, 2018). Nevertheless, nothing has been said about the users perspective so far.

Method: We conducted semi-structured interviews and used a guideline prepared in advance and included all relevant topics. All interviews were conducted online. Our sample consisted of ten individuals (M age = 45.6, SD = 17.5) who use a bionic arm prosthesis. The corresponding impairments are caused congenital (n= 7), traumatic (n= 2), and by amputations for medical reasons (n=2). The data analysis was carried out employing thematic analysis (Braun & Clarke, 2006) using MAXDQA (version: 20.0.0) based on the anonymized transcripts.

Results: When using no prostheses or low-tech ones, participants described evoking patronizing, sometimes encroaching behavior that is often seen as an implicit ascription of incompetence. This tendency changes when using a more sophisticated prosthesis so that users describe that they are seen more positively by others when using a bionic prosthesis. Overall, users feel more competent and experience higher levels of self-efficacy due to regained capabilities when using a bionic prosthesis.

Limitations: Our study comes with certain limitations. Specifically, our sample consisted only of German-speaking individuals and was gathered by convenience sampling at the first stages and combined with a snowball technique later on. Therefore the results are neither representative nor generalizable and are not simply transferable to different cultural contexts. Also, the results, despite utmost methodological cautiousness and good interrater reliability (κn = .64), may unintentionally be biased by the researchers during data collection or categorization.

Conclusions: Our findings indicate that using such devices affects how others perceive users and might induce specific behaviors toward them. For example, using bionic prostheses positively affects the acceptance of disabled people at work conveyed by the ascribed competence (Vornholt et al.,

2013), similar to able-bodied individuals. We expect that augmenting devices will also trigger these processes of social perception with positive and negative outcomes, as partially shown by Gilotta et al. (2019) and Siedl & Mara (2021). Consequently, in upcoming studies, we will address devices for augmenting user capabilities and focus on more work-related applications like exoskeletons.

Relevance: Bionic devices for reestablishing or augmenting users' capabilities (e.g., bionic prostheses or exoskeletons) are likely to proliferate in the near future. Our results indicate that using bionic prostheses influences the social perception of bionics users in multiple ways, such that users describe themselves as being seen as more competent by others. In spite of being exploratory, these findings indicate that the use of bionic technologies can affect users' self-perception, stereotypes, and interpersonal perceptions. Despite the shown inclusive potential of bionic technologies, introducing such technologies in future work contexts might have unintended social repercussions that need to be accounted for.

UN SDGs: Decent work and economic growth, reduced inequalities

Intended audience: Science & Practice

Keywords: Bionics, self- and other-perception, stereotypes

Paper 2

Effects of gender perception of humanoid robots on social perception

Bertolt Meyer, Anja Strobel & Sarah Mandl | TU Chemnitz

Goals: The research goal of the present study is to replicate prior findings on whether and if so, how, gender attributions are associated with social perception of humanoid robots. Gender as a social category plays a significant role in how humans interact with other beings (Eyssel & Kuchenbrandt, 2012). The two traditional dimensions of social perception, that is, warmth and competence generate distinct emotions (Cuddy et al., 2008) and are linked to gender stereotypes: women are perceived as less competent and warmer than men (Fiske et al., 1999). Against the background of hybrid societies, where robots are increasingly put into social roles, gender attributions are increasingly shifted into focus of reseachers. However, findings on the topic of gendered robots are still inconclusive (Neuteboom & De Graaf, 2021; Seaborn & Frank, 2022).

Theoretical Background: People assign human traits to computers (Nass et al., 1994) and attribute social dimensions, i.e., warmth, competence, sociability, and morality to robots (Bretschneider et al., 2022; Jung et al., 2022; Mandl et al., 2022). Robots are subject to gender stereotyping through morphological features (Eyssel & Hegel, 2012, but see Banks & Koban, 2022). Recently, a literature review showed that a robots' gender does not affect constructs such as likeability or acceptance of a robot (Perugia & Lisy, 2022). On the contrary, gendered robots can evoke emotional reactions (Seo, 2022) and are subject to gender stereotypes (You & Hung, 2021). Humanoid robots can be designed to resemble male or female human beings, that is, the two traditional (binary) gender expressions. This could be problematic two-fold: for one, gender should not be seen as a binary construct, but rather as a continuum. Secondly, gendered robots, especially if they are constructed as traditional male or female, could reinforce gender stereotypes. Therefore, robots which do not fall into these two categories but are gender neutral or ambiguous (Seaborn & Pennefather, 2022; Suzuki & Nomura, 2022), or even non-humanoid (Jung et al., 2022), might be more suitable for deployment in various social areas. However, with the findings to date pointing into various directions, to dismiss the significance of the topic would be premature. With our study, we provide complementary insights to add to the body of research.

Method: We are currently in the process of collecting data of n = 299 participants. Participants are presented four different images of robots which are rated with regard to (1) the perceived gender on a continuum (anchored at 1 – male and 7 – female) and (2) attributions of social dimensions (competence and anthropomorphism, sociability/morality, activity/cooperation; Mandl et al., 2022). Additionally, we investigate whether personality variables, i.e., Need for Cognition (Bless et al., 1994), Affinity for Technology Interaction (Franke et al., 2019), Attitudes Towards Robots (Nomura et al., 2008; Bartneck, 2019), and Tendency to Anthropomorphize (Waytz et al., 2010) are associated with gender attributions and/or social perception. We employ mixed models with random intercepts to account for nested data, since each participant rates each picture.

Results: We are currently in the process of collecting data of n = 299 participants. We expect results to be complete by 12/2022.

Limitations: Participants are presented unmoving pictures, no real interaction between robots and participants is included. We chose four pictures of humanoid robots, whether our findings are applicable to other robots, e.g., zoomorphic, will be focus of upcoming studies. The pictures were

chosen to be neutral in robotic facial expression, color, and background, but it is not ruled out that the stimuli were not perceived as neutral by participants. Furthermore, we collected data from a mainly high educated, German-speaking sample, so possible cultural and educational differences need to be investigated more thoroughly.

Conclusions: With the present study, we are aiming at replicating prior findings on associations between gender attributions and social perception. We point out that, even if gendered robots are subject to controversies, their research is of great importance for hybrid societies of the future.

Relevance to Congress Theme: Apart from more obvious themes of HRI, gender perception and gender stereotyping is a rather overlooked, but all the more important topic: by adopting gendered robots in stereotypically male or female areas, the reinforcement of gender stereotypes is problematic and should not be pushed. With our research, we provide a status quo of gender perception of robots as a starting point for further discussion.

Relevant UN SDGs: Gender equality, decent work and economic growth, reduced inequalities

Keywords: gender stereotypes, human robot interaction, social perception

Paper 3

Merging Bodies with Technology in Augmented Reality for Empirical Studies on Hybrid Societies

Carsten Rudolph, Bertolt Meyer & Maximilian Bretschneider | TU Chemnitz

Goals: An increasing number of humans are already merging their bodies with digital technologies. The reasons for this are diverse, however we can expect that with ever evolving forms of embodied digital technologies (EDTs), the number of persons with body-worn technology will increase in the future. As of today, it is challenging to perform studies on such technologies, due to low accessibility and a limited number of participants. We present a novel way of performing behavioral studies regarding EDTs. We developed an Augmented Reality experience where participants control a bionic prosthesis that is rendered into their natural field of view. This not only allows us to not only overcome the need for physical traditionally resources required to perform such studies, but also to expose participants with non-existing, innovative designs.

Theoretical Background: Merging humans with technology will affect the psychological processes underlying social human interaction, e.g. with respect to social perception and stereotyping. Studying such effects is important not only from a psychological, but also from a technological point of view as the findings of these investigations will help to develop technologies that adapt better to the expectations and needs of humans. Recent advancements in the area of bionics have already resulted in new high-tech bionic limbs that change how people with disabilities who wear such bionic prostheses are perceived and stereotyped (Meyer & Asbrock, 2018).

Method: In order to test the acceptance of our system we conducted a non-randomized quasi-experimental study (n = 27) where all participants were assigned to the same condition, performed the same task within the AR environment, and filled in the provided questionnaire afterwards. We designed an explorative scenario in three stages. In the questionnaire we measured for five variables: Sense of Body Ownership (Romano et al., 2021), Self Presence and Immersion (Makransky et al., 2017), User Experience (Norman, 2018) and Affinity for Technology (Franke et al, 2019).

Results: In support of our hypothesis, users experienced a sense of body ownership. Also, a feeling of self-presence is induced during the task, and participants rated the overall experience as positive. Ownership, self-presence, immersion and user experience were all unrelated to age, gender, and technology affinity. Participants experienced a significant sense of body ownership with regard to the virtual prosthesis, albeit a small one. Regarding the experience of self-presence, the results exhibit the same pattern: participant's average response was above the scale centerpoint and the difference between the scale centerpoint was highly significant and associated with a large effect.

Conclusion: We developed an Augmented Reality system that can replace the user's hand with a prosthetic hand in real-time. We investigated users' perceptions of ownership, self-presence, immersion, and user experience and correlated them with users' affinity for technology. Perceptions of ownership, self-presence, immersion, and user experience were unrelated to users' age, gender, and technological affinity. Furthermore, perceptions of ownership, self-presence, immersion, and user experience were all favorably, in the sense that users' average perceptions were significantly above the scale mean and all of these differences were associated with large effect sizes. Accordingly, the results support the hypothesis and show that the system works as intended. Our system allows to run empirical studies on perception and behavior with a significantly lower the technological barriers.

Relevance: Embodied digital technologies, especially body-enhancing technologies have the potential to strongly influence many aspects of human labor. However, the acceptance of such technologies is currently underrepresented in social sciences. This is mostly caused by the weak accessibility of such technologies. Systems like ours have the potential to run studies with much lower requirements.

UN SDGs: Reduced inequalities, Good health and wellbeing.

Keywords: Stereotyping, Augmented Reality, Social Perception

Paper 4

Self-comparisons in human and human-robot teams: Effects on threat experience and job insecurity

Nathalie Schauffel, Thomas Ellwart & Carmen-Helen Weber | Trier University

Goals: The research goal is to investigate what psychological effects sociodigital self-comparisons (SDSC) with a robot coworker can have on the perception of threat and job insecurity compared to traditional social comparisons with other human coworkers. With the introduction of robots in various work fields, aside from humans also robots become objects of comparison at work (Schauffel et al., 2022). Robots are expected to be superior at various tasks in the coming decades (Grace, 2018), and research demonstrates that robots can induce threat perceptions (Yogeeswaran et al. 2016) and fears of job replacement (Granulo et al., 2019). In an EU-project context of ship inspection, it became visible that SDSC exist. However, also in all human settings, individuals can be replaced by more qualified and competent humans. Thus, it is relevant to investigate if social comparisons and SDSC have similar consequences on threat and job insecurity, or if robot coworkers trigger different fears.

Theoretical background: Individuals have a fundamental drive to compare themselves with others in social settings (Festinger, 1954). Research shows that social comparison processes evoke complex functional and dysfunctional consequences in work teams (Margolis & Dust, 2016). Research on SDSC is scarce (Granulo et al., 2019; Schauffel et al., 2022; Spatola & Normand, 2021) but points to relations between SDSC and job-related fears. Also, first evidence indicates differences in job-related fears depending on the object of comparison (i.e., human vs. robot, Granulo et al., 2019).

Method : 303 individuals (75.2% female, M age =23.3, SD age = 6.13) participated in the study. Participants were confronted with four scenarios in which they were told to put themselves in the role of a ship inspector performing better/worse than a human/robot colleague (i.e., project context). Thus, we manipulated (within-person) the direction of comparison (upward vs. downward) and object of comparison (human vs. robot). After each scenario, participants provided self-reports of perceived threats (five items based on Yogeeswaran et al. 2016, e.g., “The increased use of robots in our everyday life is causing job losses for humans.”, $\alpha \geq .77$) and job insecurity (four items based on De Witte, 2000, e.g., “Chances are, I will soon lose my job.”, $\alpha \geq .85$). We conducted a two-factor analysis of variance (ANOVA) with repeated measure using IBM SPSS 26.

Results: Upward comparisons led to greater threat experience and job insecurity than downward comparisons. Self-comparison with a robot (i.e., SDSC) led to greater job insecurity than that with a human colleague, but not to greater threat experience. The threat experience was greater for the upward comparison than for the downward comparison, whereby this was particularly pronounced for the comparison with the robot (i.e., SDSC), compared to the self-comparison with a human colleague.

Limitations: Main limitations refer to the applied approach and the sample. First, the approach considers a fictional scenario. No real interaction between humans or humans and robots was included, restricting the external validity and generalizability of the results. Nevertheless, the applied vignette approach represents an economical way to investigate a new, partly exploratory, research field within a realistic application context of human-robot interaction in ship inspection. Second, the sample had limited experiences with robots and the scenario context of ship inspection which could

have made it difficult to put themselves in the scenarios. However, the vast majority of the participants indicated that they could easily put themselves in the scenarios.

Conclusions: Contrasting the consequences of the comparison process in human-human and human-robot interaction, this study extends limited research on social comparison in traditional work teams (Margolis & Dust, 2016) while also providing knowledge for the relatively new field of human-robot teaming (O'Neill et al., 2020; You & Robert, 2017). Especially human-robot interaction in which humans perceive themselves as outperformed by a robot coworker might have negative consequences for individuals' psychological well-being and results in job-related fears (e.g., job insecurity). Given the fundamental human drive to compare themselves (Festinger, 1954), the present results offer practical implications for the design and implementation of robots at work (e.g., cooperative vs. competitive, emphasize human uniqueness) and directions for future research (e.g., perception of fairness).

Relevance to Congress Theme: Human-robot teaming is changing the world of work. Thereby, robots at work are a double-edged sword, incorporating positive but also potential negative consequences. The study's focus on self-comparisons in human-robot teams introduces a to-date underinvestigated perspective on human-robot teaming, rooted in a well-established theory on social comparisons (Festinger, 1954).

Relevant UN SDGs: Decent work and economic growth

Keywords: Human-robot interaction; social comparison; job insecurity

Paper 5

Specific Dimensions of the User Experience of Occupational Exoskeletons

Emese Papp, Jens Krzywinski & Christian Wölfel | TU Dresden

Theoretical background: Exoskeleton technology is relatively new and its use in companies is still limited. Therefore, it is understandable that research and development projects have focused mainly on technical implementation so far, and existing research on the user´s perspective in this field is still in its infancy (Elprama et al., 2022). A few existing frameworks (Moyon et al., 2019; Fox et al., 2019, Elprama et al., 2022) provide rich insights about influencing components of acceptance and point out the importance of different aspects for the development (e.g., wearing comfort, task-fit) and implementation (e.g., familiarization time, organizational aspects). However, research on occupational exoskeleton has considered the user´s emotional experience only marginally and addressed physical aspects mainly through ergonomics (Papp et al., 2021).

New Perspectives/Contributions: This contribution will emphasize the relevance of the user experience (Thüring & Mahlke, 2007; Ludden & Van Rompay, 2015) with a particular focus on its corporeal dimension and the role the exoskeleton´s design plays in the social and self-perception of the user.

We can observe an intimate, physical alliance of the exoskeleton and the human body (Jochum et al., 2018), with a specific interaction level of union (Papp et al., 2020) or fluid human-machine cooperation (Butnaru, 2021) that affects not only the work tasks but also the user´s body and the user itself. To capture the complex and highly subjective human-exoskeleton experience (Papp et al., 2020; Torricelli et al., 2020; Butnaru, 2021), our analysis will follow the product experience framework of Ludden and Van Rompay (2015) that conceptualizes human–product interaction at three different levels: sensorial–visceral; functional–behavioral; and symbolic–reflective.

We will highlight exoskeletons´ potential to change the wearer´s appearance (sensorial level) and influence a person´s self-image and social perception (symbolic level). Many studies noted that workers´ acceptance was severely affected by workplace bullying or the fear of it (Feldmann et al., 2020; Gilotta et al., 2019; Moyon et al., 2019; Papp et al., 2020). This shows that wearing an exoskeleton could be understood as a sign of weakness (Baltrusch et al., 2021; Feldmann et al., 2020; Elprama et al., 2020; Papp et al., 2020). Since the properties of an exoskeleton might directly influence the user‘s self-image and how users are perceived by others (Papp et al., 2020), visual aesthetics will play a crucial role in avoiding possible stigmatization (Baltrusch et al., 2021; Papp et al., 2020).

Another critical insight is that exoskeletons can direct the user´s attention to its bodily capabilities on a functional and symbolic level. Wearing a support system can be a form of users´ confrontation with the possibility of future health problems (Papp et al., 2020). However, it can also help users understanding their bodies and bodily functions in a new way. In this sense, exoskeletons become a means to body awareness: self-awareness (Sonneveld & Schifferstein, 2008) or kinesthetic awareness (Jochum et al., 2018).

Conclusions – research and or practical implications: This working paper, as a complement to existing frameworks, focuses on the user´s subjective idiocratic exoskeleton experience instead of capturing the wide variety of influencing factors of acceptance. It attempts to illustrate how the different levels of experience entangle themselves around the user´s corporeality, extending from

visual and bodily impressions to self-perception. The identified experience dimensions and the intertwining of those still have to be validated and completed in further qualitative field research. Based on empirical validation, they could significantly contribute to a more exhaustive picture of the experience and acceptance of exoskeletons in the occupational context and help developers to find the right design approaches to create positive experiences with those devices.

Relevance to the Congress Theme: Through physical relief, exoskeletons could reduce work-related health hazards, times of absence, and accidents. Thus, the use of exoskeletons contributes to decent working conditions and the individual well-being of many employees working under physically demanding conditions. For widespread adoption of occupational exoskeletons, it is essential to understand the underlying mechanism, which shapes a positive user experience and actual use. Based on the established frameworks of user experience and the theory of embodied cognition, this contribution focuses on a previously poorly understood human-exoskeleton experience with its close-to-body character.

Relevant UN SDGs: Decent work and economic growth, Industry, Innovation and Infrastructure,

Good health and well-being

Keywords: Exoskeletons, Occupational Health, User Experience

Symposium S087

Critical Work and Organizational Psychology

Dieu Hack-Polay, University of Lincoln; Zoe Sanderson, University of Bristol, UK

science_practice

The symposium aims to discuss key perspectives about the meaning and approaches to work. This ponders on the importance of questioning the status quo to generating critical approaches to WOP whose foundation is to view work realities as dynamic in time and space. This affords a voice to scholars and practitioners to define future work orientations in a more humane and social form, thus transcending the technical praxis we are accustomed to. This critical WOP symposium is, thus, about reflection deeply rooted assumptions about work, some of which may no longer be relevant, therefore are obsolete, and some that require dramatic rethinking. Critical WOP puts the individual at work in a social context which can enrich not only performance for individuals and organizations, but can refocus human societies (Gerard, 2016). Through the combined efforts of academics and and practitioners, that we can see the true value of scholarship and praxis working in synchrony to transform work and the world in which we live (Teo, 2015).

It is in this spirit that that the topics submitted to this CWOP symposium are set. They have significant linkages which reinforce the critical theory-praxis integration that WOP seeks. For example, in her submission, Mara discusses platforms for doctors (doctors visiting patients online). This is set in the neoliberalist perspectives which raise significant questions about the degree to which doctors put their lives at risk to power a poorly funded public healthcare system. The work of doctors becoming more isolating due to a reduction in their institutional and organizational involvement, for then gaining more freedom and economic advance in meeting patients online. These approaches raise the critical question of doctors' mental health but problematizes healthcare privatization which only profits investors.

Christian and colleagues' submission clearly complements this by examining the high commitment model in human resource management (HRM), which despite being acclaimed as a high-performance model can exhibit significant disadvantages which have been widely acknowledged. The authors contend that some studies raise concerns that performance improvements come at the expense of workers' health. This is because highly involved individuals may overexert themselves in pursuit of their work tasks and exhibit a pattern of self-regulated work intensification with detrimental effects on occupational health.

An initiative such the platform, Premilla argues in their communication for this symposium, has emerged as a response to some of the criticisms about the timid actions to face and revisit the nature of workplace relations and practices. Many have acclaimed the potential of the platform to engage employees and create more democratically organized businesses that provide workers with new ways of connecting, cooperating and realizing meaning, but the effectiveness of this is still wide open for debate. Premilla and co-author ponder on the accuracy of these claims by examining workers' conditions in the Indian contxt by reviewing a large body of theoretical and empirical works.

Degen 's submission is not only correlated to the previous ones but provides tentative answers to the problematics posed, especially in Premilla's paper. Degen examines issues of exploitation and fantasies about work in information technology workers. Incidentally, these workers are experts in the use of technologies and online platforms. The verdict is clear from the data obtained. Degen concludes that there is a realization of an initial model focused on the vulnerability-exploitation of IT workers, broadly defined as the condition under which IT workers accept to be exploited.

Vulnerability-exploitation stands at the nexus of fantasies and actual working conditions. Although the vulnerability-exploitation condition creates the space for individualization of work, this buffer levels of exploitation perpetuating logics of postcapitalist working conditions.

Dieu's submission attempts to conceptualise 'systemic racism' in the light of structuration theory to aid its use in policy frameworks and academia. He examines the concept in the light of recent intense debate s about the notion of systemic racism. This period has seen a significant surge in racial tensions, particularly as affecting minority ethnic groups. Though some in the political and media sector acknowledge that there may be some organised discrimination against minorities, others in the same circles have persistently refuted the existence of systemic racism. This abstract casts a critical eye on the meaning of the concept and sheds light on what constitutes systemic racism and how it endangers opportunities and the psychological wellbeing of many in society.

These interesting discussions will allow a re-awakening of scholars and practitioners to the importance of consistent and systematic engaged scholarship that is attune with dynamin work, workplaces and research.

Paper 1

Doctors in the age of platforms: the new social mechanism of experiencing health care through screens and online consultation

Mara Gorli, Università Cattolica di Milano

Introduction and conceptual background

Even before the healthcare disruption caused by Covid-19, health systems were broadly struggling with well-known massive challenges rather familiar in many parts of the world. These include rising pressures for healthcare due to growing demands for the aging population, chronic diseases associated with more complex cases, lack of resources including the shortage of doctors and nurses, new technologies which often seem to increase cost pressures (Storey & Holti, 2020; Buchanan et al., 2013), and waves of institutional reforms impacting on processes and on how workplaces are perceived. In such a picture of complex and challenging conditions, Covid-19 has even further increased the strain on healthcare workers, causing increasing distress and discomfort (Heath et al 2020; Palmer et al 2022) and a reaction of progressive diminishing of the professional vocation and engagement in specific healthcare departments.

On the other side, digital platforms are branching out at many levels, and recent years have witnessed the increasing growth and expansion of medical platforms for online clinical consultation (Al-Mahdi et al 2015; Singh et al., 2021). This is a new frontier that opens unexpected opportunities for the healthcare system, as well as potential subtle risks.

The research investigates the 'silent quit' of doctors and a potential growing tendency to reduce their institutional and organizational involvement, for then gaining more freedom and economic advance in meeting patients online.

It is a very delicate topic that raises many considerations both political (the privatization of healthcare, the ownership of data, the individualization of professional contracts) and socio-organizational (how to create safe and better conditions to sustain workers in public services, thus guaranteeing a dedicated service of care).

Theoretical background

As work and organizational scholars, we are aware that contemporary workplaces and organizations are radically changing, bringing about new challenges for people and their relationships with work.

Healthcare personnel oversees complex, high-risk decisions, in contact with physical and emotional tensions, balancing scarcity of resources and high demand for fast, effective treatments. Healthcare workers are specifically involved in exceptionally high levels of dynamic, fast-paced situations often made heavier by phenomena like overcrowding, turnover, lack of resources, and exposure to physical and psychological demands (Schneider et al., 2019; Xu et al., 2020). It does not come as a surprise that levels of psychological issues such as burnout and difficulties in coping with uncertainty, and physical problems such as bad quality of sleep and musculoskeletal disorders are associated with professionals working in such field (Moukarzel et al., 2019).

Perhaps as a reaction, many doctors are now opting for different forms of patient care. The expansion of online platforms helps meet the demands of patients, whilst at the same time

guaranteeing an individual and ‘autonomous contract’ that doctors may define around their commitment.

Research goals and why the work was worth doing

Based on this scenario, the study aims to critically explore:

i) How the usage of online platforms impacts the creation of new forms of healthcare practices and doctors’ vocational values and identities

ii) How the usage of online platforms affects the lived experience and the quality of care for the patients.

Methodology

The work is based on diverse data sources, collected within one online platform in Italy,

through different methodologies:

Semi-structured interviews and focus groups reaching approximately 40 doctors; Semi-structured interviews with a sample of patients using the platform; Online questionnaire to doctors and patients;

The qualitative material collected is analysed through an inductive thematic analysis (Braun & Clarke, 2006; Vaismoradi et al., 2013), with the support of NVivo to create thematic areas and the conceptual map.

Results obtained or expected

The research illustrates the results, which reveal new emerging assumptions and positioning with respect to professional identity, sense of organizational belonging, care of the patient, and vocational values.

The analysis discusses potential risks and opportunities brought by the use of platforms for medical consultation.

Limitations

The study is directed to one platform in one sole country. Further studies could focus on comparisons among different platform systems and countries, to grasp cultural and institutional implications.

Conclusions – research and or practical implications / Relevance to the Congress Theme :

The present study proposes a picture of an evolving field that deserves wide consideration as platforms are nowadays shaping new relationships with work and with the concept of care (for the professional, for the patient), affecting experiences and identities. The research provides indications around the ethical and fruitful usage of online medical services that can inform organizational development, future work practices, and policy agendas.

Relevant UN SDGs:

Good health and wellbeing; decent work and economic growth

Keywords: Neoliberalism, healthcare, professional identity

Paper 2

PEAK PERFORMANCE—PARADOXICAL IMPACT: WHEN SUPPORTIVE HUMAN RESOURCE PRACTICES ARE TOO MUCH OF A GOOD THING

Christian Seubert, University of Innsbruck, Austria; Severin Hornung; Thomas Höge; Jürgen Glaser; Matthias Weigl

Research goals and why the work was worth doing

According to research on "high-performance work systems" (HPWS), integrated sets of complementary human resource (HR) management practices aim to cultivate specific job attitudes and behaviors that are considered beneficial for organizational performance. In particular, so-called "high-involvement" and "high-commitment" practices are postulated to be mutually beneficial for employers and employees. However, some studies raise concerns that performance improvements come at the expense of workers' health. Highly involved individuals may overexert themselves in pursuit of their work tasks and exhibit a pattern of self-regulated work intensification with detrimental effects on occupational health. This study examines moderating and mediating roles of job involvement between perceived supportive HR practices and work ability to assess the validity of these concerns.

Theoretical background

The "HPWS" label has emerged as an overarching category for certain sets of complementary HR practices that aim to develop positive synergies for the workforce and work systems. HPWS comprise high-involvement practices that emphasize employee control and influence at work (such as participation in managerial decision-making), and high-commitment practices are focused on employee welfare (such as improved work design). While most research has focused on positive HR effects, a number of studies found negative side effects on worker well-being. Given these contradictory findings, critical analyses have suggested a paradoxical "dual" role of such HR practices in enhancing work motivation and peak performance, while at the same time provoking job stress and strain as "hidden costs".

Design/Methodology/Approach/Intervention

The data stem from a large-scale commercial best employer survey study among German municipal employees (N=14,372). Two empirically distinct sets of HR practices (6 items each) were identified: participatory management style (ω[6]=.90) and decent working conditions (ω[6]=.75). Job involvement was measured with another empirically distinct set of 6 items (ω[6]=.88). Subjective work capacity was assessed with the work ability index (7 items, ω[7]=.81). Structural equation modeling was performed, controlling for gender, age, disability, organizational tenure, employment level, supervisor position, and occupational field. Latent interactions were tested using double-mean centering.

Results obtained or expected

Both participatory management style (β=.15, p<.01) and decent working conditions 4β=.49, p<.01) predicted higher levels of work ability. Job involvement acted as a partial mediator between HR practices and work ability (β=.19, 95%-BootCI [.17,.21], β=.20, 95%-BootCI [.18,.22]). Further, a buffering two-way interaction of participatory management style with job involvement (β=-.16,

p<.01) as well as an attenuating three-way interaction of job involvement, participatory management style, and decent working conditions (β=-.35, p<.01) were found.

Limitations

The cross-sectional nature of the data does not allow to trace temporal trajectories or draw causal conclusions. Ad-hoc measures of perceived HR practices and job involvement were empirically established. Future research should employ longitudinal data and objective measures of HPWS.

Conclusions – research and or practical implications

The results suggest an ambiguous role of HPWS and provide evidence of reduced work capacity under conditions of high employee involvement linked to extensive organizational use of specific sets of HR practices. Stimulating peak performance by utilizing these HR practices may yield the paradoxical impact of self-endangering, over-engaged work intensification, resulting in diminished work ability. Sustainable application of such HR practices requires not merely promoting involvement and commitment in order to boost worker productivity, but to simultaneously monitor potentially harmful side effects as well as implementing customized health-promoting interventions to secure workers' long-term health and capability to perform.

Relevance to the Congress Theme

HR departments that constantly evolve and employ HPWS practices need to balance performance considerations with preconditions of long-term work ability. Work and organizational psychologists urgently need to advocate sustainable work practices that allow workers to thrive throughout their entire careers, rather than overexerting themselves in the short term.

Relevant UN SDGs

Good health and wellbeing, decent work and economic growth.

Keywords: High-performance work system, high-commitment, HR practices

Paper 3

PLATFORM PRECARITY AND WORKER COMMODIFICATION-DECOMMODIFICATION, MEANING, EMPOWERMENT AND WELL-BEING

Premilla D'Cruz, Indian Institute of Management Ahmedabad; Ernesto Noronha

Research rationale and goals:

The rise of the platform as an organizational model is recognized as one of the most important socioeconomic developments of our time, being considered to hold the potential for creating more democratically organized businesses that provide workers with new ways of connecting and cooperating and hence realizing meaning, empowerment and well-being. We sought to examine the veracity of these claims through the experiences of Indian platform workers and to make recommendations for policy and intervention.

Theoretical background:

We used the lens of economic precarity for our study, in keeping with platforms' 'independent contractor' description of workers. Precarious work refers to increasingly insecure employment and uncertainty, linked to the loss of social protections and social dialogue and rejection of standard employment relationships/SER. Precarization is a two-fold simultaneous 'normalization' process: erosion of SER and spread of non-standard forms of employment/NSFE, often portrayed as an alternative to unemployment. We sought to understand how precarity impinges on workers' experiences of meaning, empowerment and well-being at work.

Design/methodology:

We undertook a review of academic literature on the platform economy in India, covering crowdwork and on-demand work. To conduct the review, an unrestricted date search using several terms and variations, like gig economy India, platform economy India, Zomato India, Swiggy India, Ola India and Uber India, was conducted of the Web of Science, Scopus and Google Scholar databases. Only English-language, peer-reviewed academic output was considered.

Findings:

Our findings show that platform work, comprising crowdwork and on-demand work, in India is a mixed bag. Though Indian platform workers seem to benefit in terms freeing themselves from workplace hierarchies, escaping from micro-politics, bettering their incomes, accommodating complex personal schedules and avoiding difficult commutes, risks are transferred away from employers and towards workers, resulting in job insecurity, uncertainty, instability and vulnerability, underscoring precarity. Work is individually organized through interpersonal competition. Algorithms are used to maximize the companies' business interests and economically exploit workers. Platform workers are barred from basic protections like social security, minimum wage, working hours, gratuity, overtime pay and collective bargaining rights. The COVID-19 pandemic only intensified their precarity, highlighting both the platforms' and the state's absence of actual care and accountability for workers. Indeed, platforms intensify the worst features of global capitalism, increasing inequality and disenfranchisement through working conditions of wage theft, deregulation, increased intensification of work and unprecedented workplace surveillance. Even so, resistance through worker initiatives and advocacy groups as well as nascent but fragmented union action, indicative of agency, and emergent regulation and policy, indicative of state protection, provide some counter to

the precarity. Platform workers experience ambivalence, reporting the concomitant experience of both meaningfulness and uncertainty, empowerment and helplessness, and well-being and strain.

Limitations:

The study was based on secondary literature; yet, the findings resonate with international data on the experiences of platform workers and hence have global applicability.

Conclusions/contributions/implications:

Theoretically, we demonstrate platform workers' simultaneous commodification-decommodification dynamic, indicating attempts to seek empowerment in spite of disenfranchisement and reflecting implications for meanings of work and life. Platform workers have none of the labour or workplace rights of conventional employees or collectively agreed frameworks governing crowd employment. Bereft of long-standing protections, platform freelancers are forced to shoulder risk for infrastructure, skill development, personal injury and damage to tools and assets, financial malfeasance and harassment by customers, the costs of inadequate demand and loss of earnings resulting from deactivation based on customer/client feedback. Yet, hetereogeneous experiences of the platform workforce indicate that they experience gains through flexibility and independent engagement, opportunities to earn and advance their careers, freelancer networks, attempts at collectivization and advocacy which yielded positive outcomes in terms of influencing regulation and policy. Our theoretical contribution suggests policy and intervention efforts towards augmenting decommodification, meaning, empowerment and well-being.

Relevance to the Congress theme:

The study, speaking to the latest interface between technology and work through platform work and portraying the inherent precarity of platform work, directly reflects the Congress theme in regard to the ongoing unfolding of the future and the changing nature of the world of work. Moreover, the study is relevant to the inequalities and critical streams of FOWOP due to its focus on precarity, disenfranchisement and empowerment.

Relevant UN SDGs:

No poverty, reduced inequalities, decent work and economic growth, good health and well-being, responsible workplaces endorsing justice

Keywords: Commodification, Precarization, Well-Being

Paper 4

EXPLOITATION AND FANTASIES ABOUT WORK IN INFORMATION TECHNOLOGY WORKERS: A QUALITATIVE STUDY

Johanna L. Degen, Europa-Universität Flensburg; Francesco Tommasi; Franziska Koessler

Research goals and why the work was worth doing: Studies in work and organizational psychology (WOP) rarely place an emphasis on exploitation and abuse of IT workers. Being at the core of technological developments, business-oriented and market-driven constructs represent the mainstream theme of investigations on IT workers. Conversely, from the memoir by Anne Weiner, recent social movements (e.g., Tech Workers Coalition) and European Commission claims, exploitation has been being dramatically present in implicit thinking in personal and professional ideologies. The study sought to improve our knowledge on exploitation and develop a comprehensive model based on the lived experience of information technology (IT) workers.

Theoretical background: Given goal of our study to build rather than test or elaborate theory, our methodological strategy followed a theoretical logic (Glaser and Strauss, 1967) with indications to the type of sample (i.e., IT workers) and interpretative lens (i.e., psychodynamic approach).

Design/Methodology/Approach/Intervention: The study draws on a qualitative approach based on semi-structured interviews of N = 20 IT workers. Using psychodynamic approach as a critical lens, the study on the lived experiences of vulnerability, abuse and actual exploitation of IT workers to interpret data collected.

that while studying nurses' wellbeing is worthwhile, this nonetheless risks neglecting intra-subjective and inter-subjective mechanisms (e.g., cognitive-affective, and meaning-making processes) leading to question the meaning of nurses' wellbeing.

Results obtained or expected (if not available, it must be made clear when they will be): Data analysis led to the realization of an initial model focused on the vulnerability-exploitation of IT workers, broadly defined as the condition under which IT workers accept to be exploited. Vulnerability-exploitation stands at the nexus of fantasies and actual working conditions. Although the vulnerability-exploitation condition creates the space for individualization of work, this buffer levels of exploitation perpetuating logics of postcapitalist working and organizational conditions.

Limitations: Our study is not pretentious in the sense of representability. The sample strategy recruitment was limited to the network of the authors, online forums and groups of IT workers. Moreover, participants volunteered to participate without any form of compensation. This may hinder their representative due to self-selection bias.

Conclusions – research and or practical implications/Originality/Value: The originality of the present study is threefold: a) theoretically, the originality stands in revisiting the meaning of exploitation beyond working and organizational conditions; b) methodologically, the study creates space for psychodynamic interpretative lens in WOP; c) socially, the study opens to novel approach to the work of IT by emphasising ethical and sustainable organization in the field of technology development.

Relevant UN SDGs: Decent work and economic growth; Reduced inequalities; Peace, justice, and strong institutions

Keywords: Exploitation, Abuse, IT workers

Paper 5

Framing systemic racism

Dieu Hack-Polay, University of Lincoln, UK

Introduction

This discussion paper examines the notion of systemic racism which has been prominent in recent years during two critical events: the 2020 US election that saw Donald Trump elected, and the covid-19 pandemic of 2020-2022. Both events brought back to the surface the claim that blacks and non-whites are discriminated against in various countries in most spheres of life. However, there have been narratives and counter-narratives about the existence of a phenomenon termed 'systemic racism'. This confusion derives from the fact that seldom academics and scholars have devoted sufficient attention to clarifying the contours of the term, leading to far-reaching interpretation and denials. This paper attempts to conceptualise the term in the light of structuration theory to aid its use in policy frameworks and in academia. In recent year key debates have emerge over the notion of systemic racism and its existence. These debates have intensified in this year during the covid-19 pandemic period. This period has seen a resurgence and significant surge in racial tensions, particularly as affecting minorities ethnic groups. Though some in the political and media sector acknowledge that there may be some organised discrimination against minorities, others in the same circles have persistently refuted the existence of systemic racism. In this article, I examine what might constitute systemic racism.

Examining the notion of 'systemic'

Let's first unpack the meaning of the term systemic (sometimes used interchangeably with the term systematic). The Oxford Dictionary defines the term systemic as a fact or phenomenon 'relating to a system, especially as opposed to a particular part'. Considering the phrase 'relating to a system', one can start to think about particular social systems (if we consider a given collectivity as a social system). The second part of the Oxford definition, 'as opposed to a particular part', also gives us some clues as to how systemic could be understood. This second part of the definition signifies that a systemic phenomenon or action runs through the structures of the collectivity with little exceptions. Sociologist Auguste Comte perceives system as an integrate whole which means that what happens in a part of the whole affects other parts of that whole. Comte argues that a critical condition to maintain the system in good order and for it to progress is for each element to cultivate more altruism which signifies working harmoniously with the other parts.

Case supporting systemic racism

Now returning to the notion of systemic racism, how does it meet the conditions of systemic proposed in the Oxford definition and in Comte's theorisation. Both in the USA and the UK as well as most countries struggling with racism, there is a sense that racism touches all spheres of society: employment, health care, policing, education and government and the justice system, etc. (Lewis, 2005). Let's consider some of these areas in more depth to elucidate the case.

In education and employment, for instance, there have been countless reports on how racial disadvantage is prevalent in British and American schools. In both countries, the underperformance of black and minorities is well documented. In the UK, the unemployment rate for these minorities has been consistently over twice of that of their majority counterparts for decades, currently

standing at 10% compared with just 4% for the white population (Hack-Polay , Ogbaru, Rahman & Mahmoud, 2021). This sustained minority disadvantage in education and employment has led Anthias and Yuval-Davis (1995) and MILES, (1974) to speak of migrants as being a reserve army of labour which is drawn upon only when there is a shortfall in the majority labour force. Hack-Polay (2019) has spoken of the Ghettoisation of minorities.

In policing and the justice system, it is well documented that black and minority people are twice more likely to be arrested (Lewis, 2005) and to receive long term sentences for petit crimes compared to their white counterparts in the UK and the USA (REF…). The disparities in the way in which the police deals with law and order in different communities has been prominently exemplified in recent years by the killing of Breonna Taylor and George Floyd, etc. in the USA ; the mishandling of the killing of black teenager Stephen Lawrence (UK), Native killing and dispossession. These high profile examples only represent the tip of the gigantic iceberg of black disadvantage in policing and the justice system. In an investigation of the Stephen Lawrence case in the UK, Sir McPherson found that the police force is 'institutionally' racist REF…). This institutionalism of racism has resonance in many other countries and social areas. The attempted insurrection of the Capitol Building in the USA on 6 th January 2021 and its light handling by the police and law enforcement forces has been highlighted as further evidence of the colour of policing and justice. The majority of the insurgents were white participants and only 50 arrests were made. This sharply contrasts with the mainly black protest again the killing of George Floyd and against police brutalities where several dozens were arrested, tear gas fired and the National Guards speedily deployed in great numbers.

The examples can form a long list. We cannot cover all areas of the social system but these examples show how the social system displays widespread and embedded disparities in opportunities for various racial groups (Kirton & Greene, 2015) in different countries. The evidence of widespread and embeddedness of racial disadvantage meets the first criteria in our established definition of 'systemic'.

Lasting rhetoric and Structuration Theory

A further significant point that supports the case for systemic racism is the temporal endurance in our societies. Despite formulated legal frameworks to protect different races, the social system as a whole has shown a significant inability to work effectively towards equality for all. In the UK, the Race Relations Act for formulated in 1956 but progress towards race equality has been slow. If almost a century since the legal framework came into effect, the debate about race equality is still raging, then there might significant flaws in the application of the legal framework or its enforcement. This points to a systemic aspect. In the US, since Black people earned the right to vote in the 1940s, there have been reports of tampering with their ability to exercise this critical right. For instance, recently, some polling stations have been closed without rationale in areas with Black majority, making it difficult for Blacks to vote (Levine, 2022). And suspicion of systemic discrimination is further reinforced when at the same time, there is a curb on postal voting which traditionally enabled Black voters whose work patterns did not allow them to present themselves physically at the polling stations to vote. The persistence of race inequalities could be understood through Giddens (1979) Structuration Theory.

Conclusion

In total, the statistical evidence available, the protracted period of disadvantage suffered by minorities and the inability of governments to vigorously enforce equal opportunity and diversity legislations, it is difficult to refute the suggestions about the existence of systemic racism. In this article we have substantiated two key parameters that make the claim about systemic or systematic

racism compelling: persistence and affecting all areas of the social system and the faintness or lack of political will to address the situation (this can be clearly mapped on Structuration theory). Western civilisation appears to have constructed a system that implicitly favours white supremacy (e.g. colonisation, neo-colonisation, cultural imperialism and oppression against its own ideology of freedom, democracy, equality and diversity.

Symposium S089

Moving science on workplace bullying into the future (I)

Jose M. Leon-Perez, Universidad de Sevilla; Philipp E. Sischka, University of Luxembourg

science

What will be covered and why

Workplace bullying (WB) refers to repeated and systematic negative acts towards one or more targets during a prolonged period of time (Einarsen et al., 2020). Although previous research has made significant contributions to better understanding why and how workplace bullying emerge at work (e.g., Salin & Hoel., 2020; Gupta et al., 2020), there are still some shortcomings in the field. From the theoretical and methodological side, the field needs both more longitudinal studies that allow us to know better the dynamics and patterns of workplace bullying, and multisource and multilevel designs that help to capture the group processes that interplay with organizational and personal factors in the bullying development. From the practical side, we lack information about the success of interventions to prevent and deal with workplace bullying at different levels of analysis.

In this symposium, we aim to overcome some of the above-mentioned limitations. Indeed, we have divided the symposium in two parts. The first part tries to shed some light on the bullying process and stages as well as on the role that different actors play (e.g., managers, bystanders). In the first contribution, Notelaers and colleagues explore the role of line managers (i.e., laissez-faire leadership) in how workplace bullying unfolds over time. In the second contribution, Sischka and colleagues address the interplay of workplace bullying exposure and perpetration from a person-centered approach (i.e., latent class modelling). In a similar vein, the third study conducted by Vranjes and colleagues investigate the longitudinal association between enactment of bullying and exposure to bullying. In the fourth contribution, Ng and Niven develop and validate a measure of workplace bullying bystander responses. Finally, Bastiaensen and colleagues explore bystanders' behaviors from a qualitative approach.

In the second part, we focus on a psychosocial risks approach to workplace bullying and the effectiveness of some interventions at different levels. In the first contribution, León-Pérez and colleagues confirmed cut-off scores of the Negative Acts Questionnaire in Spain and the relationship of risk categories with well-being indicators three months later. In the second contribution, Hamre and colleagues explore, in a multilevel design, the moderating role of job insecurity climate on the relationship between role stressors and workplace bullying. Then, in the third contribution, Balducci and colleagues conducted a diary study to explore the link between negative acts and post-traumatic stress disorder (PTSD) symptoms. In the fourth contribution, Rodríguez-Muñoz and colleagues present the results of an expressive-writing intervention at individual level aimed at minimizing negative consequences of being exposed to negative acts at work. Finally, Li and colleagues report a work-design intervention at the organizational level to prevent workplace bullying.

Relevance to the Congress Theme

The symposium aims to broaden our understanding of the bullying phenomenon in the context of an ever changing working world. Moreover, it discusses preventive measures and is therefore in line with the Sustainable Development Goals to foster good health and wellbeing and to create "decent work for all" (Fields, 2003).

Research/Practical Implications

The contribution of this symposium suggests that workplace bullying is a multicausal dynamic process that needs to be addressed by integrating the role of different agents and multiple levels of analysis. In addition, this symposium offers useful insights from longitudinal studies with different time lags between measures and provides findings from interventions that can help preventing and managing workplace bullying.

Overall conclusions

To move the science of workplace bullying into the future, it is of utmost importance to understand the bullying process and stages, which factors facilitate or inhibit the (de)escalation of this process and which interventions prove to be effective countermeasures.

Keywords: workplace bullying, mobbing, work design

Paper 1

Leadership in the process of workplace bullying: beware of the laissez-faire leader?

Guy Notelaers, University of Bergen; Sarah-Geneviève Trépanier, Université du Québec à Trois-Rivières; Jose M. Leon-Perez, Universidad de Sevilla; Philipp E Sischka, University of Luxembourg; Elfi Baillien, KU Leuven

Theoretical background and why the work was worth doing

Already in the early days of workplace bullying research, Leymann (1996) pointed to the devastating role of management in the workplace bullying process. This motivated scholars to investigate both active and passive destructive leadership as a risk factor. Whereas active destructive leadership may on a conceptual level be conceived as a form of bullying (i.e., downward bullying), passive destructive leadership – particularly laissez-faire leadership – fuels the development of bullying over time by not intervening and effectively managing what needs to be managed (Skogstad et al, 2007). So far, some studies scratched the surface of how laissez-faire leadership is associated with bullying: longitudinal research showed ambiguous results in terms of reporting forward as well as reversed and even reciprocal relations between both laissez-faire leadership and reports of bullying (Ågotnes et al., 2020, 2021).

However, this previous research entails some methodological limitations, which challenges the accuracy of their statistical conclusions as well as limits our current understanding of how laissez-faire leadership relates to workplace bullying over time. First, past research has focused on between-person processes rather than within-person processes, and therefore gives limited information on the role of laissez-faire leadership in how a bullying situation unfolds over time. Second, the analyses assume normally distributed measures, whereas the distributions are more likely to resemble a negative binomial distribution making classical linear modeling approaches less suitable. Third, as indicated by several more critical scholars (Hershcovis & Reich, 2013; Notelaers et al., 2018), past research treated ordinal data as continuous measures. Finally, it has predominantly regarded bullying as a continuous process, whereas both by definition as from empirical findings it is a heterogeneous process consisting of different stages (Einarsen et al., 2021; Notelaers & van der Heijden, 2020).

Research goals & Methodology

In reply to these limitations, the current study aims to test the acclaimed role of laissez-faire leadership in the process of bullying using a dual process latent class Markov model. This within-person perspective allows us to test the causal direction of the processes. When a normal or reversed model fits best, a 3-step latent state model can be used to estimate whether transitions (for instance, in the frequency of exposure to negative acts) are the results of changes in another process (for instance, laissez-faire leadership). In order to rigorously explore the longitudinal relationship between laissez-faire leadership and workplace bullying as well as cross-validate the findings, we will present the results from three different longitudinal data collections using various timeframes as well as measures of laissez-faire leadership: (1) a six-wave study (one-month interval between measures) from Luxemburg, (2) a two-wave panel study (four-month interval between measures) from Spain, and (3) a three-wave panel study (six-month interval between measures) from Belgium.

Expected results

While some of the data collections are currently in their final stage, preliminary results showed a reciprocal process between both workplace bullying and laissez-faire leadership. These bidirectional results indicate that both processes reinforce each other over time: employees that were targets or occasionally bullied, compared to employees who are not bullied, report over time more laissez- faire leadership and employees reporting earlier laissez-faire leadership, as compared employees reporting no laissez-faire leadership, are later more likely to be occasionally bullied or targets of bullying. During the conference, once all datasets are analyzed using a dual process latent class Markov model, a within-person perspective will be discussed.

Limitations

Although the present study extensively explores the longitudinal relationship between laissez-faire leadership and workplace bullying using three longitudinal datasets, the latter contain different occupational groups, different measures, and different time intervals, which can result in some heterogeneity across samples.

Conclusions

While the results and conclusions pertaining to all three samples will be discussed and compared during the oral presentation, the preliminary findings illustrate that the relation between laissez-faire leadership and workplace bullying is complex: while management not taking its responsibility can explain the development of bullying, the expectations of fair and just treatment of those exposed to negative acts at work– unfulfilled by their leader's inaction - may further fuel the process.

Relevance to the Congress Theme

Our findings will be discussed under the light of the UN Sustainable Development Goals (SDGs) as they may have relevant implications for ensuring decent work and promoting well-being at work.

Paper 2

Patterns of workplace bullying involvement and its link to personality, power and social status

Phillip E. Sischka, Georges Steffgen, Matthea Wehage & Fabrice Klinger | University of Luxembourg; Guy Notelaers, University of Bergen

Research goals and why the work was worth doing

Just like many school aggression researchers (see the review of studies in Olivier et al., 2021), many scholars investigating workplace bullying assume the existence of types of involved employees. Commonly, scholars distinguish four types of employees: Uninvolved employees, victims, perpetrator, and provocative victims (also called 'bully-victims'; e.g., Zapf & Einarsen, 2020). So far, empirical evidence supporting such a typology is lacking so far. Studies on workplace bullying mostly focused solely on the victim perspective (Einarsen et al., 2020; see also the review of studies in Gupta et al., 2020) and only a handful of studies investigate the perpetrator perspective (see the enumerated studies in Nielsen & Einarsen, 2018). Only a few studies include both perspectives (e.g., Fernández-del-Río et al., 2021; Sischka et al., 2021). However, these studies applied a variable-centered approach and treated workplace bullying exposure and perpetration as separate variables. Thus, they leave us somewhat in the dark with respect to the existence of the aforementioned typology. The current study employs a person-centered approach (i.e., latent class modelling) to identify groups of employees that show different patterns of workplace bullying involvement. Moreover, the current study aims to identify predictors of group membership.

Theoretical background

We investigate the individual disposition hypothesis (Nielsen & Einarsen, 2018), assuming that individual characteristics such as personality traits may be related to being involved in bullying and could therefore be typifying features of workplace bullying groups. Moreover, according to some researchers in workplace bullying, individual characteristics such as certain personality traits (big five dimensions, trait aggression, dominance) are particularly appropriate to identify and distinguish workplace bullying subgroups (Matthiesen & Einarsen, 2007; see also Nielsen et al., 2017). On the other hand, power and social status represent enabling structures (Salin, 2003) of workplace bullying, and power imbalance is often seen as a defining feature of workplace bullying (Einarsen et al., 2020). Thus, we investigate whether different workplace bullying groups differ with regard to perceived power and social status.

Design/Methodology

To test our hypotheses, respondents were recruited via Amazon's Mechanical Turk (MTurk; Buhrmester et al., 2011; Crump et al., 2013) using CloudResearch (Litman & Robinson, 2020) to participate in an online survey. The final sample contained 1,492 respondents (53.8% females, n = 802), with ages ranging from 19 to 77 (M = 40.2, SD = 10.8). Most respondents worked full time (91.2%, n = 1,360). The survey contained the Short-Negative Acts Questionnaire (S-NAQ; Notelaers et al., 2019) that was applied from the victim as well as from the perpetrator perspective. Furthermore, we assessed the big five with the Mini-IPIP (Donnellan et al., 2006), trait aggression with the brief aggression questionnaire (Webster et al., 2014), and dominance with the domineering subscale of the Inventory of Interpersonal Problems (Soldz et al., 1995). Moreover, power and social status were assessed with a newly developed bipartite measure of social hierarchy (Yu et al, 2019).

Results

A latent class modelling approach was employed. Statistical fit indices, substantive interpretability and utility, as well as classification diagnostics were jointly considered to determine the number of workplace bullying classes. Latent class structure analysis revealed that the classes were meaningfully linked with the big five dimensions, trait aggression, dominance, power and social status.

LimitationsThe cross-sectional and self-reported nature of the study. Conclusions – research and or practical implications

Scholars and policy makers need to be aware of different patterns of being involved in workplace bullying in order to create effective interventions. Personality factors as well as power and social status are important correlates of workplace bullying involvement.

What goes around comes around: How perpetrators of workplace bullying become targets themselves.

Ivana Vranjes, University of Tilburg; Elfi Baillien, KU Leuven; Hans De Witte, KU Leuven; Yannick Griep, Behavioural Science Institute Radboud University; Tinne Vander Elst, University of Tilburg

Research goals and why the work was worth doing

While authors univocally acknowledge the problematic nature of workplace bullying, most of what we currently know about workplace bullying stems from the targets' perspective. The few studies that did look at perpetrators found a significant association between being a perpetrator and a target of bullying (Baillien et al., 2011a; Balducci et al., 2012), and some scholars reasoned that perpetrators may over time become targets themselves (Brotheridge et al., 2012). However, this latter perspective seems at odds with the commonly accepted view on perpetrators of bullying as being more powerful than targets (Baillien et al., 2017), and with previous empirical evidence supporting this perspective (Glambek et al., 2016). This study aims to test this relationship and explain why and how perpetrators become targets themselves.

Theoretical background

In this study, we want to unravel the process in which perpetrators lose their more powerful position and ultimately become a target of bullying themselves. In doing so, we reason from the Conservation of Resources Theory ('COR'; Hobfoll, 1989) that perpetrators of bullying become targets through a loss of resources manifested in frictions with colleagues and a decrease in perceived control. In other words, the transition from a perpetrator to a target role is a gradual process that happens when the perpetrator loses his support from others, starts feeling powerless and consequently becomes vulnerable to interpersonal attacks.

Design/Methodology/Approach/Intervention

Our sample consists of a heterogeneous group of Belgian employees with a mean age of 38.2 years (SD = 10.41) and 50.2% male participants. We investigate our hypotheses in a longitudinal sequential mediated structural equation model over four time points, testing the mediating effect of interpersonal frictions and loss of control on the effect of enactment of bullying to exposure to bullying.

Results

Our results confirmed that employees who enacted bullying were more likely to become exposed to bullying 15 months later. This effect was not always confirmed with shorter time lags, suggesting longer timeframes for this process. We also found that experience of relationship may mediate this relationship, suggesting that perpetrator experience backlash following their engagement in bullying. However, we did not find support for our proposed mediating effect of perceived control loss. Our findings suggest that perpetrators of bullying may not be as untouchable as previously thought and invite further exploration into the processes that may account for this relationship.

Limitations

We experienced some drop-out of participants across the different measurement moments related to the bullying experience with bullied individuals being mor likely to respond to the surveys. Next,

common method bias could be a concern as we used self-reported measurements. We tried to decrease the risk of common method bias by highlighting the voluntary character of the study and the anonymous treatment of the data, by using items from internationally validated scales, and by using a lagged design in which predictors and outcome variables were separated in time.

Research/Practical Implications

The implications of this study are threefold. First, our study is one of the few to focus on perpetrators of workplace bullying, shedding light on an under-represented perspective in bullying interactions. Second, while previous studies have shown an association between perpetrator and target roles in bullying, this study helps us to further unpack this dynamic by investigating the mechanisms that underlie the evolution from the perpetrator to the target role over time. It also highlights the timeframe within which the relationship between enactment and exposure may unfold. Finally, this paper also has practical implications, as it highlights risks associated with enactment of bullying behavior and the potential spiraling effect of this behavior. Insight in these dynamics of workplace bullying may help policy makers and practitioners to identify factors that may interrupt these dynamics, and thus provide a strong imperative for bullying prevention strategies.

Originality/Value

While previous studies have shed light on a variety of negative outcomes for the targets of this behavior, our understanding of perpetrator outcomes has remained limited. Such imbalanced view on bullying is problematic as it neglects a key player in workplace bullying evolvement and provides us with merely a partial understanding of bullying behavior. In this study, we therefore aimed to investigate consequences of workplace bullying for perpetrators themselves.

Paper 4

Development and validation of a Bystander Typology Scale (BTS): An update

Kara Ng, University of Manchester; Karen Niven, University of Sheffield

Research goals and why the work was worth doing

Our research goals are to develop and validate a measure of workplace bullying bystander responses, known as the Bystander Typology Scale (BTS). Research has consistently shown that bullying is not just a problem between the perpetrator and target; rather, it is often a group-level issue and bullying instances are often observed by third-parties, known as bystanders. Although bystanders have traditionally been portrayed as mainly passive agents, recent work suggests that they can enact a variety of responses that can ameliorate or worsen the bullying. To date, there has been no validated scale to measure bystander behaviour in workplace bullying, which hinders researchers' ability to understand and examine what encourages different bystander responses and their effects.

Theoretical background

We draw on an established framework of workplace bullying bystanders, first proposed by Paull et al. (2012) and further developed by later scholars. This framework conceptualises bystander responses along two dimensions: Constructive to Destructive (the extent to which responses aim to improve or worsen bullying) and Active to Passive (the extent to which responses directly target the bullying situation). This creates four general bystander response types: Active constructive, active destructive, passive constructive, and passive destructive. We propose that these response types have different antecedents and outcomes, which we examine in testing our scale's nomological validity.

Design and methodology

We clarified our constructs by identifying potential attributes that represent our four bystander types through literature reviews. After developing preliminary definitions, we asked academic and practitioner subject matter experts to rate and comment on the definitions. Feedback was used to finalise our definitions and conceptualisations of the four bystander responses, and to create 36 initial items.

In Study 1, we ran an initial validation of the BTS by conducting an EFA (n = 360) and CFA (n = 288), which produced a final set of 22 items. We conducted multidimensional scaling to confirm that items produced four clusters that match our proposed taxonomy.

In Study 2, we examined the BTS's nomological validity using three samples to see how different predictors relate to the four responses. Study 2a (n = 242) examined whether morally relevant individual traits (e.g., prosocial values, trait moral disengagement) predicted whether responses would be constructive or destructive. Study 2b (n = 445) examined behavioural predictors of constructive and destructive responses, such as OCB and personal assertiveness. Study 2c (n = 488) examined how facets of organisational culture, such as conflict for climate management and team psychological safety, predicted passive or active responses.

Study 3 (data to be collected by March 2023) aims to measure outcomes of the BTS by examining target well-being and attitudes in response to bystander behaviours.

Results

The BTS's final 22 items showed good psychometric fit, internal reliability, and discriminant validity. Multidimensional scaling showed that items were grouped in four clear clusters. Study 2 confirmed that individual differences, behaviours, and aspects of organisational culture successfully predict different bystander response types. Study 3 results are forthcoming, but we predict that targets in groups with greater active constructive responses will have better outcomes than targets in groups with more destructive or passive bystanders.

Limitations

The BTS has been tested on working adults but using Prolific sampling. Future research should seek to use the scale in a field study, where we would be able to examine how bystander responses are influenced by, and influence, team and organisational characteristics.

Conclusions

This presentation aims to provide an update on our validating the BTS. We believe that the BTS will provide a standard framework to conceptualise the variety of workplace bullying responses, which will help unify future research and deepen our understanding of bullying as a social, group-level phenomenon. The BTS can also be used to measure the prevalence of different bystander responses in real organisations and can be used to evaluate bystander intervention training programmes.

Relevance to the Congress Theme

There has been evermore importance placed on workplace well-being and the effects that workplace relationships can have on our well-being. Bystander research seeks to emphasise that workplace bullying is a group issue, in which others have the power to stop or improve the situation. We hope our scale, its framework, and our findings contribute to existing efforts to reduce workplace bullying and improve future workplace relationships.

Paper 5

Mapping responses to interpersonal workplace mistreatment from the co-worker's perspective.

Caroline V. M. Bastiaensen, Lieven Brebels & Elfi Baillien | KU-Leuven

Research goals and why the work was worth doing

Research on interpersonal workplace mistreatment (IWM) – of which workplace bullying is a well-known phenomenon – increasingly incorporates co-workers as a relevant actor in (de-)escalating the social process of IWM. Scholars have typically adopted a victim-centric perspective by looking at how co-workers affect the situation for the victim. Research on this topic has thus taken a normative stance, thereby increasing the challenge of detecting non-normative responses to IWM in the study context because of social desirability and humans' motivation to maintain a positive self-concept. Nonetheless, these reactions are observed in real-life settings. Indeed, several factors – such as perceived victim deservingness (Li et al., 2019), motivated ignorance (Wieland, 2016), and moral disengagement (Bandura, 1999; Ng et al., 2019) – can explain co-workers' non-normative responses. As such, this leaves a remarkable blind spot in our current knowledge as, up until now, we have been showing limited interest in the co-worker's perspective. Co-worker's responses are not stand-alone behaviours that affect only the victim. Rather, co-workers operate within the social context of their work environment and experience broader consequences of their behavioural reactions. We aim to expand our knowledge by addressing this gap and thus orienting this study towards a co-worker-centric perspective. More specifically, in a qualitative study, we will dive deeper into how co-workers perceive the situation and their own and other co-workers' responses to IWM. Through disentangling what happened in real-life incidents of mistreatment, we also aim to link the range of behavioral responses more clearly to the social context and the co-workers' stakes in the incidents. This study thus aims to expand the focus and thereby – besides often-studied victim-supportive behaviors – also shed light on non-normative responses.

Design and methodology

Semi-structured interviews will be conducted with employees recruited to talk about how they experience social relations at work. We will not recruit on "witnessing acts of IWM" to avoid guiding interviewees in a specific direction with the focus on an alleged victim and thereby triggering an evaluative or normative mindset. Particular attention during the study will thus be distinguishing observers from victims. Moreover, IWM is a sensitive topic which may provoke emotional responses that have to be coped with by the interviewer. The interviewees will be asked to describe their own behavioural responses, and the responses they observed among others involved within the organisation (employer, other co-workers, etc.). We aim to overcome social desirability bias by expressing that we are explicitly interested in their perceptions as a co-worker and not taking a victim-centred, evaluative, or normative approach. Sharing observed behaviour of other co-workers should make it less challenging to identify the full spectrum of co-worker behaviours, including those that lead to conflict escalation. Interviewees will also be asked to reflect upon the effects the listed behaviours had on themselves and their work environment. This will help us to illustrate when and why co-workers chose a specific behavioural response.

Expected results

The results of the study will be available at the conference. We expect to a) present an inventory of co-worker reactions from different perspectives, going beyond normative responses. To b) shed light

on which behaviours are most commonly mentioned when listing actions from a certain perspective, informing us about how employees reflect on their own behaviour and that of others. And to c) disentangle how the different behaviours relate to the experienced consequences of the behaviours. With this information, we expect to introduce a framework from an inquisitive perspective regarding these co-worker behaviours instead of an evaluative categorisation that is currently used in research.

Conclusions

The inventory can be used in further research regarding when and why co-workers show these reactions. This, in turn, will support the development and implementation of successful co-worker intervention programs. It is essential to know why co-workers, within their context, choose to enact behaviours that are not necessarily victim-supportive, to create programs in which they are stimulated to take up these types of roles.

Relevance to the Congress Theme & UN SDGs

The conference theme urges us to think about how work is changing. But interventions or actions regarding changing jobs and job environments must consider that for these to succeed, a sound foundation is necessary. This study can help us on how to better understand and establish such a sound foundation concerning social relations at work. This study is relevant for the SDG's related to IWM, with the strongest connection to "decent work and economic growth" and "good health and wellbeing".

Symposium S090

Multi-Level Perspectives on Teamwork. Motivational, Affective, and Cognitive Team Emergent States, their Antecedents, and Consequences

Rebecca Müller, Conny Herbert Antoni | University Trier

science

What will be covered and why. With the increasing amount of information that has to be processed in today's working environment, the implementation of teams become more prominent in various work contexts. Teamwork provides positive outcomes, such as improved performance, reduced individual information-processing demands, and increased social support. However, teamwork also poses certain challenges, such as team members' thwarting behavior, social loafing, low team identification, or different understandings of how the work is done (i.e., different mental models). These challenges may influence outcome variables, such as the psychological contract fulfillment, emergence of motivation and team identification, or satisfaction with teamwork. The relationships between input and outcome variables in teamwork are described in so called input mediator output input models (IMOI model). The IMOI model implies variables on the individual, team, and organizational level in a nested structure that influence each other. Although individual- and team-level variables may influence each other, these relationships are rarely considered in previous research on teamwork. Previous research on teamwork often aggregates individual level variables on team level and does not employ multilevel analyses, which would provide insights in mutual influences among different levels of variables. This symposium aims to contribute to existing research on teamwork by investigating critical teamwork variables, such as the emergence of team motivation and team identification, psychological contract fulfillment, and shared/different mental models by using multi-level perspectives.

Study 1 analyzes the emergence of team motivation and team identification. Results are based on a laboratory experiment with 150 members in 50 teams. Team members' supportive or thwarting behavior on individual level influences need satisfaction/frustration with the team and this, in turn, influences the development of team identification. Further, it shows that need satisfaction predicts team-level changes in team identification over time.

Study 2 investigates the effect of social loafing on psychological contract fulfillment or breach moderated by team identification. Results are based on a field study with 344 members in 65 teams. It shows that a higher level of social loafing leads to lower collective perceptions of psychological contract fulfillment on individual and team level. This relationship is moderated by team identification, but only on the individual level. If team identification is high, the relationship between social loafing and psychological contract fulfillment becomes slightly positive.

Study 3 investigates the effect of shared vs. different mental models of information and communication technologies as a team level variable on the individual level variables of technostrain and satisfaction with teamwork. The hypotheses are analyzed in a laboratory experiment with 207 members in 69 teams. Results based on multilevel mediation analyses show that if team members have a similar understanding of their ICT-use (i.e., shared mental models) compared to different mental models of ICT-use, the individual perception of technostrain is reduced and satisfaction with teamwork is improved.

The discussant will reflect the importance of different team emergent states (i.e., collective perception of psychological contract fulfillment, team motivation, team identification, shared mental

models), their antecedents, and consequences on both individual and team level. Considering this, the aim is to highlight the importance of using multi-level perspectives when analyzing teamwork.

Relevance to the Congress Theme. In line with the congress theme "The Future is Now: the changing world of work" our symposium focuses on the challenging demands today's organizations face. With the technical progress and the increased digitalization, organizations and their employees have to process an increasing amount of information. Teams can serve as transactive memory systems that reduce individual information-processing demands. However, teamwork must also be resource-oriented and health-friendly to be sustainable and effective in the long-term. Our symposium provides insights of which aspects are important to consider to benefit from successful teamwork.

Research/Practical Implications. It is intended to illustrate that research on teamwork should incorporate more multi-level perspectives, in which both individual and team level variables can influence team processes and outcomes. From a practical perspective, we highlight how organizations and team leaders can take this multi-level perspective of variables into account for improving both team processes and outcomes as well as team member well-being.

Overall conclusions. Team processes and emergent states that influences each other among different levels are essential for a successful teamwork and individual well-being.

discussant: Jan Häusser, Justus-Liebig University Giess

Paper 1

A STUDY ON THE DYNAMICS OF THE INTERPERSONAL FEEDBACK LOOP AND ITS IMPACT ON TEAM MOTIVATION

Sandra Merino, Universidad Carlos III de Madrid; Thomas O'Neill, University of Calgary and Haydn Williams Fellow at Curtin University; Marylène Gagné, Curtin University; Ramón Rico, Universidad Carlos III de Madrid

Research goals and why the work was worth doing : Interest in explaining the processes through which work teams themselves are motivated, and why, has increased in the last years. Despite a rich body of research has empirically addressed the foundations of individual motivation, scarce attention has been paid to motivation at the team-level. To address this gap, this study explores the influence of team members' supportive behaviours on their individual needs satisfaction and team identification. This is what we have defined as the interpersonal feedback loop. We thus hypothesise that the dynamics of such feedback loop would impact the emergence of team identity, which would ultimately affect team motivation.

Theoretical background : The conceptualisation of motivation from self-determination theory (SDT; Gagné & Deci, 2005) offers a framework to disentangle team motivation from other team processes and to investigate how team motivation is impacted by the interpersonal feedback loop. Our model focuses particularly on the impact of support coming from team members on their needs satisfaction. Additionally, drawing on SDT, the effect of supportive behaviours on team members' need satisfaction may lead them to interpret and feel they are important to each other, triggering the construction of a team identity. Finally, building on dynamic processes to explain how team motivation might develop over time, we hypothesised that team identification might impact team motivation, as highly identified team members may be more motivated in the team.

Design : We conducted a laboratory experiment using a 2 x 3 mixed design, with two experimental conditions (supportive vs thwarting behaviours) and three measurement times. Each three-person team (N = 50 teams; 150 undergraduate students) worked on a computer-based real-time command-and-control fire fighting simulation (NFC; Omodei et al., 2003) for approximately 2 hours.

Results : Manipulation checks revealed that our manipulations worked out, as t -tests for the difference in the means of our variables of interest between both experimental conditions yielded significant results. In testing our main hypotheses, we were able to check through cross-lagged regression models that: (1) supportive/thwarting behaviours within teams fosters need satisfaction/frustration within the team; and (2) need satisfaction/frustration within a team influences the development of team identification. Regarding the emergence of team identity, consensus emergence modelling (CEM, Lang et al., 2018) allowed us to test that need satisfaction is a relevant predictor of team-level changes in team identification over time. Ultimately, after aggregating data to the team level, we ran linear regression models which supported the hypothesised influence of team identity on team motivation.

Limitations : Despite our results support our hypotheses, they are subject to limitations. Probably the most obvious are the fact that our research design only allowed us to observe newly formed teams over a limited period of time, and the contrived lab setting in which we could gather our data. Although our results concur with dynamic approaches of team motivation emergence suggesting that the interpersonal feedback loop may affect team motivation trajectories differently over time, we

call for future research to investigate teams working together for longer periods of time and to complement these findings with field samples. That will help to draw more reliable long-term and generalizable implications from our findings.

Conclusions : Results of the present study contribute to complement and extend extant theoretical models of team dynamics, addressing previous calls to better understand team motivation. Furthermore, this study has practical implications in promoting supportive environments for teamwork through training interventions.

Relevance to the Congress Theme : Our results will be relevant for current organisations increasingly relying on teams to address the demands of the changing and complex current socio economic environment.

Relevant UN SDGs : Results of this study are crucial for creating healthier productive workplaces, contributing to improving employees' health and well-being .

Keywords: Need satisfaction, supportive behaviour, team identity and motivation

Paper 2

"Well, that's ok": How team identification moderates the association between social loafing and psychological contract fulfillment in teams

Jeroen de Jong, Radboud University; Irina Nikolova, Maastricht University; Nina Mareen Junker, Oslo University

Research goals

Empirical evidence and theory both support the idea that successful collaboration in teams is highly dependent on the relationships between the members of the team. More specifically, research on social networks in teams shows that more tight-knit networks in teams, where information flows and social support is provided between team members, are associated with the highest team performance outcomes. Psychological Contract Theory (PCT) argues that parties within social exchange relationships (such as between one team member and the rest of the team) can form mental models about reciprocal obligations within these exchange relationships. Team members can expect from their colleagues that they meet deadlines, that they provide feedback, but also that they provide social support when necessary. Moreover, PCT argues that when these perceived obligations are breached, this can have several negative implications for employee outcomes. In this research, we aim to better understand how these collective beliefs about reciprocal obligations in teams emerge.

Theoretical Background

To benefit from working together, all team members are expected to contribute actively to team goals. However, there is strong evidence that variation in efforts exists in teams and that some team members may exert less effort when working in groups compared to when they work individually. This phenomenon is defined as social loafing, which has a rich history in group research. We propose that social loafing in teams is negatively associated with perceptions of the fulfillment of obligations by the team towards focal team members. When the team is characterized by higher levels of social loafing, fewer efforts are made to fulfill obligations towards each other, relating to higher (collective) perceptions of breach (H1). Yet, team identification (ID) (i.e., "the personal, cognitive, emotional and behavioral bond between individual and team" Somech et al., 2009, p. 363). might moderate this negative association. Specifically, high team ID might mitigate the negative effects of social loafing as team members are more likely to make additional efforts when their colleagues are contributing less to the team, and are more likely to focus on the social aspects of teamwork, such as providing emotional support. Therefore, we expect that the negative association between social loafing and fulfillment of obligations is weaker for teams characterized by high team ID compared to teams characterized by low team ID (H2).

Methodology

We test our hypotheses using a dataset of 65 teams and 344 team members. The teams were all operational teams working in different sectors in the Netherlands, ranging from education to the banking sector. We used validated scales to measure our main variables. A multilevel analysis was used to test our hypotheses, in which we distinguish between- and within-team effects.

Results obtained

The results show that social loafing has a negative association with perceived contract fulfillment on both the team (between) and individual (within) level. This confirms H1. Second, our results show that team ID moderates the association between social loafing and psychological contract fulfillment on the within-level. Specifically, the relationship between social loafing and psychological contract fulfillment is negative for low team ID, but becomes slightly positive when team ID is high, which partly confirms H2.

Limitations

The present study used a cross-sectional data set, which limits the possibility to comment on the temporality of the obtained associations.

Conclusions – research and or practical implications

This research contributes to the literature by expanding the scope of PCT to team psychological contracts and shows initial evidence of antecedents of team psychological contract fulfillment. The moderating role of team ID pinpoints the importance of team identification, while at the same time raising the question of what the underlying mechanisms are. For instance, it could be that individual team members increase their efforts to compensate for their colleagues' social loafing. However, it could also be that members with a high team ID have more insights into each other's' lives, which helps them rationalize social loafing in a more positive way by attributing it to more understandable reasons (e.g., underlying health or family issues) compared with low team ID.

Relevance to the Congress Theme

Teamwork has been steadily increasing in the last century and will further increase in the near future, which makes it crucial to understand team processes in more detail.

Relevant UN SDGs

This research particularly contributes to the UND SDG of decent work and economic growth .

Keywords: Team Identification, Social Loafing, Psychological Contract Fulfillment

Paper 3

TECHNOSTRAIN AND TEAM SATISFACTION IN TEAMS: THE EFFECT OF SHARED MENTAL MODELS OF INFORMATION AND COMMUNICATION TECHNOLOGY

Rebecca Müller, Conny Herbert Antoni, Benedikt Graf & David Schischke | University Trier

Research goals and why the work was worth doing: Challenges related to the use of information and communication technology (ICT), such as technostrain, have become more and more prominent in the changing world of work. Previous research has primarily focused on individual level causes, such as conscientiousness, ICT-competence, and self-management. Only few studies, have yet assumed dysfunctional team information exchange as team level causes of information overload or technostrain. Thus, also factors on team level can be considered as causes of individual technostrain and satisfaction with teamwork.

Theoretical background: Research has shown that shared mental models (SMM) are an important and prominent factor on team level for successful teamwork. SMM are common knowledge structures about relevant aspects of the working environment among team members. If team members have SMM about, for example, ICT-use (ICT SMM), they have similar expectations regarding their ICT-use within the team (e.g., which ICT to use for which task or purpose). Previous research has shown that, if team members have SMM, explicit coordination is reduced and motivational and affective team emergent states as well as team performance is improved. Transferring the previous insights of SMM on ICT SMM, we assume that if team members have ICT SMM, they perceive less technostrain and more team satisfaction, mediated by reduced explicit coordination of ICT-use and perceived workload.

Design: In a laboratory experiment, 69 three-person teams (N = 207 students), worked on a virtual decision-making task for forty minutes. To communicate with each other, team members could choose four different ICTs. We manipulated ICT SMM as a between-subject variable on team level, as thirty-four teams were allowed to plan their ICT-use beforehand, and thirty-five teams were not allowed to plan their ICT-use and received different ICT-preferences. Technostrain, satisfaction, and perceived workload were assessed by Likert-Scales after the teamwork. Explicit coordination of ICT-use was measured objectively by the communication content of the teams (i.e., questions about ICTs, discussion about ICT-preferences).

Results: A manipulation check showed that the experimental manipulation of ICT SMM worked. To analyse our hypotheses, we used multilevel mediation models in MPlus with ICT SMM as an exogenous variable (level 2), explicit coordination of ICT-use as an endogenous mediating variable (level 2), perceived workload as an endogenous mediating variable (level 1), and technostrain and satisfaction as dependent endogenous variables (level 1). Our results revealed that ICT SMM had a direct effect on satisfaction, explicit coordination of ICT-use, and perceived workload. Perceived workload and explicit coordination of ICT-use mediated the effect of ICT SMM on satisfaction and perceived workload indirectly on technostrain.

Limitations: Limitations of our study are the experimental design and the use of a student sample. Thus, the external validity of our study is limited and should be improved by follow-up studies using employee working teams in field studies.

Conclusions: This study contributes to existing research by showing the causal effects of ICT SMM on technostrain and satisfaction as well as by clarifying perceived workload and explicit coordination as underlying mechanisms.

Relevance to the Congress Theme: In the sense of the congress theme “The Future is Now: the changing world of work” our study focuses on the increasing implementation and use of ICTs. In our today’s world, be it at work, at university, or during leisure time, we heavily rely on ICTs to communicate with our peers. Among many benefits of these ICTs, they also pose new challenges and threats to us, such as technostrain. In our study, we provide a starting point for how teams can avoid these challenges.

Relevant UN SDGs: Good health and wellbeing: The health-oriented treatment of employees promotes the social sustainability of organizations. Satisfied employees lead to less absenteeism due to illness and less fluctuation. Thus, our study makes a significant contribution to social sustainability and gives organizations a starting point (i.e., encouraging ICT SMM in teams) to promote it.

Keywords: Shared Mental Models of Information and Communication Technology (ICT SMM), Technostrain, Team Satisfaction

Symposium S091

Moving science on workplace bullying into the future (II)

Philipp E. Sischka, University of Luxembourg; Jose M. Leon-Perez, Universidad de Sevilla

science

What will be covered and why

Workplace bullying (WB) refers to repeated and systematic negative acts towards one or more targets during a prolonged period of time (Einarsen et al., 2020). Although previous research has made significant contributions to better understanding why and how workplace bullying emerge at work (e.g., Salin & Hoel., 2020; Gupta et al., 2020), there are still some shortcomings in the field. From the theoretical and methodological side, the field needs both more longitudinal studies that allow us to know better the dynamics and patterns of workplace bullying, and multisource and multilevel designs that help to capture the group processes that interplay with organizational and personal factors in the bullying development. From the practical side, we lack information about the success of interventions to prevent and deal with workplace bullying at different levels of analysis.

In this symposium, we aim to overcome some of the above-mentioned limitations. Indeed, we have divided the symposium in two parts. The first part tries to shed some light on the bullying process and stages as well as on the role that different actors play (e.g., managers, bystanders). In the first contribution, Notelaers and colleagues explore the role of line managers (i.e., laissez-faire leadership) in how workplace bullying unfolds over time. In the second contribution, Sischka and colleagues address the interplay of workplace bullying exposure and perpetration from a person-centered approach (i.e., latent class modelling). In a similar vein, the third study conducted by Vranjes and colleagues investigate the longitudinal association between enactment of bullying and exposure to bullying. In the fourth contribution, Ng and Niven develop and validate a measure of workplace bullying bystander responses. Finally, Bastiaensen and colleagues explore bystanders' behaviors from a qualitative approach.

In the second part, we focus on a psychosocial risks approach to workplace bullying and the effectiveness of some interventions at different levels. In the first contribution, León-Pérez and colleagues confirmed cut-off scores of the Negative Acts Questionnaire in Spain and the relationship of risk categories with well-being indicators three months later. In the second contribution, Hamre and colleagues explore, in a multilevel design, the moderating role of job insecurity climate on the relationship between role stressors and workplace bullying. Then, in the third contribution, Balducci and colleagues conducted a diary study to explore the link between negative acts and post-traumatic stress disorder (PTSD) symptoms. In the fourth contribution, Rodríguez-Muñoz and colleagues present the results of an expressive-writing intervention at individual level aimed at minimizing negative consequences of being exposed to negative acts at work. Finally, Li and colleagues report a work-design intervention at the organizational level to prevent workplace bullying.

Relevance to the Congress Theme

The symposium aims to broaden our understanding of the bullying phenomenon in the context of an ever changing working world. Moreover, it discusses preventive measures and is therefore in line with the Sustainable Development Goals to foster good health and wellbeing and to create "decent work for all" (Fields, 2003).

Research/Practical Implications

The contribution of this symposium suggests that workplace bullying is a multicausal dynamic process that needs to be addressed by integrating the role of different agents and multiple levels of analysis. In addition, this symposium offers useful insights from longitudinal studies with different time lags between measures and provides findings from interventions that can help preventing and managing workplace bullying.

Overall conclusions

To move the science of workplace bullying into the future, it is of utmost importance to understand the bullying process and stages, which factors facilitate or inhibit the (de)escalation of this process and which interventions prove to be effective countermeasures.

Keywords: workplace bullying, mobbing, work design

Paper 1

Risk groups of bullying exposure based on NAQ cut-off scores and its associations with employee wellbeing over time

Jose M. Leon-Perez, Francisco J. Cantero-Sánchez & Alfonso Cárdenas-Miyar|Universidad de Sevilla

Research goals and why the work was worth doing

Workplace bullying refers to the repeated and sustained occurrence of negative acts directed towards one or more targets who, during the process, may be unable to defend themselves, usually due to being in a position of inferiority with respect to the perpetrator/s and/or lacking support from their remaining coworkers (Mikkelsen et al., 2020)

In recent years there has been an intense debate about the measurement of bullying at work and establishing whether a person is a victim of bullying (Nielsen et al., 2020; Notelaers et al., 2021). In this study we aim to provide further evidence of the cut-off points of the short version of the Negative Acts Questionnaire (S-NAQ) to establish three risk groups for exposure to bullying: low, moderate and high. As criterion validity of these risk groups we will use measures of well-being obtained three months later.

Theoretical background

Prevalence levels of bullying have been discussed in recent years, with data ranging from 0.6% to 79.1% in Europe, depending on the estimation method (Leon-Perez et al., 2021). Therefore, there is a need for more reliable methods to establish whether a person has been subjected to bullying in the work environment. Moreover, the consequences of bullying are devastating, bullying is considered to be one of the most relevant social stressors in the workplace, as people who suffer from bullying often manifest symptomatology similar to post-traumatic stress disorders, depression and even increased risk of insomnia (Hogh et al., 2021; Nielsen & Einarsen, 2018).

Previous research has focused on establishing cut-off scores that can help Occupational Health and Safety practitioners to differentiate risk groups of workplace bullying. However, previous research has relied mainly on cross-sectional data and lack of replications. We aim to corroborate the cut-off scores in Spain and explore potential negative consequences on employee well-being some months later.

Design/Methodology/Approach/Intervention

We conducted a two-wave panel study with a four-month time lag (Nt1 = 5000; Nt2 = 2500). At time 1, we measured workplace bullying and categorized participants' responses, considering the cut-off scores validated by León-Pérez and colleagues (2019), into high, moderate, and low risk of being bullied at work. Then, at time 2, we measured psychological distress (i.e., emotional exhaustion, and anxiety) and work engagement. We conducted an ANOVA with the bullying risk categories as between-subjects factor and psychological distress and work engagement as dependent variables.

Results

Our results confirm that the cut-off scores showed significative differences in anxiety levels ($F(2,2002) = 157.94$; $p < .001$), exhaustion ($F(2,2002) = 114.22$; $p < .001$) and engagement ($F(2,2002) = 54.74$; $p < .001$). In particular, participants categorized into the high risk of workplace bullying ($n = 281$) scored higher in anxiety symptoms ($M = 1.37$; $SD = 0.81$) and exhaustion ($M = 3.29$; $SD = 1.02$)

than those in the categories moderate (M Diff. = .25; CI95% (.09; .42); p < .001) and low risk of workplace bullying (M Diff. = .79; CI95% (.64; .94); p < .001). Similarly, participants categorized into the high risk of workplace bullying (n = 281) scored lower in work engagement (M = 2.87; SD = .93) than those in the categories moderate (M Diff. = .04; CI95% (.20; .14); p < .001) and low risk of workplace bullying (M Diff. = .53; CI95% (.57; .47); p < .001). Then, participants categorized into the moderate risk of workplace bullying (n = 557) scored higher in anxiety symptoms (M = 1; SD = .67) and exhaustion (M = 3.04; SD = 0.94), but lower in work engagement (M = 3.04; SD = .89), than those in the low risk (n = 1167) of workplace bullying (M Diff = .35; CI95% (.38; .33); p < .001).

Limitations

The main limitation of this study is that it does not capture workplace bullying from a dynamic perspective (i.e., no transitions were explored). Future research may explore within-subjects transitions and the (protective and vulnerability) factors (both at individual, group and organizational level) that make it more possible to move from one risk group to another.

Conclusions

In conclusion, our findings support the established cut-off scores of the S-NAQ in Spain, showing that higher risk of being bullied is associated with higher levels of emotional exhaustion and anxiety, and lower levels of work engagement. Indeed, we challenge the idea that six months are required to label a situation as bullying because our results showed that even four months after categorizing people into risk groups can be associated with relevant negative consequences and therefore there is no need to wait to intervene in order to prevent further harm. Thus, our findings are relevant to the UN SDGs #8 Decent work and economic growth, and #3 Good health and wellbeing.

Paper 2

No offense, but I'm trying to retain my job. How a job insecurity climate amplifies the relationship between role conflict and workplace bullying

Guy Notelaers & Ståle V. Einarsen | University of Bergen; Hans De Witte & Elfi Baillien | KU-Leuven; Kristina V. Hamre, University of Bergen

Research goals and why the work was worth doing

Workplace bullying, besides being a social stressor, is a social strain that is caused by various stressors from the work environment; referred to as the 'Work Environment Hypothesis'. Driven by this hypothesis, scholars have identified a wide range of work-related stressors of bullying (e.g., Balducci, Conway, & van Heugten, 2018) of which role conflict is the most prominent one (Van den Brande, Baillien, De Witte, Vander Elst, & Godderis, 2016). However, despite extensive empirical evidence for role conflict as a stressor of bullying (e.g., Reknes, Einarsen, Knardahl, & Lau, 2014) some scholars failed to replicate similar findings (Hauge, Skogstad, & Einarsen, 2011). One explanation could be that the role conflict – bullying relationship could dependent on individual factors, such as the coping style of the target (cf. Van den Brande et al., 2020). On the other hand, role conflict and bullying are inherently social (Bowling, & Beehr, 2006) and their relationship could be sensitive to the social context in which these are embedded (Bishop, 2018). In this respect, this study introduces an emerging facet of the organizational climate in occupational health studies, namely the job insecurity climate, as a contextual factor. Relying upon Conservation of Resources Theory, we hypothesize that such a climate will strengthen the relationship between role conflicts and bullying.

Theoretical background

Conservation of Resources Theory (Hobfoll, 1998; 2008).

Design/Methodology

To test this cross-level interaction we employ a university sample from the Low Lands. The response rate was 48.8% and the total sample consisted of 1354 employees working in 134 units. We controlled for occupational position and took account for social support.

Results

The results show that in both low and high insecurity departments the relationship between role conflicts and bullying was positive. More importantly, however, the relationship between both was steeper in departments where job insecurity was high.

Limitations

The cross-sectional and self-reported nature of the design.

Conclusions

The current study contributes to a more complete understanding of the circumstances under which bullying may occur. Although in this organization workplace bullying and role conflict are positive related in either case, the finding that the relationship is stronger in high insecure environments brings an aggravating condition to the fore that seem to function as the opposite of resources passageway. Demands across levels have not only an additive effect but also an interaction effect,

making the situation worse for those in these environments. Therefore, guiding and communication about organizational change and prospect of future employment is advisable to prevent both the additive and the interaction effect of job insecurity climate.

Paper 3

A weekly diary, within individual investigation on the relationship between exposure to bullying behavior and post-traumatic stress symptomatology

Cristian Balducci, University of Bologna; Michela Vignoli, University of Trento

Research goals

Most studies on bullying have adopted a between-person approach, focusing on individual differences in exposure to bullying and linking these differences with work-environmental and personal variables. However, the evidence built on between-person studies completely neglects the existence of within individual variance in workplace bullying, the modelling of which is essential for elucidating processual aspects and mechanisms involved in the phenomenon, which is naturally dynamic in nature. Thus, the present study will adopt a within individual approach with the main aim of investigating whether weekly fluctuations in the experience of bullying explain parallel fluctuations in post-traumatic stress disorder symptomatology, which has often been found to be associated with bullying at the between level.

Theoretical background

It has long been recognized that the different symptoms commonly reported by victims of bullying such as anxiety and irritability, sleeping problems, and concentration difficulties are very similar to those characterizing Post-Traumatic Stress Disorder (PTSD), a very debilitating anxiety-related disorder. Although it may be questioned whether bullying has similar characteristics to those events which have been often observed in association with PTSD, it is also true that trauma may be defined as an event or situation with the capacity to shatter the individual's basic cognitive schemas about the world, other people, and the self and that bullying may satisfy such definition. Based on recent discoveries on traumatic experiences and PTSD (e.g., Nadal, 2018), we contend that even short-term exposure to low intensity bullying behavior – such as the exposure that characterizes a worker when the time window considered is a working week – may already have an important psychological impact as indicated by the experience of PTSD symptoms. Additionally, we also hypothesise that the development of workplace phobia reactions may act as a mechanism linking exposure to bullying during the week and the reported PTSD symptomatology. This is because the fear reactions associated with bullying may first manifest in the form of workplace phobia (i.e., a context-specific form of anxiety) and then generalize to a more extreme and debilitating form of anxiety (i.e., PTSD symptomatology) transcending the workplace and impacting more significantly on the individual psychosocial functioning.

Design/Methodology

We had available data on 158 employees, who provided a total of 860 weekly observations with a mean of 5.44 observations per participant (SD = 1.00). The final sample was made by women in 60.1% of the cases and had a mean age of 36.76 years (SD = 11.95). Participants worked an average of 36.23 hours per week (SD = 9.76) and in 75.9% of the cases, their work requested direct contact with customers/clients. Data collection was carried out electronically via the web platform Qualtrics and consisted in the administration of a preliminary questionnaire and six weekly diary surveys which were filled in by the participant each Monday for six consecutive working weeks. Each weekly survey collected information regarding the previous week. The links to the different surveys were sent to the e-mails of the participants and each survey included an anonymous code made by factual

personal information which preserved anonymity. At the end of the study the different datasets obtained (i.e., one dataset for each survey) were matched through the anonymous code. We measured the crucial study variables (bullying, PTSD and workplace phobia symptoms) with adapted scales, which showed adequate psychometric properties at both the between person and within person levels. To test the study hypotheses we implemented multilevel modelling.

Results

The weekly measures showed a substantial amount of variance at both the within and between levels ($.58 < ICC < .74$). Results of multilevel modelling revealed that weekly bullying was significantly and positively related with weekly PTSD symptoms ($b = .19$; $p = 0.015$) at the within level, which supported our first hypothesis. Additionally, at the within level, mediation analysis revealed that weekly-level bullying was significantly related with weekly workplace phobia ($b = 0.44$, $SE = 0.07$, $t = 6.31$, $p < .001$) and weekly workplace phobia was significantly related with weekly PTSD symptoms ($b = 0.26$, $SE = 0.04$, $t = 6.34$, $p < .001$). The direct relationship between weekly-level bullying and PTSD symptoms was not significant when controlling for workplace phobia. A test of the postulated within indirect 'effect' resulted significant (estimate = 0.11, $SE = 0.025$, $Z = 4.45$, $p < .001$) with Montecarlo confidence intervals ranging from 0.067 to 0.166. This supported our second hypothesis, with workplace phobia fully mediating the within relationship between bullying and PTSD symptoms. Further analyses on moderating variables are underway.

Limitations

The most important limitation is the convenience sample obtained, including participants from different occupations and sectors. Additionally, the relatively low number of participants (i.e., level-2 units) may constitute a further study limitation.

Conclusion

Exposure to bullying behavior significantly fluctuates from week to week and such fluctuation is consequential in terms of experiencing workplace phobia and PTSD symptoms within individuals. The results suggest that even non-persistent forms of exposure to bullying, such as those that may be captured during an exposure period of one week, may already produce significant health impairment and initiate trauma-like consequences in the targeted individual. This accentuates the need to move towards primary preventive interventions on bullying, that is, acting before even more milder forms of the phenomenon takes place.

Relevance to the congress theme

Bullying and intimidating behavior at work constitute relatively prevalent problems with the capacity to impact profoundly workers' mental health. There is a need of change toward zero-bullying work environments to create better and healthier working conditions in post-pandemic workplaces.

Paper 4

Workplace bullying and expressive writing: An intensive longitudinal randomized trial

Alfredo Rodríguez-Muñoz, Francisco J. Estupiñá, Paula Ruiz-Zorrilla & Mirko Antino | Universidad Complutense de Madrid

Research goals and why the work was worth doing

This research aims to test the effectiveness of a longitudinal randomized trial to reduce the negative consequences of exposure to workplace bullying behaviours on different well-being indicators.

Theoretical background

An extensive body of research has indicated the negative repercussions that the workplace can have on employees' health and well-being (e.g., Nielsen & Einarsen, 2012). Within this context, the past decade has witnessed a growing interest in conducting interventions for preventing bullying and minimizing the negative outcomes of this phenomenon. In this study, we respond to the call to conduct brief and low-cost interventions (e.g., Kazdin, Rabbitt, 2013). One promising intervention is expressive writing.

Design/Methodology/Approach/Intervention

All the participants had to answer 3 weeks of daily questionnaires. The first week represents our baseline. At the end of the first week, we executed the intervention (both experimental and control group), randomly assigning the participants to the emotional writing condition or the neutral writing condition. We repeated the intervention at the end of the second week, and we ended the intensive longitudinal data collection after the third week. Long-term follow-up is actually under execution. Participants data: n level 1 (day level) = 1812, N level 2 (person level) = 151.

Results obtained

Provisional results show a high amount of within-level variability. It shows more effects during the first week than during the second week (when comparing the impact on a double discontinuity growth model). Results will be discussed by comparing the evolution of the outcomes with and without the inclusion of an objective counting of the emotions that were expressed during the intervention, as we observed a high variability within the experimental group.

Limitations

Data collection is not completed, although the long-term effects (3 months and 6 months follow-up) will be available and discussed. The online nature of the data collection seems to have generated a high variability in emotional content within the experimental group. To understand the validity of this experimental approach, we consider that analysis run on the definitive sample will provide some light.

Research/Practical Implications

Despite the pernicious effects of bullying, there is a surprising lack of empirical intervention studies in this area (Nielsen & Einarsen, 2018). The paper offers clues about the validity of an intervention from an established approach such as the expressive-writing.

Relevance to the Congress Theme

Our research is in line with the congress delivery line. How do we mitigate harassment? Is it effective?

Relevant UN SDGs

This research relates to the UN Sustainable Development Goal of decent work and economic growth.

Paper 5

Changing the underlying conditions relevant to workplace bullying through organisational redesign

Yiqiong Li, School of Business, University of Queensland; Annabelle Neall, School of Psychology, University of Queensland; Alice Rose & Michelle Tuckey | Centre for Workplace Excellence, UniSA Justice & Society, University of South Australia

Research goals

The overarching goal was to implement and empirically evaluate an organizational intervention for the prevention of workplace bullying, based on theory and research on workplace bullying antecedents . The present study describes the background, design, and protocol of the intervention with a focus on changing/improving organizational systems, procedures and practices relating to how people are managed and coordinated. It also evaluates the effectiveness of the intervention using objective and subjective criteria.

Background

When seeking to prevent workplace bullying through evidence-based approaches, there is a discrepancy between anti-bullying approaches used in organisations, which typically treat bullying as an interpersonal problem, and the academic evidence base, which highlights job characteristics as the primary contributing factors. For example, half of the 12 bullying intervention studies in Hodgins et al.'s review (2014) did not tackle aspects of work and organizational design. Rather, the interventions addressed individual-level factors only, consistent with the notion that bullying is routinely viewed as an individual interpersonal problem.

Two potential reasons may explain this discrepancy. The first reason is that the general advice based on existing academic evidence may not be specific enough to guide practical risk management efforts to prevent bullying and the associated harms. The second reason is the lack of intervention studies to bridge the knowledge gap between existing research findings and tools that can be applied in practice. The evidence on prevention and intervention initiatives is severely limited (Hodgins et al., 2014), especially primary interventions (Hershcovis et al., 2015). Most intervention studies centered on improving social interactions in the workplace focus on broad and general issues such as respect or dignity instead of specifically and explicitly addressing bullying (Einarsen et al., 2020). Few workplace bullying intervention studies have been empirically implemented and evaluated for efficacy and effectiveness (Caponecchia et al., 2019; Einarsen et al., 2020; Escartín, 2016). Moreover, few intervention evaluation studies have been conducted with a high-quality research design (Einarsen et al., 2020).

Intervention and approach

Rather than focusing on the workplace bullying policy (which alone does not shape effective organizational responses to bullying) or on negative acts themselves (which can be regarded as a product of problems in work and organizational systems), our study aims to tackle the underlying risk conditions for workplace bullying by identifying, monitoring, and changing aspects of the risk contexts. We focus on improving people management practices in nine different contexts (e.g., managing underperformance, clarifying job roles and duties, coordinating working hours, and entitlements). During the intervention, the risk contexts were assessed to identify problems using a diagnostic risk audit tool, generated and validated based on analysis of 342 workplace bullying

complaints officially lodged with the local work health and safety regulator (Tuckey et al., 2022). Based on the diagnostic information participatory processes were used to support staff and managers to generate and implement solutions targeting these risk contexts.

The highlight of this intervention is the use of a co-design approach throughout the intervention, manifested in five phases: Preparation, Diagnosis, Solutions, Implementation and Evaluation.

Method

The intervention was implemented across 10 stores of an Australian supermarket stores within one Australian state. All store employees were invited to complete a pre-intervention diagnostic survey (Time 1) and a post-intervention evaluative survey (Time 2), administered 10 months apart. A total of 399 and 339 respondents across 10 stores responded the surveys at Time 1 and 2, respectively, whose responses were aggregated for store-level analysis. Further at department-level, 34 departments had 261 and 246 participants at Time 1 and 2 respectively, used for department-level analysis. Respondents were asked to rate people management practices using the risk audit tool, exposure to workplace bullying, job demands and job resources at Time 1 and 2.

Results

The t-test results revealed that exposure to workplace bullying significantly reduced over the course of the intervention by a mean decrease of .25, 95% CI [.40, 2.10], $t(9) = 4.01$, $p = .003$ at store level, and by a mean decrease of .24, 95% CI [.19, .91], $t(33) = 3.21$, $p = .003$ at department level. These results support the effectiveness of the intervention on bullying reduction at both store and department levels.

The records of bullying compensation claims also demonstrate the effectiveness of the intervention at store level in comparison with neighbouring stores that were not exposed to the intervention. In the intervention stores, complaints decreased from 0.8 cases by store in the pre-intervention period January-September 2020 to 0.1 cases per store over the intervention period October 2020-June 2021. By way of comparison, in the 991 neighbouring stores, complaints increased from 0.5 to 0.6 cases per store over the same timeframe.

We further ran mediation analyses to explore the underlying mechanism that explains how the intervention, which is centred around changing people management practices, leads to bullying reduction. Given that there were only 10 stores, we did not run the mediation analysis at store level. Instead, the analyses were conducted at department level. At the department level, people management practices (Time 2) were positively related to job resources ($b = .21$, $p = .005$) and negatively related to job demands ($b = –.23$, $p = .004$) at Time 2, while controlling for job resources and demands respectively at Time 1. Workplace bullying was positively related to job demands ($b = .44$, $p = .000$) at Time 2 while controlling for workplace bullying at Time 1. The indirect effect between people management practice and workplace bullying via job demands was significant (indirect effect = –.11, Boot SE = .04, 95% CI [– .19, – .02]). However, workplace bullying was not related to job resources ($b = -.17$, $p = .113$).

Conclusions

Building upon the risk audit tool, this project generates the specific information needed for effective bullying prevention and intervention by developing and evaluating an intervention framework that tackles the organisational risk contexts for bullying. These risk contexts offer clear focal points for risk management efforts to build an anti-bullying organizational system.

Symposium S093

(Hyper)Normalization and the New Normal: Interrogating Concepts of Normality and Normalizing an Ethics of Care

Matthijs Bal, University of Lincoln

science

What will be covered and why (including the contribution of any discussant)

This symposium investigates concepts of normality, normalization and the New Normal. Since the start of the Covid pandemic, there has been talk throughout both global media and scientific circles about a 'New Normal'. During the Covid lockdowns, we suddenly witnessed dolphins swimming in the Venice lakes, and clear skies unpolluted by airplane emissions. There was suddenly space to envision a new reality, that in which people cared for each other, where there was appreciation and recognition of the work done by essential workers (health care, food industry, etc), and most importantly, a window was opened for the protection and restoration of our broken planet. However, the Covid pandemic lasted at least 2 years, and the conceptualizations of a potential for a 'New Normal' were quickly forgotten. What was left was a notion of new normalities with regards to remote and virtual working, and the possibility for people to have more flexible arrangements with regards to their work and private lives.

The goal of this symposium is to return to the concept of 'New Normal', and to interrogate the meanings of normal, normalization and hypernormalization in more depth. Moreover, our goal is to investigate how new normalities may be constructed through an ethics of care.

The symposium contains three presentations which follow up on each other in building an understanding of how normality unfolds, and how we can work towards the normalization of greater care in workplaces for people, the environment, and ultimately, the planet itself.

Matthijs Bal will start the series with a presentation on the hypernormalization of absurdity. Building on a recent book that has been published on this topic, Bal will discuss the theoretical notions of normalization processes, and how the normal is constructed on the basis of an ideological fantasy of what should be perceived as within the structures of normality, while at the same time excluding all that is considered to be abnormal or absurd.

John Mendy will follow up with an interrogation of the hypernormalization of Equality, Diversity and Inclusion (EDI) initiatives in organizations which have little impact on the realities of people at work, especially marginalized communities. Based on a study of focus groups of autistic employees, he shows the gap between authoritative discourse (i.e., formal EDI initiatives) and actual practice, as evidenced through the lived experience of marginalized groups.

The presentation by Sara Petrilli et al. forms a bridge to better understanding of the alternative frameworks that can constitute the new normal: based on interviews with managers, the authors three areas that exemplify a new normal that is caring: care for people, work and for organizations. The presentation shows how new normals can be constructed that extend beyond the perpetuation of the status-quo that is imminent to hypernormalization as shown in the first two presentations.

Finally, we have secured Edina Dóci to act as Discussant for the session. Dóci has ample experience in critical work in WOP, and based on her previous work around neoliberal ideology and inequalities in the workplace, she will be able to provide critical insights into the overall set of presentations,

seeing beyond the individual stories to conceptualize new understandings of how we can think of normal, abnormal and the hypernormal.

Relevance to the Congress Theme

The symposium is about the New Normal, which fits closely with the Future of Work.

Research/Practical Implications

The symposium offers research implications about how we can study the New Normal as emerging in the workplace, but also being critical of the perpetuation of the status-quo under a legitimization of authoritative discourse which bears little relationship with really existing practices. The task of the scientist is to critically evaluate such processes, and to be able to distinguish between what belongs to the space of imaginary discourse, and what can be considered to be actually taking place – this knowledge is key to generate, as this also constitutes are duty towards practice: to inform practitioners in the world outside of academia of the processes of normalization and constructions of New Normals.

Overall conclusions

This symposium offers an exciting set of presentations that are timely and investigate the ways through which we perceive the current world and workplace as 'normal'. Yet, we also offer insights into a more sustainable future by emphasizing the need to normalize an ethic of care in organizational life.

discussant: Edina Dóci, VU University Amsterdam

Keywords: Normalization, New Normal, Ethics of Care

Paper 1

The Absurdity of a Hypernormalized Status Quo in Society and Workplaces

Matthijs Bal, University of Lincoln

Theoretical background

The world and workplaces are in existential crisis – climate change, the breakdown of democracy and ever-rising inequalities threaten the viability and sustainability of our planet, our ways of living and our institutionalized economic systems. We are constantly faced with the absurdities of such manifestations, while at the same time, we are observing an increasing inertia towards tackling the greatest societal challenges of today. For instance, the wealth inequalities in global society have increased such that now eight men own as much as the poorest half of the global population. At the same time, there is little indication we are effectively addressing such inequalities, and as a result millions of people are struggling to survive, and not just in the global periphery, but across the world, and in the wealthiest nations, where people are forced to choose between 'heating or eating'. The absurdity of this is that even though we know about this, we are unable to find effective solutions to such grand problems. The current paper addresses these absurdities and in particular focuses on how these absurdities are normalized. Borrowing from the Russian anthropologist Alexei Yurchak, we use the term hypernormalization to explain how absurdities are normalized in our contemporary society and workplaces. Hypernormalization denotes the process of the current status-quo is normalized as something that cannot be changed fundamentally. This plays out primarily through ideological fantasy. This means that absurdities that we are faced with (e.g., the absurdity of wealth inequality) are legitimized as a 'normal' consequence of the current structures, through which the winners are praised for their entrepreneurial spirit, while the losers are blamed for not having worked hard enough. Hence, ideological fantasy supports the status-quo, and even when absurdities are 'exposed', people can cling on even more strongly to their fantasies, as absurdity exposure may threaten ontological security of the human being.

New Perspectives/Contributions

The current paper is based on a book published in 2022 (Bal et al., 2022) on the absurd workplace and how such absurdities are hypernormalized. To understand why the status-quo remains perpetuated, and what can be done, we have used a hypernormalization lens to study the emergence of absurdity in society, and how this is ideologically maintained through the force of hypernormalization . We thereby contribute to a better understanding of absurdity in the workplace and in society, and how it is perpetuated. Understanding contemporary issues in society and the workplace as absurd and its related hypernormalization process provides a better perspective on where we are and how we can more effectively problematize absurdity, and find ways to overcome absurdity

Conclusions – research and or practical implications

The absurdity and hypernormalization lens offers many new insights, particularly in the field of WOP. While WOP research has been influenced profoundly by a natural science-like paradigm, whereby objective research is conducted on workplace attitudes and behaviors, an absurdity lens moves beyond this by studying how logic itself dissolves into the hypernormal. In this case, we are no longer studying phenomena in the workplace that are defined through logic and reason (e.g., the basis of social exchange theory, which postulates a rather rational exchange between employee and

organization), but workplaces where logic has dissolved altogether, and where an analysis of the workplace as absurd may provide new understandings of the more unconscious nature of behavior in the workplace.

Relevance to the Congress Theme

The theme of the conference pertains to the future of work, which is heavily influenced by notions of what can be considered normal in the workplace – i.e., interrogation of what is abnormal or hypernormal therefore aids to a better understanding of the future of work.

Relevant UN SDGs

The paper investigates not just the normality of our social constructions, but also questions them – in that spirit the SDGs should also be analyzed as a way through the status quo is maintained through authoritative discourse: the SDGs form the impression of meaningful engagement with the world's grand societal issues, but the question remains to what extent we are truly engaging in meaningful action to change our world.

Keywords: hypernormalization, absurdity, climate inertia

Paper 2

Reimagining Inequality in Contemporary Organizations and Society: A Hypernormalization Lens

John Mendy, University of Lincoln

Research background

Recent grand challenges around the world ranging from the Coronavirus health pandemic to the socio-political and economic disruptions (Caligiuri et al., 2020) affecting people's and organizations' sense of 'normalcy' highlight that the world is already in a new state of the 'hypernormal' – a construct that makes meaning of the disconnect between authoritative and often authoritarian discourse on reality and people's mutative, experienced understandings of that reality. This study focuses and problematizes how the official, traditional and authoritative discourse of EDI highlights absurdities of inequality experienced by marginalized groups such as autistic jobseekers in workplaces and society. I focus on the absurd irrationality felt by autistic jobseekers when they encounter hiring and retention practices that are significantly paradoxical to the authoritarian rhetoric of principles of libertarianism, equality, diversity and inclusion in EDI discourse Caligiuri et al. (2020) among others.

Research goals and why the work was worth doing

To investigate how the authoritative and authoritarian EDI discourse has paradoxically created/entrenched a hypernormalized state of workplace, work and worker inequality and an ethics of injustice and authoritarianism in contemporary workplaces and society.

To reimagine workplace and worker inequality from the foundational paradigm of EDI by showing what a less authoritarian and autocratic discourse of autistic jobseekers' perspectives could offer in addressing organizational and societal inequalities and insecurities.

To problematize hypernormalization of the absurd EDI and HRM practices of hiring and retention within a postsocialist Soviet Union and a postcolonial world where emerging digitalization and the flexibilization of work, the workplace and the worker pose renewed challenges to equality of opportunities and possibilities.

To propose a contemporary and more meaningful framework to EDI and the UN SDGs to help in meaningfully addressing the current hypernormalized state of irrationality of workplace and worker inequality.

Whilst previous studies have normalized the benefits of the Equality, Diversity and Inclusion perspective, I highlight the need for a new normal of EDI, by problematizing the disconnect between the enunciated EDI benefits and their re-conceptualized realities from marginalized communities. The proposed reconceptualization and reimagination examine how renewed calls to digitalize (Colber et al., 2016), to flexibilize and hybridize (Bal & Izak, 2020), to technologize and to show official HR proceduralist practices around hiring and retention of already marginalized workers have increased (Georgiadou & Antonacopoulou, 2021), instead of reduced workplace and worker inequality. This unsustainable state of hypernormalization of inequality has warranted my development of a framework on worker, work and workplace ethicality, equality and sustainability which shows the institutional, ideological, cultural and socio-politico-economic conditions of the hypernormalized inequality and the accompanying necessary conditions out of the contemporary state of inequalities.

Theoretical frame

Hypernormalization is this study's theoretical focus. It is the normalization of absurdity or irrationality in contemporary society and organization (Yurchak, 2003, 2005). It is a construct that helps in identifying and understanding the divide between ideological, authoritarian and autocratic enunciations of the rulers in the Soviet Union of the 1960s – 1980s. Absurd ideologies, practices and measures thrive on fantasy (Žižek, 1989) in order to create safe spaces for their internalization, materialization (Yurchak, 2015) practicalization and securitization in individuals in society and workplaces (Mitzen, 2006). When such hypernormalization is attained, it paradoxically creates a fundamental gap between the official rhetoric/enunciation on EDI, for example, (e.g. organizations' strategic value statements on treasuring equality, diversity, inclusion and wellbeing) and the practical realities of how staff and potential employees experience EDI interventions (e.g. lack of access to promotion, to career development, to employment access, to the entrenchment of inequality). I therefore extend Yurchak's hypernormalization to include how marginalized worker communities (e.g. autistic jobseekers) experience a persistent, stagnant state of absurd employment practices whose normalization has hypernormalized inequality in workplaces and worsened their quality of life. Furthermore, I show the socio-economic, political and cultural, institutional, structural and ideological conditions that have led to this state of hypernormalized inequality in workplaces, and, by extension society. This process helps in further developing our understanding of hypernormalization by moving it beyond Yurchak's dichotomous divide between authoritarian discourse and the public's reality of that discourse. By focusing on exposing and problematizing conditions and processes of hypernormalization, I not only reflect and critique the individual and collective ideological fantasies and internalizations but show how the gaps between the official and the real could be bridged by a more sustainable framework including the conditions, processes and problematization of hypernormalization. In the proposed frame, I problematize, reimagine, reconceptualize and ethicalize a hypernormalization framework for equality in contemporary and future workplaces.

Methodology

The study's methodological design is based on focus group with from 24 autistic jobseekers in the UK. The thematised results are used as the basis to develop an epistemology and ontology toolkit that managers can use in developing a meaningful understanding of how to identify and address autistic jobseekers' workplace needs and mitigate against the grand inequality challenges of the workplace of the future. This design and analysis highlight the paradox between the authoritative discourse of EDI framework, the experienced socio-economic and political, ideological logics of autistic jobseekers in the tradition of hybridity discourse analysis (Bhabha, 2012; Said, 2012) and moves the debates and discussions on hypernormalization beyond discourse-reality to include conditions, processes, problematization and ethicality.

Results

The initial results highlight:

employment brick walls faced by the autistic jobseekers when they attempted to transition into work in the UK. Whilst this finding concurs with previous studies conducted (Lai & Szatmari, 2019; Hedley et al. 2017b; Raymaker, 2017), it highlights the hypernormalization of inequality.

socio-cultural and financial discrimination which aligns with Ngoasong and Groves (2016) but differs from Nicolaidis et al. (2015b) and Kaboski et al. (2017) whose advocacy for greater agency for communities suffering from inequality does not concur with the hypernormalized state of inequality experienced by autistic people.

entrenched marginalization as confirmed earlier by Guerci (2019) but in contrast with Bardoel et al. (2014) who expected faster adaptation despite the hypernormalized inequality experienced by autistic people

Relevance to Congress

This study fits the congress's theme.

Relevance to UN SDGs

This study is relevant to issues around inequality, the normalization of exclusion and marginalization in workplaces and society, peace, justice and strong institutions and the future of workplaces.

Keywords: *societal and worker inequality, authoritarian discourse, experiential discourse, hypernormalization*

Paper 3

Care Ethics management and redesign organization in the New Normal: Individual and Organizational implications of the Covid 19 Pandemic

Sara Petrilli, Silvio Carlo Ripamonti & Laura Galuppo | Università Cattolica del Sacro Cuore

Introduction and conceptual background

This contribution aims to highlight the dimensions of care and ethics put in place by HR managers in COVID-19. The objective that animated the authors have focused on the HRM level of medium and large companies to highlight the protective actions towards people and the organization in the period COVID 19, highlighting what were the ethical values and actions of care put in place.

In the scenario of New Normal, it seemed crucial to us to understand how in the accounts given by managers of organizational processes, who had the task of transitioning their organization during the pandemic period, they evoked themes related to the ethics of care in the management of people while simultaneously keeping in mind the survival of the organization.

Theoretical background

In the present article, we refer to the theme of care ethics proposed by Gilligan (1982), drawing inspiration from which we can define organizations as a network of relationships whose quality can be safeguarded by specific managerial actions. Some of these actions can support the construction of trust, while others can undermine the feeling of interconnectedness in the organization.

The concept of care ethics does not assume an agent who autonomously and rationally decides the course of actions. Still, it considers the possibility of giving people a voice and making the interests in the field visible by taking into account their diversity of desires and interests (Gilligan, 1995).

Design/Methodology/Approach/Intervention

The researchers interviewed 45 managers, including 21 women and 24 men. The managers interviewed are all university graduates, aged between 40 and 55 years old. The sectors they belonged to were manufacturing, IT, and services. Public companies were not included in the sample. The following diagram details the type of organizations involved in our Italian context.

The respondents were given a narrative interview outline that primarily touched on the following points:

Effects of COVID on HR management policies.

Proposed projects to support people.

Management priorities over the next 12 months.

Reconfiguration of how we work with other functions.

The interviews were recorded and disgorged, and we obtained a 380-page corpus. The interview analysis methodology was guided by content analysis (Braun and Clarke, 2006).

Results obtained or expected

The results were organized by identifying some core themes. All the references to the concept of "caring" were grouped into three different categories, representing three different levels/objects of care: people, work, and organization.

1 Caring About People

In this first category are the narratives of managers who, in the pandemic period and in the New Normal reorganization that follows, were focused on safeguarding the possibility that people could work in an acceptable state of well-being (Raya and Panneerselvam, 2013). The issues governing their managerial activity centered on helping people contain the time they worked remotely, modulating the commitment over time, and providing support to have a sustainable life-work balance (Koinig and Diehl, 2021).

2 Caring About Work

In this category, there are narratives of managers who assumed that the pandemic changes altered the very nature of work. Here again, two main challenges emerged: a) The polarity efficiency vs. creativity expresses a considerable challenge that impacted on HRMs' concerns and b) Challenge between increased commitment and possible retention over time.

3 Caring of Organizations

In this third category, the caring efforts concerned the organization as a "complex social subject" (reconfigured and fragmented work, acceleration of new technologies and psychological contract).

Limitations

The sample size is not large. Another limitation could be found in the limited and heterogeneous sample involved that cannot allow the generalization of results. Finally, the sample used in this study were just from Italy; there might be a specific bias in the perception of sustainability, onboarding and organizational practices due to the particular Italian labor market.

Conclusions – research and or practical implications/Originality/Value

The three "clusters" of care highlighted in the interviews showed how human resource managers had difficulty containing the situation's complexity in the pandemic and in the New Normal period.

The most challenging HR managers interviewed was specifically this ability to "take care in the New Normal" of the interactions between the three levels, work organization and people (Giancaspro et al., 2021).

Relevance to the Congress Theme

We think our research is in line with the themes of the congress because it talks about change in the world of work and how people live within this change. In addition, we feel it is important to bring times such as care and ethics into organizations because now more than ever, in an ever-changing world of work, these should be the reference values and not only those of commitment, satisfaction, achievement and socialization.

Symposium S094

Employee Physical Activity: Antecedents, Processes, and Outcomes

Sascha Abdel Hadi, Justus-Liebig University Giessen; Malte Roswag, University of Hildesheim

science

What will be covered and why

Being physically active has well-known beneficial effects on various health- and performance-related outcomes as indicated by a plethora of research. Studies show that physical activity is not only a promoter of physical health but also mental well-being. However, studies show that individuals (at least in industrialized societies) are becoming increasingly inactive and that this might be also due to work-related factors. Building on these findings, this symposium is dedicated to an integrative evaluation of current research on the dynamical interplay between work and physical activity. We aim to bring together research with multiple perspectives on consequences as well as antecedents of employees' physical activity. The symposium has three objectives: Firstly, it aims to shed light on positive effects of physical activity looking at various potential work-related outcomes of physical activity that is pursued at different times of the day. Secondly, the buffering role of physical activity for the adverse effects of workplace stressors will be discussed. Finally, the presentations will focus on work-related factors that are proposed to influence employee physical activity.

In the first study, Roswag et al. investigate the role of physical activity before work on appraisal of workplace stressors on the same day, and how these effects subsequently extend to work-related well-being during the workday.

In the following presentation, Calderwood et al. test the resource generating potential of physical activity with a special focus on explaining a physical activity spillover to various work-related outcomes across different time frames and aspects of physical activity (e.g., duration, intensity).

In the presentation by Junker et al., physical activity is considered as a buffer against negative work-related influences. The authors examine the moderating effect of physical activity on the relationship between daily challenge versus hindrance stressors, and work-family conflict and work-family enrichment.

The final studies by Koch et al. and Abdel Hadi et al. focus on the role of work-related factors and mechanisms to explain how work affects physical activity and well-being. Koch et al. examine whether detaching from work on days with high work stress serves as a mediator between workload and after work-physical activity, while Abdel Hadi et al. apply an experimental paradigm to test for differential effects of different subtypes of job demands on physical activity through self-regulatory capacity.

Relevance to the congress theme

A better understanding of the interplay between work-related aspects and employee physical activity is highly relevant to the topic of the EAWOP '23 theme: "The future is now: the changing world of work". Increasing knowledge about how physical activity affects individuals as well as how physical activity is affected by work is important to shape a positive relationship between work and leisure. This is important to sustain and increase work-related health and well-being.

Research/practical implications

The symposium brings together different perspectives on employee physical activity that complement each other and add to a broader understanding of the interplay between work and physical activity. Gaining a deeper understanding of how these factors are related to each other helps to develop theory-building in the context of occupational health psychology and increases our understanding of the role of physical activity for employee well-being. On a practical note, the studies presented in this symposium highlight the importance of an active lifestyle not only to maintain health and well-being but also to improve work-related outcomes. Furthermore, it points to the relevance of job characteristics as factors that influence physical activity.

Overall conclusions

Integrating the findings of the presentations, physical activity is a crucial factor to employee well-being and other work-related outcomes. Hence, taking actions toward supporting physical activity has positive implications for both employees and employers. Considering work-related factors as facilitators of the engagement in physical activity can help to better understand how organizations can positively influence individual functioning.

Keywords: employee physical activity, well-being, work design

Paper 1

The Daily Relationship Between Physical Activity and Employee Well-Being: The Mediating Role of Appraisal of Workplace Stressors

Malte Roswag, University of Hildesheim; Sascha Abdel Hadi, Justus-Liebig University Giessen; Andreas Mojzisch, University of Hildesheim; Jan A. Häusser, Justus-Liebig University Giessen

Research goals and why the work was worth doing

Physical activity is beneficial for employee's well-being, especially when it is pursued outside of the working time (i.e., leisure time physical activity; Wiese et al., 2018). However, we still lack understanding of the mechanisms mediating this effect, which is highly important for better theoretical and practical understanding of physical activity in the work context. While previous research has predominantly investigated physical activity as a recovery activity after work (e.g., van Hooff et al., 2019) this framework neglects the idea that physical activity may also have positive effects for employee well-being when it is conducted before work . In a preregistered study, we addressed this limitation by examining the mechanisms through which physical activity before work benefits employee well-being.

Theoretical background

Building on the transactional theory of stress (Lazarus & Folkman, 1984), we argue that physical activity before work changes how employees appraise their workplace stressors which, in turn, is positively related to employee well-being. As outcome variables, we measured three proximal indicators of employee well-being: work engagement, emotional exhaustion, and job-related anxiety. Integrating research on beneficial short-term effects of physical activity and the transactional theory of stress, our key hypothesis is that the effects of physical activity before work on employee well-being are mediated by employees' primary appraisal of workplace stressors. More specifically, we hypothesized and preregistered that physical activity before work increases challenge appraisal and decreases both hindrance and threat appraisal which, in turn, increases work engagement, and decreases emotional exhaustion and job-related anxiety. Thus, we propose three distinct pathways from physical activity before work to employee well-being: Physical activity before work is positively related to work engagement through challenge appraisal (Hypothesis 1), physical activity before work is negatively related to emotional exhaustion at the end of work through hindrance appraisal (Hypothesis 2), and physical activity before work is negatively related to job-related anxiety through threat appraisal (Hypothesis 3)

Method and results

We conducted a daily diary study over ten workdays with two daily measurements (one questionnaire at the beginning of the working time and one in the afternoon after work) to test our hypotheses. In total, 300 employees who worked at least 20 hours per week participated in our study and 269 employees who answered questionnaires on at least three days were included in the data analysis. Multilevel structural equation analyses showed partial support for our preregistered model. Physical activity before work had a positive indirect effect on work engagement through challenge appraisal (Hypothesis 1) and a negative indirect effect on job-related anxiety through threat appraisal (Hypothesis 3). However, we found no evidence for an indirect effect of physical activity before work on emotional exhaustion (Hypothesis 2). In an exploratory analysis, we further found that threat appraisal mediated the effect of physical activity before work on emotional exhaustion.

Limitations

Besides many strengths (preregistration, large sample, various occupational types, time-lagged daily measurement) our study is subject to some limitations. First, our study is correlational and therefore does not allow causal conclusions to be drawn. Further, we used only self-report measures which are prone to recall bias, social desirability, and measurement reactivity (in the case of physical activity). Future research could therefore utilize experimental designs and measure physical activity objectively, for example through activity trackers.

Conclusions – research and or practical implications

In conclusion, our study adds to the literature on the interplay of work and physical activity by showing that physical activity before work is beneficial for employee well-being and, furthermore, by identifying employee's appraisal of workplace stressors as a mediator of this relationship on a day-to-day basis. Finally, our results advance our knowledge on the transactional process of work stress by identifying physical activity before work as a situational predictor of employees' appraisal of workplace stressors. On a practical note, our study shows that being physically active before work can be a successful strategy to improve employee well-being and should be supported by employers.

Relevance to the congress theme and UN SDGs

This study is relevant to the congress theme because it highlights the importance of physical activity in a changing world of work that is increasingly sedentary and, furthermore, because it shows that physical activity is also beneficial for organizational outcomes which should further incentivize employers to promote their employees' physical activity. We thereby also address the UN SDG of health and well-being.

Keywords: employee well-being, appraisal, physical activity

Paper 2

Understanding the Spillover of Physical Activity to Performance Criteria at Work and at Home

Charles Calderwood, Virginia Tech; Lieke L. ten Brummelhuis, Simon Fraser University; Christopher C. Rosen, University of Arkansas; Allison S. Gabriel, University of Arizona; Fiyinfunjah Dosumu, Virginia Tech

Research goals and theoretical background

Employee physical activity, which represents bodily movement produced by skeletal muscles that expends energy (Caspersen et al., 1985), is theorized within the resource-based model of physical activity to generate physical (e.g., lower fatigue), affective (e.g., greater positive affect), and cognitive (e.g., heightened attentiveness) personal resources that have downstream implications for performance criteria (Calderwood, Ten Brummelhuis et al., 2021). Within the Work – Home Resources Model (WH-R; Ten Brummelhuis & Bakker, 2012), personal resources of this nature are theorized to be the central linchpins that connect experiences at work to home outcome and vice versa. Accordingly, synthesizing the resource-based model of physical activity with tenets of the WH-R, it would be expected that physical activity at work (home) can generate physical, affective, and cognitive personal resources that employees carry with them across the work / non-work interface to invest in performance criteria at home (work). The goal of this project is to evaluate this potential physical activity spillover to performance criteria across the work/non-work interface, with particular attention to alternative temporal windows (e.g., within-day, across-days, weekday-to-weekend), various aspects of physical activity (e.g., steps, caloric expenditure), and specific personal resources (e.g., physical, affective, cognitive) that may be differentially relevant to this process.

The current project is intended to address three critical unanswered questions about physical activity spillover. First, from the perspective of alternative temporal windows that could be considered (e.g., day-to-day transitions from work to home or home to work; weekday-to-weekend or weekend-to-weekday transitions), within what timeframe(s) does physical activity spillover occur (Research Question 1)? Second, when considering that there are numerous ways to measure and operationalize physical activity engagement (e.g., steps, caloric expenditure, engagement in more intense physical activity; Calderwood et al., 2021; Van Hooff et al., 2019), what aspects of physical activity drive the process of physical activity spillover (Research Question 2) to performance criteria? Third, when considering that a range of types of personal resources (e.g., physical, affective, cognitive) have been argued to link physical activity to performance criteria, which categories of personal resources are most critical to the physical activity spillover process (Research Question 3)?

Design

Participants were staff employees working full-time, five days a week in traditional business hours (Monday – Friday; 9 a.m. – 5 p.m.) at a large university in the Southeastern United States. A total of 106 participants accessed an initial opt-in survey, with 83 participants advancing to a subsequent 10-day daily survey period (Monday – the following Wednesday) during which participants completed three surveys a day (morning survey , completed between 6 a.m. – 9 a.m.; afternoon survey , completed between 4 p.m. – 7 p.m.; bedtime survey , completed within 30 minutes before going to sleep) while wearing a research grade actigraph device (Actigraph, 2018) that continuously tracked physical activity across the entire 10-day daily survey period. After screening out 12 participants for various protocol compliance issues (e.g., little to no actigraphy data available; reporting not working

on a majority of weekday study days), the final sample consisted of 71 participants who provided valid study data at 2,019 out of 2,130 possible time points across the 10-day study (Response rate = 94.7%).

Preliminary results overview

While the full analysis of our data to evaluate our three research questions is still in progress, we have obtained numerous interesting preliminary results to date, including that (1) affective resources (e.g., state positive affect) appear particularly critical to linking daily workday physical activity to family performance criteria (e.g., family absorption, family social support), (2) taking more daily steps has downstream benefits for next-day job performance criteria (e.g., greater personal initiative), but engaging in particularly intense daily exercise may incur next-day job performance costs (e.g., lower next-day personal initiative, diminished next-day work goal progress), and that (3) the potential for physical activity to spillover to performance criteria within the day (e.g., workday physical activity to same-day family performance criteria) and across days (e.g., leisure time physical activity to next-day job performance criteria) appears more robust that the potential of physical activity to spillover to performance criteria across segments within the week (e.g., work week to weekend; weekend to next work week). In combination, we expect addressing the three research questions outlined in this project will significantly expand understanding and applications of physical activity spillover to a range of performance criteria at work and at home.

Keywords: physical activity spillover, personal resources

Paper 3

Challenging at Work and at Home? How and When Work-Related Rumination Prolongs the Consequences of Time Pressure to the Home Domain

Nina M. Junker, University of Oslo; Thomas Rigotti, Johannes-Gutenberg-University Mainz; Jan A. Häusser, Justus-Liebig University Giessen; Julia Heimrich, Goethe University Frankfurt

Research goals and why the work was worth doing

Challenge demands, such as time pressure (i.e., the experience of not having enough time to accomplish one's work tasks; Maruping et al., 2015), not only affect workplace behaviors and well-being but also extend to the home domain. As a result, more challenge demands are associated with more work-to-family conflict (i.e., the perception that the work role interferes with participation in the family role; WFC; Greenhaus & Beutell, 1985). At the same time, these are inconclusively associated with work-to-family enrichment (i.e., the perception that the work role benefits the family role; WFE; Greenhaus & Powell, 2006; see Webster & Adams, 2019). To explain these inconsistencies, we propose two forms of work-related rumination (i.e., thinking about work during nonwork time; Cropley et al., 2012) as mechanisms through which challenge demands (here, time pressure) affect WFC and WFE and study how post-work physical activity affects this mechanism.

Theoretical background

Our research is grounded in the job demands-resources theory (Demerouti et al., 2001; Bakker & Demerouti, 2017), which proposes that job demands are resource-draining because individuals need to cope with such demands, thus diminishing their available resources and negatively impacting their well-being and family lives. Later extensions differentiated job demands into challenge and hindrance demands. Whereas hindrance demands are only resource-draining, challenge demands, such as time pressure, are also motivational. Thus, these have the potential to increase resources. We contextualize affective rumination (i.e., being stuck in negative emotions evoked by recurrent thinking about work during nonwork time; Cropley et al., 2012) as a mechanism through which the resource-draining consequences of challenge demands extend to the home domain, resulting in more WFC and less WFE. We further propose problem-solving pondering (i.e., constructively thinking about work during nonwork time; Cropley et al., 2012) as a mechanism through which the resource-gaining potential of challenge demands extends to the home domain, resulting in more WFE. We suggest that post-work physical activity (here, walking or running) buffers the resource-draining path but does not affect the resource-gaining path as it down-regulates negative emotions.

Design and methodology

We tested our assumptions in a diary study across 10 workdays and with two daily measurement points among a sample of 118 at least part-time employed individuals. We used established measures, which we adapted to the daily context to assess our variables.

Results obtained

Overall, our results support our assumptions. In particular, daily time pressure was indirectly and positively associated with daily WFC and negatively with WFE via more daily affective rumination. Conversely, daily time pressure was indirectly and positively associated with daily WFE via more daily problem-solving pondering. We found differential effects for work-related rumination assessed at

the beginning and at the end of leisure time. Moreover, post-work physical activity modulated the resource-draining path but did not affect the resource-gaining path of challenge demands.

Limitations

We used self-report measures. Although these are the most commonly used form of assessing our variables, they have the risk of common-method bias and social desirability, which might have affected our results. However, we took great care to reduce these risks when designing this study.

Conclusions – research and or practical implications

We advance job demands-resource theory by introducing two specific mechanisms through which challenge demands extend to affect the home domain, thereby providing an explanation for its inconsistent associations with WFE in prior research. Post-work physical activity represents a remedy against its negative consequences and is a cost-free activity that most individuals can use daily – and even when social distancing measures are in place.

Relevance to the congress theme

Due to recent changes in how we work, the boundaries between work and home get increasingly blurred, increasing individuals' tendencies to bring work home – not only physically but also mentally. Our study puts mentally bringing work home by continuing to think about work upfront and presents one way of coping with such mental integration.

Relevant UN SDGs

This study particularly speaks to supporting the goal of good health and well-being, which needs to include family-related well-being.

Keywords: time pressure, work-related rumination, physical activity

Paper 4

Psychological Detachment Matters Right After Work: Engaging in Physical Exercise After Stressful Workdays

Theresa J. S. Koch, Sabine Sonnentag, Jette Völker & Hadar Nesher Shoshan| University of Mannheim

Research goals

Regular physical exercise is beneficial for health and well-being. In contemporary work life dominated by sedentary behaviour, physical exercise during leisure is a crucial recovery activity. Interestingly, there seems to be a paradoxical pattern between work and physical exercise: Especially on stressful workdays, employees tend to engage less in physical exercise (Ng & Jeffery, 2003; Sonnentag & Jelden, 2009), although physical exercise would be beneficial for their well-being (Rost et al., 2021; ten Brummelhuis & Bakker, 2012). Considering the benefits of physical exercise, this paradoxical pattern raises the need for a better understanding of mechanisms hindering physical exercise after stressful workdays. We address this need and focus on psychological detachment right after work (i.e., mentally switching off from job-related thoughts; Sonnentag & Fritz, 2007) explaining the paradoxical pattern between job stressors, physical exercise, and – as a consequence – well-being.

Theory

We build our research on the recovery paradox (Sonnentag, 2018) stating that high levels of job stressors prevent employees from engaging in recovery, whereas recovery is needed most on stressful workdays. We apply this framework to physical exercise as an effortful recovery activity (Tenenbaum & Hutchinson, 2007). Specifically, we suggest that high levels of job stressors (workload, self-control demands) prevent employees from psychologically detaching right after work. Lower psychological detachment, in turn, should explain why employees engage less in physical exercise – namely, because of an ongoing focus on work. We further propose that physical exercise promotes employees' well-being (high vigour, low fatigue) the next morning. Taken together, we suggest a serial indirect relation between job stressors and well-being via reduced psychological detachment and physical exercise.

Methods and results

We collected daily diary data from 97 employees (534 days). Applying multi-level path analysis (Preacher et al., 2010), we found that psychological detachment right after work served as an explaining mechanism in the paradoxical relation between job stressors (workload, self-control demands) and physical exercise. Interestingly, we only found a negative direct relation between time spent on physical exercise and next-morning vigour (not fatigue), suggesting that employees felt less vigorous after spending more time on physical exercise. Thus, we also only found partial support for the serial indirect effect regarding well-being the next morning.

Limitations

Our findings may, however, be interpreted in view of limitations, because we only considered time spent on physical exercise as an indicator for physical exercise. Future research should address other aspects, such as timing of or happiness during physical exercise. Specifically, exercising before going to bed might hamper employees' sleep (Buxton et al., 2003), thereby negatively affecting vigour the

next morning. Moreover, employees may feel less happy when engaging in physical exercise after a stressful workday but feeling happy while exercising is essential for recovery (Oerlemans et al., 2014). These insights may allow a more fine-grained understanding of when and how physical exercise can be a beneficial recovery activity.

Implications and conclusion

Still, our research importantly contributes to literature on physical exercise and recovery from work. We advance the understanding of why stressful workdays impede physical exercise by showing that psychological detachment right after work can serve as an explaining mechanism. We thereby propose a new perspective on the timing of psychological detachment – which might not only be relevant in the evening as an outcome of physical exercise (Rost et al., 2021; ten Brummelhuis & Bakker, 2012), but also already right after work as a predictor of physical exercise. It might be a promising avenue for future research to apply this idea to other (effortful) recovery activities following psychological detachment right after work. Such insights may help to better understand of the role of psychological detachment as a necessary prerequisite for recovery activities.

Practitioners implementing interventions to increase physical exercise after work can gain an essential starting point from our research. Beyond addressing the increase of physical exercise directly, targeting an increase of psychological detachment right after work might be fruitful. Indeed, interventions for improving psychological detachment have been shown effective (Hahn et al., 2011). Overall, such interventions are important to foster employees' health and well-being – particularly after stressful workdays.

Relevance to congress theme and UN SDGs

In this context, our research ties in with the congress theme of the changing world of work by emphasising the need of physical exercise during leisure while employees are increasingly less physically active at work. Further relating to the UN Sustainable Development Goals, we hope to inspire research and practice in promoting good health and well-being.

Keywords: job stressors, psychological detachment, physical exercise

Paper 5

An Experimental Study to Investigate the Effects of Emotional Versus Cognitive Job Demands on Physical Activity After Work

Sascha Abdel Hadi & Jan A. Häusser | Justus-Liebig University Giessen; Andreas Mojzisch, University of Hildesheim

Research goals

This preregistered experimental study was to investigate the differential (negative) effects of emotional versus cognitive job demands on physical activity after work. Furthermore, we aimed to test self-regulatory capacity as an underlying mechanism for the effects of both job demands on physical activity.

We conducted an experimental work simulation with manipulations of emotional and cognitive job demands. Physical activity was assessed by a physical activity task (cycling on a bicycle ergometer) after participants completed the work simulation.

Theoretical background

Research shows that physical activity has important functions for employees' health and well-being. However, individuals frequently fail to exercise after work thereby setting health and well-being at risk. Theorizing points to the idea that work-related factors such as job demands could negatively impact physical activity behavior (Häusser & Mojzisch, 2017). However, looking at the empirical basis for such effects findings seem to be mixed as some studies found support for negative relationships whereas others revealed null effects. Differentiating between subtypes of job demands should increase knowledge about the relationships (Cavanaugh et al., 2000): On the one hand, research points to the idea that especially those types of demands with a hindering potential for goal attainment and motivation (hindrance demands, such as emotional demands) could be negatively related to physical activity. On the other hand, job demands that are positively related to goal attainment and motivation (challenge demands, such as cognitive demands) might be less harmful for physical activity behavior.

Furthermore, research on the underlying mechanisms of the effects is sparse. A few studies point to the role of self-regulatory capacity as a mediating variable (e.g., Sonnentag & Jelden, 2009): Job demands are assumed to negatively affect self-regulatory capacity, that in turn, is positively related to physical activity. We expect that the mediating effect of self-regulatory capacity should be especially evident with regard to emotional demands (compared to cognitive demands) as their negative impact on self-regulatory capacity should be more pronounced.

Methods

To test the causal relationships of emotional and cognitive demands, physical activity, and self-regulatory capacity, we conducted an experimental work simulation consisting of customer requests and arithmetic tasks. Emotional job demands were manipulated in terms of customer unfriendliness whereas cognitive demands were manipulated in terms of (arithmetic) task difficulty. After the work simulation, participants had to complete a physical activity task (cycling on a bicycle ergometer). We analyzed data of 120 participants. All participants were randomly assigned to one of three experimental conditions that had different levels of emotional and cognitive demands (i. low

emotional and low cognitive demands versus ii. high emotional demands [and low cognitive demands] versus iii. high cognitive demands [and low emotional demands]).

Results and conclusions

Preliminary analyzes point to no differences in the amount of time spent on the bicycle ergometer among the experimental groups and did not reveal self-regulatory capacity as a mediator. However, we found that, although unrelated to self-regulatory capacity after work, physical activity was positively related to self-regulatory capacity after cycling on the bicycle ergometer.

Hence, our first analyzes do not support the idea of differential effects of emotional versus cognitive demands on physical activity. However, we unexpectedly found that self-regulatory capacity was positively impacted by physical activity. Hence, our data suggest a beneficial effect of physical activity to replenish self-regulatory capacity.

Limitations

A limitation of this study is the use of a student sample to test the assumptions.

Relevance to the congress theme and to UN SDG's

Our research fits well with the congress theme of EAWOP '23 "The future is now: the changing world of work" and the UND SDG'S ("Good health and wellbeing" and "Decent work and economic growth") as it increases knowledge on the relationships between healthy workplaces and physical activity. Furthermore, it identifies strategies (i.e., physical activity) to overcome negative work-related effects.

Keywords: job demands, physical activity, experimental work simulation

Symposium S095

The Future of Organizational Decision-Making: Advancing Research on Attitudes Toward and Outcomes of Using Artificial Intelligence at Work

Sophie Kerstan, Federico Magni | ETH Zurich

science

Content: Organizations increasingly rely on Artificial intelligence (AI) in decision-making contexts to boost efficiency and accuracy. This trend is observable across various processes and domains, including human resource management, public administration, and healthcare. Although the literature on how people react to and leverage AI as a decision-making agent has been thriving in the past years, there are still many unresolved questions about (a) humans' preferences for how AI should be used, (b) how the implementation of AI-supported decision-making affects work processes, and (c) what the impact on work outcomes will be. This symposium compiles five research projects that shed light on these issues by considering the role of AI as a recommendation provider, evaluator of human decisions, and agentic decision-maker.

Specifically, Magni & Jeong look at AI in the role of an evaluator. They investigate how being evaluated by AI rather than humans influences people's decision-making (e.g., choosing between alternatives with different risk profiles) and their generative behaviors in the context of organizational creativity.

Mengchen and colleagues study people's emotions, intrinsic motivation, and perceived fairness when subject to a human manager's vs AI's evaluative decisions. By leveraging an experimental design, they compare people's expectations for algorithmic vs human management against their actual experiences.

Schneider and Leyer investigate how perceived trustworthiness and ascribing either governmental or corporate ownership to AI affect people's willingness to accept and use agentic AI in decision-making contexts. In a series of experiments, they further differentiate between the perspectives of people making decisions and those affected by them.

Through a qualitative, longitudinal field study, Bunzel and colleagues explore individuals' experiences around implementing an AI-based decision support system in a company. They apply a socio-technical system perspective to examine how multiple stakeholders shape the use of AI and how, in turn, AI shapes work over time.

Finally, Kerstan and colleagues investigate how decision errors that occur due to over- or under-reliance on AI-based recommendations can be prevented. They experimentally test whether holding ambivalent (rather than monovalent negative or positive) attitudes toward AI improves AI-supported medical decision-making.

Relevance to the Congress Theme: This symposium considers how the future of work is and will be characterized by using AI to inform decision-making in organizations. By advancing our knowledge of how people react to and interact with AI, the research projects cumulatively suggest ways to integrate AI into organizational processes to enhance performance and well-being. We point to a human-centered perspective in this matter by calling attention to humans' preferences for how much agency AI should receive and how human-AI collaboration at work should be configured to foster beneficial outcomes for individuals and organizations.

Research/Practical Implications: This symposium will help advance multiple theoretical pillars of the human-AI decision-making literature. Particularly, the featured work will deepen our knowledge about drivers of algorithmic aversion and appreciation, uncover biases that people hold when interacting with AI, and refine theories of trust in AI. In this regard, the contributions allow for much-needed comparison and differentiation between theories of organizational processes that solely involve human actors compared to those involving AI.

Concerning practical implications, we provide holistic recommendations for designing and implementing AI by considering the views of multiple stakeholders in organizational decision-making. Since the symposium comprises a range of AI application cases, we will further be able to uncover similarities and differences across contexts.

The symposium provides a theoretically grounded and practically relevant contribution by pairing experimental laboratory designs with field research.

Conclusions: The five research projects in this symposium investigate how humans react to AI, how AI shapes and is shaped by work processes, and what outcomes emerge from incorporating AI across different roles in decision contexts. Specifically, we compile work that considers AI as a decision-support system—e.g., providing recommendations—and as an active decision-maker—e.g., in a managerial or evaluative role—to provide a multifaceted perspective on the future of organizational decision-making with AI.

Based on the broad theoretical perspectives and methodological approaches applied throughout the featured studies, we will gather empirical evidence and advance knowledge about human-AI interaction at work. We also hope to help the practical implementation of AI in ways that are beneficial to individuals and fruitful for organizations and inspire future research on AI's involvement in decision-making.

Keywords: future of work, human-AI interaction, organizational decision-making

Paper 1

The Behavioral Consequences of Being Evaluated by AI in Terms of Organizational Creativity

Federico Magni, ETH Zurich; Martha Jeong, Hong Kong University of Science and Technology

Research Goals: As AI is increasingly prevalent in organizational processes, we aim to better understand how this phenomenon affects people's decision-making processes and organizational behaviors. Specifically, we study how appropriate people find the utilization of AI as an evaluator in diverse tasks and how knowing that one's work or choices will be evaluated by AI changes one's decisions and behaviors in the context of creativity at work.

Theoretical Background: The usage of AI in organizational processes such as recruiting, customer relations, and product development is booming. However, we still know little about how people react to the usage of AI in organizational processes, and specifically whether this affects their decision-making and their behaviors. Theories of algorithm aversion and algorithm appreciation both found empirical support, suggesting that individuals' reactions to AI-powered agents vary based on factors such as context, individual differences, and task characteristics. With this research, we aim to better understand how people react to instances in which their choices and productions will be evaluated by AI, and specifically how AI evaluation influences their decision-making in terms of risk and creativity. We expect that, given that AI analyzes objects based on a set of pre-determined criteria, people would be more conservative and norm-conforming in their choices when they know that they are evaluated by AI rather than humans, which can impair their creativity.

Design/Methodology: We conducted three studies: in Study 1, we assigned 504 participants to one of five tasks (creative writing, logo design, alternative use idea generation task, Lego building, and business pitch) and asked them to report their preferences for being evaluated by AI or human on that task and the reasons behind that preference. In Study 2 we asked 399 participants to come up with creative uses for a ping pong ball and told them that they would be rated by either an AI or a human. In Study 3 we presented 384 participants with two ideas (one described as riskier and more unconventional than the other) and told them to choose which idea they would submit to the evaluation of either a human or an AI.

Results Obtained: Study 1 results showed that people prefer a human evaluator for all five tasks, most strongly for logo design and least strongly for assessing a Lego building. The qualitative data showed that people base their preferences on factors such as emotions, fairness, perceived judgment capabilities (e.g., flexibility, creativity), being able to take advantage of the evaluator, and task characteristics. In Study 2 we did not find a significant direct effect of the evaluator's identity as AI (vs human) on idea creativity, but we did find a moderation by need for uniqueness (NFU), such that people with high NFU generated more creative ideas when they were told they would be evaluated by a human rather than AI. In Study 3 we found that people found human evaluators to be more moral, warm, and competent, with competence making participants more likely to select the less risky idea (against our prediction). We also found that the effect of the evaluator's identity on perceptions of the evaluator was moderated by people's algorithm aversion.

Limitations: So far, we have not found a direct effect of the evaluator's identity on either creativity or creativity-prone decision-making. We will test these hypotheses again with different designs. In Study 3, many participants failed the manipulation check, pointing that our design can be improved. Finally, no studies were in the field.

Conclusions: We found that people generally prefer human evaluators in a variety of generative tasks, and that the evaluator's identity as AI (vs human) seems to not have a direct— but rather a more nuanced—effect on decision-making and behaviors. Individual characteristics such as NFU and algorithm aversion impact this effect.

Relevance to the Congress Theme: Instances in which people need to engage in decision-making when interacting with AI evaluators in organizations are increasing, and the future of work will see an increase in AI-human interactions. For this reason, it is greatly important to understand whether knowing that one's work and decisions will be assessed by AI does impact decision-making and creativity.

Paper 2

Working in the Metaverse: Feelings and Behaviors Under AI Management in A Minecraft Game

Mengchen Dong & Iyad Rahwan | Max Planck Institute for Human Development; Jean-François Bonnefon, Toulouse School of Economics; Xinyu Zhang & Shihan Wang | Utrecht University; Levin Brinkmann, Max Planck Institute for Human Development

Research Goals: The Metaverse may revolutionize people's work experience in the near future, featured by interactions in the virtual space, through avatars, and with Artificial Intelligence (AI) agents. In a Metaverse-like Minecraft game environment, we aim to examine (1) people's feelings and behaviors under AI versus human management, and (2) the extent to which people's expectation resembles their actual experience of AI management.

Theoretical Background: The concept of Metaverse has recently attracted massive business attention and inspired many product innovations. While customers and service providers may be equally excited about creating a more immersive experience, it may not be the case in work-related contexts where employees and employers have unequal power and status. A recent survey shows that employees can be less enthusiastic about working in the Metaverse, partly due to concerns about the systematic deployment of AI for surveillance and management. However, people's negative expectations may not necessarily represent actual feelings after experiencing AI management in the Metaverse. On the one hand, previous studies on algorithmic management suggest that, as compared to human management, people expect AI managers to be demotivating, dehumanizing, and unfair. On the other hand, psychological research also suggests that people are not good at predicting future emotional states and can have overly vigilant reactions when a situation implies their inferior status. Then, is AI management in the Metaverse still demotivating and unfair after (vs. before) experiencing it? And would the virtual environments and avatars blur the boundary between human and AI management?

Design/Methodology: Participants will complete a two-wave experiment. They will first be invited to take a survey about expected emotions, motivation and fairness under AI management. On a different day, they will be invited to participate in the Minecraft experiment, working in an "iron pickaxe factory" for three repetitive rounds. Participants will be randomly assigned to an AI manager or a human manager condition. For those who are assigned to the human manager condition, participants will be further assigned to a manager or a worker role. In contrast, participants will all be assigned to the worker role in the AI manager condition. The AI manager is a three-level classifier model trained on random forest algorithms. Both human managers and the AI manager will monitor workers in real time on building an iron pickaxe, and then evaluate their performance at a beginner, intermediate, or advanced level – corresponding to different monetary incentives. Before receiving the evaluations, workers will indicate their experienced intrinsic motivation. And after receiving the evaluations, they will be asked about actual emotions and fairness perceptions.

Results Expected: We will systematically compare people's expected emotions, motivation and fairness with their experienced ones, and observe how these feelings change over the course of working on the repetitive task. We will also compare feelings in the AI and human management conditions, and explore whether people behave differently in the two conditions.

Limitations: The iron pickaxe task comprises multiple subtasks and can be completed in different ways, which allow people to form different impressions of AI in evaluating them. However, as

compared to many subjective tasks requiring intuition or creativity, our task may be seen as relatively easy to quantify and thus acceptable in the case of AI management.

Conclusions: To be continued after data analysis.

Relevance to the Congress Theme: While the Metaverse has triggered heated discussion in the business world, little empirical evidence can be drawn to understand its psychological and ethical implications. Our work simulates the future workplaces in the Metaverse in a game environment, and may shed light on facts and challenges of human-centered management in the context of intelligent and autonomous machines.

Paper 3

Whom Do We Trust in Decision-Making? Perceptions of Managers and Politicians vs. Agentic AI

Sabrina Schneider, Management Center Innsbruck; Michael Leyer, University of Marburg

Research Goals : This study aims at exploring the perceptions of trustworthiness that decision-makers and those affected by decision outcomes have of agentic AI as decision agents. More precisely, we aim to answer the following research question: How do perceptions of trustworthiness of (a) agentic AI and (b) the agentic AI's owner effect one's acceptance and usage of agentic AI in decision-making? This work is worthwhile doing as we live in a world with increasingly powerful and available AI-enabled solutions for decision-making (e.g., Lindebaum et al., 2020; Wing, 2021). We however know that humans tend to be reluctant to use agentic AI due to negative predispositions (such as algorithm aversion, e.g. Berger et al., 2021; Burton et al., 2020; Dietvorst et al., 2015, 2018) and anxieties (e.g., Dirsehan & Can, 2020; Suseno et al., 2020). Learning how we can overcome such reluctance will not only help organizations and society to remain competitive, but also to influence the design how we use agentic AI in the future.

Theoretical Background: Theoretically, this study builds on agency and organizational trust theories. We discuss the perception of trustworthiness of AI-enabled, technological agents acknowledging that machine agency exists, despite being different and weaker than human agency (e.g., Leonardi, 2011; Puranam & Vanneste, 2022). We thereby rely on the traditional understanding of trust as a three-part relationship in which one trusts another to do something (Kim & Routledge, 2022) and trust depending on subjective perceptions of the trustworthiness of the decision agent and one's personal trust propensity (Mayer et al., 1995; McKnight et al., 1998).

Design/Methodology: Methodologically, this study builds on a series of experimental studies comparing perceptions of different decision-making agents (human vs. agentic AI) in situations of varying levels of decision magnitude (high vs. low) and different organizations (companies vs. governments) being in charge. Furthermore, we distinguish between the perspective of those offered to delegate a decision to a decision agent and those affected by a decision made by somebody else. The independent variables measured center on the trustworthiness of the decision agent and its owner. Our dependent variables focus on one's willingness-to-use a technological agent or to accept the decisions made by the agent. In total, the study's sample comprises more than 400 participants.

Results Obtained : Our findings show that agentic AI changes whom we trust. Perceptions of trustworthiness of both the decision agent and its owner/principal influence decision acceptance and delegation. Further, individuals prefer human decision-makers only in corporate, but not in governmental, decision contexts. Additionally, our findings reveal that individuals find it easier to accept decisions made by agentic AI than to delegate decisions to agentic AI.

Limitations : Limitations of this study include the scenario-based, experimental research design; the national emphasis on one cultural background (Germany); and the failure to measure novel elements of trustworthiness relevant for AI-enabled, but not human agents.

Conclusions : This paper contributes to the literature on agentic AI in decision-making. In line with recent contributions, we show the need to focus on perceptions of trustworthiness (Puranam & Vanneste, 2022). Going beyond this, however, we emphasize the relevance of the role of the trustee's owner—a perspective that has often been neglected in traditional trust concepts (e.g., Mayer et al., 1995; Schoorman et al., 2007). Further, we highlight the relevance of trustee

benevolence and integrity, in combination with the challenge that we are not capable of identifying motivating behaviors of agentic AI, as a major hurdle to achieving perceptions of trustworthiness. This emphasizes the need to consider human-in-the-loop constellations that allow for sufficient justification of the decision-making behaviors for all actors involved.

Relevance to the Congress Theme : This study contributes to the congress theme emphasizing the changing world of work by looking at novel, technological decision agents that challenge established perceptions of exclusive human agency in managerial decision-making. The emergence and further diffusion of agentic AI in corporate decision-making is likely to change the role of managers and consequently, it will affect work design considerations.

Relevant UN SDGs : Relevant UN SDGs addressed directly in this research are #8 “Decent Work and Economic Growth” in combination with #9 “Industry, Innovation and Infrastructure”. However, given the potential impact of agentic AI in decision-making to improve the overall quality of decision-making, the study’s indirect contribution can contribute to a much broader range of UN SDGs.

Keywords: agentic AI, trust, acceptance of AI

Paper 4

Friend or Foe? - A Qualitative Study on the Socialization Process of AI-Augmented Decision-Making at a Public Organization

Carlotta Bunzel, University of Amsterdam; Robert Verburg, TU Delft; Deanne N. den Hartog & Corine Boon | University of Amsterdam

Research Goals: Using artificial intelligence (AI) to augment decision-making bares the promise to increase efficiency, consistency and quality of decisions. Despite a growing body of experimental studies on AI decision-making, there is a noticeable lack of studies that examine the intra- and interpersonal effects of implementing AI decision-support systems (Langer & Landers, 2021). Thus, in the present study we examine the implementation of an AI decision-support in a public organization with a qualitative, longitudinal, multi-stakeholder approach. By integrating socialization and work design perspectives, we address the following questions with our research: How do individuals experience and shape the implementation of an AI decision-making system, and how does the AI system affect individuals' work design over time?

Theoretical Background: The Socio Technical Framework of AI Socialization (Makarius et al., 2020) defines AI socialization as a core process that the determines the success of integrating AI into organizations. The authors underscore the centrality of employee experience in the socialization process for creating intangible socio-technical capital. Based on the idea of AI socialization we aim to explore the implementation of an AI decision-support system. In doing so, we not only focus on how individuals shape the meaning of AI but also how AI is shaping the design of individuals' work. Therefore, we combine the AI socialization framework with a work design approach (Parker & Grote, 2020) to examine how the experience of job autonomy, skill variety and use, feedback, and relational aspects of work evolve throughout the AI socialization process.

Design/Methodology: In the present study we take a qualitative, longitudinal approach to accompany an implementation of AI decision-support at a public organization in the Netherlands. The AI decision-support was built and trained to support employees in the handling of special support requests. For example, individuals can request special financial support for when costs occur in their daily life that they cannot finance on their own. Across three points in time (pre-, per-, post-implementation) we conduct semi-structured interviews and investigate how multiple stakeholders perceive the implementation of the system: team members (N=8), team managers (N=2), as well as people who regularly rely on special support (N=3). Apart from the interviews we will also use available information provided by the start-up that provides the AI decision-support as well as from the public organization.

Expected Results: We will use a theoretically guided thematic analysis approach to analyze interview and case study data. Nonetheless, we plan to remain open for themes that might emerge during the data collection process. We conducted the pre-implementation interviews in the beginning of October 2022 and will most likely have finished the rest of data collection until early 2023.

Limitations: One of the main limitations of our study is the small sample size which is grounded in the size of the department where the decision-support is implemented. Another limitation concerns the generalizability of our study as we are examining the implementation within one single public organization department.

Research/Practical Implications: With our present study we aim to provide new insights into the effects of implementing AI-augmented decision-making. Through our unique methodological approach, we examine how multiple stakeholders are affected by the implementation over time. More specifically, we focus on how individuals shape the meaning of the AI-based decision support and how the system in turn shapes individuals' work. Thereby, we add to the socio-technical theory of AI socialization and work design. Finally, our study will provide valuable insights for practitioners on how they can support employees and other stakeholders throughout different phases of the socialization process.

Relevance to the Congress Theme: The implementation of AI-based solutions into organizational dynamics is redefining the nature and future of work. Therewith, new challenges for organizations and individuals arise. It is upon us as researchers to evaluate how new socio-technological systems are reshaping work and to provide guidance for individuals and organizations alike. Our study contributes to this goal by studying the socialization process of AI-augmented decision-making.

Relevant UN SDGs: Our study contributes to the UN SDG of "reduced inequalities". With the rapidly developing capabilities of AI decision-making systems, both the risk for creating more inequality, and for reducing inequalities between individuals increases. Thus, in our study we plan to carefully examine the effect on individuals when augmenting decision-making with AI. This allows us to provide recommendations on how AI can contribute to reducing inequalities rather than contribute to amplifying them.

Keywords: AI-augmented decision-making, AI socialization, work design

Paper 5

Good AND Bad: Can Ambivalence Toward AI Help Mitigate Errors in AI-Supported Medical Decision-Making?

Sophie Kerstan & Gudela Grote | ETH Zurich; Jan B. Schmutz, University of Zurich

Research Goals: The use of AI at work to improve decision-making is increasing. However, people tend to wrongfully accept or discard AI-based decision-making recommendations. In healthcare, such mistakes can be extremely costly. To identify ways to mitigate these errors, we examine how holding ambivalent attitudes toward AI might condition more thorough examinations of AI-based recommendations in medical image evaluations, thus fostering more accurate diagnostic decisions.

Theoretical Background: Research on human-AI interaction has conceptualized favorable vs unfavorable attitudes toward AI as opposing ends of a continuum. Based on this literature, wrongfully accepting or discarding AI-based advice is attributed to possessing attitudes toward AI that are either overly positive or negative. This view neglects ambivalence, as a state in which strong positive and negative thoughts or feelings toward an attitude object exist simultaneously. In the broader psychology and management research sphere, studies have shown that ambivalence is prevalent and influential in humans' daily lives. For example, being ambivalent can broaden people's attention scope and motivate them to engage in a more holistic and balanced consideration of available information. Particularly, being ambivalent can help to decrease decision-making biases when people correctly identify the source of their ambivalence. We project these findings onto AI-supported decision-making and argue that people with ambivalent attitudes toward AI will intend to rely on AI-based recommendations less than those with more monovalent positive attitudes but more than people holding negative attitudes. Furthermore, we hypothesize that people with ambivalent attitudes toward AI will make fewer mistakes in an AI-supported decision-making task than people with positive or negative attitudes.

Design/Methodology: In our first online experiment, we tested the success of manipulating attitudes toward AI as a between-subject factor (positive vs negative vs ambivalent) with 60 medical students. We also measured participants' intention to rely on AI-based advice in a medical diagnosis scenario. We apply the previously tested manipulation in a second online experiment (currently 40 medical students). In addition to the three experimental groups, we added a control group for which there is no manipulation of AI-related attitudes. All participants receive pre-recorded video training for a mammography evaluation task. They then classify mammographs regarding whether they show signs of cancer. The images are accompanied by what participants assume are AI-based classification recommendations.

Results Obtained: Experiment I revealed that participants in the ambivalent condition reported lower intentions to fully rely on AI than the positive attitude group and higher intentions than the negative attitude group. This finding is in line with our expectations. A preliminary analysis of experiment II data indicated that for cases where AI-based recommendations were incorrect, the ambivalent attitude group made fewer mistakes than all other groups. For cases where AI-based recommendations were correct, the ambivalent and positive attitude groups performed comparably and better than the negative attitude and control groups. These analyses will be repeated when data collection for experiment II (with a target sample size of 150) is complete, which we expect for December 2022.

Limitations: Beyond the uncompleted data collection for experiment II, our study has two main limitations. Firstly, our samples consist of students. Follow-up studies with working professionals are needed to replicate the findings. Secondly, the mammography decision-making task is highly context-specific, which prohibits the generalization of our findings. Future research could consider a broader range of decision-making contexts to examine the extent to which ambivalence toward AI affects AI-supported decision-making more broadly.

Conclusions: Our initial findings suggest that being ambivalent toward AI might help mitigate decision-making errors in AI-supported medical decision-making, especially in cases where AI makes mistakes. The main theoretical implication of this finding is that the literature on AI use might benefit from incorporating multidimensional attitudinal facets, e.g., ambivalence, compared to exclusively considering attitudes as a unidimensional, bipolar construct. Furthermore, the provided insights can help develop recommendations for training healthcare professionals interacting with AI.

Relevance to the Congress Theme: The fact that AI is increasingly deployed in organizations to support decision-making might make it seem as if the future is now. However, we must carefully address the biases and flaws that AI-supported decision-making introduces and have yet to find ways to contain these. In this regard, our study will help to outline how minding people's attitudes toward AI can support the design of a safer, more effective future of human-AI decision-making.

Keywords: attitudes toward AI, medical decision-making, decision-making biases

Symposium S096

Times of precariousness: Happy, healthy, and productive workers within new forms of work

Annabelle Hofer, University of Cologne

science

What will be covered and why?

This symposium focuses on advancing the scholarly knowledge of new forms of work. Research in this area has gained significant momentum in light of the COVID-19 pandemic and the war in Ukraine, which increased the precariousness of workers and resulted in an increase in new forms of work (Spurk & Straub, 2020). New forms of work bring new risks and chances, which in turn ask for further personal and contextual resources to deal with them (Ashford et al., 2018; Ashford et al., 2007; Fieseler et al., 2019; Kuhn & Maleki, 2017). However, research is still developing, and further insights are needed to advance our knowledge in this area to understand better how it is possible for workers to be happy, healthy, and productive in precarious times within new forms of work. This symposium addresses existing gaps by using (longitudinal) quantitative research from Germany, Switzerland, and Ukraine on the factors shaping and the experiences unfolding in people's careers working within new forms of work and within/during precarious times such as war and COVID-19. The contributions cover diverse sample from nurses, academics, and gig workers. The four studies advance insights into workers' perceptions and behavior in precarious times.

The first study aimed to identify and describe nurse work arrangements and investigate the effects of fairness issues across and within different work arrangements. This study investigates inequity perceptions across 287 nurses with different work arrangements (staff, per-diem & travel) in Switzerland. The authors show how inequity perceptions are related to happiness (job satisfaction) and health (exhaustion).

The second study, „Successfully engaged in creativity? - The longitudinal interplay of career success, work engagement and creativity in academia." addresses the career success of academic scientists in Germany. Data (N = 1385) were collected via a longitudinal online survey (four measurement points, one-year intervals) on academic scientists. The work conditions in academia are demanding due to short-term contracts, part-time payment, and insecure career perspectives. In a longitudinal design, this study tested a gain spiral between a personal resource, a motivational process (work engagement), and work performance (creativity).

While studies 1 and 2 focused on specific professional groups, studies 3 and 4 are devoted to various tasks performed in the gig economy in times of crisis (i.e., COVID-19, war). The third study aims to shed light on how women's employment on online platforms affects their future opportunities in the labor market and their gross wage income. Furthermore, the study provides insights into female workers' current activities, intentions, and perceptions. The author conduced a 300 female gig workers survey via a German micro-tasking platform. Two waves were collected shortly before the pandemic outbreak and shortly after. The study results are linked to objective career success (income) and address a specific career shock (i.e., COVID-19).

The war within Ukraine is affecting career-related decisions for working individuals. However, there needs to be more knowledge on how and if war-related circumstances are seen as career shocks and how these career shocks affect career-related outcomes. Therefore, the fourth study examines war-related career shocks and their impact on gig workers' career outcomes in Ukraine.

Relevance to the Congress Theme

Our symposium fits the theme excellently, as it sheds light on new forms of work.

The future is now. Our symposium shows the extent to which work arrangements have already changed and how it has been possible for new forms of work to develop quickly.

The future is now! Our symposium highlighted the urgency of better understanding new forms of work.

The future is now? Precarious work arrangements are associated with advantages and disadvantages. For example, the gig economy provides short-term income when other sources of income are eliminated, but what are the longer-term consequences for workers, companies, and society?

Research/Practical Implications

The symposium highlights the complexity and the factors shaping sustainable career development within new forms of work in precious times. We extend career research and foster further theory development by studying topical issues relating to new forms of work.

Overall conclusions

This symposium shows that it is of utmost importance to understand precarious work types in precarious times better. In all, the symposium helps advance empirical knowledge of sustainable career development of workers, being happy, healthy, and productive within new forms of work.

Keywords: new forms of work, career success, career shocks

Paper 1

Successfully engaged in creativity? - The longitudinal interplay of career success, work engagement and creativity in academia

Larissa A. Reis, Simone Kauffeld & Markus Szczesny | Technische Universität Braunschweig; Daniel Spurk, University of Bern

Research goals and why the work was worth doing

The number of university graduates who start their career in academia is rising (Maher & Sureda Anfres, 2016). The work conditions in academia, however, are demanding: short-term contracts, part-time payment, insecure career perspectives; just to name some of the inherent problems (cf. Kauffeld & Spurk, 2019; Ortlieb & Weiß, 2018). To face these challenges young researchers need resources. We follow the recent resource perspective on subjective career success (SCS) and bring it together with creativity in academia as a desired outcome. In line with COR-theory (Hobfoll et al., 2018) we hypothesize SCS functions as a personal resource under stress, that increases employee's future work engagement and indirectly their future creative work performance. Furthermore, we state that performing creativity leads to a higher future perception of success. To sum up, we are testing a positive indirect feedback loop between SCS, work engagement, and creativity over time (SCS to work engagement to creativity to SCS).

Theoretical background

Connected to the beforementioned precarious work conditions in academia is also the predominant way to measure success in academia with quantity of publications, h-index and co. The German psychological society discusses the question of how to rate success in academia better. Quality of research (such as open access, creativity, and innovativeness of outputs) gains momentum when it comes to academic careers (Abele-Brehm & Bühner, 2016).

At once, a recent vocational research and societal focus is on subjective evaluation processes when it comes to success in careers (Akkermans & Kubasch, 2017 ; Spurk et al., 2019). SCS is defined as the individual evaluation or experience of valued career goals (Ng & Feldmann, 2014). Young generations prefer happiness and satisfaction over objective success, such as promotion (Lalić et al., 2020). Spurk et al. (2019) stated that it is not only interesting how SCS emerges but also if SCS can play a role as a resource for other desired outcomes in academia (such as motivation and creativity).

Design/Methodology/Approach/Intervention

Data (N = 1385) were collected via a longitudinal online survey (2014-2017; four measurement points, one-year intervals) on German academic scientist (PHD candidates and PHD holders). We specified a measurement model with sixteen latent factors conducting several measurement invariance analyses and found support for metric invariance. Therefore, we conducted the final cross-lagged panel model with constrained factor loadings over time (model fit: $\chi 2(1871) = 3136.68$, $p < .001$; RMSEA = 0.02; CFI = 0.96; TLI = 0.95; SRMR = 0.06).

Results obtained

Results show significant cross-lagged paths from SCS to work engagement (all $\beta s = 0.04 - 0.05$, all ps <.05) as well as from work engagement to creativity (all $\beta s = 0.06$, all $ps < .01$). As expected, an increase in SCS leads to an increase in work engagement over time, and an increase in work

engagement leads to an increase in creativity over time. However, we find no significant paths from creativity to SCS (βs = -0.02, all ps = .33).

Limitations

The study lacks an experimental design. Therefore, we cannot control for all possible influences of third variables. All variables were measured via self-report. Especially creativity should be discussed in this regard. All study variables show high stabilities over time.

Conclusions – research and or practical implications

This study tested a gain spiral between a personal resource (SCS), a motivational process (work engagement) and work performance (creativity) in a longitudinal design. We add new insights on the role of SCS as predictor/ resource in combination with COR-theory.

Our findings stress the need for frequent reflection over the own achievements as important instrument for a happy and productive career development in academia. The institutions need to provide time and latitude for self-reflections and creative research. Last, our findings support the need for a shift of career evaluations in academia.

Relevance to the Congress Theme

This work contributes to (1) Careers and the Labour Market, as it investigates a sample in precarious work conditions namely: part-time and short-term work in academia. Moreover, we add knowledge to (3) Creativity, Innovation and Risk-taking , as the results show that success and motivation foster creativity in academia.

Relevant UN SDGs

The work is related to the SDG 8: Decent work and economic growth , as we study an interplay of career- and work-related variables that foster a healthy and productive career development. Furthermore, facing climate change and contributing to worldwide SDGs it is worthy to study how creative solutions can be fostered in academia (SDG 9).

Keywords: Subjective career success, Creativity, Cross-lagged model

Paper 2

War-related career shocks and career outcomes of gig workers in Ukraine

Tetiana Tverdushka, Bern University of Applied Sciences; Annabelle Hofer, University of Cologne; Daniel Spurk, University of Bern; Caroline Straub, Bern University of Applied Sciences

Research goals and why the work is worth doing

The war within Ukraine is presumably affecting career-related decisions for working individuals. However, there is a lack of knowledge on how and if war-related circumstances are seen as career shocks and how these career shocks affect career-related outcomes. Therefore, this study examines war-related career shocks and their impact on gig workers' career outcomes. Gig work represents a substantial amount of paid work within the Ukrainian labor market and can be seen as a flexible and adaptable work type, which seems specifically relevant within the recent Ukrainian context.

Theoretical background

Research on career shocks has received increased research attention in the career literature. Seibert et al. (2013) and Akkermans et al. (2018) conceptualize career shocks as "disruptive and extraordinary events that are, at least to some degree, caused by factors outside the focal individual's control and that trigger a deliberate thought process concerning one's career". Career shocks shape an individual's career path and can both hinder and enhance career development (Blokker et al., 2019; Hofer et al., 2021; Kraimer et al., 2019). Career shocks relate to an individual's job search behavior and can promote entrepreneurial intentions to start a business (Akkermans et al., 2021). Hence, it is a crucial research question how war-related career shocks affect career outcomes. Our assumption is that war-related career shocks are generally detrimental for career outcomes like career optimism and career satisfaction. Furthermore, we assume that career salience plays a buffering role for those relations. Because career shocks might also be positive and not only negative, we also examine whether war-related career shocks might have positive effects for some individuals and if gig work per se provides opportunities to adapt to war-related career shocks.

Design/Methodology/Approach/Intervention

Because it is the first study in this context, we chose a cross sectional design for a first understanding of our core constructs within a war context. We adapted the career shock measure to account for the war context and ask several career and war related questions to better understand how gig workers combine career and work-related issues with experienced circumstances due to the recent war. Besides this, we applied well accepted measures from past research (e.g., career optimism and career and job satisfaction).

Data will be collected in autumn 2022 and empirical findings can be presented at the EAWOP conference. The data collection is part of a larger research project on "Platform work in Europe" which is funded by the Swiss National Science Foundation as part of its National Research Program 77 for Digital Transformation.

Limitations

Due to shortage of time, we can present only cross-sectional data but plan to follow up with a second measurement point.

Conclusions – research and or practical implications

We hope that our research will inspire scholars both within and outside of the field of career research to better understand how career shocks may impact the way in which gig workers in Europe develop their careers. Moreover, this research is insightful for supporting gig workers within the Ukrainian war context and can provide useful insights for policy makers.

Relevance to the Congress Theme

The last year has changed the economic preconditions for the world of work. Gig workers that may work remotely and flexible on the global labor market can play a vital role within those changes. Against the recent Ukrainian background, the flexible gig work market may have a specifically relevant role for the population in general. Results of our study can help gig workers thrive in this new employment relationship and to prompt platforms and organizations to treat them fairly while benefitting from their contributions.

Relevant UN SDGs

This study will reveal important opportunities that platform work provides for Ukrainian gig workers these days, but it also raises important and relevant answers to UN SDGs questions on the sustainability and equality of this work.

Keywords: gig work, war, career success, career shocks

Paper 3

Equity Theory Predictions Across (and Within) Different Work Arrangements

Caroline Gahrmann, Petra Liselotte Klumb & Bernhard Piskernik | University of Fribourg

Research goals and why the work was worth doing . As the Covid-19 pandemic aggravated precarious working conditions in health care, nurses increasingly left the profession or chose temporary work arrangements that promised flexibility and better hourly pay. We consider nursing an exemplary case for professions in which different work arrangements coexist. Consequently, nurses may work side-by-side and take care of the same tasks but be employed through different contracts. This heterogeneity in contracts raises important questions regarding fairness. These questions deserve particular attention within the context of nursing, as nurses' skills are highly demanded, making social comparisons and fairness issues especially potent.

Theoretical background. To explain nurses' reactions to fairness issues, we draw on equity theory. Hence, we assume that nurses in all work arrangements use social comparisons to determine the relative distribution of received outcomes compared to invested input. Based on dynamics specific to the nursing profession, we assume that staff nurses perceive this distribution as less equitable than travel nurses who are employed by external agencies. In line with equity theory, we assume that inequity perceptions are positively linked to exhaustion and negatively linked to job satisfaction across nurse work arrangements. Furthermore, we extend equity theory predictions in two ways. First, we consider the role of resource trade-offs. Specifically, we posit that appreciation is an additional resource that buffers detrimental reactions to inequity. Second, we investigate how the accessibility of information for social comparisons may impact effects of inequity. More specifically, we investigate how staff nurses' exposure to temporary nurses influences their reactions to inequity.

Design/Methodology. A total of 366 nurses (246 staff, 120 travel) participated in the complete two-wave survey study. We used a three-step approach within a multi-group framework to investigate differences between arrangements. First, treating item responses as ordered categories in a confirmatory factor analysis (CFA), a (partially) invariant measurement model of all factors was established. Second, the CFA was expanded to a structural equation model to compare the main effects between groups. Lastly, invariance-adjusted factor scores were used in a random-slopes model to test whether the degree of moderation differs between groups.

Results . In line with our assumptions, staff nurses reported higher levels of inequity than travel nurses. Inequity perceptions were negatively related to job satisfaction and positively related to exhaustion across nurse work arrangements. As expected, appreciation buffered detrimental effects of inequity in temporary nurses. Contrary to our assumptions, effects of inequity on job satisfaction and exhaustion were stronger for permanent nurses who reported more (vs less) appreciation from colleagues. Lastly, exposure to temporary nurses strengthened the effects of inequity on exhaustion but not job satisfaction.

Limitations . We restricted data collection to Swiss nurses. While this approach enables precise conclusions about arrangement-specific differences in a sample that works under otherwise similar conditions, further research is needed to investigate whether these findings can be generalized to other contexts. In addition, while we separated assessments of predictor and outcome variables by two weeks, we cannot completely exclude common-method bias because of the reliance on self-

reports from one source. Finally, despite the temporal distance between questionnaires, our data are cross-sectional and prohibit insight into the directionality of effects.

Conclusions – research and or practical implications. Our work demonstrates that inequity perceptions and associated strain are harmful side-effects of contract heterogeneity. These side-effects can lead to severe disruptions in fields where labour markets are tight, and employees are highly coveted, allowing them to leave an unsatisfying situation for one with better conditions.

Relevance to the Congress Theme . Employment relationships are constantly evolving as advances in digitalization match longstanding trends towards the flexibilization of work. This trend applies to the nursing profession, where the percentage of nursing hours put in by temporary nurses who are booked for single shifts (per-diem nurses) is rapidly increasing. Our research offers insight into how these changes affect nurses' experiences, focusing on the role of fairness issues between different nurse work arrangements.

Relevant UN SDGs . Identifying and highlighting inequity in employment exchanges are first steps toward achieving "reduced inequalities" and "decent work" for employees across different work arrangements.

Keywords: work arrangements, Equity Theory

Symposium S097

A world in change: Applying multiple lenses to examine change processes and interventions for individuals and organizations

Pedro Neves, Nova School of Business and Economics; Regina Mulder, Universität Regensburg

science

What will be covered and why

The world of work has gone through significant changes in the past few years, accelerated by a sequence of crises (financial and health) that forced individuals and organizations to quickly adapt. This symposium aims to provide a collection of studies on change, at the individual and organizational levels, to foster discussion on the challenges associated with such efforts. Changes in self-regulated learning, in learning activities as part of professional development and in social identification are focused on in the presentations. Furthermore, attention will be paid in this session to the determinants and conditions of these changes, such as at the individual level resistance to change, self-concept, and technostress, at the organizational level the learning culture, and at societal level dynamic contexts caused by for instance COVID.

The first study, conducted by Kaltianen and Hakanen, examines longitudinally how a move towards telework during the pandemic impacted changes in social identification in a sample of Finish employees. The authors draw from social identity theory to identify four profiles of identification change and provide new insights into how identification with different organizational entities evolved during a major organizational disruption.

Deronchène et. al., present a qualitative study on career changes of teachers. They examine how the prior experience of second career teachers adds value for the school context. The collection of interviews provides insights on the required personal resources and how organizational resources foster and/or restrain the applicability of such personal resources.

Cuyvers et. al., follow with the discussion of an intervention designed to help develop nurses' self-regulation of professional learning, a competence that is lacking in the clinical context. The study used a multiple baseline design to explore different patterns of response to the co-regulation intervention and to argue that there are no one-size-fits-all solutions.

Our fourth presentation (Neves & van Dam) explores the interplay between individual adaptability and leader-member exchange in fostering trust in change management and openness to change in a Dutch sample. The findings suggest that both elements – personal characteristics and situational factors - are important for change management and need to be integrated in managerial practices.

Finally, Mulder et. al., investigates the changes in work at the beginning of the COVID pandemic in the work of university teachers, the changes in learning activities as part of their professional development that caused, and what the mediating effects are of technostress and learning culture on the relationships between changes at work and the professional development that emanates from that. Analyses of the survey data among university teachers in Germany indicate that characteristics of work changed, led to several learning activities with mediated effects.

Relevance to the Congress Theme

The symposium precisely taps the center of the congress theme: the changing world of work. We examine these changes in multiple contexts (e.g., nursing, teaching, telework, diverse samples) and

combining different methodologies (e.g., intervention, interviews, survey, longitudinal/time-lagged designs) to provide a rich and nuanced view of the processes underlying individual and organizational change.

Research/Practical Implications

This collection of studies is clearly aligned with SDG 8 (Decent work and economic growth) and contributes for SDG3, Health and Well-Being (Cuypers et al; Kaltianen & Hakanen) and SDG16, peace, justice, and strong institutions (Neves & van Dam). The implications are as vast as the set of studies as described in each abstract.

Overall conclusions

Indeed, the world of work is changing. This collection of studies demonstrates how complex the processes of individual and organizational change are, and how solutions are (more often than not) clearly context bound.

Keywords: Organizational change, individual change, context

Paper 1

Changes in social identification at work amongst teleworkers during COVID-19: A person-centered approach

Janne Kaltiainen & Jari Hakanen | Finnish Institute of Occupational Health

Research goals and why the work was worth doing

Given the increase in teleworking due to COVID-19, it is essential to understand how teleworking may impact belongingness (social identification) at work and if such effects may differ across groups. This is important as social identification has been identified as a major predictor, for instance, of higher employee performance and well-being. We aimed to identify different emerging groups, i.e., heterogeneity in the sample of teleworkers, that may vary in levels and changes in identification (i.e., the person-centered approach). We also provide insights regarding the promotion and implications of social identification amongst teleworkers.

Theoretical background

Drawing from the social identity approach, we examined levels and changes in three foci of identification (organizational, supervisory, and co-worker identification) during a major shift to teleworking. Identification refers to the extent to which an employee defines her/himself in terms of the social entity such as membership in an organization and is manifested as an emotional and cognitive bond with an entity.

Design/Methodology/Approach/Intervention

We collected a three-wave longitudinal panel sample of teleworkers (N =875) from seven Finnish organizations representing a wide range of industries across Fall 2019 (T1), 2020 (T2), and 2021 (T3) thus capturing time points before and after the COVID-19 outbreak. The sample included respondents who teleworked at least ¼ of their working hours at T2 and T3 and who reported increases in telework since the COVID-19 outbreak. Data were analyzed by growth mixture modeling.

Results

The analysis supported a solution of four theoretically meaningful profiles. The majority (55 %) belonged to a profile where all three foci of identification (organizational, supervisory, and co-worker) were high at T1 and did not change over time. For 26 %, identification levels were low and stable except slight decrease in co-worker identification. For 11 %, identification levels were relatively high but decreased substantially. For the minority (8 %), initial identification levels were low but increased notably. Taken together, the majority (81 %) belonged to profiles with no or only minor (co-worker identification) changes in identification levels.

Time spent teleworking increased the likelihood of belonging to a decreasing identification profile in comparison to an increasing identification profile. Especially those who belonged to profiles with initially high levels of identification reported more fairness, servant leadership, and social support at T1.

The profile of high and stable identification was characterized by lower turnover intentions and burnout and higher work engagement at T3 in comparison to other three profiles. Employees in this profile also generally reported more positive attitudes towards working also at the office (in contrast to full-time teleworking) at T3.

Limitations

While we examined longitudinal data with matched respondents across time, our data was correlational and thus cannot establish causal effects.

Conclusions – research and or practical implications/Originality/Value

This is one of the rare studies which have tracked levels of social identification with several different social entities over time. We provide new insights into how identification with different organizational entities evolved during a major organizational disruption (COVID-19 outbreak) amongst teleworkers and how such changes differed within the sample. Notably, we found four profiles that differed in how identification changed over time.

For most teleworkers, identification may remain stable at least across two years. Yet, a tenth of the teleworkers may experience a substantial loss of social identification with several entities at work and employees in this profile teleworked than employees whose identification increased. Teleworking may impair especially co-worker identification as 36 % of teleworkers belonged to profiles where co-worker identification decreased.

Perceptions of organizational fairness, supervisor's servant leadership, and social support from co-workers are likely to promote organizational, supervisory, and co-worker identification. Also, high initial levels of identification may protect against identification decrease albeit for a small minority, low initial identification co-occurred with identification increases. While our findings further corroborate the negative effects of low and decreasing identification for employee well-being and commitment, we show that identification deterioration may also amplify employees' wishes to telework more also in the future. This may lead to spiraling effects between teleworking and decreasing identification, and its associated negative outcomes, in workplaces over time.

Relevance to the Congress Theme

Teleworking is and will be a central way of working in the future as well. This study illuminates its potential consequences and ways to mitigate them in workplaces.

Relevant UN SDGs

Decent work and economic growth

Keywords: social identification, telework, person-centered approach

Paper 2

Transitioning into the teaching profession as a second career. A qualitative study examining the role of previous experiences for making this change

Isabel Raemdonck, University of Louvain ; Thibault Coppe, University of Groningen ; Alexandra Deronchène, University of Louvain

Research goals

Second career teachers (SCT) are professionals who decided to leave a prior occupation to become teachers (Tigchelaar et al., 2010). In the scientific literature, they are seen as an important solution to tackle the growing teacher shortage (Paniagua & Sánchez-Martí, 2018) and as a resource for schools because of their previous professional background (Hunter-Johnson, 2015; Nielsen, 2016; Tigchelaar et al., 2008). In addition, SCTs experience is also a resource for themselves to facilitate their professional transition and overcome the well-known difficulties of the teachers' induction process (Wilkins & Combier, 2015). Indeed, part of SCTs successful induction is determined by the recognition of previously acquired skills and experience by the school staff (Coppe et al., 2022).

The literature seems to agree on the important role of SCTs' previous experience, although little empirical evidence is provided about the added value of these experiences for the school context and for themselves. As SCTs are becoming a significant and growing proportion of the teaching workforce (Coppe et al., 2021) the main objective is to gain insight into how SCTs' previous experience is a resource for the school and for themselves, and to what extent SCTs are recognized for that by the school staff .

Theoretical background

We built our theoretical framework using the Job Demand-Resource model (Bakker et al., 2007). This model is well-known for enabling to take different perspectives of analysis. In our case, this framework is relevant as it gave us insights into how personal resources can help to overcome the demands of the job (i.e., the difficulties pertaining to the induction process) and how personal resources in their own right positively impact engagement, growth and competence development (Van der Heijden et al., 2014; Xanthopoulou et al., 2007). Also, this model sheds light on how organizational resources can foster or restrain the personal resources of workers.

Method

This study built on a qualitative case study design (Yin, 2001). We interviewed nine SCTs in the early phase of their professional transition (< 5 years of seniority in the teaching profession). Our interview guidelines included questions regarding their experience of the transition process, how they live their induction in the teaching profession, what resources help them to overcome the difficulties, how they can participate actively in the development of their schools, if they feel valued for the resources they bring to the school etc. We first assigned codes to the quotes of the participants. Second, we regrouped these codes into categories. Third, we aggregated these categories within relevant themes.

Results

SCTs professional background serves as an important resource for making their first step into the teaching profession. They built their credibility in their classrooms using concrete examples from

their previous professional practice. They prepare their lesson with the learning objectives in mind and with the aim of preparing the students to implement what is learned in real work situations. Our participants also reported knowing how to make use of the resources available in the workplace, as they learned to do so in their previous professional life. SCTs proactively built their social capital by interacting with colleagues. Finally, as they already experienced one (or several) induction process in their career path, they have constructed a psychological capital making them resilient in times of change.

SCTs perceive their own experience as an added value to the school. The participants are convinced that they actually can contribute to the school at an organizational level. Their colleagues and the leadership team however, do not seem to perceive their value added. Although SCTs are willing to participate in school development initiatives, they are often refrained by the school leader or are not taken seriously by their colleagues.

Limitations

The main limitation of this study is our sole focus on the voice of the SCTs. Interviewing leaders and first career teacher colleagues could have provided additional information regarding how the school perceives the SCTs as resource.

Conclusions

This study highlights the added value of SCTs experience for the school workplace. School leaders should be aware of the importance of previous experiences and make optimal use of them.

Relevance to the Congress Theme: Career transitions are the norm in the changing world of work

Relevant UN SDG's: goal 8 decent work as SCTs have the right to be recognized for their professional work experience by the school

Keywords: career transition, teaching, prior experiences

Paper 3

Development of self-regulated professional learning, nurses, single-case experiment

Katrien Cuyvers, Department of Training and Education Sciences, Faculty of Social Sciences, University of Antwerp; Veerle Struben, Spaarne Gasthuis, Hoofddorp; Maaike Endedijk, Department of Educational Science, Faculty of Behavioural, Management and Social Sciences, Universiteit of Twente; Catharina Van Oostveen, Spaarne Gasthuis, Hoofddorp

Research goals

Research on nurses' self-regulation of professional learning (SRpL) showed that this competence is not so adequately developed (Cuyvers et al., 2021). Also, although there is a growing awareness on the importance of co-regulation involving transitional and flexible stimulation of self-regulated learning (SRL) (Hadwin et al., 2018), research investigating how its (further) development beyond graduation should be promoted, is scarce (Brydges et al., 2020). This study aimed to investigate the impact of a co-regulation intervention on the development of SRpL of nurses.

Theoretical background

Nursing is a dynamic profession where in the midst of continuing technological and healthcare innovations high standard quality care needs to be delivered (Adriaansen, 2018; Liljedahl, 2018). As a consequence, the ability to self-regulate one's professional learning is assumed to be of major importance for ongoing performance improvement in the clinical environment (Cuyvers et al., 2021; Brydges et al., 2020).

SRpL in the clinical environment refers to the ability to engage in behavioral, cognitive, metacognitive, and affective strategies to shape the learning process evoked by the challenges of daily practice (Cuyvers et al., 2021). The different SRpL-strategies engaged in (see Figure 1), are conditional (readiness strategies) for initiating (agents), advancing (mechanisms), and appraising (appraisals) the learning process dynamically. Interrelated strategies (marked with arrows in Figure 1) and feedback loops dynamically compose the unfolding SRpL process over time (Cuyvers et al., 2021). SRpL is evoked by work but can also be interrupted by work and/or be highly integrated with work (Cuyvers et al., 2021).

In the existing literature, fostering self-regulated learning (SRL) is referred to as co-regulation (Hadwin et al., 2018). In co-regulation, the engagement in SRL strategy-use is facilitated in interpersonal interactions, and/or technological tools. Thereby, the learner is transitionally supported towards productive SRL strategy-use (Bransen et al., 2022; Hadwin et al., 2018). Co-regulation interventions aim to support the shift in regulatory ownership to the individual, and as such develop SRL.

Methodology

A multiple baseline design (MBD) with additional post-intervention phase, as a type of single-case experimental design (Cuyvers, 2021; Tanious & Onghena, 2019) was used to investigate the effects of a co-regulation intervention on the development of SRpL. Five nurses of the chirurgical department in a hospital in the Netherlands participated. Ethical approval was obtained. A multi-method approach with repeated quantitative and qualitative measurements was used to collect data on SRpL. The co-regulation intervention was designed and implemented by the first author who is educated in educational sciences and coaching in organisations, and as a physical therapist highly

acquainted with the healthcare context. Here, we report on the results of the work-daily short questionnaire. The data were first explored using visual analysis, which has been the primary method of data-analysis in single-case research (Wolfe et al., 2019). Further, the baseline corrected TAU analysis was used, investigating the within-person change in SRpL between the different phases in the MBD (Tarlow, 2017; Wolfe et al., 2019).

Results

Visual exploration of the data showed that positive changes in SRpL-strategies based on the co-regulation intervention could be expected for three participating nurses. The statistical analysis first showed that no significant baseline trends could be found. Furthermore, diverse results with significant effects in some SRpL measures between phases were found. For one nurse in particular, strong positive effects were found on all the SRpL-strategies between the baseline and the post-intervention phase, indicating the hypothesized change in SRpL.

Limitations

As 'work in progress', all mixed-method data should be interpreted in relation to each other, to gain more converging evidence on the impact of the co-regulation intervention. Further, the most recent methodology literature points at the baseline corrected TAU as a method for investigating intervention effects in single case experimental research. However, different other indices can be found, and there is a lot of debate in this field.

Conclusions

Different intervention effects for different nurses were found indicating that no one-size fits all intervention can be designed to support the development of SRpL of all nurses in a hospital or other healthcare organisation. Further research should investigate which interventions impact the development of SRpL under different context and tasks specific circumstances.

Relevance to the conference theme

In a changing world of work, SRpL is assumed to be a very important competence. This contribution offers important insights on the development of this competence and is as such highly relevant.

Relevant UN SDG's

Continuous SRpL important to deliver high-quality healthcare, related to UNSDG3.

SRpL is assumed to play an important role in sustainable career paths and employability, related to UNSDG8.

Keywords: Development of self-regulated professional learning, nurses, single-case experiment

Paper 4

Adapt but don't forget to connect: How adaptability and LMX foster openness to change

Pedro Neves, Nova School of Business and Economics; Karen van Dam, Open University of the Netherlands

Research goals

The purpose of this study is to examine whether LMX enhances the impact of employee adaptability on his/her change responses. In light of Uncertainty Reduction Theory, we argue that employee adaptability is an important precursor of trust in change management, which in turn should promote openness to change. We also put forth that adaptive behavior, like all employee behavior, takes place within the socio-political arena of an organization, and therefore, the quality of the social exchanges should serve as an important condition for employees' responses to change (Sweet et al., 2015).

Theoretical background

The increasing turbulence within and around organizations has led to a growing need for an adaptive workforce, with employees who are open to changing and cope with uncertain work situations (Baard et al., 2014; Carpini et al., 2017; Jundt et al., 2015). As employees play an important role in implementing workplace changes and are expected to proactively address the challenges that arise from change implementation, employee adaptability and openness to change is crucial for organizations undergoing change (Cullen et al., 2014; Van Dam, 2013).

Given that employee behavior occurs within a social system, employees' perceptions of the social relationships in which they are engaged at work are key aspects of their work environment (Sweet et al., 2015). The exchange relationship employees have with their supervising leaders, i.e. the Leader-Member Exchange (LMX) relationship, should be an important factor in determining the positive impact of employee adaptability on responses to change. LMX theory (Dansereau et al., 1975; Graen & Uhl-Bien, 1995) and Uncertainty Reduction Theory (URT; Berger & Calabrese, 1975) emphasize the role of reciprocity and predictability as key concerns in interactions, particularly in uncertain situations.

Design/Methodology/Approach/Intervention

Participants were Dutch employees of different organizations that were undergoing large-scale organizational changes. Data were collected at two times with a 4-week interval. Respondents were recruited by approaching organizations and managers via e-mail, telephone, or social media, explaining the purpose and conditions of the study.

In total 468 participants completed the questionnaire at Time 1 and 244 participants completed the questionnaire at Time 2 (response rate 52%). Respondents reported that their organization was undergoing a change process that was either at the beginning (15%), in the middle (73%) or nearing the end (12%).

Results

The findings support the relevance of adaptability as an individual characteristic for employee change responses. Highly adaptable employees were more open to the change that was taking place in their organization, as measured one month later, compared to employees with low adaptability.

Compared to low adaptable employees, highly adaptable employees also reported more trust in the managers who were responsible for the change, which in turn was an important precursor for their openness to the change. Finally, we also found that LMX influences (i.e. moderates) how adaptability is transformed into higher levels of trust in change management and openness to change, the latter also via increased trust (i.e. moderated mediation effect). Highly adaptable employees who were in high-LMX relationships experienced more trust in the management responsible for the change and were more open to change.

Limitations

We only used one source of information (i.e., employees) and account only for two moments in time. Future research should use cross-lagged panel designs to test for causality and use other sources such as peers or supervisors.

Conclusions

This study contributes to the literature in several ways. First, we support earlier research showing that better adapters show less resistance to change (Van Dam & Meulders, 2020). Second, we provide evidence on one of the underlying mechanisms (trust in change management). Third, our findings suggest that, in order to determine whether employees trust change agents, we need to take into account personal characteristics, such as adaptability, as well as situational factors, such as the quality of the relationship between subordinates and supervisors.

Relevance to the Congress Theme

Adaptability is a core competence to cope with the changing world of work, as reflected in our findings. Openness to change is a key indicator of the ability of organizations to create the future now.

Relevant UN SDGs

Decent work and economic growth (8); Peace, justice, and strong institutions (16).

Keywords: adaptability, LMX, openness to change

Paper 5

Learning culture and technostress in the professional development of university teachers emanating from technology-driven changes in their work

Regina Mulder, Faculty of Human Sciences, University of Regensburg; Mireille Post-Hubers , Faculty of Behavioural, Management and Social Sciences, University of Twente; Louisa Reinheimer, Faculty of Human Sciences, University of Regensburg

The Covid-19 pandemic changed the work of university teachers by demanding innovative, digital teaching methods (Li & Wang, 2021). Changes triggered by technological developments can disrupt routines and complement the execution of work tasks which can lead to changes in work characteristics such as autonomy (Beer & Mulder, 2020). To successfully deal with such changes, professional development (PD) is required. PD contains 'elaborating' learning activities such as reflection, 'expanding' learning activities such as asking colleagues and 'externalizing' learning activities which leads to team or organization development (Simons & Ruijters, 2004). Empirical evidence on organisational aspects supporting PD in universities is needed to remain competitive and deliver high-quality teaching, but is scarce. Therefore, the research question is: What changes in PD emanate from technology-driven changes in the work of university teachers?

The JD-R theory distinguishes job demands and job resources (e.g. Bakker & Demerouti, 2007) which both can affect PD. PD may be fostered by a supportive environment such as an organisational learning culture (Kyndt & Baert, 2013). Moreover, university teachers that are required to adapt to technological developments may experience technostress causing negative consequences (Li & Wang, 2021). The second research question is: To what extent do organisational learning culture and technostress creators and inhibitors moderate these relationships? We hypothesize moderating effects of organisational learning culture (OLC: organisation's effort to create learning opportunities for all members; Marsick & Watkins, 2003) and organisational technostress creators and inhibitors (TSC: organisational aspect that create stress caused by technologies; TSI: organisational mechanism that can reduce stress caused by technologies; Ragu-Nathan et al., 2008).

With a cross-sectional study data was collected from 350 teachers at different universities in Germany after the first semester under Covid-19 restrictions. The questionnaire contained: (1) a 3x3-items Change in PD scale, capturing changes in 'elaborating', 'expanding' and 'externalizing' learning activities with a range from 1=much less often to 7=much more often; (2) four items measuring perceived change in work (in autonomy , workload , complexity and role expectations with a range from 1=strongly decreased to 7=strongly increased; (3) 21-item short version of the DLOQ (Kortsch & Kauffeld, 2019) measuring OLC ; (4) a 4-item scale measuring TSC and a 4-item and 5-item scale measuring TSI (Ragu-Nathan et al., 2008) were used with a six-point Likert-scale answering mode. All scales had satisfactory Cronbachs α (.72–.94).

An increase in performance of all three categories of learning activities (M=4.47-5.2) was found. Correlations were found between elaboration and complexity and role expectations (r= .29; r= .28) and expansion and autonomy (r= .18). Externalisation correlated with complexity and role expectations (r= .11; r= .17) as well as OLC and TSC (r= .18; r= .13). Furthermore, the direction of the change (increase/decrease) and the intensity (no, little and strong change) seem to have different effects in relation to the changes in PD. The results of preliminary linear regression analyses indicate that perceived changes in role expectations and OLC positively relate with an increase in

externalising learning activities. The results of further analyses will be elaborated on in the presentation.

One limitation was that the sample was not equally divided among the different scientific disciplines. The DLOQ does not seem to fit optimally to organisations such as universities. This is a cross-sectional study, and there might be additional changes (apart from the technological ones) that might have affected in part changes in PD.

The actual perceived changes in work as a result of new technologies have been measured. These changes affect the different components of PD and technostress seems to be a mediator.

This study measures changes at work caused by the use of new technologies and the changes in professional development of university teachers caused by them.

Symposium S092

How can i-deals facilitate work in a BANI environment?: individual, group and organizational contributions.

INÉS MARTÍNEZ-CORTS, University of Seville, Spain; PATRICIA ELGOIBAR, University of Barcelona, Spain

science

What will be covered and why?

Today we have moved from VUCA (Volatile-Uncertain-Complex-Ambiguous) environments to BANI (Brittle-Anxious-No Linear-Incomprehensible) environments, which is leading organizations to make continuous changes at the helm and face complex and changing challenges. In these environments, it is particularly important to focus on a differentiation approach in human resource management practices instead of a traditional and standard perspective. The negotiation of idiosyncratic deals (I-deals) or put it differently the negotiation of individualized work agreements, is one of the most important tool in the differentiation perspective. In addition, the context of (post) pandemic offer on one side, many companies the possibility to think outside the box and adapt to employees needs in terms for example of working from home. On the other side, from employees 'perspective, asking for individual agreements is becoming a trend for example in terms of development I-deals in order to gain employability. However, "not all that glitters is gold" and the dark side of this individualization needs to be also analyzed. In that, the fairness perceived by co-workers whom don´t get these agreements, or the dignity of workers are key aspects to explore under the new trend of individualized human resources practices as I-deals.

Drawing in different theories –e.g. social exchange theory, social comparison theory, job-demands theory- the literature explains why employees and employers negotiate i-deals and the conditions under which they are effective in achieving a mutually beneficial outcomes. In this symposium we aim to discuss how i-deals contribute to the new work environment exploring the individual level – power and influence in the negotiation process, employees' career development; group level – i-deal effect on coworkers; and organizational level – diversity and dignity.

This symposium is structured in two parts. In a first part the focus will be at organizational level understanding the impact of organizational factors in the initiation and development of I-deals as well as at group level. At the end of this part professor Dr. Euwema and will lead the discussion. In the second part, the focus will be on presenting empirical works analyzing I-deals and its impact on employees, taking into consideration the context in which the organizations are embedded (i.e. Start ups, SMEs) as well as personal factor such as gender or power and influence. At the end of this part professor Medina will lead the discussion.

Relevance to the Congress Theme

Nowadays, managing i-deals at organizations is a key issue for the effectiveness of sustainable human resource practices and talent retention because I-deals aim to meet either organizational and other stakeholders (e.g. employees) needs. This symposium is aligned with the goals proposed by the United Nations for the 2030 agenda. Specifically, we want to contribute to the Sustainable Development Goals: Good health and well-being; Gender equality; Decent and economic work; and Reducing inequalities.

Research/Practical Implications

Theoretical implications at organizationa, group and individual levels are presented. Among the organizational level implications we can highlight the understanding of the human dignity at work in relation to the I-deals phenomenon; or the creation of a scale to measure the “i-deal” climate, incorparting facilitators and barriers for I-deal negotiaions at organizational level. At group level, the theoretical implications of studying the emotions and perceptions of fairness of co-workers, stakeholders of the I-deals however, studies focusing on them are still in an initial phase. And finally at individual level, the impact of the gender in the I-deals negotiation, the relation with well-being and the diverse perspectives about this phenomenon for employees and employers in SMEs and Start up.

Regarding practical implications, the studies presented in this two-parts symposium have a strong applicability in organizations, particularly in SME and start ups. This is due to the trend towards the individualization of human resources to attract, motivate and retain employees. For organizations, I-deals are becoming a relevant tool under the current circunstances and managers as well as employees need to be aware of the diverse factors that can impact a successful negotiation and management of I-deals at the three levels (individual, group and organization).

Overall conclusions

The overall conclusions of this symposium provide insights about the relevance of the role of the organizations in the I-deal negotiation process. This is understood from a theoretical and empirical perspective through the different works presented. In summary, organizations are key actors to promote diversity and dignity for workers in the current context, also when applying the I-deal managerial tool. During the time for discussion in each part, these conclusions will be considered

Paper 1

A Workplace Dignity Perspective on Idiosyncratic Deals at Work

Matthijs Bal, University of Lincoln, UK

Theoretical background

Research on idiosyncratic deals (i-deals) has received increasing attention in the last decade(-s). Many relevant insights have been generated by the rise of empirical and conceptual research on the topic. However, thus far, i-deals have remained conceptualized largely within a neoliberal-capitalist framework, emphasizing the instrumental benefit of i-deals for organizations in terms of employee productivity and retention. Such approach risks the potential value of i-deals to be instrumentalized and exploited for corporate benefit beyond individual concern. The current paper attempts to humanize research on i-deals by arguing the distinct role of the individual human being in negotiation and distribution of i-deals in workplaces. The paper introduces the new paradigm of human dignity to study and understand i-deals better and in new ways. If human dignity is central in the negotiation and distribution of i-deals, the question is no longer about who is best in negotiating i-deals, and how people may compete for i-deal negotiation, but how each human being can be treated with inherent respect and how resources can be distributed in a way that they respect the dignity of workers inside the organization and people beyond the organization (e.g., communities; Bal, 2017; Bal & De Jong, 2017).

New Perspectives/Contributions

This paper argues for a dignity perspective on i-deals. Through a critique of i-deals as being anchored in neoliberal-capitalist ideology, the current study asks whether and how it is possible to move beyond such narrow limitation of restricting i-deals to purely instrumental needs of both workers and organizations. Such perspective neglects the inherent dignity of the worker as a human being, and the workplace as a space not merely existing for profit generation, but also as a space where people connect with each other and find meaning in life. By explicitly integrating human dignity perspectives into i-deals research, new questions and research avenues can be defined in relation to the conceptual development and research on i-deals.

Conclusions – research and or practical implications

The implications of this paper are threefold. First, it introduces a new paradigmatic approach to the study of i-deals through which radically new meanings can be found for i-deals research and practice. Through the introduction of a dignity perspective into the i-deals literature, new meanings can be found for individual deals in organizations. Second, the implications of this research extend beyond i-deals, and pertain to the notion of individualization of work (arrangements). Through integration of a human dignity perspective on individualization at work, new meanings can be found for the role of the individual in the workplace, whereby a dignity perspective takes into account both the need for individuality (and individual expression) of each human being (i.e., to be an individual in the workplace, and treated as such), and the need for belonging, which can be expressed through the relationality of dignity manifestation: it is through the relationships between people that dignity can be articulated, expressed, and respected. Finally, this paper provides implications for practice, as organizations may be guided better in terms of how they can approach the process of individualization of work relationships. While the norm for a long time has been that employees should be treated the same to ensure fairness, a dignity perspective provides an alternative

perspective focused on equality and equity: that is, people should be treated with respect for their human dignity, which takes into consideration the background, personality and individuality of each human being.

Relevance to the Congress Theme

The paper has radical meanings in relation to the theme of the conference: the Future is Now: the paper provides a dignity perspective on WOP concepts, and thereby highlights how the future of the discipline may develop, in line with the respect for the dignity of each human being on this planet.

Relevant UN SDGs

The paper is strongly related to the broad range of SDGs, and in particular the focus on human dignity, which has been the underpinning of the Universal Declaration of Human Rights in 1949. In this sense, the focus on dignity at work underpins the very foundation of the UN, and thereby the SDGs.

Paper 2

Looking for the "I-deal" climate: scale development and validation

INÉS MARTÍNEZ-CORTS, FRANCISCO J. MEDINA & DONATELLA DI MARCO | University of Seville, Spain; PATRICIA ELGOIBAR, University of Barcelona, Spain

Research goals and why the work was worth doing

Recent studies on I-deals development have largely conclude the benefits that this managerial practice has for the employees and the organizations, such as job performance, well-being, and motivation among others. Surprisingly, not many employers and employees utilize them. In that, we wonder how organizations have a supportive or a hindrance role to negotiate I-deals. Investigating organizational factors is important, because by facilitating the negotiation of I-deals, organizations can gain the mutually beneficial effects of I-deals for the employees and for themselves.

Literature emphasizes that the organizational level impacts the way employees feel about negotiating I-deals. As stated by Bal and colleagues (2012, p. 312) "for management practices, such as I-deals, to have an effect, an appropriate organizational climate is necessary". Despite this previous evidence, a scale measuring to what extent organizations are "pro I-deals" or avoid this phenomenon to happen has not yet been developed. In this study we aim to develop and validate a scale that measures the organizational climate in relation to I-deal negotiation, named "I-deal climate".

Theoretical background

We draw on theoretical concepts such as voice, procedural and informational justice, and psychological safety as a framework to provide the basis for the development of the I-deal climate scale.

Design and methodology

We conduct 4 sub-studies. In study 1 we follow a qualitative methodology to identify the most salient constructs to define the organizational climate for initiating I-deals negotiation. For this aim, we interviewed 51 employees and 17 employers in Spain. In study 2, based on findings from study 1, items are developed for measuring the I-deal climate. We conduct a quantitative study to analyze the factor structure of the scale and we check the construct validity analyzing the relationship with other related constructs -e.g. organizational justice, voice climate, psychological safety climate-. In study 3, in a quantitative study we test the scale criterion validity in relation to the type of I-deal. In study 4 we conduct a multi-group validation to analyze if this "I-deal climate" is indeed ideal for everyone or if the organizational variables impact differently by groups (i.e. gender, age, seniority...). Data for all the quantitative studies will be collected through a survey distributed among a sample of employees who had registered at the website Prolific Academic (https://www.prolific.ac).

Results expected

In study 1, through a thematic analysis we identified organizational (e.g. informational and procedural justice), supervisor (e.g. trust, emotional support, negotiation openness) and coworkers (e.g. emotional, instrumental and cognitive support) related factors to be included in the scale. Hindrance organizational (e.g. standardized process), supervisor (lack of ambition) and coworkers

(e.g. envy, task independence) factors were also identified. Results of the planned studies 2, 3 and 4 are expected to be available for its presentation at the conference.

Conclusions

Across four studies, we will develop a reliable scale with a multidimensional factor structure and replicate it across separate samples. Study 1 was aimed at appropriately identify the organizational factors that facilitate or inhibit I-deals negotiation. In Study 2, a measure of I-deal climate is developed and confirmed its reliability and factor structure. Studies 3 and 4 provide further evidence for the psychometric properties of the I-deal climate measure.

Research and practical implications

These four studies contribute to the theory on I-deals by first developing and validating a scale that measures the organizational climate that facilitates I-deal initiation. Although different constructs have been identified in previous studies (justice, voice, etc.) as I-deal negotiation motivators, an "I-deal climate" scale goes a step further by putting together both motivating and hindrance factors and analyzing their interactive effect on the initiation of the I-deal negotiation.

From a practical perspective, this study contributes by providing a tool to measure how organizations facilitate the initiation of I-deals. Given the competitive business context and the difficulties organizations face to retain talent, ensuring that employees perceive their organization is open to the negotiation of I-deals can contribute to positive outcomes for all the parties. Moreover, following Bal (2022), we expect that finding the right climate for I-deals contributes to increasing the dignity of workers by encouraging the initiation of I-deals to everyone.

Relevance to the Congress Theme

This study contribute to develop a new WOP concept such as i-deal climate allowing organizations to evaluate how they facilitate or hindrance i-deals negotiation between all their employees.

Relevant UN SDGs

This work is related to the SDG 3: Good health and well – being; and the SDG 8: Decent work and economic growth

Paper 3

Negotiating idiosyncratic deals to attract, motivate and retain STEM value-added employees from start-ups

IRENE SÁNCHEZ, CLAUDIO CRUZ & PATRICIA ELGOIBAR | University of Barcelona, Spain

Research goals and why the work was worth doing.

Employees individual negotiations about their job conditions are known as idiosyncratic deals (i-deals for short) and are a prominent trend in today's employment that has been accelerated by the COVID-19 pandemic and by a decline of the collective bargaining. Despite the relevance of i-deals and the recent literature on the topic, little is known about how it relates to start-ups. However, start-ups have a decisive impact in the economic and social development of countries by fostering new innovations and rapid job creation. Indeed, on average across OECD countries start-ups with 5 years old or less account for about 20% of employment and create almost half of new jobs. Therefore, employees with valuable work competences are an indisputable source of competitive advantage for start-ups and i-deals could be an essential tool to attract, motivate and retain (AMR) them, reducing turnover and increasing job satisfaction.

Hence the objective of this qualitative study is to understand how the i-deals phenomenon work in the context of health technology start-ups in Spain. Specifically, how heterogeneous i-deals are in time, scope and content, how they relate to higher talent AMR and what are the needs and aspirations of i-dealers particularly in competitive fields such as science, technology, engineering and mathematics (STEM).

Theoretical background

Theoretical concepts of i-deal, social exchange and resource exchange theory are used as a framework to provide a better description of the exchange derived from i-deals negotiations between STEM employees, C-level employers and their start-up.

Design/Methodology/Approach/Intervention

Forty-two semi-structured interviews have been conducted with a STEM employee and a C-level employer from 21 health technology start-ups in Spain. For transcripts coding and analysis Atlas.Ti has been used.

Results obtained

The findings show that in start-ups a range of i-deals are negotiated not only for personal needs but also for organisation needs in terms of funding, resources and tasks evolution. I-deals related to radical changes in tasks, salary or a reduced working hours present great difficulties in their implementation and are perceived as more difficult or not possible to be negotiated. The results support SET and RET proof as a combined explanatory mechanism of i-deals. Given that start-ups limited access to funds and headcounts, there is a tendency to substitute hard concrete i-deals such as salary, radical tasks, or certain forms of schedule flexibility i-deals by soft and symbolic i-deals as phantom shares, developmental and location flexibility i-deals. Those i-deals negotiations are facilitated by the start-up culture of flexibility and open communication and employees' proactive behavior. A successful i-deals negotiations promote a good work environment, helping start-ups to AMR value-added employees and gaining competitive advantage through employee performance.

Limitations

Despite the start-ups sample was diverse with an equal distribution of working technologies, the organizations represented in the study were micro and small enterprises. It is therefore unknown whether these same findings are prevalent in bigger organizations or organizations with different leadership norms and structures, such as family firms or multinationals.

Research/Practical Implications

From a theoretical perspective this study represents a first exploration of i-deals in the innovative context of start-ups. Previous research has mainly focus on big and medium-sized organization or public institutions. Secondly, our research push beyond the dominant perspective of the SET and explores i-deals from a SET and RET. Adding the RET perspective contribute to understanding how start-ups limited resources influence how and which i-deals are negotiated and granted. Thirdly, our findings suggest that existing types of content i-deals need a refinement at least for start-ups. A new category of 'phantom shares' have been defined as financial in-kind contributions. In addition, flexibility i-deals seem to be granted by the nature of the organization, in comparison to previous research.

On a practical level, the research should be useful to support health technology start-ups to promote, individualized working arrangements that can be leveraged to AMR outstanding and highly qualified employees. As i-deals content are occupation specific, it is critical to foster a culture of communication in which in one hand employees feel empowered to express their personal needs button-up and on the other hand, the start-up set up periodic top-down updates to set up expectations for requesting and granting i-deals.

Relevance to the Congress Theme:

I-deals are a key tool in the changing world of work, and particularly for Start ups, a context in which this managerial practice has not been explored yet.

Relevant UN SDGs

This work is related to the SDG 3: Good health and well – being; and the SDG 8: Decent work and economic growth.

Keywords: I-DEAL, START-UPS, NEGOTIATION

Paper 4

I-deals and conflict in start-ups

MARTIN EUWEMA, KU Leuven, Belgium; GOSIA KOZUSZNIK, Ghent University, Belgium

Research goals:

Start-up founders often find themselves in highly challenging conditions. On one hand they are free to define their own job, however they also team up with co-founders, and lead a young and usually turbulent company. This is highly stressful and creates all to often conflicts.

In this study we focus on female founders of start-ups and explore how they work together, also in perceived regulation of their jobs. Particular focus here is on the type of composition for the startup; are women teaming up with friends, family, life partner, or business partner, and does this impact the way they organize their i-deals?

Theoretical background

This research is informed by theories on stress, conflict and role theory, specific work-home balance.

Design/Methodology/Approach/Intervention:

We interviewed 50 female start up founders in the Netherlands.

Results obtained or expected:

We show clear differences between type of i-deals of female founders of start=ups in relation with the type of partners in their business.

Keywords: I-DEALS, INTERPERSONAL CONFLICT, GENDER

Paper 5

How are i-deals negotiated in small and medium enterprises? The perspective of the employer and the employee

SANTIAGO RENEDO, INÉS MARTÍNEZ-CORTS, FRANCISCO J. MEDINA & DONATELLA DI MARCO, University of Seville, Spain

Research goals and why the work was worth doing

Small and medium-sized enterprises (SMEs) represent a significant segment of the economy in many countries (e.g., 99,0% in Spain and 99,7% in Europe). SMEs differ from large companies in that they do not usually have formal HR policies; the owner and the manager overlap; relationships between employers and employees are usually closer and informal; and tasks are more flexible. In this context, employers and employees might have a better understanding of each other's needs, facilitating the negotiation of idiosyncratic deals (i-deals). I-deals are special employment conditions granted to an employee. Success in such negotiations might depend on the ability to exert influence and power, which might be different for women and men. So far, few studies have focused on the negotiation of i-deals in SMEs, taking into account the power and the influence of people involved in the negotiation. Therefore, the goals of this research are to identify what types of i-deals are negotiated in SMEs and to understand power and influence dynamics in negotiating i-deals from a gender perspective.

Theoretical background

Currently, negotiations between employers and employees have become widespread, making i-deals a resource for fostering employee's motivation and attracting and retaining talented employees. So far, theories on i-deals negotiations have focused on individual needs, social comparison and consequences of the negotiation. However, they ignore the role of the relative power of the actors involved, and how it is materialised through the influence tactics (Simosi et al., 2021). The current study tries to understand the i-deals negotiation process applying a theoretical framework based on power and influence theories, such as the approach/inhibition theory of power (Keltner et al., 2003). In addition, gender role theories are used to explain differences between women and men in this process.

Design/Methodology/Approach/Intervention

Semi-structured interviews were conducted with 51 employees and 17 employers in Spanish SMEs from different sectors. Data were analysed with the software ATLAS.ti 8, thematic analysis was carried out.

Results obtained or expected

Three themes were identified: types of ideals, influence tactics and power to negotiate. Results show that task and flexibility i-deals are particularly relevant in SMEs. The results also suggest that SMEs reproduce a traditional Human Resource Management System, where employers initiate the negotiation with empowered employees, assuming that they have sufficient power to negotiate. However, employees need to perceive themselves with sufficient power to initiate the negotiation. Moreover, results show that rational tactics are used to negotiate aspects related to work development; soft tactics are implemented to negotiate aspects connected to employment; and hard

tactics are used for negotiations related to work flexibility. Gender differences in the negotiation process of i-deals in SMEs have been found (e.g., men used more hard tactics than women).

Limitations

Although gender diversity was considered in this research, other groups (e.g., employees close to retirement or employees with disabilities), with special needs, should be included in future research. Furthermore, the study analysed successful negotiations. However, unsuccessful negotiations could be explored to identify which influence tactics were used and what power relations were established at that moment. Finally, given that the study was carried out in Spain, it would be necessary to conduct cross-cultural research to identify specific cultural aspects that may influence the negotiation of i-deals.

Conclusion/research and or practical implications

This study sheds light on the black box of i-deal negotiation in SMEs. This study, through a dual perspective (employee-employer), analyses the process globally, identifying the power and influence tactics used in the negotiation of i-deals by both parts. It also sheds light into the gendered power and influence dynamics in SMEs.

Relevance to the Congress Theme

In this changing world of work, SMEs need committed employees to face the continuous changes arising from the turbulent socio-economic environment. Nevertheless, employees are empowered to proactively manage their own career development. Describing power and influence dynamics will contribute to improve both employers and employees i-deals negotiation skills.

Relevant UN SDGs.

This study is strongly related to the broad range of SDGs, specifically with the promotion of decent work and economic growth (goal 8) and gender equality (goal 5). The negotiation of i-deals implies a win-win solution between employee and employer and helps to achieve full and productive employment and decent work for all women and men (target 5 and 8).

Keywords: I-DEALS, POWER, INFLUENCE

Paper 6

Gender Differences in the Relationship Between I-deals and Eudaimonic Well-being: A cross lagged panel study

NURIA TORDERA, University of Valencia, Spain; ESTHER VILLAJOS, Politecnic University of Valencia, Spain; HILAL KEKLIK, University of Valencia, Spain

Objectives and Theoretical Background

Idiosyncratic deals (i-deals) are defined as voluntary, personalized agreements of a nonstandard nature negotiated between individual employees and their employers. Although i-deals exist in work settings for long, only recently, with growing need for a more active workforce and workers' heightened expectations for a voice on matters affecting them at work, the subject gets considerable attention. I-deals are expected to contribute positively to employees and their organizations, and empirical research has found them to be related to performance and well-being of workers. However, despite the research about hedonic well-being outcomes of ideals, eudaimonic well-being outcomes are less explored. Research has also suggested that personal factors such as gender might moderate i-deals-well-being relationship. Thus, this study explores the effects of ideals on eudaimonic well-being in work settings and the role of gender differences on this interplay between ideals and eudaimonic well-being in the long run.

Method

A cross lagged panel design was used to test the proposed hypothesis. Data were obtained from 275 employees working in 12 different Spanish organizations at two time points. Hypothesis were tested through hierarchical regression analysis using SPSS 24.

Results

We found significant positive relationship between i-deals and eudaimonic well-being in both time points. We could not find support for the crosslaged effects of I-deals (T1) on eudaimonic well-being (T2), once the stability of eudaimonic wellbeing, and the levels of I-deals at T2 were controlled for. However, changes in i-deals from T1 to T2 were positively related to changes in eudaimonic well-being from T1 to T2. We also found support for the moderator role of gender on this relationship. Changes in i-deals showed a higher effect on changes in eudaimonic well-being for men than women.

Conclusions

The study contributes to understand the relationship between idiosyncratic deals and well-being literature by extending this analysis to incorporate the study of eudaimonic well-being and showing evidence of how the changes in the former is related to changes in the later. Providing evidence for this connection has important implications for HR professionals.

Keywords: i-deals, gender, eudaimonic well-being

Symposium S099

Alternative Approaches to Assessing Validity and Effectiveness of Assessments in Use

Rab MacIver, R&D Director @ Saville Assessment

practice

What will be covered and why

The first paper, 'Exploring Operational Validity in Screening through Meta-analysis', explores three approaches to measuring the validity of personality assessment, one of which involves combining differentially-weighted individual scales to create an optimised scoring algorithm. The methods are compared through meta-analyses of local validation studies, with the results providing an insight into how operational validity can be optimised in practice within a job screening context.

The second paper, 'Maximising Validity and Fairness in a New Way of Assessing Potential', outlines the approach taken to develop a new algorithm for identifying future leadership potential. This approach utilised over 15 years of personality and performance data, as well as international fairness data. The result was a measure of potential which cross-validated in three different samples and demonstrated no difference between scores for men and women in two different samples.

The third paper, 'The Validity and Utility of Virtual Candidate Feedback on Personality and Business Reasoning Assessment Results', shares the results of an ongoing research programme to investigate the effectiveness of virtual feedback, straight after and three months after receiving feedback. The research was undertaken following a shift from face-to-face to virtual feedback to understand what impact this may have on candidate reactions to feedback. It was found that despite the virtual format of the feedback, most respondents reported very positive experiences.

Relevance to the Congress Theme

The three papers relate to the theme 'The Future is Now: the changing world of work" as they are focused on how assessment across different applications has adapted based on the changing workplace environment. The first paper explores how the measurement of personality assessment validity has progressed, and continues to evolve based on how assessment measures themselves are evolving in their format and practical implementation to meet the changing needs of recruiters and job applicants. The second responds to the need to move away from traditional ways of identifying high potential individuals, which can lead to inaccurate identification of potential and a leadership pipeline lacking diversity. Finally, the third paper reflects the shift towards delivering assessments and feedback in a virtual way, which was necessitated by the Covid-19 pandemic, but has resulted in a more enduring shift away from the default of in-person interactions.

Research/Practical Implications

The results of paper one provide evidence of how the operational validity of personality assessment varies dependent on how its scoring algorithms are created. This offers value within a screening context in particular, where in practice a single score is created and used for sifting job applicants. Optimising a score used for screening – and as a result maximising the assessment's operational validity – increases how effective it is in identifying individuals that are better suited to performing in a given role.

Paper two outlines the development of a robust predictor of potential based on over 15 years of competency potential and performance data. By building the reduction of adverse impact into the

development of the algorithm, more women will be identified for leadership roles than previously as organisations look to increase the skills and diversity of their leadership teams, and hopefully contribute towards reducing the gender pay gap.

The findings of the third paper endorse the candidate acceptance of the validity and diagnostic value of the assessment as a basis for the accuracy of the feedback experience. A key purpose of providing feedback is in itself to serve as an intervention to prompt development actions, and the current research findings demonstrate that even receiving virtual feedback can still prompt growth and development. Given the ubiquitous virtual context in which most are working, these findings can confirm the validity and utility of assessment feedback practices in a virtual environment.

Overall Conclusions

It is important that the field of psychometrics maintains a balance between remaining grounded in established research and recognising the changing world of work. Adapting to changes within the working world is an important challenge that the authors seek to meet, whether that is establishing new ways of increasing the operational validity of modern, flexible screening assessments, moving beyond traditional ways of identifying leadership potential, or providing effective feedback in a virtual format.

Keywords: Validity, Assessment, Leadership

Paper 1

Exploring Operational Validity in Screening through Meta-analysis

Jake Smith, Senior Research Psychologist @ Saville Assessment; Rab MacIver, R&D Director @ Saville Assessment

Research goals and why the work was worth doing

Accurately measuring the criterion-related validity of multi-scale personality assessments has historically been problematic. An early approach involved calculating a mean average of predictor scales and criteria. This is unrealistic in practice as not every predictor scale would be expected to relate to each and every criterion.

Subsequent research involved the creation of unit-weighted composite scales, combined from individual scales selected based on a priori mapping to different criteria. This more targeted approach yielded improved validities that were arguably more representative of true operational validity.

This thinking can be taken further; another method explored in this paper is the creation of a single differentially-weighted composite scale, with individual scales and weights determined through a combination of job analysis and local validation data, to measure performance in a specific job role. In this paper, this method is compared with the two aforementioned approaches through meta-analyses of local validation studies using hard and soft criteria.

The research goal is to gain a better understanding of the validities produced by these methods. In turn, this understanding may offer insight into how behavioural assessments can be optimally implemented in practice, particularly in a screening context where a single job fit score is typically created for efficient sifting of applicants.

Theoretical background

Early research into the averaging and unit weighting methods of validity measurement was carried out by Schmidt and Hunter (1977) and Robertson & Kinder (1993).

A meta-analysis review into the validity of different assessment methods was conducted by Hunter & Schmidt (1998). This was recently reviewed by Sackett et al. (2021) based on a fundamental concern of overcorrection for restriction of range.

Methodology

18 primary concurrent validation studies were ran for different organisations covering multiple roles. The predictor measure was Match 6.5, a 36 item behavioural assessment measuring 12 section scales, weighted into a composite based on the three methods outlined below. Criteria varied by study, including manager ratings of overall effectiveness, organisational annual performance ratings, and annual sales performance figures.

Criterion-related validity was calculated for each primary study using three methods:

Averaging the validity of the twelve Match 6.5 scales.

Creating a single, unit-weighted composite score from selected individual section scales that are deemed related to job performance in each particular study, based on a combination of their importance to the role (determined by subject matter experts) and individual scale validity.

Creating a single, differentially-weighted composite score. Alongside determining which scales should be included based on role importance and individual validity, weights were also applied based on this information.

Meta-analysis was run for each method using a Hedges-Vevea random-effects model.

Results obtained

Mean effects observed (K=18, N=4121 for each meta-analysis):

Averaging method = .08 (95%-CI [.05, .11], Z=5.01, p<0.01, Q=2.23, p(Q)>0.99, T 2 =0.00)

Unit-weighting method = .33 (95%-CI [.27, .40], Z=9.37, p<0.01, Q=82.78, p(Q)<.01, T 2 =0.02)

Differential-weighting method = .39 (95%-CI [.29, .48], Z=7.30, p<0.01, Q=195.74, p(Q)<0.01, T 2 =0.05)

Increased validity was found for the differential-weighting method (.39). This indicates that applying differential weightings when creating a composite scale can increase its operational validity.

Limitations

Local validation data was used in the differential-weighting method to support the selection of individual scales and weights for each job role. A clear limitation therefore is where validation data is unavailable. The method could still be employed, but based on using scale importance information determined by subject matter experts in isolation. Further investigation of this approach is required to understand any effect on the validity obtained.

Conclusions – research and or practical implications

The results provide evidence that the operational validity estimate of the Match 6.5 behavioural assessment can vary significantly according to the approach taken to how it is measured and how composite scales are created. Increased validity was observed for the differential-weighting method, suggesting this to be an effective approach to creating job fit scores that can be used for screening applicants in practice.

Further research might explore the effect of combining and weighting scores from additional assessments. For example, combining a differentially-weighted composite behavioural scale with a job relevant cognitive test scale or measure of situational judgement. A potential benefit could be gaining incremental validity, and a more rounded view of an individual's potential effectiveness for a specific job role.

Relevance to the Congress Theme

This paper furthers the evolution of validity research on personality/behavioural questionnaires, providing a more realistic picture of the operational validity of a behavioural tool when used in a screening application.

Relevant UN SDGs

This paper is relevant to the goal of 'decent work and economic growth', adding to our understanding of how the validity of behavioural assessments can be optimised in practice.

Assessments with increased validity provide assurance that better suited applicants will be recruited in roles and have more chance of succeeding in an organisation.

Paper 2

Maximising Validity and Fairness in a New Way of Assessing Potential

Lauren Jeffery-Smith, Wave Portfolio Manager @ Saville Assessment; Rab MacIver, R&D Director @ Saville Assessment; Hannah Mullaney, Client Solutions Director @ Saville Assessment

Research goals and why the work was worth doing

To improve the diversity of leadership pipelines for a new world of work, we need to look at how individuals are identified as high potential. Most nominations onto leadership development programs involve the manager, however it is questionable the degree to which they can accurately identify potential. Where there is no structure, rigor or objectivity in a process involving people being assessed, this can lead to bias. Where leaders and managers identify those similar to themselves as high potential, for example, this may not only be inaccurate, but lead to a leadership pipeline lacking diversity.

Theoretical background

Organisations that have the ability to identify potential in individuals will have a competitive advantage (Silzer & Dowell, 2010) and investing in the right people will maximise an organization's profits. Research has also show that across different jobs and industries, high-potential individuals tend to share a range of measurable qualities (Chamorro-Premuzic, Adlet & Kaiser, 2017).

Increasing diversity is not only the right thing to do for DE&I, but will also increase the breadth of capabilities within the leadership pipeline. Research indicates that where there is greater variety of roles or ways of working by individuals in a team, they are likely to be more effective than those with less (Benne & Sheats, 1948; Belbin, 1996; Fisher, Hunter & MacRosson, 2001).

Design/Methodology/Approach/Intervention

An algorithm was developed to identify future leadership potential based on completions of an established and well-validated personality questionnaire. Initial development of this "i-Potential" equation focused on over 7,000 ratings to identify the behaviours in the model which are the best forecasters of potential. The preliminary equation was created based on this validity evidence.

A key development aim for i-Potential was to increase fairness and reduce adverse impact, as well as maximising validity. During the development process, fairness analysis was run and where potential adverse impact was identified, the equation was further refined. Specifically, initial versions of the equation were slightly favoring men, so behaviors which tended to be higher in males were deprioritised and behaviors which tended to be higher in females were brought in or weighted higher. It was initially assumed that this would slightly reduce the validity of the equation (an acceptable trade-off), however the validity did not drop.

Results obtained

Validity:

Our research showed that i-Potential was significantly related to external ratings of the criterion of 'Demonstrating Potential', which was measured using a 360 questionnaire. This is a critical underpinning of predicting potential and provides good evidence for the use of i-Potential to identify

future potential. Replicating this across different samples also demonstrates cross-validation evidence and means that these relationships are able to be generalised.

Concurrent Criterion-Related Validity of i-Potential matched against external ratings of Demonstrating Potential:

Study 1: Research Sample (N=369)

r = .33

r c = .53

Study 2: Operational Sample

Boss (N=1887)

r = .16

r c = .24

Peer (N=1976)

r = .13

r c = .28

Study 3: Standardization Research Sample (N=622)

r = .31

r c = .50

Correlations are statistically significant at the $p<.05$ level (one-tailed).Corrected validities (r c) were corrected for attenuation based on the reliability of the criteria. No further corrections were applied (e.g. restriction of range, predictor unreliability).

Fairness:

The fairness of the algorithm was evaluated using Cohen's d in two large international samples (N=18,154 and N=24,827). For gender, there was no difference between scores for males and females in either group. For age and ethnicity, differences ranged from non-existent to small; no moderate or large differences were found.

Limitations

The i-Potential algorithm has been developed as a 'one size fits all' approach for identifying potential, but this may not always be suitable for more unique organisations. The algorithm provides a robust basis for general identification of potential but it is recognised it may need to be adjusted to fit specific organisational contexts.

Conclusions – research and or practical implications

We have developed a robust predictor of potential based on over 15 years of competency potential and performance data. By building the reduction of adverse impact into the development of the algorithm, more women will be identified for leadership roles than previously as organisations look to increase the skills and diversity of their leadership teams, and hopefully contribute towards reducing the gender pay gap.

Relevance to the Congress Theme

The new algorithm developed based on validity and fairness data responds to the need to move away from traditional ways of identifying high potential individuals, which can lead to inaccurate identification of potential and a leadership pipeline lacking diversity.

Paper 3

The Validity and Utility of Virtual Candidate Feedback on Personality and Business Reasoning Assessment Results

Hennie Kriek, Professor Extraordinarius @ University of South Africa and CEO @ TTS-Top Talent Solutions

Research goals and why the work was worth doing

The rapid shift to virtual working in uncertain economic conditions has exacerbated many challenges in the talent assessment space, with a key question for assessment practitioners being how to still demonstrate the value of assessment practices in a virtual environment. This is firstly to focus on the practical administration of assessment virtually, but a question that is not always addressed, is whether virtual feedback of assessment results still carries the same utility as face-to-face feedback. Addressing one avenue of this question, this paper shares the current results from an ongoing investigation into the experience and impact of virtual feedback practices.

Theoretical background

A key objective of providing assessment feedback is to present candidates with their assessment results and identify likely development areas and associated actions (Meyer, 1998). The provision of feedback alone is insufficient to guarantee candidates will act on their development areas though, as research suggests acceptance of feedback as valid and a truthful representation of the self, is critical for subsequent behavioural changes since candidates are more likely to engage in developmental efforts if they believe it will be worthwhile and accurate (Bell & Arthur, 2008). In this paper, the presenter will share an overview of perspectives on the importance of feedback and challenges experienced with delivering feedback virtually. Second, observations of candidates' experiences of receiving assessment feedback virtually will be shared, followed by a view of candidates' reflections three months after receiving the feedback. Finally, the presenter will share lessons learned from feedback providers and reflect on possible applications for increased validity of feedback acceptance.

Design/Methodology/Approach/Intervention

The research to be shared is part of an ongoing research program carried out by a South African based consulting company. Feedback recipients were invited to complete a short online survey following the completion of their feedback session (at the time of writing, N=1,190), and individuals responding to the survey then received a short follow-up survey three months after their original feedback session to evaluate behavioural changes over time (at the time of writing, N=258). All feedback recipients had received their feedback virtually, using MS Teams or a similar online platform that allows for video and file sharing. Learnings from virtual feedback providers were also collected through an online survey, complemented by anecdotal stories shared with the presenter.

Results Obtained

Despite the shift from face-to-face to virtual feedback sessions necessitated by the COVID-19 pandemic, most respondents reported very positive experiences. For example, 87% of respondents reported gaining new insights into their preferred style of behaving and accepted the accuracy of the feedback, while 94% were confident they would be able to improve in their developmental areas following the feedback. Three months later, 85% of respondents reported making more use of the

strengths identified during the feedback session to solve problems at work, and 92% reported still being motivated to change their behaviour in line with the feedback received.

Limitations

All the results and findings of the current study is based on self-report questionnaires completed by the candidates. It is possible to also involve third party observers in future studies, such as the candidate's direct manager.

Conclusions – research and or practical implications

The results of the current study were gathered from candidates who had undergone online Personality and Ability assessment. We believe these observations, as well as the learnings shared from the virtual feedback providers, are of value for practitioners for two main reasons. Firstly, these findings endorse the candidate acceptance of the validity and diagnostic value of the assessment as a basis for the accuracy of the feedback experience. Secondly, a key purpose of providing feedback is in itself to serve as an intervention to prompt development actions, and the current research findings demonstrate that even receiving virtual feedback can still prompt growth and development. Given the ubiquitous virtual context in which most are working, we believe these findings can confirm the validity and utility of assessment feedback practices in a virtual environment.

Relevance to the Congress Theme and UN SDGs

This paper is in line with the UN ADG of "Good health and wellbeing". This presentation and paper provides practical advice on the effective use of Online Psychometric Assessment results to ensure the personal growth and effectiveness of participants in development interventions.

Keywords: Validity, Assessment, Feedback

Symposium S101

When and why do people craft? Zooming in on predictors and the role of psychological needs

Lina Marie Mülder, Department of Work, Organizational, and Business Psychology, Johannes Gutenberg University Mainz, Germany

science

What will be covered and why:

The three socioeconomic mega trends of rising competition, informatization, and globalization are driving factors in the changing world of work that impact job characteristics. A common characteristic of modern work, facilitated through the COVID-19 pandemic, is the blurring of spatial and temporal boundaries. For example, the significant increases in flexible work arrangements such as working from remote locations (e.g., at home, on the train, in a cafe) and flexible working hours can encourage employees to work at unusual hours in the evenings or during the weekends. These aspects seem not only driven by global, or societal trends, but also by changing needs, values, and preferences of employees. Instead of reacting passively to job characteristics and tasks, employees can proactively increase their job resources and challenging demands (approach crafting) and decrease hindering demands (avoidance crafting). These self-initated behaviors, known as crafting, are shown to be beneficial for employees' health- and well-being. Therefore, it is important to examine drivers of this beneficial behavior. This symposium presents a collection of rigorous research projects that explore personal, job and contextual resources as predictors of crafting behaviors. In a set of four presentations and a discussion by Dr. Jessica de Bloom, we present new insights and explanatory mechanisms of crafting.

Contributing to the potential challenges and opportunities of boundaryless work, the study presented by Ho et al. provides an innovative approach by simultaneously investigating personal resources (e.g., energy levels) and environmental situational factors (e.g., nature exposure and relatedness, location, time of the day) as predictors of daily crafting behaviors of employees using intensive longitudinal data sampling across six days over two weeks. The study sheds light on the dynamic interplay between different life domains as well as personal factors related to crafting behavior, which in turn relates to well-being outcomes (e.g., work engagement and job performance).

Building on the needs-based job crafting model , Tušl et al. explore the role of proactive needs satisfaction in the gain spiral of the job demands-resources model. The study uses a two-wave longitudinal design to examine whether proactive needs satisfaction can build up resources and foster motivation at work. This presentation will thus critically examine the reciprocal relationships between job resources, sense of coherence as a personal resource, needs-based job crafting, and work engagement.

Adding the process of need satisfaction and frustration and relating subjectification opportunities and challenges of work, Bolschakow et al. will focus on the model of proactive motivation . Specifically, the " reason to"-state and basic psychological needs theory (competence, autonomy, and relatedness) are integrated and differential within- and between-person effects on job crafting will be examined. Parts of the Integrative Needs Model of Crafting will be tested using a daily diary study covering two work weeks.

Lopper et al. address the still limited understanding of the interplay of approach and avoidance crafting in interaction with job demands, health, and well-being outcomes. Combining Job-Demand-

Resources Theory and the propositions of the Conservation of Resources Theory regarding gain- and loss-spirals , daily diary data over five consecutive workdays are analyzed to reveal approach crafting causing higher levels of job resources. Further, the role of avoidance crafting as either an adaptive strategy to cope with high demands, or a maladaptive strategy which hampers personal development is investigated.

Relevance to the Congress Theme:

Crafting in different contexts provides opportunities for workers to increase the fit of their needs and job characteristics, which can greatly impact well-being and performance. Job crafting is highly relevant given the progressively increasing boundarylessness and subjectification of work.

Research/Practical Implications:

The insights presented in this symposium contribute to both research and practice. We offer new directions for future research and hands-on strategies to guide healthy and effective job crafting strategies during work and leisure time. A refined understanding of predictors of crafting behavior, underlying mechanisms, as well as relevant boundary conditions, will help practitioners to understand and support crafting.

Overall conclusion:

This symposium addresses important questions about the nature of crafting predictors and need satisfaction using diverse methods and time lags. We bring together four presentations that each provide unique insights on crafting conceptualizations as well as relevant predictors.

Paper 1

Situational and daily crafting patterns across life domains during working days: The role of personal resources and environmental situational factors

Kang Leng Ho & Georg F. Bauer | Division of Public & Organizational Health/ Center of Salutogenesis Epidemiology, Biostatistics, and Prevention Institute University of Zurich, Switzerland; Jessica de Bloom, Department of HRM&OB, Faculty of Economics and Business, University of Groningen, The Netherlands & Faculty of Social Sciences (Psychology), Tampere University, Finland; Philipp Kerksieck, Division of Public & Organizational Health/ Center of Salutogenesis Epidemiology, Biostatistics, and Prevention Institute University of Zurich, Switzerland

Theoretical background, research goals and why the work was worth doing:

Research has often examined crafting behaviors in the work and non-work domain, and at the boundary between the two domains (e.g., Demerouti et al., 2020; Petrou et al., 2012; see Rudolph et al., 2017; Frederick & VanderWeele, 2020). A large and growing body of evidence has consistently shown that crafting in the work and non-work domain positively predicted well-being outcomes (see Wang et al., 2016; Rudolph et al., 2017; Tims et al., 2021). Moreover, a few existing studies on short-term day-to-day crafting behavior in work and non-work domains investigated job as well as home demands and resources as antecedents of crafting (e.g., Demerouti et al., 2020; Petrou et al., 2012). However, little is known about how personal resources (e.g., energy levels) and environmental situational factors (e.g., nature exposure and relatedness, location, time of the day) can influence the daily crafting behaviors of employees in their naturalistic environment across life domains, as well as how these crafting behaviors are associated with well-being outcomes. Additionally, to gain more detailed insights to these dynamic mechanisms among crafting behaviors across life domains, its predictors and outcomes, these variables of interests could also be investigated repeatedly using shorter time intervals with higher frequency.

Using the recently developed needs-based crafting which aimed at satisfying six psychological needs (i.e., detachment, relaxation, autonomy, mastery, meaning, affiliation; DRAMMA) (de Bloom et al., 2020), this ecological momentary assessment (EMA) study therefore repeatedly assessed employees in real time and aims to investigate: (1) how needs-based crafting efforts change throughout working days across these different life domains, (2) how energy levels (i.e., vitality, fatigue) are associated with needs-based crafting and needs satisfaction across life domains throughout the day, (3) how environmental situational factors (e.g., nature exposure and nature relatedness, location, time of the day) influence the effect of energy levels on crafting behaviors, (4) how crafting throughout working days predicts well-being (i.e., work engagement and job performance).

Design/Methodology/Approach/Intervention:

Ecological Momentary Assessments were conducted from May to July 2022 across six working days over two weeks with six measurement points per day of three-hours interval between measurements. 415 German-speaking employees from Germany, Austria and the German-speaking part of Switzerland participated in the survey and responded to 10,922 questionnaires (M = 26.3, SD = 8.62). The survey covers needs-based crafting across life domains (i.e., job, off-job, both job and off-job), needs satisfaction across life domains, energy levels (i.e., vitality, fatigue), positive and negative affect schedule (PANAS), nature exposure and relatedness, location, time of the day, work engagement and job performance over the past three hours. The data will be analyzed with advanced mixed modeling methods for modelling time series intensive longitudinal data.

Results obtained or expected:

Results are not currently available and will be presented at the conference.

Limitations:

The EMA study examined nature exposure and relatedness and emotional states repeatedly across multiple time points and days can result in measurement reactivity (i.e., measures may inform participants of desired behavioural outcomes of the study, leading to more mindful self-monitoring which influences actual behaviors) (French & Sutton, 2010; Shadish et al., 2002). For example, participants are more likely to take walks in the parks when participating in the study than usual.

Participants are not likely to respond on measurement occasions when they are particularly busy, stressed or occupied with the actual crafting behavior, resulting in selective non-response.

Conclusions – research and or practical implications:

The findings will expand knowledge on the dynamic processes of crafting behaviors across life domains during the working day, as well as their associations with personal resources, environmental situational factors and needs satisfaction. We will also gain insights on how these crafting processes will affect well-being over time. In addition, the findings will have practical implications for companies to develop crafting interventions in employees' daily life to improve their well-being.

Relevance to the Congress Theme:

Covid-19 has intensified the blurring boundaries between work and life, and crafting is a worker-driven strategy to better fit employees' personal skills and interests in response to organizational changes, changes in their private lives and the interface of these two domains.

Relevant UN SDGs:

The study would be highly relevant for the UN SDGs: "Good health and wellbeing" and "Decent work and economic growth".

Paper 2

Needs-based job crafting and the gain spiral: Psychological needs as an explanatory mechanism

Martin Tušl & Georg F. Bauer | Public and Organizational Health, Center of Salutogenesis, Epidemiology, Biostatistics and Prevention Institute, University of Zurich, Switzerland; Jessica de Bloom, Department of Psychology, Tampere University, Finland & Faculty of Economics and Business, University of Groningen, The Netherlands

Research goals:

Our study aims to examine whether a needs-based approach to job crafting (de Bloom et al., 2020) could explain the processes in the gain spiral of the job demands-resources model (JD-R; Bakker & Demerouti, 2017). Specifically, we examine the relationships between job resources, sense of coherence (SOC) as a personal resource, needs-based job crafting, and work engagement.

Theoretical background:

The gain spiral in the JD-R model describes how engaged employees can use job crafting to build up their resources and further strengthen their motivation (Bakker & Demerouti, 2017). The assumption of gain spiral implies reciprocal relationships between resources, work engagement, and job crafting. Although, there has been evidence for single paths within the gain spiral, there is still a lack of evidence for the full gain spiral.

A large body of evidence supports the core path of the original JD-R model (Bakker & Demerouti, 2007) from job resources to work engagement (Schaufeli & Taris, 2014). Less attention has been paid to the role of personal resources, but the evidence thus far supports their importance (e.g., Xanthopoulou et al., 2009; Vogt et al., 2016). The role of job crafting in the gain spiral is still somewhat unclear as the evidence on different job crafting strategies and the direction of relationship with resources and work engagement is rather mixed (Mäkikangas, 2018).

Thus, as an alternative approach, we apply the identity-based integrative needs approach to job crafting which sees psychological needs as the drivers and outcomes of job crafting efforts (de Bloom et al., 2020). Our study explores whether such needs-based job crafting could explain the processes in the gain spiral, as proactive needs satisfaction can build up resources and foster motivation. Furthermore, we examine the role of sense of coherence (SOC) as a personal resource in the gain spiral. SOC is the main pillar of the salutogenic model of health (Antonovsky, 1979, 1987) defined as a global orientation to life determining the degree to which life is perceived as comprehensible, manageable, and meaningful. SOC has been positively linked to job resources and work engagement indicating that it is a relevant personal resource in the work environment (Vogt et al., 2015).

Design and Methods:

The study has a two-wave longitudinal panel design with a time interval of six months between the waves. We collected data via an online questionnaire from Swiss and German adult employees in June 2022 and November 2022. The final sample will include approximately 1200 participants who will have completed the survey at both times. Job resources were assessed using an indicator tool developed by the UK Health and Safety Executive (Cousins et al., 2004). SOC was assessed using a German version of the 9-item scale SOC-L9 (Schumacher et al., 2000). Work engagement was assessed with the 9-item version of the Utrecht Work Engagement Scale (Schaufeli et al., 2006). Job crafting was assessed with the 18-item Needs-based job crafting scale (Tušl, Bauer, & de Bloom, in

preparation). Data analysis will be conducted in R 4.0.2 (R Core Team, 2022) using the lavaan package (Rosseel, 2012).

Expected results:

In line with the gain spiral (Bakker & Demerouti, 2017), we expect to find a positive reciprocal relationship between job resources, SOC, job crafting, and work engagement. Results will be available in January 2023.

Limitations:

Main limitation of the study is related to the method of data collection. To obtain a larger longitudinal sample, we collect the data using an online survey and self-reported data may be subject to common method biases (Podsakoff et al., 2003). We addressed this risk by implementing various strategies in the questionnaire such as using disqualifying items to prevent invalid answers. Moreover, we contracted a professional panel data service that guarantees high quality data and we conducted a thorough data cleaning prior to the data analysis.

Research and practical implications:

Our study contributes to the theoretical understanding of the gain spiral in the JD-R model via proactive needs satisfaction at work. In practice, our study will add to the evidence on the benefits of creating a resourceful work environment and strengthening job crafting behaviors among employees.

Relevance to the Congress theme:

The changing world of work brings more flexibility and increases opportunities for individuals to proactively shape their work environment and foster their workplace well-being. Therefore, it is relevant to examine the mechanisms that enable employees to create their own gain spiral.

Relevant UN SDGs:

Good health and well-being, Decent work and economic growth

Keywords: Sense of coherence, Job crafting, Psychological needs

Paper 3

Needs and proactive motivation – drivers of crafting behaviours at work

Xenia Bolschakow & Lina Marie Mülder | Department of Work, Organizational, and Business Psychology, Johannes Gutenberg University Mainz, Germany; Thomas Rigotti, Department of Work, Organizational, and Business Psychology, Johannes Gutenberg University Mainz, Mainz, Germany & Leibniz-Institute for Resilience Research Mainz, Germany; Miriam Arnold, Leibniz-Institute for Resilience Research Mainz, Germany

Research goals:

Proactive behaviour at work, such as job crafting, is of increasing importance in our digitalized and flexible work settings nowadays. Outcomes and consequences of this behavior have been thoroughly studied since the introduction of job crafting two decades ago. However, it is essential to investigate motivational antecedents of crafting, especially because there is a consensus that engagement in such behaviours can also be costly for the individual as it might deplete their energy or meet resistance from others.

The model of proactive motivation posits three pathways: can do , reason to and energized to . Earlier empirical evidence for this model has focused on individual aspects, however, the present study contributes by including the interaction of all three motivational states in predicting actual crafting behaviour on a daily basis. Furthermore, we aim at theoretically and empirically integrating needs as reason-to state in the model of proactive motivation to refine our understanding regarding this motivational state. Furthermore, we examine oppositional assumptions regarding relationships of need satisfaction and need frustration with crafting behaviours.

Theoretical background:

Building on the model of proactive motivation and focusing on the reason to state, the present research integrates this framework with recent approaches to crafting which focus on needs. We hereby draw on basic psychological needs theory, showing that the needs for competence, autonomy and relatedness are universal and satisfaction of these is necessary for optimal functioning. We posit needs to act as reason-to state, constituting “why” individuals craft their jobs or other domains such as home or leisure. Building on the Integrative Needs Model of Crafting, we assume different crafting behaviours to be stimulated by different needs. For example, an individual whose need for relatedness is not fulfilled, will likely engage in crafting towards connection and community with others.

As needs can also be thwarted, need frustration is considered alongside need satisfaction in the present study. According to research building on the Two-Process-Model of Needs, need frustration may be the most motivating aspect of needs, initiating behaviour aimed at reducing this unfulfilling state. As only need frustration represents a state of threat, it should activate energy resources to counteract the need thwarting situation. In contrast, Self-Determination Theory argues that need frustration triggers engagement in compensatory behaviours and the pursuit of need substitutes, which do not help to ultimately satisfy the unfulfilled need. Similarly, Conservation of Resources Theory would also suggest dysfunctional behaviours following need frustration, positing that in such a state, individuals do not have sufficient resources and will therefore behave defensively to protect their remaining resources. Including both need satisfaction as well as need frustration in our study

allows for the empirical test of these two oppositional assumptions regarding the relationships of needs with daily crafting.

Design:

Data was collected using a diary study spanning two work weeks between June and September 2022, sampling employees of a German university. Participants provided information on motivational states (need satisfaction, need frustration, self-efficacy, and vigour) around noon and reported their job crafting behaviours in a second questionnaire after work.

Results obtained or expected:

Data will be analysed using multilevel modelling with interaction analyses. As data collection has just finished, final analyses will be presented at the conference. Preliminary analyses indicate differential relationships of need satisfaction and frustration with job crafting dimensions on the within- and the between-level.

Limitations:

As data was collected in a diary setting, motivational states were assessed using relatively short scales. Furthermore, generalizability of results to other work contexts may be limited as participants were all employees of the same university.

Conclusions:

The present research contributes by theoretically integrating need and proactive motivation frameworks. It will also provide deeper insight into the interplay of need satisfaction, need frustration and other motivational states in predicting daily job crafting behaviours.

Relevance to the Congress Theme:

This research addresses crafting behaviours at work, which are increasingly important in the “changing world of work” we live in. A comprehensive understanding of underlying motivational processes of such crafting behaviours is fundamental to foster and nurture behaviours which are sustainable and enable the well-being of individuals at work.

Relevant UN SDGs:

By shedding light onto antecedents of proactive work behaviour, this research promotes the goals of “Good health and wellbeing” and “Decent work and economic growth”.

Paper 4

Reverse effects within the JDR-model: The role of approach and avoidance crafting

Elisa Lopper & Annekatrin Hoppe| Humboldt University Berlin, Germany; Jenny S. Wesche, Freie Universität Berlin, Germany; Malte Roswag, University Hildesheim, Germany

Goals:

Combining Job Demand-Resources model (JD-R; Demerouti et al., 2001) and Conservation of Resources Theory (COR; Hobfoll, 1989), there is evidence that the often confirmed effects of job resources and job demands on work engagement and exhaustion respectively also occur in reverse. The present study examines underlying mechanism of the reverse effects and proposed that a) approach crafting mediates the link between work engagement and job resources (i.e., job autonomy, empowering leadership) and b) avoidance crafting mediates the link between exhaustion and job demands (i.e., time pressure).

Theoretical background:

Extending the propositions of unidirectional relationships within the JD-R model, recent studies have shown that job resources and job demands not only affect work engagement and exhaustion, respectively, but that reverse effects between these variables prevail. Building on the COR theory which states that employees strive to maintain, protect or enhance their resources at work, employees can be active and change their job resources and job demands depending on their experienced level of work engagement and exhaustion, respectively. Such self-initiated changes are called job crafting. Job crafting includes employee-initiated actions with the intent to expand (i.e., approach crafting) or reduce (i.e., avoidance crafting) aspects of the job.Research suggests that engaged employees are motivated to stay engaged and generate their own resources at work. Approach crafting (e.g., increasing job resources) includes employees' actions to optimize their work environment and create their own job resources. Thus, work engagement can trigger approach crafting which further leads to higher levels of job resources. In contrast, experiencing high levels of exhaustion can signal a possible loss of resources, which – according to COR theory – stimulates employees to conserve their resources. To preserve their resources employees can reduce aspects at work, for instances, by avoidance crafting. Although avoidance crafting is intended to help employees dealing with job demands, it might be rather maladaptive for the following reason: Avoidance crafting requires an investment of resources towards a goal that possibly cannot be achieved as job demands are given and often little changeable in today's work environment. Such a futile investment and loss of resources in turn may lead to higher levels of job demands. Consequently, exhaustion may stimulate avoidance crafting which further results in higher job demands.

Methodology:

Daily diary data were collected over a period of five consecutive workdays. Overall, 171 employees working from home were included in the data analyses.

Results:

Initial multilevel mediation analyses revealed that daily approach crafting mediates the link between daily work engagement and empowering leadership at the end of the working week. This result was

not found for job autonomy. Furthermore, daily avoidance crafting did not mediate the relation between daily exhaustion and time pressure at the end of the working week.

Limitations:

Results should be interpreted and generalized with caution as data were collected under the circumstances of COVID-19 pandemic.

Conclusions:

Results indicated that higher levels of work engagement motivate employees to expand positive aspects of their job (i.e., approach crafting) which can further increase the job resource empowering leadership. Engaged employees are able to craft their job and are, in turn, more often encouraged by leaders to act proactively. Thus, engaged employees can create their own gain spiral of resources through approach crafting. However, it seems that employees with high levels of exhaustion do not use their remaining resources to become active and try to conserve their resources by stepping away from negative aspects at work (i.e., avoidance crafting). Future research is needed to explain the reverse effect of exhaustion on job demands (e.g., Demerouti et al., 2004). For practice, job resources and job demands do not exclusively influence by managers or the organization (top-down) but can also be influenced via job crafting by employees stimulated from their work-related well-being. This can be considered when developing interventions.

Relevance to the Congress Theme:

In a changing world of work, it becomes more important for employees to be proactive and adjust aspects at work by oneself (i.e., job crafting). Also, organizations benefit from employees who craft their job. The study reveals how work-related well-being brings employees to optimize their work environment.

Symposium S102

Psychosocial safety climate: Advances in research and practice (Part one)

May Young Loh & Maureen Dollard | Psychosocial Safety Climate Global Observatory, University of South Australia

science_practice

What will be covered and why

This symposium covers the latest research on psychosocial safety climate (PSC), an emerging construct that has received a vast amount of attention in theoretical, empirical, and practical work. PSC is the corporate climate for workers' psychological health. It is the leading indicator of workplace psychosocial risk factors and employees' work and health outcomes. Therefore, assessing PSC is important for building a psychologically healthy workplace. This is the Part one of a symposium that mainly focusing on the advancement in PSC theoretical propositions. In Part one of this symposium, we start with an introduction using system theory to understand the impact of PSC. This is followed by three presentations expanding the theory of PSC to positive behaviours, psychological needs, and illegitimate tasks.

The first presentation will be presented by Dollard, Loh and de Jonge . This presentation is a study using organisational system theory in exploring the top-down influences and emergent process of PSC, and how it influences leadership, which in turn reduces the likelihood of bullying and harassment. The authors used a multi-source data from Australian public sector organisations. A three-level structural equation model found that (1) senior management espoused PSC was positively related to mid-level supervisors' perceptions of PSC that related to bullying and harassment, and (2) agency PSC as perceived by mid-level supervisors'(only) boosted the effectiveness of their work unit supportive supervision in reducing bullying and harassment.

The second study included in this symposium is a paper by Idris and Idris . Using multilevel, multi-source longitudinal data, the authors studied the mediational pathway of PSC and employees' organisational citizenship behaviours (OCB) through supervisor support. The authors found that supervisors' supportive behaviours mediated the relationship between PSC on employees' OCB.

The third presentation is a study by Shee, Idris and Dormann on the role of PSC on worker well being through psychological needs. Using a two-wave longitudinal study from Malaysian workers, the authors found that within-organisation PSC related to work engagement and emotional exhaustion through increasing needs satisfaction and reducing needs frustration. Between-level PSC was related to collective needs satisfaction and frustration, but the indirect effect was not supported.

The fourth presentation is a study by Dormann and Munz . Using a four-wave diary study sample, they conducted cross-lagged models on the relationship between illegitimate tasks and worries. They analysed if PSC can moderate the reciprocal effects between the two vocal variables. The findings suggested that PSC is an important contextual factor to reduce the negative strain effect of worries on illegitimate tasks. Hence, when there is high PSC, workers who suffer with worries will be less likely to perceive illegitimate tasks.

The practical advancement in the PSC theory will be presented in the part two of this symposium.

Relevance to the Congress Theme

The world of work is changing with an increasing need for more profits and production creating a huge challenge to balance productivity and employees' psychological health. Designing a workplace with less psychosocial threats, using the theory of PSC, is hence important and timely. Our symposium responds to the call of UN SDG in relation to decent work and economic growth.

Research/Practical Implications & Overall conclusions

The symposium affirms the importance of PSC in reducing the prevalence of psychosocial hazards, such as bullying, strengthening individual personal resources, such as recovery experience and needs fulfillment, and improving employees' positive behaviours (i.e., OCB). It also helps to cease the vicious cycle between stressors and strains.

Paper 1

PSC and Leadership in an Organizational Systems Approach to Bullying and Harassment; A Multisource, Multilevel study

Maureen Dollard & May Young Loh | Psychosocial Safety Climate Global Observatory, University of South Australia; Jan de Jonge, Eindhoven University of Technology

Research goals, why the work is worth doing and theoretical background

A multilevel paradigm is required to understand and prevent the devastating effects of workplace bullying and harassment on employee mental health and organizational productivity. Drawing on organizational systems and context theory, we explore top-down functional and structural level processes together. We propose that bullying and harassment experienced by workers is due to: (1) a mediated functional trickle-down process at the agency level whereby senior management set the tone for a specific climate (e.g., the psychosocial safety climate, PSC), and through climate-to-climate transmission and collective social learning shape mid-level supervisors climate aligned actions; and (2) a context cross-level structural moderator effect whereby PSC at the agency level affects mid-level supervisors' supportive leadership behaviors at the work unit level.

Methodology

Our multisource Australian public sector study linked data from hierarchical functional (1372 senior managers, 5341 mid-level supervisors, 22171 workers) and structural (33 public sector agencies, 413 work units) levels. A three-level structural equation model was conducted to test our hypothesis.

Results

We found, (1) senior management espoused PSC was positively related to mid-level supervisors' perceptions of PSC that related to bullying and harassment, and (2) agency PSC as perceived by mid-level supervisors'(only) boosted the effectiveness of their work unit supportive supervision in reducing bullying and harassment.

Limitations

We relied on secondary data which limited our capacity to influence measures (e.g., a single item may confound bullying and harassment). The cross-sectional design limits our capacity to draw causal conclusions.

Conclusion

Using an organizational systems and context framework exemplified in a three-level structural equation model, we provided a rare glimpse for scholarship into the internal multilevel functioning of an organizational system with implications for workplace bullying and harassment.

PSC emanates from the highest levels, and in a top-down power driven collective social learning process, transmits at the agency level from top/senior management to mid-level supervisors to affect average agency worker reports of bullying and harassment. In a downward safety signaling process, agency level PSC as perceived by mid-level supervisors, boosts the negative relation between supportive supervisory behavior and bullying and harassment at the work unit level, strengthening the relation when the climate is right (higher PSC). Despite the propensity for mid-level supervisors to act to prevent bullying and harassment they may lack power to do so when the climate is not

right. PSC as espoused by senior managers is an efficient marker for mid-supervisor PSC and workplace bullying and harassment.

Relevance to the theme and UN SDGs

This study is relevant to the aim of building decent work and economic growth in the changing world of work.

Keywords: psychosocial safety climate; bullying and harassment; organizational climate

Paper 2

The Effects of Psychosocial Safety Climate on Employees' Citizenship Behaviour: The Role of Supervisor Supportive Behaviour as mediator

Idasuzana Idris & Mohd Awang Idris | Dept. Anthropology/Sociology, Faculty of Arts and Social Sciences University of Malaya, Malaysia

Research goals and why the work was worth doing

Psychosocial Safety Climate (PSC) is an organisational climate that can boost job resources, and also functions as a safety signal that provide cues to the middle managers about ways of behaving and action according to the norm set by the upper-level management. While most studies to date have investigated the influence of PSC on several job resources with work engagement as an outcome, it remains unclear how PSC could increase employee-individual organisational citizenship behaviours (OCB-I) through supervisor support. Thus, the aim of the current study is to examine how organisational PSC could increase OCB, via supervisor support.

We postulate several hypotheses:

Hypothesis 1: Psychosocial Safety Climate (PSC) is positively related to Supervisors' Supportive Behaviour;

Hypothesis 2: Supervisors' Supportive Behaviour is positively related to employees' OCB-I; and

Hypothesis 3: Supervisors' Supportive Behaviour mediates the positive relationship between PSC and employees' OCB-I.

Theoretical background

As the espoused-enacted theory posits that the alignment between what has been said and what has been done is essential to ensure the most effective impact of an espoused theory. We hypothesised that PSC is important and useful in encouraging more positive organisational behaviours as a result of reciprocity. In which employees engage in positive behaviours when they perceived that their working environment is treating them in a good way. But this effect will be exemplified when the supervisor enacted the espoused climate through, they daily practices.

Methodology

Using Cole and Maxwell (2007)'s recommendation, we used a three-wave longitudinal design with 4-month time intervals among private sector participants in Malaysia. We randomly selected 200 organisations from a list of registered companies. An online questionnaire was provided to the selected organisations via email. A total of 192 organisations were willing to participate. Out of 690 participants from 192 organisations who had been approached, only 538 participants from 70 organisations remain in all three waves of data collection.

Results

Due to the nature of multilevel data, we used M Plus software to test all hypotheses. In general, as expected, we found that PSC Time 1 is positively related to Supervisors' Supportive Behaviour Time 2. We also found that PSC Time 1 predicted OCB-I Time 3. We also found support for our hypothesis that Supervisors' Supportive Behaviour Time 2 mediated the relationship between PSC Time 1 and OCB-I Time 3.

Limitations

Our study has some limitations. First, we only tested a causality effect from PSC to OCB-I but did not investigate the reverse or reciprocal effect that might occur. It is possible that higher OCB-I will increase PSC in organisations. Second, while using longitudinal design may reduce some issues associated with common method variance, the self-rated questionnaires in the current study might lead to bias.

Conclusion

Theoretically, our study adds new knowledge on the role of PSC in improving employees' OCB, particularly through supervisor support. Practically, our study suggests that training and coaching should be provided to improve PSC in organisations, which in turn influences supervisor support and employees' OCB-I. Ameliorating PSC and supportive managerial practices would improve OCB-I which benefits others within organisations. In conclusion, we found that PSC plays a pivotal role in increasing OCB-I, mainly via Supportive Supervisors' Behaviour which reinforced the importance espoused PSC on enacted supportive supervisors' behaviour. The expectation of top management (espoused theories) on work-related performance by supervisors' support is salient only if there is an alignment between what is being suggested (strategies and plans) and what is being acted (Settoon & Mossholder, 2002).

Paper 3

Does Psychosocial Safety Climate Predicts Basic Psychological Needs at Work? A Longitudinal Multilevel Mediation Analysis

Pay Yee Shee, Faculty of Arts and Social Sciences, University of Malaya; Christian Dormann, Johannes Gutenberg-University Mainz, Germany; Mohd Awang Idris, Faculty of Arts and Social Sciences, University of Malaya

Research goals and why the work was worth doing

Since the introduction of psychosocial safety climate (PSC) in 2010, it has been supported empirically as one of the precursors to job characteristics, specifically, the role of PSC in delineating job demands and increasing job resources. By using job-demand resource (JD-R) model as a guiding framework, PSC indirectly facilitates positive work outcomes and improves employee psychological wellbeing. However, the vast majority of PSC studies have used job characteristics model, it remains unclear how PSC influence employees' psychological needs at work. This is important as researchers have regularly hypothesized and consistently found that satisfaction of basic psychological needs is essential for optimal functioning and psychological wellbeing in a variety of settings, including workplace (e.g., Deci, Olafsen & Ryan, 2017; Van den Broeck, Ferris, Chang, & Rosen, 2016). Despite the theoretical and empirical attention paid to the role of PSC in workplace psychological health, past research barely explores how PSC relates to psychological need supporting/thwarting in creating a flourishing workplace.

Theoretical background

In the context of the current study, by integrating self-determination theory into PSC theory, our aim is to explore the effects of PSC on employee outcome (i.e., work engagement) and wellbeing (i.e., emotional exhaustion) via satisfaction/frustration of the employees' basic psychological needs (i.e., competence, autonomy, and relatedness). We predicted PSC to be positively related to work engagement and negatively related to emotional exhaustion and these relations would be mediated through need satisfaction/frustration.

Methodology and results

Data were collected using two-wave longitudinal design (with a time gap of 4 months) from 857 employees among 49 organizations within the industry of community and social services in Malaysia. All hypotheses were tested using Multilevel Structural Equation Modelling (MSEM) in Mplus 8.3. To test the hypotheses longitudinally, we used independent variable (i.e., PSC) as measured at T1, mediators (i.e., need satisfaction/frustration) and outcome variables (i.e., work engagement, emotional exhaustion) as measured at T2 (i.e., T1 → T2 → T2[MD1]). We further controlled for the baseline (T1) of the mediator and outcome measure. At the individual level, there were significant effects of within-organization PSC perceptions on competence need satisfaction, competence need frustration, autonomy need satisfaction, autonomy need frustration, relatedness need satisfaction, and relatedness need frustration. The indirect effects of within-organization PSC → competence need satisfaction → work engagement, within-organization PSC → autonomy need satisfaction → work engagement / emotional exhaustion, and within-organization PSC → autonomy need frustration → emotional exhaustion were significant. On the between level, PSC was significantly related to group means of competence need satisfaction, competence need frustration, autonomy

need frustration, and relatedness need frustration. The between-cluster indirect effects of the variables were not supported. [MD2]

Limitations

One possible limitation of the current research is the “half-longitudinal” design in which the mediators and outcome variables are measured at the same time point. As such, the final pathways in our model (need satisfaction/frustration T2 → work engagement/emotional exhaustion T2) were cross-sectional. Further studies involving three (or more) time points (i.e., T1→T2→T3) would permit the examination of a more accurate longitudinal mediational process.

Conclusion

Overall, we found that, PSC does not only precede working conditions as often discussed in the literature, but also manifested as an intrinsic form of motivation, satisfying the basic psychological needs of the employees. [MD3]

Paper 4

Longitudinal moderation effects of PSC on reciprocal relations between illegitimate tasks and worrying

Dormann Christian & Julia Munz | Johannes Gutenberg-University Mainz, Germany

Research goals and why the work was worth doing:

The effect of stressors on strains has been studied many times. Interestingly, a longitudinal meta-analysis found that the reverse 'strain effect' of burnout on stressors is twice as large as the 'stressor effect' of stressors on burnout (Guthier et al., 2020). Thus far, reciprocal relations between stressors and strain have almost never been studied in diary studies. In particular, this applies to illegitimate tasks. Further, PSC as a potential and simultaneous moderator of both stressor effects and of strain effects was not yet investigated. Since such moderator effects are important as they could mitigate the vicious circle of stressors and strains, our study fills in this gap. In particular, we investigate PSC as a moderator of stressor effects and strain effects among illegitimate tasks and worries.

Theoretical background:

Illegitimate tasks are perceived as unnecessary or unreasonable (Semmer et al., 2010). Illegitimate tasks can threaten one's identity (Semmer et al., 2015). According to the Stress-as-Offense-to-Self (SOS) framework, illegitimate tasks as a stressor result from a task associated with a negative social message that can result in a threat to the positive self-image (Semmer et al., 2015). Any kind of threat (e.g., social, emotional, physical) causes stress reactions such as worries. However, work-related worries may also increase perceptions of illegitimate tasks. I Therefore, we expect that both illegitimate tasks increase worries and worries increases illegitimate tasks. Since perceptions of illegitimate tasks is dependent on the context, we assume that the reciprocal effects will differ depending on the level of psychosocial safety climate (PSC). For example, in a high PSC environment where employees' psychological health is protected, people may be more likely to focus on positive aspects of stress. Thus, a reducing moderation effect of PSC can be assumed.

Design/Methodology:

Data were collected online, with 492 nurses registered to participate. Of these, 354 nurses participated at Time 1 (T1) and provided information on sociodemographic data (301 of them participated at T2, 230 at T3, and 192 at T4, which means a response rate of 54.2%). Of all participants, 79.5% were female. Mean age was 39.9 (SD = 11.7) years. On average, they worked 30.3 (SD = 9.4) hours per week and had a tenure of 14.7 (SD = 10.9) years. Most of them worked in shifts (81.0%), and 42.2% had managerial responsibility. The Bern Illegitimate Tasks Scale (Semmer et al., 2010) were used to measure supervisor-related and colleague-related assignments of illegitimate tasks. Work-related worries were assessed by means of a scale by Pereira et al. (2013). Data were analyzed with moderated structural equation modeling using random intercept cross-lagged models (RI-CLPM), which eliminate trait variance and yield within person effects.

Results

In line with Guthier et al, we found the strain effect of worries on illegitimate tasks assigned by colleagues was stronger than the reversed stressor effects of illegitimate tasks on worries. This applied to both CLPM and RI-CLPM. Similarly, in both types of models, PSC T1 significantly reduced the strain effect on illegitimate tasks assigned by coworkers. Thus, in PSC environments, people

suffering from worries are less likely to perceive illegitimate tasks assigned by colleagues compared to low PSC environments. For illegitimate tasks assigned by supervisors, no effect was found in RI-CLPM.

Limitation & Conclusions:

The results confirm the meta-analytical established effect of strain on stressors. Strain effects should therefore be considered in theoretical models and future studies to better understand how they emerge. Further, PSC moderates the strain effect on illegitimate tasks assigned by colleagues. There is a need to better understand how exactly this moderating effect emerges, and future studies should investigate this effect in more detail.

Keywords: psychosocial safety climate, reciprocal relationship, illegitimate task

Symposium S103

Psychosocial safety climate: Advances in research and practice (Part two)

May Young Loh & Maureen Dollard | Psychosocial Safety Climate Global Observatory, University of South Australia

science_practice

In this symposium, we present recent research in relation to psychosocial safety climate (PSC) in workplaces, its influence beyond the work domain and its cost effectiveness across multiple cultural backgrounds and occupations. This symposium is the Part Two of a PSC symposium. Part one of this symposium has focused on some recent theoretical advancement. This part of the symposium includes studies in relation to PSC and organisational effectiveness in terms of workplace absenteeism, presenteeism, and turnover. We also expand PSC literature to different cultures by validating the PSC scale in a different language (i.e., Italian). Lastly, we provide some real case examples of how to build and improve PSC in organisations and its economic benefits.

The first presentation is by Mansour and colleagues on a study about the effect of PSC on workplace presenteeism during the pandemic. The authors conducted a two-wave longitudinal study among Canadian nurses. Using a moderated mediation model, the authors found that PSC reduced nurses' presenteeism through reducing work intensification. In addition, PSC was a moderator that reduce the negative effect of work intensification on presenteeism.

The second contribution of this symposium is by Fattori and colleagues who conducted a validation study on the Italian version of PSC-4 scale. Using cross-sectional data from Italian healthcare workers, the authors validated their PSC-4 tool and found that PSC related to job demands and job resources. They suggest that PSC should be used as a focus of an occupational health intervention in the Italian context.

The third presentation is a longitudinal study by Johari and Idris . The authors conducted a two-wave longitudinal study among Malaysian academics. They assessed the role of PSC and influences at work on the moderating effect of psychological detachment on the relationship between cognitive demands and emotional exhaustion. The findings revealed that PSC was a moderator of moderators providing resources to compensate for low detachment to reduce the impact of cognitive demands on emotional exhaustion.

The final presentation is by Loh and Dollard on two intervention case studies aimed to improve organisational PSC through an organisational participatory intervention. The authors conducted a follow-up assessment in two organisations on the level of PSC pre- and post- intervention. In addition, the authors estimated the cost of human capital and productivity loss that is averted using the level of PSC and sickness absence and turnover suggesting that medium sized organisations can save an estimated AU$ 1-4 million dollars by improving PSC.

Relevance to the Congress Theme

The world of work is changing with an increasing demand for more profits and production creating a huge challenge to balance employees' psychological health with productivity imperatives . Designing a workplace with less psychosocial threats, using the theory of PSC, is hence important and timely. Our symposium responds to the call of UN SDG in relation to decent work and economic growth.

Research/Practical Implications & Overall conclusions

The symposium affirms the importance of PSC in improving organisational effectiveness and productivity. In addition it shows how PSC could benefit employees beyond their working lives. More importantly, the symposium provides practical insights and guidelines about how to improve PSC and the benefits gained through cost reduction associated with reduced sickness absence and turnover. Building PSC is important.

Paper 1

How Psychosocial Safety Climate Helped Alleviate Work Intensification Effects on Presenteeism during the COVID-19 Crisis? A Moderated Mediation Model

Maureen Dollard, Psychosocial Safety Climate Global Observatory, University of South Australia;
Sari Mansour, TÉLUQ University of Quebec, Montreal, Canada

Research goals and why the work was worth doing

Healthcare sector organizations have long been facing the issue of productivity loss due to presenteeism which is affected by psychosocial safety climate (PSC) and work intensification. Presenteeism has visibly increased among nurses during COVID-19 pandemic period. Presenteeism can be defined as employees' attendance behavior at workplace, when they don't exhibit adequate performance due to physical and/or psychological (i.e., cognitive, or emotional) problems or due to being ill. Presenteeism intensifies in a situation where pressures to remain working during illness persist for a longer period such as during pandemics of COVID-19. It is composed of two dimensions, that is, work completion (i.e., work outcome) and 'avoiding distraction' (i.e., work process). Researchers advance that employees continue working even when they are sick to balance health constraints and performance demands. Management of presenteeism is considered a long-term investment for both individuals' and organizational wellbeing and PSC could be an effective tool to do this.

Theoretical background

Grounded in the conversation of resources (COR) theory and sensemaking theory, the current study aimed to examine the role PSC plays as driver or moderator to reduce presenteeism by lessening work intensification over time and the impact of work intensification over time on presenteeism during the COVID-19 pandemic.

Methodology and results

Adopting a time-lagged research design, this study gathered data from randomly selected registered nurses, practicing in Québec, Canada in two phases, i.e., 800 at Time 1 (between October and November 2020) and 344 at Time 2 (between June and July 2021) through email surveys. The first lockdown in Quebec-Canada was on 15 March 2020). The study results showed that (1) PSC reduces presenteeism over time by reducing work intensification at time 1; (2) PSC moderates the relationship between work intensification at Time 1 and work intensification at Time 2; and (3) PSC as moderator also lessens the detrimental effect of work intensification at Time 2 on presenteeism at Time 2.

Limitations/Conclusions

Presenteeism among nurses affects their health and psychological well-being. We find that PSC is likely an effective organizational tool particularly in crises situations, by providing an organizational mechanism to assist nurses cope (through a resource caravan and management support) with managing intensified work. Although in general we might think that the level of presenteeism could have been decreased because healthcare workers were not allowed to go to work, this does not apply to our study conducted in the province of Quebec in Canada where the severe shortage of medical professionals has pushed the government and employers to allow those with COVID-19 but without symptoms to go to work. This is also less the case because our measure of presenteeism

excluded covid-symptoms and focused only on physical and/or psychological symptoms. This is plausible for the ongoing work intensification from T1 to T2 and due to the uncertainty and enhanced pressure on nurses during COVID-19, nurses are forced to expand their energies (i.e., additional resource investment) to manage the extensive workloads. Indeed, when nurses perceive a high workload, they may be afraid about the growth of COVID-19 which would intensify their workload in the future, leading them to continue working while being sick, especially with the shortages in healthcare organizations.

Paper 2

Psychosocial safety climate (PSC) at middle management level in the healthcare sector: A contribution to the Italian validation of PSC-4

Maureen Dollard, Psychosocial Safety Climate Global Observatory, University of South Australia;
Alice Fattori, IRCCS Maggiore Policlinico Hospital, Ca 'Granda Foundation, Milan, Italy

Research goals and why the work was worth doing

Psychosocial safety climate (PSC) refers to workers' shared perceptions of organizational policies, practices and procedures for the protection of psychological health and safety. PSC offers a multilevel organizational approach that expands traditional models of workplace stress, giving a more comprehensive understanding of occupational health and safety issues. Although considerable research on psychosocial risks in the healthcare sector has been conducted, few studies have explored the role of PSC among healthcare workers at middle management level. Additionally, no validated version of PSC is available in Italian language.

Theoretical background

The aim of this study is to contribute to the validation of the Italian 4-item version of the PSC and to explore this theory within the Job Demands-Resources model (JD-R) among a sample of Italian healthcare workers by testing PSC at the middle management level.

Methodology and results

We used cross-sectional data from 276 employees working in 17 different wards in a large Italian hospital. Intra-class coefficient (ICC) coefficient and agreement index were used to test PSC as a climate construct (data nested to hospital ward level). We performed hierarchical linear models to test mediation and moderation effects. The Italian version of PSC-4 proved to have good psychometric properties and confirmed its role as a group-level construct. Multilevel random coefficient models showed PSC was associated with Job Demands and Job Resources. Results confirmed the indirect effect of PSC on Psychological (Burnout) and Occupational Health (Job Satisfaction) outcomes supporting the role of Job Resources and Job Demands as mediators. The multilevel analysis did not find a significant interaction terms between PSC and Job Demands on Burnout therefore the moderation hypothesis was not supported.

Limitations/Conclusions

The Italian version of PSC-4 is a valid tool to evaluate PSC. These findings sustain the multilevel framework of PSC and the significant role played by mid-leaders in both the health impairment and motivational path. Further studies should explore the buffering effect of PSC at higher baseline levels as well as the adoption of PSC as a target for occupational health intervention the Italian context.

Paper 3

Translating PSC research into practice: PSC intervention case studies and cost analysis

May Young Loh & Maureen Dollard | Psychosocial Safety Climate Global Observatory, University of South Australia

Research goals and why the work was worth doing

Work-related stress has enormous consequences for organisational productivity, absenteeism, performance and employee turnover. Considering this tense situation, all stakeholders should reduce psychological threats and promote decent work at workplaces globally (World Economic Forum, 2022). Scholars have increasingly directed attention towards improving employee well-being through organisational interventions. Studies have suggested that interventions that target the sources of work stress (i.e., job design and organisational system, such as Psychosocial Safety Climate [PSC]) should achieve an optimal effect. Psychosocial Safety Climate (PSC) is an organisational climate focusing on workers' psychological health. Previous research has consistently supported that PSC is a leading indicator of job design, such as job demands, job resources, and psychological health outcomes. Although PSC intervention research has gradually received attention in the field, this intervention research is often short-lived, and problems likely arise after researchers have left the participatory organisation. Therefore, we argued that one way to create sustainable change in an organisation is to build an intervention around the existing policies and day-to-day practices. In this presentation, we provide two examples of how organisations could incorporate intervention in their mainstream policies and psychosocial safety management system.

Theoretical background

In alignment with the proposition that PSC is the 'cause of causes' of employees' psychological health and safety (Dollard & Bakker, 2010), PSC is considered a lead indicator of several psychosocial factors, such as job autonomy, supervisor support, and rewards. In addition, PSC is also important for worker motivation and productivity. It is thus useful in the risk management process. Several studies suggest that PSC should be the main target of an organisational intervention to manage work stress and well-being, especially in turbulent times (Biron et al., 2018; Dollard & Bailey, 2021). Since PSC is a 'cause of the causes', we propose that improving the psychological health of workers should focus on PSC. We hypothesised that PSC would be improved by the actions taken to improve management priority, commitment, communication and participation.

Intervention

Two intervention case studies were included in this presentation. Following best practice principles in work stress intervention, two organisations conducted a risk assessment, created action plans, involved their stakeholders' participation and underwent follow-up assessment. We measured whether PSC changed over time and documented the activities and programs conducted in the organisations as evidence of an intervention and as examples for future interventions. The level of PSC in the organisations was collected through online surveys pre-and post-intervention. Intervention activities focused on the four main elements of PSC principles through different activities and programs such as leadership workshops, programs to reduce stigma on work stress, recruitment of employee representatives, and psychoeducation on coping skills. We also conducted a cost analysis on sickness absence and turnover due to low PSC and estimated how much an organisation could save when they improve their PSC.

Results

We found that interventions that focus on the four PSC elements improved the PSC level over time in Case study 1 and sustained the PSC level in Case study 2. An economic analysis of sickness absence and turnover attributed to low PSC also informs the importance of building PSC in workplaces to enhance organisational productivity and save organisations significant amounts of preventable cost. From the cost analysis, we found that organisations can save nearly one million per year for productivity lost due to sickness absence and over 4 million per year due to the cost of turnover if they could improve their organisation PSC.

Limitations

The case studies were not designed with the suggested gold standard of the randomised controlled trials (RCTs; Tetrick & Winslow, 2015) but focused on a field setting. No overall evaluation of the intervention components impact was conducted. The intervention conducted in the selected period was vast, and it is difficult to control specific intervention that most effectively boosts PSC over time.

Relevance to congress theme and UN SDGs

This study has provided some examples of how to promote decent work and economic growth (UN SDG) in this new changing world of work that contains increasing psychosocial risks.

Keywords: psychosocial safety climate, intervention, cost analysis

Paper 4

Psychosocial safety climate as a moderator of moderators of the relationship between cognitive demands and psychological detachment on emotional exhau

Farah Shazlin Johari & Mohd Awang Idris | Department Anthropology and Sociology, Faculty of Arts and Social Sciences, University of Malaya, Kuala Lumpur, Malaysia

Abstract

Research goals and why the study was worth doing: Psychological detachment is recognised as an important recovery mechanism for mitigating the effect of job demands on employees' exhaustion. While vast research so far has supported the notion that individuals suffering from high job demands are looking for recovery, it is less clear how different job resources (e.g., psychosocial safety climate) would increase the effectiveness of recovery. Thus, the main aim of the current study is to investigate how psychosocial safety climate (PSC), as an important organisational resources, strengthen the effect of detachment and indirectly mitigate the association between job demands and emotional exhaustion.

Theoretical background: The conservation of resources (COR) theory is used to depict the role of resources in facing enormous job demands and improving psychological health. If some resources are threatened in an adverse work environment, employees may strive to restore resources through detachment during non-work hours. In alignment to COR theory, PSC can be portrayed as a resource caravan passageway for the protection and acquisition of other resources. PSC also helps buffer the detrimental effect of demands while simultaneously creating a spectrum of resources for employees.

Design/Methodology/Approach: We conducted our research among academics at Malaysian public universities. Data were collected from academics over a four-month period using a multilevel longitudinal design (two-wave survey, at Time 1 , n=248 ; at Time 2, n=125). At Time 2, 125 academics (50% response rate) completed an anonymous web-based survey. All study variables were collected at both Time 1 and Time 2. Research hypotheses were tested using quantitative analyses via Hierarchical Linear Modelling (HLM) software.

Result obtained or expected: Psychological detachment did not act as a mediator, causing PSC to be unable to moderate the mediated relationships between job demands and emotional exhaustion via detachment. However, the study found that detachment acts as a moderator between job demands (emotional and cognitive demands) and emotional exhaustion. The three-way interaction of PSC, psychological detachment, and physical demands [PSC*PD*PH] revealed that PSC could moderate detachment in the stressor-detachment relationships. It demonstrates that PSC was a moderator of moderators providing resources to compensate for low detachment to reduce the negative effect of physical demands on emotional exhaustion.

Limitations: First, we only used a self-rated questionnaire. As a result of the common-method bias, the relationship between variables may be inflated. By employing a multilevel longitudinal design, our method may help in the elimination of common method biases (Cole & Maxwell, 2009). Second, we only used two-waves, indicating half-longitudinal data. Third, we used only two-dimension of PSC scale (management support and commitment; and management priority) to represent PSC as a multilevel construct. Finally, the study's sample was primarily academics, which may limit its generalisability to other professions. Future research should consider using a multisource design with

multiple waves data to reveal the causal association between organisational resources and psychological health across different professions.

Conclusions: Given the importance of PSC as a moderator of moderators in stressor-strain relationships, it helps to mitigate the negative impact of cognitive demands on employees' emotional exhaustion. It offers empirically supported insights into PSC's role as a resource passageway in this model's supplementing range of resources. The findings can be used to create resources in organisational interventions to reduce the impact of employees' job demands and foster ability to detach from work. This may decrease employees' stress and help to maintain their psychological health and well-being.

Relevance to Congress Theme: Employees in contemporary's workplace experience greater demands and work under stressful conditions. Many researchers attempted to discover better ways to reduce stressor-strain reactions and promote better well-being. By prioritizing organisational resources such as PSC, it is possible to protect employees' psychological health at work. Indeed, PSC allows employers to provide more resources to their employees, such as improving psychological detachment during off-job recovery, resulting in decreased psychological strains. Detaching from work has significantly reduced the cost of mental and physical energy depletion.

Relevant UN SDGs: The working world is regarded as a critical source of work stress experiences, causing more employees to suffer from detrimental events. It has prompted many researchers to investigate stressor-strain issues in the modern workplace. The study contributes to the third Sustainable Development Goals in ensuring healthy lives and promotes well-being.

Symposium S104

Examining the work-nonwork interface from special perspectives

Anna M. Stertz, RWTH Aachen University, Germany

science

What will be covered and why: The work-nonwork interface has been recognized as an import research area within work and organizational psychology for several decades. The importance of understanding how individuals experience and manage the interplay of work and nonwork is illustrated by the steadily increasing number of studies in this area. However, despite the considerable advances that have broadened our understanding of many important facets of the work–nonwork interface, specific life phases and situations in which working people find themselves during their careers have not been considered sufficiently in research so far. This symposium brings together four empirical studies that draw attention on specific groups of people and the work–nonwork interface in their lives.

The first study focuses on single childless employees, a group that has received relatively little attention in research on the work–nonwork interface due to their less obvious family obligations. The authors examine the impact of perceptions of singles-friendly work culture on singles' job performance and well-being and the mediating role of recovery experiences and work-life balance. The next study also focuses on singles, but single mothers and fathers, and examines how single parents are perceived regarding job and parental competence (among others) depending on their working status and the reason for this status. In the following article, attention is given to working mothers in a special phase, namely when returning to work after the birth of their children. The authors investigate (missing) job flexibility and workload as predictors of mothers' intent to leave the organization or the workforce in the early family phase and the mediating role of job strain. In the final study, the focus remains on working parents, but on those who face the challenge of having children with disabilities. This study examines the predictive value of individual/family and work-organizational factors for work-family facilitation in this specific group of working parents.

Relevance to the Congress Theme: Employees with different and special life situations play an important role in the changing world of work, and as diversity increases, so does the diversity of employees' private situations. Accordingly, it is crucial to keep this in mind when investigating the interface of work and nonwork.

Research/Practical Implications: Understanding the dynamics between work and nonwork in employees' lives is important for scholars and practitioners. Promoting practices and work situations that help workers in their specific situations, contribute to their well-being, performance, and retention is a crucial endeavor. The studies presented in the symposium help to increase our knowledge of the organizational influences that are worth addressing in this regard.

Overall Conclusion: Being in a special situation or phase is sometimes voluntary, sometimes involuntary. Sometimes it is rather a phase that is undergone as a normative developmental task, such as the re-entry to the labor market of women after the birth of their children. Sometimes, however, employees have to deal with situations that are not normative and desired, like having a disabled child. Employees, including their specific private situations, are an essential part of our world of work. This should not be neglected and the studies of this symposium contribute to ensuring that it is not done. At the same time, the studies contribute to a more comprehensive understanding of the interface between work and nonwork.

Paper 1

Single-friendly work cultures, job performance and well-being of single employees: The mediating role of recovery experiences and work-life balance

Kathrine Marie Jørgensen, Aarhus University, Denmark; Maja Fartek, Spyrosoft Solutions, Croatia; Carolina Garraio, University of Porto, Portugal; Audrey Ansay Antonio, University of Bologna, Italy; Ana Šimunić, University of Zadar, Croatia

The impact of a singles-friendly work culture (SFWC) on organizational commitment and well-being may be explained by levels of work-life balance of single individuals, that implies a combination of work and life in a pursuable manner (Akanji et al., 2015). Employees with higher levels of work-life balance were shown to have better health indicators and higher levels of well-being (Zheng et al., 2015). Another intervening factor of the impact of SFWC on well-being may be recovery experiences (psychological detachment from work, relaxation, control, and mastery in free time), which have been linked to higher well-being and job performance (Sonnentag et al., 2017). The (in)voluntariness of singlehood needs to also be considered, since stereotypes may be founded according to more positive evaluations of marital status choices that reflect the ideology of marriage and family (Morris & Osburn, 2016).

The aim of this research was to investigate perceptions of a SFWC as a predictor of recovery experiences, work-life balance, well-being, job performance, and affective organizational commitment. Job performance and organizational commitment were assumed to be correlated. A SFWC was expected to be associated with higher recovery experiences, which would determine perceptions of higher work-life balance and well-being, and subsequently higher job performance and affective organizational commitment. Thus, recovery experience, work-life balance, and well-being are viewed as mediators in the relationship between SFWC and organizational outcomes. As for the relationships between the mediators, it was assumed that recovery experiences would predict the perceived level of work-life balance, and that both variables would predict one's well-being. The model of these relationships was tested both for a group of 513 involuntary and of 209 voluntary single individuals, expecting lower relationships between variables in voluntary singles. The study was conducted during the EFPSA 2020 Research programme by a team of researchers from Italy, Denmark, Portugal, and Croatia, during the COVID-19 pandemic. Thus, an online questionnaire was conducted on employed childless singles from these four countries.

Structural equation modelling was conducted, and the results showed a better fit of a partial mediation model in comparison to excluding direct links between a SFWC and the dependent variables. The model explained 47% of well-being in involuntary and 35% in voluntary singles, 15% of affective organizational commitment in both groups, and 47% of job performance in involuntary and 54% in voluntary singles. When considering predictors of well-being , in both groups it was directly positively predicted by recovery experiences and work-life balance and indirectly predicted by a SFWC through greater recovery experiences and work-life balance. In involuntary singles it was also predicted indirectly by a SFWC solely through greater recovery experiences and directly by a SFWC. Affective organizational commitment was directly positively predicted by a SFWC in both groups. In involuntary singles, it was positively indirectly predicted by a SFWC through all the examined mediators, that is, well-being, both recovery experiences and well-being, recovery experiences and

work-life balance, and recovery experiences, work-life balance, and well-being. In voluntary singles, the same positive indirect prediction of affective organizational commitment including all examined mediators and recovery experiences (probably due to relaxation) and work-life balance was obtained. Well-being did not show a significant mediating role when its prediction by work-life balance was not included, and the indirect relationship of affective organizational commitment and a SFWC was negative when mediated only by recovery experiences (likely due to psychological detachment and mastery experiences). Namely, perceptions of a SFWC were related to greater recovery experiences, recovery experiences were negatively related to affective organizational commitment in voluntary singles. Job performance was positively directly predicted by work-life balance and a SFWC in both groups, and by well-being and recovery experiences in involuntary singles. All the specified indirect relationships of job performance and a SFWC through recovery experiences, work-life balance, and well-being were significant. In voluntary singles, the only significant indirect prediction of job performance by a SFWC was through greater recovery experiences and work-life balance.

The limitations of the study are related to the subjectivity of self-assessments and impossibility of drawing conclusions about cause-and-effect relationships. The research results imply that the practices of promoting a SFWC and work-life balance in organizations (and the society) may increase workforce morale and well-being, which in turn, minimizes negative job-related outcomes such as turnover intentions and absenteeism. Considering the changing demographics of the future workforce and the increasing presence of single employees in the world of work, the results bring awareness to different reasons of singlehood and imply more sensitivity and respect towards employees' private life and activities in the workplace.

Paper 2

Leaving the organization or quitting the workforce? A longitudinal study on working mothers' turnover intentions in the early family phase

Anna M. Stertz, Bettina S. Wiese, Aida Alisic & Lena Müller-Frommeyer| RWTH Aachen University, Germany

Aim: Most women become mothers during their careers. In industrialized countries, the transition to motherhood is usually accompanied by a transition out of and back into the labor market. After having returned to work, a major challenge for mothers is meeting the dual-demands of family and work. Although the interplay of work and family is firmly anchored in organizational research, the early family life phase has received little attention. And, most importantly, work-specific influences on mothers' turnover intentions have been mostly neglected so far (Paustian-Underdahl et al., 2019). We address these aspects in our study and focus on job characteristics that might contribute to mothers' sustainable transition back to work. In particular, we investigate (a) how job time flexibility and workload affect withdrawal intentions in mothers who have recently returned to work and (b) whether job strain explains these relationships.

Theoretical Background: Based on the integration of the unfolding model of voluntary employee turnover (Lee & Mitchell, 1994) and the job demands-resources model (Bakker & Demerouti, 2007), we investigate the influence of job characteristics and subjective strain experiences on postpartum mothers' turnover intentions. We selected two job characteristics that are applicable across different fields of occupations, namely, workload as a stressor and time flexibility as a resource. Building on the stressor-strain perspective, we propose that job stressors indirectly influence the development of turnover intentions via job strain (e.g., Podsakoff et al., 2007), while job resources prevent from enduring strain experiences, thereby decreasing the likelihood of turnover intentions to occur. Regarding turnover, we differentiate between intentions to leave the organization and the workforce, that is, two forms of turnover intentions with different consequences for working mothers, employers, and the labor market.

Methodology: We analyzed longitudinal data from N = 159 working mothers (Mean age: 32.5, SD = 3.8) surveyed 12 and 24 months after childbirth. Factor analyses demonstrated the intent to leave a) the employing organization and b) the workforce to be two distinct forms of turnover intentions.

We found a direct link between time flexibility and intentions to leave the workforce with a lack of time flexibility leading to higher intentions to leave the workforce. Job strain fully mediated the influence of workload and time flexibility on both the intent to change the employer and to leave the workforce. The effects of time flexibility via strain on both types of turnover intentions were positive, indicating a decrease in turnover intentions, whereas the effects of workload via strain on turnover intentions were negative, indicating an increase in turnover intentions.

Limitations: Most participating mothers worked part-time. Compared to full-time working counterparts, they might be less inclined to (further) reduce working hours to decrease their workload and instead consider leaving the workforce.

Conclusions: We encourage future research to distinguish more strongly between different forms of turnover intentions and to study their antecedents in more depth. According to our results, job characteristics that include both a high workload and limited time flexibility lead to job strain among working mothers during their return to work, which, in turn, causes intentions to leave the

organization or even the workforce. Moreover, it seems that high workload only strengthens mothers' turnover intentions in the case that this demand causes subjective strain. A lack of time flexibility, in contrast, also has an immediate impact on mothers' intentions to leave the workforce. Overall, the results suggest that time flexibility is an important resource for work-life balance in the early family phase and that there is no hope for more flexibility even with other employers, at least from the women's perspective. Instead, we assume that experiencing a strenuous lack of time flexibility fuels the impression that leaving the workforce is the best way to meet family demands in the future.

Relevance to the Congress Theme: In the changing world of work, successfully returning to work will continue to be a challenge for postpartum mothers, and is also important for organizations and the society. Our study offers explanations why mothers who initially chose to pursue their careers, upon their return, start to consider turnover. We offer advice how to prevent these withdrawal tendencies.

Paper 3

Predictors of work-family facilitation in parents of children with disabilities living in Croatia

Ana Šimunić, University of Zadar, Croatia; Lisa Stewart, California State University Monterey Bay, USA; Theresa Brown, Georgian Court University, USA; Marija Ljubičić, Andrea Tokić, Jelena Ombla, Matilda Nikolić Ivanišević & Ana Slišković | University of Zadar, Croatia

The topic of integrating work and family roles has been researched to a lesser extent on the population of parents of children with disabilities, although it was shown that this group of employees experiences higher levels of conflict between work and family roles in both directions (negative spillover of work demands into the family domain and family demands into the work domain) compared to employees who have typical family obligations (e.g. Stewart, 2013). Brown and Clark (2017) reviewed 54 scientific papers that dealt with the balance of work and family roles of working parents of children with disabilities up to 18 years of age and pointed out numerous individual/family and work-organizational factors that can explain the (im)balance. However, the authors themselves warn about the lack of serious quantitative research in the area. Also, there is a lack of research on the positive aspects of work-family integration, that is, how being employed facilitates family life and vice versa. Additionally, the original papers in this review come from countries with very heterogeneous organizational policies aimed at balancing work and family roles, so national research on this topic is necessary. Thus, the aim of this research was to examine the predictive value of several individual/family and work-organizational factors in explaining work-to-family (WFF) and family-to-work facilitation (FWF) in working parents of children with disabilities up to 18 years of age in the Croatian context.

A total of 572 working parents (90.4% female and 9.6% male between 23 and 66 years of age) filled out an online set of self-assessment questionnaires. The set of predictors considered for each dependent variable were: 1) gender, age, level of education, size of place of residence; 2) personal protective factors (optimism, self-efficacy, posttraumatic growth - personal strength and appreciation for life); 3) emotional regulation strategies; 4) family and personal life characteristics (satisfaction with family financial status, number of children, age of oldest child, number of children with disabilities, level of disability, parental stress, social support in the family, and managing leisure time - enjoying and relaxing during free time); 5) work-organizational characteristics (satisfaction with personal income, working full time or not, in shifts or not, private or public sector, management position, work-time flexibility and predictability, work control, psychological work demands, and social support at work); 6) the importance of self-realization through professional life. The examined predictors were selected based on a previous qualitative study on parents of children with developmental disabilities in the Republic of Croatia.

Two hierarchical regression analyses were conducted. All the sets of predictors significantly explained the variance of the dependent variables, except work characteristics and importance of professional life realization for FWF. In the final step, WFF (37.4% of variance) was predicted by greater self-efficacy, a higher tendency towards positive reassessment, managing leisure time, working in shifts, having higher control and social support at work, and greater professional life importance. FWF (48.7% of variance) was predicted by a greater tendency towards planning, greater personal strength and life appreciation, greater number of children, lower parental stress, and more social support in the family domain. Additional analyses showed that WFF and FWF were positively correlated with assessments of mental health and satisfaction with life.

The main limitations of the study include assessment subjectivity and impossibility of making causal inferences. Also, we were not able to collect a representative sample of the given population of parents and to include enough varieties (e.g., men). The research results imply that there are certain specificities in the integration of work and family roles in employees with children with disabilities that should be considered and further studied. Accordingly, findings of such studies should be integrated into practices of promoting these employees' work-life balance and well-being, which is beneficial for the organization, family, and society in a whole.

Keywords: Children with disabilities, Work-family facilitation, Importance of professional life

Symposium S105

Faking in assessments of personality and competencies: Current advances in prevention and correction methods

Gerianne de Klerk - van Someren, YSC Consulting

science_practice

Test users in organizations have long been concerned by the use of self-reported measures for assessing personality, competencies and similar constructs because these measures are open to response distortions. Of a particular concern are motivated distortions occurring whenever the assessments have important consequences for the test takers. In organisational selection contexts, candidates may be motivated to manipulate responses to create the best impression (aka 'fake good'). Such impression management behaviours (IMBs) can range from exaggeration of positive characteristics and downplaying the negative ones to outright faking (Robie et al, 2007). Considerable evidence has accumulated that IMBs are widespread (König et al, 2011) and cause sizeable distortions to test score distributions (Birkeland et al, 2006), construct validity (Schmit & Ryan, 1993), and validity of selection decisions (Rosse et al, 1998).

To overcome IMB-related distortions, we can either prevent such distortions from occurring in the first place or correct them (statistically) after they have occurred.

To prevent respondents from endorsing all desirable traits or behaviours, comparative response formats have been proposed. These include the popular 'forced choice', where two or more items are presented simultaneously, and the respondent must rank the items with respect to how well they describe them. The extent to which items are preferred to each other can also be collected, for example by asking respondents to distribute a fixed number of points between items ('proportion-of-total' format). Preferences collected with such formats are relative within the person, leading to major psychometric challenges – interpersonally incomparable (ipsative) data. Thurstonian IRT models (Brown, 2016; Brown & Maydeu-Olivares, 2011, 2018) have been developed to enable proper (normative) scaling of data collected with comparative response formats. Ipsative data can also be derived from normative ratings, by subtracting the person's average from each rating (process called 'ipsatization') thus eliminating the effects of uniform over-reporting on desirable items.

In terms of statistical correction , many interesting methods have been proposed recently ranging from overclaiming techniques (Bensch et al, 2019) to more sophisticated latent variable models (Brown & Böckenholt, 2022; e.g. Falk & Cai, 2016). One interesting approach is trifactor-mixture modelling that captures the latent score shift due to the change of assessment stakes, while accounting for response biases and effects of repeated item exposure (Guenole et al, 2022).

This symposium will provide an overview of current research on the faking prevention and correction methods, all applied to assessments in organisational contexts.

Fuechtenhans will present an experimental study investigating the influence of forced-choice block designs on the nature of response behaviour, focusing on deliberate manipulations of responses leading to increased response times and increased number of response changes.

Guenole and Brown will present a novel trifactor-mixture modelling approach to analysis of normative data collected repeatedly in low and high stakes, applied to assessment of maladaptive traits in the workplace.

Chandrasekaran, Brown & De Klerk - van Someren will present a project developing a leadership assessment tool that aimed to capture a leader's strengths and development areas using a novel graded preference response format to prevent impression management.

Kurz will report the results of a project developing a set of matched constructs from the predictor and criterion domains and comparing criterion-related validities of these constructs measured using normative and ipsatized scores.

Relevance to the Congress Theme

With the advent of technology, assessments in the workplace become cheaper and easier to conduct in practice, leading to the ever-increasing exposure of job applicants and incumbents to such assessments. As the test takers become savvier, the potential for motivated response distortions increases and it becomes more important to monitor and counteract such distortions.

Research/Practical Implications

Research presented in this symposium aims to identify questionnaire designs that elicit the least response manipulation and propose measurement models to quantify the extent of faking and its effect on the true scores.

Overall conclusions

It is possible to reduce the effects of faking on assessments of personality, competencies, and similar constructs by either using prevention or statistical correction methods. In terms of prevention, comparative response formats can be used successfully. In terms of statistical correction, score ipsatization or the use of latent trait models capturing the true score shift in a controlled fashion can also be applied. In these pursuits, it remains essential to retain focus on demonstrating the validity of tools and their underpinning frameworks.

Keywords: Faking, response behaviour, personality

Paper 1

An experimental study investigating the influence of forced-choice block designs on the nature of response behaviour

Miriam Fuechtenhans (M.Fuechtenhans@kent.ac.uk), University of Kent, UK

Background. Faking on personality assessments remains an unsolved issue, raising major concerns regarding their validity and fairness (Kuncel, Goldberg, & Kiger, 2011). To date, scholars have developed numerous faking models focused primarily on either the antecedents of faking or its consequences (Ziegler, MacCann, & Roberts, 2011). Although this research has provided insightful results, it reveals little about the actual faking behavior. Yet, it could be argued that only when we understand the cognitive processes and subsequent response decisions, can we begin to extract valid and useful information from assessments.

In this pursuit, Holtgraves (2004) investigated response mechanism in which social desirability responding might operate. He argued that social desirability responding and instructed faking might follow different cognitive processes because under faking good instruction test takers respond much faster than participants instructed to respond honestly. Subsequently, he hypothesised that if social desirability responding operates as an editing process that occurs after recalling the true response, then it should result in slower response times; and if it prevents people from retrieving their true response then it should result in faster response times. Across three experiments, Holtgraves instructed participants to respond to a set of items (either traits or behaviours) under instructions that either decreased or increased the concern with social desirability, whilst measuring response latencies. The results across all three studies suggested that social desirability operates as a response editing mechanism, increasing response latency every time the participants were concerned whether they appeared desirable.

However, the research by Holtgraves (2004) investigated the rating scale (RS) format, which is particularly susceptible to faking because respondents can easily endorse categories that they perceive to be most desirable (Wetzel, Böhnke, & Brown, 2016). To prevent respondents from endorsing all desirable options, the forced-choice (FC) format has been introduced (e.g., Dilchert & Ones, 2011). In the forced-choice format test takers are presented with two or more items simultaneously and are asked to rank order them. Research has indicated that the MFC format can reduce faking substantially (Salgado, Anderson, Neil, & Tauriz, 2015); however, its effectiveness depends on how well the items within blocks are matched on their desirability (Wetzel, Frick, & Brown, 2021; Cao & Drasgow, 2019).

Objectives. The aim of this study was to investigate how social desirability responding operates in forced-choice questionnaires. To this end, we are set to replicate Holtgraves' study but utilising behavioural items presented in FC pairs rather than individually. We are interested to see whether social desirability operates as a response editing mechanism (or alternatively, prevents retrieval of true answer) when participants are presented with FC pairs that differ in terms of their desirability matching. Uncovering this mechanism would inform development of FC questionnaires that are robust to social desirability responding.

Method. This study will employ a mixed design in which we manipulate desirability concern between participants, forming the conditions of high and low desirability concern. Furthermore, we will manipulate block type within participants, forming 3 levels of mixed versus matched desirable and matched undesirable pairs of everyday behaviours. Under laboratory conditions N=150 participants will be randomly assigned to one of the two conditions and instructed to choose the behaviour that describes them best. On a computer screen, all participants will be presented with all block types in a randomised order. We will record participants choices as well as response times for each pair.

Expected Findings. We expect responses to be slower in the high social desirability concern condition, as test-takers are motivated to edit their true answers that appear undesirable. Additionally, we expect participants to be faster when answering blocks with items of mixed desirability compared to blocks with items that are matched on their desirability. This is because identifying the desirable option should be easier on mixed blocks. On matched blocks, it might be faster to make a choice when all alternatives are desirable rather than undesirable because in the latter case, all choices are incongruent with the goal of presenting self in a positive light, thus eliciting higher concern with social desirability and engaging more editing of one's true responses.

Implications for Practice. This research will provide the evidence base needed for creating FC personality questionnaires that are robust to social desirability responding, through utilizing FC blocks that elicit the least social desirability concern. This is particularly important for high-stakes assessments in organisations, where the motivation and the potential for impression management and faking behaviour are high.

Paper 2

The Trifactor Change Model: Instructed Faking on a Maladaptive Trait Measure

Nigel Guenole & Anna Brown

Theoretical background. Work-related personality traits are commonly assessed with standardized self-report questionnaires using rating scales. Many concerns have been raised about invariant functioning of such questionnaires in different assessment contexts, necessitating the development of methods to evaluate change in the level and structure of measured traits. However, the assessment of change is complicated by several factors. First is whether the participants interpret questions similarly across contexts. Researchers have identified different forms of change such as alpha, beta, and gamma change (Golembiewski, Billingsley, and Yeager 1976), which may violate measurement invariance. A second challenge in assessing change is response biases. Biases might operate uniformly across items, such as acquiescence, or non-uniformly, such as socially desirable responding. Measurement biases detrimentally affect conclusions of measurement invariance tests (Liu et al. 2017).

To address these issues, Guenole, Brown and Lim (2022) introduced a trifactor change model to measure change on a trait assessment in an instructed faking design. The model simultaneously assesses change over time on substantive constructs, ensures items measure equivalently across occasions, accounts for dependencies due to repeated exposure, and accounts for common method biases. The model extends the work of Bauer et al. (2013), which integrates the ratings of multiple raters by modelling a common factor, rater perspective factors, and item specific factors. Guenole et al.'s model takes advantage of repeated-measures experimental designs to enable separate identification of substantive factors modelled across occasions (with a mean structure to capture level of change), condition specific common method factors, and item-specific unique factors that are stable across occasions. A mixture component accommodates subpopulations with different response processes – for example, those who did not follow experimental instructions.

Research objectives. Guenole et al. applied this model to data from 516 participants taking part in an instructed faking design to examine the functioning of dedicated social desirability scales in such conditions. The participants answered the Balanced Inventory of Desirable Responding (Paulhus 1984) measuring self-deceptive enhancement and impression management. Model fit was acceptable and model parameters were readily interpretable, suggesting the model is effective at separating sources of variance. However, this study was specific to dedicated social desirability scales, and more work, both empirical and simulation based, is needed to see whether the model can be used to understand the functioning of trait assessments when social desirability concerns are high, for example in high-stakes selection situations. We will present the analysis of an inventory assessing work related maladaptive traits using the trifactor change approach.

Methodology. We analysed responses of 516 participants to the Goldsmiths-60 (G-60-SS) questionnaire (Guenole, Brown, & Cooper, 2016), a six dimension, 60 item inventory assessing work related maladaptive traits based on the DSM-5 Section III trait model. The G-60-SS uses a 5-point Likert-type scale ranging from "strongly disagree" to "strongly agree" to measure six scales - antagonism, compulsivity, detachment, disinhibition, negative affect, and psychoticism. The respondents took the G-60-ss twice, under "honest" instruction, and under instruction to respond as though they were applying for a job they really wanted ("instructed faking").

Results. The trifactor model has many constraints to implement, so we fitted the model iteratively, building up to six factors, with all but one of the 60 items successfully included in the model. The fit for the model with invariance constraints imposed was as follows: $\chi 2 = 12304.25$, df = 6541, RMSEA = .04, CFI=.81, TLI =.80, SRMR = .07. The RMSEA and SRMR meet common thresholds for adequate fit, while CFI and TLI reflect what is well known about these indices, i.e., higher values are rarely

observed with so many factors and items. While more analysis is needed to investigate any areas of non-invariance, we can use these preliminary results to interpret the change on the maladaptive scales. The analysis revealed changes on all scales in socially desirable directions under the "instructed faking" condition, meaning substantial decreases in neuroticism, disinhibition, antagonism, detachment, eccentricity, and an increase in compulsivity.

Preliminary Conclusions and Further Research. Based on these preliminary results, the trifactor model appears to capture the change due to instructed faking, while accounting for response biases and effects of repeated item exposure. The data analysis is ongoing, and we will shortly implement detailed measurement invariance checks as well as the mixture component to fully account for all sources of variance in the data. In the talk, we will report results of these full analyses, and provide conclusions on viability of the trifactor approach to make sense of assessment data collected in high stakes, with implications for assessment of maladaptive traits in the workplace.

Paper 3

The development of a comprehensive leadership assessment using a novel response format to reduce faking

Lakshmi Chandrasekaran; Anna Brown & Gerianne De Klerk

Introduction

After decades of research into leadership and personality, organizations today are moving away from generic models of personality when it comes to assessing leadership-related traits, and developing assessments that are directly applicable to leaders. This often leads to adopting a criterion-centric approach (Bartram, 2005). This first specifies leadership performance criteria and then develops tools to predict them. The criterion-centric approach is better suited to leadership assessment in practice, where it is important to inform practical decisions about leadership development, assessing potential, and evaluation of performance (Baker, Scott, Nye, & Chernyshenko, 2022). However, any self-report questionnaires are susceptible to impression management by respondents, which is particularly relevant to leadership selection contexts. Therefore, a leadership assessment needs to be robust to reduce impression management by candidates (aka 'faking'). In response to this need, the Leadership Styles Questionnaire (LSQ) assessment was developed.

Research Objectives

The aim of the project was three-fold. Firstly, to develop a comprehensive leadership model that is originated in the criterion domain but formulated using the language of personality. Secondly, to develop an assessment that is able to reliably capture and describe a leader's strengths and development areas. Thirdly, to reduce the extent of impression management and faking of responses by introducing a novel response format using comparative judgements instead of normative ratings.

Methodology

Text mining software was used to identify consequential leadership attributes during the developmental stage. Firstly, qualitative data from over 1000 client developmental reports from the sponsoring organization were used as a foundation for identifying distinct behaviours such as "seeks to build relationships" or "wants to change things". A range of the most frequently quoted phrases were collated for item development. Subsequently, the universal Competency Framework (Bartram, 2005), and personality measures such as OPQ32 (SHL, 2006), and HEXACO (Ashton & Lee, 2009) were used to inspect conceptual mapping and coverage.

Using the conceptual mapping, an initial 27 scales of the leadership assessment were created. Over 500 items were developed and trialled through two field trials. Two trials were conducted to estimate the item parameters, this included trialling items on full-time employees with leadership responsibilities. 277 participants were initially tested with 358 items in total, using a 7-point Likert scale ('Rating scale trial'). This was followed by testing 422 participants using the 7-point-total format, with 264 items in total ('Graded preference trial').

The final questionnaire utilized the graded preference format, it consisted of 88 blocks with 264 items and 24 scales. Each block comprised of 3 items that were matched based on their means and factor loadings. The best combination included having all 3 items with similar means and different factor loadings (i.e., two items with high positive factor loadings and 1 item with either a weaker loading or negative loading).

To overcome distortions due to impression management, we utilized a novel response format whereby respondents have to distribute a fixed number of points (7 in total) between three items. Respondents have to indicate how each of the three items compare in how they describe their behavioural preferences. This format is comparative in nature, but unlike the popular "forced choice" where respondents make binary choices between statements (for example, choose A over B, or choose B over C), here they can quantify their preferences by assigning more or less points to particular statements. Response process research showed that the 7-point-total format elicits

“graded preferences” in respondents; thus, when deciding how many points to assign, respondents compare alternatives in terms like “A is a little more like me than B”, or “B is much more like me than C” and assign points accordingly. This type of data can be analysed and scored with the Thurstonian IRT model for graded comparisons, which enables proper scaling of psychological attributes to allow inter-individual comparisons (Brown & Maydeu-Olivares, 2018).

Results

The graded preference model fitted to the 7-point-total data provided item factor loadings, residual variances, and correlations in the expected range and consistent with the Rating scale trial. However, the graded preferences yielded close-to-normal score distributions and a well-defined factor structure, unlike the rating scale responses, which showed highly skewed distribution and excessively high scale intercorrelations evident of impression management distortions. An estimate of internal consistency was derived by applying the empirical reliability index approach. Reliabilities of the scales ranged from 0.71 to 0.89. Additional analysis was conducted to determine external validity by testing for convergent and discriminant validity against HEXACO (Ashton & Lee, 2009). Correlational analysis demonstrated promising evidence for both convergent and discriminant validity.

Conclusions

To make leadership assessments more accessible, interpretable, and relevant to decision-makers, the Leadership Styles Questionnaire (LSQ) was developed that measures 24 scales. The novel response format captured more nuanced information than forced-choice formats. Unlike the normative rating scales, graded preferences do not allow indiscriminately giving high ratings to all desirable statements, thus reducing the effects of impression management.

Limitations

More data is needed to collect insights on performance and other criterion-related outcomes i.e., motivation, ability, inclusive leadership, and team potential. This will provide the ability to extend research into the measurement model, its functions, and psychometric properties.

Paper 4

Normative and Ipsatised Measurement of the Great Eight Factors

Rainer Kurz, Chief Psychologist, HUCAMA Analytics Ltd

Research goals and why the work was worth doing

The Great Eight factors were developed by Kurz & Bartram (2002) to account for historical personality and ability assessment validation result patterns with competency criterion areas.
Bartram (2005) presented a meta-analysis where the average observed validity of Great 8 personality predictors with reviewer ratings across Great 8 factors was .17. Bartram (2007) on a sub-set of studies with normative and ipsative line manager criterion data found that correlations averaged .146 and .219 respectively.
Bartram (1996) investigated the properties of ipsatised scales where response style (the mean across all normative ratings) is removed from scale scores.
The present study compares the validities of newly developed normative and ipsatised predictor as well as criterion measures of the Great 8 factors.
The following research goals were set to explore the nature of the new measures of the Great Eight:

1. Understand how normative and ipsatised measures interrelate within a predictor instrument.
2. Understand how normative and ipsatised measures interrelate within a criterion instrument.
3. Investigate the validities of normative and ipsatised predictor as well as criterion measures of the Great 8 factors.

Theoretical background

While the Great Eight Competencies were developed to link established personality and criterion variables in the present study predictor and criterion measures are developed from scratch.
The value of normative and ipsative assessments has been widely debated in the literature but largely excluded the notion of ipsatisation as outlined by Bartram (1996) which is applied in the present study at item rather than scale-level.

Methodology

Great Eight criterion measures with three items were created by splitting each factor into two aspects. One item was composed of the shortened factor title in bold followed by the two aspects e.g.:
Effective at Analysing - Solving Problems; Evaluating Information.
Each Aspect item featured the title in bold followed by three sub-ordinated competencies e.g.:
Effective at Solving Problems - Investigating Problems; Resolving Complexities; Applying Specialist Expertise
Items were rated on a 9-point accuracy scale adapted from Goldberg's (1992) Trait Descriptive Adjectives (TDA) measure
On the predictor side 48 facets were developed grouped into 8 factors. For each Aspect the facet most closely associated with Great 8 and Big 5 personality constructs was used to create a predictor measure for each factor.

Results obtained

Construct Validity

An average correlation of .80 (N=466) was observed between the normative and ipsatised Great 8 scores on the predictor measure and an average of .75 for the criterion measure.

Criterion-related Validity

The mean observed validity between the matched predictors and criteria was .55 when both measures were normative and .44 when both measures were ipsative. Correlations dropped considerably to around .35 for mixtures of normative and ipsatised measures.
The correlation of the sum of normative predictor and criterion measures was .72. The sum of ipsatised measures is a constant precluding the calculation of correlations.
The results are in line with Bartram (2007) where all results were based on an ipsative predictor measure and validity was higher for ipsative criterion ratings. However, the validities of the normative

predictor-criterion pairs in this study exceed those of the other matched pair as they benefit from shared method variance on both sides.

Limitations
This research used a preliminary criterion model so that further research is needed with the final version. The study relies on self-report data so that future research should replicate this with external ratings.

Conclusions – research and or practical implications
The results support the construct validity of the new Great 8 factors.
The results confirm the superiority of normative scales in assessment. Ipsatised scales show a considerable level of validity that could be harnessed as supplementary scores, especially as ‘Fit’ scores based on job information.

Relevance to the Congress Theme
As the world of assessment evolves and technology-based assessments become ever more widely available it is important to clarify the constructs underpinning potential and performance, and the effects of response format on measurement. It remains essential to retain focus on demonstrating the validity of tools and their underpinning frameworks.

Relevant UN SDGs
This paper is relevant to ‘decent work and economic growth’, with a focus on developing valid assessment tools that match the right people into the right roles.

Symposium S106

Silence and Voice in Context(s) - Understanding when and why people express and withhold critical issues at work

Michael Knoll, University of Leipzig, Germany; Sarah Brooks, Sheffield University Management School, UK

science_practice

The symposium provides a forum for international researchers and practitioners to exchange and advance knowledge and experiences aiming at a contextualized understanding of employee silence and voice. Whether employees express (i.e., voice) or withhold (i.e., silence) their ideas, questions, opinions, and concerns at work affects individual and collective learning and well-being (Bashshur & Oc, 2010; Morrison & Milliken, 2000). Employee voice is a precondition for employees to realize their full potential, and it is essential for the functioning of current management strategies (e.g., total quality management, agile teams) that draw upon proactive and empowered workers. If, in turn, employees do not want to or feel that they cannot address critical issue or make suggestions for change, unhealthy, inefficient, and toxic work environments endure. Moreover, as media reports show time and again, silence enables unethical practices including fraud, abuse, and discrimination to persist over time, harming cohorts of people repeatedly and at times over many years. Notably, cases of silence and its detrimental effects are not only observed in the corporate world or in singular countries, they also happen in sports teams, educational establishments, religious institutions, law enforcement agencies, and the military all over the world.

Given that silence has been identified as hampering the sustainable development of organizations and societies in a broad variety of countries and contexts, surprisingly little systematic knowledge is available on the role of context as an antecedent of silence, and as a factor that influences the effects of more proximal antecedents of silence. Meta-analyses and reviews (Morrison, 2014; Sherf et al., 2021) show that research on voice and silence focused on the proximal context emphasizing the role of team climate (e.g., psychological safety), leadership (e.g., managerial responsiveness), and organizational voice opportunities (e.g., grievance and suggestion schemes). The more distal context(s) in which employees, teams, managers, and organizations are embedded, however, has been neglected. This is problematic as factors that are situated at the distal context including societal and professional norms and values, legal systems, and industry specifics influence individuals via primary and secondary socialization, and they provide the ground on which teams and organizations operate (Johns, 2006). Moreover, a lack of systematic consideration of the distal context prevents understanding the similarities and differences of silence in contexts such as professions (e.g., police, health care, manufacturing), societal domains (e.g., sports, pedagogical and religious institutions, politics), and cultures (e.g., societies).

We think that a symposium at EAWOP is a great opportunity to invite scholars and practitioners from a broad range of domains and countries to elaborate on a contextualized understanding of voice and silence. A better contextualization may help not only create better theories but also tailored interventions. Moreover, our symposium can inspire policy-making attempts which are tightly embedded in their respective professional and national contexts (e.g., health care, education, sports, business, law enforcement), but lack the perspective and tools necessary to learn from similar attempts in other contexts. To provide such perspective, we will invite collaborators from the largest international study on silence at work (Knoll et al., 2021) to share their insights, and the symposium provides an opportunity to follow-up on our EAWOP Small Group Meeting on “Voice and silence in the caring professions”, and our EAWOP impact incubator “Silence is golden?”.

The symposium is proposed to comprise four talks and an extended discussion. Martin Götz and Michael Knoll start with an overview of silence research in diverse domains and elaborate on what the achieved insights contribute to a “silence-theory-of-context” and “silence-theory-in-context” (Whetten, 2006). For selected contexts (e.g., industry, culture), the authors use data from a large international study (Knoll et al., 2021) to illustrate their elaborations. In the second talk, Pawel Jurek and Sylwiusz Retowski present findings from their research on silence in Poland and elaborate on the specifics of the Eastern European context. Roberta Fida et al. focus on societal tendencies to work incessantly and climates of self-interest as they are common in selected industries. The authors show findings from UK on how a bottom-line mentality affects silence and voice. Anindo Bhattacharjee and colleagues present findings from an interview study on employee silence in India, and they use these findings to elaborate on silence in the context of dynamically-developing countries and emergent markets. Finally, Rosalind Searle leads the discussion and builds bridges to policy-making based on her experiences as the leader of EAWOP impact incubator.

Paper 1

Moving towards a contextualized theory of silence and voice - A review and agenda

Michael Knoll, University of Leipzig, Germany; Martin Götz, University of Zurich, Switzerland

Our talk aims at providing an overview of current research on voice and silence in organizations and exploring ways to overcome a deadlock in research and policy-making concerned with encouraging and enabling organizational stakeholders to express (i.e., voice) rather than withhold (i.e., silence) their ideas, questions, opinions, and concerns. We aim to advocate for the idea that research that aims at producing generalizable knowledge on voice and silence neglects the conditions and requirements that are specific to the contexts in which employees face situations that may require voice. Thus, while a flourishing interdisciplinary and increasingly international domain (see Knoll et al., 2016; Morrison, 2022; Sherf et al., 2021), research on voice and silence struggles with providing knowledge for application. Policy-making attempts (e.g., duty of candor), in turn, are tightly embedded in their respective professional and national contexts (e.g., health care, education, sports, business, law enforcement), but lack the perspective and tools necessary to learn from similar attempts in other contexts. In the talk, we aim to contextualize established knowledge and elaborate on how the many facets of context (e.g., professional, geographical, temporal, cultural, content, organizational and individual history) provide insights on voice and silence that may advance policy-making and contextualized theory-building.

We will start with giving a brief review on current state-of-the- art in voice and silence research, particularly focusing on their antecedents and effects. The review will include examples from publicly visible cases as well as developments in research on everyday-decision making of employees who face situations that may require voice (e.g., observations of inefficient practices, poor or destructive leadership and coworker behavior, ethical and security threats). As will become visible, silence within organizations enables unethical practices including fraud, abuse, and discrimination to persist over time, harming cohorts of people repeatedly and at times over many years. Moreover, these cases were observed in many contexts including corporate organizations, sports teams, educational establishments, religious institutions, law enforcement agencies, and the military. Other cases in which employees withhold their ideas, questions, opinions, and concerns receive less public attention but – when considering the working population – have even more detrimental effects (Bashshur & Oc, 2015; Morrison, 2014). With respect to the negative effects, we apply a multi-level approach (see Knoll et al., 2016). We show that at the individual level, silence negatively affects employees' health and well-being and prevents them from realizing their full potential at work (e.g., Knoll et al., 2019). At the collective level, silence hampers individual and collective learning and the detection of errors, safety issues, and unethical and illegal behavior (Edmondson, 2019; Morrison & Milliken, 2000). Finally, at the societal level, people who do not have a say at work show less civic engagement, whilst health care and pension systems have to compensate higher sickness rates, turnover, and early retirement as a result (e.g., Weber, Unterrainer, Schmid, 2009; Wilkinson et al., 2021).

With respect to antecedents of silence, we will elaborate on the various reasons' employees have for withholding their views as identified in prior research. Based on our review of a broad range of literature (e.g., organization behavior, human resource management, communication and political science, ethnography, social and developmental psychology) that might contribute to this understanding, it will become evident that unhealthy, inefficient, and toxic work environments endure, because employees do not want to or feel that they cannot address critical issue or make

suggestions for change, but also that employees remain silent to protect others and their own knowledge advantage, do not feel they have the competence or legitimacy to speak up. We will show that during the last years, scholars and practitioners from many disciplines, countries, and professional domains were concerned with the negative effects of silence and the need to encourage and enable voice among organizational members and stakeholders. Their studies and consulting revealed long lists of antecedents of voice and silence at the individual, team, organizational, and even societal level; and they identified many contingencies that strengthened, weakened, substituted, and neutralized of these antecedents' effects (Bashshur & Oc, 2015; Morrison, 2022). While the growing body of knowledge and its publication in top-tier journals reflects the importance of the issue, it remains scattered and thus hampering cumulative theory building. Moreover, the scope of potential influences on voice and silence behaviors leaves practitioners and policy-makers with little solid ground for developing and implementing mechanisms and recommendations to break the silence in their respective organizations or domains.

That is why, in the second part of our talk, we elaborate on the possibility to develop a contextualized theory of voice and silence. We first introduce conceptual ideas on the role of context in understanding and explaining organizational phenomena (e.g., Johns, 2011; Whetten, 2009). Based on these conceptual contributions, we elaborate on the question whether and how does considering context advance or organize our established knowledge on voice and silence. Furthermore, we aim at identifying context characteristics that relate to silence or voice across domains similar to personality characteristics that are influential across domains. These domains may include industry and societal context such as branches, professional and industry cultures, national cultures and laws, organizational context such as company age or size, but also facets of individual context such as gender and age). We will use data from our own cross-cultural research project (Knoll et al., 2021) to provide first evidence for our suggestions. We will furthermore explore which specific dimensions of context are most relevant. Following Johns' (2006) dimensions of context, these could include aspects of the omnibus context which raises questions such as: Are voice or silence more prevalent among representatives of specific occupations (e.g., finance sector, military, health care) or employment relationships (e.g., freelancers), members of marginalized groups (e.g., women in male dominated workplaces, people with disabilities, members of minority groups), core vs. peripheral employees (Bolinger et al., 2018), and managerial or non-managerial employees. Are there international or regional differences? Does it make a difference whether employees work in the (single or open-plan) office, the factory, mobile or at home? Are there events that make voice or silence likely? Which influence do prior voice/silence episodes and anticipated future events have? Do employees withheld or expressed their views might also be important. Furthermore, dimensions of the discrete context (Johns, 2006) could be relevant as reflected in questions such as: Are voice or silence more prevalent among workers with high autonomy, job insecurity, who have complex or rather simple tasks? Do climates within organizations substitute or neutralize higher- or lower-level influences? Does it make a difference whether employees are co-present or work from home and thus communicate via technology? How does physical distance affect motivation and ability to speak up?

We hope that our talk opens the symposium and provides a basis for the following talks that focus on specific facets of context. The discussant Rosalind Searle will pick up some of our suggestions and provide insights from her work on poliy development and implementation.

Paper 2

Communal versus agentic workplace climate and organizational silence: The role of negative job attitudes and the Eastern European context

Pawel Jurek, University of Gdansk, Poland; Sylwiusz Retowski, SWPS University, Poland

Research goals and why the work was worth doing

In general, our study aims to expand existing research exploring the relationship between workplace climate, attitudes toward organization, and employee silence by investigating whether communal and agentic work environments through positive and negative attitudes accounted for quiescent and acquiescent silence. We expected that communal, as well as the agentic workplace environment, are negatively related to employee silence and that these relationships are mediated by emotional attitudes towards the organization.

Theoretical background

The concept of communality and agency in the context of work climate was introduced to define a facet-specific workplace climate that involved people-oriented and results-oriented values. Communal Climate (CC) highlights managerial priorities for employees' wellbeing, while Agentic Climate (AC) highlights managerial priorities for employees' productivity. Workplace climate is consequently related to how jobs are designed, what kind of people are promoted, and what is the most important while decision making. Whether employees withhold (i.e., silence) their ideas, questions, opinions, and concerns at work could be affected by work environment perceived by employees.

Design/Methodology/Approach/Intervention

In order to test the hypotheses, we designed a cross-sectional study with the participation of N = 566 employees from various organizations. Participants completed a set of scales that measured the variables examined in the study: The Communal and Agentic Workplace Climate Scale, the Positive and Negative Attitude towards Organization Scale, and the Four Forms of Employee Silence Scale. We used Path Analysis in testing models describing hypothetical relationships between the workplace climate, attitudes towards the organization and employee silence. To test the mediation effects, we calculated average causal mediation effects (ACME), average direct effects (ADE) and average proportion mediated. We used the lavaan and mediation packages in the R environment for all analyses.

Results obtained or expected (if not available, it must be made clear when they will be)

The mediation analysis showed that the effect of communal workplace climate on employee quiescent silence was fully mediated by negative emotional attitude towards the organization. This effect was significant when employees' gender, seniority and job position were controlled. These findings were also observed in testing the model predicting acquiescent silence. However, the relationship between communal workplace climate and employee acquiescent silence was mediated not only by a negative attitude towards the organization, but also by a positive attitude. Moreover, contrary to expectations, in both tested models, there was a small, but statistically significant, positive, and direct effect of agentic workplace climate on employee silence.

Limitations

Our study has some limitations. The cross-sectional design does not allow causal inference. The data collected was based solely on self-reports. So, we have the common method problem unsolved. In future research, it would be necessary to use longitudinal designs to draw conclusions about cause-and-effect relationships. We also acknowledge that the multilevel approach would provide additional data about the specific role of the team. Another aspect concerns cross-cultural differences. Research was carried out only in Poland. A cross-cultural comparison would be desired extension of the study.

Conclusions – research and or practical implications

Communal and agentic workplace climate turned out to be significant direct or indirect predictors of organizational silence. Attitudes toward the organization mediated the relationship between workplace climate and organizational silence. Contrary to expectations, we detected statistically significant, positive, and direct effects of agentic workplace climate on employee silence. The open question is whether it is a specific Eastern European phenomenon or a global pattern. The question of which type of organizational climate is more closely associated with a better level of performance also remains an open question. The positive relationship of the agentic workplace climate with organizational silence may indicate an important conclusion for innovative organizations. It can be assumed that the communal workplace climate seems necessary to stimulate organizational voice, which is then a positive predictor of innovative activities.

Relevance to the Congress Theme

The results of our research can inspire organizations to introduce changes that will help reduce employee silence. We have indicated that the communal environment at work is a priority in building an inclusive work environment.

Relevant UN SDGs

Our research is in line with the 8 th goal of the Sustainable Development Goals of the UN related to promoting productive employment and decent work for all.

Paper 3

Does being drawn to work make us quiet? The influence of working too hard and self-interest climate on silence

Roberta Fida, Norwich Business School at University of East Anglia, UK; Michael Knoll, University of LEipzig, Germany; Catherine E. Connelly, McMaster University, Ontario, Canada; Rosalind Searle, Adam Smith Business School, University of Glasgow, UK; Ivan Marzocchi, University of Rome La Sapienza, Italy

Research goals and why the work was worth doing

Despite technological advancements and innovations, work broadens its grip on people's lives due to increased work demands for some and infinite opportunities for others. In their attempt to catch up with the growing demands and opportunities, some people already predisposed may develop an inner pressure to work, have incessant and incontrollable thoughts about work, feel negative emotions when not working (or when prevented from working), and work far beyond what is required and expected (Clark et al., 2020). This phenomenon, called workaholism (Oates, 1971), has well-established implications for employee health and performance (Clark et al., 2016). In the current study, we contribute to extend existing literature on workaholism by examining the hitherto omitted issue of the ethical implications of working too hard, and exploring the mechanisms that drive and strengthen these effects. Building on previous research which mainly focused on "acts of commission" (i.e., workplace deviance), we focus on "acts of omission", i.e. employee silence, which are still harmful for employees and organisations. We hypothesise that working too hard due to external (workload) and internal pressures (workaholism) may lead to more employee silence and less voice. We expect these relationships to be mediated by moral disengagement, namely the set of social-cognitive strategies which alleviate employees' moral pressure to address critical issues (Bandura, 2002). Additionally, because negative behaviours do not occur in a vacuum, we suggest that self-interest climate could act as an important moderator which can amplify the negative effect of workload and workaholism on moral disengagement.

Theoretical background

We rely on Conservation of Resources Theory (COR; (Hobfoll, 1989) and Social Cognitive Theory (SCT; Bandura, 1986) to investigate our research questions. In line with COR, we expect that working hard may exhaust workers' energy so that they refrain from behaviour that goes beyond their immediate work task (Ng et al., 2016), such as voicing concerns or opinions for overall organisational improvements. Moreover, because engaging in employee silence when voice is needed makes employees feel uneasy and guilty (Kirrane et al., 2017), consistent with SCT we expect that the psychological process of moral disengagement may allow people to engage in acts of omission without experiencing these tensions.

Methodology

We performed a three-wave study on a sample of UK employees. Time 1 (T1) comprised 1046 employees. At T2 participants were recontacted one month later (N = 594). After five months, the final sample at T3 included 292 employees. Workaholism (Clark et al., 2020), workload (Siegrist et al., 2014) and self-interest climate (Elçi & Alpkan, 2009) were measured at T1; moral disengagement (Fida et al., 2015) at T2; silence (Knoll & van Dick, 2013) and voice (Liang et al., 2012) at T3. We

employed Structural Equation Modelling and Latent Moderated Structural Equation model (LMS; Klein & Moosbrugger, 2000) to investigate our hypotheses.

Results

Our results showed that the cognitive and emotional facets of workaholism were significantly related to (more) silence and (less) voice through the mediating effect of moral disengagement. Workload was not associated with moral disengagement but had a positive impact on silence. Our moderated-mediation model showed that the conditional indirect effects of emotional workaholism on (more) silence and (less) voice via moral disengagement were intensified as levels of self-interest climate increased.

Limitations

The constructs were measured with self-report scales. Moreover, the study was conducted in a specific country (UK), thus we cannot provide insights into how workaholism would affect silence and voice in other countries or cultures.

Conclusions and research/practical implications

Our research contributes to the understanding of how workaholism affects not only employee well-being, but also voice and silence; behaviours that have far-reaching ethical consequences. To our knowledge, this is the first study which empirically tests these associations; moreover, the use of a three-wave study is an additional strength. Practically speaking, our results suggest that human resource practitioners and managers should be particularly attentive to employees displaying high levels of workaholism, i.e. by creating "healthier" work environments to avoid triggering workaholism tendencies.

Relevance to the congress theme

Organisations are increasingly pushing their employees to work harder and longer to remain competitive in a rapidly changing labour market. Thus, we believe it is important to fully understand the implications of working hard in organisations not only to protect well-being, but also to prevent unethical behaviours in terms of acts of commission and omission.

Keywords: workaholism, silence, ethics

Symposium S107

Predicting trajectories of adaptation at work

Cornelia Niessen, Friedrich-Alexander-Universitaet, Erlangen-Nuernberg; Sandra Ohly, University of Kassel

science

Due to economic and technological changes, many organizations are challenged to initiate change, for example by implementing new forms of work and technologies. It is expected that employees adapt to these changes as quickly and efficiently as possible (Baard et al., 2014; Jundt et al., 2015). Adaptation to change is defined as "individual's response to new demands or ill-defined problems created by uncertainty, complexity, mergers, and any rapid change in the work situation" (Chan, 2014) or "cognitive, affective, motivational, and behavioral modifications made in response to the demands of a new or changing environment, or situational demands".

Adaptation is a process that unfolds over time. This symposium focuses on the trajectories of adaptation to new tasks and technologies. Specifically, the four presentations in this symposium examine how various person-related and context-related predictors shape these trajectories. The presentations contribute to the literature on adaptation by giving insight into the dynamics of adaptation, and its prediction, a so far under-researched area.

In the first presentation, Lang and colleagues investigated whether self-efficacy predicts performance after a sudden emergence of a more difficult task situation. Self-efficacy has been shown to be an important predictor of performance at a between level, but its role in adaptive transfer is still unclear. Lang and colleagues investigated this question with two simulation experiments (flying a helicopter) including 30 trials (15 before and after task change). Discontinuous growth models revealed, that the relationship between self-efficacy and performance was positive before, but altered after task change. The relationship was weaker and became even negative for one performance outcome.

Trust has been shown to be crucial for the successful implementation and use of new technologies. In the second presentation, Müller and Hertel have examined changes in trust after implementing a new information system (IS). They theorize that trust in IS should increase over time and that the relevance of different predictors of trust should vary with time. Müller and Hertel conducted a field study over a period of 11 month with four measurement points (before and after the implementation of the IS system). Latent growth curve modeling revealed an upward non-linear trajectory of trust which was shaped by different factors at different time points during adaptation to the IS system.

The third presentation investigates if and how employees adapt to a potentially aversive technology, such as electronic performance monitoring. Based on the communication privacy management theory and self-determination theory, Niessen and Wolff propose that the trajectories of privacy concerns and wellbeing are moderated by the invasiveness of the electronic performance monitoring technology, the quality of the social relationships with the leader and colleagues and, and the acquisition of competencies. They conducted a longitudinal field study (4 measurement points, 12 month) with newcomers who were monitored in their new organization.

The fourth presentation of Oreg and colleagues examined situational characteristics in the relationship of routine tasks and subsequent task performance. Using data from daily diary study and laboratory study, they link the situational characteristics of familiarity and straightforwardness to

subsequent task performance. The results suggest that routine tasks can facilitate behavior relevant for adaptivity in daily work.

The symposium includes Maria Vakola as a discussant. Maria is an internationally known expert for organizational change. She has published several studies on change and adaptation in high ranked international journals.

Relevance to the congress theme. Understanding and predicting adaptation to new demands is crucial in a changing world of work, for employers and employees.

Research / Practical implications. Predicting the dynamics of adaptation contributes to theory development on the adaptation process and expands the literature on predicting different phases of adaptation. From a practical perspective, the study results can contribute to the design of interventions which aim to empower people to deal with change.

Overall conclusion . This symposium presents research which show that different predictors predict of trajectories at different points of time.

discussant: Maria Vakola, Athens University of Economics

Keywords: Adaptation, time, work demands

Paper 1

Self-efficacy, task performance, and adaptive transfer

Jonas W. B. Lang, Business School University of Exeter; Paul Bliese, Moore School of Business University of South Carolina; Sascha Herr, University of Bamberg; Zen Goh, Monash University; Jon Hendricks, University of Nebraska Lincoln; Alex de Voogt, Drew University

Research goals. Most organizational training is designed to both help employees improve their performance and make performance robust to task changes by facilitating adaptive transfer (Aguinis & Kraiger, 2009; Keith & Frese, 2005; Niessen & Lang, 2020). At a practical level, self-efficacy has been assumed to be important within training contexts and for expediting adaptive transfer (Davis et al., 2000) because self-efficacy appears to be at least partially malleable through training (Gist, Schwoerer, & Rosen, 1989). This article integrates research on self-efficacy's relationship with performance with research on adaptive transfer in complex task environments, and investigates how self-efficacy's association with performance is altered when people encounter a change in a task that requires adaptive transfer.

Theoretical background. Adaptive transfer studies generally require participants to learn a complex task (in this research a helicopter simulator) until they reach a performance plateau. In the next step, the participants are confronted with an altered task situation (a high-altitude airfield) to study the degree to which performance is robust to change. Empirical studies have documented that self-efficacy is often positively related to performance at a between-person level, such that individuals with high efficacy tend to have high overall performance and either positively or negatively at the within-person or trial-by trial level. A positive relationship is well in line with the tenets of social cognitive theory (Bandura, 1986; Bandura & Locke, 2003). Powers (1991) suggested that a model based on perceptual control theory (e.g., Powers, 1973) would predict a negative relationship on the within-person level and research has also supported this idea (Ballard et al., 2016; Sitzmann & Yeo, 2013). Recent research has focused on empirical evidence suggesting that within-person relationships between self-efficacy and performance can be context-dependent—positive when feedback ambiguity is low but negative when feedback ambiguity is high (Bandura, 2012; Schmidt & DeShon, 2010; Vancouver & Purl, 2017). Researchers have also argued that self-efficacy/performance relationships may be partly or even fully be driven by past performance (Heggestad & Kanfer, 2005; Sitzmann & Yeo, 2013).The role of self-efficacy in adaptive transfer—especially immediately after the change has occurred—is not well understood so far. We build on engagement-disengagement theories (Carver & Scheier, 1998, 2020; Gendolla et al., 2012; Kukla, 1972; Wortman & Brehm, 1975; Wright, 1996) to develop theoretical predictions on what should happen in this situation. Engagement-disengagement theories suggest that the sudden emergence of a much more difficult task situation can lead to a sudden breakdown in performance because people shift from a situation of engagement to a sudden situation of disengagement. Engagement-disengagement theories have been considered in the self-efficacy/performance literature before (Beattie & Davies, 2010; Lang & Lang, 2010; Vancouver et al., 2008) but are typically thought to be relevant to only a limited number of participants or to extreme conditions in typical studies on self-efficacy. The role of self-efficacy in disengagement situations in complex work tasks has thus rarely been studied.

Methodology. Our two studies ($N = 120$ with $k = 3{,}578$; $N = 60$ with $k = 1{,}800$) used a discontinuous change design that can provide some insights into causality because it utilizes an exogenous event (Bliese et al., 2020; Bliese & Lang, 2016; Hausman & Rapson, 2018). First, participants practiced 30 take-offs in a helicopter simulator. Then, they were asked to execute

another 30 take-offs under performance conditions and indicate their level of self-efficacy prior to each take-off. After 15 of these 30 trials under performance conditions were completed, the task changed to a high-altitude airfield, which required participants to adapt to the new behavior of helicopter, the steering devices, and the instruments.

Results. Discontinuous growth models revealed that within-person self-efficacy and average self-efficacy across the 15 trials prior to the task-change were positively related to performance even after controlling for past performance. Importantly, however, the task-change substantively reduced performance and all self-efficacy/performance relationships. For one of the two performance criteria, the reduction in the within-person self-efficacy/performance relationship was so strong that the relationship became significantly negative.

Limitations. Our studies were conducted in a laboratory context with non-expert pilots.

Conclusions. Our findings suggest that typical adaptive transfer requirements that introduce a significant obstacle into a task can substantially alter self-efficacy/performance relationships, and that performance advantages associated with higher self-efficacy are not robust to such changes.

Relevance to the congress theme. Adaptive transfer is likely particularly relevant in a future world of work with frequent changes in work environments.

Relevance to UN SDGs. This research is directly relevant for designing future training and for understanding challenges at complex workplaces and thus contributes to the goals “Decent work and economic growth” and “Quality education”.

Keywords: Self-efficacy, performance, discountious growth model

Paper 2

Adopting Information Systems at Work: A Longitudinal Examination of Trust Dynamics and Outcomes

Lea S. Mueller & Guido Hertel | University of Muenster

Research goals: Advanced information systems (IS) provide multiple benefits for organizations, however, their introduction requires users' adoption to new work processes. During these processes, trust in IS has been initially suggested as central precondition of successful adoption of IS (Lippert & Swiercz, 2005; Turel & Gefen, 2013), but we still lack insights into its development over time. The current research examines trust in IS during the introduction process within a larger public administration in Germany, investigating (1) trust development over time, (2) trust relations with multiple predictors at different time points, and (3) trust relations with different outcomes across time. Thus, this research contributes to theory development on trust dynamics with respect to technology use, and provides specific suggestions for more efficient introductions of IS in organizations.

Theoretical background: Established models on trust usually include dynamic components, predicting experiences with a trustee to influence trustors' further evaluations of the trustee (Mayer et al., 1996; Hoff & Bashir, 2015). In a similar way, trust in technology is defined as a "dynamic construct that is prone to changes" (Glikson & Woolley, 2020; p.10). Opposingly, empirical research rarely examined longitudinal dynamics of trust (Hoehle et al., 2012; Zheng et al., 2014), and theoretical models remain rather general on the specifics of such developments. Applying a longitudinal approach, our study started with the following assumptions: First, trust in IS should generally develop in upward trajectories. Second, the relevance of different predictors of trust should vary with time. In line with extant theoretical work (Meeßen et al., 2020), we assumed users' trust disposition to be a stronger predictor of trust at initial time points, while IS trustworthiness assessments increase as predictor over time. Finally, we assumed that trust in IS is positively related to users' reliance on the IS and job performance, and negatively with users' strain (Hertel et al., 2019; Petter et al., 2008).

Methodology: We evaluated the introduction of a new IS within a larger public administration in Germany across 11 months. Specifically, we conducted online surveys with N = 313 users of the IS at four time points: (1) before launch, (2) after initial usage, (3) five months, and (4) ten months after launch. Users were asked to rate their trust disposition, the IS perceived trustworthiness (reliability, credibility, usability, design aesthetics), organizational context (support, participation, abilities of persons involved), their current trust in as well as their current reliance on the IS, job performance and experienced strain. We applied latent growth curve modeling using AMOS to model trust dynamics and its association with predictors and outcomes at different time points.

Results: Results support our assumption that trust in the IS develops in an upward, although non-linear trajectory. Further, results confirm that the relevance of trust predictors varies systematically across time. While person factors were stronger predictors of trust in early phases, perceived IS characteristics were stronger predictors at later times. Finally, the results also confirmed that trust in the IS correlates positively with users' reliance on the IS, their performance, and their well-being.

Limitations: First, we investigated a specific IS in a specific organization. In order to generalize our findings, replications in other contexts (e.g., different IS, organizations, business sector and cultural

settings) is required. Further, missing data in our study were compensated by estimation methods, replication studies with complete data would be more reliable. Finally, our results are based on self-reports only, so that the inclusion of objective data (e.g., user behavior, performance) would be fruitful in future research.

Conclusions/Implications: Our findings underline the relevance of trust for the efficient adoption of novel IS at the workplace over time. We provide one of the first longitudinal investigations of trust dynamics, taking both predictors and outcomes into account. The findings contribute to our theoretical understanding of trust dynamics within the field of technology at work. Moreover, our findings underline the significance of organizations' efficient trust management, also after IS launch. Organizations should therefore involve end-users and establish regular checkups that reveale malfunctions and ensure high data quality.

Relevance to Congress Theme: Technology is a major driver of change in the world of work. While employees need to adapt to the usage of the technology itself, the introduction of IS to the workplace is further accompanied by the adaption of complete work processes in most cases. Understanding and monitoring trust in an IS over time contributes to the success of such changes.

Relevant UN SDGs: 3) Good health and well-being; 8) Decent work and economic growth; 9) Industry, innovation and infrastructure

Keywords: Adaptation, trust development, information systems

Paper 3

Can you get used to electronic performance monitoring at work? A longitudinal study

Cornelia Niessen & Mauren Wolff | Friedrich-Alexander University Erlangen-Nürnberg

Research goals . As new technology, and, recently, Covid19, have brought profound changes to the ways people work, electronic performance monitoring (EPM) is becoming increasingly attractive for employers to manage their employees. EPM refers to the use of technology to observe, record, and analyze information directly or indirectly related to work behaviors (Alge & Hansen, 2014; Ravid et al., 2020). Research on EPM has revealed some benefits (e.g., increasing performance of simple tasks), but mainly negative affective (e.g., strain), cognitive (e.g., privacy concerns), and behavioral (deviant behavior) reactions of employees (Ravid et al., 2022; Siegel et al., 2021). The majority of research on employee responses on EPM was conducted with experiments in the laboratory, online experiments (vignette studies) or with cross-sectional surveys, covering only a short period of time in which individuals had to deal with EPM. Thus, we do not know whether employee reactions are stable over a longer period of time. It might be possible that employees become used to EPM over time. In contrast, employees can also become increasingly aware of the fact that that they are constantly monitored, resulting in stronger negative reactions over time (Ravid et al. 2020). In the present study, we ask if and when employees become desensitized to the effects of EPM or even more sensitized with stronger reactions (privacy concerns, wellbeing) over time. We examine personal (e.g., competence) and situational characteristics (invasiveness of technology, social integration) as moderators of these relationships.

Theoretical background . Our reasoning is based on communication privacy theory (Petronio, 2002) and self-determination theory (Deci et al., 2017). We propose that the trajectories of privacy concerns and wellbeing are moderated by the invasiveness of the EPM technology, the quality of the social relationships with the leader and colleagues and, and the acquisition of competencies. Invasiveness of EPM (e.g., taking screen shots, face reading) might threaten the privacy boundary between the self and other and evoke that employees fear losing control over the access of information, which they consider private and do not want to share with others because they might draw the wrong conclusions or do not trust the other people. Therefore, the more invasive EPM is the stronger privacy concerns should increase over time. Moreover, invasive EPM evoke evaluation anxiety and threaten basic needs for autonomy and competence by controlling employees' behavior, which might result in a decrease of wellbeing over time. In contrast, increasing social integration during socialization (development of good relationships with leader and colleagues) should buffer the negative trajectories as social integration provides psychological safety. Furthermore, when employees acquire competencies over time they might experience less evaluation anxiety, and therefore less privacy concerns and higher wellbeing over time.

Design/Methodology . We have conducted a four-wave longitudinal field study (time lag three month) with 828 newcomers (45.7% identified as female, 54.1% identified as male) at Time 1 who in the last three months have taken up jobs where new EPM technologies are implemented. Mean age was 37.89 years (SD =10.17); 31% of the participants reported time tracking, the other monitoring of screen activity (33,5%), social interactions (30,8%), location (22.5 %), environment (12.3%), emotions (9.5%), concentration (10%), and face (6.9%). Furthermore, 42.4% of participants indicated to already have experience with EPM at work. At Time 2, 300 employees, at Time 3 266 employees, and at Time 4 258 employees participated in the study.

Results . The data are currently being analyzed with growth curve models in R, and will be presented at the conference.

Limitations . We assessed our data with self-report.

Conclusion . Our study will give insight into the dynamics of employee adaptation to a potentially aversive technology at work, namely EPM. It is important to know how employees react to EPM at their workplaces and if and how the effects of digital control on employee reactions change over time.

Relevance for the congress theme . How employees adapt to the increasing digitalization at work is an important topic and fits to the congress theme.

Relevant UN SDGs . We contribute to the goal of good health and well-being and decent work with our study on EPM and adaptation.

Keywords: Adaptation, electronic performance monitoring, growth modelling

Paper 4

Adaptivity and situational characteristics

Sandra Ohly, University of Kassel; Marcel Kern, Ruhr University of Bochum; Laura Klein, University of Kassel; Shaul Oreg, Hebrew University of Jerusalem

Research goal. „The importance of workers' ability to adapt to novel situations in the workplace and perform at an elevated level may currently be more crucial than ever." (Huang et al 2014.) Although research points out that individual characteristics are related to higher adaptivity, for a sound understanding of the phenomenon, the process by which individuals realize the need for change, and their ensuing behaviors needs to be studied. By examining situational characteristics, this study adresses this gap in the literature.

Theoretical background. Task routinization (i.e. the automatic execution of task-relevant behavior) may improve adaptativity by saving time and energy (Ohly et al. 2006) and fostering a sense of familiarity and security (Avni-Babad, 2011). By saving crucial resources which might be invested later on, and by providing a safe working context, the performance on a subsequent task including creative performance can be enhanced.

Methodology. In a daily diary study (N = 73, k = 265), participants provided ratings of task routinization three times a day, and worked on a creativity task in the evening. In a lab study, task routinization was first established using practice trials, and participants completed an anagram task as secondary task later on. In both studies, task perceptions were assessed using the Situation Six (Oreg).

Results. For the diary study, multilevel analyses simulteanously modeling within- and between-subjects relationships suggest that routinized tasks are perceived as high on familiarity and low on demandingness across all time points. In turn, familiarity predicts subsequent originality on the creativity task. No relationship with negativity were found. Results of the lab study replicated the relationships of routinization with familiarity (positive) and demanding (negative), and in addition yielded positive relationships with positivity, and (marginally) with straightforwardness. In turn, straightforwardness was positively associated with performance on a secondary task.

Limitations. Alongside the consistent findings, several of them, including those for straightforwardness, which was not assessed in the diary study, were not obtained in both studies.

Conclusions/Implications. The results suggest that situational characteristics can be linked to task performance on subsequent tasks. By incorporating the Situation Six taxonomy we uncover the basic situational characteristics that underlie the effects of task routinization and shed light on a specific form of adaptativity.

Relevance to the congress theme. Adapting to changing tasks and situations is a requirement in the changing world of work. This paper sheds light on the mechnisms how this can be achieved.

Relevance to SDG. Good health and wellbeing; Decent work and economic growth

Keywords: Adaptation, routines, situational characteristics

Symposium S108

Post-Covid Adaptation in Work and Organizations

Filipa Castanheira, Nova School of Business and Economics, UNL; Portugal; Marisa Salanova, Department of Social Psychology, WANT Research Team, Universitat Jaume l, Spain

science

The Covid-19 pandemic caused by a virus imposed rapidly measures and actions on companies and their workers without time to plan and to implement. Thus, this situation may be considered a crisis that is perceived and felt as a threat, given the associated difficulties that exceed one's usual resources and coping mechanisms. In the awake of the pandemic crisis, it is of utmost relevance to analyze its consequences for workers and their well-being.

This symposium includes five empirical oral presentations from three different countries: Portugal, Spain, and Italy, and through different methodologies, samples and contexts, provide an integrative and comprehensive picture including the management side, the workers perceptions and multilevel combinations on workers and units. The studies were developed in different phases of the pandemic crisis, including the lockdown periods and the post-pandemic period as workers and organizations are bouncing back to the "new working reality", reflecting on what has changed and how to move on. Two studies included management teams (HR Directors from several private organizations and the Executive Management Committee of a Public University) and analyzed how teleworking was experienced and what are the learnings, the challenges, and the constraints as the world move to the post pandemic phase. Another study introduced and validated a scale of technostress, a psychosocial risk associated with the use of Information and Communication Technologies (ICTs) to work. This study is timely as the work is currently discussing hybrid formats of working and, therefore, ICTs to work are expected to be more common and broadly implemented. Another study validated the Emotional Styles Questionnaire (ESQ) (Kesebir et al., 2019) and developed an intervention protocol oriented towards improving the different components of healthy emotionality and tested its preliminary efficacy in a group of workers. Finally, the fifth study sampled two groups of hospital workers to test the cross-level hypothesis that proposes that personal social resources, age, and team's age diversity interact and influence job performance

Theoretically, this symposium offers contributions to analyze a context as specific as that of the awake of the pandemic crisis, how the lockdowns have shaped the workers' experience, and how different theories (e.g. work-family border theory (Clark, 2000), Socioemotional Selectivity Theory (SST; Carstensen et al., 1999), stress theory (Lazarus & Folkman, 1984) can be applied to understand the repercussions of this context for well-being. Moreover, noteworthy contribution of this symposium is the alignment of its aims with some of the sustainable development goals (SDG) advocated by the United Nations (2020) which, as already highlighted, are more important than ever for the recovery of the impact of COVID-19. Firstly, this symposium will contribute to the specific socio-occupational health aim - „health and well-being" (SDG 3). Secondly, the United Nations (2020) also highlights the "employment, decent work for all and social protection" aim (SGD 8). Understanding the changes imposed by the Covid-19 pandemic and its consequences for workers and their working conditions will help define the limits to be set in these working conditions, thus contributing to the promotion of decent work. Overall, it is the aim of this symposium to provide evidence to support the promotion of inclusive and sustainable working conditions that ensure the well-being of workers.

This symposium is directed to academic and practitioners and shows that to ensure workers well-being in the awake of a crisis it will be important to develop their healthy emotionality, the trust building mechanisms in teams, to understand how workers are using ICTs to work to avoid technostress and, particularly in the telework situation, to be aware of the factors that may hinder a successful adoption of this work arrangement.

Keywords: Post Covid-19, workers' well-being, working conditions

Paper 1

Rethinking Telework of Administrative Staff after COVID-19: Lessons learnt in a Spanish Public University

Esther García - Buades, Consuelo Hernández-Guerra, Silvia Ortiz - Bonnin & Elena Sureda - Demeulemeester | University of the Balearic Islands (Palma de Mallorca, Spain)

Research goals

The research goal is to assess the positive and negative aspects of telework during COVID-19 in a Spanish Public University both for the institution and for the wellbeing and productivity of administrative employees. The second goal is to provide recommendations on how to improve the effectiveness and sustainability of telework in the future.

Theoretical background

Research on pandemic-induced telework has highlighted advantages and disadvantages of telework for workers, organizations, and society (Belzunegui-Eraso & Erro-Garcés, 2020; Blahopoulou et al., 2022). The success or failure of telework implementation has been associated to factors such as previous organizational experience on teleworking, organization of work, availability of technical resources, leadership skills, employees' characteristics, and digital competencies. Post-COVID-19 telework needs to be revised after reflecting on the achievements and mistakes experienced through pandemic-induced implementation, in order to make it the most beneficial for all (Chambel et al., 2022).

Design/ Methodology

This qualitative study relied on individual reports (N= 8) and a focus group conducted among the members of an Executive Management Committee at a Spanish Public University (5 men and 3 women). This Committee is responsible for the management of administrative staff, services, and facilities. The topics explored were: (1) positive and negative aspects of telework during lockdown, (2) telework evolution after COVID-19, (3) how to review current telework regulations and conditions to maximise its benefits.

Results

Pandemic-induced telework had an abrupt and improvised start, for which university was caught unprepared. Regarding the positive and negative aspects of the telework experience during lockdown, the senior management committee described it as both a challenge and an opportunity. Besides keeping staff COVID-safe at home, the positive aspects highlighted were related to the fast institutional reaction, i.e. in a matter of days the institution managed to provide education and administrative services online. Negative aspects were reduced productivity for some workers, the level of digitalization was limited, and having to deal with technological and work organization issues.

Regarding the evolution of telework after lockdown, the committee praises achievements already in place such as the existence of new telework regulation at national and institutional level; the re-thinking of work organization towards work objectives rather than presence; technology equipment is updated; the progress made towards virtual organization of work (virtual desktops, procedures, and processes).

Regarding how to review current telework to maximise its benefits, the committee identified future trends and challenges. One challenge for the institution is to create an appropriate “telework culture” (differentiating proper telework vs. a pseudo-day off ; deciding when and for whom telework is an option); keep progress towards re-designing work and jobs (by goal accomplishment, adequate performance measurement, staff availability online, training, safety issues), keep refining existing regulation, dealing with leaders’ resistance.

Limitations

This research is at a preliminary stage and based on a case-study therefore generalization is limited. Further, the view of administrative departmental supervisors (middle-management) and administrative employees should be incorporated in future steps of the project.

Research/Practical implications

Future research should explore how different Public administrations have implemented telework and which strategies and actions they have put in place to be more efficient and beneficial for institutions, employees, and users. Although qualitative analysis is very rich, quantitative data should complement the assessment of the success and failures of telework implementation and adaptation.

Practical implications rely on recommendations to maintain the advantages gained through pandemic-induced telework, and review weaknesses identified by management.

Relevance to the Congress Theme.

This study is very much on the “changing world of work” in a public administration setting. After analysing how top management assesses the telework experience during and post-COVID19, we aim to set the next steps in (re)designing work in a more efficient and sustainable way.

Relevant UN Sustainable Development Goals (SDGs).

SDG number 8 seeks to promote decent work for all.

Keywords: Telework, organizational change, HR management

Paper 2

Facilitators and constraints of adoption of teleworking in Pos-Covid time

Filipa Castanheira, Nova School of Business and Economics, Universidade Nova de Lisboa; Alda Santos, Vânia Carvalho & Maria José Chambel | Faculdade de Psicologia Universidade de Lisboa

Research goals

After the 2-year adaptation to telework, this study aims at understanding how teleworking was implemented and identifying company's characteristics and its human resources management practices that can be considered facilitating or constraining factors in the adoption of telework.

Theoretical background

Many companies around the world were forced to adopt full-time telework during COVID-19. For many workers this was a positive experience, and there is the expectation of maintaining this type of work arrangement in the post-pandemic period. However, its adoption in the post-pandemic period implies an organizational change that may encounter many difficulties and resistances, and it can be expected that in a post-pandemic period, many companies may abandon it. For many companies and workers, this period represented the first experience teleworking and the success or failure of telework further adoption will largely depend on the capacity to identify factors that facilitate and eliminate or minimize those constraints that were present during the pandemic period. Indeed, post-COVID-19 telework needs to be revised after reflecting on the achievements and mistakes experienced through pandemic-induced implementation, in order to make it the most beneficial for all (Chambel et al., 2022).

Design/ Methodology

We carried out a qualitative longitudinal study in 40 companies from different sectors in Portugal. We interviewed the respective human resources directors at two different times: October-November 2021; October-November 2022.

Results

At first, we observed that in sectors where it was possible to have the majority of workers with this modality (e.g. IT, consulting), there was a greater investment to support the adoption (e.g. training of managers and teams, equipment adaptation), and there is also a greater intention to adopt this modality in a more comprehensive way in the future. However, we observed that in these sectors, as in those where teleworking could only be adopted in some functional areas (e.g. hotels, banks), only a few intended to continue adopting telework in the future. With the data collected in this second moment, we intend to verify the paths of companies, analyzing to what extent they followed or changed their planning, to identify trajectories related to the adoption of teleworking in this post-COVID period.

Limitations

This research is at a preliminary stage, and we still have to collect 2 nd moment interviews. Nevertheless, the contacts are made, and most interviews are already scheduled.

Research/Practical implications

Future research should explore the different experiences that crafted the trajectories related to the adoption of teleworking in this post-COVID period. This study provides the management view on the implementation of these processes and therefore, employees' responses to these events should complement the assessment of the facilitators and constraints of telework.

Practical implications rely on recommendations to maintain the advantages gained through pandemic-induced telework, and review weaknesses identified by management.

Relevance to the Congress Theme.

This study covers the process of adaptation of several organizations as they implemented (and one year after the implamentation) of teleworking due to Covid-19 pandemic. It taps on the "changing world of work" with a diverse sample of companies and sectors. After analysing how HR managers reflect on the telework experience during and post-COVID19, we aim to identify the main facilitators and constraints to (re)designing telework in a more efficient and sustainable way.

Relevant UN Sustainable Development Goals (SDGs).

SDG number 8 seeks to promote decent work for all.

Keywords: Teleworking, HR management, Longitudinal

Paper 3

Spanish Validation of the Technostress Creators Scale

Arenas Alicia, Donatella Di Marco, Valeria Terán & Francisco J. Sanclemente | Universidad de Sevilla, Spain

Research goals: This study aims to provide validity evidence of the Technostress Creators Scale in Spain, and to test the measurement invariance in terms of gender.

Theoretical Background: The COVID-19 pandemic has changed the way organizations operate, forcing many of them to opt for telework as an alternative to face-to-face mode. This global phenomenon has increased the importance of studying the psychosocial risks linked to the use of Information and Communication Technologies (ICTs), such as technostress.

Design/ Methodology: We analyzed the psychometric properties of the scale, its factor solution, and gender invariance in a sample of 931 employees from Spain.

Results: The Exploratory Factor Analysis (EFA) showed that the Spanish version maintained the five factors of the original version: techno-overload, techno-invasion, techno-complexity, techno-insecurity, and techno-uncertainty. Likewise, the instrument showed adequate reliability. The results of the Confirmatory Factor Analysis (CFA) also replicated the five-factor structure of the English version. Additionally, measurement invariance tests indicate differences between genders.

Research/Practical implications: The resulting Spanish scale has 18 items, shorter than the original version. The implications and limitations of the Spanish version of the instrument are detailed in the discussion.

Relevance to the Congress Theme.

This study validates an instrument to measure technostress that arises with the maladaptive usage of ICTs to work. This is related to the “changing world of work” as the implementation of ICTs is spread across sectors and industries and is transforming the way individuals work and interact with each other in organizations.

Relevant UN Sustainable Development Goals (SDGs).

SDG number 8 seeks to promote decent work for all.

Keywords: Technostress, management of ICTs; confirmatory factor analysis

Paper 4

Emotional Styles Questionnaire Validation in Spain and an Intervention Protocol Pilot

Marisa Salanova, WANT Research Team, Department of Development Educational, and Social Psychology and Methodology, Universitat Jaume I, Castellón de la Plana, Spain; Ari Wilson Gómez, WANT Research Team, University Jaume I, Spain; Cristián Coo, WANT Research Team, Department of Development Educational, and Social Psychology and Methodology, Universitat Jaume I, Castellón de la Plana, Spain

Research goals: The goal of the present research project is twofold: First, to validate the Emotional Styles Questionnaire (ESQ) (Kesebir et al., 2019) for Spanish working population as a novel measure of healthy emotionality, a highly relevant construct related to psychological well-being and mental health. Secondly to develop an intervention protocol oriented towards improving the different components of healthy emotionality and test its preliminary efficacy in a group of Spanish workers during the COVID lockdown.

This study is highly relevant due the heavy burden on psychological well-being and mental health COVID measures have imposed on society as a whole, and particularly on the active working population. Our overarching goal is to develop validated measurement and intervention tools to support an active working population in the face of changing working conditions, high levels of uncertainty and increasing stress.

Theoretical background: The construct of healthy emotionality is based on neuroscientific studies of emotion developed throughout the last three decades (Davidson & Begley, 2012). The model establishes six key dimensions of emotional life, all of them highly relevant for psychological well-being and mental health. Namely, Attention, Self-Awareness, Outlook, Resilience, Social Intuition and Sensibility to Context. Each one of these dimensions is described as a continuum between two extremes that mirror different levels of activity in underlying brain circuits. More specifically, each dimension is related to a particular behavior linked to the emotional states we experience, their duration, intensity, and how we manage them. And where we fall in the different points of the continuum on each dimension is our unique individual signature, a combination of heritable genetic influences and also everyday experiences. This construct is trainable but no psychological intervention in the working population has been performed as far as we know.

Design/Methodology: For the scale validation study, we gathered a sample of (N =1,200) active workers during the COVID lockdown in Spain distributed in various medium and large organizations, 52% of the workers were female, 37% were between 18 and 35 years old, 34% between 36 and 45, 19% between 46 and 55, and 10% 56 or more. Statistical analyses were conducted using JASP (JASP Team, 2020) and included CFA, correlations, reliability indexes and descriptive statistics. Secondly , we develop an intervention protocol based on the guidelines suggested by Davidson & Begley, (2012). The intervention protocol had three 150-minute sessions and was delivered online in synchronic sessions. A small group (N = 42) participants from a large Spanish organization took part in the intervention and answered pre-post measures of emotional styles and other relevant well-being measures. 66% of the participants were female, and their average age was 36 (SD = 8.22).

Results: For the validation study, we could not replicate the original psychometric properties of the ESQ and the original 24-item six-factor and a single second order factor yielded inadequate fit indexes (χ 2 = 1348.804, df = 246, CFI = 0.78, TLI = 0.75, RMSEA [.06; .07]), and a second solution of

24-items and six factors improved the fit indexes but still remained unsatisfactory ($\chi 2$ = 1159.987, df = 237, CFI=0.81, TLI =0.78, RMSEA [.06; .07]). In light of these results, we tested a briefer 18-item six factor solution that significantly improved the fit indexes to an acceptable condition ($\chi 2$ = 988.356, df = 129, CFI=0.87, TLI =0.85, GFI = 0.93, RMSEA [.061; .06]).

For the intervention study we conducted paired sample t-tests using the pre-post measurement points and found significant positive differences for Emotional Styles (as a global construct) and particularly on Positivity, as well as diminished levels of Perceived Stress and Burnout at a descriptive level.

Limitations. The main limitation of the present project is the lack of a control group from the evaluation of the intervention protocol as well as the less-than-optimal on-line delivery method.

Research/Practical Implications. The main practical implications revolve around the development of novel measures and intervention protocols to help active workers cope with stress and burnout and improve their psychological well-being during times of uncertainty and suffering.

Relevance to the Congress Theme: The exploration and validation of measures and intervention strategies developed from sound neuroscientific studies focusing on the constituents of psychological well-being and mental health is a novel contribution to the field of work and organizational psychology.

Relevant UN Sustainable Development Goals (SDGs).

SDG number 8 seeks to promote decent work for all and number 3 (health and well-being).

Keywords: Emotional Styles, Validation, Intervention

Paper 5

Age and performance in dancing: the three-way effect of age, age-diversity and job social resources on performance

Juan J. Reyes, Department of Social Psychology, WANT Research Team, Universitat Jaume I, Spain; Mirko Antino, Department of Behaviour Science Methodology, Universidad Complutense de Madrid, Spain; Valeria Cruz-Ortiz, Department of Social Psychology, WANT Research Team, Universitat Jaume I, Spain; Marisa Salanova

Research goal and why the work was worth doing:

This research aims to 1) test a cross-level hypothesis that proposes that personal social resources, age and team's age diversity interact and influence individuals' job performance and 2) scale the proposed model to team's performance. This approach extends the sight of the research on aging at work by considering age in relation with team's age diversity. It also serves as initial standpoint for studying the COVID impact among hospital workers and teams considering their age.

Theoretical background:

According to Socioemotional Selectivity Theory (SST; Carstensen et al., 1999), motivations evolve throughout life due to remaining time perception. Elder workers have a more limited time perception that leads to prioritizing having satisfactory experiences rather than long term job-related goals' pursuit. The search for positive socio-emotional experiences has been related to increases in job performance attending underlying mechanisms such as trust building (Lau & Cobb, 2010, NG & Feldman, 2013). However, people usually work in teams, and individual age processes interact with other age-related factors at group level, such as team's age diversity, which may risk the involvement in socio-emotional experiences. Age diversity has been studied as a complex phenomenon that potentially generates unpleasant social experiences such as conflicts between group members (Wegge & Schmidt, 2009). This study aims to fill the existent gap in the literature on the study of the relationship between age, team age diversity, job social resources and performance. It also to contributes to the neglected team level of analysis (Rudolph & Zacher, 2022) by extending the proposed hypotheses.

Design/Methodology:

Two hospital workers databases with multilevel data structure (i.e.: professionals, units, hospitals) were used for testing the hypothesis. For the first study, performance, social resources, and age were collected online through HERO-Check questionnaire (short version of HERO questionnaire; Salanova et al., 2012). Multilevel models were tested to appraise the cross-level hypothesis (n level 1 = 1297, n level 2 = 70). For the second study, the hypothesis was tested at the unit level. Participants data (n level 1=875) was collected with HERO questionnaire (Salanova et al., 2012) and aggregated at the unit-level (n level 2=50).

Results Obtained:

Results of the first study fully support the cross-level interaction ($t(1221)=2.38$, $p = .02$). Elder workers' social resources interact with team diversity enhancing performance when both are high. Meanwhile, younger workers take more advantage of social resources in low age-diverse teams. Second study results show the same effect at the team level ($t(42)=2.17$, $p = .04$).

Conclusions:

Results support our hypothesis, showing that team age-diversity, individuals age and social resources significantly influence performance in individuals, and tends to influence this relation in teams. Changes in motivation across lifespan make social resources significantly more relevant for older

employees' performance, particularly when they are involved in age-diverse contexts, where positive social experiences could be undermined by conflict dynamics. This result tends to be the same when considering the team performance, so that older teams take more advantage of social resources in presence of age diversity.

Limitations:

This research is not free from limitations; however, some means were adopted to mitigate their impact and considerations for future research were made. First, performance in both studies was measured as a self-reported assessment which might be considered a non-objective measure. Yet, study 1 pointed to team performance and its measure as unit consensus leads to a more objective measure. Also, HERO-Check questionnaire assesses each variable from a unique item. To extend the validity of these preliminary results, we conceive future research contemplating longitudinal designs and alternative measures of the constructs.

Relevance to the Congress Theme:

For scholars, this study extends the prior research in ageing literature, opening new research questions that point to the effect of social context variables and team age composition in performance across lifespan. For HR practitioners in the healthcare sector, it highlights the importance of considering age composition of teams and social resources when implementing HR programs and policies oriented to improve performance.

Relevant UN SDGs:

This research might be framed in the 8th objective of the 2030 agenda (decent work and economic growth) as it generates knowledge about individuals and teams' performance considering lifespan related needs and age diversity within teams.

Keywords: Job social resources, team diversity, performance

Symposium S110

Motivation to Lead Across Honor and Dignity Cultures

Nevra Cem Ersoy, İzmir University of Economics

science_practice

Motivation to lead (MTL; Chan & Drasgow, 2001) is an individual difference variable that signifies the energizing factors behind becoming a leader. Three papers in this symposium focus on the antecedents and outcomes of MTL among employees across different cultures such as Netherlands, Turkey, Germany and Venezuela. Janssen and Born examined the link between dark personality traits and motivation to lead in Dutch leaders. This study contributes to the distal proximal model of leadership by suggesting that MTL mediates the relationship between dark personality traits and leadership effectiveness. Second paper in the symposium examines the antecedents and outcomes of motivation to lead. Cem Ersoy and Peker examined the interaction of implicit self-theories and culture of honor, which was conceptualized as an individual differences variable, as an antecedent of MTL. They also showed the mediating effect of MTL on the relationship between implicit self-theories and leader emergence. The last paper empirically integrates data on the motivation to lead in employee samples from Germany, Turkey, Venezuela, and the Netherlands to test the moderating effect of culture on the relationship between personality and motivation to lead, and in its turn, the relationship with leader emergence. The discussant Birgit Schnys is a distinguished professor at NEOMA Business School, Paris. Her research focuses on leadership specifically the link between leadership and dark personality traits and implicit personality theory. Because her research field has a lot in common with the congress theme, we believe she will have a great of contribution.

Relevance. The congress theme is “The Future is Now: the changing world of work”. Our symposium is very relevant to the congress theme because leaders have important roles in solving urgent issues such as economic crisis, pandemics, migration, violence against women. Leaders not only should promote organizations, but they also have social responsibilities towards our changing world. It is therefore important to investigate the factors that motivate people to lead. The symposium highlights the importance of the motivation to take up leadership roles despite personal costs or from a sense of responsibility for selecting and training effective leaders.

Research and Practical Implications. The symposium has important research and practical implications. Presentations in the symposium not only focuses on personality traits but also culture of honor endorsement in predicting who becomes a leader and who functions as leaders effectively. These results have important implications because in order to meet the challenges of our world, organizations require people who will become effective leaders. It is also important to understand who is motivated to emerge as a leader in honor and dignity cultures, which have not been investigated before.

Conclusion. The future is now! Leaders in organizations should be eager to deal with issues of sustainability, economic crisis, social change, and pandemics. This is only possible by leaders who are eager to exceed requirements. To this end, what drives people to want to become a leader across cultures and how personality relates to employees’ motivations are important aspects that the symposium will deal with.

Paper 1

The Relationship Between Dark Personality Traits and Motivation To Lead In Dutch Leaders

Diddo Van Zand; Marise Ph Born, Erasmus University Rotterdam; Nadine Janssen, Department of Psychology, Education, and Child Studies, Erasmus University Rotterdam

Theoretical background. Meta-analyses have shown that extraversion, emotional stability and openness to experience predict leadership emergence (Ensari et al., 2011). What, however, remained uncertain is the role of personality in becoming an effective leader. In the distal-proximal model of motivation and leadership (Badura et al., 2020), Motivation to Lead (MTL) is proposed as the mechanism through which personality traits affect leadership effectiveness. MTL forms the drive to fulfill the requirements of the leader role effectively (Chan & Drasgow, 2001). Chan and Drasgow (2001) recognized three types of motivation to lead: affective-identity (being enthusiastic about the role of leader), social-normative (having a sense of duty) and non-calculative MTL (willing to lead despite personal costs). Earlier meta-analytic findings, using primarily studies which focused on big five traits as antecedents of leadership effectiveness, indeed supported that MTL mediates the relationship between personality traits, leadership behaviors and leadership effectiveness. The question remains how dark triad personality traits fit in the distal-proximal model of motivation and leadership.

Individuals with dark personalities are naturally drawn to positions of power and social dominance, that is leadership positions (Furtner et al., 2017). Although dark leadership is related to maladaptive work behavior and negative organizational outcomes, not all studies found negative effects of narcissistic and machiavellianistic traits in leaders (cf Furtner et al., 2017). Psychopathy in leaders, has the strongest association with negative organizational outcomes (Boddy, 2015; Mathieu et al., 2014). Considering that dark personality traits of leaders may harm employees and organizations, we need to better understand how dark personality traits affect leadership by examining mediators of this relationship. In the current study we aim to contribute to the distal-proximal modeling of the personality traits-leadership effectiveness relationship and the nomological network of MTL by examining 1) MTL as a mediator and 2) dark personality traits as antecedents of MTL, leadership behavior and leadership effectiveness in a sample of Dutch leaders.

Methodology. Members of the Dutch Association of Supervisory directors and Directors were asked to complete the adaptive Work-related Personality Inventory (Pelt et al., 2018), the Short Dark triad (Jones & Paulhus, 2014), the MTL questionnaire (Chan & Drasgow, 2001) and the leadership styles and effectiveness scales of the Multifactor Leadership Questionnaire (Bass & Avolio, 1990).

Results. Data collection (estimated n =400) will continue until February 2023 . Preliminary regression analyses (n =138) showed that narcissism positively predicted affective-identity MTL, while machiavellianism and psychopathy were negative predictors of non-calculative MTL. All three MTL types positively predicted transformational leadership behaviors. Only non-calculative MTL had a (negative) association with transactional leadership. The laissez-faire style was negatively predicted by non-calculative and affective-identity motivation and positively predicted by social-normative motivation. Leadership effectiveness was strongly related to a transformational leadership style.

Limitations. The sample size excluded the possibility to test the full proposed mediation model by means of structural equation modeling. Additional data collection should be able to address this

limitation. Leadership effectiveness was measured using a self-report questionnaire. In a follow-up study we address this by including a peer-rating of leadership effectiveness.

Conclusions. These preliminary results contribute to the distal proximal model of leadership by suggesting that MTL mediates the relationship between dark personality traits and leadership effectiveness. As proposed by Judge and colleagues (2009) narcissism is positively related to intrinsic motivation. Machiavellianism and psychopathy are associated with an extrinsic motivation to attain leadership roles. MTL is related to transformational and transactional leadership behaviors and subsequently to leadership effectiveness.

Relevance. This study is relevant for the congress theme since the focus on leaders' dark traits, motivation and effective leadership in a real-world sample of leaders expands the distal proximal model of leadership effectiveness. The results suggest that dark personality traits are related to a self-serving interest in leadership roles. To meet the challenges of our time, organizations require talented people who will become effective leaders that ‘go the extra mile’ to promote employee welfare while improving sustainability and maintaining economic growth. These findings highlight the importance of the motivation to take up leadership roles despite personal costs or from a sense of responsibility for recruitment and development of effective leaders.

Keywords: Motivation to lead, Dark triad, Leadership effectiveness

Paper 2

Implicit Leadership Theory and Motivation to Lead as Predictors of Leader Emergence: The Role of Culture of Honor

Nevra Cem Ersoy, Izmir University of Economics; Mehmet Peker, Ege University

Research goals

This study aimed to examine the mediating role of motivation to lead in the relationship between implicit self-theories and leader emergence among Turkish employees. The study focuses on the culture of honor as some dimensions of implicit leadership theories are highly relevant to the culture of honor. Therefore, the moderating role of honor culture on the relationship between implicit leadership theories and leader emergence was investigated.

Theoretical Background

Leaders are crucial for organizations. Leaders vary from each other in terms of their motivation to attain and expend effort to accomplish leader role requirements. Motivation to lead (MTL; Chan & Drasgow, 2001) is an individual difference variable that signifies the energizing factors behind becoming a leader. It has three dimensions: affective MTL is the degree to which one enjoys leadership roles, social-normative MTL describes whether one perceives leadership role as a duty, and non-calculative MTL which one sees leadership opportunities positively. Although MTL is important, there is a scarcity of research that aims to identify the antecedents and outcomes of MTL (Badura et al., 2020). This research aims to fill this gap. Badura et al. (2019) proposed leader emergence as one of the outcomes of MTL. Leader emergence refers to being viewed as a leader by in leaderless groups (Judge et al., 2002). In a meta-analytic review, affective motivation to lead was shown to be the strongest predictor of leader emergence (Badura et al, 2019). Being perceived as leaderlike is highly related to behaving in line with the leader prototypes in society (Leaper & Ayres, 2007). These cognitive representations of leaders are conceptualized in implicit leadership theory (ILT). According to ILT, leaders are characterized by dimensions such as masculinity, strength, tyranny, creativity, dedication, intelligence, charisma, and sensitivity (Offerman et al., 1994). Emerging research has started to investigate people's cognitive representations about self concerning leadership qualities. Perceptions of a leader, as well as perceptions about the self (called implicit self-theories; IST), are deemed important for important leadership attitudes such as leader self-efficacy and motivation to lead (Guillén et al., 2015; Scyhns et al., 2020). In line with this research stream, this study focused on the role of ISTs and hypothesized that they are related to leader emergence, particularly through affective MTL (cf. Badura et al). As earlier research has showed that ILTs are influenced by culture (Lord et al., 2020),we argue that ILTs interact with cultural factors. Turkey is a culture of honor (Uskul et al., 2010), in which social reputation is very important (Pitt-Rivers, 1966). Characteristics associated with manhood namely braveness and toughness are salient in the honor cultures (Nisbett & Cohen, 1996). Some dimensions of ISTs, namely strength, tyranny, masculinity, sensitivity, and creativity are particularly relevant for the culture of honor. Therefore, we expected honor norm endorsement to moderate the relationship between implicit self-theories and affective motivation to lead, such that this relationship is stronger when the norm is endorsed more strongly

Design/Methodology

A cross-sectional study was conducted with 210 white-collar employees from Turkey (M age = 35.07, SD = 10.09) via survey software Qualtrics. Participant filled out a questionnaire form containing scales of implicit self-theory adapted from Offerman and Coats, (2018) as in Schyns et al. (2020; i.e., sensitivity, α = .89, tyranny, α = .87, strength α = .84, creativity α = .86, masculinity, α = .86), honor norm endorsement (IJzerman & Cohen, 2011; α = .86), affective motivation to lead (Chan & Drasgow, 2001; α = .93), and leader emergence (α. = 74).

Results

The analyses tested the moderating effect of honor norm endorsement on the mediated relationship between five IST dimensions and leader emergence through affective MTL. The results revealed honor norm endorsement moderates the relationship between three IST dimensions (i.e., strength, creativity, and masculinity) and leader emergence, as mediated through affective MTL.

Limitations and Future Research: Turkey representing honor culture was investigated in this research. Future studies can include countries that represent the cultures of face and dignity. This study has a cross-sectional design; future studies can measure the culture of honor with vignettes. Leader effectiveness can be predicted as the dependent variable in future studies because it may be expected that the predictors of leader emergence and leader effectivenesswill differ.

Relevance. This research highlights the importance of salient cultural characteristics in honor cultures that makes people want to be a leader and emerge as a leader. Having implicit self-views that are in line with the culture one endorses increases the likelihood of affective motivation to lead. Affective motivation to lead in turn leads to leader emergence. A research implications is that it can be predicted who becomes leader in an honor culture. Organizations may use this information in promoting employees to leadership positions.

Originality/Value: This research investigates predictors of leader emergence in an honor culture such as Turkey. It is the first research that integrates implicit self-theories with affective motivation to lead in predicting who emerges as leader. It is also the first study that investigates norm endorsement of honor as moderator in the relationship between employees' leadership perceptions about the self andleadership motivation.

Intended audience

Both academics and practitioners

Paper 3

Motivation to lead, its antecedents and its relationship to leadership emergence: A comparison across honor and dignity cultures

Marise Ph Born, Erasmus University Rotterdam, The Netherlands; Mehmet Peker, Ege University; Nevra Cem Ersoy, Izmir University of Economics

Theoretical background and research goals

This study empirically integrates data on the motivation to lead in employee samples from Germany, Turkey, Venezuela, and the Netherlands to test the moderating effect of culture on the relationship between personality and motivation to lead, and in its turn, the relationship with leader emergence.

Starting from earlier work by Chan and Drasgow (2001), who demonstrated that personality characteristics relate to leadership outcomes via motivation to lead, this study answers the call by Badura et al. (2020) to investigate whether such relations are moderated by national culture and whether apart from the traditional Big Five, other antecedents of motivation to lead can be identified. To this end, we used the framework of Leung and Cohen (2011), who proposed a cultural framework distinguishing between dignity, face, and honor cultures. Leung and Cohen state that cultures differ from each other in terms of which of these three is the most important source of self-worth. In honor cultures, such as Turkey and Venezuela, self-worth is driven by peoples' reputations and what others think of them (Aslani et al., 2016). Western societies, such as the UK and Germany, can be described as dignity cultures, in which one's self-worth tends to be dependent on intrinsic assessments of oneself in terms of, for instance, one's achievements. Face cultures' focus, such as in China, is on the respectability of persons by virtue of their position in a social hierarchy. In the present study, we included Turkey and Venezuela as representatives of high honor cultures, and Germany and the Netherlands as representative of high dignity culture (note that the present study will not include face cultures). Furthermore, we included the Dark Triad traits next to the Big Five traits as potentially relevant antecedents of motivation to lead.

In general, we expect that culture will moderate the relationship between personality traits and motivation to lead. Our expectations, more specifically, relate to one or more of the three components of motivation to lead, namely affective identity, social-normative, and non-calculative motivation to lead (Chan & Drasgow, 2001). Based on the logics of a dignity culture, we expect that the relationship between extraversion, narcissism, and psychopathy on the one hand, and affective-identity motivation to lead on the other hand, is stronger for individuals from a high dignity culture. Grounded in the logics of honor culture, we expect that the relationship between conscientiousness and narcissism on the one hand, and socio-normative motivation to lead on the other hand, is stronger for individuals from a high honor culture. Other expectations include that honor versus dignity culture will not affect relationships with non-calculative motivation to lead, which component we believe is more relevant to high face cultures.

In all samples, we also assessed individual level measures of honor and dignity culture, leader emergence as an outcome variable, and several demographics.

Methodology

This study integrates the samples from the study reported by Ersoy et al., with employee sample from Germany, the Netherlands and Venezuela. Scales included in these samples underwent a

translation-backtranslation procedures according to the International Test Commission guidelines. Qualtrics-based survey results from all four countries are analyzed, after matching samples in terms of demographics and checking for scale reliabilities and for invariance. Comparing score means across countries is avoided unless scale invariance allows for this. The aimed sample size ($N > 150$ per country) has been reached for Turkey and is almost attained in the other countries.

Expected Results

We expect confirmation of our hypotheses by means of hierarchical regression analyses. Presently, however, data collection has not as yet been fully completed in Germany and the Netherlands.

Limitations

Sample sizes will not be large enough for structural equation modeling. For the present study a face culture could not yet be included (cf. Leung and Cohen, 2011).

Expected conclusions

Cross-cultural research traditionally uses Hofstede's (2001) culture dimensions to compare findings on psychological phenomena across countries. We believe that Leung and Cohen's framework of honor, dignity and face cultures, instead, conceptually is a better fit with the motivation to lead theme, expecting that our results will confirm this belief. We foresee that by including dark triad traits, our results will confirm Badura et al.'s (2020) call to focus on more than the traditional antecedents of motivation to lead.

Relevance

This paper ties into the issue what drives people to want to become a leader across cultures and how this is affected by the way personality relates to employees' motivations to lead. Leadership potential is urgent in the immensely changing world we are living in among employees coming from many different cultural backgrounds.

Keywords: motivation to lead, honor and dignity cultures, dark triad

Symposium S111

Psychosocial work demands, salutogenic resources and interventions, and their effects on employee health and well-being

Conny Herbert Antoni, Trier University

science_practice

What will be covered and why. In recent years mental illness has caused increasing numbers of sick leave and forced early retirement. Research shows clear evidence that psychosocial work demands, such as increasing work intensity, excessive time pressure, long and irregular working hours, conflicting demands, and lack of job resources such as appreciation from supervisors or colleagues or job control, impair employee well-being and contribute over time to the development physical and mental illness. Therefore, employers have to systematically assess and reduce psychosocial risks and any other kind of risks for health and safety in the workplace as far as possible. Although there has been much research in recent years, there is still few knowledge about how to assess the risk probability of psychosocial hazards, how companies actually deal with and manage risks, and the relevance of salutogenic concepts and intervention approaches. This symposium will contribute to bridge this gap.

Study 1 compares the validity of different risk estimators as metrices for psychosocial hazards regarding their power in predicting recorded sick leave on an organizational level. For this purpose, the data of a psychosocial risk analysis and recorded sick leave of more than N=7.000 workers within 75-95 working areas of the German Steel Industry are analyzed. Suggestions are derived which risk metrices can be best applied in organizational settings.

Study 2 provides evidence for the buffering effects of the work-related sense of coherence (Work SoC), in the relationship of effort reward imbalance (ERI,) overcommitment and emotional exhaustion. Based on the analysis of an online survey of 1096 employees of a state agency in Germany the study shows that Work SoC is an influential construct for health promotion in the working context and discusses interaction effects between ERI, overcommitment, WorkSoc, and emotional exhaustion.

Study 3 is a case study and analyzes based on a salutogenic process model the quantitative and qualitative results of a survey and 98 workshops the psychosocial risk assessment and management in a large organization. It shows how salutogenic actions can be meaningfully derived and how this can be done with the participation of the entire workforce and respective supervisors.

The discussant will discuss the concepts and approaches to psychosocial risk assessment and the use of different risk estimators as base for risk management and intervention. In particular the discussant will reflect on how artificial intelligence might be used in perspective to assess work load and psychosocial risks.

Relevance to the Congress Theme. In line with the congress theme “The Future is Now: the changing world of work” our symposium focuses on the challenging psychosocial job demands today’s employees, management and organizations face in volatile, uncertain, complex and ambiguous markets and environments.

Research/Practical Implications. With respect to research we will contribute to the development of risk estimators predicting employee health and salutogenic models for risk assessment and intervention. From a practical perspective, we highlight how organizations and team leaders can

assess psychosocial risks, derive and implement interventions for improving both employee well-being and health.

Overall conclusions. Psychosocial risks need to be assessed with valid risk estimators in order to develop participatory effective autogenetic preventive interventions and to improve employee well-being and health.

discussant: Vera Hagemann , University of Bremen

Keywords: psychosocial risk assessment, sense of work coherence, effort-reward imbalance

Paper 1

An Organizational Level Approach for Evaluating Risk Metrices of Psychosocial Hazards by Recorded Sick Leave

Yannick Metzler, Leibniz Research Centre for Working Environment and Human Factors, Department of Ergonomics; Andreas Mueller & Yacine Taibi | University of Duisburg-Essen, Psychology, Work & Organizational Psychology

Research goals and why the work was worth doing

Organizations are obliged to integrate psychosocial stressors as hazards into general risk assessment by various statutory amendments throughout the European Union. Numerous theoretical models, associated instruments, as well as methods and procedures, are available to both assess and evaluate psychosocial hazards. Such variety inevitably impacts subsequent risk mitigation, the crucial step in which the transition from analysis to action is performed, to an unknown extent. Hence, precisely estimating the risk probability of psychosocial hazards remains poorly understood and is often linked to the instrument applied for identification: Measures of location or frequency, traffic-light systems, multivariate procedures, exposure matrices, or risk equations are usually cited in this respect. To support researchers and practitioners with this issue, we aim to compare the validity of different risk estimators as metrices for psychosocial hazards regarding their power in predicting recorded sick leave on an organizational level.

Theoretical background

Generally, combating hazards at work comprises the three steps of risk identification, evaluation, and mitigation, altogether known as the process of risk assessment. Psychosocial hazards are factors that potentially affect psychological and physical well-being of the workforce, arising predominantly out of poor work design, organization, or management. The adverse impact of such factors has already been evidenced in numerous studies concerning numerous outcomes. The multitude of different instruments available for both psychosocial hazard evaluation has already been shown to result in differing evaluations of risk. Understanding how especially risk evaluation can be conducted in a more standardized way is thereby crucial to improve the process of risk assessment and to, consequently, comply as best as possible to the overall goal of protecting and promoting health and well-being of the workforce.

Design & Methodology

The sample consists of more than N =7.000 workers of the German Steel Industry, nested within 75-95 working areas. Grounded on the multifactorial hazard model of the German version of the Copenhagen Psychosocial Questionnaire, additional covariates assessed are gender, age, fixed-term work, level of seniority, and experience on the job. Outcomes are recorded sick leave by organizational unit at the time of editing the questionnaire and on several following time points: +1, +3, +6 and +12 months afterwards. The metrices conceived as predictors are (1) a standard linear regression model, (2) a threshold approach based on available references of a job-exposure matrice, and (3) an approach based on standard risk formula conceiving risk as a product of frequency of a hazard and its level of severity. Including available self-reported data on sick leave and presenteeism is pending and needs to be checked. Statistical preconditions were checked by interrater agreement statistics for most of the organizational units. Both figures of rWG (within group agreement coefficient) range from .5 - .9 and ICC2 (reliability of group means) for each scale range between .91

- .98, thus showing satisfying result. The metrices are compared regarding their potential in explaining variance in recorded sick leave by organizational unit.

Results obtained & expected

Initial findings indicate an overall low to moderate relation of all metrices with recorded sick leave. Stronger associations are consistently found at T0 and T12. In addition, the approach referring to the standard risk formula seems to demonstrate a more robust and greater predictive power compared to the other metrices. Final results will be obtained at the time of the conference.

Limitations

Albeit the data being nested, conducting classical multilevel analysis was not possible because the outcome data is only available at the group level. In addition, no job specific approach was possible because the group level consists of broader clusters of working areas. Besides the three metrices we apply in our study, there are more potential risk metrices that could be of interest for comparison. The inherent linear approch furthermore might disregard often cited U-shaped or other non-linear relationships. Finally, the outcome recorded sick leave could not be further distinguished to attain information on possible causes, also outside work.

Conclusions

Our findings suggest that more attention should be paid to evaluating risks more precisley. Furthermore, a stronger focus is indicated on how working conditions can be conceived as an outcome in work re-design compared to traditional interventions research. Regarding the practical scope, the results can indicate which risk metrices can be best applied in organizational settings. In addition, we enable future work design research to better understand the mechanisms that result in better risk evaluation and improved approaches to workplace interventions.

Relevance to the Congress Theme. Elements of psychological work analysis and work design have found their way into practice in the scope of occupational health & safety. Shifts in occupational risks always correspond to the constant changing nature of work. Therefore, this research provides an approach on how risk evaluation of psychosocial hazards as a rising risk factor of future work can be best performed.

Relevant UN SDGs. Our research adresses both the goals of promoting health and well-being, and decent work, by providing a view on the crucial phase of risk evaluation of psychosocial hazards. This step is where the transition from analysis to action is performed, aiming to best comply with the overall goal of promoting health and safety of the workforce.

Keywords: Psychosocial Hazards, risk evaluation, sick leave

Paper 2

Interaction Effects between Effort-Reward-Imbalance and Sense of Work Coherence on Emotional Exhaustion

Conny Herbert Antoni & Mona Rynek | Trier University

Research goals and why the work was worth doing. An imbalance between efforts and rewards (ERI) is stressful and has far-reaching negative consequences for employees' health and well-being (e.g. emotional exhaustion, distress, fatigue), which is increased by overcommitment. During the last years, the sense of work coherence (Work SoC), with the aspects understandability, manageability and meaningfulness of work, has been derived from the psychological health construct sense of coherence of the salutogenic model. Studies have showen that it offers high potential to explain why people remain healthy despite adverse conditions at work beyond the general sense of coherence. In this study, we aim to provide evidence of the promising buffering effects of Work SoC in the relationship of ERI and emotional exhaustion and to highlight that Work SoC is an influential construct for health promotion in the working context.

Theoretical Backround. Research on the ERI model has addressed a diverse range of negative health-related consequences of ERI. However, the investigation of possible moderators of this relationship has been primarily limited to overcommitment as a person characteristic. Studies have shown that overcommitment can potentiate the negative effects of ERI. In contrast, only few studies have examined possible resources that buffer the negative effects of ERI on health-related outcomes, such as resilience or emotional intelligence.

Research has shown that Work SoC is a crucial resource for promoting health and well-being, which can be influenced also by work design, and used for buffering the negative effects of stressors in the working context. we assume it as a resources that can buffer the negative effects of ERI on health-related outcomes. So far neither the general sense of coherence nor WorkSoc has yet been considered as a possible moderator of the relation between ERI and health outcomes, although there are a few studies indicating positive effects of a general sense of coherence and negative effects of ERI on health-related outcomes.

In an online survey study, we investigate Work SoC as a possible moderator of the relationship between ERI and emotional exhaustion, in addition to overcommitment. Effort, reward, emotional exhaustion, overcommitment, and Work SoC were assessed by an online questionnaire. 1096 employees of a state agency in Germany participated in the survey.

Results. The results of the multiple hierarchical moderated regression analyses indicate that ERI and overcommitment were positively associated with high levels of employees' emotional exhaustion. Work SoC was negatively related emotional exhaustion. We also found significant positive two-way interaction effect of ERI x overcommitment and a three-way interaction effect ERI x overcommitment x Work SoC (on emotional exhaustion. All results are statistically significant at $p < .05$, and within 95% bootstrapping confidence interval not including zero. Results of the three-way interaction indicate that if overcommitment is low the association between ERI and emotional exhaustion is stronger if Work SoC is low compared to average or high Work SoC, supporting the assumed buffering effect. If overcommitment is high and WorkSoc is low there appears to be no association between ERI and emotional exhaustion due to ceiling effects, while for average and high

WorkSoc there is a strong association between ERI and emotional exhaustion with higer levels of exhaustion for lower levels WorkSoc.

Limitations. One limitation of this study is the cross-sectional design. We cannot conclude the causality of relations. However, ERI and its associations with mental health are well-proven and have already been analyzed longitudinally. Hence, we are confident about having tested the relevant relationships.

Conclusion. We did find some evidence for the expected buffering effect of Work SoC on the relationship between ERI and emotional exhaustion, particularly when overcommitment is low. When overcommitment is high Work SoC has only a limited buffering effect. Nevertheless, compared to the personal rsik factor overcommitment, Work SoC appears to be a resource which can be strengthened also by work design and used to prevent emotional exhaustion even in situations of effort rewad imbalance. Therefore, this study provides evidence that Work SoC is a promising construct for health promotion.

Relevance to the Congress Theme. Artificial intelligence, automation, crisis like COVID-19 change our working world. To make employees able to cope with these new challenges in a resilient manner and to develop new solutions to the problems, today and in the future, it is important to maintain and promote health of employees. Our study contributes to this topic by examining Work SoC as a promising construct for health promotion in the workplace.

Relevant UN SDGs . This study contributes to the Un SDGs No 3 and addresses Work SoC as a possible starting point for promoting employee health.

Keywords: sense of work coherence, effort-reward imbalance, overcommitment

Paper 3

From risk, to solution, to action – Best practice results of an analysis of workshops to develop salutogenic actions against psychological risks

Benedikt Graf, Trier University; Jonas Gerstmann, Blue Walnut GmbH, Berlin

Research goals. Too often, organizations fail to derive and implement meaningful, salutogenic actions (measures to maintain and increase the health of employees) from survey results of psychological risk assessments. This research addresses participatory, salutogenic employee workshops that create a collaborative understanding of problems, generate solutions to counteract risks, and ultimately create a sense of responsibility for change among employees, based on a quantitative and qualitative study design including the results of 98 workshops.

Theoretical background. Recent literature underpins the importance to include employees in the process of psychological risk assessments not only by survey them, but also to let them participate in finding solutions to identified risks. We use a salutogenic process model that identifies the need to include all employees in finding salutogenic solutions to psychological risks at the workplace. Moreover, literature from the last decades confirms the high relevance of employee participation for enabling change processes.

Method . Psychological risks at the workplace were estimated according to relative measures (questionnaire) and a participatory evaluation in the workshop. We assessed quantitative data from a large organization in Germany (N O = 1150) from the production sector covering many different departments and task profiles (production, logistics, development, etc.), using a systemic salutogene organization analysis tool for psychosocial risk assement . Thereafter, we conducted salutogenic workshops (90 min) in all surveyed departments to reflect the results, and to identify and record joint solution ideas for existing risks. After the salutogenic workshops with employees, the joint solution ideas were then taken to the respective supervisors to derive salutogenic actions from those ideas.

Results. Overall, 326 risk mentions were discussed in N W = 98 workshops based on 56 departments and associated supervisors, and most risk types were discussed around quantitative overload (42), development opportunities (36) appreciation (30), and time pressure (29). This matches the overall results of the psychological risk assessment in the organization, where quantitative overload (3.44), appreciation (3.60), development opportunities (3.46), and time pressure (3.35) were rated as among the most stressful risk types, all assessed on a scale ranging from 1 (high risk) to 6 (low risk). Qualitative results show that the overall level of satisfaction with the workshops was very high and that across all departments the results were rated as fitting.

199 salutogenic actions were formulated, of which 48.99 % have an estimated short implementation period of only 0-3 months. Only 9.81 % of the actions have an estimated implementation period of longer than nine months. 21.74 % are localized at a merely organizational level, 13.83 % at a mere staff level, and only 3.39 % at a merely technical level, the rest related to more than one area.

Limitations. No follow-up survey is planned, so no effectiveness can be determined regarding the implementation of the salutogenic actions. However, implementation is likely, as specific goal setting is more likely to be realized, and in general, effectiveness of implemented actions need to be assessed in the psychological risk assessment. In contact with the organization, the first actions have already been implemented.

Conclusions – research and or practical implications. This approach proved highly effective and helpful in assessing and evaluating psychological risks at the workplace. Moreover, this research shows a best practice example of how salutogenic actions can be meaningfully derived from a survey in a large organization, and how this can be done with the participation of the entire workforce. Thus, every employee is involved in the salutogenic goal process, and a responsibility of health-promoting actions is borne by the entire organization.

Relevance to the Congress Theme. The future of the working world will be characterized by increasing complexity and high absenteeism due to mental illness predicted by the WHO. This study shows practical solutions that result from research and can counteract exactly these developments.

Relevant UN SDGs. This research addresses health and well-being by providing useful and practical guidance for the successful implementation of psychological risk assessment processes that promote employee mental health. Furthermore, a successful counteraction against psychological risks leads to strong institutions as well as decent work and economic growth.

Disclosure. The data of the workshops and psychological risk assessment were generated via a commercial assignment by Blue Walnut GmbH and Benedikt Graf.

Keywords: Salutogenic workshops, action derivation, psychological risk assessment

Symposium S109

Safety culture and safety performance (I)

Mario Martínez-Córcoles & Francisco J. Gracia | IDOCAL-University of Valencia (Spain)

science_practice

What will be covered and why (including the contribution of any discussant)

There are some industries where process or operational safety is critical. Nuclear power, air traffic management, healthcare or the chemical industry are some examples. Since the late 80s, all hazard industries have adopted safety culture as their banner in the efforts to promote safety in their installations and operations. Safety culture and safety performance have been considerably studied over the last two decades, as they are main triggers of safety outcomes. However, despite the existing numerous studies, safety culture and safety performance are still somewhat controversial, complex, and ambiguous concepts that need further theoretical and empirical elaboration. The present symposium aims to provide new findings in that direction.

More specifically, Gracia et al.'s contribution proposes a new model of safety performance and develops and validates an instrument for its operationalization, the five-safety performance questionnaire (5-SPQ) that is empirically tested in a sample of 555 employees from a nuclear power plant.

Mezentseva et al.'s contribution explores a moderated-mediation model of antecedents of mindful organising in an Air Traffic Management company. Mindful organizing is the collective ability of a team or organization to anticipate unexpected events and contain them and be resilient once triggered. In their model, they proposed that safety climate mediates the relationship between empowering leadership and mindful organizing and that safety culture moderates the effect of empowering leadership on safety climate.

Two other contributions are qualitative studies in hospitals. Since 2000, there has been a call to understand the many interacting factors across entire healthcare systems which can affect healthcare safety performance, to improve patient outcomes. In this sense, Poots et al. investigate the role of telephone triage technology on safety performance. Despite widespread adoption and use, telephone triage services have been implicated in patient death and malpractice claims, and research investigating their safety is lacking. During the COVID-19 pandemic, telephone triage was adopted rapidly to help curb its spread, by offering an alternative to face-to-face healthcare and the use of these services is set to remain at a high level post-pandemic. Corrigan et al.'s contribution aim to analyse and understand the problem of retained foreign object (RFOs) in surgical and maternity settings and develop hospital-specific interventions. Widely recognized as a preventable event, RFOs continue to remain a current patient safety concern.

Finally, Teperi and Juveni use Systemic Human Factors (HF) and Systems Intelligence (SI) to evaluate the current state and areas in need of development through human factor implementation in the chemical industry. In previous studies, the HF Tool has efficiently improved safety thinking and procedures by considering human contribution in a holistic, participative, positive, and solution-based manner. However, the use of the HF Tool has not yet been researched in the chemical industry nor combined with other lines of research.

Relevance to the Congress Theme

A constantly changing work environment poses a great threat and challenge for all those organizations that cannot afford to fail and where safety is critical. In our symposium we have a wide representation of these kind of organizations (nuclear power plants, air traffic management centers, hospitals, and chemical plants).

Research/Practical Implications

This symposium provides novel contributions to the field of safety culture and safety performance in organizations. Particularly, it will contribute to existing research in several ways: 1) new conceptualization and operationalization of safety performance, 2) widening the nomological network of predictors of mindful organizing (an indicator of team safety performance), by clarifying the role of empowering leadership, safety culture and safety climate, 3) developing preventive intervention strategies to improve patient safety culture and patient safety outcomes, and 4) widening the knowledge and understanding of human factor in the chemical industry, and helping supervisors and managers to lead safety culture.

Overall conclusions

This symposium advances scientific knowledge on safety culture and safety performance in high-risk industries. These contributions can be used by managers to improve safety management in their organizations with a higher understanding of the human factor and the set of individual, team and organizational variables that contributes to the development of a strong safety culture and enhances employees' safety performance.

Paper 1

Testing the validity of the IAEA's Harmonized Model of Safety Culture

Mario Martínez-Córcoles, Diana Seitkanova, Inmaculada Silla & Francisco J. Gracia | IDOCAL. University of Valencia

Research goals and why the work was worth doing

The Harmonized Model of Safety Culture created by the International Atomic Energy Agency (2020) is a new guideline made so that nuclear organizations all over the world can understand, assess and enhance their safety culture. To ensure a rigorous and correct application of this model in nuclear organizations, it is necessary to test its validity. Unfortunately, as far as we know, the Harmonized Model of Safety Culture has not been validated yet. In this study we aim to test its validity.

Theoretical background

Over the last years, nuclear organizations had been experiencing challenges in meeting the requirements of different safety culture models which were different in structure (e.g., WANO, IAEA, or INPO). This can create unnecessary confusion and uncertainty in nuclear organizations to meet agencies and regulators' expectations. Specifically, professionals may have doubts about what aspects they should include to assess safety culture, or they should consider to enhance safety culture. The Harmonized Safety Culture Model IAEA aims to harmonize those different models, and focus on the gaps between existing frameworks. The model provides a description of 43 exemplary behaviors (indicators of a healthy safety culture), which are encompassed in 10 attributes.

Methodology

Our sample was composed of 555 employees from two Spanish nuclear facilities and their headquarters. Data was collected in 2022.

Results obtained

Reliability values were satisfactory for the ten subscales. A Confirmatory Factor Analyses (CFA) was performed to test the ten-factor model proposed by the IAEA This model provided an excellent fit ($\chi 2 = 1483.41$, $df = 815$, $p < .01$; RMSEA = .039; CFI = .997; NNFI = .997), and all the estimated parameters were statistically significant ($p < .05$). Results indicated that each item saturated in its corresponding scale. However, results on the discriminant validity of the ten dimensions were not satisfactory. The correlation coefficients among the ten dimensions of the IAEA model were extremely high, ranging most of them between .90 and 1. According to Kline (2005) discriminant validity can be established when inter-factor correlations are below .85.

The large correlations among the ten dimensions of the IAEA's model suggested that a one-factor model could be more suitable to represent the IAEA's attributes. To evaluate this possibility, we fit a one-factor model and compared the results to the ten-factor model. The single-factor model provided an excellent fit as well ($\chi 2 = 3082,17$, $df= 860$, $p < .01$; RMSEA = .070; CFI = .990; NNFI = .989). As CFAs results showed negligible differences between both factorial structures, we decided to explore the internal structure of the IAEA model without the restrictions imposed by a confirmatory analysis. Therefore, we run a PCA for the 43-item safety culture model, which produced three factors with eigenvalues greater than 1 (Kaiser Criterion) that accounted for 66,13% of the total variance. The way the attributes were grouped by the PCA was very different from the IAEA's proposal. First,

59,80% of the total variance explained was accounted for by the first factor, and the scree plot clearly suggested retaining only one factor. Second, when trying to label the three factors that met the Kaiser rule, researchers found difficulties in conceptually interpreting each of these factors. Third, some of the items cross-loaded on more than one factor (i.e. crossloadings ≥.30). Later analyses could not support any alternative multidimensional structure either.

Limitations

According to the specifications of the Harmonized Model of Safety Culture "the model is not a behavioral code or checklist but represents overarching principles that provide traits and attributes that are present in organizations with a healthy culture for safety" (IAEA, 2020). A number of these attributes are double and triple barreled, and as such, respondents can agree with one part of the item but perhaps not with the other.

Conclusions

Our results failed to clearly support the ten-factor dimensionality of the IAEA's model. Results from our analyses could not support any alternative multidimensional structure either, and indicate that the IAEA's model may have a one-dimensional structure instead of the ten dimensions proposed by the IAEA.

This novel safety culture model will be a reference in the global nuclear industry on the next years. As far as we know, this is the first study checking the validity of the IAEA's model. Our results invite to reflect on this model and open the door for its improvement.

Relevance to the Congress Theme

Reliable performance in high hazard organizations is critical for avoiding devastating consequences in the future.

Relevant UN SDGs

Our study contributes to the following UN SDGs: 3, 7, 11 and 13.

Paper 2

A Safety Culture Model and Measure for the UK Nuclear Industry

David Holman, University of Manchester; Nick Shaw, Office for Nuclear Regulation, UK; Lina Siegl, David J. Hugues & Sharon Clarke | University of Manchester

Research goals : Organisational safety culture is critical to support the nuclear industry in maintaining nuclear safety, and for regulators to achieve their regulatory mission. Failings in nuclear safety culture have been highlighted as contributing to a number of high-profile nuclear accidents, such as Three Mile Island, Chernobyl, Davis Besse and Fukushima. The IAEA defines safety culture as that "assembly of characteristics and attitudes in organizations and individuals which establishes that, as an overriding priority, nuclear plant safety issues receive the attention warranted by their significance" (IAEA, 1991). But, despite considerable research and attention within the industry, the construct remains largely intangible and difficult to quantify. This makes it challenging for nuclear dutyholders to develop and maintain their safety culture. Existing guidance for nuclear dutyholders provides a framework for understanding culture for safety (e.g., Harmonised Safety Culture Model published by the IAEA, 2020), but critiques of existing safety culture models point to the lack of conceptual basis, and difficulty in operationalisation (e.g., De Castro et al., 2013). Building on existing work, we aim to develop a novel conceptual model of safety culture for the UK nuclear industry, and operationalise the model to create a quantitative measure of safety culture. Nuclear energy is of increasing importance in a world with greater needs for the production of clean, affordable energy (UN SDG 7), but maintaining the safety of nuclear power remains critical, as well as providing a safe and healthy work environment (UN SDG 3). Our work contributes to theory, research, and practice through the conceptualisation of nuclear safety culture in a UK context, and the development of a quantitative measure for use within the industry.

Theoretical background : Our theorising is based on the Schein (1985) model of organisational culture, with safety as a content-specific aspect of culture, integrated with Reason's (1997) model of 'informed' culture. We conceptualised culture as driven by underlying basic assumptions, but manifest in visible artefacts, behaviours, norms, and attitudes. We focus on the enacted values (as opposed to the espoused values) which actually drive behaviours in practice, and are most strongly predictive of safety performance (e.g., Grote & Kunzler, 2000; De Castro et al., 2017). Existing literature emphasizes the 'conflicts' or 'paradoxes' in efforts to ensure safety in high hazard environments (e.g., Reiman & Rollenhagen, 2012; Casey et al., 2017), for example, the paradox of stability versus flexibility (Grote, 2015). This emphasizes the importance of balancing flexibility (which enables learning and adaptation as the work environment changes) alongside stability and control, and leans into Reason's idea of the 'flexible' culture. Our model draws on these ideas in the conceptualisation of safety culture in nuclear context, which requires both flexibility and stability.

Design / Methodology : We used a mixed-methods approach to the development of the safety culture model, combining a targeted literature review, and semi-structured interviews with 10 subject-matter experts. Reading and re-reading the interview transcriptions led to the identification of themes and subthemes within the data. These were cross-checked with the themes emerging from the literature review. The safety culture model, which emerged through the analysis, has six dimensions, and 16 subdimensions. To develop a questionnaire, based on the conceptual model of safety culture, we conducted 15 interviews with participants from the UK nuclear industry, and undertook a review of previous safety culture surveys to develop an initial pool of items. We used 14 cognitive interviews to refine the items, including think-aloud protocols, to produce a final pool of

items for a questionnaire. The survey will be launched across 7 UK nuclear dutyholders (N = 1000) in November 2022, which will allow us to report our initial findings in May 2023.

Findings : based on the SME interviews and literature review, we developed a model of nuclear safety culture. The model differentiates between the underlying foundations of culture, in terms of policies, processes, training, and communications, which organisations have in place to support the safety culture, and the elements of the culture which reflect the underlying values, beliefs, and attitudes towards safety. The latter comprise dimensions of leadership, immersion, accountability, challenge, reporting, and compliance, where each element lays the foundation of the next. In addition to the model, we will present the findings on the initial validation of the survey to the conference in May 2023.

Limitations : the safety culture model and measure are developed specifically for the UK nuclear industry, and would require further testing to ensure their wider applicability.

Conclusions : We have developed a conceptual model of safety culture for the UK nuclear industry, which is theoretically sound, and has significant practical use. This forms the basis of a quantitative measure to identify elements of safety culture, and support efforts to monitor and improve safety culture.

Paper 3

Leading Mindful Organizing for Safety: A moderated serial mediation model in Air Traffic Control

Diana Seitkanova, Mario Martínez-Córcoles, Francisco J. Gracia & Inmaculada Silla | IDOCAL. University of Valencia

Research goals and why the work was worth doing

This paper examines the moderating effect of promotion of participation and mediating effects of trust in leadership and critical upward communication in a relationship between empowering leadership (EL) and mindful organizing (MO). MO refers to the joint capability to bring rich awareness of discriminatory detail and a capacity for action in teams (Weick et al., 1999).

We hypothesized that promotion of employee participation will moderate the relationship between EL and trust in leadership, whilst trust in leadership and critical upward communication will sequentially mediate the link between EL and MO.We also hypothesized a direct effect of EL on MO, as well as serial mediation of the latter link through trust in leadership and critical upward communication.

The findings of this paper are crucial to the safety research as they contribute to the formation of the theoretical framework of MO, a key predictor of safety operation in HROs including air-traffic control. We've identified a lack of research on the underlying mechanisms of influence between EL and MO, and with this study, we bridge the existing gap in the literature.

Theoretical background

MO has been studied actively in the recent years (Knight, 2004; Vogus & Sutcliffe, 2007; Rerup, 2009; Sutcliffe et al., 2016) and was found to be one of the main predictors of high reliable performance in HROs (Roberts, 1990; Schulman, 1993; Weick et al., 1999; Weick & Sutcliffe, 2007; Sutcliffe et al., 2016). Respectively, empowering leadership behaviors have proven to predict safety-related outcomes in employees, especially in the nuclear field (Martínez-Córcoles et al., 2011; Martínez-Córcoles et al., 2012).

Some studies have shown the predictive power of EL over MO in HROs (Hoy et al., 2006; Sutcliffe et al., 2016; Gracia et al., 2020). In this paper we aim to explore the underlying mechanisms of influence of this relationship.

Our choice of serial mediators is backed by previous research on upward voice and trust in leadership in nuclear power plants (Silla et al., 2020), and our choice of the moderator is based on Renecle et al.'s (2020) study on developing MO in teams through participation climate and perceived feeling of safety in nuclear power plants.

Methodology

73 air-traffic controllers working in six different ATC towers and its headquarters around Spain filled the questionnaires. Moderation, mediation and moderated mediation analyses were performed via PROCESS Macro (Hayes, 2013) to test the three outlined hypotheses.

All questionnaires were used and validated in previous research on safety culture in HROs.

Why this sample? Studying the ATC industry is especially important in the current economic and social context as the need for uncertainty management and higher flexibility has increased. There is a

heightened need to understand the specifics of operation of air-traffic controllers to keep enhancing reliability.

Results

All variables show acceptable to excellent reliability, ranging from Cronbach alphas of 0.71 to 0.97. Main variables have significant and positive relationships ($p<0.01$).

A confirmatory factor analysis has shown a poor fit of the model ($X^2 = 2661$, $df = 1165$, $p < .001$; RMSEA = .13; CFI = .67; TLI = .65). A possible explanation for the bad fit of the model might be a small sample size. Despite the obtained results, we run the analyses as all scales used were validated in previous studies and proven useful in predicting relevant safety outcomes in HRO context.

For serial mediation analysis a significant direct effect of EL on MO was found ($b = .37$, $p = .025$), but no significant indirect effect of empowering leadership on mindful organizing through trust in leadership and critical upward communication was revealed. For the whole path of moderated serial mediation, no significant results were found. However, apart from the hypotheses posed, significant correlations between EL and trust in leadership ($b = .77$, $p<.001$), trust in leadership and critical upward communication ($b = .38$, $p <.001$), as well as EL and upward communication ($b = .61$, $p<001$) were revealed.

Limitations

A small sample size characteristic to the ATC sector, which might decrease statistical power for the analyses.

Conclusions – research and/or practical implications

Empowering Leadership predicts Mindful Organizing in air-traffic controllers, which confirms previous similar findings in HROs. This study has also revealed significant relationships that were not part of the hypotheses. For instance, empowering leadership turned to be a relevant predictor for trust in leadership and critical upward communication, some of the critical variables in the safe operation of HROs. These findings add to similar results from previous studies.

Practically, these results can be used by management boards in HROs looking to foster and increase mindful organizing in order to prevent accidents that might have disastrous human, environmental and economic implications.

Relevance to the Congress Theme

The theme of safety climate and culture is crucial within the context of high-reliability organizations simply because of the high stakes an error might cost. Hence, predictors of safe performance such as Mindful Organizing and Empowering Leadership behaviors are vital to achieve impeccable safety outcomes.

Relevant UN SDGs

This study contributes to the following SDGs:

Good Health and Well-Being = number 3

Sustainable Cities and Communities = number 11

Climate Action = number 13

Keywords: Mindful organizing; Empowering leadership; Upward communication

Paper 4

A multilevel investigation of the antecedents of safety performance in a sample of UK heavy mobile plant drivers

Laura Jackson, Matteo Curcuruto & Jim Morgan | Leeds Beckett University

Research Goals and Why the Work Was Worth Doing

The aim of this research is to investigate the multilevel antecedents of heavy mobile plant drivers' safety performance within the UK mineral products industry. A large proportion of safety incidents in this industry are related to heavy mobile equipment (e.g., excavators, loading shovels and dump trucks). Due to their size, these machines have the potential to cause serious harm to individuals and severe damage to company assets. This is a salient issue for many organisations involved in the extraction and manufacture of construction materials, and the construction industry more generally, which is considered a high-risk industry for injury and death (Pinto, Nunes and Ribeiro, 2011; Lingard, Cooke and Gharaie, 2013; Amiri et al, 2016). Despite advancements in safety management systems, many organisations that operate heavy mobile plant in high-risk environments still have relatively high incident rates (Renecle et al, 2021). There is a pressing need to reduce mobile plant incidents rates, but there is currently a dearth of research in this area. Therefore, the present research aims to add to the limited knowledge-base by investigating the multilevel influences on the safety behaviour and performance of these drivers.

Theoretical Background

The start of the construction process involves the extraction of minerals (quarrying) and the manufacture of construction materials. Safety incidents related to heavy mobile plant operations have been an ongoing issue for the organisations that conduct this safety-critical work. Disruptions to the operation of mobile plant caused by such incidents is both costly for organisations, but also for the employees involved. Given these occupational health and safety implications, it is surprising that there is very little research involving heavy mobile plant drivers, although the studies concerning work-related driving more generally have been steadily increasing (Wills, Watson & Biggs, 2006).

Because of the lack of research in this specific setting, the present study draws on the wider safety science literature to explore the potential role of multilevel influences. The role of safety climate is investigated both at the organisational level and group level, and is a valuable construct to explore as it conceptualises the way in which an entire organisation perceives safety values, priorities and procedures (Curcuruto, Griffin, Kandola and Morgan, 2018). Safety climate can shape the motivation to work safely (Griffin and Curcuruto, 2016) and has also been shown to predict safety behaviours (Clarke, 2006; 2010). While organisational and managerial influences are important in shaping safety-related outcomes, it is important to recognise that the operation of mobile plant is, for the most part, considered a lone-working task. As a result, it is important to also explore the role of individual level safety antecedents (e.g., safety motivation, job-related well-being, safety self-efficacy etc), context-specific safety behaviours, and the relationships between them, as well as their influence on incident occurrence. Although much of the literature assumes that the relationship between safety climate and safety outcomes is at least partially mediated by individual behaviours, little is known about the mechanisms by which safety climate impacts individual behaviours within organisations. (Griffin and Curcuruto, 2016).

Methodology

A questionnaire study will be conducted in the winter of 2022/2023. Participants will be employees of a mineral products extraction and construction company, who operate heavy mobile plant within the aggregates or asphalt divisions. Mobile plant includes machines such as excavators, loading shovels and dump trucks. The potential research population is composed of 483 truck drivers employed in the company on a permanent contract. The questionnaire will be available for participants to complete both online and on paper. The scales included were decided upon after a scoping exercise conducted at the company by the lead author. This involved the analysis of company incident data, onsite observations, and discussions with mobile plant drivers and subject-matter experts, as well as a review of the current academic literature. The scales include; safety climate, safety motivation, attention failure, job-related well-being, risk propensity, reporting attitudes, safety self-efficacy, tendency towards driving violations, safety envisioning, and safety citizenship behaviour. There will also be a measure of context-specific target safety behaviours; acknowledgement, checking mirrors, requesting assistance, and being patient. Finally, as an outcome measure, participants will be asked to rate the frequency of their incident experiences, describe what happened and any consequences that occurred as a result. The data collected will be analysed through statistical analysis including factor analysis (to test the dimensionality of safety climate in this particular research sample characterized by lone workers) and path analyses (to test causal effects among the variables included in the survey, in accordance with hypotheses derived from the relevant literature).

Results

The study will be completed in early 2023 and detailed results will be available at the Congress. We aim to present the findings emerging from at least half of the workforce population of the company (approximatively a sample of 250 workers).

Limitations

To narrow the scope of the project and ensure it is logistically manageable, data will only be collected from employees working within the aggregates and asphalt divisions of the host organisation. This may make it more difficult to generalise to other areas of the business, (e.g., cement, ready-mix concrete, surfacing or concrete products), although many facets of driving operations are similar.

Implications

This study will advance the current knowledge on multilevel influences on heavy plant safety within a material extraction and construction industry context. Better knowledge and understanding about these influences and interactions may help inform safety interventions which aim to reduce risk, incident rates, and injuries and fatalities within safety-critical environments.

Originality/Value

We aim to extend the limited safety research knowledge concerning a specific work-related driving context common to the material extraction and construction industry: the operation of mobile plant. This is considered a high-risk activity that accounts for a large proportion of industry incidents, hazards and near-misses.

Keywords: Safety performance; Multilevel; Mineral products industry

Symposium S113

(Chronic) illness at work: Insights into organizational health-diversity

Alexandra Cook, University of Amsterdam; Alexander Zill, University of Applied Sciences - Hochschule Mittweida

science

What will be covered and why?

The Covid-19 pandemic has put a new focus on people working with pre-existing conditions. One-third of the European population has at least one chronic health impairment, and the numbers are expected to rise due to the increased prevalence of autoimmune disorders and the aging workforce. Yet, in psychological research on work and health, chronic health conditions and their consequences are rarely attended to. As we know little about how to successfully manage a health-diverse workforce at this point, there is an urgency to place health diversity in the spotlight of organizational research and interventions.

This symposium investigates chronic health impairments and work: The first presentation focuses on the potential effects of a chronic health impairment on members of a specific organizational group: leaders. Although leaders are considered crucial for employee health, their health is often neglected in research and theory. This study investigates if and how an existing health impairment impacts one's leadership style. The second presentation provides a new perspective on an established construct in organization psychology, namely job crafting, by investigating how differences in perceived energy and the difficulty in managing one's energy while balancing work and illness management are related to different types of job crafting amongst people with chronic health conditions. Furthermore, it investigates whether the positive findings regarding the effects of job crafting on work and well-being outcomes can be replicated in a sample of people with health impairments. The third presentation focuses on the perceptions of employees with chronic illness towards organizational interventions and leadership behaviors focusing on improving health and the reduction of stigmatization. Furthermore, the presented study investigates the associations between organizational interventions, leadership and co-worker behaviors, and work-related burnout. Following the three presentations, we will have a summary and discussion with our discussant, an expert in the field of job insecurity and proactive career behaviors. Our discussant will aim to find common questions from all three presentations and link these questions to employability and career planning.

Relevance to the congress theme:

The increase in health diversity in the workforce is an important element in the changing world of work. Together with the shortage of skilled workers and the increase in economic burden due to early retirements, these changes create a strong need for organizations to create working conditions that allow good and healthy work, not just for people in good health but also for people with existing impairments. It is the task of work and organizational psychologists to identify factors that improve or exacerbate work-life employees with health impairments and to provide avenues to provide adequate support for organizations and leaders and, subsequently, create healthy and resilient organizations and societies.

Research and practical implications

All three presentations in this symposium will contribute to the inclusion of health status into theories and research on organizational behavior and, more specifically, occupational health and well-being to develop and conduct relevant research questions and adequate research designs that investigate how to create good and “healthy” working conditions for a health-diverse workforce. The three presentations will demonstrate the need to consider the perspectives of people with (chronic) health conditions, as this perspective change may result in the need to adapt established assumptions towards “healthy” and good work. Moreover, the second and third presentations contribute to developing or adjusting interventions. Whereas Presentation 2 provides insights into adding health status as an important factor in interventions based on the established concept of job crafting, Presentation 3 provides valuable insights for the development of specific organizational interventions to address the needs and difficulties of people living and working with chronic health conditions. Finally, we believe our symposium may contribute to the conference above and beyond theory and practice as we encourage congress participants with personal experiences with chronic health conditions to join our symposium and share insights and important questions.

Overall conclusions

A chronic health impairment can significantly affect work-life as it may impact one’s baseline well-being, individual resources and behavior at work in various ways. Furthermore, it can create the need for the adjustment or development of interventions to address specific difficulties and needs at work. Including health status in theory and research is, therefore, essential to provide evidence-based interventions and support for employees and organizations.

discussant: Maarten van Bezouw, Utrecht University

Keywords: chronic illness, diversity, occupational health

Paper 1

Healthy or ill? How a leader's health condition affects leadership behavior

Tobias Struck, Hannes Zacher & Michael Knoll | Universität Leipzig

Goals: This research aims to understand changes in the leadership process that may occur in the interplay of actual health conditions and defining oneself as a leader, specifically when a leader's health condition contradicts the image of a strong and dedicated leader. We investigate whether the presence of a health impairment or a chronic illness affects a leader's socio-cognitive processes and resource experience, which, in turn, may interfere with effective leadership behaviors. The topic's importance stems from the powerful and exposed position leaders hold, which qualifies them to potentially facilitate or hamper the well-being and performance of their followers and the organization. Understanding the effects of health on leaders' self-view and role implementation provides opportunities to support both the individual leader and the context in which leaders operate.

Theory: Drawing on a Conservation of Resources perspective, physical and mental health can function as an energetic resource. A resource shortage can impede meeting work-related goals and reduce the availability of increasing or obtaining individual resources. Threats (e.g., impairments and chronic burdens) reduce the amount of health as a personal resource, consequently changing leaders' motivation and stress experience. Transferred to leaders with health impairments, we conclude that health impairments represent a reduction in personal resources that, in turn, evokes both negative cognitive responses (reduced identification and motivation to be a leader) and a higher strain experience. We expect the maladaptive response to affect certain leadership styles that require high effort, such as transformational and transactional leadership. These leadership behaviors seem less promising for leaders experiencing deteriorating health, resulting in fewer of these beneficial behaviors.

Methods: We conducted a longitudinal online survey with four waves starting in August 2022. N = 1496 leaders from different occupations in Germany participated at the first time of measurement and were monthly re-invited to participate in the following waves. The data collection for the final wave will take place in November 2022.

Results : Data will be analyzed after data collection, with results available at the end of 2022. We expect that health impairments and chronic conditions reduce transformational and transactional leadership and increase passive-avoidant leadership over time. This effect is probably partly explained by resource experience (more strain) and social-cognitive processes (a diminished self-view and identification as a leader). Analyses based on the first round of data collection indicate effects in the expected direction.

Limitations: Although we surveyed a large and heterogeneous sample of leaders, leaders only self-reported their health, attitudes, and leadership behavior. Future research should consider ratings from a third-person perspective (e.g., employees or team members) to objectively estimate the effects of noticeable changes in leadership behavior. Second, by asking leaders monthly, we may miss out on some dynamics outside a section of mid-term changes in health and leadership, for example, daily fluctuations in symptoms or a long-term treatment outcome required to complement the picture.

Conclusions: Health impairments and chronic conditions influence leaders' perception and exertion of leadership. Thus, besides addressing how leaders affect follower health, researchers and practitioners concerned with occupational health and leadership need to consider the leader's own health conditions. Our research reveals processes that human resource departments and managers could use to help leaders fulfill their potential through suitable cognitive strategies.

Congress theme: This research reflects the changing world of work by directing attention to individual health conditions at every job level. Due to demographic changes, health is already an important factor for promoting sustained development and good working lives, and its importance will likely increase in the future. When governments raise the legal retirement age and/or more people extend their working life, the share of working people with health impairments and chronic illness may further increase. Although the changing world of work also implies that leaders change, research on leaders' health and illnesses is scarce. However, addressing individual health conditions at the leader level might be an effective way to shape the future of work. Beneficial or detrimental effects for the individual leader can crossover to work teams, whole organizations and perhaps society. Creating a deeper understanding for research on health and leadership may be one element towards a more inclusive and diverse workforce.

UN SDGs: Good health and well-being, Reduced inequalities, Decent work and economic growth

Keywords: leadership, health, illness

Paper 2

Enough energy to craft? Investigating job crafting amongst employees with chronic health conditions

Alexandra (Sasha) Cook, University of Amsterdam

Goals: Recent evidence emphasizes the benefits of job crafting for employee job satisfaction and well-being. However, there are many open questions regarding the applicability and feasibility of job crafting for people with impaired resources. This is especially crucial as surveys among the countries of the European Union indicate that about one-third of the working-age population has at least one longstanding health condition. First, insights on job crafting amongst people with disabilities show that, although they engage in crafting, they do so at a substantially lower level compared to non-disabled people. The goal of this research is to investigate the roles of energy and perceived conflicts between work life and illness management amongst employed people with chronic health conditions (CHC). Moreover, this research examines whether established associations between job crafting and well-being outcomes can be replicated among people with CHC.

Theory: In the Job Demands-Resources framework, job crafting is a way in which employees can redesign their work by increasing their job resources or lowering their job demands. However, as engaging in job crafting requires additional effort beyond regular job activities, employees first need to invest energy before they can benefit from job crafting. Employees with CHC often experience limitations caused by the condition itself or its treatment. According to the Conservation of Resources model, we can conceptualize limitations due to impacted health as a diminished energy resource. People with CHC experiencing a loss of energy will be more likely to protect their resources instead of investing them in acquiring new resources through job crafting. This study, therefore, investigates the association between perceived energy and the four job crafting types (increasing structural resources, increasing social resources, increasing challenging demands, and decreasing hindering job demands). As individual energy resources may also be depleted due to the additional demands of managing one's CHC while working, this study investigates the relationship between perceived energy-related work-health management interference (WHMI-E) and job crafting. Furthermore, I investigate whether established relations between the four job crafting types and health and well-being outcomes can be replicated amongst employees with CHC.

Methods : Data was collected amongst 178 people with chronic medical illnesses and mental disorders using the platform Prolific academic. I assessed energy, WHMI and job crafting at baseline and the potential outcomes of job crafting one month later. Gender, age, perceived illness symptom severity and the type of the primary health condition (mental versus physical) were assessed as covariates.

Results: Regression analyses show that perceived energy is positively and significantly associated with all four types of job crafting, indicating that employees with lower energy levels tend to engage in job crafting to a lesser degree. Perceived energy and perceived energy-related work-health management interference were negatively and significantly correlated ($r = -.61$). However, WHMI-E was positively associated with increasing structural and social job resources and decreasing hindering job demands. An additional finding of the baseline analysis was that people with a mental primary health condition reported engaging less in the job crafting type focused on increasing structural job demands. Controlling for energy and WHMI, job crafting was not a significant predictor of job satisfaction. Whereas participants engaging in increasing challenging job demands reported less

exhaustion burnout, increasing job and social resources were negatively, and decreasing hindering job demands was positively associated with disengagement burnout. Controlling for energy and WMHI-E in the analysis of the effects of job crafting indicates potential partial mediation effects.

Limitations: Due to the nature of the dataset, claims of causality in the associations between energy and WHMI-E can't be made. Moreover, the current dataset allows only limited insights into the individual working conditions, which should be addressed in future studies.

Conclusions : This study indicates that the ability to engage in job crafting may depend on the individual employee's energy levels. As energy resources can be diminished due to a chronic health condition, this raises the question of how to design job crafting interventions for employees with CHC. Contrary to the expectations, people perceiving that their energy is insufficient to manage work and their illness also reported more job crafting. However, more longitudinal insights are necessary to determine the directional causality of this relation. Although the longitudinal analyses found negative effects of job crafting on burnout, job crafting did not explain variance in job satisfaction above and beyond the predictors.

Congress Theme : Health diversity in the workforce is changing due to the increase in chronic illnesses (e.g., autoimmune diseases) and demographic change, leading to an urgent need to include the perspective of people with health limitations in occupational health research.

UN SDGs: Good health and well-being, Reduced inequalities, Decent work and economic growth

Keywords: job crafting, energy, burnout

Paper 3

Organizational interventions for employees with chronic illnesses and their impact on work-related burnout

Alexander Zill, University of Applied Sciences - Hochschule Mittweida

Goals: The recent study aims to get a deeper insight into the relevance and mechanism of organizational interventions for employees with chronic illnesses to improve their situation at work. The results of this study can make an important contribution to how organizations can support employees with a chronic illness or condition.

Theory: A quarter to a third of all working people have a chronic health condition. Skilled worker shortage and an aging workforce require organizations to look closely at his issue. Two major problems for the mental health of employees with a chronic illness condition are the compatibility of work and health management (e.g., doctor visits and adherence to treatment schedules) and the experiences of stigmatization at work. Previous research in organizational psychology has shown the positive impact of leaders, coworkers and organizational climate on employees' mental health. Organizations have to develop specific interventions to transfer and systematize these general positive effects to employees with a chronic illness condition and their problems. We assume that specific organizational interventions for employees with a chronic illness condition positively affect leadership behavior, coworker support and organizational care in general, reducing work health management interferences and experienced stigmatization and thus strengthening mental health.

Methods: 625 employees with at least one chronic health condition participated in an online study regarding chronic illness at work. They were recruited via self-help organizations in Germany. The sample includes employees with physical or mental illness conditions, with employees with major depression, migraine, or endometriosis representing the largest proportion of the sample. Participants answered questions about organizational interventions aimed at chronically ill employees (e.g., information, support offers, design of working conditions, anti-stigmatization campaigns), perceived leader illness orientation, coworker support, organizational care, work health management interferences, experienced stigmatization and work-related burnout.

Results : We found a negative relationship between the existence of an organizational intervention aimed at chronically ill employees in the workplace and work-related burnout, meaning that employees who perceive their organization to provide interventions reported lower burnout levels. This relationship is serially mediated in three ways: through perceived leader illness orientation and work health management interferences; perceived leader illness orientation and experienced stigmatization; organizational care and experienced stigmatization. First, organizational interventions are positively related to perceived leader illness orientation which is negatively related to work health management interference, which is positively related to work-related burnout. Second, organizational interventions are positively related to perceived leader illness orientation which is negatively related to experienced stigmatization that is positively related to work-related burnout. Third, organizational interventions are positively related to organizational care, which is negatively related to experienced stigmatization that is positively related to work-related burnout. Moreover, we found a small positive relationship between organizational interventions and coworker support, which disappeared in the path analysis. Nevertheless, coworker support is negatively related to experienced stigmatization.

Limitations: First, the current study investigated employees with different chronic health conditions. Unfortunately, the number of chronic diseases and comorbidities varied greatly, so no systematic comparisons between illnesses can be carried out. Second, this is a cross-sectional study, and all mediating processes should be interpreted cautiously. Third, to better understand which format of organizational interventions is best, future research should focus more in detail on the content of interventions, for example, using qualitative methods.

Conclusions : This study shows the positive impact of organizational interventions to strengthen the working conditions of chronically ill employees. Particularly perceived leader illness orientation and organizational care seem to be either influenced organizational measures or represent organizational interventions in the eyes of the employees. This, in turn, could reduce work health management interferences and the experience of stigmatization of employees with chronic conditions, thus reducing work-related burnout. In sum, organizations should invest in interventions for employees with chronic conditions due to the potential positive effect on mental health. Moreover, it contributes to reducing inequality and hence more integration of people with any impairment.

Congress Theme : Many sectors of the economy are currently confronted with a shortage of skilled workers. Supporting people with chronic conditions by providing appropriate working conditions improves this phenomenon. It can increase the recruitment of people with impairments and prevent early retirement and turnover among current employees.

UN SDGs: Good health and well-being, Reduced inequalities, Decent work and economic growth

Symposium S114

Decent Work and Well-Being in a Changing World of Work: Studies in four countries

Leonor Pais, University of Coimbra, Portugal

science_practice

In line with this year's conference theme, "The future is now: The changing world of work," this symposium focuses on studies or approaches that guide practitioners in their interventions to align them with decent work contexts. Ensuring decent work contexts is an essential prerequisite for respecting human rights and, therefore, a relevant contribution to ensuring that changes in the world of work do not adversely affect life at work and beyond.

The symposium focuses on the relationship between decent work and well-being in work contexts in four countries.

First, the results of the Decent Work Questionnaire (DWQ) adaptation and validation processes in those countries are presented. Subsequently, the relationships between the dimensions configuring decent work and those related to well-being, assessed through work engagement and burnout, are presented and discussed. In this context, in its positive (empowering) and negative (toxic) dimensions, leadership is still discussed and related to work motivation.

Papers presented in this symposium will focus on decent work, well-being (engagement and burnout), leadership, and work motivation and represent initiatives from 4 European countries: Portugal, Spain, the United Kingdom, and Russia. With the following presentations, we hope to inspire the debate on making organizations better places to work in a changing world of work.

In a post-modern and post-industrial world, Work and Organizational Psychology must attend to new trends and develop new assessment and intervention tools that allow psychologists to play a central role in promoting essential values in a work context. Identifying work factors influencing the well-being of workers, in both its positive and negative facets, is a significant step in this endeavour by allowing for the development of effective organizational intervention programs in this regard. These questions are central in the first paper, reporting results obtained in the United Kingdom.

The second paper describes the psychometric properties of the Russian version of the Decent Work Questionnaire and the relationships of decent work with well-being variables, such as burnout and work engagement.

Similarly, the third paper presents the adaptation and validation of the Spanish version of the Decent Work Questionnaire and the relationships between decent work and work engagement and decent work and burnout.

The fourth paper investigates to what extent toxic and empowering leadership dimensions influence the various work motivation types differently. Furthermore, taking the different dimensions of the two types of leadership, the goal was to create different leadership worker profiles and analyze the way they associate with the several motivation types.

Research/Practical Implications

Each of the papers in this symposium analyzes in detail the uniqueness of its contributions to a better/decent place to work in a changing world of work. At the end of the four presentations, we will present an integrative summary, highlighting the most relevant aspects from the point of view of

research and intervention. Its relevance is all the more remarkable as they emerge from studies carried out concerning the work contexts of four different countries.

Overall conclusions

Decent work is an essential feature of work contexts for promoting well-being, and interventions in organizations must have evidence-based guidelines to become better workplaces in a changing world of work.

Intended audience

Both academics and practitioners

Keywords: Decent Work; Well-Being; Changing World

Paper 1

Decent work: Studies in the United Kingdom

Leonor Pais, University of Coimbra, Portugal; João Moreira, University of Lisbon, Portugal ; Nuno Dos Santos, Universidade de Évora, Portugal; Tânia Ferraro, Universidade Portucalense, Portugal

Research goals and why the work was worth doing: In a post-modern and post-industrial world, the overwhelming focus on economic development and wealth has given place to reaffirming human values such as justice, inclusion, respect for the environment, health, well-being, etc. Work and Organizational Psychology must attend to these trends and develop new assessment and intervention tools that allow psychologists to play a central role in promoting these values in a work context in a changing world of work. Identifying work factors influencing the well-being of workers, in both its positive and negative facets, is a significant step in this endeavour by allowing for the development of effective organizational intervention programs in this regard.

Theoretical background: One of the most promising constructs for promoting quality of life and well-being at work in a changing world of work is that of Decent Work (DW). Developed under the aegis of the International Labour Organization (ILO) as a conceptual framework for the promotion of human rights and social justice at work, DW has the potential to be a highly heuristic concept in guiding the exploration of factors contributing to well-being at work, and the development of interventions that help work and organizational psychologists to pursue fundamental human values. The application of the DW framework in the current study used the Decent Work Questionnaire (DWQ), a multidimensional self-report instrument assessing workers' perceptions of the degree to which their current job fulfills the main aspirations instituted in the ILO framework. Developed in an international context and closely following the framework mentioned earlier, the DWQ has already shown solid psychometric qualities and predictive capabilities in several languages.

Design/Method: This study employed, for the first time, the newly developed English version of the DWQ. The sample was composed of 621 workers from all four countries of the United Kingdom (England, Scotland, Wales, and Northern Ireland), with an overrepresentation of highly qualified workers (e.g., professors, researchers, physicians, lawyers, etc.), due to the larger research project of which this study was a part. The DWQ is a 31-item self-report questionnaire comprising a global DW scale and 7-factor scales corresponding to facets of the ILO framework but established initially based on exploratory factor analyses. Well-being at work was measured in its negative (burnout) and positive (engagement) facets, employing the Utrecht Work Engagement Scale and the Personal Burnout subscale of the Copenhagen Burnout Inventory. First, a confirmatory factor analysis (CFA) was conducted to test the psychometric properties of the new English version of the DWQ. Subsequently, the value of DW facets in predicting well-being was explored using zero-order correlations and multiple regression analyses.

Results obtained: The CFA showed good adjustment to the theoretical model established with previous versions of the DWQ, especially after introducing some additional, theoretically sensible paths similar to those considered in other versions. Cronbach alphas were also adequate for the global score and factor scores. Multiple regression analyses identified the Fulfilling and Productive Work factor of the DWQ as the major contributor to Work Engagement and the Adequate Working Time and Workload factor as the best predictor of burnout.

Research/Practical Implications

In addition to demonstrating the psychometric qualities of the English version of the DWQ, opening the door to the development of research with this concept and instrument in the internationally preponderant community of English-speaking countries, this study has again supported the advantage of a multidimensional approach to the assessment of DW, by showing that specific facets of the construct may influence equally specific factors of workers' well-being. Therefore, these findings may help work and organizational psychologists hone their intervention strategies in situations where a particular aspect of well-being seems to be especially lacking.

Originality/Value

In addition to the availability of an English version of the DWQ, the demonstration that similar factors appear to influence different facets of well-being in different countries, together with the availability of instruments in an increasing number of languages, should encourage the development of further cross-cultural studies in this domain.

Limitations

The major limitation of this study is the focus on highly qualified workers, which may doubt the generalizability of the results. Future studies should include other types of workers' populations to establish the validity and usefulness of the DW concepts and the DWQ in other contexts. Examining different outcomes, for example, in health domains or the work-family interface, could also open new avenues for research and interventions.

Intended audience

Both Academics and Practitioners

Keywords: Decent Work; Work Engagement; Personal Burnout

Paper 2

Decent Work Questionnaire: Psychometric properties of the Russian version

Salvatore Zappalà, University of Bologna, Italy; Elena Kamneva & Svetlana Bockhareva | Financial University under the Government of Russian Federation, Russia; Tânia Ferraro | Universidade Portucalense, Portugal

Research goals

The present study describes the psychometric properties of the Russian version of the Decent Work Questionnaire (DWQ) and the relationships of decent work construct with well-being variables such as burnout and work engagement.

Theoretical background and why the work was worth doing

Decent work (DW) is a very comprehensive concept in work-related sciences and concerns people's aspirations for their working lives. DW's idea has been introduced as an aspirational statement about work conditions and context, as decent work conditions continue to be relatively infrequent in many countries and at-risk in developed ones. The DW concept defines a set of universally considered desirable work characteristics; however, it is not easy to measure. Ferraro et al. (2018) developed the Decent Work Questionnaire (DWQ); it measures seven dimensions that assess how employees perceive and evaluate their work content and context. The questionnaire was developed and validated in Portuguese (Ferraro et al., 2018) and Italian (Ferraro et al., 2021). The DWQ must be made available also in other languages, and the present study describes the preliminary results of the Russian version of the instrument. This step is essential for researchers and practitioners to use the DWQ in Russian workplaces and assess how much employees perceive their respective workplaces as decent. Previous studies with DWQ showed a relevant role in promoting work engagement and the prevention of burnout.

Method

A questionnaire in the Russian language was available online, from March 22 to May 10, 2021, on the Qualtrics platform. Information about the questionnaire was spread using social media, and Russian professional organizations were contacted to facilitate recruiting. Respondents had to be employed, have at least six months of professional experience, and get paid for their work. Answered the survey 222 respondents, but only 181 completed the survey in full.

In addition to the Russian version of the DWQ, the survey included the Russian-validated version of work engagement (Scahufeli & Bakker, 2004) and the Oldenburg burnout inventory (Demerouti et al., 2010; Russian version by Smirnova, 2017). When the Russian version was unavailable, scales were translated and back-translated by Russian and English native speakers.

Results

The results of this study are preliminary and still being processed. An Exploratory Factor Analysis shows six dimensions, with an eigenvalue greater than 1, explaining 65,8% of the variance. A confirmatory factor analysis on the seven dimensions proposed by Ferraro et al. (2018), conducted with Mplus, shows acceptable results with indicators that very slightly increase when correlating the errors of two items in the same dimension. Cronbach's alpha of the seven dimension range between .72 (Social protection) and .88 (Meaningful remuneration). A global DW scale was computed,

showing a positive and significant correlation with work engagement (r = .68), and a negative correlation with burnout (r = -.58).

The study also made it possible to empirically support the positive relationships between decent work and work engagement and the negative relationships between decent work and burnout.

Research/Practical Implications

From a theoretical perspective, this study shows that the DWQ is a valid and reliable instrument even when submitted to Russian workers. From a practical point of view, this study suggests continuing the validation process of the Russian version so that scholars and practitioners can measure employees' perception of the various aspects that constitute the decent work concept to introduce some improvements in work conditions.

Originality/Value/Limitations

This study, conducted on Russian employees, includes validating the Russian version of the Decent work questionnaire. The instrument validation in other languages will offer the basis for work and organizational perspective on decent work. Limitations concern the online data collection: respondents belong to different organizations, the number of respondents is not very high, and employees using social media had more opportunities to answer the questionnaire.

Intended audience

Both Academics and Practitioners

Paper 3

Decent work and well-being in a Spanish work context

Leonor Pais, University of Coimbra, Portugal; Vicente Martinez-Tur, University of Valencia, Spain; Nuno Dos Santos, Universidade de Évora, Portugal; Tânia Ferraro, Universidade Portucalense, Portugal

Research goals and why the work was worth doing

The growing attention to business ethics and integrity and the concern for human rights at work has been an increasingly relevant issue in the changing world of work. Decent work is an essential work-related concept representing the defence and promotion of human rights at work and business and the fulfilling and productive work maintained with social dialogue. This is relevant in any setting and gains relevance in professional environments. The workplaces are fulcral to physical and mental health, personal and professional development, and organizational and societal innovation and advances. Promoting, ensuring, and protecting human rights means ensuring fundamental individual freedoms in different forms and levels. Having fundamental rights respected at work can be decisive for people to achieve their aspirations and well-being. The current study presents the adaptation and validation of the Spanish version of the Decent Work Questionnaire (DWQ) and the relationships between DW and work engagement and DW and burnout.

Theoretical background

Despite some progress in improving DW, deterioration has been observed in recent years. Precarious work is growing to create new forms of DW deficit. The study of DW has been undertaken to map its presence/absence in different countries and regions. Considering the scarcity of psychological instruments for measuring DW, previous studies developed and validated the Decent Work Questionnaire for Portuguese-speaking countries (Portugal and Brazil; Ferraro et al., 2018) and Italian workers (Ferraro et al., 2021). This instrument is based on International Labour Organization propositions and covers the full range of the decent work construct, measuring workers' perception of their work content and context.

Design/Method

The DWQ Spanish version was applied in a high-skilled workers sample (N = 1528) in Spain. The inclusion criteria adopted for participants in this research were: (a) having at least six months of professional experience; (b) being currently employed; and (c) receiving payment for the work carried out. The research protocol includes a Spanish-validated version of Work engagement (Schaufeli et al., 2002) and Personal burnout, a subscale of the Copenhagen Burnout Inventory (Kristensen et al., 2005 Spanish version by Molinero-Ruiz, Quintero, & Moncada-Lluis, 2013). The data were submitted to exploratory factor analysis, followed by cross-validation in confirmatory factor analysis.

Results obtained

The Exploratory Factor Analysis shows seven dimensions accounting for 69% of the total variance. The Confirmatory factor analyses confirmed both the original high-order model with 7-factors of the DWQ, a very good model fit, and good internal consistency reliability ($\alpha = .94$). Convergent and discriminant validity, tested using Work Engagement, and Personal Burnout scales were supported

by the data. Therefore, the DWQ Spanish version yielded a reliable and valid multidimensional measurement tool and strengthened it as a good cross-cultural measure of DW.

Research/Practical Implications

For future research, the evolution of the DW concept from a Work, Organizational, and Personnel Psychology (WOPP) perspective may bring new theories to this field. The DW concept and its application have been developed based on the contribution of different disciplines and areas of knowledge at different levels of analysis. Research in the WOPP field has advanced and shown that this is a relevant and up-to-date concept. Efforts for its practice in professional environments can be a pertinent factor for the health and well-being of people and organizations. At the same time, researching and promoting the application of DW in work settings and relationships at work is a way to rescue WOPP' humanist tradition (Grandey et al., 2015; Lefkowitz, 2008). The inclusion of a DW Agenda as a humanistic agenda for WOPP professionals represents, simultaneously, the valorization of human beings in their work and seeks to meet broader societal concerns. Applying a DW approach in conceiving strategic HR interventions can promote innovative work/job (re)design and improve workplace well-being.

Originality/Value

More than 480 million people worldwide have Spanish as their first language. The DWQ' Spanish version will be a helpful tool to explore aspects that influence DW for workers who speak this language. This psychometric instrument could bring a better understanding of DW to different cultures and businesses worldwide. The application of DWQ could open new avenues for theoretical and empirical development of the concept and practical HR interventions.

Limitations

Future research needs to continue to test the structure of these seven dimensions in other cultures. Future studies are relevant for enlarging the DW nomological network and deepening understanding of how the seven dimensions interact. These steps will enrich our knowledge of the social issues surrounding DW and add to DWQ’s usefulness.

Intended audience

Both Academics and Practitioners

Paper 4

Leadership as a contribution to high-quality work motivation

Carla Semedo, Universidade de Évora, Portugal; Leonor Pais, University of Coimbra, Portugal; Ana Salvador, Tyco Electronics, Évora, Portugal; Lisete Mónico, University of Coimbra, Portugal; Nuno Dos Santos, Universidade de Évora, Portugal

Research goals and why the work was worth doing

This study aims to verify to what extent toxic and empowering leadership dimensions influence the various work motivation types differently. Furthermore, taking the different dimensions of the two types of leadership, our goal was to create different leadership worker profiles and analyze the way they associate with the several motivation types. The importance of this research is due to the more accurate analysis of the influence of different leadership dimensions on different types of work motivation.

Theoretical background

Leadership is defined as a social influence process over others in pursuing goals. That process can be performed both by empowering and promoting others or undermining them. These two types of leadership are well-known as empowering and toxic leadership. Furthermore, those opposite types of leadership impact differently in several aspects of the quality of working life. The present study focuses on that influence of different types of work motivation. According to the self-determination theory, work motivation varies from more controlled to more autonomous regulation. The more autonomous regulation is considered a higher quality type of work motivation. In this case, they are mainly considered intrinsic and identified work motivation. These higher types of quality work motivation are close to two of the Decent Work dimensions, namely, fulfilling and productive work and Opportunities. On the other hand, more controlled regulation, such as extrinsic and introjected regulation, are closely related to different decent work dimensions, such as social protection, health and safety, and meaningful remuneration for exercising citizenship.

Design/Method

A convenience sample of 408 Portuguese workers participated in this study. Data was collected through the Toxic Leadership Scale (TLS), the Empowering Leadership Questionnaire (ELQ), and the Multidimensional Work Motivation Scale (MWMS).

Results

Among the ELQ factors, those that correlate most highly with the MWMS dimensions were Coaching , Information, and Show concern . We found that all dimensions of ELQ are related to motivation to work, and this relationship is more evident with Intrinsic Motivation . Regarding the TLS, we verified the greatest number of correlations not statistically significant, namely with the dimensions Social and Material External Regulation and Introjected motivation . TLS correlated weakly with Amotivation (positive correlation) and Identified Regulation and Intrinsic Motivation (negative correlations). The TLS factors with the highest negative correlations with the MWMS dimensions were Abusive Leadership, Self-promotion , and Unpredictability .

Concerning the created leadership profiles, the worker-empowering leadership profile is associated with the most intrinsic form of motivation. The worker narcissistic empowerment pattern is highly

associated with identified regulation and intrinsic motivation and lowest with amotivation. Leaders' narcissism appears to be well tolerated by subordinates if high scores on all dimensions of empowerment are associated.

Limitations

The effects of sociodemographic variables should also be appreciated in future studies. A longitudinal study about empowering and toxic leadership's effects on subordinates' work motivation would be recommended to capture the evolution in the associations between the variables. In the same way, the role of different subordinates' characteristics as moderators of leadership style will be a relevant research topic. Enlightening the effect of the leaders' characteristics (e.g., personality, positive and negative work experiences) in adopting empowerment or toxic style would be a matter of deep interest.

Research/Practical Implications

This investigation points out that how people perceive their leaders is related to their motivation for work. This reaffirms the importance of changes in the design of people management policies and practices, namely in the sub-processes of recruiting, selecting, integrating, and developing leaders and the metrics used to measure performance.

Originality/Value

The value of this investigation is based mainly on the consideration that it will bring an essential contribution to the design of strategies and practices of people management in organizations.

Intended audience

Both Academics and Practitioners

Keywords: Empowering Leadership, Toxic Leadership, Work Motivation

Symposium S115

The importance of interpersonal relations for proactive actions and their outcomes.

Anita Starzyk, NEOMA Business School, Rouen, France; Shereen Fatimah, Singapore Management University

science

Introduction. Managers and colleagues are critical factors for employee proactivity. Although proactive actions are self-initiated and discrete (Parker et al., 2010; Grant & Ashford, 2008), these actions depend on the interpersonal work environment. Employees take notice of managers and colleagues to sense whether and in which form proactive actions are wanted (Starzyk & Sonnentag, 2019; Vough et al., 2017). After employees decide to take charge, managers and colleagues remain crucial to successful initiatives (Farh et al., 2020; Satterstrom et al., 2021). This symposium acknowledges the core role of managers and colleagues and addresses two overlooked aspects. First, how do different contexts alter the relevance of interpersonal relations for employee proactivity? Second, why is attention to interpersonal relations beneficial for proactive performance?

Research and Practical Implications. This symposium answers how to capitalize on interpersonal relations to initiate change and perform better. It bridges research on various proactive behaviours (i.e., personal initiative, career consultation, job crafting, and voice), diverse methods (i.e., experiments, dairy studies, multi-wave and network field surveys), and multiple levels (i.e., within-person, individual, dyads, and teams):

The first contribution, an experimental vignette study, explores the importance of proactive personality, experienced uncertainty, and LMX in situations of crisis. The preliminary results indicate that proactive personality and LMX predict personal initiative in such contexts.

The second contribution applies the sociometer theory of self-esteem to explain when proactive career consultation is more likely to translate into managerial mentoring. A four-wave study finds that highly power-distance-oriented managers respond with more mentoring when newcomers proactively consult them.

The third contribution proposes that the work context affects whether expanding or limiting work relations is more advantageous for employees' energy and performance. Their experience sampling study shows that promotion-focused (vs prevention-focused) job crafting benefits employees with high (vs low) task interdependence.

The fourth contribution takes a social network approach to study the benefits of cross-expertise voice on employees' relational energy and the performance of their teams. The field survey results indicate that employees who speak out across expertise areas feel more energized and perform better in certain but not uncertain contexts.

Our discussant will integrate all contributions into the broader literature. She will also highlight directions for future research on interpersonal relations to elevate the benefits of proactivity for employees and their organizations.

Relevance to Congress. Employees do not await how the world of work might evolve but take proactive actions to create desirable future work and career conditions. Insights from this symposium help support employees to become more accomplished change agents. Employees will better understand how to adapt to uncertain work contexts and align their interpersonal relations to lead their change initiatives successfully.

Overall Conclusions. Interpersonal relations remain critical even under crisis and uncertainty. However, the best amount and type of relations are context-dependent. Employees will only elevate performance when they consider the task, manager, and business context while initiating change. Finally, individual and relational energy explain why proactive actions may (not) contribute to better performance.

discussant: Shereen Fatimah, Singapore Management Universit

Keywords: proactive behaviours, interpersonal context, performance

Paper 1

Working in times of crisis – does proactive personality, level of uncertainty and LMX make a difference?

Sandra Ohly & Christina Veronica | University of Kassel, Germany

Research Goals and Theoretical Background. Crises are characterized by high levels of uncertainty which could stimulate proactive behaviors. Although uncertainty is thought to motivate proactive behaviors such as feedback seeking which can directly reduce the uncertainty (Grant & Ashforth, 2008), it is currently unclear how other proactive behaviors can be fostered, and which additional factors might play a role. Based on trait activation theory and situational strength theory, we expect an interaction between proactive personality as the stable tendency to exert proactive behaviors across time and contexts, and promoting factors such as LMX and uncertainty.

Methodology. Competing hypotheses about the nature of this interaction are tested using an experimental design referring to crisis scenario in a sample of N = 184 employees. In the scenarios, the level of uncertainty was manipulated. Proactive personality, proactive behaviors and LMX were assessed using established scales.

Results. First analyses show significant main effects of proactive personality and LMX on proactive behavior in crisis situation. The relationship of proactive personality and proactive behavior is independent of level of uncertainty and LMX. We also found no evidence of an effect of uncertainty level on proactive behaviour. Final results will be available by the end of 2022.

Limitations. Although participants will have natural experiences in crisis situations due to current world affairs, the use of vignettes limits the external validity of study findings. Moreover, the intention to show proactive behavior might be overstated in the self-reports and may not translate into actual behavior, and the relationships might be inflated by same-source bias.

Conclusions. Results of this study will enhance our understanding of proactive behavior in crisis situations, and enable the development of appropriate interventions. When dealing with crisis situation, it is recommendable to select employees high on proactive personality, and to foster relationships based on mutual trust, respect and commitment between leaders and employees.

Relevance to the Congress Theme. Proactive individuals create changes in the work setting, and they might be better able to deal with imposed changes.

Relevant UN Sustainable Development Goals. This study fits within the goals of (1) enabling decent work and organizational growth and (2) promoting the good health and well-being of employees.

Keywords: personal initiative, LMX, uncertainty

Paper 2

Why and when newcomer career consultation elicits supervisor career mentoring: A sociometer explanation from supervisors' perspective

Chia-Huei Wu, University of Leeds, UK, & China Medical University, Taichung, Taiwan; Yuhuan Xia, Beijing Jiaotong University, China; Wen Wu, Beijing Jiaotong University, China; Yuyan Zheng , University of Surrey, UK; Ying Wang, RMIT University, Australia

Research Goals . This study seeks to examine how supervisors respond to newcomers' career consultations behaviors. For newcomers' career consultation behaviors to materialize into concrete support from supervisors, it is important to understand how and when supervisors may be impacted by newcomers' career consultation. We provide a detailed examination of why newcomers' career consultation can elicit supervisors' career mentoring (i.e., the psychological mechanism), and under what conditions supervisors are more likely to offer mentoring to newcomers (i.e., the individual differences in supervisors).

Theoretical Background . The sociometer theory of self-esteem draws upon an evolutionary perspective and argues that being accepted by others is important for human survival and reproduction, and therefore individuals develop an internal regulatory system that monitors the success of their interpersonal acceptance, or their "relational value" to significant others (Leary, 2005). Accordingly, we expect that newcomers' proactive consultation could signal how they respect and value their supervisors and show their endorsement to the supervisors' status, thereby increasing supervisors' organization-based self-esteem. Also, supervisors are motivated to respond actively and positively to newcomers' requests for career help, by providing them more career mentoring. Further, sociometer research has noted that some people are particularly sensitive and reactive to acceptance cues (Downey & Feldman, 1996). We expect that supervisors with higher levels of power distance orientation who tend to believe that subordinates are supposed to respect and value them and who prefer being admired by subordinates (Farh et al., 2007), are likely to see newcomers' consultation behaviors as affirming their status as someone who is dominant and takes charge and gives strong directions towards employees (Hu et al., 2018). These supervisors view newcomers' career consultation behaviors as not only confirming their usefulness as a source of career advice but also reinforcing their power status.

Methodology . Our data were collected from a large electric appliance company located in the eastern region of China We sent out the first round of surveys when the newcomers first joined the company (Time 1). We asked both newcomers and supervisors to report their demographics, and supervisors also reported their power distance orientation. One month later (Time 2), we asked newcomers to report their career consultation behaviors toward their supervisors during the past month. One month after Time 2 (Time 3), supervisors were asked to report their levels of OBSE. Finally, at Time 4 (another month after Time 3) newcomers were asked to rate career mentoring they had received from their supervisors. We received 238 dyadic pairs at Time 4 (response rate of 55.74%).

Results . Our results supported the moderated mediation effect. Newcomers' career consultation behaviors led to supervisors' OBSE ($B = .44$, $p < .001$), which further led to more career mentoring being provided to newcomers ($B = .18$, $p < .01$); supervisors' power distance moderated the relationship between newcomers' career consultation behaviors and supervisors' OBSE ($B = .35$, p

<.01). The indirect effect of supervisors' OBSE was higher when supervisors' power distance is higher (effect size = .12, CIs [.02, .31]) than when it was lower (effect size = .02, CIs [−.06, .13]).

Limitations . Although we assessed the predicator, mediator, and outcome at different time points, we cannot make causal inferences with this design. Also, we only tested power distance orientation from supervisors and did not consider newcomers' power distance orientation, or the level of compatibility between the two parties. Finally, we collected our sample from China, where people have relatively high levels of power distance orientation compared to those in Western cultural contexts.

Conclusions . Newcomer career consultation behaviors contribute to enhanced supervisor OBSE, which subsequently motivates supervisors to provide more career mentoring to newcomers. We also reveal supervisors' power distance orientation as a critical personal attribute that influenced this relationship, such that supervisors with higher standing on power distance orientation were more sensitive to newcomer career consultation behaviors, hence their OBSE and career mentoring behaviors were more subject to the influence of these newcomer behaviors.

Relevance to the Congress Theme and UN Sustainable Development Goals . Our study highlights that newcomers can strategically utilize career consultation behaviors to exert an influence on supervisors, to benefit their career development in a new organization. We further highlight that newcomer career consultation behaviors are particularly important for supervisors with high standing on power distance orientation. Thus, newcomers need to pay attention to, and make sense of, their supervisors' personal tendencies and styles during their socialization process.

Keywords: newcomer career consultation, mentoring, power-distance orientation

Paper 3

Shaping the energy sweet spot: A contextualized perspective on how within-person relational job crafting influences task performance

Wiebke Doden, King's College London, UK; Dana Unger, UiT The Arctic University of Norway; Uta K. Bindl, King's College London, UK

Research Goals and Why the Work Was Worth Doing. While social interactions and connections are often predetermined by formal top-down relational job design (Grant, 2007; Grant & Parker, 2009), more recent discussions on relational job crafting (e.g., Wrzesniewski & Dutton, 2001) indicate employees also engage in efforts to shape social interactions and connections at work bottom-up. Relational job crafting is defined as self-initiated, proactive behaviors through which employees make changes in how they interact and build relationships with others at work (Bindl et al., 2019; Rofcanin et al., 2019). Employees may engage in promotion-oriented relational job crafting, which is aimed at expanding the type or number of interactions or in prevention-oriented relational job crafting, which is aimed at limiting the number of interactions at work and focusing on relationships with trusted and familiar colleagues only (e.g., Bindl et al., 2019). Across studies promotion-oriented relational job crafting has been associated with positive work outcomes (i.e., task performance), whereas research has taken an overall negative stance on prevention-oriented forms of job crafting (Bruning & Campion, 2018; Lichtenthaler & Fischbach, 2019) and found that limiting interactions and relationships at work may rather deteriorate task performance (e.g., Rofcanin et al., 2019). In our research, we suggest both promotion- and prevention-oriented relational job crafting may represent purposeful work behaviors to achieve desirable goals (e.g., Bindl et al., 2019) and demonstrate how and when promotion- versus prevention-oriented relational job crafting are beneficial for task performance.

Theoretical Background. Conservation of resources (COR) theory (Hobfoll, 1989) provides the theoretical framework for our research. A central tenet of COR theory is that individuals are motivated to build and protect their resources for goal attainment (Halbesleben et al., 2014; Hobfoll, 1989). We propose that relational job crafting may help employees create social circumstances to build and protect their energetic resources with positive implications for task performance. Most importantly, we argue that these effects may depend on the top-down relational job design context, indicated by overall task interdependence (i.e., the degree to which group members rely on each other to perform their tasks; Pearce & Gregersen, 1991). We propose that in work contexts with low task interdependence—where employees may feel more disconnected or socially isolated from others—promotion-oriented relational job crafting may be particularly beneficial for employees' energy and subsequent task performance. Interpersonal interactions and connections generally enhance positive feelings and, thus, are experienced as energizing (Owens et al., 2016). In contrast, we propose prevention-oriented relational job crafting will be beneficial for employees' energy and, in turn, task performance in contexts with high task interdependence. High levels of task interdependence require greater emotional and behavioral regulation (Trougakos et al., 2015) and may drain employee's energetic resources (Windeler et al., 2017). Purposefully minimizing further interactions and actively focusing on familiar relationships may be most beneficial in these contexts.

Methodology. We conducted an experience sampling study (10 workdays with two daily measurement points; N day-level = 845) with 126 full-time employees across various organizations during the first COVID-19 lockdown in the UK.

Results. In support of our hypotheses, multilevel path modeling indicated promotion-oriented relational job crafting was positively associated with subsequent task performance via increased energy levels, but only when overall task interdependence was low. In contrast, prevention-oriented relational job crafting was positively associated with energy levels and task performance at high levels of task interdependence.

Limitations. Our findings could be limited to employees starting to work predominantly from home as we collected data during the first COVID-19 lockdown in the UK.

Conclusions. Our findings suggest different forms of day-to-day bottom-up relational job crafting are relevant for employee performance, but their effectiveness depends on the overarching top-down relational job design context. Thereby, our findings also contribute to the ongoing debate on whether promotion- vs. prevention-oriented job crafting can be considered "good" vs. "bad" forms of job crafting, respectively and may shift the perspective of prevention-oriented forms of proactivity to being adaptive for desirable organizational outcomes in certain job design contexts. Employees may use different within-person relational strategies to proactively shape their 'energy sweet spot', so that they feel positively energized but avoid a negative too-much interaction effect.

Relevance to the Congress Theme. The substantial shift toward remote work during COVID-19 meant a variety of relational challenges for employees. Our research helps to understand how employees adapt to changing ways of work.

Relevant UN Sustainable Development Goals. This study relates to the goal of decent work and economic growth for all.

Keywords: relational job crafting, energetic resources, task performance

Paper 4

How cross-expertise voice facilitates team performance: A relational energy perspective

Jing Wu, BI Norwegian Business School; Pengcheng Zhang, Huazhong University of Science and Technology, China; Steffen R. Giessner, Erasmus University Rotterdam, Netherlands; Daan van Knippenberg, Rice University, US; Subra Tangirala, University of Maryland, US

Research Goals and Theoretical Background. Employee voice—employees' expression of challenging yet constructive work-related opinions and suggestions (Van Dyne & LePine, 1998)—has been touted as an important conduit whereby teams can utilize the members' expertise to improve collective outcomes (e.g., Frazier & Bowler, 2015). Indeed, extant research has acknowledged that voice from team members could contribute to desired team outcomes (e.g., Detert, Burris, Harrison, & Martin, 2013; Li, Liao, Tangirala, & Firth, 2017; Liang, Shu, & Farh, 2019). These studies have focused on the overall volume of voice, assuming that influences of voice were exerted on the team as a whole. This approach, however, has restrained us from developing a more nuanced understanding of the influences of team voice (Sherf, Sinha, Tangirala, & Awasty, 2018). To address this issue, we propose that voice might be better understood as being communicated to one or a few, not necessarily all, team members. This points to the necessity of studying voice configuration, that is, who voice to whom in teams. Drawing on relational energy theory (Dutton, 2003; Owens, Baker, Sumpter & Cameron, 2016), we seek to explicate how and when cross-expertise voice, or voice that occurs between team members of different expertise backgrounds, could influence team performance. When voice flows across team members of dissimilar expertise, this may give rise to difficulties in communicating ideas to one another. To overcome the difficulties, it is important to create energy or excitement for others when voicing to them and galvanize them into actions toward improving collective performance. Hence, we predict that cross-expertise voice is likely to enhance team performance through fostering relational energy within the team, because ideas from peers of different expertise backgrounds can provide cognitive simulation, arouse positive affect, and mobilize the recipients to engage in actions for changes (Oven et al., 2016). Furthermore, we predict that the above effect is more pronounced when the business environment is less uncertain because environmental uncertainty likely triggers the intergroup bias and, in turn, prevents individuals from being open-minded toward outgroup members.

Methodology. To test our model, we conducted a field survey study in six companies in Central China. They were all engaged in IT-related industries. The final sample consisted of 60 teams. Voice flow was measured with a network approach. Each employee rated how frequently every other team member shared his/her work-related suggestions with the focal person. All participants indicated their college major, based on which we identified four categories of expertise. Cross-expertise voice was calculated as the amount of voice that occurred between expertise-similar dyads divided by the possible maximum amount of voice for each team (Krackhardt & Stern, 1988). We also asked each participant to assess the extent to which every other team member affected the focal person's energy level, and computed density (Kilduff & Brass, 2010) to capture team relational energy. We used adapted or established measures to capture environmental uncertainty (Miller & Dröge, 1986) and team performance (Keller, 2006).

Results. Regression analyses revealed that cross-expertise voice was positively related to team relational energy ($b = 0.27$, $SE = 0.07$, $p < .01$) and environmental uncertainty moderated the relationship between cross-expertise voice and relational energy ($b = -0.21$, $SE = 0.10$, $p < .05$).

Monte Carlo test showed that the conditional indirect effect was significant (b = 0.72, 95% CI = [0.22, 1.35]). These results supported our predictions.

Limitations. Despite the contributions, this study has limitations: The cross-sectional design and a focus on the IT industry. It would be useful for future research to examine our theoretical model using an experimental design to provide evidence for causality and considering other industries to strengthen generalizability of our findings.

Conclusions. Via this study, we enrich voice literature by examining the unique influence of voice configuration above and beyond the volume of voice in teams. Specifically, we identified the mechanism whereby cross-expertise voice could facilitate team performance and the circumstance under which this was more likely to happen. As such, we provided managers with implications on how they may better harness the diversity of employees' expertise by being mindful about team voice flow.

Relevance to the Congress Theme and Relevant UN Sustainable Development Goal. Casting light on environmental uncertainty, our study is relevant to the Congress theme that emphasizes the changing world of work. Since we highlighted the performance implication of cross-expertise communication in an uncertain environment, our study also informed how to manage uncertainty and leverage diverse expertise and would thus contribute to decent work and economic growth and peace, (justice,) and strong institutions, as part of the UN Sustainable Development Goals.

Keywords: cross-expertise voice, team performance, uncertainty

Symposium S117

Not burnout as it was before: New empirical research on the conceptualization, impact, recovery and social nature of burnout

Anja Van den Broeck, KU Leuven

science

Content: Burnout is a well-known phenomenon. Abundant research, generally defining burnout in terms of exhaustion and cynicism (Maslach et al., 2001), largely focusses on its emergence in a context of high job demands and few job resources. Despite – or maybe just because of - the proliferation of this line of research, there are still many aspects of burnout that remain unknown. Adding to the call for more research on the new directions in burnout research (Demerouti et al., 2021), this symposium aims to bring forward a set of empirical contributions that aim to further our understanding of this phenomenon.

First, while previous research has equated burnout with its measurement in terms of the Maslach Burnout Inventory, in the first contribution of this symposium De Beer et al. set of to study the concept of burnout from the Burnout Assessment Tool (BAT), emphasizing that – besides exhaustion and mental distancing – burnout is also characterized by cognitive and emotional impairment, and comes with psychological and psychosomatic complaints. Moreover, using state of the art methodology (i.e. bifactor ESEM), De Beer expands on the processes underlying burnout, which are assumed to be energetic in nature, by showing that (a frustration of) employee motivation is predictive of burnout, even when taking into account social desirable responding.

Second, while past research has mostly focused on examining the burnout as a dependent variable or examined its relevance for employee health and well-being, attitudes and behavior, Michailidis et al. expand on how we consider the impact of burnout by indicating its relevance in influencing other processes in the work context. Specifically, using both between and within person analysis, Michailidis et al. prove that – especially at the within person level – exhaustion, as main component of burnout, may aggravate detrimental processes at work such as when employees become embittered and subsequently start ruminating after being confronted with illegitimate tasks.

Third, whereas to date, most research on burnout is limited in examining the antecedents of burnout or return to work after recovery, Vysniauskaite et al. embark in uncharted waters by deepening our understanding of an individual's recovery process after burnout. Taking an identity lens and focusing on employee values, their qualitative research indicate that the way in which burnout disrupts employees' values may differentially impact their identity work. Specifically, those who become burned-out because they may not express their values in the workplace, retain their identity, while those who are actively opposed in their (masculine) values seem to lose their identity. Finally, those who manage to develop masculine values post-burnout are those who change identity.

Fourth, De Rijk and colleagues open the scope of the burnout research by pointing out its inherent social character. When an employee develops burnout and drops out, also others are involved, not in the least the supervisor of the burned-out employee. Using qualitative case study research in Belgium and The Netherlands, De Rijk et al. indicate that supervisors may pick up early signals of employees developing burnout, much in line with the conceptualization of burnout in the BAT, but that such picking up is influenced by both personal (e.g., has burnout been on their radar before) and work related factors (e.g., organizational culture, team size and working relationship). If being aware of an employee developing burned, these supervisors may feel powerless or, in contrast, take an active role in either supporting actions at the individual (e.g. dealing with work stress, solving

personal problems) or tasks (e.g., adapting job demands and job resources) level. In any case, being confronted with burnout helps supervisors to learn from this experience and improve their actions to prevent burnout in the future.

Relevance: This symposium is relevant to the congress theme “The Future is Now./!/?” as it fosters the understanding of burnout as an urgent important contemporary problem in the workplace, affecting at least 10% of the population.

Implications: This symposium brings together contributions from researchers from across Europe and beyond, using innovative theoretical lenses and different methodological approaches to change the way we understand and do research on burnout and may leads ways on how it can be prevented or overcome.

Conclusion: In sum, this symposium advances our understanding of burnout in terms of its conceptualization, impact, and recovery process for the individual burned-out employee and sets of to explore the social component of burnout by examining the development of burnout through the eyes of the supervisors of the burned-out employee as an important stakeholder.

Paper 1

Does self-deceptive enhancement play a role in the relationships from need satisfaction and need frustration to burnout and work engagement?

Leon De Beer, North-West University, South Africa; Norwegian University of Science and Technology, Norway; Leoni Van der Vaart, Optentia Research Unit, North-West University, South Africa

Research goals and why the work was worth doing

The research goal was to investigate the impact that self-deceptive enhancement (SDE), as an indicator of socially desirable responding, may have in the relationships between basic need satisfaction and frustration on burnout and work engagement.

Theoretical background

The self-determination theory focuses on three basic psychological needs: autonomy (i.e., feeling one's actions are in line with one's wishes), competence (i.e., feeling one can master tasks), and relatedness (i.e., feeling cared for) (Vansteenkiste et al., 2020). The satisfaction of these three needs accounts for positive employee outcomes. Contrastingly, need frustration accounts for adverse outcomes (Coxen et al., 2021). However, little is known about how socially desirable responding might play a role in influencing the impact of these needs. Research has shown SDE to be superior to impression management (IM) scales to control for potential response bias (see Uziel, 2014; Uziel & Cohen, 2020). This study uses SDE – referring to socially desirable responding when the person is not aware of it – as a latent control variable to ascertain the potential influence of this response style on the results of need satisfaction and frustration on burnout and work engagement. SDE is, therefore, about self-deception and not other-deception.

Methodology

Mplus 8.8 was used to estimate a mixture model with weighted least squares (mean- and variance-adjusted) to create factor scores. That is, need satisfaction and need frustration was indicated by their average scores for each of the three corresponding needs. The remaining items were specified as categorical. For example, burnout was measured by the new Burnout Assessment Tool, and specifically, a bifactor exploratory structural model within CFA was specified for this tool in line with De Beer et al. (2022). Work engagement (UWES-9) was specified as a one-factor structure in line with literature. SDE (see Paulhus, 1991) was measured with an adapted five-item scale used by Mokgata et al. (2022) as a pragmatic indicator. The factor scores for two models were saved (one model including SDE and the other without) and estimated with the robust version of maximum likelihood. Specifically, burnout and work engagement were regressed on need satisfaction and need frustration. In the model with SDE included, the latent factor was specified to be orthogonal, having not only its corresponding items loading onto it but also all other items in the model – in line with the marker variable method to control for the potential bias.

Results

The results revealed that both models fitted the data well: CFI and TLI >0.95; RMSEA < 0.08. Furthermore, the standardised results showed that controlling for SDE at item level reduced the significant beta path coefficient values and also lowered the variance explained in the outcome variables of burnout (β SDE = 0.634 vs β = 0.677; R^2 SDE = 33.9% vs R^2 = 50.7%; 16.8% difference = medium effect) and work engagement (β SDE = 0.697 vs β = 0.811; R^2 SDE = 54.8% vs R^2 =

71.7%; 16.9% difference = medium effect). This indicates that SDE, or at least socially desirable responding, may play a nuanced role in basic need satisfaction research and should be considered in future studies as a control variable to obviate inaccuracies in the generation of parameter estimates. All in all, the substantive results showed that need satisfaction is important for work engagement and that need frustration positively impacts burnout. The opposing relationships were not statistically significant, e.g., need satisfaction did not explain significant variance in burnout beyond need frustration ($\beta = -0.048$; $p = .561$).

Limitations

Even though SDE is controlled for in this study with a pragmatic shortened scale, it was done with an adapted, shortened scale, and a more comprehensive SDE and IM scale might reveal finer nuances. Specifically, the shortened SDE scale does not include the sensitive item regarding sexual performance.

Conclusions – research and or practical implications

The results of this study show that the socially desirable responding, in this case SDE, may play an important role in the consideration of burnout and work engagement in the context of basic psychological need satisfaction and frustration. Researchers should strongly consider including an indicator of SDE in their future models to ensure accurate estimates.

Relevance to the Congress Theme

Burnout remains an important aspect of employee well-being in the changing world of work.

Relevant UN SDGs

Paper 2

Illegitimate tasks, workplace embitterment and work-related rumination after work: Are exhausted employees at higher risk?

Evie Michailidis, School of Business, University of Nicosia, Cyprus; Margarita Tartabouka, Maria Blantemi & Despoina Xanthopoulou | School of Psychology, Aristotle University of Thessaloniki, Greece

Research goals and why the work was worth doing

Embitterment is defined as an emotional response to unjust experiences (e.g., exposure to illegitimate tasks) that can have a toll on employee wellbeing. Also, previous research suggests that embitterment may promote preservative thinking about work (i.e., work-related rumination) and prevent detaching psychologically from work. However, little is known about the boundary conditions that determine who and when is at a higher risk of feeling embittered, and when embittered employees are more likely to ruminate about work during off-job time. To address this gap in the literature, the aim of this study was to investigate whether employee exhaustion moderates the indirect relationship between ITs and work-related rumination via embitterment. Addressing this research aim is relevant because it will expand our understanding on the antecedents and consequences of workplace embitterment, as well as the conditions under which embitterment is more likely to occur and more detrimental for employees.

Theoretical background

According to the "Stress-as-Offense-to-Self" (SOS) theory (Semmer, 2007), threats to one's self-image (i.e., anything that signals a lack of appreciation and respect), can trigger stress and unfavorable outcomes. Within this framework, illegitimate tasks (ITs) refer to tasks that are considered as unnecessary and/or unreasonable, and, as such, may threaten one's self esteem and violate justice rules. In line with this theory, it is argued that exposure to ITs may trigger feelings of embitterment that in turn, promote thinking about work during leisure (i.e., affective rumination and problem-solving pondering) and prevent detachment from work. In line with conservation of resources theory (Hobfoll, 1989) we argue that exhaustion may moderate these relationships because it indicates a lack of energetic resources. Exhausted employees have less energy to invest in order to deal successfully with ITs and as a result ITs are more likely to promote feelings of embitterment for exhausted employees. Similarly, exhausted employees are less able to regulate their feelings of embitterment, and this is likely to boost the positive relationship of embitterment with affective rumination and its negative relationship with detachment. In contrast, exhausted employees are less likely to engage in successful problem-solving pondering when feeling embittered. As such, the positive relationship between embitterment and exhaustion will be weaker for exhausted employees.

Design/Methodology

The study hypotheses were tested in a cross-sectional study (Study 1, N = 194) and a daily diary study (Study 2, N = 45), in order to capture within-person variations in the examined processes.

Results

The results of Study 1 indicated that unreasonable tasks related positively to embitterment. Also, unreasonable tasks related positively and indirectly to affective rumination via increased levels of

embitterment. Exhaustion did not moderate the proposed indirect relationships. Only a marginal moderating effect was found showing that the positive relationship between embitterment and affective rumination was stronger for those higher (vs. lower) in exhaustion. Results of multilevel analyses (Study 2) indicated that the positive relationship between daily ITs and daily embitterment was moderated by daily exhaustion. Specifically, the positive relationship between daily ITs and daily embitterment was significant only on days employees experienced higher levels of exhaustion than usual. Analyses also indicated that the positive relationship between daily embitterment and daily affective rumination was stronger on days employees experienced higher (vs. lower) exhaustion than usual.

Limitations

Important limitations are the relatively small sample size and the use of self-reported data.

Conclusions – research and or practical implications

The study findings contribute in better understanding how and under which conditions ITs enact feelings of embitterment and when embitterment is more likely to promote work-related rumination during off-job time. Exhausted employees seem to be at a higher risk to feel embittered when exposed to ITs and are more likely to ruminate about work when feeling embittered. Hence, organizations should make sure to eliminate ITs and unjust work environments.

Relevance to the Congress Theme

The study is relevant to the Congress Theme, as research on workplace embitterment is growing exponentially during the past years with important implications for employee well-being.

Relevant UN SDGs

The topic is relevant to the Sustainable Development Goals and especially to the goal for good health and wellbeing, and justice and strong institutions.

Keywords: Embitterment, Rumination, Exhaustion

Paper 3

How Masculine and Feminine Value Orientations Constrain and Enable Identity Work After Burnout

Anja Van den Broeck, Work and Organisation Studies, Faculty of Economics and Business, KU Leuven, Belgium; Mailys George, EDHEC Business School; Ausrine Vysniauskaite, Work and Organisation Studies, Faculty of Economics and Business, KU Leuven, Belgium

Research goals and why the work was worth doing

Psychological processes underlying recovery from burnout remain a black box which is concerning given the evidence that recovering from burnout can be challenging and relapse is common (Maricuţoiu et al., 2016, Pijpker et al., 2019). This paper brings forward identity work as an important psychological activity that burnout patients engage in during their recovery. The goal of this paper is to investigate the process of recovery from burnout by introducing the theoretical lens of identity work as a novel perspective (Bataille & Vough, 2020).

Theoretical background

Identities are people's interpretations of who they are based on their personal and demographic characteristics, the groups they belong to, and the roles they play in society (Caza et al., 2018). People have multiple identities (e.g., related to work, family, religion) (Gecas, 1982; Stryker & Serpe, 1994). When employees undergo burnout, "a state of exhaustion in which [they are] cynical about the value of [their] occupation and doubtful of [their] capacity to perform" (Maslach et al., 1996, p. 20), this will call into question their work identities and–consequently–simultaneously influence their non-work identities (Bataille & Vough, 2020). This will prompt employees to engage in identity work, that is to revise their identities (Caza et al., 2018).

Methodology

The first author conducted 19 interviews with 6 men and 13 women working in Belgium and aged between 27 to 50. The interviews were conducted online between December 2021 and July 2022 and lasted on average one hour. The interviews were conducted in English, and were recorded, and transcribed verbatim. The data was then analysed in grounded theory fashion.

Results obtained or expected (if not available, it must be made clear when they will be)

For our 19 study participants, we identified three main identity trajectories after burnout: liminality, affirmation, or change. Additionally, interviewees' masculine and feminine value orientations—e.g., careerism and independence, as masculine versus intuition and nurturing as feminine values (Alvesson, 1998, Buzzanell & Lucas, 2006)—were a key factor affecting their engagement in a given trajectory. Post burnout identity work was affected by distinct value orientations in the following three respects: 1) participants who perceived that their burnout arose from not being able to exercise masculine/feminine values in the workplace tended to maintain their identity after burnout, 2) participants who perceived their burnout as disrupting prior masculine value orientation tended to feel liminal, in-between, after burnout, and 3) participants who developed masculine value orientations after burnout tended to position themselves as identity changers. These findings contribute to the under-explored, yet key relationship between identity and values (Turner, 1968, p. 97). Further, this study demonstrates the role of the social structure in

burnout emergence (through disruption of values) while also highlighting individuals' agency in using newly developed values as a resource for identity work.

Limitations

While the findings are based on a relatively small sample (19 interviews), this sample size in line with extant published qualitative studies (e.g., LaPointe, 2013) and data collection is ongoing. Another potential limitation is that study participants are all from Belgium, a country with highly established and relatively straightforward burnout treatment and resources for recovery. Therefore, future research should investigate identity trajectories of burned-out individuals in countries that vary in the degree to which burnout is recognized and treated.

Conclusions – research and or practical implications/Originality/Value

The paper provides important knowledge about the fundamental psychological processes in burnout recovery for burnout scholars as well as practitioners by demonstrating that people's identities may change during burnout and that feminine/masculine value orientations are an important factor explaining engagement in distinct identity trajectories.

Relevance to the Congress Theme

By introducing a novel approach to practical and theoretical knowledge on employee burnout, this paper corresponds to the interests matching topic 15 - Stress and Dysfunction.

Relevant UN SDGs

The paper seeks to promote well-being for the working population—enhancing employee health and happiness—by expanding theoretical and practical knowledge on burnout. Based on the findings, our research team sets out to build guidelines for the long-term recovery from the syndrome that have been lacking so far.

Keywords: Values, Identity, Burnout

Paper 4

Noticing and addressing early signs of burnout or not: qualitative research among line managers in Belgium and the Netherlands

Angelique de Rijk, Department of Social Medicine, Care and Public Health Research Institute, Faculty of Health; Inge Houkes, Department of Social Medicine, Care and Public Health Research Institute (CAPHRI), Faculty of Health, Medicine and Life Sciences, Maastricht University, Maastricht, the Netherlands; Laura Berger, Department Research and Business Development, HumanTotalCare Occupational Health Service, Utrecht, the Netherlands; Robin Kok, Department Research and Business Development, HumanTotalCare Occupational Health Service, Utrecht, the Netherlands; Iris Huijsmans, Faculty of Health, Medicine and Life Science, Maastricht University, the Netherlands; Manon Claes, Faculty of Health, Medicine and Life Science, Maastricht University, the Netherlands

Research goals and why the work was worth doing

Despite our knowledge on risk factors for burnout, there is a lack of knowledge on the role that line-managers play in preventing burnout. We aimed to explore how line managers in Belgium and in the Netherlands recognize early signals of burnout among their employees and if so, which actions they take to prevent their employees to become burned out.

Theoretical background

Theory on burnout dimensions and the Job Demands Resources model were loosely used as a lense for this qualitative study. Theoretically, three aspects are characteristic for burnout. First exhaustion, which captures the energetic aspect that is expressed in through the inability to carry out one's work properly because of chronic fatigue. Second mental distance, which highlights the motivational aspect that is expressed by the unwillingness to perform because of mental distance towards one's job. Thirdly the impaired functional capacity to regulate one's emotional processes and cognitive processes. Line managers might notice the various symptoms of burnout, but might also hold their own definition of burnout. Next, as regards causes of the burnout and actions to be taken, line-managers might change their employee's demands and/or resources.

Design/Methodology/Approach/Intervention

Two subsequent case-studies were designed. In Belgium, 17 line managers (14 females, aged 43-62) were interviews during spring 2021. They were working in the educational and health care/local government sectors. In the Netherlands, 16 line managers (7 females, aged 36-61) were interviewed in Spring 2022. They worked in the public and private sector. Because males had been underrepresented in Belgium, the recruitment emphasized welcoming male line-managers to participate. In addition, also other sectors than health and education (in which female line-managers are overrepresented) were targeted. In both countries only line-managers were included who had been confronted with the sickness absence of at least one employee due to burnout in the past five years. The topiclist included: background information of line-manager and employee(s) with burnout, perceived signals of burnout, perceived causes of burnout, how the situation developed including actions taken by the line-manager, reflection and lessons learned. In the Netherlands, also the definition of burnout and how private life issues were handled, were added. Interviews were transcribed verbatim, coded in NVivo, and analyzed according to principles of thematic analysis. The Belgian and Dutch data were analysed separately.

Results obtained

Both in Belgium and the Netherlands, three different, successive phases could be recognized: picking up signals, taking action, and reflection. Line managers' personal frame of reference (e.g., having experience with burnout) related to whether and how they picked up signals of burnout. In the Netherlands, evidence was also found for the organizational culture to play a role as well as the working relationship and workload / teamsize played a role feeling able to notice signals. The managers noticed symptoms of fatigue, emotional disruptions and lack of concentration. If they picked up these signals, they generally took an active role: they started a conversation and changed work tasks. In the Netherlands, line managers also educated their employees on how to handle work stress, took actions to support private life issues and referred to the occupational physician or social worker. In Belgium, the line-managers confessed often feeling powerless. In both countries, the line-managers revealed that they learned from the experience. Particularly in the Netherlands, regular contact with their subordinates was mentioned as a means to prevent burnout.

Limitations

Male line-managers were underrepresented in the Belgian study; the Belgian sample also lacked private sector manager. Even though, the results in the Dutch study did not seem to be linked to gender or sector.

Conclusion research/practical implications

This study shows that improving line managers' knowledge on preventing burnout, e.g., by organizing meetings and/or training, may help them to detect early signals of burnout and take action. Further, an open organizational culture and a smaller teamsize facilitates have good contact with ones subordinates, and subsequently picking up signals and being able to take actions. There were subtle differences between Belgian and the Netherlands.

Relevance to the Congress Theme

To the best of our knowledge, the prevention of burnout symptoms has not been studied yet from a line-manager's perspective.

Relevant UN SDGs

Knowledge on how managers notice early signals of burnout and react on them links to the SDGs 'Good health and wellbeing' and 'Decent work and economic growth.'

Keywords: Burnout, Line managers, Intervention

Symposium S121

Inequalities at the Workplace: Critical Perspectives and Future Avenues

Edina Doci, Vrije Universiteit Amsterdam; John Mendy, Univeristy of Lincoln

science

What will be covered and why

Inequalities are on the rise (Piketty, 2013). Covid and the unfolding climate crisis have shown that when global adversities hit, marginalized groups are hit hardest, leading to the further widening of inequalities. Marginalized and minoritized groups are on average more likely to be exposed to precarious working conditions, unemployment, workplace maltreatment and mental health problems. At the same time, diversity programs in organizations tend to fail to achieve structural changes, as a result of organizational resistance and lack of appropriate managerial support and financial resources.

As organizations are central institutions where the reproduction of social inequalities unfolds, studying the mental health impact of inequalities on the one hand, and the individual, relational and organizational processes through which inequalities are reproduced or challenged on the other, are crucial concerns for work psychologists. This is especially true in times of increasing inequalities and crisis.

However, the field of work psychology is relatively silent in this regard. Many work and organizational psychology studies are conducted with the participation of a narrow segment of the population, whose lived experiences and problems differ considerably from those of minoritized and marginalized group members. While our theories and models often build on the experiences of dominant society, we tend to consider these models and processes universal.

Furhtermore, the field tends to individualize psychological experiences, (the antecedents of) organizational behavior and individual outcomes at the workplace. Many of our organizational processes, practices and interventions are based on these individualised models that do not take into account how social stratification and social group membership (gender, ethnicity, dis/ability, sexuality, religion etc.), and related inequalities shape radically people's experiences at the workplace. While these interventions build on and cater to the experiences of dominant society, they are often unavailable to disadvantaged workers, or not applicaple to their experiences and situation. The adverse circumstances that marginalized and minoritized workers are subjected to, such as discrimination, harassment or precarity, are of a collective and social nature and tend to be much more severe than the experiences of dominant society. Individualizing workplace psychological processes, and therefore the responsibility for one’s well-being, is thus neither adequate nor complete.

The current symposium aims to investigate the lived experience and impact of inequal treatment in the workplace, and the inequalities manifesting in the workplace. Moreover, the symposium aims to investigate the various processes through which inequality structures emerge and get reproduced at the workplace and their psychological impact on employees. The symposium brings together presentations based on both conceptual and empirical work, including both quantitative and qualitative empirical research, and ranging from research on autism at work, the experiences of lesbians and gays in India, inequalities in psychological capital, and precarious work. Overall, the presentations offer deep insights into the wide nature of inequalities at work.

Relevance to the Congress Theme

The symposium highlights the increasingly unequal and precarious nature of the contemporary workplace, where protection of vulnerable workers is not guaranteed. The theme of the conference points toward the need to change the world of work to enhance greater fairness and equality for workers. To do so, we need to better understand the lived experiences of workers, especially those who are unequally treated due to their 'otherness' in comparison to the prototypical worker. Hence, the symposium fits well with the theme of the conference, and on the basis of the presentations included, provides practical suggestions for how the world of work can be changed toward greater fairness and equality.

Research/Practical Implications

The symposium has important implications for both research and practice. First, the presentations in the symposium elucidate the nature of how inequalities are experienced in the workplace, and how they relate to well-being. Jointly, they provide insights into the experiences of inequality in the workplace. Second, the practical implications of the symposium include the insights into the manifestation of inequality and the ways through which this could be remediated in organizational life.

Overall conclusions

This symposium offers new perspectives on inequalities at work, and provides in-depth insights into the lived experience of people disadvantaged at work.

Keywords: workplace inequality, marginalization, precarity

Paper 1

Rethinking Workplace Inequality: where Transactional HR serves as marginalization tool for autistic jobseekers

Mendy John, University of Lincoln

Research Background:

Whilst social class, gender pay, migration, ethnic and racial stratification and even within and beyond-nation inequalities have attracted the attention of Social Science scholars from Psychology to Business and Management, focusing on and problematizing workplace inequality from the experiences of marginalized, autistic jobseekers, has received limited research attention. This study highlights how the transactional dominant logic with which Human Resource Management recruitment and selection practices are conducted at the interview stage on disabled people such as 24 autistic jobseekers exposes a wider societal challenge risking the achievement of the UN SDG on reducing inequality in workplaces and society.

Research goals and why the work was worth doing

Previous workplace inequality research and theory focused on the factors causing inequality (e.g. wrong organizational strategy, lack of implementation of equality, diversity and inclusion practices, lack of engagement of more diverse, minoritized and marginalized groups, ontological insecurities felt by implementers of equality, diversity and inclusion initiatives, and inappropriate use of managerial power). Such a focus has traditionally been on understanding inequality from those already in work thereby hypernormalizing a fake reality of what workplace inequality really involves. People with varying physical, mental, emotional and cognitive challenges were quite often omitted from research endeavors. This study problematizes this significant gap in workplace inequality research and practice from the perspective and experiences of autistic jobseekers and thereby challenges the traditional, transactional approach with which previous scholarship on the use and benefits of HRM practices on employee quota filling on disabled and marginalized groups. Therefore, whilst recruiting, selecting and interviewing potential employees with disability may have seemingly ticked organizations' boxes on meeting diversity and inclusion targets, this current study suggests that more needs to be done if organizations and society are to be truly inclusive.

This study therefore focuses on the following research goals:

To problematize the bureaucratic, standardized and transactional nature with which HRM job selection practices are conducted to examine their impact on reducing organizational and societal inequality.

To examine the psychological wellbeing and welfare of vulnerable and marginalized groups to ascertain the current (and potential future) state of workplace inequality research and to evaluate impacts on attaining the reduction of inequality in organizations and society.

To rethink workplace inequality from a less dominant autistic jobseekers' perspective as an urgent organizational, societal and global challenges and to propose practical resolutions.

To propose a framework to complement the UN SDGs to help reduce workplace inequality in contemporary society and organizations.

Design/Methodology/Approach

The study collected empirical data from 24 autistic jobseekers in the UK using a questionnaire and focus groups.

Results

The first result is employment brick walls faced by the autistic jobseekers when they attempted to transition into work in the UK. Whilst this finding concurs with previous studies conducted (Lai & Szatmari, 2019; Hedley et al. 2017b; Raymaker, 2017), it highlights the urgency of the inequality challenge of marginalized communities.

The second result is socio-cultural and financial discrimination which aligns with Ngoasong and Groves (2016) but differs from Nicolaidis et al. (2015b) and Kaboski et al. (2017) who advocate for greater agency for communities suffering from inequality.

The third result is entrenched marginalization as confirmed earlier by Guerci (2019) but in contrast with Bardoel et al. (2014) who expected faster adaptation from marginalized groups.

Relevance to Congress

Given that previous research related to Work Psychology and Management tends to focus on either the contributing factors of the inequality or the benefits of safeguarding the psycho-social and wellbeing of staff through the adoption of logical and appropriate recruitment and selection, performance and reward management policies and procedures. However, what the problematized examination of HRM practices around recruiting, interviewing and selecting autistic jobseekers highlights is the absurdity of standardizing such practices for all potential employees without due consideration onto individuals and certain groups personal, sensory and professional and educational needs. This poses a fundamental organizational challenge in terms of workplace inequality especially for autistic employees. The workplace of the future needs to preempt inequality from already marginalized groups and to develop actions that seek to address their inabilities to access full employment and engagement with society and developing bottom-up strategies that are autism-knowledge-based to resolve the workplace inequalities.

Relevance to UN SDGs

This study is relevant to reducing inequality. I extend the SDG by spotlighting the adverse experiences of autistic jobseekers being treated unequally. I also surface the transactionality with which HRM practices are conducted to show 1) how it serves to politicize contemporary discourses on inequality; 2) the complex and problematic nature of employee-employer transactional relations that promote organizational, societal and ontological inequalities 3) the urgency of the inequality challenge facing organizations and society and what actions need to be taken politically, ideologically and ethically; 4) how the internalization of dominant logics of transactionality may risk internally, organizationally and externally reifying inequality and challenge restitutive actions from individuals, civil society and other groups.

Keywords: workplace inequality, autistic jobseekers, HRM

Paper 2

Lesbians' and Gays' Conquest of Fear and Bullying through Courage: From Individual to Organizational Levels

Noronha Ernesto, Indian Institute of Management Ahmedabad; Bisht Nidhi, Management Development Institute Gurgaon; D'Cruz Premilla, Indian Institute of Management Ahmedabad

Research rationale and goals:

Our interests in workplace diversity and inclusion; ethical, responsible and empowered workplaces; workplace dignity; and workplace bullying led us to this study. We noted a gap in academic scholarship around LGBTQI issues in organizations. This gap was alarming given the commonly reported mistreatment this community is subjected to. We realized the crucial need for systematic and rigorous research to provide a solid base for policy and practice aimed at facilitating inclusion and integration of all sexual orientations.

Theoretical background:

The study was anchored in the workplace courage literature. Courage is a positive and ethical response to threats, involving the readiness to take upon oneself negativity anticipated by fear, for the sake of a fuller positivity. The courageous choice results in authenticity because it opens the possibility of becoming who one is, realizing one's potential and lessening fear and anxiety by developing meaning in one's life. Workplace courage is largely conceptualized as a personal disposition, ignoring its social dimensions which bind the seemingly solitary actor to a broader community, thereby motivating the individual agent to act. Not surprisingly, most courage scholars acknowledge that fear and courage are closely entwined. A person who shows courage respects fear, attempts to master fear and acts despite some level of fear being present. Courage is a voluntary act executed after mindful deliberation in the face of fear or risk.

Design/methodology:

A hermeneutic phenomenological study in two phases over a three-year period was undertaken in two major Indian cities. Lesbians and gays, identified through the researchers' personal contacts and snowball sampling, participated in semi-structured interviews. Data were subject to sententious and selective thematic analyses.

Findings:

We found that fear marks lesbians' and gays' (LGs') experiences of work in Indian organizations, being subjected to unethical acts of workplace bullying which get manifested through constant guesswork, comments and questioning about their sexual identity in a hostile social context. LGs usually cope through 'passing' and 'covering' strategies, opting for secrecy and leading a double life, in order to manage economic, social and psychological risks. Even so, the attempt to be courageous and endeavour to live authentic lives despite the hostile broader organizational and social context is evident. LGs' courage at work is manifested mainly through deliberate micro-disclosures and a sense of defiance which can be enhanced if organizations are designed to be more inclusive and ethical. To this end, organizations must be crafted and sustained to be courageous within a hostile social climate, for employees to overcome their fears. Leaders and top management have a crucial role to play in this. Courage must necessarily go beyond the individual to the workplace. In this way, our findings rewrite the negative tenor of lesbians, gays, bisexuals and transexuals research by

emphasizing courage as an empowering and positive antidote to the fear and trauma which accompanies an alternative sexual orientation.

Limitations:

The study did not include bisexuals and others with alternative sexual orientations.

Conclusions/contributions/implications:

Academically, the study (a) addresses a gap in the literature on LGBTQIs at work and on the category-based workplace bullying experienced by sexual minorities; (b) extends the workplace courage literature beyond its existing focus on personal courage to emphasize organizational courage; and (c) provides a conceptualization and definition of inclusive ethical organizations. Policy-wise, the study (a) emphasizes the importance of leaders' and top managers' courage in creating truly inclusive ethical organizations, even in the face of hostile societal contexts; (b) underscores the crucial role regulation plays in making workplaces inclusive, particularly in terms of policy design and deployment, which not only sets the tone for organizational values and ethos, but equally importantly, serves as a protective shield that mistreated targets can invoke when needed, thereby facilitating empowerment and well-being.

Relevance to the Congress theme:

The study, speaking to workplace diversity and inclusion and to ethical inclusive and responsible workplaces, directly reflects the Congress theme in regard to the ongoing unfolding of the future and the changing nature of the world of work. Moreover, the study is relevant to the inequalities and critical streams of FOWOP due to its focus on the social category of sexual orientation and its emphasis on personal and workplace courage as means of empowerment.

Relevant UN SDGs:

Reduced inequalities, decent work and economic growth, good health and well-being, responsible workplaces endorsing justice

Keywords: diversity and inclusion, LGBTQI, workplace bullying

Paper 3

The predicaments of precariousness: Relationships of conditions and experiences of precarious employment with psychological health and wellbeing

Severin Hornung, Jurgen Glaser, Lisa Seubert, Christian Seubert & Carla Czilczer | University of Innsbruck

Research goals and why the work was worth doing:

Labour market changes in recent decades have proliferated conditional and temporary work arrangements, increasingly replacing full-time long-term employment. Resulting insecurity and economic risks for workers socially mandates research into precariousness. After reviewing conceptualizations of objective conditions and subjective experiences of precarious employment, we empirically operationalize these and report their associations with employee health and well-being, based on cross-sectional and longitudinal data from a representative survey conducted in 2015 and 2017 by the German Federal Institute of Occupational Safety and Health (FIOSH or BAuA).

Theoretical background:

Sensitivity to work-related uncertainty and insecurity has increased, yet, precarious employment is hardly well-defined. A review of the sociological literature suggests job insecurity, wages below subsistence level, lacking access to social security systems, and reduced opportunities for control and influence as constitutive factors. These converge with a recent systematic review on definitions of precarious employment, identifying employment insecurity, income inadequacy, and lack of worker rights and protection as objective dimensions. Associated subjective experiences are conceptualized in a five-dimensional taxonomy of reproductive–material, social–communicative, legal–institutional, status and recognition, and meaningful–subject-related aspects. Building on this integrative multidimensional framework, we examine the roles and relevance of objective and subjective characteristics of precarious employment with regard to health and well-being.

Design/Methodology/Approach/Intervention:

Data stem from two waves (2015 and 2017) of a representative survey among employed persons in Germany (BAuA Working Time Survey), using computer-assisted telephone interviews with randomly generated phone numbers. Analysed are cross-sectional data from the first wave (N = 20,030) and the longitudinal panel (N = 6,539). Questions assessed sociodemographic variables, work and employment conditions, and personal experiences and health. Suitable proxy variables were identified to represent objective and subjective indicators of precarious employment. Estimated work ability, psychological complaints, and psychosomatic symptoms were selected as health-related outcomes. Employed methods were confirmatory factor analysis and structural equation modelling.

Results obtained or expected:

Eight indicators of “objectively” precarious working conditions were allocated to the dimensions of employment insecurity (e.g., job cuts, involuntary underemployment), income inadequacy (less than 1500 Euros per month), and lack of employee rights and protection (e.g., scope of decision-making, unscheduled overtime, insufficient work breaks). Subjective experiences were operationalized with nine items representing the reproductive–material (e.g., making ends meet), social–communicative (e.g., lack of community), legal–institutional (e.g., perceived opportunities for participation), and meaningful–subject-related (i.e., satisfaction with work) dimensions. Measurement models were

established in confirmatory factor analyses. Cross-sectional and longitudinal analyses based on structural equation modelling supported significant relationships between objective indicators of precarious employment and negative health-related outcomes, partially mediated by subjective experiences of precariousness.

Limitations:

Analysing an existing data set, proxy variables were used and not all concepts could be fully represented empirically in all their dimensions. The questionnaires in the 2015 and 2017 waves differed somewhat, restricting longitudinal analyses. Future studies should be designed with improved measurement of targeted constructs.

Conclusions – research and or practical implications:

Previous studies tend to focus on single aspects of precarious employment. Multidimensional conceptualizations facilitate broader understanding of relevant factors that constitute precarious employment and its psychosocial effects. Our analyses allow inferences on the relative importance of different objective conditions and subjective experiences of precariousness for health and well-being. Based on these, interventions can be designed and recommendations for policy-makers derived, to counteract the most dysfunctional aspects of precarious employment.

Relevance to the Congress Theme:

Employment relationships in Europe have become increasingly polarized and precarious. In the future, this trend threatens to be accelerated by economic crisis. Work and organizational psychologist urgently need to deliver on their professional responsibility by contributing to calling out, challenging, and reversing this socially corrosive and decivilizing symptom of economic exploitation, eroding society and public health.

Relevant UN SDGs:

No poverty, good health and wellbeing, reduced inequalities, decent work and economic growth.

Keywords: Precarious employment, conditions and experiences, health and wellbeing

Paper 4

The hidden social inequalities behind psychological capital: A plea to integrate psychological capital in the study of social reproduction

Edina Doci, Vrije Universiteit Amsterdam; Christophe Vanroelen, Joeri Hofmans, Deborah De Moortel & Bram Spruyt | Vrije Universiteit Brussel

Theoretical background

During the past decade, a rich literature emerged focusing on 'psychological capital', a multidimensional concept referring to self-efficacy, hope, optimism and resilience. So far psychological capital has been predominantly studied as an individual level variable, in the areas of work and organizational psychology, management, and organizational behavior. In this paper, we argue to take a sociological perspective on psychological capital by integrating it into Bourdieu's capital framework. By doing so, we can better understand how social inequalities are reproduced through labour market and workplace processes. In his seminal work, Bourdieu (2021) differentiates between social, cultural and economic capital. Bourdieu argues that different types of capital (social, cultural, economic) can be converted to each other, and that this conversion of capitals plays an important role in the reproduction of the social structure by allowing for a disguised transmission of power and privileges within dominant social groups. We propose to include psychological capital within this framework.

New perspectives / Contributions

We postulate that psychological capital corresponds with Bourdieu's definition of capital (2021: 16) which describes capital as "accumulated history" that contains "a form of power that is effective within a certain space, where it produces effects – in particular effects of differentiation […]". First, psychological capital is accumulated history and gets accumulated through transmission processes in people's social and career trajectories. People invest time and energy into achieving goals, and the resulting mastery experiences produce psychological capital. The more psychological capital people possess, the more likely they will set high goals and pursue achievements, which in turn reinforce their high levels of psychological capital, setting positive cycles in motion. Psychological capital accumulates as history because of repeated success experiences, positive assessments, social feedback and recognition. Second, psychological capital enhances productivity and pays off. A plethora of research documented how psychological capital and related positive psychological characteristics enhance productivity and 'buy' career success and status (e.g., Avey, Nimnicht, & Pigeon, 2010). Third, psychological capital is unequally distributed in society and in organizations and is a basis for social distinction and exclusion (e.g. Francis & Jones, 1996). Psychological capital is a quality that signifies worth in workplaces and society. People from higher societal echelons tend to convey high levels of psychological capital, indicating their class status this way, and they are rewarded for it by recognition, high level jobs and inclusion in prestigious networks (Hartmann, 2000). Fourth, psychological capital is a form of capital that can be clearly distinguished from economic capital and can be transformed to other forms of capital. Constituents of psychological capital, such as confidence, optimism, resilience and a positive outlook on the future are highly valued in organizations. Because these characteristics are perceived as signifiers of worth, competence and leadership potential, they are often rewarded with recognition, trust and positive selection and promotion decisions (Hartmann, 2000), and are thus relatively easily convertible to economic and social capital.

We postulate that psychological capital plays an important role in the reproduction of inequalities in organizations and society and in the reinforcement of social stratification in organizations. Managers (who are mostly from dominant social groups) create opportunities for some employees to develop psychological capital and deprive others thereof, and their behaviors differ when targeting in-group and out-group members. Through relational processes, psychological capital is maintained and reproduced within dominant social groups in the workplace, for example through offering opportunities for mastery and success to in-group members; recognizing, appreciating and supporting in-group members; offering in-group members more time, attention, information, visibility and credit and evaluating their performance more positively than they would do in the case of others; and offering them high status assignments and responsibilities and thus setting in-group members up for success (Dóci, Knappert, Nijs, & Hofmans, 2022).

Furthermore, dominant group members are not only more likely to develop high levels of psychological capital in the first place, but they also recognize, appreciate and reward these very qualities in others as signs of familiarity and trustworthiness. This points at the crucial role of psychological capital in social reproduction, that is, in the masked transmission of power within dominant social groups and in the maintenance of social hierarchies over time. At the same time, social, economic and cultural capital can also be converted to psychological capital. For example, research shows that belonging to higher social classes, and thus having access to a high-status social network (social capital), good education (cultural capital) and wealth (economic capital) enhances one's self-esteem and self-efficacy (e.g. Francis & Jones, 1996). This way, capital begets capital.

That economic, social and cultural capital are unequally distributed in society between members of different classes, ethnic groups and genders has been long acknowledged. High status societal groups tend to accumulate all forms of capital through their conversion, thereby maintaining their rich capital pool within the group both intra- and intergenerationally and reproducing their elite position in society. At the same time, low power social groups tend to experience deprivation of all forms of capital. Similarly to social, economic and cultural capital, we put forward that high status social groups maintain and reproduce high levels of psychological capital within the group which contributes to reproducing their elite position in organizations and society.

Conclusions, research implications

Psychological capital to date have been mainly studied in WOP / OB research, on the individual level and as a predictor of work outcomes. We argue that the relevance of psychological capital is broader, that understanding its social origins and its role in social reproduction is crucial and thus it needs to be studied in interaction with other forms of capital. Studying these processes would show how inequalities in one context spill-over or reinforce inequalities in other contexts. We believe that the notion of psychological capital offers excellent opportunities for interdisciplinary research and will stimulate productive exchange between disciplines that so far have often talked past each other.

Relevance to the congress theme

In times of multiple crises and growing inequalities, it becomes an important task of work psychologists to understand the (socio)psychological processes through which inequalities are reproduced at the workplace.

Relevant UN SDGs

SDG 5: Gender Equality

SDG 10: Reduced Inequalities

Keywords: psychological capital, workplace inequalities, social reproduction

Symposium S124

EFPA Survey of Attitudes to Tests and Testing - findings and impact for WO psychologists

Nigel Evans, NEC, UK; Dragos Illescu , University of Bucharest, Romania

science_practice

What will be covered and why?

The main goal of the European Federation of Psychologists 'Associations (EFPA) Board of Assessment (BoA) is the improvement of testing practices in European countries. In order to reach this goal, the BoA carries out various actions and projects.

To better inform its work, the EFPA BoA decided to survey the opinions of professional psychologists on testing practices, started in 2000, and then extended, due to the pandemic, across 20 European countries.

The emphasis in this symposium will be on the new data but comparisons with the results from the previous surveys will also be presented. Five main dimensions were distinguished in the survey: concern over incorrect test use, regulations on tests and testing, Internet testing, appreciation of tests, and knowledge and training relating to tests and test use.

Relevance to the Congress Theme:

Advances in technology alongside requirements of fairness in work assessment increases the need to monitor test perceptions and practice by WO psychologists. Psychologists then informing and supporting allied professionals wthin commerce and government is critical to advancing future assessment practice.

Research and Practical Considerations:

The EFPA Questionnaire on Test Attitudes of Psychologists (EFPA EQTAP) has been designed to cover five thematic domains in professional use. The survey asked questions about the structure of the sample (age, gender and professional speciality) and preferences on tests of used in individual practice. Each Member Association was also able to include additional questions specific for their purpose and context.

Overall Conclusions:

Important differences between countries were found on these five dimensions. Also the most commonly used tests were questioned. Finally, some future perspectives will be discussed including the impact of practice and legislation, with particular reference to WO practice. The extended reach of the EFPA Test Model and Methodology outside of Europe was also welcomed.

Keywords: Tests, Assessment, Quality

Paper 1

The Attitudes of European Psychologists Toward Tests and Testing: 2012 and 2020

Paul Jimenez, University of Graz, Austria

Background: It is important to know about the testing practices and the attitudes towards tests and testing amongst Professional Psychologists working across Europe given the importance placed on quality assessments in decision making.

Goals: To gain a pan-European view of tests and testing perceptions with a common methodology.

Methodology: A survey on the opinions of professional psychologists on testing practices was carried out in 2000 (in six countries) and 2009-2012 (in 17 countries, N > 12000) and now in 2020/21 as a third wave. The current sample in 2020/21 includes approx. 12000 persons from 20 countries (Austria, Belgium, Brazil, Croatia, Cyprus, Czech Republic, Germany, Italy, Lebanon, Lithuania, Netherlands, Norway, Poland, Romania, Slovakia, Slovenia, Spain, Turkey, Ukraine, United Kingdom). The same questionnaire as in 2009 was used to allow comparisons. It contained 24 attitude items, one item about test-use problems (with 8 subitems) and one open question about the most frequently used tests. The evaluated areas in the survey covered attitudes towards the following aspects: Concerns over incorrect test use, Regulations on tests and testing, Internet testing, Appreciation of tests, Knowledge and training. The survey was conducted in each country on its own, partly additional items and research questions were added in the countries.

Results : An overview of the sample and first results in general will be presented. Overall, only minor differences can be found between the results from 2012 and 2020, e.g. over all countries, only the agreement on the use of internet testing increased compared to the last survey in 2012. Among other results which will be presented the current survey also shows differences regarding concerns over incorrect test use between the age groups (<30, 30-39, 40-49, >50). We find higher concerns within younger psychologists over all countries, these age differences don't appear for each country.

Limitations: Different sample sizes across European populations.

Conclusions: The data will guide the actions and measures taken by EFPA, but also ITC and other stakeholders and contribute to training and awareness campaigns to improve psychologists' use of tests across Europe.

Relevance to the Congress Theme: Perceptions to tests and testing need to be monitored in a rapidly changing world.

Relevant UN SDGs: Partnerships for the goals

Keywords: Tests, Practice, Improvements

Paper 2

Professional identity of a WO psychologist: findings based on results of the Polish edition of the European survey on tests attitudes of psychologists

Urszula Brzezinska, Practest, Poland

Background: In 2020 Polish psychologists were surveyed on their attitudes on tests and testing. This was the second time when Poland participated in a European programme of monitoring the testing culture.

The EFPA Questionnaire on Test Attitudes of Psychologists (EFPA EQTAP) is designed to cover five thematic domains: concern over incorrect test use, regulations on test and testing, Internet testing, appreciation of tests, and knowledge and training relating to tests and tests use. Beside that the survey asked questions about the structure of the sample (age, gender and professional speciality and preferences on tests of first choice used in individual practice).

Goals: the objective of this paper is to highlight the challenges in coding professional specialties among psychologists. The issues of an emerging identity of test users working in a multicontextual environment will be introduced. The WO context will be used as a showcase. Tests are an important source of information used in high stake situations in a range of contexts that are regulated by the Polish state law. One of them is the assessment of how a person fits the job he/she has chosen in favour of legitimate proper selection of candidates. In Poland this context of test use is especially important for jobs understood as so called dirty, dangerous and demanding.

Methodology : dataset of 650 records from 2020 edition of the survey will be exploited to analyse how psychologists use labels to present their areas of expertise.

Results: proposal of a new system of coding specialties, based on pointing out what actually a psychologist is competent to and not on the speciality he/she was artificially assigned to. The list of extended cafeteria of professional specialities that better reflects the scope of work that psychologists do on a daily basis will be presented.

Limitations: sample imperfections like lack of randomness and representativeness that are a strong argument against the generalization of the results

Conclusions: measuring testing culture in the longitudinal approach require not only keeping content of the questionnaire up to date but understanding the changes imposed to the identity of the profession of a psychologist. It is important to analyse not only the results but also who the participants are because it helps to understand how the real structure of the psychological workforce looks like in Poland.

Relevance to the Congress Theme: Rapid changing world forces the matching of career paths to the reality of the labour market and not to the categories imposed by universities

Relevant UN SDGs: Partnerships for the goals

Keywords: training, qualifications, workforce

Paper 3

Improving testing practices in European Work and Organizational Psychology: the case of Spain

Ana Hernandez, University of Valencia, Spain; José Muñiz, Nebrija University, Spain; José R. Fernández-Hermida, University of Oviedo, Spain; Francisco J Abad, Autonomous University of Madrid, Spain; Paula Elosua, University of the Basque Country, Spain

Background: Tests are essential tools in work and organizational (WO) contexts. They are used for different purposes (selection, placement, assessment of training needs, evaluation of intervention effectiveness, etc.), and contribute to making decisions that are crucial for employees and organizations. Therefore, the inadequate use of tests can cause serious harm.

To improve tests and testing practices, the Spanish Test Commission, aligned with the EFPA Board of Assessment (BoA) has been taking different actions and projects.

Goals: In this presentation we share the results of two projects:

1) The survey on attitudes of WO psychologists regarding tests and testing practices. It is crucial to know the opinions and problems perceived by practitioners in order to design and implement effective actions; and

2) The report on the use of psychological tests for personnel selection in Public Administrations. This report is motivated by a recent court judgment that settled case-law on test use for personnel selection in these contexts.

Methodology: For project 1, we analyzed the responses of 69 psychologists in the field of WO psychology. Data was collected in 2020. Participants responded to a 30-item questionnaire using a 5-point response scale (1-5). Specifically 5 dimensions were assessed: 1) attitudes towards tests, 2) problems in use of the tests, 3) test and test users' regulations, 4) training and knowledge about tests, and 5) skepticism regarding internet, computerization, and automation in testing. For project 2, we analyzed 8 judicial appeals and court decisions on the use of psychological tests for selection purposes in Spanish Public Administrations.

Results: Participants in the survey show favorable attitudes towards psychological tests, when used properly (M=4.09, SD=.56), and they are in favor of increasing the control and regulation of test use (M=4.14; SD=.56). Although the surveyed WO psychologists show certain skepticism regarding the incorporation of new technologies in testing practices (M=2.63; SD=.59), they are more open to the incorporation of these technologies than clinical and educational psychologists. Participants also acknowledge the need for continuous training in testing, because the average score on knowledge and information is relatively low (M=2.76, SD=.79). Finally, regarding the problems of using the tests WO psychologists recognize that there are aspects in need of improvement. Although below 3.5 in a scale that ranges from 1 to 5 in frequency of occurrence, the most frequent problems are the following: Not being up to date, not contrasting interpretations with others, not taking into account the measurement errors of the scores, and not restricting the application of tests to qualified personnel.

When focusing on the use of test for personnel selection in Public Administrations, the appeals and court decisions analyzed also indicate the need of improving testing practices in this context, especially regarding the justification and documentation of the decisions made during the process. However, it also shows that, in some instances, legal operators such as lawyers and judges lack

information about the idiosyncrasy of psychological testing. The report provides a series of good practice recommendations for the public administration and testing services, and clarifies the particularities of psychological testing, and the differences from testing other variables, such as professional knowledge or physical competences.

Limitations: The sample was not random and was small (for both the WO surveyed practitioners and the number of appeals and court decisions analyzed), which precludes generalization.

Conclusions: Tests are considered useful tools by WO practitioners. However, there is room for improving testing practices in WO contexts, including Public Administration services. Dissemination of information and good practices, continuous training and an increase of control and regulation can be useful ways of improving testing practices. The actions and projects boosted by the EFPA Board of Assessment serve as a framework of cooperation and exchange that can contribute to improving testing practices around the world.

Relevance to the Congress Theme : Technological advances in testing (internet, computerization, automation) and increasing testing fairness are crucial for the changing world of work.

Relevant UN SDGs: Partnerships for the goals

Keywords: testing, opinions, selection

Paper 4

Using the European Model to Survey Australian Psychologist's opinions on Tests and Testing

Peter Macqueen, Compass Consulting, Australia

Background: It has been over 30 years since Australian psychologists have been surveyed on their use of, and attitudes to, psychological testing and assessment. This contrasts with several administrations of a European centric survey conducted via ITC/EFPA since 2000.

Goals: To gather information on Australian psychologists' test usage and attitudes, and to compare the findings with earlier studies.

Methodology: A survey was conducted over seven months from November 2021 to June 2022. It was designed to capture views of psychologists on attitudes to psychological testing, perceived training needs, and data on actual test usage across various contexts. To make comparisons, the survey included all items from the ITC/EFPA survey, with 34 Likert scaled items in total. Some additional items were written to assess topics considered by the present researchers to be important in the context in which the survey was to be administered. Extensive demographic information was gathered, including work settings and years of practice. In order to ensure good coverage of the domain of interest, as well as item relevance and clarity, the survey was pretested in full using a snowballing sample of psychologists known to the researchers.

Results: Initial results confirmed much of the factor structure of Evers et al (2017), with acceptable reliabilities obtained for all but one factor. With 821 respondents, which included 4.3% of fully registered psychologists holding Australian Psychological Society (APS) membership, a range of interesting findings should be provided. Content analysis of the qualitative component of the survey should add to the richness of these findings.

Limitations: Small sample size to caution on over generalising findings.

Conclusions: This paper's focus is primarily on the Technology (7 items) and Standards (9 items) scales where there is much potential for disparate views across age groupings and areas of practice, critically involving the WO domain.

Relevance to the Congress Theme: Test Standards need to be maintained, despite the advances in Technology and changing demands amidst global uncertainty.

Relevant UN SDGs : Partnerships for the goals

Keywords: testing, practice, opinions

Paper 5

Work & Organisational Psychologists influence on UK Survey – Remaining positive despite observing bad test practice

Nigel Evans, NEC, UK

Background: The European Federation of Psychologists' Association (EFPA) study on Tests and Test Attitudes included the UK as a key partner and promoter since conception.

Goals: To affirm that perceptions of Tests and Testing in the UK is positive and further support practitioner psychologists in the use of test within assessment.

Methodology: The methodology of the UK survey responses, co-ordinated by the British Psychological Society (BPS), utilised the EFPA Questionnaire on Test Attitudes of Psychologists (EFPA EQTAP) European Questionnaire. Survey items and analysis followed established guidelines of previous studies (Evers et al, 2017). The survey ran in Spring 2021 and was disseminated to the BPS membership through various internal and external communication channels.

Results: A total of 351 respondents completed the survey, with a high representation of work and organisational (WO) psychologists in the sample. The results generally show a positive attitude of the participants towards the use of tests to benefit their practice. However, respondents reported seeing frequent instances of bad test practice, including some in breach of legal and contractual obligations when using tests.

Limitations: A small sample size and WO skewed perspective cautions against over generalising findings.

Conclusions: Respondents are calling for more legislation to stop the abuses of testing, along with wanting the BPS as the National Psychology Association, to do more to improve test use. Implications of the survey findings for users, test providers, clients, alongside wider stakeholders are discussed.

Relevance to the Congress Theme : Standards in test and testing need to be monitored, even in mature markets so that fairness and equality prevails in high stakes assessment.

Relevant UN SDGs: Partnerships for the goals

Keywords: testing, opinions, legislation

Symposium S022

Balancing work and life in a healthy way: Predicting spillover processes by organizational, cognitive, and behavioral factors in longitudinal studies

Carmen Binnewies, Micha Hilbert | University of Muenster

science

This symposium aims at a deeper understanding how employees can balance work and life in a healthy way which is important in times of high stress and increasingly blurring boundaries between life domains. The group will cover five presentations with presenters from four different countries (Austria, Germany, Greece, Switzerland) that will each focus on different aspects and phases of spillover processes between the work and non-work domain. Presentations will focus on different workplace characteristics (e.g., workload, job autonomy, segmentation norm), environmental characteristics experienced during recovery time (e.g., natural environments), positive and negatives thought processes during recovery time and about recovery time, behavioral responses (e.g., technology assisted supplemental work, boundary management strategies), recovery experiences (psychological detachment from work, relaxation), psychological well-being as well as performance-related outcomes. In sum, the presentations examine both spillover processes from the work domain to the nonwork domain and vice versa, all using longitudinal designs covering different time frames from daily effects up to weekly effects over several months. Therefore, the collection of contributions enables us to disentangle how spillover processes between life domains develop and to shed light on mediating and moderating effects and the outcomes in terms of well-being and performance-related outcomes.

The presentation of Baierer and Glaser focusses daily work stressors as predictors of active (self-determined) and passive (externally motivated) technology assisted supplemental work (TASW) and daily psychological detachment and relaxation during leisure time as outcomes of daily TASW. Baierer and Glaser conducted a daily diary study over seven days with two measurement occasions per day (in the evening and next morning) in a sample of 43 employees (241 days). For nearly half of the sample they also gathered objective smartphone behavior via an app to validate the self-report measure of TASW.

The presentation of Hilbert, Binnewies, and Berkemeyer addresses environmental characteristics during recovery time (i.e., natural and attractive environments) as predictors of daily psychological detachment, relaxation, and affective well-being. Hilbert et al. used a daily diary design over two consecutive weekends with three measurement occasions per day (in the morning, evening, and at bedtime) and gathered data from 81 employees (239 days).

The presentation of Noja and Kubicek investigates main and interactive effects of job autonomy and cognitive flexibility on negative and positive cognitive-affective involvement in work during leisure time and on subsequent work-related well-being. Noja and Kubicek gathered data of 314 employees in a three-wave longitudinal study design with a time lag of one month.

The presentation of Meier and Cho examines workplace segmentation norms and employees' own and their partner's segmentation preference as predictors of boundary management strategies as actual segmentation behavior. Boundary management strategies are hypothesized to be negatively related to work-family conflict and to function as a buffer in the relationship between workload and work-family conflict. Meier and Cho performed a longitudinal study over 10 consecutive weeks (every Friday evening) and collected data of 270 employees.

The presentation of Xanthopoulou, Gkamotsos, Gkorezis, Bellou, and Bakker will focus on the spillover from the nonwork domain to the work domain by investigating the reflection about a specific recovery activity during weekend leisure time and outcomes for well-being and performance-related outcomes at the start of the working week. Specifically, the authors focused on soccer fans and examined positive and negative reflection about a game of their favorite team during the weekend as predictors of vigor, flow, and performance after the weekend at work. Data was gathered from 60 soccer fans using a weekly diary study over the course of three to six weeks with two measurement occasions on Mondays (in the morning and afternoon).

In sum, all five presentations reveal important results that extend our theoretical knowledge and imply various practical implications for workplace design, developing cognitive and behavioral strategies how to balance work and life in a healthy way, and thus for sustaining high performance at work. The symposium helps us to understand how employees can cope with a changing world of work with blurring boundaries and increasing demands and autonomy at work and help us develop proactive solutions for individuals and the workplace.

Keywords: Spillover processs, Recovery, Boundary Management

Paper 1

Job stressors, technology-assisted supplemental work and recovery: a daily diary study utilizing smartphone sensor logs

Ferdinand Baierer & Jürgen Glaser | University of Innsbruck

Relevance, goals, background. Smartphones are increasingly used by employees to engage in work related activities during non-work time, thus impeding recovery. In the wake of the ongoing digital transformation, technology assisted supplemental work (TASW) is expected to be a widespread phenomenon. Therefore, the goals of this study were threefold. First, drawing from Action Regulation Theory and Self-Determination Theory we wanted to show that job stressors lead to active (self-determined) and passive (externally motivated) TASW-behavior. Second, we tested how TASW-behavior impedes recovery experiences based on the stressor-detachment model. Third, following numerous calls we explored if objectively obtained data are comparable to subjective data or may even be advantageous in measuring TASW.

Design, methodology . We conducted a daily diary study over seven consecutive days. To collect subjective data N = 43 participants filled in two questionnaires per day in an interval-contingent design to assess job stressors (work interruptions, work overload) and (active vs. passive) TASW-behavior every evening and recovery experiences (psychological detachment, relaxation) in the following morning. Data from 241 days nested within 43 employees could be included in the analyses. To obtain objective data, n = 19 participants installed an open-source app for mobile sensing which logged their smartphone behavior. For discriminating private from TASW-smartphone-use an event-contingent diary design was established. The data was analyzed using multilevel modeling.

Results. Daily active, but not passive TASW is predicted by daily work interruptions and daily work overload, especially on weekends. In line with the stressor-detachment model, daily active TASW behavior impedes daily relaxation in the evening, mediated by a lack of psychological detachment from work. Daily objective smartphone data correlates highly with questionnaire data of TASW-smartphone-use suggesting convergent validity. However, objective data fitted better with subjective data when discriminating active and passive TASW behavior rather than using one overall TASW construct.

Limitations. Time granularity used in our study does not suffice to make causal claims. We focused on two specific job stressors assumed to impair finishing work tasks during working time. Further job stressors might be relevant to especially explain passive TASW behavior which is heavily dependent on colleagues', supervisors' or customers' availability expectations. Moreover, we encountered certain problems with the installation and utilization of the sensing app which resulted in several corrupted smartphone logs.

In a second study we plan to replicate our results and improve some of the limitations by incorporating further job stressors and improving the collection method of smartphone logs. Preliminary results are expected by May 2023.

Conclusions. Job stressors are prolonged into leisure time due to actively engaging in daily TASW behavior. Through a lack of psychological detachment from work, TASW behavior then impedes relaxation experiences. We can show that objective smartphone data is worth pursuing in future research as it provides additional context information on triggers and actions of TASW behavior.

Relevance to SDG. Excessive empirical evidence demonstrates the importance of successfully recovering from work for the workforce's well-being and health. By showing that job stressor-related TASW behavior restricts recreational experiences necessary to recover, our research contributes to the SDG Good Health and Well-Being

Relevance to congress theme. To be able to design work which preserves and boosts employee's health, it is crucial to show how recovery is impacted by job stressors and work behavior in the changing world of work, where unpaid labor creeps into leisure time by means of TASW behavior, facilitated via the ubiquity of digital technologies and devices.

Keywords: technology assisted supplemental work, recovery experiences, job stressors

Paper 2

Nature Is Calling: A Daily Diary Study on Natural Environments, Recovery Experiences, and Affective Well-Being

Micha Hilbert, Carmen Binnewies & Laura Berkemeyer | University of Muenster

Up to now, recovery research focused on recovery activities (i.e., social, physical, and low-effort activities) and recovery experiences (i.e., detachment, relaxation) as predictors of recovery from work (Sonnentag, 2001; Sonnentag et al., 2008), which is relevant for employees' long-termed physical health, psychological well-being, and job performance (Sonnentag, 2017). Previous research showed the beneficial effects of contact with nature on physical health and psychological well-being (Bowler et al., 2010; Hartig et al., 2014; Twohig-Bennett & Jones, 2018; Ulrich, 1984). In this study, we addressed environmental predictors (i.e., natural and attractive environments) of recovery from work in order to extend the existing recovery framework by an environmental component. Drawing on appraisal theory of emotion and recovery experiences (Roseman & Smith, 2001; Sonnentag et al., 2008), we proposed a serial mediation model of the relation between experiencing nature and indicators affective well-being (i.e., high positive activation, low negative activation, high serenity, low fatigue) with perceived attractiveness as a 1 st -stage mediator and recovery experiences (i.e., relaxation and psychological detachment) as 2 nd -stage mediators.

In a daily diary design over two consecutive weekends, 81 employees filled in three daily questionnaires (i.e., in the morning, evening, and at bedtime) about perceived environments, recovery experiences, and affective well-being via smartphone on 239 days. Mediation analyses based on the Monte Carlo method (Tingley et al., 2014) revealed indirect relations between contact with nature and affective well-being via perceived attractiveness and relaxation in the case of high serenity and low negative activation, but not for high positive activation and low fatigue. No direct relation between contact with nature and affective well-being was found. Surprisingly, contact with nature was negatively related to detachment. Additional multilevel path analyses based on multilevel structural equation modeling (Preacher et al., 2010) gave evidence for our proposed serial mediation model with attractiveness as a 1 st -stage mediator and relaxation as a 2 nd -stage mediator.

Considering limitations, we relied on self-report measures and therefore common method variance could be a problem (Podsakoff et al., 2003). Assessing objective data like greening via satellite pictures might be useful to reduce common method bias (Goward et al., 1991).[CB1] [MH2] Moreover, the mainly female and highly educated sample with a high proportion of leaders is not representative for all German employees. Referring to the circadian rhythm, a biphasic response to nature might be possible, with a stimulating effect as a short-term and a calming effect as a middle-term outcome. Therefore, different time lags should be used to distinguish these potential short- and middle-term effects of contact with nature.

Our study contributes to research on recovery by showing that environmental characteristics have incremental validity over recovery activities predicting relaxation and indirectly indicators of affective well-being (i.e., high serenity, low negative activation). We discuss practical implications for policy makers (e.g., conservation of natural environments), organizations (e.g., workplace design), and employees (e.g., weekend activities). The current results are relevant to achieve the UN sustainable development goals 3 (i.e., good health and well-being) and 11 (i.e., sustainable cities and communities) by showing the relevance of nature in residential areas for recovery. Healthy employees are especially relevant to master the everchanging world of work.

Keywords: Recovery Experiences, Natural Environments, Diary Study

Paper 3

Job- and person-related antecedents of positive and negative cognitive-affective involvement in work during leisure time: A moderated mediation model

Noja Andrea & Kubicek Bettina | University of Graz; Tement Sara, University of Maribor

Research goals: Due to increasing digitalization and flexibilization, the boundaries between work and private life are gradually blurring and employees are increasingly involved in work during their leisure time through positive and negative cognitions and emotions. This involvement, specifically the so-called positive cognitive-affective involvement, may build employees' resources and increase work-related well-being. Negative cognitive-affective involvement, on the other hand, may hamper the necessary recovery from work and may result in impaired work-related well-being. While there is some evidence on the (work-related) consequences of positive and negative cognitive-affective involvement, the job-related (i.e., autonomy) and person-related (i.e., cognitive flexibility) antecedents of negative and specifically of positive involvement are less well understood. Therefore, the aim of the present research was to investigate the main and interactive effects of job autonomy and cognitive flexibility on positive and negative cognitive-affective involvement in work during leisure time and on subsequent work-related well-being (i.e., work engagement, emotional exhaustion, cynicism).

Theoretical background: Based on the Conservation of Resources Theory (Hobfoll, 1989), we assume that job resources, such as job autonomy (i.e., the extent to which the job provides freedom and independence in decision making) may increase resource-building experiences such as positive cognitive-affective involvement and decrease resource-depleting experiences such as negative cognitive-affective involvement in work during leisure time. Moreover, cognitive flexibility (i.e., the ability to shift perspective and adapt to a changing environment) may interact with job autonomy in predicting positive and negative cognitive-affective involvement. Specifically, high cognitive flexibility may strengthen the associations between job autonomy and cognitive-affective involvement and strengthen the indirect effects of job autonomy on work-related well-being (i.e., work engagement, emotional exhaustion, cynicism) via positive and negative cognitive-affective involvement.

Design and methodology: Using a three-wave longitudinal study design with a time lag of one month, we collected data via the online panel Prolific Academic in the United Kingdom. The final sample comprised 357 employees that fully completed the survey in all three waves. The age of the participants ranged from 20 to 64 years (M = 37.76, SD = 9.94) and there was a balanced gender ratio (45% female). The employees worked on average 40 hours per week (SD = 4.97). All measures were assessed at all three waves of data collection. However, we only used data from the predictors of the first wave of data collection, the mediators of the second wave and the outcomes of the third wave to test the study hypotheses.

Results: Results from path analysis revealed that cognitive flexibility strengthens the relationships between autonomy and both positive and negative cognitive-affective involvement. We found a significant positive association between autonomy and positive cognitive-affective involvement for individuals with high cognitive flexibility, but not for individuals with low cognitive flexibility. For negative cognitive-affective involvement, we found a significant negative association with autonomy for individuals with high cognitive flexibility, but not for individuals with low cognitive flexibility. Our study also indicated that both positive and negative cognitive-affective involvement mediate the relationship between autonomy and work-related well-being (i.e., work engagement, emotional

exhaustion, cynicism). In addition, cognitive flexibility moderates the indirect effects of job autonomy on work-related well-being via positive and negative cognitive-affective involvement.

Limitations: One limitation of the study is the use of self-reported data. Thus, common method variance could have biased the results. However, this may be reduced by using a time lag of one month between predictors, mediators, and outcome variables. Second, data were collected via an online panel, which may have some disadvantages (e.g., panel bias). However, the online panel used, Prolific Academic, ensures representative samples by recruiting new participants, keeping the participation frequency low and intrinsic motivation high. Nevertheless, the replication of the results is required to enhance generalizability.

Conclusions: The results expand scholarly knowledge about the antecedents and outcomes of positive and negative cognitive-affective involvement in work during leisure time. They also indicate that employees can benefit from interventions to increase job autonomy and trainings to foster cognitive flexibility.

Relevance to the Congress Theme: Current changes in the world of work, such as the increasing spread of telework arrangements, blur the boundaries between work and private life. Therefore, it is paramount to better understand when positive or negative involvement in work during leisure time occurs and which effects this might have on work-related well-being.

Relevant UN SDGs (=United Nations Sustainable Development Goals):

Good health and wellbeing

Decent work and economic growth

Keywords: Positive and negative cognitive-affective involvement, cognitive flexibility, work-related well-being

Paper 4

A Dynamic and Multi-Dimensional Approach towards Work-Family Boundary Management: A 10-Week Longitudinal Study

Laurenz Meier, University of Neuchâtel; Eunae Cho, National Chengchi University

Research goals and why the work was worth doing

The future of 'working from anywhere, at anytime' has become a reality for many workers. With an ongoing digitalization of work, an increasing use of information and communication technology (ICT), and the COVID-19 pandemic, working-from-home has been widely endorsed as a new way of working. Evidence to date suggests that these changes blur boundaries between work and private life, making it difficult for individuals to separate the life domains. Such difficulty may lead to greater work-to-family conflict, especially for those who desire to segment the two life spheres. As such, it is critical to understand effective ways to manage work-family boundaries in the new world of work. Although previous research has identified work-family boundary management strategies, much remains to be known about whether and when different strategies are used, what characteristics of the work, home, and the individual influence the use, and to what extent the use impacts employees' work-to-family conflict. A better understanding of the antecedents and outcomes of boundary management strategies not only advances boundary management theories but also generates knowledge of practical relevance that can be taught in workshops to promote work-life balance.

Theoretical background

Boundary management strategies are tactics that individuals use to create or maintain their ideal level of work-home segmentation or integration (Kreiner et al., 2009). Previous research identified various types of tactics (e.g., physical, temporal, social, ICT-use related; see Kreiner et al., 2009, 2016) and showed that individuals differ in the extent to which they use these tactics (Carson et al., 2016). However, little is known whether these differences are evident for all types of strategies and to what extent individuals use these strategies in a routine manner (e.g., more or less to the same extent across weeks) versus a situation-specific way (e.g., depending on the demands of the work week). As an exploratory research question, we, therefore, investigate the temporal dynamics of work-family boundary management and test to what extent boundary management strategies are used in a stable versus fluctuating manner.

We also examine antecedents of the use of boundary management strategies. Preliminary findings suggest that individuals who prefer to segment work and private life use strategies more often than individuals who prefer to integrate life domains (Carlson et al., 2016). Extending this, we propose that one's partner's segmentation preference and one's team norms affect the use of strategies. Specifically, we hypothesize that (H1a) employees', (H1b) their partner's segmentation preferences, and (H1c) workplace segmentation norms predict greater engagement in segmentation-oriented boundary management.

Furthermore, we investigate to what extent the use of strategies reduces work-to-family conflict. Findings from cross-sectional studies suggest that individuals who use more tactics report better work-life balance and well-being than individuals who use few tactics (e.g., Reinke & Gerlach, 2022). Extending this line of research, we hypothesize that (H2a) the use of boundary management tactics is negatively related to work-to-family conflict and that (H2b) the use of boundary management tactics buffers the positive effect of workload on work-to-family conflict.

Design/methodology/approach/intervention.

Longitudinal study of approximately 270 employed individuals who completed an online questionnaire on Friday evenings for 10 consecutive weeks.

The exploratory research question will be addressed using latent trait-state models (Steyer et al., 1992), and the hypotheses will be tested using multilevel analyses (Hox et al., 2019).

Results obtained or expected (if not available, it must be made clear when they will be)

Data and results will be available in December 2022 and ready to be presented at the conference in May 2023.

Limitations

All measures are self-reports.

Conclusions: Research/Practical Implications /Originality/Value

As the first study that takes a dynamic approach on the multi-dimensional work-family boundary management strategies, this study will offer a more nuanced understanding about temporal changes of different types of boundary management tactics, determinants of the use of different tactics, and benefits of using such tactics. Flexible work is here to stay, hence further knowledge about work-family boundary management will be of great practical value.

Relevance to the Congress Theme

In the changing world of work, 'working from anywhere, at anytime' is part of the new normal. This study informs employees' use of various types of boundary management tactics, predictors of the use, and benefits of the use in reducing work-to-family conflict, a critical stressor known to predict suboptimal well-being.

Relevant UN SDGs

Good health and well-being of employees

Keywords: Work-Family Boundary Management, segementation preference and norms, dynamic longitudinal modelling

Paper 5

The spillover of football games to work: A test of the work-home resources model among employed football fans

Despoina Xanthopoulou, University of Thessaloniki; Arnold B. Bakker, University Rotterdam; Victoria Bellou, University of Thessaly; Panagiotis Gkorezis & Georgios Gkamotsos | University of Thessaloniki

Research goals: Negative and positive work reflection during off-job time is considered a relevant determinant of the recovery process. Previous research suggests that when employees engage in negative work-related thoughts during their free time, their resources are drained. As a result, they have fewer resources to invest in order to recover from the effort they devoted at work. In contrast, positive work-reflection during off-job time may result in resource gains that facilitate successful recovery. Although the process of recovering from job demands is cyclical and expands from work to off-job time and vice versa, previous studies have only looked at how people reflect about their work during leisure, and how this type of reflection promotes or impedes recovery. However, studies so far generally neglected the role of recovery-related reflection during work. This is an important omission because employees are likely to think about their recovery activities during work, and the way they think about these activities may determine how well they function. To address this gap in the literature, we focused on the role of reflection about leisure-time activities during work time, and investigated whether reflecting about a recovery activity in a positive or negative way during work may function as a boundary condition that determines the degree to which state of recovery before work promotes work- related outcomes. We focused on a specific category of employees -those who are also football fans- because previous research suggests that following the game of one's favorite team is a relevant recovery activity that may spill over to the work domain and determine fans' work engagement and job performance.

Theoretical background: In line with the work-home resources (W-HR) model and the recovery literature, we hypothesized that employees' satisfaction with the recovery activity (i.e., the performance of their team in the previous game during the weekend) indicates resource replenishment, and as such will relate positively with their state of recovery (i.e., vigor) on Monday morning. In turn, vigor in the morning will associate positively with work-related well-being (i.e., flow) and (task and contextual) performance during work on Monday. This is because employees, who have more energy before starting work, they have the necessary resources to become absorbed in their tasks and to fulfill their work goals. Furthermore, in line with the cognitive perseverance hypothesis, we argued that negative game-reflection during work on Monday will deplete employee's (emotional and mental) resources, while positive game-reflection during work will replenish resources. Hence, the positive relationship between vigor in the morning on the one hand, and flow and job performance on the other hand, will be stronger on days employees reflect more positively and weaker on days employees reflect more negatively about the recovery activity during work.

Methodology: Sixty football fans with a paid job (93% men) completed a weekly diary study for three to six weeks, twice every Monday: in the morning after waking up and before starting work, and in the afternoon, when finishing work.

Results: Multilevel analyses revealed that satisfaction with the team performance related positively and indirectly to flow and contextual performance during work via its positive association with vigor

on Monday morning (after controlling for positive and negative affect on Monday morning). The moderating role of positive and negative game reflection on the link between vigor and flow/performance was not supported. However, additional analyses showed that positive game reflection moderated the relationship between positive affect in the morning and flow, in a way that the relationship was positive only on days employees were reflecting about their team in a more positive way during work.

Limitations: The relatively small sample size and the use of self-reported data are possible study limitations.

Conclusions: The study findings support the main tenets of the WH-R model, since they highlight the positive spillover of recovery activities during off-job time on work-related well-being and performance during work via the promotion of employees' energy levels. Also, the results underscore the relevant role of reflecting about off-job activities for employee functioning during work. These results are relevant for theory and practice because they reveal important cognitive mechanisms that help understand the complex interplay between work and nonwork time.

Relevance to Congress Theme: The study is relevant to the Congress Theme, as research on recovery has important implications for employee well-being and job performance.

Relevant UN Sustainable Development Goals: The topic is relevant to the Sustainable Development Goals and especially to the goal for good health and wellbeing.

Keywords: Spillover from Non-work domain to work domain, Positive and negative reflection about recovery, Performance

Symposium S074

Career calling across cultures, contexts, and time: new answers to "old" questions

Anna Dalla Rosa, University of Padua

science_practice

What will be covered and why. Perceiving work as a calling has been shown to be a way to gain greater well-being, satisfaction, and health at work. Career calling can be broadly understood as a purposeful, meaningful, and passion-driven engagement in a career that one feels drawn to pursue and that contributes to a greater good. Despite the promising increase in the study of career calling, the understanding of the generalizability of the concept to different cultures and its development over time are still limited and raise issues for the theoretical development of the field and the applicability of results to organizational contexts. First, the lack of a systemic analysis of the meaning and equivalence of calling across cultures limits the generalizability of theory and practice to research with culturally diverse workers. Second, the limited knowledge about organizational and social predictors of calling limits the development of interventions to promote its development at work. Finally, the absence of knowledge on the dynamic nature of calling prevents the understanding of how calling can be maintained and developed every day. To address these questions, the symposium brings together four empirical contributions to share new and original insights.

The first presentation, by Vianello et al., will discuss cross-cultural differences in the conceptualization of calling. Using samples from India, Turkey, China, Italy, the United States, and The Netherlands, they observed that the concept of calling may be universal in its structure and, surprisingly, that the level of calling is higher in non-western countries.

Next, Gerdel et al. will focus on predictors of calling and specifically on the role of leader's calling in promoting follower's calling through perceived supervisor support and leader-member exchange. The preliminary results supported the partial mediation of perceived supervisor support and leader-member exchange in a trickle-down effect from perceived leader's calling to follower's calling. This study, which will be enriched by longitudinal data at the time of the conference, addresses the need in the literature for more studies that investigate predictors of calling at the social and organizational levels.

The third and fourth contributions will explore calling as a dynamic phenomenon. The third contribution by Conway and Clinton will focus on career calling enactment and consequences in everyday life using two daily diary studies. The results showed that the intensity of calling positively influences the level of engagement in daily activities and influences the report of positive and negative events, which in turn affect daily wellbeing and motivation. For the first time, evidence will be provided that calling affects behaviors and perceptions on a daily basis, highlighting the need for more research that investigates the dynamic of calling with an even-base perspective.

The fourth contribution by Schleithoff and Uslu will present the results of a mixed method study including qualitative semi-structured interviews and a quantitative diary study. The findings revealed that people dynamically change their orientation from perceiving work as a calling or a career and that the way people approach their calling, in terms of identification and purpose, affect the daily stability and resilience of their calling orientation.

The presentations will be followed by a discussion led by Dr. Anna Dalla Rosa who will provide comments on each presentation as well as recommendations for future research on calling.

Relevance to the Congress Theme. The symposium aligns with the goal of the congress by focusing on the future of work as more equal, diverse, and inclusive. Understanding how people approach work and how a meaningful and healthy approach to work as a calling can be developed will be critical to creating more decent, healthy and sustainable careers for everyone in the future.

Research/Practical Implications. The symposium has both theoretical and practical implications. All presentations address relevant and under investigated open questions about career calling. Contributors will provide valuable insights for practitioners by giving advice on how workers from different cultural contexts interpret career calling, and on how calling can be promoted and influence people in the workplace.

Overall conclusions. In conclusion, the symposium will present results that support the generalizability of research and theory on calling across different cultures, identify predictors of calling at the organizational and social levels, and suggest that calling is a dynamic phenomenon that changes and influences daily work experience.

Intended audience. The symposium is of interest to both academics and practitioners.

Keywords: Career Calling, Calling Orientation

Paper 1

Is Calling Conceptualized Equivalently across Cultures? A Comparative Study across Six Countries

Michelangelo Vianello, University of Padua; Anna Dalla Rosa, University of Padua; Jingzhou Pan, Tianjin University; Evgenia I. Lysova, Vrije Universiteit Amsterdam; Serdar Karabati, Istanbul Bilgi University; Jince Gomez, Indian Institute of Technology; Nelson D'Silva, Xavier School of Management; Brittany C. Buis, Northern Illinois University

The concept of calling is deeply rooted in western culture, but research in other cultures is increasing. In the last 25 years, the concept has been applied to work, giving rise to a large and increasing corpus of studies on why and how individuals approach work as a calling. Researchers from many non-Western nations began to study the construct of career calling, which seemed to be relevant in their societies. Yet, the equivalence of the concept of calling has not been adequately investigated, construct and measurement equivalence of existing measures has been assumed rather than tested, and the influence of culture on calling has been overlooked. Also, some authors suggested that the concept of calling does not exist outside Christianity (Cahalan & Shuurman, 2016).

Yet, many non-western traditions prescribe, suggest, or at least implicitly include a reflection on the importance of approaching work as a way to find a purpose in life, to build a personal identity, to help others or the society, even indirectly, and to answer a transcendent summons, either coming from within or from a greater entity. Calling might change in meaning across cultures or be a universal human experience, and researchers might have overstated the generalizability of previous empirical evidence or the importance of its Western origins.

Using a recent conceptualization of calling (Vianello et al., 2018) that unifies the different theoretical approaches that emerged in the literature we investigated the cross-cultural generalizability of calling across six nations (N = 2491): India, Turkey, China, Italy, the United States, and The Netherlands. Calling was measured with the Unified Multidimensional Calling Scale (UMCS; Vianello et al., 2018) that defines calling as composed by seven facets: Passion, Sacrifice, Transcendent Summons, Prosociality, Pervasiveness, Purposeful Work, and Identity. Participants were active business college students; Countries were selected to maximize cultural differences according to Hofstede's six cultural dimensions (Hofstede, 2011; van de Vijver & Tanzer, 2004).

Using multi-group structural equations model, we ascertained invariance and estimated unbiased factor scores. We observed that the multidimensional structure of calling and the relative importance of the different dimensions of calling in defining the construct are the same across cultures. This result contributes to the theoretical debate on the conceptualization of calling and its generalizability. Drawing on an integrated model of calling, we show that a conceptualization that combines both neoclassical and modern components is valid in countries that were deeply influenced by such varying philosophical and religious traditions as Christianity, Confucianism, Islam, Buddhism, and Hinduism. Pursuing work as a calling is an important factor of people's work experiences, regardless of their heritage (Steger et al., 2010).

We also surprisingly observed that the overall level of calling is higher in non-western countries, putting into question the western origin of the concept and opening important research questions. Small cross-cultural differences were observed in the intensity with which people from different countries approach their calling domain. Comparisons conducted at the level of facets indicated that Italian and Dutch participants scored lower in Transcendent Summons and Pervasiveness, while

Chinese participants scored the highest. Callings in India are especially high in the Purpose and Identity components. These results are based on convenience samples of business students; hence, results cannot be generalized to the whole nation, nor to nations that were not included in our sample.

The main contribution of this research is the empirical evidence that approaching work as a pervasive and transcendent source of purpose, passion, prosociality, self-sacrifice, and personal identity is an experience that is shared across very different cultures. This is in line with the surprisingly high agreement across religious traditions about the way individuals should approach their work.

Calling may be universal in its structure and meaning, and this result validates the many studies that investigated calling and its nomological network in cultures that are different from those in which the construct or its measurement were originally conceived. Also, the different profiles of calling that we identified and that characterize different nations are useful to practitioners and counselors who work in the increasing number of multicultural work environments because they inform on the extent to which people, who have been influenced by different traditions, approach their work as a source of meaning and passion. Furthermore, perceiving work as a calling is a resource that leads to greater well-being and resilience. Hence, this study is also relevant to the 3 rd and 8 th Sustainable Development Goals, which tackle well-being, decent work, and economic growth.

Paper 2

How Leader's Calling Changes Employees' Calling through the Means of Perceived Supervisor Support and Leader-Member Exchange

Sophie Gerdel & Michelangelo Vianello | University of Padua; Sabine Bergner, University of Graz

Employees with a career calling are passionate about their work, derive a sense of life purpose from their work which engulfs their life, is central to their identity and useful to society. They are willing to make sacrifices and they think they have been called by something greater to do their work (Vianello et al., 2018). Empirical evidence suggests that employees who experience their job as a career calling are more satisfied, have fewer turnover intentions and perform better in their job (e.g. Duffy et al., 2018; Vianello et al., 2021). It has been shown that calling is not stable and fluctuates daily and throughout life (Duffy et al., 2014; Vianello et al., 2020; Zhu et al., 2021). Identifying organizational antecedents of calling and investigating its longitudinal development are relevant for practice, given the many positives outcomes of calling, and for the theoretical development of the field. However, the literature on calling antecedents and its development is scarce, especially regarding the organizational processes that can promote the development of a calling. To better understand the origin of calling and its changes, it is important to investigate key antecedents: What are the organizational antecedents of a calling and how can leaders influence their employees' calling?

We draw on social exchange theory and argue that employees' career calling is stronger when they experience their leaders to have stronger callings. Perceiving that one's leader is called to perform their job might create a stimulating and passionate work environment which is perceived as supporting. Perceiving support from the leader enhances the quality of the relationship between the leader and the employee. It is then this enhanced relationship quality that empowers employees to develop their very own career calling.

In a two-wave study, we investigated the mediation of perceived supervisor support (PSS) and Leader-Member Exchange (LMX) on the relation between perceived leader's calling and follower's calling. In three different Italian organizations, employees and their leaders were asked to fill in an online questionnaire. Multilevel models in Mplus were used to separate effects that occur across individuals and across teams. The intraclass correlation coefficient ranged from .07 to .13, indicating that team membership explained considerable variance in individual ratings of PSS, LMX and calling. Results from the first wave of data collection ($N = 461$) at the individual level showed that perceived leaders' calling is positively related to followers' calling ($\gamma 10 = .23$, $p < .001$) through the partial mediation of PSS and LMX (indirect effect: .08, $p < .05$). Specifically, perceived leaders' calling was positively related to PSS ($\gamma 20 = .54$, $p < .001$), but not to LMX ($\gamma 30 = .06$, $p > .05$). LMX, but not PSS ($\gamma 50 = .09$, $p > .05$), was positively related to employees' calling ($\gamma 40 = .22$, $p < .05$). The relation between PSS and LMX was positive ($\gamma 60 = .7$, $p < .001$). Between effects were small and non-significant. The second data collection, that will allow testing for the longitudinal direction of the relations is in progress, and results will be available in March 2023.

Limitations of this study might be the small cluster size which could lead to an overestimation of results. Further, other mediators (e.g. trust) could explain the relation between leader's and follower's calling.

Having called leaders who perceive their work as a calling is beneficial because followers are more likely to be called too. This positive effect also benefits work teams that are more likely to show

higher performance and be more satisfied overall. The results inform human resource managers, providing suggestions on how to manage leaders and teamwork in order to increase the perception of having a calling. This study informs the theory regarding calling development in the organizational context and is relevant for the Sustainable Development Goals of well-being, decent work and economic growth.

Paper 3

An event-based analysis of calling intensity

Neil Conway; Michael Clinton

Research goals and why the work was worth doing

We examine the degree to which calling intensity has its effects on daily moods/ motivations via the everyday activities that people perform. We consider calling intensity both in terms of how it directly affects engaging in everyday activities and, in turn, daily moods and motivation, and whether calling intensity amplifies (i.e., moderates) the effects of activities and events on outcomes.

The research is worth doing because it shows how the lived experience of calling rests crucially on everyday activities, from which many implications follow. For example, how can organizations and individuals clear the path for people with a calling to pursue relevant daily activities.

Theoretical background

The broad theoretical background is the event-based turn in organizational research that acknowledges everyday events as crucial to understanding employee mood, motivation, and behaviour (Morgeson, Mitchell & Liu, 2015). Beyond organizational research, there is a strand of literature that investigates how individual differences (e.g., personality traits) are enacted in everyday behaviour. Our research considers how a prominent individual difference relevant to calling – calling intensity – is enacted in everyday behaviour, along with its implications. We argue that people with calling intensity have an outlook characterized by, for example, personal mission, being called-to-action, serving others, and making the world a better place, which establishes a mental frame of reference that disposes them cognitively and motivationally to seek out everyday activities and interpret daily events consistent with this outlook.

Method

We examine our research goals via quantitative and qualitative data from two daily diary studies of Church of England ministers. In study 1, 193 Church of England ministers (22% of original target sample) completed a background survey and then up to seven consecutive daily diaries (N = 1,111 days of data). In study 2, a different sample of 105 Church of England ministers (18.8% of original target sample) completed a background survey and two online diaries a day for up to seven consecutive days (N = 486 complete diary days of data).

Calling intensity was measured in the background surveys. Daily activities and events were measured in the daily diaries, alongside perceived features of the activities and events (e.g., relevance to calling, perceived competence), and measures of daily mood and motivation.

Results obtained

Preliminary findings from multilevel analyses show that calling intensity related to daily activities in several respects. Participants with higher calling intensity were more likely to perform certain activities relevant to their calling (e.g., prayer), and more likely to perform activities where they perceived themselves as competent overall. Calling intensity also predicted reports of unexpected positive or negative events occurring during the day, where calling intensity positively predicted perceiving the occurrence of unexpected negative events, but was unrelated to unexpected positive events. Written descriptions of the events offered explanations for some of these associations.

Further analysis shows how calling intensity is connected to daily wellbeing and motivations in both positive and negative ways via these the enactment of these everyday activities and experience of these unexpected work events.

Limitations

Self-reported data.

Conclusions

Overall, findings show calling intensity operates in part through daily activities and events, which in turn affect daily wellbeing and motivation outcomes. This is original as it shows how a dispositional orientation within the field of calling – calling intensity – is enacted through everyday activities which have implications for the lived experience of the calling. Practical implications include how parties (individuals with callings, organizations and occupational bodies, and professional occupational counsellors) can facilitate opportunities for people with callings to more readily enact their callings on a daily basis.

Relevance to the Congress Theme

The world of work is currently grappling with how occupations can balance employees achieving meaningful work and quality of working lives against a backdrop of neo-liberal capitalism, work intensification, AI substitution, and many economies facing recessions and stagnation. Our focus on calling speaks directly to debates of meaningful work.

Relevant UN SDG

Our study of calling intensity, events, and daily wellbeing is relevant to all occupations (particularly those regarded as called-to occupations) and therefore relevant to the SDGs of ‘Good health and wellbeing’ and ‘Decent work and economic growth’.

Keywords: Career calling, Daily Diary Studies, Wellbeing

Paper 4

Exploring the fluctuation of calling experiences in the field of diversity and inclusion

Schleithoff Claire Schulze & Uslu Dilek | Vrije Universiteit Amsterdam

Today a significant number of people expect more from their work than just a source of income and financial rewards (Cascio, 2003) but rather choose to pursue a purposeful occupation with a deep sense meaningfulness (e.g., Berg et al., 2010). Therefore, it is not surprising that callings, which are the belief that one's work is personally fulfilling, contribute to the common good and are viewed as individual's purpose in life (Bunderson & Thompson, 2009; Wrzesniewski et al., 1997), have attracted various scholars in the past (e.g., Lysova et al., 2018; Schabram & Maitlis, 2017).

However, much of the research looks at calling as a stable phenomenon, yet, some limited research draws attention to the dynamic nature of calling (e.g. Dobrow, 2013; Schabram et al., 2022). The absence of knowledge on how calling develops or changes over time is problematic as it limits our understanding of how calling can be maintained in difficult and challenging times (e.g., Duffy & Dik, 2013). The relevance and importance of exploring calling as a dynamic phenomenon finds support in calls of OB scholars for the inclusion of the role of time in studying experiences in the context of work (e.g., Aguinis & Bakker, 2020; Tang et al., 2020).

To address these outlined knowledge shortages, we aim to answer how do individuals working in the diversity and inclusion field perceive calling as a work orientation and how do difficulties shape these calling experiences? We thought it would be particularly promising to take a temporal lens on the concept of callings by utilizing a mixed method study. More specifically, we started our research by conducting qualitative semi-structured interviews on a sample of (N=30) to continue with quantitative diary studies (N=100) for ten working days. Diary studies have been chosen as they exemplify a particular promising research design to capture time and fluctuations (e.g., Vantilborgh et al., 2018).

Our study draws on the context of D&I practitioners for three key reasons. First, despite individuals working in D&I are often driven by personal values (i.e., fairness) and the intrinsic motivation to foster equality throughout organizations, they also face high job demands and drawbacks (i.e., negotiations about budget, disagreements, insults etc.). Thus, we expect that their calling orientations are likely to underly fluctuations. Second, we answer the calls of prior scholars (e.g., Schabram et al., 2022) and aim to get insights from a less extreme context than usually provided in the calling literature (i.e., animal shelter, zookeeper etc.). Lastly, although surprising for the aforementioned reasoning, to the best of our knowledge this study is the first that combines the calling literature with D&I.

Our preliminary findings reveal that most D&I practitioners view their work with a calling orientation. In line with the iterative nature of our qualitative study phase the concept of calling was not selected a priori. Rather, the construct was considered during data collection and analysis as we realized that the descriptions of our interviewee's work orientations are in line with prior definitions of callings (Charmaz, 2006; Strauss & Corbin, 1998). However, we saw differences in how individuals perceive their callings with impacts on the fluctuation of their deeply meaningful work experiences.

In fact, while some individuals are driven by their intrinsic motivation and purpose and actively decouple their personal identify from their calling orientation others strongly identified with their work. More specifically, while the first experienced their calling as stable and resilient towards

difficulties, the latest experienced it as being very unstable and even questioned the D&I approach. Based on these findings we propose that there is an “ideal level” of work identification for calling orientations and experiences of deeply meaningful work. These insights further build on the study of Schabram and Maitlis (2017) on animal shelter workers with “good” and “bad” calling paths.

In addition, we demonstrate the dynamic of work orientations (Schabram et al., 2022) since some of our participants emphasized that they deliberately decided to view their work as a career as they aim to protect themselves from the dark side of callings, which has been investigated in the past (e.g., Bunderson & Thomposon, 2009). This switching from calling to career orientation may demonstrate the fluctuating nature of work orientations (Schabram et al., 2022).

We believe that our study significantly contributes to the congress theme as the wish for deeply meaningful work is a main driver for many people, especially of the younger generation. In addition, we help to develop strategies to enhance the benefits of callings which will subsequently lead to more sustainable careers by fostering happiness, health and productivity (De Vos et al., 2020).

Symposium S035

Current directions in Australian work wellbeing intervention research: Examples, opportunities, and recommendations

Paula Brough, Griffith University

science_practice

Organisational interventions aim to change workplace policies, practices, or procedures through collaborative action in order improve the health and wellbeing of employees. Sharing intervention research – not only the evaluation of intervention processes and outcomes, but also the realities of carrying out such research – can improve the design of future interventions and advance intervention theory and research. This symposium consists of four papers describing innovations in recent work wellbeing intervention research, conducted by three researchers and one practitioner based at different Australian universities. The programs are trialled in different occupation groups.

Paper 1 presents three individual case studies based on the interconnections between organisational culture, leaders, and workers in order to design and produce effective work wellbeing intervention programs. Paper 1 summarises the lessons learnt from these intervention programs, including the key hinderances and benefits, the impact of culture and leadership upon employee wellbeing, and the implications for theoretical explanations of employee wellbeing.

Paper 2 presents learnings from the process evaluation of a five-phase intervention, delivered as a primary prevention strategy for workplace bullying. Grounded theory analysis (Gioia et al., 2013) of multiple data sources from multiple applications of the intervention across diverse industries was used to identify enablers and barriers for intervention effectiveness and distinguish mechanisms of change. Findings suggest that the intervention contributes to changing culture, creating safety, and cultivating connection. Success is aided by integrating each intervention stage within organisational operations; finding the right cadence for intervention activities; and enabling two-way communication. These findings advance knowledge about the foundations of change in wellbeing interventions, and highlight core practical considerations for change execution.

Paper 3 presents findings from the first stage of a study designed to increase employee resilience in mining. Interviews and a national survey yielded evidence that is being incorporated into a series of workplace interventions. A key finding was that employee assessment of job-related attributes as stressful demands or supportive resources was influenced by their subjective appraisal, pointing to the important role of cognition as an influential factor in resilience. Our design of a series of workplace resilience interventions will consequently focus on attention and cognition (for example, Junker et al., 2020; Knowles et al., 2016; Salguero et al., 2021) as well as employee experience. This finding is practically important and informs the design of a series of workplace resilience interventions that will consequently focus on attention and cognition in our understanding of job demands and resources (for example, Junker et al., 2020; Knowles et al., 2016; Salguero et al., 2021).

Finally, paper 4 describes the lived 'reality' of implementation and conducting work wellbeing intervention programs from a practitioner's point of view. Paper 4 discusses the impact of different types of occupational stress upon workers, including the tendency for some to overwork to 'rescue' critical and urgent work disruptions, subsequently resulting in burnout. Paper 4 also identifies organisational culture as an influential factor in these programs, albeit in terms of workers perceiving themselves to be part of a community, sharing values and stressors.

Relevance to the congress theme: This symposium directly relates to two congress themes: (#15) stress and dysfunction (stress and burnout), and (#18) wellbeing (mental health). This symposium also advances discussion of two of the UN Sustainable Development Goals (2015): good health and wellbeing, and decent work and economic growth.

Research/practical implications: The four papers present innovations in work wellbeing intervention research concerning both theory testing and methodological considerations, as is highly recommended (Burgess et al., 2020). Specifically, the interventions tested theoretical explanations of occupational stress, primarily the Job-Demands Resources model (Demerouti et al, 2001). Also, the interventions were primarily based on quasi-experimental research designs, to estimate the actual social and economic impacts of the programs compared to control groups of workers. The practical reality of the long-term adoptions of these programs in our workplaces is also discussed.

Overall conclusions: This symposium advances discussions of why workplace wellbeing interventions are rarely effective and in general, have minimal impact on the increasing social and economic costs of occupational stress reported by workers. The symposium emphasises the 'reality' of why the long-term implementations of these carefully designed programs are rarely adopted.

Keywords: Intervention, wellbeing, research

Paper 1

Optimising occupational wellbeing: Workers, leaders, and culture

Paula Brough, Griffith University

Research goals: This presentation aims to clarify the connections between organisational culture, leaders, and workers for the effective occupational wellbeing of employees. The discussion reminds researchers of these inter-connections in order to produce well designed and effective wellbeing interventions.

Theoretical background: Theoretical explanations of occupational stress generally present consistent content since Cooper and Marshall's (1976) initial description. These theoretical explanations specify that adverse work conditions focused on job demands (e.g., work hours), inadequate levels of job control, social support, and work-life balance (and other job resources), activate employee's cognitive stress appraisals and coping responses (Brough et al., 2013; Lazarus & Folkman, 1984). These, in turn, affect individual outcomes (job attitudes; e.g., job satisfaction and engagement), work performance (e.g., productivity, attendance, presenteeism), wellbeing (e.g., strain, mental health, fatigue), and organisational outcomes (e.g., productivity, sick leave, stress claims, profits; Brough et al., 2018). Recent evidence indicates the stress process is also influenced by other specific factors, including organisational climates and cultures (Dollard & Bakker, 2010); future-orientated coping to manage anticipated stressors (Drummond & Brough, 2016); specific taxonomies of job demands (Raper & Brough, 2021; Searle, Tuckey, & Brough, 2022); and the impact of non-work contexts (e.g., work-life balance) on work stress (Brough et al., 2014; Brough, Wall, & Cooper, 2022). Multiple industries have applied these theoretical explanations via their employee wellbeing programs with varying degrees of success (Clinchamps et al., 2021). However, the social and economic costs of occupational stress continue to rise, with stress perceived to be a global predicament (Brough et al., 2021), a "sizeable financial burden on society" (Hassard et al., 2018, p.1), and a key justification for the renewed emphasis on methods to effectively managing workers' wellbeing (Guest, 2017). Additionally, approximately 53% of organisational occupational health programs are athoeretical, that is, are not based on research evidence (Burgess et al., 2020). The majority of organisational wellbeing programs are thus, not evidence-based and typically produce limited success, especially for long-term outcomes of staff wellbeing and retention and program cost-effectiveness.

Design: Three examples of occupational wellbeing programs are described. Each program was conducted in a large organisation, adopted quasi-experimental research designs (longitudinal, repeated measures, control and experimental groups), and consisted of multiple mixed methods components (interview, focus groups, surveys, intervention, evaluations).

Results: Significant results are summarised, with the programs producing significant improvements for employee wellbeing over time in regards to perceived stress, strain, job engagement and retention. Results regarding leadership practices and the influence of organisational cultures are also presented.

Limitations: The limitations of each program are discussed and include the lack of objective HR data to demonstrate cost savings in occupational stress injury claims over time, the lack of clear evidence of the return on investment for each program, and the lack of long-term intervention adoption by each organisation.

Conclusions: The presentation ends with summarising the lessons learnt from these organisation wellbeing intervention programs, including the key hinderances and benefits, the impact of culture and leadership upon employee wellbeing, and the implications for theoretical explanations of employee wellbeing. Practical recommendations about pertinent emerging constructs are discussed, including the assessment of ethical leadership and distributive leadership. Recommendations concerning the delivery of these interventions are also highlighted, including evidence about the utility of of web-based programs which aim to accommodate the needs of flexible and remote workers. Finally, the utility of adopting occupational-specific approaches are also discussed, such as health-service leadership models.

Keywords: Wellbeing, leaders, culture

Paper 2

Changing the underlying conditions relevant to workplace bullying through organisational redesign

Michelle Tuckey, University of South Australia; Yiqiong Li, University of Queensland; Annabelle Neall, University of Queensland; Alice Rose, University of South Australia

Background: Participatory organisational interventions aim to change workplace policies, practices, or procedures through collaborative action in order to improve the health and well-being of employees (Nielsen & Christensen, 2021). At their core, such interventions target how work is organised, designed, and managed. In the case of interventions for workplace bullying, an additional goal is to transform the organisational conditions relevant to bullying prevention (Murray et al., 2020). Understanding factors that influence the success of interventions is critical to achieving the most favourable outcomes possible (Murray et al., 2020). Though the general literature on participatory organisational interventions provides some guidance, knowledge of success factors for workplace bullying interventions is barely at a foundational stage (Murray et al., 2020). It's important to evaluate workplace bullying interventions specifically within the broader field because experiencing bullying can shape employees' perceptions of the work environment (Agervold & Mikkelsen, 2004). In addition to identifying critical success factors, mapping the mechanisms through which organisational conditions relevant to bullying can be changed is a crucial knowledge gap. Evidence from the wider literature indicates that the success of health and well-being interventions is contingent on activating intended or emergent mechanisms of change (Daniels et al., 2021). There is no published data on this issue for workplace bullying interventions, limiting our understanding of how to effectively prevent bullying.

Intervention and approach: Three case studies were included in the research, in which the organisational redesign intervention was applied in: (1) 60 supermarket stores; (2) four government departments; and (3) two youth justice centres. The intervention process had five phases:1. Preparation builds awareness of the project and readiness for action. 2. Diagnosis uses an evidence-based risk audit tool to guide the selection of the focal areas for the intervention in combination with organisational data. 3. Solutions involve staff members, team leaders, and managers, working together in co-design workshops to unpack the challenges and generate intervention strategies in the focal areas. 4. Implementation involves activating the solutions generated at the workshop at multiple levels. 5. Finally, Evaluation involves re-surveying to demonstrate the impact of the solutions and conducting focus groups and interviews to investigate success factors and mechanisms of change. Following the Gioia method for inductive qualitative research (Gioia et al., 2013), we generated insights into intervention success factors and mechanisms of change using multiple data sources for each case study: focus groups, interviews, workshop materials, implementation meeting notes, and field notes. Data were collected in three waves, with preliminary analysis in each wave informing data collection in the next wave.

Results: Final data analysis across all data sources is in progress and will be completed in January 2023. Emerging findings suggest that the system mindset and participatory processes underpinning the intervention contribute to changing organisational culture, creating a safe space for making positive changes, and cultivating connections among employees. The data also suggest that intervention success is aided by integrating each stage within the organisations' daily operations; optimising the cadence of the intervention activities to capitalise on the momentum that builds in each stage; and enabling two-way communication across different levels of the organisation throughout the intervention process.

Conclusions: The findings of this study are unique within the literature in highlighting the value of participatory intervention processes for preventing workplace bullying. In particular, our research advances bullying prevention knowledge and practice by demonstrating how workplace conditions linked to the emergence of bullying can be effectively changed through collaborative efforts. Through changing culture, creating safety, and cultivating connection, co-design processes enable sustained changes to working practices, policies, and procedures relevant to bullying risk, revealing the potential to 'design out' bullying from workplaces.

Keywords: Bullying, redesign, wellbeing

Paper 3

The Impact of Workplace Factors on Employee Resilience in Mining

Rebecca Mitchell & Raymond Trau | Macquarie University; Brendan Boyle, University of Newcastle; Jane Maley, Sabanci University

Background: The mining occupational environment includes unique stressors that contribute to psychological distress and decreased mental health (Ling et al., 2016). Recent studies have found that mining employees had psychological distress levels that were significantly greater than a comparable community sample (Bowers et al., 2018; Considine et al., 2017). This increased recognition of mental health issues faced by the mining industry (Bowers et al., 2018; Considine et al., 2017) has prompted a surge of research interest into the potential impact of work and organisational factors on mining employees' mental health and suicide (Considine et al., 2017). Early studies indicate that workplace factors are a substantial contributor to distress and poor mental health (James, Tynan, Roach et al, 2018).

While previous research has provided empirical evidence regarding the negative impact of work characteristics on mental health and in the mining industry (Considine et al., 2017), the positive impact of work supports and resources on resilience have yet to be studied. Resilience reflects the capacity to effectively negotiate, adapt to or manage significant sources of stress or adversity (Windle, 2011) Resilience has been shown to decrease the negative impact of workplace stressors and is associated with increased quality of life, improved mental and physical health and effective adaptation (Caza & Milton, 2012). Resilience has been shown to enhance mental health in a range of industries. Previous research into resilience has focused on individual traits and interventions (King et al., 2016). Interventions have been demonstrated to improve help-seeking behaviour and reduce stigma associated with mental health (Tynan, James Considine et al, 2018) however there remains little understanding of the organisational and work-related factors that influence resilience and may, therefore prevent mental health issues arising (King et al., 2016). There is emerging evidence however, that a range of workplace characteristics may have the potential to build employee resilience (Hartmann et al., 2019; Khan et al., 2019; Khan et al., 2017; Meneghel et al., 2016), but this work is still in its infancy.

Approach: In order to achieve our research aims, we first undertook a two-phase study to ascertain the workplace factors that support resilience. The first phase used interviews to explore the perceptions and practices of employees and senior leaders regarding the strategies and practices that are successful in supporting resilience and mental health and the barriers that may lessen or undermine this goal. The second quantitative phase used a survey to investigate the pattern of factors that are most likely to explain and predict resilience at work. Data was collected from more than 300 mining employees in two time points to minimise the risk of bias due to common source (Podsakoff et al., 2012). The survey reflected first phase data in addition to validated scales, including the Brief Resilience Scale (Smith et al., 2008).

Results: A number of factors that helped workers develop resilience and mitigate stress were identified through the analysis, such as job satisfaction, teamwork, social support and belonging, as well as the ability to psychologically detach at the end of the shift. Workers and their families also saw positive changes associated with shift patterns and employment benefits. Factors such as gaps in communication, concerns about safety, work patterns, physical conditions and high workload levels, were demonstrated to be detrimental to resiliency. Key themes related to the erosion of resilience

were the volatility and uncertainty of the mining sector. Our participants provided evidence that their assessment of job-related attributes as stressful demands or supportive resources was influenced by their subjective appraisal which, in turn, was influenced by the focus of their attention and the experienced impact of these factors. For example, employees noted that the societal impact of mining contributed to resilience. Where employees assessed the contribution of mining in terms of its historical, local and economic impact, they appraised this as an important source of resilience. In contrast, appraisal of the mining's impact in terms of climate change was perceived as resilience-depleting. This finding allows us to make an important contribution by confirming the important role of cognitive appraisal in occupational resilience. Our design of a series of workplace resilience interventions will consequently focus on attention and cognition (for example, Junker et al., 2020; Knowles et al., 2016; Salguero et al., 2021) as well as employee experience.

Conclusions: Our key findings suggest that employees may assess the same pivotal job-related attribute as either supporting or undermining their resilience, which has significant implications for their wellbeing and the suite of interventions we are designing to build resilient-strengthening workplaces (Métais et al., 2022). Theoretically, our findings have potential to extend Job-Demands Resource (JD-R theory), by highlighting role of appraisal in JD-R and the circumstances that may affect such appraisal.

Paper 4

Rethinking workplace stress with what we already know: Considerations for wellbeing interventions from a practitioner's perspective.

Wendy Muller, Griffith University

Theoretical background: The Transactional Stress and Coping Model describes stress as an individual decision based on one's cognitive appraisal, where demands are perceived to be stressful according to the subjective negative appraisal of the person experiencing it (Lazarus & Folkman, 1984). However, as opposed to Selye's suggestion of stress as an involuntary response, Lazarus and Folkman viewed stress as an interactive process that incorporates intra-level stress stimulus and response, influenced by factors in one's external environment (Kalliath, Brough, O'Driscoll, Manimala, Siu, & Parker, 2013). When faced with a stressor, individuals will evaluate the potential threat (primary appraisal) and make a judgment about its significance. The second appraisal follows, as an assessment of resources. Finally, efforts aimed at regulating the threat enable strategies for coping (Kalliath et al., 2013).

Such theoretical frameworks have greatly influenced organisational psychological perspectives for the explanation of stress and wellbeing in the workplace, emphasising appraisal, engagement, and resilience for how individuals and teams feel, behave, and react at work. Arguably though, traditional views of stress as a linear process aimed at 'eliminating' singular threats do not generally represent workplace environments. Nor does the notion that workplaces focus on specific stressors or strain effects. For many individuals and teams, wellbeing is not perceived to be the absence of stress (e.g., working business as usual, as per job descriptions), but rather, accepting how to 'work with' the presence of perpetuating and external stressors beyond their control, regardless of their individual or collective cognitive appraisal/s. Notwithstanding, the act of merely accepting stress as 'the new normal' is not a sustainable coping strategy for mitigating workplace strain in the long term. Extent stress literature emphasises the stress perception, rather than stress presence (Kalliath et al., 2013). Whilst it is important to recognise individual differences for the ways in which stressors are appraised, it is undeniable that the consequences of COVID-19 have been severe, impacting labour shortages, work demands and expectations, both for self and others (McKinsey Global Institute, 2021; OECD, 2021). The pandemic has disrupted and reformed how work is conducted. For example, some occupations adjusted locations to working from home and communicating via virtual methodologies. For occupations involving the maintenance of physical proximity with clients or equipment, whilst fewer changes were made operationally, work roles required additional processes to take place for health and safety compliance. Such determinations highlighted stress for those working 'towards the threat' of COVID-19 (e.g., frontline and service roles), and highlighted wellbeing concerns related to communication, micromanagement, fairness, work life balance and the impact on relationships at home (Brough, Muller, & Westman, 2018; McKinsey Global Institute, 2021).

Contributions: As a practitioner involved in the provision of wellbeing inventions, three contributions are offered:

1. Occupational versus organisational stress. Workshops/ team level discussions unpacking stress types, especially when tendencies towards feelings of blame or guilt exist for 'underperforming' to achieve outcomes beyond their control (COVID-19 or otherwise) or propensities to overwork are present to 'rescue' ongoing urgent disruptions.

2. Tripartite model. Murphy (1988) proposed three levels of stress management interventions, each aimed at addressing workplace stress according to focus (i.e., primary, secondary, tertiary). As a practitioner, the preferred approach to wellbeing interventions is an integrated approach. In reality, however, many requests for service involve single, and reactive interventions to remedy multiple and ongoing issues. Whilst secondary (e.g., psych-education) and tertiary (e.g., employee assistance) inventions are beneficial, in isolation, their individualistic approach is seemingly superfluous without changes considered at systemic levels. Furthermore, it deflects potential organisational accountability. Holistic programs across multiple time points are recommended.

3. Human needs. Feedback from a wellbeing intervention focused on the discussion of wellbeing strategies, found that rather than the content, participants valued being part of a community, sense of belonging, and felt validated in their perceptions of stress (COVID-19 or otherwise). Most of all, they felt that sharing laugher and taking a moment to 'pause' increased work productivity.

As the impact of COVID-19 continues, and the focus shifts towards 'new ways to work', creating engaged and resilient teams and hybrid workforces, it is imperative that wellbeing interventions evolve to align with the realities of how stress is truly experienced and the manifestations for individuals at work and home (McKinsey Global Institute, 2021; Muller & Brough, 2017).

1. Occupational versus organisational stress. 'I love my job, but I hate the workplace' - from a practitioner standpoint, this profound comment differentiated between the occupation (provides internal motivation) and the organisation (provides external motivation) stress. Wellbeing is threatened when there is a misalignment between the two, especially when the latter is out of their control. Proactive inventions to improve coping mechanisms that incorporate control and influence frameworks are necessary.

2. Triparlite model. It is imperative that primary interventions that directly address the changing world of work, evaluate work roles, team culture, monitor work demands and available resources occur. Not implementing an integrated approach to wellbeing interventions can hinder the effectiveness of secondary and tertiary programs.

3. Human needs. Whilst workplace stress is not a novel concept by any means, individuals report increased feelings of exhaustion and burnout, contributing to negative workplace behaviours (OECD, 2021). It is important to actively discuss appropriate workplace behaviours, including meetings, virtual interactions and all communication methodologies.

Keywords: Practitioner, stress, interventions

Symposium S076

Attitudes and Mindsets During Organisational Transformation

Hui Zhang, The University of Sheffield, UK

science

Organisational transformation is increasingly common in workplaces due to various triggers (e.g., digital technologies, environmental conditions). Employees are crucial in transformational processes because they are the actors who implement the changes made by organisations. Employees' acceptance of or resistance to a transformation is influenced by their attitudes, which reflect their mindsets and beliefs about personal and contextual resources available within a transformation (e.g., self-efficacy, organisational support; Edison & Geissler, 2003; Solberg et al., 2020). This symposium aims to explore what and how personal and contextual factors affect employees' attitudes towards organisational transformation via a literature review, measure development, empirical and intervention studies.

This symposium starts by providing a comprehensive overview of the attitudes research landscape within the context of digital transformation (Zhang et al.). Digital transformation is a prevalent process within organisations that has been made possible by the extensive use of digital technologies (e.g., AI, automation, hybrid cloud, and other digital technologies). Since employees have a significant impact on the actual use of new technologies and implementation of digital tools, there is a need to understand their attitudes to digital transformation processes. This review thus aims to map the key definitions and operationalisations of digital attitudes, what factors influence digital attitudes, and the consequences of digital attitudes.

Next, this symposium introduces a new comprehensive measure of employees' digital attitudes from a multilevel and multidimensional perspective (Grozev et al.). In this measure, personal attitudes towards technology are combined with people's beliefs about the nature of resources available within the context of digital transformation at four levels – individual, group, leader, and organisational. This multilevel and multidimensional measure forms the basis of a toolkit that aims to pinpoint maladaptive digital attitudes, the findings from which could then be used to enhance transformation processes and attitudes within organisations.

The impact of contextual factors on employees' attitudes is further supported by an empirical study that investigates how resources at the leader level play a significant role in relation to employee attitudes and outcomes (Adamska). This empirical study examines the interaction effects of leaders' and employees' mindsets (Dweck, 1999) on employees' job burnout during the COVID-19 pandemic. When employees had to quickly adapt to new digital work solutions (i.e., the way employees work changes), leaders' growth mindset may act as a valuable resource in protecting employees from job burnout and in building a supportive workplace culture. This finding suggests that organisations might benefit from undertaking interventions to stimulate leaders' growth mindsets.

Finally, this symposium presents an intervention study (Quataert et al.). The mindset intervention - 'Digital For All' - was developed to stimulate positive beliefs about digital transformation and digital skills. In order to benefit from the ongoing introduction of novel technologies and organisational transformation, it is important for employees' mindsets to be growth-orientated (i.e., viewing transformation as providing opportunities and resources for professional growth). These positive beliefs influence the extent to which employees engage in transformation and allow them to respond to transformational challenges in an effective manner. Managers and employees can use the mindset

intervention to proactively stimulate and leverage growth mindsets for organisational transformation.

The symposium closes with an open discussion on how personal and contextual resources can be improved to promote employees' positive attitudes towards organisational transformation. Providing resources at all levels of an organisation is important to create a work environment that is conducive to individual acceptance of the changing world of work caused by organisational transformation.

This symposium showcases new research on attitudes and mindsets in organisations. The literature review and the case study provide valuable insights into the importance of personal and contextual resources on employees' attitudes in a time of organisational transformation. The new measure toolkit offers a road map that identifies what resources should be improved and action plans for prompting employees' positive digital attitudes. The mindset intervention serves as a starting point for improving personal resources and promoting employees' growth mindset in the context of digital transformation. Future research can extend these study findings to consider both personal and contextual resources as part of an action plan to cultivate a work environment that promotes more positive attitudes to organisational transformation.

Paper 1

Digital Attitudes: A review of the literature and a research agenda

Hui Zhang, The University of Sheffield, UK; Jo Yarker, Affinity Health at Work, UK; Nathan Palmer, Affinity Health at Work, UK; Vladislav Grozev, Karina Nielsen & Carolyn Axtell | The University of Sheffield, UK

Theoretical background

In recent years, understanding the dynamics that can influence employees' acceptance of new technologies and digital changes have become increasingly important due to rapid digital transformation in organisations (Maran et al., 2022; Paganin & Simbula, 2021). The majority of research available on the topic has focused on why and how employees' beliefs about technological attributes (e.g., ease of use, usefulness; Mohr & Kuhl, 2021) and personal resources (e.g., digital self efficacy, mindsets; Edison & Geissler, 2003; Solberg et al., 2020) can influence employees' technology acceptance and adoption. More recent research proposed that employees' technology acceptance is also based on their beliefs about the wider resources within the context of a digital transformation. That is, employees' beliefs about the nature of resources available at all levels of an organisation create variation in the way employees engage in or withdraw from a digital transformation (e.g., supervisor support, organisational support; Guo et al., 2019; Solberg et al., 2020). We refer to these beliefs towards digital transformation as an employee's "digital attitudes".

Research goals and why the work was worth doing

Research of employees' digital attitudes has been narrowly focused on individuals up until recently. Thus as we enter this era of development that studies the impact of contextual factors on digital attitudes, we review the literature with the goal of clarifying the state of the art in the field. More specifically, we examine: (1) What are existing conceptualizations and operationalisations of digital attitudes? (2) What are the consequences of digital attitudes? (3) What is known about contextual factors (individual, group, leader or organisational) which affect digital attitudes?

Understanding employees' attitudes towards both technology and how organisations undertake digital transformation can help individuals and organisations develop action plans and cultivate conditions at all levels of an organisation that yield employee engagement in digital transformation processes.

Methods

The Preferred Reporting Items for Systematic Reviews (PRISMA) was used to guide the reporting of this review (Pageet al., 2021). We identified search terms through a scoping review and discussion with the research team. These terms were used to search the ABI, Academic Search Complete, Business Source Premier and PsychInfo databases. All searches were limited to peer-reviewed, academic journals in English that were published from January 2016 until the data of the search in January 2022. 180 titles from the searches of these databases were collected in Zotero and then deduplicated (n=132). We identified K =40 studies that met the inclusion criteria of our review. Of the identified papers, 6 were reviews (a combination of meta-analyses and systematic reviews), 31 were research studies using cross-sectional data and 3 were case studies of individual organisations.

Results, Conclusions, and Implications

Results and Conclusions. In general, there was a broad range of literature on employees' attitudes about technology itself and technology acceptance / resistance (Venkatesh et al., 2003), but very little studying employees' attitudes towards digital transformation processes and the wider resources (Solberg et al., 2020), which has been a newer addition to the literature. Our review revealed research on digital attitudes using quantitative measures is limited and fails to consider the interaction of resources available at all levels of an organisation, in affecting employees' attitudes and behaviours during a digital transformation. Consequently, we propose the need for a new integrative definition with a sound theoretical basis to better operationalize digital attitudes for future research. Finally, we advocate the importance of attending to the context in which employees are embedded, including psychological climate, supervisor support, organisational support, industry factors, and social influence.

Implications. It is well recognised that many digital transformations often struggle to deliver on their aims because people are reluctant to accept and use technological innovations (Venkatesh et al., 2003). Enabling people to develop more positive digital attitudes will help improve inclusion of different people in digital transformations (Solberg et al., 2020). It will also allow organisations who are making greater use of technology to identify those in need of support and help them to deal more effectively with changes associated with introducing new technologies (Solberg et al., 2020).

Relevance to the Congress Theme

Much has been said about the impact of new technologies and digital transformation on jobs and the future of work. By understanding employees' digital attitudes towards digital transformation and the wider resources, individuals and organisations can positively shape attitudes and prepare employees to work alongside new technologies and digital transformation.

Paper 2

Development and Validation of a New Measure of Digital Attitudes in Organisations

Vladislav Grozev & Hui Zhang | The University of Sheffield, UK; Jo Yarker & Nathan Palmer | Affinity Health at Work, UK; Karina Nielsen & Carolyn Axtell | The University of Sheffield, UK

Research goals and why the work was worth doing

Digital attitudes – or employees' attitudes towards digital transformation in their organisation – are important predictors of the success of digital transformation. Nonetheless, the majority of current scales that measure attitudes towards technology at the workplace focus only on a specific attitude or are not specifically oriented towards digital transformation. Thus, in order to measure attitudes towards digital transformation at the workplace more comprehensively, we sought to create a new measure of digital attitudes in organisations.

Theoretical background

A current review of the digital attitudes literature (Zhang et al., this symposium) revealed that while different digital attitude scales exist, those scales capture only some attitudes (e.g., digital mindsets, computer self-efficacy, personal innovativeness) that employees may hold towards the implementation of new digital tools in their workplace. The review also revealed that the effect of digital attitudes on successful digital transformation will be influenced by personal (e.g., experience) and contextual (e.g., supervisor support) factors at the workplace. Therefore, in the new measure we considered employees' previous experiences with new technology being introduced to their workplace and we differentiated between the support given to employees at different levels of the organisation through incorporating the IGLO framework (referring to the individual, group, leader and organisational levels of an organisation; Nielsen et al., 2017).

Methodology and results obtained

In order to create and validate our augmented measure of digital attitudes in organisations, we are following best practice recommendations for measure development (Wright et al., 2017). We first examined the other scales measuring digital attitudes in organisations and adapted their items to refer explicitly to digital transformation. Next, we conducted interviews with employees who had undergone digital transformation, which prompted us to add new items which referred to the perceptions of the support given to employees at IGLO levels, as well as items that referred to previous experience or risks and opportunities of technology adoption. Conceptual validation was ensured through administering all items in a questionnaire to eight employees who had undergone digital transformation and asking for their feedback using semi-structured interviews immediately afterwards. After revision, we ended up with a list of pre-existing and new items that we believed measure digital attitudes. We also added measures of closely related constructs to digital attitudes (e.g., global mindset) as well as established outcome factors of digital attitudes in the literature to establish concurrent validity.

We invited Prolific participants who had undergone digital transformation in their workplaces to participate in two surveys in order to establish predictive validity for our new measure. Exploratory factor analysis and reliability analysis will be conducted on the Time 1 data, and confirmatory factor analysis and reliability analysis will be conducted on the Time 2 data. To establish measurement invariance between samples, we are also currently administering the questionnaires in an

organisation that is undergoing digital transformation. Due to ongoing data collection, we will present information about the psychometric properties of the measure (reliability, construct and concurrent validity) during the symposium.

Limitation of the present research

A limitation of our work is that we conducted our initial measure validation test with a convenience sample from a survey panel site rather than with a sample from a particular institution. As the sample was heterogeneous in terms of workplaces, the degree to which their workplaces have undergone digital transformation may also vary. Such discrepancies in the timing of digital transformation could affect the factor structure of the data and produce measurement variance between the initial sample and the sample from our partner organisation.

Conclusion

Our goal is to produce a new measure of digital attitudes in organisations. Firstly, we believe that our new measure will help organisations manage digital changes more effectively and create interventions to develop more positive attitudes towards technology within the organisation. Finally, we hope that this measure will help other researchers in finding ways to transform maladaptive digital attitudes.

Relevance to the Congress Theme and United Nations Sustainable Development Goals

The current movement towards Industry 4.0 has predetermined the central role of technology in the workforces of tomorrow, yet we maintain that the successful adoption of this technology is dependent on employees' accommodating digital attitudes. Thus, we envision that the development of our measure will help the successful adoption of technology at the workplace and facilitate the move towards Industry 4.0 as we are working towards the United Nations Goal of ensuring decent work and economic growth at the workplace.

Paper 3

When leaders' and employees' mindsets don't match – influence on the job burnout during the COVID-19 pandemic

Katarzyna Adamska, Norwegian Business School, Norway

Research goals and why the work was worth doing

Burnout is a state of chronic exhaustion at work. People are more likely to be burned out in situations of little control. COVID-19 pandemic is such a crisis situation, especially that many people must now work remotely and may feel disconnected from their leaders and other support. We need to identify psychological resources, which might make employees more resilient. This research examined if leaders' and employees' growth mindset can be such a protective buffer and under what circumstances.

Theoretical background

Fixed and growth mindset (also called entity and incremental implicit theories) are beliefs about ability of people to change the levels of their skills (Dweck, 1999). While growth mindset (GM) assumes that it is possible to increase our basic ability and attributes (intelligence, personality, skills), fixed mindset (FM) assumes they are stable and unlikely to change. While majority of research is grounded in educational setting, GM has also been linked with positive outcomes in the work context, i.e. GM leaders provide better coaching to employees (Heslin et al., 2006). I predicted that because GM increases the sense of agency in employees, those with higher GM will suffer from less burnout during COVID-19 pandemic. I expected this influence to be moderated by perception of leader's fixed mindset and one's intolerance of uncertainty (a personality-like variable indicating how anxious one feels in uncertain situations).

Design/Methodology/Approach/Intervention

Study 1: The data was collected as a two-wave online survey at a retail organization in Norway. GM, FM, leader's perceived FM, and intolerance of uncertainty were measured at T1. Burnout was measured at T2. I controlled for self-efficacy. The survey yielded 116 matched responses across both time points.

Study 2: The data was collected via Prolific and resulted in a sample of 406 UK-based employees. GM, FM, leader's perceived FM were measured at T1 and burnout was measured at T2 in a two-week interval.

Results obtained

The results were obtained by testing moderated regression models using the PROCESS macro (version 3.5) for IBM SPSS (version 27). The key findings consistently supported in both studies were that employees FM and perceived manager's FM positively predicted burnout reported two weeks later. GM alone was only a significant (negative) predictor of burnout in Study 2. Additionally, Study 1 (but not Study 2) found an interactive influence of GM and perceived manager's FM, where employees inclined to strongly agree with GM statements paired with managers they perceived as fixed reported highest burnout. Contrary to expectations, there was no interaction between IU and employees' GM or FM when burnout was predicted in Study 1.

Limitations

The data was survey-based. Considering the recent popularity of the GM concept in organizations and potential for the GM answers being more socially desirable than FM, it may be more useful to ask for behavioral examples of GM, rather than assess it by survey.

I only assessed perceived leader's mindsets rather than the leaders' own self-rating of mindset. Future studies could assess leader's mindset directly which can shed light on how those self-assessments relate to employees' perceptions.

Research/Practical Implications

Mindsets can be trained, so if perceiving a leader as less fixed relates to less burnout in employees, it may be a cost-efficient intervention. Perception of the leader's mindset seems to predict burnout more consistently than employees own GM or FM, which suggests interventions may predominantly focus on leaders.

Relevance to the Congress Theme

Since the pandemic the world is changing towards more remote solutions for many types of work. This can lead to burnout in some employees who feel unsupported. This research suggests that in such crisis situations, leaders perceived as fixed may have a negative influence on employees such that they report more burnout. Training leaders away from fixed mindset so that they rather project a message of growth might be a valuable resource when we are building the culture of the future workplaces, which are 1) robust during crisis 2) supportive for remote work solutions.

Paper 4

DIGITAL FOR ALL: Developing and Evaluating an Intervention to Stimulate the Digital Growth Mindset of Knowledge Workers

Sarah Quataert, Koen Dewettinck, Dirk Buyens & Valérie Legrand | Vlerick Business School, Belgium

In a rapidly changing and digitalising world of work, in which new professional roles are emerging and skill requirements are shifting, change readiness and learning motivation have become crucial assets for employees. In order to thrive at work, workers need a growth mindset (Dweck, 2007), characterised by positive self-beliefs, such as high self-efficacy and strong malleability beliefs about one's ability to learn new skills. A digital growth mindset, in particular, which we define as having a growth mindset towards digitalisation and digital skills, has become a necessity for workers in all industries. This is especially the case for knowledge workers, as their jobs are becoming more complex due to automation and new business models, leading to new skill demands that are more technical, digital, and interpersonal.

Consequently, there's a growing interest within the field of Work and Organisational Psychology when it comes to developing workplace interventions that stimulate positive self-beliefs, as they positively impact people's motivation to learn and actual learning behaviour (Bandura, 1977; Burnette, O'Boyle, VanEpps, Pollack, Finkel, 2013; Mangels, Butterfield, Lamb, Good, Dweck, 2006; Rigolizzo, 2021). A related challenge is the quest for effective yet pragmatic methods to assess the effectiveness of these interventions and understand why certain interventions work while others don't (Berge, 2008; Griffin, 2011).

Relying on the Double Diamond Process (British Design Council) and following an iterative process of prototyping and user testing, the online mindset intervention 'Digital For All' (DFA) was developed in 2020-2021, to positively shape mindset beliefs of knowledge workers in the context of digital transformation and digital skills. The intervention consists of 8 different learning modules, all related to the general concept of the growth mindset: (1) digital awareness, (2) digital technology, (3) digital growth mindset, (4) digital (re)thinking, (5) digital self-leadership, (6) careers in the digital world, (7) digital resilience and (8) digital data.

From February to June 2022, DFA has been implemented in several organisational contexts to evaluate its effectiveness by means of case studies. In line with the formulated selection criteria and striving at a diverse set of cases (diversity in terms of employment status, function, age and gender), the research team selected and analysed a total of 12 cases. We relied on multiple data sources for the case studies: interviews with participants, interviews with observers or coaches who were part of the intervention, and survey data. Process tracing analysis (Beach & Pedersen, 2013) was used as a within-case method for theory-based impact evaluation to understand how our intervention led to increased growth mindset beliefs in most of our cases, and why positive effects were missing in others. Process tracing is seen as a promising methodological avenue for empirically studying causal mechanisms, especially in social science disciplines (Beach & Pedersen; 2013; George & Bennett, 2005; Bennett, 2008).

As part of the symposium 'Attitudes and Mindsets During Organisational Transformation', we will first introduce our developed DFA intervention to practitioners and scholars in the field of Work and Organisational Psychology. Secondly, we will provide an overview of the insights and results derived from the conducted case studies, and we will elaborate on the causal mechanisms explaining how

DFA has led to its hypothesised effects. Thirdly, we will share our lessons learned with the audience and reflect on limitations of our research. Doing so, we want to inspire practitioners seeking for effective and rigorous ways to support employees in futureproofing their skillset via mindset interventions. Also, we want to inspire academics interested in exploring process tracing as a research method for evaluating those interventions. For Work and Organisational Psychologists conducting research in real-world business settings, process tracing might be an interesting approach to assess and increase the effectiveness of certain practices in a profound yet pragmatic manner.

We hope to contribute to two Sustainable Development Goals, as described by the United Nations. First, our work is relevant in relation to 'Decent work and economic growth', by encouraging employees to invest in their employability and considering growth mindsets as a prerequisite for sustainable employment and economic growth. Second, we will contribute to 'Quality education', considering DFA as a training intervention stimulating lifelong learning.

Keywords: Digital Mindsets, Intervention, Digital Transformation

Symposium S058

New horizons of crafting: Needs-based crafting in changing working lives

Miika Kujanpää, School of Business, University of South-Eastern Norway

science

Contributions:

The changing world of work presents multiple challenges and opportunities for employees and leaders. This trend requires them to make proactive adjustments in order to meet psychological needs. Recently, a conceptual framework for needs-based crafting has been developed based on the Integrative Needs Model of Crafting (de Bloom et al., 2020; Kujanpää et al., 2022). More specifically, employees engage in efforts to shape their job and off-job lives in order to meet DRAMMA needs (i.e., detachment, relaxation, autonomy, mastery, meaning, and affiliation; Brauchli et al., 2022; Newman et al., 2014). As such, needs-based crafting provides a holistic perspective on employees' crafting efforts across different life domains. Moreover, the concept can be extended to examine leaders' proactive efforts focused at shaping their employees' psychological needs, thereby having the potential to lead to new conceptualizations. Distinct approaches for measuring crafting efforts and outcomes can also be developed based on needs-based crafting. In this symposium, we present three novel contributions to the crafting literature, each examining needs-based crafting in a different context: in the first contribution, Kerksieck et al. examine future-oriented job crafting based on the DRAMMA model. They studied 18.000 employees in 35 countries, investigating the role of anticipated needs-based crafting as the perceived opportunity to shape their future of work. To understand the systematic spread of such crafting efforts around the globe, they assess how crafting is related to horizontal/vertical individualism and collectivism (HVIC) in the surveyed countries. In the second contribution, Toyama et al. focus on leaders' crafting efforts using the DRAMMA model. They conducted a pilot study among Finnish managers to investigate whether leaders craft their own leadership behaviors with the aim of meeting psychological needs of their subordinates. Their study provides preliminary evidence on the psychometric characteristics of a measure of needs-based leadership and the scientific utility of the concept. In the final contribution, Kujanpää and Olafsen examine off-job crafting efforts in the context of recovery experiences in a daily diary study at the within-person level among Norwegian employees. Complementing the literature focusing on recovery experiences, they discuss how needs-based crafting can act as a proactive strategy for recovery attainment, with potential benefits for occupational health and performance.

Relevance to the Congress Theme: Work-related challenges may become increasingly individualized and personal in the future of work, with a need for employees and leaders to manage their own wellbeing and to proactively adjust to changes across life domains. The concept of needs-based crafting can be helpful in understanding how individuals adapt to such challenges and take action in order to meet their psychological needs.

Research and practical implications: Needs-based crafting is a dynamic concept that is relevant for employees and leaders to meet new challenges occurring in the future of work. As needs-based crafting centers on shaping psychological needs, it can be flexibly used to adjust to changes both in the self and the environment and can be trained in interventions.

Conclusions: Needs-based crafting is a newly developed conceptual framework that explains how employees and leaders proactively adjust job and off-job time in order to meet psychological needs. Such proactive adjustments through needs-based crafting efforts may be increasingly important in the face of pressing societal and economic crises. Combining organizational efforts (e.g., leadership

crafting to support subordinates need satisfaction) with employees' individual crafting efforts (e.g., future-oriented crafting, crafting recovery time) may yield best results in terms of producing sustainable job and off-job lives that offer a plenty of opportunities for need satisfaction.

Georg F. Bauer

Paper 1

Future-oriented job crafting. How crafting shapes employees' perception of the future of work. A survey on 18.000 employees in 35 countries.

Philipp Kerksieck, Georg F. Bauer & Kang Leng Ho | Division of Public & Organizational Health/ Center of Salutogenesis Epidemiology, Biostatistics, and Prevention Institute, University of Zurich, Switzerland

Theoretical background

The future of work holds challenges but also opportunities for individualized work design (Demerouti, 2022; Parker & Grote, 2022; Schlogl et al., 2021). We are interested in employees' perspectives regarding their agency for change concerning the future of their work. Particularly, do they foresee opportunities for pro-actively shaping (crafting) this future of work (Parker & Grote, 2022) according to their own needs and standards?

We build on pioneering needs-based job crafting research (De Bloom et al., 2020; Newman et al., 2014). Assessing by how far employees anticipate that they can pro-actively shape the future of their work ("future-oriented job crafting") to meet their DRAMMA needs (crafting for detachment, relaxation, autonomy, mastery, meaning, affiliation; Kujanpää et al., 2020). Anticipating the chance to adjust proactively and craft work can influence employees' subjective perspective of the future of work. Therefore, future-oriented job crafting may be associated with people's expectations of future opportunities at work (Zacher & Frese, 2011). Further, we are interested in how future-oriented job crafting as an individual-level behaviour is related to participants' appraisal of horizontal/vertical individualism and collectivism (HVIC) in their respective societies (Triandis & Gelfand, 1998). Consequently, we will study HVIC as a moderator of the relationship between future-oriented job crafting and expected future opportunities at work.

Design/Methodology: We surveyed 18,100 gainfully employed individuals in 35 countries. Combining established and newly developed scales, we will assess i) if employees intend to job craft for meeting their DRAMMA needs in the future (De Bloom et al., 2020) by using an adapted 18-item scale that measures crafting for these six needs, ii) how this is associated with employees rating on the future opportunities at work scale (Zacher & Frese, 2011), and iii) the role of HVIC for such future-oriented job crafting around the globe.

Results obtained: i) taking a global perspective involving all countries at once, we identified significant associations between future-oriented job crafting and HVIC ranging from $r = .17$ to .51 ($p < .01$) across all crafting DRAMMA needs. ii) taking a country-specific perspective, we identified associations between future-oriented job crafting and future opportunities at work ranging from $r = .34$ to .68 ($p < .01$).

Limitations

Our study used self-report measures, which might limit accuracy, and is cross-sectional. Cultural differences in response to this self-report survey might be present (Harzing, 2006).

Conclusion – research and practical implications

Addressing these questions will help identify and promote beneficial individual-level strategies and behaviours for employees to adjust their situation at work proactively. In this way, our research can

support society at large and individuals themselves to better prepare for changes and challenges due to the accelerating digitalization processes in the work context.

Relevance to the Congress Theme

Future-oriented organizational behaviours such as future-oriented job crafting are linking very well to this upcoming EAWOP conference topic. Moreover bottom-up work design through job crafting offers an important behaviour for adapting to e.g. technological change (Parker & Grote, 2022).

Paper 2

Shaping leadership behaviors to meet the psychological needs of subordinates: Toward a concept of proactive leadership design

Hiroyuki Toyama, Katariina Salmela-Aro & Katja Upadyaya | Faculty of Educational Sciences, University of Helsinki, Finland

Theoretical background: Proactive behavior—self-initiating change, or "making things happen," with the aim of achieving a different future (Parker et al., 2010)—has been prized by organizations for its potential advantages to both employees and organizations. In particular, such behavior among leaders is of key importance for maintaining effective functioning, competitiveness, and the development of organizations in today's increasingly complex and dynamic job landscape. Nevertheless, in proactivity research, little attention has been directed toward leaders' proactivity. Where leadership roles are concerned, it is possible that proactivity may have different meanings than those held by ordinary employees in terms of its content and purpose (Wu & Wang, 2011). Thus, it is important to shed light on leaders' proactive behavior in their leadership roles. In the present study, we introduce the concept of proactive leadership design, namely leaders' proactive changes in their leadership behaviors aiming at subordinates' psychological needs satisfaction . By combining proactivity theory (the basic ideas of the Integrative Needs Model of Crafting; de Bloom et al., 2020) and leadership models based on psychological needs theory (e.g., the Self-Determination Theory; Deci & Ryan, 1985), we argue that leaders may proactively shape their own leadership behaviors in order to meet the psychological needs of their subordinates (e.g., DRAMMA needs: detachment from work, relaxation, autonomy, mastery, meaning, and affiliation; Kujanpää et al., 2020; Newman et al., 2014), and this may ultimately contribute to the optimal functioning of the subordinates or teams they lead. In this presentation, we provide an outline of this new concept along with preliminary evidence on the scientific utility of the construct.

Methodology: A cross-sectional pilot study was conducted with 150 IT managers in 2022. Participants completed online questionnaires on job crafting, leadership crafting, work engagement, psychological needs satisfaction at work, team effectiveness, team proactivity, and followership. The data were analyzed using SPSS 27.0.

Results: The Proactive Leadership Design Scale (PLBS) showed sufficient internal consistency (α = .92). The mean of the overall scale was 4.1 (SD = .44). The scale showed a moderate correlation with the Needs-based Job Crafting Scale (r = .44, p = .001). The correlation analysis where age, gender, and needs-based job crafting were controlled, showed that off-job crafting dimensions are significantly related to higher team well-being, team performance, and positive followership.

Limitations: The main limitations of this study are the use of a small sample obtained exclusively from IT managers and the application of a cross-sectional study design that does not allow for inferring the causality of observed associations.

Implications: The results of this study suggest that leaders may proactively shape their leadership behaviors targeting the psychological needs satisfaction of their subordinates. This in turn may contribute to team well-being, performance, and followership. The concept of proactive leadership design extends traditional taxonomic leadership approaches that rely heavily on subordinates' evaluations by shedding light on leaders' subjective experiences in shaping their leadership on their own initiative.

Originality/Value: This study introduces a new concept, proactive leadership design, which describes leaders' proactive efforts to shape their leadership behaviors in a way that meets subordinates' psychological needs.

Relevance to the congress theme:

Organizations are facing tremendous challenges in today's increasingly complex and dynamic work environment. In this context, proactive leaders are crucial to ensure organizational growth and success. This study suggests that leaders may be able to take proactive steps to address these challenges by making deliberate efforts to shape their leadership behaviors to support the psychological needs of their subordinates.

Keywords: Leadership, needs-based crafting, psychological needs

Paper 3

Take action, recover well? The role of proactive recovery strategies for day-level recovery processes

Miika Kujanpää & Anja H. Olafsen | School of Business, University of South-Eastern Norway

Purpose: As a process of reducing and eliminating physical and psychological strain symptoms caused by work (Sonnentag & Fritz, 2007), recovery from work is increasingly important in today's knowledge society where the boundaries between work and off-job time are often blurred. Over the past decade, a research stream has highlighted the importance of such recovery processes for employees' occupational health and performance (for a review, see Sonnentag et al., 2022). Recent research has called for studies that focus not only on whether experienced recovery from work is directly beneficial for occupational health and job performance, but also on more intricate person-level processes that can better capture how recovery is enacted in daily life (Steed et al., 2021). Notably, although experiences of recovery have been widely studied, whether and how employees may proactively seek to attain these experiences in daily life has not been examined. In this study, based on the Integrative Needs Model of Crafting, Conservation of Resources theory, and Self-Determination Theory as our frameworks, we focus on daily proactive off-job recovery strategies (i.e., shaping off-job time in a proactive and self-initiated way in order to attain recovery experiences) and their role in benefiting daily recovery experiences, occupational health, and performance.

Methodology: Daily diary measurements were conducted among a sample of 383 Norwegian employees across a period of two weeks in February 2022 (from Monday to Thursday, i.e., eight measurement days in total). Participants answered questionnaires on occupational health and performance during afternoons (at work), and questionnaires on occupational health, and recovery strategies and experiences during evenings (at off-job time). Proactive recovery strategies were measured with the recently validated Needs-based Off-job Crafting Scale. Mediation models are tested in Mplus 8.7 to examine the daily relationships between recovery processes, occupational health, and performance at the within-level.

Results: Proactive recovery strategies, recovery experiences, and occupational health and performance indicators show sufficient variability both within and between persons. Preliminary results show that daily proactive recovery strategies are positively associated with daily recovery experiences. Moreover, using proactive recovery strategies during off-job time is positively related to occupational health indicators measured in the evening. Mixed results are found regarding the spillover effects of daily proactive recovery strategies for occupational health and work performance on the following day.

Limitations: Our data collection relies on self-report questionnaires, thus providing initial evidence for the role of proactive recovery strategies in daily recovery that could be complemented with other methods in future studies (e.g., using objective measures).

Implications: This study advances the field of job recovery by focusing on daily recovery processes (i.e., proactive strategies for recovery, recovery experiences). Taking care of daily recovery can be challenging in a changing and intensifying working life. Leaders, HR experts, and occupational health practitioners can benefit from learning about recovery processes as they take place in "life as it is lived".

Originality/Value: So far, recovery has only rarely been investigated from the perspective of proactive recovery efforts. This study focuses on how employees may seek to attain recovery experiences through proactive recovery strategies, and whether these strategies are successful, complementing earlier studies on positive effects of recovery experiences which have generally not commented on how employees attain those experiences.

Relevance to the congress theme: The context of work and off-job time is rapidly changing due to technological advances and unforeseen challenges, such as the COVID-19 pandemic. By crafting their recovery time, employees can meet some of these challenges proactively in order to promote their health and wellbeing among different, changing life circumstances.

Relevant UN SDGs: Good health and wellbeing

Keywords: Proactive recovery strategies, recovery experiences, off-job crafting

Symposium S122

Time is on your side! How adopting a dynamic lens can challenge our understanding of workplace phenomena

Joeri Hofmans, Vrije Universiteit Brussel; Omar Solinger, Vrije Universiteit Amsterdam

science

State of the Art: Around 500 BC, Heraclitus famously stated “Change is the only constant in life”, and what is true for life in general is also true for our working lives. Indeed, virtually all workplace phenomena are in constant change. Think about how our motivation or performance changes from one moment to the next. Or how socialization or organizational change are processes that dynamically unfold over time. As these examples show, many of the key constructs of interest to work and organizational psychologists emerge, evolve, and dissolve over time. Oddly enough, most of our studies have factored out such dynamism. This has important implications because it restricts our understanding of key constructs and phenomena in our field. Fortunately, however, we stand on the edge of a new frontier. Thanks to theoretical (e.g., theories based on dynamic system thinking), methodological (e.g., experience sampling and sensor research), and statistical advancements (e.g., continuous time modeling), a temporal dynamic perspective on workplace phenomena no longer is a pipe dream.

New Perspectives/Contributions: This symposium brings together five studies that adopt a dynamic lens to a variety of workplace phenomena, showcasing the relevance of time and dynamics in understanding work. For each of these phenomena (i.e., counterdispositional behavior, witnessed incivility, motivation, organizational change, and leader-member exchange), the authors demonstrate how adopting a radically dynamic lens challenges and/or expands our current knowledge. Moreover, several of the talks are characterized by substantive-methodological synergy, with the authors demonstrating how novel methodological and statistical tools can help in the study of workplace dynamics.

Presentations: In the first presentation José Navarro will present an event-based approach to studying emotions at work. Using a diary study among 58 employees (N = 751 repeated measurements), they show that different situational features trigger different discrete emotions, thereby providing support for the importance of events in generating basic emotions. In the second presentation Joanna Ritz will discuss the theoretical and practical value of looking at organizational change through the lens of dynamic systems theory. By doing so, she argues, research can shift from simply describing organizational change to explaining and predicting it. In the third presentation, Sarah Cameron will present a radically dynamic and dyadic perspective on Leader-Member Exchange (LMX) relationship development. Using narrative analysis of interviews with 32 leaders and followers, five prototypical narratives of LMX development were found, with these narratives offering a detailed explanation of how LMX relationships of varying quality develop. In the fourth presentation, Evy Kuijpers will present the findings of two experience sampling studies in which she studied the affective consequences of engaging in counter-typical conscientiousness-related behaviors. Studying concurrent, delayed, and cumulative effects, she demonstrates that self-rated conscientious behavior is generally beneficial, even if this behavior goes against one’s typical behavior. In the final presentation, Yara Bouckaert discusses the findings of a longitudinal study in which she studied the dynamic relationship between witnessed incivility and instigated incivility. Her findings show that observing how others perform incivility acts can explain why observers conduct incivility acts later themselves.

Research/Practical Implications: Adopting a dynamic lens when looking at workplace phenomena helps us understand what happens, how things happen, and why things happen at the workplace. Such knowledge clarifies how and when organizational interventions should be set up.

Keywords: dynamic, time, change

Paper 1

Dynamic Interplay between Emotions and Motivation at Work: An Application of the Affective Events Theory

José Navarro, David Leiva & Rita Berger | University of Barcelona; Rita Rueff-Lopes, Esade Business School

Research goals and why the work was worth doing: There is an important body of evidence about the changes of work motivation over time. At short term (e.g., hours, days) there has been estimated that around the 54% of the variance in work motivation can be attributable to the within-participant level (Navarro et al., 2022). However, the causes of these motivational changes continues to be unclear. A serious potential candidate could be the emotions and affective reactions that employees experience at work. The link emotions/affective reactions and motivation is a classic in psychological literature but it has not been fully explored in work setting. For example, there already are empirical evidence about the relation between affect (positive and negative) and work motivation, but little is know about the role of discrete and basic emotions (e.g., joy, anger, surprise).

Theoretical background: The affective events theory (AET; Weiss and Cropanzano, 1996) is a framework that allows us to understand the causes and consequences of affect and emotions in work contexts. This framework proposes that events happen at work that are not neutral generating affective responses that, in turn, influence on employees' behaviors and attitudes. As a theory AET is reputed in the field having encouraged a lot of empirical research. Work attitudes such as job satisfaction, for instance, is now recognized as a consequence of the previous affective experience lived by the employee. There is also some evidence of this affective influence on motivational related phenomena (i.e., attention) but this theory has not been directly apply to understand work motivation as we have trying to do in this research. This would be the main goal here.

Methodology: Using a diary study 751 repeated assessments were collected from 58 employees from different professions. In order to measure emotions, we used the event reconstruction technique (Kahneman et al., 2004). Participants had to remember an important recent event and answer then about how they felt. We measured the six basic emotions (i.e., joy, anger, sadness, disgust, fear and surprise) and also some important dimensions of that event (i.e., relevance, novelty). After we asked about the task the employee was doing at that moment and asked about their level of motivation about that task using a 3-item scale created ad hoc for this purpose (multilevel reliability RkF = .98). All the data are analyzed at within-participant level.

Results obtained: The results found support of the importance of events in generating emotions. Specifically, novelty, valence (positive or negative) and relevance of events are significantly related to all the basic emotions (anger, joy, sadness, fear, disgust and surprise). For example, novel events produce the reaction of surprise ($r = .39$, $p < .01$); or relevant events produce reactions of joy ($r = .24$, $p < .01$) or fear ($r = .19$, $p < .01$). In addition, some of these emotions, for example joy, are also significantly related to task motivation ($r = .13$, $p < .01$).

Limitations: Sample size and type (e.g., the majority of workers can be characterize as white-collar workers) have to be amended in future research.

Conclusions: AET can be a fruitful framework to understand motivational dynamics at work. From a practical point of view, the theory and these results invite us to consider two elements in the people management field. First, we should pay attention to the emotions that our employees experience on

a daily basis, for example, having assessment systems for this. And second, it would be necessary to do a detailed analysis on what type of work events generate these emotional responses.

Relevance to the Congress Theme: This research contributes to understand the relevance of emotions at work and the importance to consider work setting as places rich in triggering emotional responses.

Relevant UN SDGs: Promoting well-being at work just considering emotional well-being as critical facet of that employee well-being.

Keywords: work motivation, emotions at work, intensive longitudinal design

Paper 2

A dynamic systems approach to organisational change: Implications for theory, research and practice

Ritz Joanna, University of Amsterdam; Creelman David, Creelman Research; Doci Edina, Vrije Universiteit Amsterdam; Vullinghs Jesse, Vrije Universiteit Brussel

Theoretical background: Typically, theoretical models of organisational change offer step-by-step guidelines for practitioners that focus on the sequential states that organisations must go through to successfully achieve change (e.g., Lewin's (1951) three-step model, Bullock & Batten's (1985) model, or Kotter's (1995) eight-step program). However, because organisations are complex, constantly changing, and virtually impossible to fully control, managers often struggle to apply these programs in practice (Buchanan, Claydon & Doyle, 1999; Burnes, 2014; Dawson, 2011). In response to that, some researchers started to conceptualize change as a continuous and dynamic process that emerges in an unpredictable and unplanned fashion – emergent change (Arnold et al., 2016). Yet, the emergent approach and the assumption that change is chaotic and unpredictable means it is difficult to translate it into research and practice (Burnes, 2005; 2014). So, neither the 'full control' nor the 'no control' approach is suitable for change in the modern workplace, as the former appears untannable in practice and the latter would make management literature on organizational change obsolete altogether. In this paper, we address this issue by taking a dynamic systems perspective to organisational change, which conceptualises organisations as complex, adaptive systems that change over time. By doing so, we can identify the generic principles that drive (seemingly unpredictable) organizational change, without submitting to the illusion of full control, but also without sacrificing its complexity.

New perspectives and contributions: To offer an analytical, structured way to analyse processes within organisations from a dynamic systems perspective, we integrate research on organisational change and research on dynamic systems. In particular, we discuss three main themes: (1) elements of the system (e.g., levels, subsystems, complexity, environment), (2) interactions between the elements (e.g., synergies, feedback loops, interdependence), and (3) self- organisation of the system (i.e., emergence). Each theoretical part is illustrated with examples from organizational domain and combined with practitioner points that should be considered when planning and implementing change. Next, we discuss how the dynamics of organisational change can be examined empirically. In particular, we provide concrete suggestions for conceptualising organisational change for research purposes, for designing and collecting appropriate data, and for statistical methods that can be used to study the dynamics of organizational change.

Research and practical implications: Typically, research on organizational change focuses on comparing the organizational before and after the change, which represents the content of change (Barnett, 1995). Yet, in order to empirically examine change from a dynamic perspective, researchers have to consider not only the content of change, but also the processes that drive it (i.e., how the change occurs). In addition, the technological advances and increased use of Big Data allows to examine complex dynamics of a system and how it evolves over time and across different sources of information (Calvard, 2016). By doing so, the researchers can shift from simply describing organizational change to explaining and predicting it. From a practical perspective, dynamic systems theory on organizational change has a potential for a wide variety of applications due to its focus on the mechanisms that drive change, rather than attempting to prescribe a step-by-step progression of events or conceptualizing change as chaotic and uncontrollable. The focus of practitioners operating

under this paradigm should be to leverage the principles of change in an organization to amplify their limited degree of control.

Originality and value: The dynamic systems perspective we focus on has been shown useful in various domains in organizational science. In this paper, we combine insights from several disciplines to provide a theoretical account of organizational change that is relevant to research and practice. By capturing the complexity of organizational change in a practically relevant way, we provide a set of tools that are a step forward in building comprehensive account of organizational change. Though effective change management can be a daunting task, often at risk of failure, the approach we offer here has a potential to improve organizational change interventions.

Keywords: organizational change, dynamic systems, ecosystems

Paper 3

"What Makes a Match?": A Narrative Investigation of LMX Development

Cameron Sarah & Vullinghs Jesse | Vrije Universiteit Brussel; Solinger Omar & ter Schure Anne | Vrije Universiteit Amsterdam

For over 40 years, Leader-Member Exchange (LMX) theory has received significant attention in the leadership literature, with a host of studies demonstrating the correlation of LMX with organisational outcomes such as job performance, organizational citizenship behaviours and organisational commitment (Dulebohn et al., 2012, Graen & Uhl Bien, 1995, Gerstner & Day, 1997). LMX theory distinguishes itself from other extant leadership theories in approaching LMX as a fundamentally social process, formed through a series of exchanges or "double-interacts" between leader and follower. In doing so, LMX theory acknowledges the role both leaders and followers play in defining the nature of the relationship (Day & Miscenko, 2015, Dulebohn et. al, 2012).

Despite the inherent dynamism in early conceptualizations of LMX theory, research in recent years has adopted a more variance oriented approach in focusing on the antecedents, correlates and outcomes of LMX (McClean et al., 2019; Nahrgang & Seo, 2015). Specifically, research on how LMX relationships develop remains scant, with the three phase role making model of Graen and Scandura (1987) being the only extant theorization, with limited empirical support (Nahrgang & Seo, 2015). Thus, to more thoroughly understand the process through which LMX relationships develop, this study adopts an exploratory research design (Langley, 1999). The design allows for an investigation of how the form and sequencing of exchanges between leader and follower accumulate over time to determine the nature of the relationship.

The value of this work is twofold. Firstly, in applying a dynamic approach to studying LMX development, this research provides insights into the temporal patterns of the behaviours, cognitions and affective responses that determine how and why an LMX relationship reaches a certain level of quality, responding to numerous recent calls to include the concept of time in leadership research (Castillo & Trinh, 2018; Hofmans et al., 2019; Vantilborgh et al., 2018). Secondly, in using the dyad as the central point of analysis, this research sheds further light on the role followers play in the leadership process (Sin & Nahrgang, 2009).

For this study, interviews with 32 leaders and followers were conducted. Participants were asked to retrospectively tell the story of how their LMX relationships developed over time, divide this story into distinct chapters, and provide ratings of LMX quality at each chapter. LMX Quality was measured using the LMX-MDM scale (Liden & Maslyn, 1998). These ratings resulted in graphs of LMX quality over time for each narrative (see Appendix 1). Narrative analysis of the qualitative interviews revealed five prototypical narratives of LMX development: Symbiotic Growth, Honeymoon Hangover, Keep Calm and Carry On, Struggle and Accept, and Crash and Burn. Each narrative is subsequently divided into three or four developmental phases. The five narratives capture the broad developmental pathways of LMX relationships, while the individual phases detail the precise mechanisms that occur within each phase to determine the quality and nature of the relationship. In doing so, these narratives offer a more detailed explanation of how LMX relationships of varying quality develop.

The narratives presented in this study specifically account the role of time in the development of LMX, and highlight how the sequencing of specific exchanges (e.g. affective events) impact

developmental trajectories. For example, the Struggle and Accept narrative demonstrates how dyads experience and move beyond negative affective events, and how these negative events impact the state of the relationship after initial development. Furthermore, these results question the extent to which LMX relationships ever achieve stabilization, as participants recount how expectations of their dyad pair continue to evolve well beyond the initial developmental phases.

The primary limitation of this research pertains to the recall bias of participants due to retrospective interviewing. Future studies would benefit from a longitudinal approach, with participants interviewed at weekly or monthly intervals to more accurately capture the moment to moment exchanges that contribute to the relationship development.

For practitioners, these results provide more detailed insights into the mechanisms that drive changes in the nature and quality of leader-follower relationships. For example, the behaviours and affective responses highlighted in the Symbiotic Growth narrative demonstrate how experiencing personal events together can serve as a catalyst for the development of a higher quality relationship, while the Keep Calm and Carry On narrative highlights the temporality of cognitive coping. In summary, the results of this study offer insight into the dynamism inherent in leader-follower relationship development and maintenance, and how the sequencing of behaviours, cognitions and affective responses contributes to LMX quality.

Keywords: Leader-Member Exchange, Temporal, Development

Paper 4

Does it Pay Off to Act Conscientiously, Both Now and Later? Examining Concurrent, Lagged, and Cumulative Effects of State Conscientiousness.

Kuijpers Evy, Vrije Universiteit Brussel; Wille Bart, Ghent University; Hofmans Joeri, Vrije Universiteit Brussel

Research goals: The aim of this study was to look at the relationship between state conscientiousness, emotional exhaustion, and negative affect, not only concurrently, but also delayed, and cumulated over time. Although several studies indicate that both trait and state conscientiousness are positively related to desirable life and work outcomes, there are also studies that suggest that conscientiousness might be a double-edged sword, leading to later fatigue. Furthermore, the Behavioral Concordance Model posits that out of character behavior might be costly for the individual. Because we expect that the depleting effect of (counterhabitual) conscientious behavior might not become evident immediately, we examine how these effects may evolve over time.

Theoretical background: Conscientiousness has often been identified as the personality dimension that is predictive of health behaviors, academic success, and work success. This raises the question of why we do not uniformly invest in becoming more conscientious. In the present paper, we suggest that the answer may lie in the fact that between-person relationships might not straightforwardly translate to the within-person level. So far, most studies have looked at the effects of counterhabitual behavior in the moment or examined the effects of acting out of character immediately after the behavior took place. However, because the effects of counterhabitual behavior might (a) build over time and (b) need some time to 'sink in', we believed it is crucial to examine how the effects of (counterhabitual) conscientiousness materialize over time.

Methodology: We relied on two Experience Sampling Method (ESM) designs using 157 and 96 participants (N= 1,699 and N = 2,151, respectively).

Results: Results revealed that higher levels of conscientiousness are concurrently related to lower levels of emotional exhaustion, resource depletion, and negative affect. When looking at delayed effects, no conclusive evidence was found for affective or cognitive costs of counterhabitual conscientiousness. Finally, analyzing cumulative effects revealed that repeated negative deviations from one's typical level of conscientiousness were positively associated to exhaustion, depletion, and negative affect, while repeated positive deviations were negatively associated with depletion and unrelated to exhaustion and negative affect. Altogether, our findings suggest that self-rated conscientious behavior is generally beneficial, even if this behavior goes against one's typical behavior.

Limitations: First, we relied on self-reports to measure our focal variables, and although this way of measurement is not uncommon with these constructs, it makes our findings susceptible to common method bias. Second, it should be noted that causality could not be established with our study design.

Research/ practical implications: Previous research has shown that the consequences of counterhabitual behavior might differ depending on the time frame that is adopted. We wanted to add to this by looking at both concurrent, delayed, and cumulative effects simultaneously. Despite the importance of this issue, several studies still (implicitly) assume that effects at a certain moment

in time (here and now) can be directly translated to different time scales (later). By combing different time perspectives within one study and by moving away from the isolated focus on the present, we gain insight in what happens when we act out of character, and when. This understanding can help us when designing interventions that act upon incongruences at work.

Relevance to the Congress Theme: Ever changing demands in the workplace force people to act in a way that is inconsistent or even counter to their typical behavior. We evaluate whether these behaviors are indeed costly.

Relevant UN SDGs: Good health and well-being

Keywords: conscientiousness, counterhabitual behavior, emotional exhaustion

Paper 5

Should I Look Away? A Dynamic Perspective on the Relationships Between Witnessed Incivility, Exhaustion, and Instigated Incivility

Yara Bouckaert, Vrije Universiteit Brussel; Michael Gielnik, Leuphana University of Lüneburg; Vicente González-Romá, University of Valencia

Research goals: The aim of this study was to look at the dynamic relationship between two previously overlooked incivility components, namely witnessed incivility and instigated incivility. Whereas previous research has taken a static rather than a dynamic approach to studying workplace incivility, we proposed that the rate of change in witnessed incivility was positively related to the rate of change in instigated incivility via changes in exhaustion. Accordingly, we obtained insights into how these relationships develop over time.

Theoretical background: Workplace incivility is "low-intensity deviant workplace behavior with ambiguous intent to harm the target, in violation of workplace norms for mutual respect" (Andersson & Pearson, 1999, p. 457). Uncivil behaviors are rude, discourteous, and display a lack of regard for others. Workplace incivility consists of three types: experienced incivility entails being the target of uncivil behavior, witnessed incivility involves the consequences of uncivil encounters with bystanders, and instigated incivility denotes the performance of uncivil acts toward others (Schilpzand et al., 2016).

Drawing upon social learning theory (Bandura, 1977) and incivility spiral theory (Andersson & Pearson, 1999), we investigated the relationship between witnessed incivility and instigated incivility. We reasoned that incivility spreads through the workplace because employees directly observe others repeatedly violating norms of civility, prompting incivility to become the new workplace norm. Moreover, in line with the job demands-resources theory (Bakker & Demerouti, 2017), we propose that exhaustion, a dimension of burnout defined as "a severe loss of energy that results in feelings of both physical and mental exhaustion" (Schaufeli et al., 2020, p. 27), mediates the association between witnessed incivility and instigated incivility.

Methodology: We adopted a longitudinal research design with three measurement occasions separated by one-week time lags. Dutch-speaking employees (N = 429) filled out online questionnaires. We tested the hypotheses using a parallel process mediation latent growth curve model.

Results: Results illustrated that the rate of change in witnessed incivility is positively related to the rate of change in instigated incivility, indicating that employees who experience an increase (or a decrease) in witnessing uncivil events also increased (or decreased) in their display of uncivil events. Furthermore, the rate of change in witnessed incivility was positively related to the rate of change in exhaustion, indicating that when employees experienced an increase (or decrease) in witnessing uncivil events, their feelings of exhaustion subsequently increased (or decreased). Finally, the rate of displaying incivility did not change as a result of increased (or decreased) feelings of exhaustion.

Limitation: Our measure of exhaustion tapped into both physical and emotional aspects of exhaustion, with the former one probably being less relevant.

Implications: Theoretically, the results suggest that social learning is a key mechanism for rapid incivility spread in the workplace. That is, our findings point out that observing how others perform

incivility acts can explain why observers conduct incivility acts later themselves. Moreover, we show that changes in exhaustion is an outcome of changes in witnessed incivility, which expands the nomological network of witnessed incivility to emotional outcomes. Practically, the results recommend that organizations should continuously monitor their workplace incivility trends and take tailored-based approaches toward organization-wide prevention for both targets and witnesses of incivility.

Relevance to the congress theme: Incivility spreads rapidly in the workplace. To better understand this spread, we take a dynamic rather than a static approach to studying workplace incivility and thereby investigate whether social learning is a key mechanism for this rapid incivility spread.

Relevant UN SDGs: Good Health and Well-being, Decent Work and Economic Growth

Keywords: incivility, witnessed incivility, exhaustion

Symposium S079

Burnout Assessment Tool (BAT) advancements II: The dynamics of burnout measured with the BAT and using longitudinal designs

Angelique De Rijk, Department of Social Medicine, Care and Public Health Research Institute, Faculty of Health, Medicine and Life Sciences, Maastricht University, the Netherlands; Jari Hakanen, Finnish Institute of Occupational Health; Helsinki, Finland

science

Title Burnout Assessment Tool (BAT) advancements II: The dynamics of burnout measured with the BAT and using longitudinal designs

What will be covered and why? Recently, a new burnout questionnaire has been developed to support better understanding of burnout in research and practice: the Burnout Assessment Tool (BAT; Schaufeli, Desart & De Witte, 2020). According to the BAT, burnout is a syndrome that includes four core dimensions (exhaustion, mental distancing and cognitive and emotional impairment), as well as secondary symptoms (e.g., irritability, sleeping problems, and tension headaches). An international consortium is currently using the BAT as the instrument of choice to measure burnout. This two-part symposium presents advancements regarding I) the dynamics within the BAT and its clinical validation and II) the dynamics of burnout measured with the BAT and using longitudinal designs. Symposium II comprises four contributions from different countries presenting results using BAT in longitudinal designs, in order to shed light on the dynamics of burnout. Various theories were used: the Job Demands Resources model, the Conservation of Resources theory and the Self-Determinantion Theory, First, Basińska and colleagues developed profiles of employees' wellbeing with latent profile and latent transition analysis in a Polish sample using BAT-12 in a two-wave study. Second, Li and colleagues tested longitudinal relationships between indicators of employee well-being and mental health in a Finnish sample using BAT-12. Third, Hakanen studied whether burnout, boredom, work addiction, work engagement and job satisfaction are equally important for employee outcomes. They did so with BAT-23 In a two-year follow-up study in the Finnish general working population. Finally, Glaser tested the relationships between basic psychological needs, meaning in work and burnout (measured with BAT-23), with a three-wave study in the German and Austrian workforce.

Relevance to the Congress theme Burnout with its heavy human and economic cost is a persistent challenge for organizations in the changing world of work. These studies support the view that the BAT can provide valuable scientific and practical tool to tackle the burnout problem. Moreover, these longitudinal studies suggest that investing in job resources and fulfilling the employees' psychological needs will prevent burnout while mitigating burnout is beneficial for promoting employee health, workability, and work-related attitudes. This knowledge helps to build a sustainable future of work.

Research/practical implications The BAT has been translated in more than 20 languages, and validations studies have been published. It is now important to use the BAT in longitudinal studies. Next, these insights into the dynamics of burnout will support better monitoring practices and will promote intervention development for preventing burnout.

Overall conclusions These longitudinal studies emphasize the work-related character of burnout, with individual behaviour reinforcing detrimental processes. Lack of job resources and lack of addressing employee psychological needs increase burnout, while strongly burned-out employees lose their resources while continuing to invest them. Moreover, burnout in turn affects job attitudes

and health outcomes negatively. This ‘burnout-process’ differentiates from that found in relation to engagement, depression and anxiety.

Keywords: Burnout Assessment Tool (BAT), longitudinal designs

Paper 1

Profiles of employees' well-being in two time points: latent profile and latent transition analysis

Beata Basińska, Gdansk University of Technology, Gdansk, Poland; Wilmar Schaufeli, KU Leuven, Leuven, Belgium; Hans De Witte, KU Leuven, Leuven, Belgium; Marta Kuc–Czarnecka, Gdansk University of Technology, Gdansk, Poland ; Ewa Gruszczyńska, SWPS University, Warsaw, Poland

Research goals and why the work was worth doing This study examines profiles of employees' well-being as a combination of job burnout and work engagement as well as the within-person stability of these profiles across a one-year period. It also presents the implications of the profiles for employees' job satisfaction and general health and investigates the role of job demands (work overload and illegitimate tasks) as a covariate of profile membership.

Theoretical background Job burnout is a syndrome of four core symptoms, namely, exhaustion, mental distance, and cognitive and emotional impairment. In line with the circumplex model of affect, occupational well-being is viewed as the interplay between the independent dimensions of job burnout and of work engagement, which may lead to different profiles. According to the Job Demands-Resources theory, job demands (work overload and illegitimate tasks) are expected to be related to well-being profiles, because when excessive, they can impair employees' overall health and job satisfaction over time.

Design/Methodology A sample of 1201 Polish employees took part in a longitudinal study consisting of two measurement points. Data were collected in 2019 (before the pandemic) and one year later (during the first lockdown). The drop-out rate was 32%. Employees were 42±10.2 years old and on average reported job tenure of 19±10.9 years. Among the participants, there were professionals (education, health care, public administration and IT) mainly with higher education (90%). Women represented 66% of the sample.

The participants completed the Burnout Assessment Tool (BAT-12), Utrecht Work Engagement Scale (UWES-3), Bern Illegitimate Tasks Scale, and Work overload, job satisfaction and self-rated general health from the Energy Compass. Latent profile analysis was used to identify subgroups of employees with different profiles of occupational well-being. The decision for the final profile solution was driven by theoretical considerations as well as by the fit indices of the specified models. Latent transition analysis was applied to examine a stability of profile membership between both time points.

Results Latent profile analysis revealed five distinct occupational well-being profiles representing highly engaged (14.4% of the sample), moderately engaged (40.2%), mildly burned-out (30.5%), strongly burned-out (12.4%) and disengaged employees (2.5%). The last two profiles had the highest level of burnout, but with some differences regarding its components. Disengaged employees showed a deficit on the identification dimension (i.e., higher level of mental distance vs. lack of work engagement), while strongly burned-out employees scored high on all symptoms of burnout. The profiles differed significantly on the level of job demands (work overload and illegitimate tasks) as well as on the level of the outcomes (job satisfaction and general health). Negative outcomes and excessive demands were reported by the burned-out employees, however, the lowest level of job satisfaction at both measurement points was reported by the disengaged employees. Nonetheless, the burned-out and disengaged employees experienced positive changes during the pandemic. They declared significantly better health and higher job satisfaction.

In a temporal perspective, significant changes in belonging to a given profile were observed. For the strongly and moderately engaged, and strongly burned-out profiles, stability of 62%, 60%, and 50%, respectively, was noted. For the disengaged profile a transition of membership was observed, mainly to the strongly burned-out profile, whereas members of the moderately burned-out profile migrated in both directions, i.e., to moderately engaged and strongly burned-out profiles.

Limitations Employees volunteered for the study, thus, the sample was not representative. The timeframe of the study covered large changes in work practices due to the pandemic and related social processes. Moreover, the second measurement point took place during the first lockdown, thus, drop-out among more exhausted employees, perhaps also due to new work conditions, might have been significantly higher.

Conclusions – research and or practical implications/Originality/Value In line with theoretical rationales of the Conservation of Resources theory, strongly burned-out employees lose their resources while continuing to invest them. In contrast, disengaged employees seem likely to withdraw their resources, which manifests in a lack of identification with work and the organization. In the study, we observed a lack of stability of profiles within one year, which may reflect dynamics triggered mainly by unusual external circumstances. The results of this study showed that a person-centred approach may give substantial insights into individual pathways of employees' well-being.

Relevance to the Congress Theme Stress and dysfunction (Stress and burnout)

Relevant UN SDGs Good health and wellbeing

Paper 2

Cross-lagged associations between burnout and anxiety and depression

Jie Li, Jari Hakanen & Janne Kaltiainen | Finnish Institute of Occupational Health, Helsinki, Finland

Research goals and why the work was worth doing The goal of our study is to investigate associations between burnout and two general mental illness symptoms: depression and anxiety. Mental illness issues are one of the most prevailing concerns of today and are among the top reasons for applying for sickness benefits among others in Finland. Despite various studies showing the distinctiveness of burnout compared to other general mood disorders, some studies are still questioning the validity of the concept. While acknowledging that work-related and general ill-being are interrelated, from a practical point of view it is important to gain knowledge on how they affect each other.

Theoretical background The theoretical background builds upon the Burnout Assessment Tool (BAT), which is a new measure based on novel conceptualization of burnout. BAT conceptualizes depression as a secondary symptom but due to the comorbid nature of depression, it is reasonable to investigate anxiety symptoms as well. Our study also builds upon the Conservation of Resources theory, which states that resource loss at work could lead to loss spirals and deteriorated well-being.

Design and Methodology A randomized population survey of Finnish citizens (ages 23-65) was utilized. The first survey was collected in the summer of 2021 (T1) and the follow-up survey was collected in the summer of 2022 (T2). For the analysis, we included participants that participated in both time points and reported at least 10 working hours in a week in T1 as well as in T2 (n = 849). Burnout was measured using the 12 item version of the BAT, anxiety was measured using the Generalized Anxiety Disorder Questionnaire, and depression was measured with four items drawn from the Four-Dimensional Symptom Questionnaire.

Structural equation modeling was used to estimate over-time associations. Latent change scores were utilized to capture within-person changes in outcomes and path estimates from prior levels of predictor variables. We estimated and compared four plausible models to determine the superior model. Model 1 had autoregressive effects estimated from all indicators at T1 to changes from T1 to T2. Model 2 included cross-lagged effects from burnout at T1 to changes in depression and anxiety symptoms from T1 to T2, as well as autoregressive effects to control the baseline levels. Model 3 included cross-lagged effects from depression and anxiety symptoms at T1 to changes in burnout from T1 to T2, as well as the autoregressive effects. In model 4, we estimated all previously mentioned effects. The models were estimated using the maximum likelihood estimation with robust standard errors to account for non-normality in some of the items. The model comparison was conducted using the Satorra-Bentler chi-square test.

Results All estimated models fit the data well. However, model 2 is superior compared to model 1 ($\Delta\chi^2$ (2) = 19.739, p = .000) and model 4 ($\Delta\chi^2$ (2) = .352), p = .838). Model 4 is superior to model 3 ($\Delta\chi^2$ (2) = 17.328, p = .000). Burnout at T1 predicts changes in depression symptoms from T1 to T2 (.174 (.065) p = .008) as well as changes in anxiety symptoms from T1 to T2 (.289(.101) p = .004). Models 3 and 4 did not show any significant cross-lagged effects from mental illness indicators to burnout. Our results suggest that burnout spills over to general mental health symptoms.

Limitations We do not have more time points available for our analysis. Hence, we can only provide preliminary evidence for the causal relations.

Conclusions – research and or practical implications Confirmatory factor analysis revealed that burnout is distinctive from general types of ill-being. Furthermore, we provided evidence for one-way spillover effects from burnout to both anxiety and depression symptoms. Our study suggests that it is vital to create and maintain working conditions that mitigate burnout since it also spills over to employees' general mental health symptoms. By separating work-related ill-being from general mental illness, we suggest that effective attempts of mitigating burnout primarily stem from the workplace and not from other life domains.

Relevance to the Congress Theme The rising prevalence of mental illness remains a looming threat to individuals' work ability. During these challenging times of post-pandemia and tensions in Europe, workplaces can support employees' general mental health by mitigating burnout at work.

Relevant UN SDGs Our study contributes to the good health and well-being -goals of the UN SDG as well as the decent work and economic growth goals. We provide a strong statement about workplaces that share responsibility for employees' general mental health development.

Keywords: burnout, anxiety, depression

Paper 3

Are burnout, boredom, work addiction, work engagement and job satisfaction equally important for outcomes? A Finnish two-year follow-up study

Jari Hakanen & Janne Kaltiainen | Finnish Institute of Occupational Health, Helsinki, Finland

Research goals and why the work was worth doing The aim of this two-year follow-up study was to investigate the relative contributions of five different states of employee well-being to changes in various health-related and work attitude-related outcomes. Often only one or two (e.g., burnout and engagement) states of employee-well-being are included in research models in work and organizational psychology. Therefore, little is known whether certain states of employee well-being are relatively more important for health and other outcomes compared to other states. This study aimed to examine the predictive power of negative (burnout, job boredom and work addiction) and positive (work engagement and job satisfaction) employee well-being relatively to each other for seven employee outcomes related to health and work attitudes in the general working population.

Theoretical background Conceptually, different states of employee well-being (their affective components) can be plotted into the Circumplex model of affect. In this model, two dimensions constitute affective well-being, namely pleasure (how one is feeling) and activation (mobilization of energy). Burnout and job boredom (negative low arousal), work addiction (negative high arousal), work engagement (positive high arousal) and job satisfaction (positive low arousal) appear in different quadrants in the model. Based on the Conservation of Resources (COR) theory) it could be hypothesized that resource threats (e.g., negative states of employee well-being) are more strongly related to various outcomes than resource gains (e.g., positive states of well-being).

Methodology A two-wave two-year follow-up study among a randomized working population sample in Finland was used. T1 data were collected at the end of 2019 and T2 data at the end of 2021. Altogether 446 employees responded to both surveys, were employed throughout the follow-up period and worked 10 hours per week at minimum. The five predictors at T1 were burnout (measured with BAT-23), job boredom, work addiction, work engagement, and job satisfaction. The health-related outcomes were depressive symptoms, life satisfaction, workability, and presenteeism, whereas work attitude-related outcomes were organizational identification, job insecurity and intentions to leave. Dominance analysis and change scores were used to study relative strength of predictors of T1-T2 changes in the outcomes.

Results The five predictors of employee well-being explained from 0.9% (life satisfaction) to 4.0% (presenteeism) of the changes in health-related outcomes and from 1.4% (organizational identification) to 3,2% (turnover intentions) of the changes in work attitude-variables over the two-year period. Burnout was the first or second most important predictor for 6 out of 7 outcomes and most important for changes in organizational identification and job insecurity. Thus, burnout seemed to be even more important for attitude-related than for health-related outcomes. Interestingly each of the five types of employee well-being was the strongest predictor of at least one of the outcomes: job boredom to (decrease in) life satisfaction, work addiction to (increase in) presenteeism and (decrease in) workability, work engagement to (decrease in) depressive symptoms and job satisfaction to (decrease in) turnover intentions.

Limitations Only the relative (based on direct, indirect, and total effects) contributions of different types of employee well-being were compared. For example, mediated models including working

conditions could have provided a more comprehensive understanding of the process why employee well-being may impact the outcomes.

Conclusions – research and or practical implications Burnout as measured with the Burnout Assessment Tool (BAT) seems to contribute most to the studied variables (particularly to changes in the work attitudes) during the follow-up period, which is consistent with COR-theory's assumption of the primacy of resource loss. These results suggest that mitigating burnout may be more beneficial for promoting employee health, workability, and work-related attitudes than mitigating work addiction, job boredom, or promoting work engagement or job satisfaction.

Relevance to the Congress Theme Employee wellbeing, including burnout, are highly crucial for sustainability of employees and organizations in the changing world of work. For example, according to World Economic Forum among top skills required in the future work-life are analytical skills, active learning, creativity, resilience and problem-solving – all skills that become possible only for employees that are motivated and feel well and energized at work.

Relevant UN SDGs 3 - Good health and well-being; 8 - Decent work and economic growth

Paper 4

Basic psychological needs, meaning in work and burnout: a three-wave study on their relationships and dynamics

Lucas Maunz & Jürgen Glaser | University of Innsbruck, Department of Psychology, Innsbruck, Austria

Research goals and why the work was worth doing. The fulfillment of psychological needs might reduce the risk of burnout by increasing functional coping behaviors, vitality, and energy. Meta-analytic findings showed moderate (for competence, relatedness) to strong (for autonomy) negative relations with burnout. However, burnout has been examined in this meta-analysis as an overall score of the Maslach Burnout Inventory, which is not consistent with theoretical assumptions of this instrument. Thus, the first goal of our study is to disentangle the relationships between need fulfillment and (core components of) burnout measured by the Burnout Assessment Tool. Meaning in work might prevent burnout as meaningless tasks require more energy to accomplish. Hence, a second goal is to unravel relationships between meaning, need fulfillment, and burnout. Since most of the prior research employed cross-sectional designs, we examine temporal dynamics in a longitudinal design.

Theoretical background. Self-determination theory proposes autonomy, competence, and relatedness as universal psychological needs. Psychological need fulfillment at work has been shown to be associated with several work-related antecedents (e.g., job resources, stressors) as well as beneficial outcomes (e.g., motivation, engagement). Further, meaning in work has been studied with a focus on satisfaction, engagement, or well-being, but relations to burnout and psychological need fulfillment remain unclear.

Design, methodology . We conducted a three-wave study in a German and Austrian workforce. Time lags between waves were set to 6 months. N = 781 employees completed questionnaires over a period of one year. Fulfillment of psychological needs was assessed by an adapted version of the Work-related Basic Need Satisfaction Questionnaire (9 items; Deci et al., 2001). Meaning in work was examined by the Work as Meaning Inventory (WAMI) distinguishing three components (i.e., positive meaning, meaning-making through work, greater good motivation). Burnout was measured by the Burnout Assessment Tool (BAT-23), a new validated instrument, distinguishing four core components of burnout (i.e., exhaustion, mental distance, cognitive and emotional impairment). Structural validity was tested with confirmatory factor analysis (CFA) and relations between constructs were examined through three-wave cross-lagged panel modeling.

Results obtained and expected. The proposed factor structures of three separate needs and four core components of burnout as well as a global burnout score could be supported. A two-factor solution of meaning in work distinguishing “personal” from “greater good” meaning fitted the data best. Moderate positive psychological need fulfillment and meaning in work and rather low burnout were reported. As expected, burnout, need fulfillment, and meaning remained highly stable over time. We found direct and reciprocal relations between the constructs. Burnout showed negative direct- and cross-lagged effects on competence and autonomy whereas relatedness and burnout did not affect each other. Fulfillment of each psychological need demonstrated positive lagged effects on greater good meaning, reversed effects appear less plausible. Personal meaning showed positive direct and reciprocal relations to competence and autonomy over time, whereas associations to relatedness are less likely. Finally, personal meaning was negatively (directly and reciprocally) related to burnout between T1 and T2 but not between T2 and T3. Further results on the relationships with

core components of burnout will be reported. More detailed results on relations between the burnout core components, need fulfillment, and meaning in work will be presented and discussed.

Limitations. Strong causal claims cannot be inferred as omitted third variables may have caused the true effects. Self-reports might be inflated by common method bias. The employee sample was representative for Austria and Germany in terms of age and gender, but not of industries or occupations. Job characteristics (e.g., job stressors) were excluded to reduced complexity but could be added in future research.

Conclusions. Fulfillment of psychological needs might prevent burnout by enabling self-determined work, promoting competence experiences, and cultivating social relationships at work. Personal meaning might be enhanced by communicating goals as well as individual contributions to these goals and to a greater good in the society. Meaning in work and burnout are reciprocally interrelated.

Relevance to SDG. Fulfillment of psychological needs and experiences of meaningful work are important factors to promote well-being and health as well as decent work. Burnout as a work-related disorder is an important indicator for the SDG Good Health and Well-Being.

Relevance to congress theme. Basic psychological need fulfillment and meaning are essentials of a "good life" and are important for eudaimonic well-being of employees at contemporary workplaces.

Keywords: Psychological need fulfillment, meaning in work, burnout

Symposium S126

The Great 8 Success Factors in the World of Work: Past, Present and Future

Rainer Kurz, HUCAMA Analytics

science_practice

The comprehensive World of Work (WoW) model outlined by Kurz & Bartram (2002) covers how person and environment characteristics can be measured and how they interact to produce performance and wellbeing. At the heart of the model are the 'Great 8 Competencies' that emerged out of a series of validation studies relating verbal and numerical reasoning tests as well as personality scales to competencies. This symposium is concerned with the origin of the model, contemporary applications and redevelopment into 'Success Factors' for the future.

Paper 1 and 4 are based on a reconceptualisation as the 'Great 8 Success Factors' that span across aligned personality (predictor) and competency (criterion) hierarchies. New measures were designed from scratch and aligned to the Schwartz (1993) circumplex model of universal values. A 2*2 theoretical model differentiates people and task orientation crossed with an innovative take on DeYoung's Stability and Plasticity meta-factors including higher-order scores rarely seen in operational practice. 15 Emotional Intelligence constructs were integrated triggering refinements of the original constructs in line with Woods & Hardy (2012).

What will be covered and why

1. Kurz & Mikhailov will present research where NEO IPIP facets are mapped on the Periodic Table of Personality (PToP) based on varimax rotated PCA components extracted from its facets. Furthermore, the Great 8 Competencies are mapped on the PToP with many expected but also some surprising results.

2. Smith, Jeffery-Smith & MacIver will present on the validity of the short Match 6.5 screening questionnaire mapped against the original Great 8 Competencies. When the Great 8 Competencies were first outlined by Kurz & Bartram (2002). Due to the asymptotic nature of scale validity increments due to additional items, the measure provides substantial levels of validity in spite of its brevity.

3. Desson & Cannon will present on the validities of Great 8 mappings based on Lumina Spark and Lumina Emotion assessments. Lumina Spark covers four of the Big 5 (excluding Neuroticism) by measuring both ends separately. Lumina Emotion adds one quality to each of the 8 Spark Aspects, and assesses 4 qualities each at either pole of the Emotional Stability-Neuroticism continuum. As this approach is diametrically opposed to the unipolar constructs and positive weight mapping typical for Great 8 research, it is a welcome exploration which could potentially pave the way for reverse scored facets in prediction systems.

4. Guarini & Vernazza will present on the development and validation of a mapping of HUCAMA FACTORS to the well-established Primary Colours of Leadership model. It provides an alternative to the Corporate Leadership model originally developed with the Great 8.

5. Moussa & Kurz will present on a study in multi-cultural Mauritius where predictors of the Great 8 were successfully validated across 221 managers. A sub-sample allowed exploration of the validity of ability test variables, composite predictors as well as predictors combined across personality and ability variables using three different methods. Sackett, Zhang, Berry & Lievens (2022) published an influential article reappraising the validity of many dispositional variables which knocked back slightly

General Mental Ability. It documents substantial validity for each of the Big 5 personality factors but neither their joint validity nor the validity of a personality composite. Validities of composites across personality and ability remain rare, and are usually at an overall performance level thus making this an important contribution building on Bartram (2005).

Relevance to the Congress Theme

As the world of work is changing, the fundamental personality and ability characteristics, which are well-understood, remain the same. Performance however is a more dynamic construct which is less well understood. The Great 8 Competencies have made inroads in science and practice. The present research offers updated perspectives and conceptualisation that refresh the model after 20 years of use to embrace current and future challenges in the world of work.

Research/Practical Implications

Research presented in this symposium showcases successful applications of the Great 8 Competencies and outlines the Great 8 Success Factors as a contemporary variation that straddles across personality, ability, and competency modalities.

Overall Conclusions

Performance at the workplace needs to be described in non-psychological terms to be readily understood by employees, managers and HR. Competencies provide a common language that can be applied across the employee life cycle. The Great 8 Competencies are now a well-established model of performance with clear linkages to personality and ability variables. In the light of two decades of science and practice a Success Factors variation of the model holds promise to provide a unifying framework across personality, ability, and competency constructs.

Keywords: Personality, Ability, Competency

Paper 1

Mapping NEO IPIP Facets and Great 8 Competencies on the Periodic Table of Personality

Rainer Kurz, HUCAMA Analytics; Nikita Mikhailov, PsyPub

Research goals and motivation

The goal of this research is to examine the statistical properties of a NEO IPIP variation, explore its suitability for mapping constructs to the Periodic Table of Personality (PToP) outlined by Woods & Anderson (2016) and to map a new measure designed to cover the Great 8 Competencies (Kurz & Bartram, 2002).

Theoretical background

Woods & Anderson (2016) mapped personality scale to the Periodic Table of Personality based on correlations with 5 orthogonal factors extracted from item level responses to the Trait Descriptive Adjectives (TDA) questionnaire developed by Goldberg (1992). Woods & Kurz (2016) found the PToP methodology viable even when TDA domain scores were used (when item level TDA was unavailable) and found PAPI 2 mappings to broadly correspond to the results of Woods & Anderson (2016). Kurz (2016) successfully deployed NEO Facet scores to create PToP mappings.

Kurz (2012) investigated the criterion-related validity of Big 5 Total scores based on NEO as an alternative to extracting the first unrotated principal component. After partialling out a Big 5 Total, Agreeableness correlated negatively with job performance whereas Achievement Striving and Assertiveness retained significant positive correlations thus corroborating the Great 8 Competencies.

Kurz (2020) outlined the Periodic Table of Personality and illustrated its characteristics by mapping scales of a new measure. However, the orthogonal solution extracted from NEO IPIP at item-level was somewhat unsatisfactory with Openness featuring loadings of some Conscientiousness, Need for Achievement and Assertiveness items.

It is expected that facet level extraction of five varimax rotated orthogonal components from NEO IPIP will provide a satisfactory approximation of PToP mappings. Demonstrating satisfactory psychometric qualities and mappings would open up new opportunities for mapping personality scales to the PToP where NEO IPIP (rather than TDA) has been used alongside.

Method

466 professionals and managers participated in the study as research volunteers. Many participants were completing part-time Psychology and Human Resources university courses alongside full-time employment. As a consequence the proportion of females (341) was substantially higher than males (125), and the median age 28. The sample covered a cross-section of organisational levels including President (1%), CEO (3%), Board Member (6%), Manager (7%), Supervisor/Team Leader (9%), Experienced Professional (32%), Entry-level Professional 25 (6%), Administrative (16%), Front Line / Support Staff (5%) and Blue Collar (15%).

They completed 300 items adapted from NEO IPIP using the 9 point accuracy rating scale featured in TDA and 80 personality items designated to cover the Big 5 personality factors and predict the Great 8 Competencies. Five principal components were extracted from the 30 NEO IPIP facets and varimax rotated to represent the Big 5 factors for PToP mapping. Great 8 Competencies were constructed with one item for each aspects of a factor (e.g. Generating Ideas and Exploring Possibilities for

Creating & Conceptualising), and a single word item deemed to be at the heart of the factor e.g. Creating.

Results

The average Cronbach's Alpha internal consistency reliability of the 30 NEO IPIP construct was .79 which is comparable to the .81 average reported by Goldberg (1999). Reliabilities dropped below .70 for Liberalism (.60 instead of .86 previously) and Activity Level (.62 instead of .71 previously).

The first five components extracted from the 300 NEO IPIP items accounted for only 29% of the variance. Their counterparts extracted from 30 facets accounted for the 64% of the variance and following varimax rotation factor scores were saved that corresponded to the Big 5. With view to the PToP mapping process it was observed that most facets had their primary mapping with the factor allocated in the NEO model structure. However, Assertiveness was marginally stronger associated with the negative pole of Agreeableness than with Extraversion, and Emotionality was marginally stronger associated with Neuroticism than with Openness.

For the new measure of the Great 8 Competencies the mappings were largely as expected for the factors that are direct Big 5 counterparts. For Analysing and Influencing however, Openness and Extraversion were hypothesied by Kurz & Bartram (2002) to be the strongest correlate but they neither achieved primary nor secondary loadings.

Creating correlated most strongly with Openness (.46) followed by Emotional Stability (.25) whereas for Analysing the primary was Emotional Stability (.27) followed by secondary Conscientiousness (.24) followed closely by Openness (.23).

Structuring correlated strongly with Conscientiousness (.52) and marginally with Agreeableness (.13) whereas Striving correlated highest with Conscientiousness (.35) followed by Emotional Stability (.27).

Interacting correlated strongly with Extraversion (.41) and had Openness (.25) as a secondary mapping followed closely by Emotional Stability (.24). Influencing correlated most highly with Emotional Stability (.32) followed by Conscientiousness (.28) whereas Openness (.24) and Agreeableness (-.24) were tied and the correlation with Extraversion was the lowest (.18) which was entirely counter to expectations.

Coping had its Primary mapping with Emotional Stability (.36) followed by Openness (.29). Supporting had its primary mapping with Agreeableness (.40) followed by Extraversion (.25).

Limitations

The current study demonstrates that NEO IPIP Facets can be used to map to the PToP. However as the results for Analysing and Influencing were very surprising, future studies should utilise TDA for mapping the Great 8 to enable comparisons.

Research/Practical Implications

The results suggest that NEO IPIP has good reliability and that varimax rotated orthogonal components extracted from facets are a reasonable representation of the Big 5 personality factors. 8 factor scales modelled on the Great Eight Competencies had a distinct pattern of primary and secondary loadings broady in line with their theoretical origin but with surprises for Analysing and Influencing.

Paper 2

Short Behavioural Screening and the Great Eight

Jake Smith, Rab MacIver & Lauren Jeffery-Smith | Saville Assessment

Research goals and why the work was worth doing

The Great Eight competency framework was instrumental in the development of the Wave model, which underpins multiple behavioural assessments. By mapping to the Great Eight competencies using detailed predictor constructs, criterion-related validity from the individual construct level up to the overall assessment has been established across many Wave assessments. These assessments have a range of applications, with detailed constructs enabling reporting of individual scores to provide feedback to assessees.

However, in certain contexts, gaining rich detail for feedback is less of a concern. In job screening, considerations including providing candidates with a short assessment experience and facilitating recruiters with a single optimised behavioural score for efficient sifting hold more importance. The Match 6.5 assessment was developed from Wave using just 36 items to address these considerations. A far shorter assessment, it relies on flexibly combining broader scales to create a single behavioural fit score for measuring performance in a specific job role.

The following research goals were set to assess the effectiveness of Match 6.5 in measuring the Great Eight:

Understand how mapping to the Great Eight with higher order, broader scales compares to traditionally used detailed constructs

Assess the validity of Match 6.5 in predicting performance across the Great Eight

Assessment validity remains a vital concern for test publishers, recruiters and job applicants; establishing this for new assessments is a key requirement.

Theoretical background

Great Eight

The Great Eight competency framework (Kurz & Bartram, 2002) was developed to measure organisational effectiveness across eight areas of work performance.

Candidate Experience

Many candidates apply to more than one organisation at a time (The Must-Know Student Recruitment Trends for 2019 – Oleeo and Universum). Respecting a candidate's time shown to be the third-biggest contributor to a positive interview or recruiting experience (40% of those surveyed) (Recruiting Daily Market Research, 2019).

Methodology

Great Eight predictor constructs were created using the twelve broad Wave section scales from the Match 6.5 assessment:

Analysing & Interpreting:

Evaluating Problems x 3

Creating & Conceptualising:

Creating Innovation x 2

Investigating Issues x 1

Interacting & Presenting:

Building Relationships x 2

Communicating Information x 1

Leading &Deciding:

Providing Leadership x 3

Supporting & Cooperating:

Giving Support x 3

Adapting & Coping:

Showing Resilience x 2

Adjusting to Change x 1

Organizing & Executing:

Processing Details x 2

Structuring Tasks x 1

Enterprising & Performing:

Driving Success x 3

Using a research sample, these Great Eight predictor constructs created from a longer Wave assessment were correlated with equivalent Great Eight constructs created from OPQ scales (originating from Bartram, 2005), to provide a measure of construct validity for the section level mapping against an established, independent framework.

The Great Eight predictor constructs created from Match 6.5 were then cross-validated against matched criteria measured through manager ratings of effectiveness using:

A research sample of N=308 individuals across multiple occupations with varying management responsibility

An operational sample of N=969 individual contributors and managers across multiple roles from a global chemicals manufacturer

Results obtained

Construct Validity

An average correlation of .64 (N=350) was observed between the Great Eight created from Wave sections and from OPQ scales. This provides construct validity evidence for the Great Eight predictor

competencies created from Wave sections. An average for unmatched correlations of -.01 demonstrates discriminant validity.

Criterion-related Validity

The mean average validity (i.e., the convergent validity) between the Match 6.5 predictors and matched criteria was .35 for the research sample and .41 for the operational sample.

Discriminant validity is demonstrated through comparing the unadjusted convergent validity figure (.18 and .21), with the mean average of non-matched predictor-criteria correlations (.03 and .03).

Limitations

This research considers theoretical validity for Match 6.5 based on an established, independent model. Yet an argument can be made that this approach is not fully representative, as in practice operational validity will vary based on the role context; Match 6.5 uses a particular configuration of sections to create a behavioural fit score for a specific job role.

Consequently, data borne from different local validation studies should provide a more accurate picture of operational validity.

Conclusions – research and or practical implications

The results support the construct validity of Wave in measuring the Great Eight competencies accurately and validly.

Having underlying construct validity is an important pillar supporting a behavioural tool's application in screening, enabling the combining and weighting of scales to produce flexible behavioural fit scores that forecast success in specific job roles. Further research is important in demonstrating the criterion-related operational validity of the resulting fit scores across different jobs.

Relevance to the Congress Theme

As the world of assessment evolves it is important to adapt to changes in the job market. Increasingly, there is a need for flexible, short assessments, with efficiency and speed key considerations for recruiters and candidates. It's also essential to retain focus on demonstrating the validity of new tools, and using well-established frameworks is critical to this.

Keywords: Validity, Screening, Job Fit

Paper 3

Validation of Lumina Spark and Emotion against the Great Eight Competencies

Desson Stewart & Cannon Jonathan | Lumina Learning

Research goals and why the work was worth doing

The paper outlines research validating the combined personality model of Lumina Spark 24 and Lumina Emotion 16 against the Great Eight Competencies. Criterion validity of the two discrete models is presented, along with the incremental validity afforded by the combined model – Lumina Spark 40.

Measures

Lumina Spark 24 is a personality measure based on the Big Five model of personality with Jungian influences. It assesses four of the Big Five – Openness, Conscientiousness, Extraversion, and Agreeableness. The four factors are bifurcated into their opposite poles, with a total of 8 discrete factors being assessed. Each factor is further divided into 3 sub-factors each, with a total of 24 sub-factors. Each quality is assessed on 3 "personas", reflecting the dynamic nature of personality. These personas aim to capture within-individual dynamics in personality with regards to preferences, everyday behaviours, and maladaptive manifestations of personality.

Lumina Emotion 16 is a measure of Neuroticism, the Big Five factor missing from Lumina Spark 24, along with 8 sub-factors of the 8 factors of Lumina Spark 24 which reflect emotional components of the aspects. As with the factors assessed in Lumina Spark 24, Neuroticism is also bifurcated into opposite poles, with each end divided into 4 sub-factors.

The Great Eight Competencies are competencies identified by Kurz and Bartram (2002) that represent an overarching framework of work-related competencies, designed to be a concise and generalisable competency framework by concentrating previous work on developing competency frameworks into 8 general factors of work performance; these were later adapted by Kurz (2003) in order to provide more applied titles to the competencies.

Method

In order to establish criterion validity of the measures, a standard methodology proposed by Bartram (2005) was used. This method involved the mapping of scale sub-factors to the Great Eight Competencies, which is then used to create composites of the sub-factors.

The Bartram (2005) methodology proposes that a composite would be comprised of 3 sub-factors, with a double weight for the top sub-factor, and a single weight for the 2 subsequent factors. In this study, an additional rule was set forth whereby the mappings of the Lumina Spark 40 sub-factors would include at least one sub-factor from each end of each factor-spectrum; this rule was implemented to satisfy the Jungian principle of valuing both ends of each spectrum equally. This rule was also loosely applied to the mappings of the 2 discrete models, but not strictly enforced.

Mapping of sub-factors to the Great Eight Competencies was informed by validity coefficients of the sub-factors against the competencies, where self-assessed sub-factor scores were assessed against externally-rated competency scores using Pearson correlations. For the purpose of this study, "effective" sub-factor scores (Underlying + Everyday) were used. The strength of validity coefficients

was used as the main criteria for the creation of sub-factor composites, further informed by expert judgement in order to maintain adherence to the aforementioned rules.

Sample

375 professionals had self-rated on Lumina Spark 24, and had received external-ratings on the Great Eight Competencies. The mean age was 44.84 years, with 46.9% male and 53.1% female; of this sample, 307 had additionally self-rated on Lumina Emotion 16.

Results

Based on the validity coefficients, composites were created by combining the three mapped sub-factors for each competency. These were then combined into aggregate scores which were assessed against externally-rated competency scores using Pearson correlations in order to assess the criterion-validity of each composite.

Validity coefficients of the composites created using Lumina Spark 24 sub-factors ranged from $r = .20$ to $r = .37$, $p < .01$; for composites created from Lumina Emotion 16, the range was $r = .28$ to $r = .39$, $p < .01$; and for the combined Lumina Spark 40 model, $r = .34$ to $r = .45$, $p < .01$. Mean validity coefficients across the eight competencies was $r = .29$ for Lumina Spark 24, $r = .33$ for Lumina Emotion 16, and $r = .38$ for Lumina Spark 40.

Discussion

The aim of the research presented in this paper was to provide evidence for the criterion validity of the Lumina Spark 24 and Lumina Emotion 16 models, through application of the methodology of Bartram (2005) against the Great Eight Competencies. Results found that through the mapping of sub-factors to the competencies and the creation of composites, both models were able to demonstrate robust criterion validity when assessed against the Great Eight competencies.

A further purpose of the research was to assess a criterion-centric justification for the merging of Lumina Spark 24 and Lumina Emotion 16 into a combined model – Lumina Spark 40. By applying the Bartram (2005) methodology to the combined model, results show evidence for incremental validity provided by the merging of the two models, with a high mean validity when compared to the two models separately, providing a robust argument for the combined Lumina Spark 40 model.

Finally, this research also provides evidence that even when valuing both ends of each Big Five spectrum, through having to incorporate at least one sub-factor from each end, robust criterion validity is still achievable, while contributing to the construct validity of the models through a high-fidelity approach.

Limitations

A limitation of the research presented is the lack of criterion validity for sub-factors of low Conscientiousness in the Lumina Spark 24 model, whereby no sub-factors were able to be mapped to the criterion-variables. This, however, does provide more evidence for the combined model, as the low Conscientiousness sub-factor from Lumina Emotion 16 – 'Follows Feelings' was used in the predictive composite for the competency 'Creating Concepts', showing that through combining both models, robust criterion validity can be evidenced while also valuing all ends of all personality spectrums considered.

Future Research

Future research should aim to cross-validate these findings across different samples in order to provide evidence for the generalisability of these findings, building on the robust evidence-base provided in the current research; this research should focus on the combined Lumina Spark 40 model as evidence presented in this paper suggests improved validity over and above the separate models.

Keywords: Personality, Competency, Emotion

Paper 4

Success Factors underpinning the Primary Colours of Leadership

Michele Guarini, HUCAMA GROUP; Ben Vernazza, Edgecumbe

Research goals and motivation

The goal of this research is to examine how a new model of Success Factors derived from the Great 8 Competencies (Kurz & Bartram, 2002) relates to the Primary Colours of Leadership model originally published by Pendleton & Furnham (2012).

Theoretical background

Judge, Bono, Ilies, & Gerhardt (2002) found high (adjusted) validities for the Big 5 personality factors in the prediction of leadership emergence and performance for Extraversion (.31), Conscientiousness (.28), Openness to Experience (.24) and Emotional Stability (.24) with a modest value for Agreeableness (.08) and a multiple correlation of .48.

Judge, Piccolo, & Ilies (2004) revisited under the headline of 'The Forgotten Ones? The Validity of Consideration and Initiating Structure in Leadership Research' the results of the Ohio Leadership Studies in the 1960s and found a mean observed correlation of .41 for Consideration and .24 for Initiating Structure.

Consideration could be viewed as People Leadership underpinned by Extraversion, Agreeableness and Emotional Stability and Initiating Structure as Task Leadership underpinned by Conscientiousness and Openness to Experience.

Kurz (2020) developed the Great 8 competencies into a Success Factors model with a People and a Task axis modelled on the work of Judge and colleagues. Building on the Schwarz (1993) universal values circumplex model as well as the meta-factors Alpha and Beta (Digman, 1997) that DeYoung, Peterson & Higgins (2001) renamed Stability and Plasticity, the model allocates factors to the poles of each axis. It thus forms an overarching model of potential and performance at the work place that integrates the leading personality assessment advances of the last four decades.

In their widely cited book, Pendleton & Furnham (2012) outlined 7 leadership tasks that are grouped into Strategic, Interpersonal and Operational Domains. These describe the core tasks leaders must perform in order to create the conditions for success e.g. Setting Strategic Direction, Building and Sustaining Relationships and Delivering Results etc. A 360 assessment as well as a sophisticated NEO report were developed which also covered Coping with Pressure. In the third edition of the book, Pendleton, Furnham & Cowell (2021) added the latter as an 8 th leadership task.

In order to operationalise the model, a mapping was created to the Personality Factors (PF48) measure that was developed by Kurz (2020) to assess the dispositional aspects of the Great 8 Success Factors.

Broad People vs Task orientation themes featured explicitly in both models so that the term Leadership Functions, used by Bartram, Kurz & Baron (2003) for an OPQ based Leadership report, was adopted. Three Sub-Functions were developed to bridge between the 48 Facets in Personality Factors and the 8 Leadership Functions.

For the 'Coping with Pressure' Leadership Function the six Facets in the Resilience Factors were grouped into Showing Confidence, Demonstrating Resilience and Managing Emotions Sub-functions. For all other Functions a mix of Facets drawn from at least two Factors was used. For example, the first Leadership Function Setting Strategic Direction was sub-divided into:

Exploring Possibilities – mapped to Change Orientation and Opportunity Focus

Handling Complexity – mapped to Analysis and Complexity Orientation

Creating a Vision – mapped to Originality and Imagination

Method

The observed validity of the resultant mapping was calculated on a Personality Factors (PF48) validation study where participants also completed the structurally aligned Competency Factors (CF48) measure on which they were also rated by external reviewers.

113 professionals and managers completed Personality Factors (PF48) with 240 statements and Competency Factors (CF48) with 48 statements. Both used a 9 point 'accuracy' Likert rating scale as featured in the Trait Descriptive Adjectives (TDA) tool developed by Goldberg (1992).

Sub-Function, Function, Domain and overall Leadership Focus scores were calculated in SPSS for Personality Factors and Competency Factors (self-report ratings and reviewer ratings), and subsequently correlated.

Results

The average validity for Leadership Sub-Functions was .34 for reviewer ratings and .61 for self-ratings. The respective values for Leadership Functions were .45 and .74, and for Leadership Domains .49 and .79. The overall Leadership Focus score correlated .50 and .80 respectively.

The validities are more than twice the size of the .16 average for factors reported in the widely cited meta-analysis of Bartram (2005) where the methodology used the Great 8 as an organising framework linking hitherto entirely separate models of personality (OPQ versions) and competency (primarily IMC and PMC versions). In contrast the current study features measures that were a priori aligned based on a substantial study of 466 professionals and managers (Kurz, 2020). Ratings were provided solely by Boss raters, whereas the current study features primarily peer raters, who presumably can observe more accurately a wider range of behaviours. Finally, the ipsative nature of most of the OPQ versions used will have limited the validity coefficients as a fixed number of points was allocated across the various predictor scales. Based on multiple regression Bartram (2005) found overall observed validities around .30 whereas the present study found a value of .50 using parsimonious unit weights.

Limitations

The current study demonstrates that Personality Factors can be successfully mapped to the Primary Colours of Leadership model, but further studies should consider a, how Big 5 domains relate to the model and b, what outcomes relate to the model.

Research/Practical Implications

The results suggest outstanding levels of observed validity at the Leadership Sub-Function, Leadership Function, Leadership Domain and overall Leadership Focus levels. The broad study

sample suggest universal applicability not just for existing leaders but also for the identification of leadership potential.

The high correlations between personality and competency self-report data at all levels of the hierarchy supports the notion of Success Factors as constructs that straddle across personality and competency modalities covering dispositional predictors and behavioural criteria respectively.

Originality/Value

The study opens new opportunities for the application of the Primary Colours of Leadership model across the employee life cycle from recruitment through to selection to development interventions.

The convergence of the Primary Colours of Leadership model and the Success Factors model attests to the power of the underpinning theoretical models which is boosted further by their integration.

Paper 5

Predicting Competency from Personality and Ability Assessments: A Multicultural Case Study

Rainer Kurz, HUCAMA Analytics; Nailah Moussa, Nailah Moussa Consulting

Research goals and why the work was worth doing

In a pioneering meta-analysis Robertson & Kinder (1993) outlined how personality and ability variables predict 13 criterion areas. Kurz (1999) conducted follow-up research predicting 16 managerial competencies that culminated in the Great Eight Competencies (Kurz & Bartram, 2002) that are underpinned by the Big 5 personality factors, Need for Power, Need for Achievement and General Mental Ability. While Bartram's (2005) research paper demonstrated that personality scales correlate with all Great Eight Competencies, ability correlated higher than personality only on Analysing/Interpreting but did not at all correlate with Supporting/Cooperating and Enterprising/Performing. The seminal research puts forward a lesser role to ability in predicting overall performance while cumulating research (e.g, Hunter & Hunter, 1984) positioned ability test as the single best predictor of training and performance. Sackett, Zhang, Berry & Lievens (2022) corrected downwards ability validities and covered Big 5 personality factors but neither a personality composite nor composites across personality and ability. This research seeks to explore the validity of personality and ability variables in a cross-cultural context and establish their relative value and combined validities applying the advancements made in I/O Psychology in research years.

The following research goals were set in proposing a new method of using personality and ability in predicting workplace performance:

Understand the roles that personality and ability assessment play in predicting managerial performance using the Great Eight as the organising framework.

Validate existing Great 8 algorithms with a multicultural group.

Define valid algorithms for the culturally specific sample in light of the data and the Great 8 Success Factors proposed by Kurz (2022).

Explore the validity of various methods of combined scoring of personality and ability assessment in predicting performance at work by using The Great Eight Competency as the organising framework for both the predictor and the criterion sides.

Theoretical background

This research explores how to combine personality and ability in predicting performance at work.

Using ability as a selection predictor measure presents the problem of adverse impact on certain groups of employees and in order to address this issue, we need to create ability measures that minimise cultural bias. Kurz (2022) proposed the use of the Ability Factors assessment consisting of Diagrammatic Reasoning, Number Series and Spatial Reasoning test where all 60 items are language free. The question arises what observed validity such a composite can achieve and whether a verbal test would increment validity in a culturally diverse sample.

The Great Eight competencies (Kurz & Bartram, 2002) were developed as an overarching model to account for the validity patterns of personality and ability variables forming an extension and alternative to the Big 5 model.

Recent research by Sackett, Zhang & Lievens (2022) highlights the central role that ability plays in predicting performance, and the predictive validity of the Big 5 personality factors on work performance but fails to quantify their combined validity.

This research seeks to apply a priori specified Great 8 algorithms and explore alternative in the light of the Great 8 Success Factors model proposed by Kurz (2022). In the Success Factors model a 3:1 personality:ability weighting is proposed for Supporting and Interacting factors, a 1:3 weighting for Investigating and Achieving factors, and equal weighting for the remaining four factors.

Methodology

The research was conducted with N= 221 professionals and managers across multiple occupations in Mauritius. All completed a personality questionnaire and a competency questionnaire and had at least one external reviewer completing the same competency questionnaire. A subsample of 49 (denoted P-A-C) had also completed 9 tests covering six content areas.

Great Eight construct variables for the personality predictor and competency criterion measures were created using the Project Epsom mapping of Saville, Kurz & MacIver (2009).

Alternative Great Eight construct variables for the personality predictor and competency criterion measures were created in the light of the Success Factor model (Kurz, 2022) and the culturally diverse data set which consisted of the P-A-C sample of N=49 and the P-C sample of N=172 with the total research sample consisting of of N= 221 managers across multiple occupations in Mauritius - a multicultural and multilingual island.

Ability test validities were calculated for each content area and integrated into an entirely non-verbal ability composite (denoted DNS) based on diagrammatic, numerical and spatial tests, and a GMA composite (denoted DNSV)

Personality and ability variables were combined with a, Regression Weights used by Bartram (2005), b, Unit Weights and c, Integer Weights guided by Kurz (2022), and correlated with competency performance criteria based on the average of boss, peer and subordinate ratings of effectiveness.

Results obtained

Criterion-related Validity

The personality factors validities were calculated for the Great 8 Competencies (Kurz & Bartram, 2002) and the culturally adjusted Great 8 Success Factors (Kurz, 2022) for the P-A-C sample (N=49), the P-C sample (N=172) and the total sample (N=221).

The original algorithms achieved an average observed (i.e. uncorrected) validity of .13 which is slightly lower than the value of .16 found in Bartram (2005). Adjustments made to the algorithms in the light of the Success Factors model and the P-A-C data increased observed validity from .12 to 18 and in the P-C group from .14 to .16 with an average observed validity of .16 across the full sample.

In terms of ability variables, the highest observed validity was found for spatial (.41), followed by diagrammatic (.33), numerical (.28), checking (.15), verbal (.15) and mechanical (.06).

The non-verbal DNS ability composite (diagrammatic, numerical, and spatial) had a reliability of .78 and an observed validity of .40 whereas values for DNSV (with verbal added) were .82 and .36 respectively.

Z-scores were calculated for the personality composites of the Great Eight Success Factors and non-verbal ability composite DNS, and combined using three methods:

Beta Weights from Bartram (2005)

Unit Weights

Integer Weights based on Kurz (2022)

On the P-A-C sample of N=49 applying the regression weights of Bartram (2005) achieved the lowest combined validity (.31) followed by the unit weight method (.39) with the highest validity (.41) for the integer weight method.

Limitations

This research is based on a Mauritian sample of 221 managers with personality and performance criterion data. However only 49 had ability data. The localised personality algorithms improved validity for the P-A-C group by 50% and also somewhat for the cross-validation P-C group. The applicability for western samples should be explored in the light of the revised Success Factors model. In order to confirm the combined assessments of personality and ability and the integer weight scoring in predicting performance, this study should be replicated in different, larger samples across organisational levels.

Conclusions – research and or practical implications

The results support the use of The Great Eight as a generic model of performance at work across cultures with substantial validity improvements through modelling the Success Factors variation on multicultural data. The proposed approach to measure ability with non-verbal items optimises predictive power for selection and development and is likely to reduce the adverse impact that would be introduced through a verbal component. Finally, the new advancement in scoring personality and ability as composite using integer weights based on their relative validity could enhance prediction of performance.

Symposium S100

Improving the safety training: literature reviewing, engaging the participants, developing models

Marco Giovanni Mariani, Department of Psychology "Renzo Canestrari", University of Bologna, Italy

science_practice

What will be covered and why. There were 3355 fatal accidents at work in the EU in 2020 (Eurostat, 2022). Efficient norms and organizational processes are not sufficient to assure occupational well-being. Human error is one of the primary causes of failure in a variety of working contexts, such as chemical and petrochemical (Kariuki & Löwe, 2007), marine (Ren et al., 2008), and aviation sectors (Sexton et al., 2000). In this regard, training is a tool that can improve the impact of HF and expand Safety in the workplace, but the waited results are not always reached (Ricci et al., 2016).

So the symposium wants to present some evidence of research and experiences that can help in the complex tasks of projecting and carrying out effective training courses on Safety.

The first study by Priolo and colleagues describes a systematic review of risk perception and safety behaviors, with the perspective of improving safety training on situational awareness too. The results underline the issues of the definition of risk perception, its measures, and the relationship with safety behaviors. A more comprehensive analysis of risk perception in the workplace, with its cognitive and emotional dimensions, can develop efficient training to increase Safety.

The second research, by Mariani and colleagues, studies, with a two waves design, the role of training engagement and motivation to learn on the actual transfer of training in relation to a course of non-technical skills for Safety. The results suggest some practical ways to improve safety training interventions. So, understanding how to increase the involvement of participants in safety training has significant repercussions both from a research and intervention point of view.

The third study, by Ricci and Nucci, presents a safety training model named SIM-t (Safety Integrated Model-training) and its evaluation based on longitudinal research design: the results showed that the average safety performance at the end of the training was significantly better than the initial level. The SIM-t and its evaluation methodology are useful suggestions for prevention in the safety field.

The fourth study, by Panari and colleagues, focuses on the factors, such as knowledge and Safety culture, that can influence safe individual performance after training. The result underlines that the knowledge of the rules, regulations, procedures, and roles of the prevention system and unsafe behaviors, as developed in safety training, are critical for safety performance.

Finally, the fifth study of Bracco develops an accident investigation model and related tools which have the characteristics of effectively representing accident dynamics and of providing trainers and safety managers with a metaphor that can be shared across the whole organization, for promoting safety culture.

Relevance to the Congress Theme . The symposium focuses on a central and urgent topic of sustainability as Safety and is born on the basis of the need to gain a better understanding of how we can improve occupational health and safety training. The results of this symposium are relevant not only to change the „world of safety training" but to at least UN SDGs, by the work-related injuries prevention, as Good health and well-being, Decent work and economic growth, and Industry and Innovation and Infrastructure.

Research/Practical Implications . The symposium suggests future keys to developing competencies through training programs in the occupational health field. The theoretical and practical implications regard the constructs of risk perception with respect to Safety: how we can monitor it in the workplace and how we can improve situational awareness. How the training engagement can be used to enhance the intention to training transfer and how integrated safety training methods can improve individual safety performance. Finally, the symposium contributions tend to explain the importance of the training to enhance knowledge of the rules, regulations, procedures, and roles of the prevention system.

Overall conclusions. Many companies are increasing the frequency and content of health and safety training programs (ISTAT, 2020); however, the effectiveness of safety training courses can vary widely (Ricci et al., 2016). In this scenario, it is crucial to work on different aspects of training to improve it. The symposium, with specific focuses on constructs of training programs (as risk perception), participant motivation (as engagement), model of training (as SIM-t), and safety performance (as compliance), can suggest ways for better understanding and effectiveness of safety training processes.

Keywords: safety, training, effectiveness

Paper 1

Risk perception in high-risk sectors: are we addressing it properly? A systematic literature review informing the development of safety training inter

Michela Vignoli, Department of Psychology and Cognitive Science, University of Trento, Italy; Karina Nielsen, Sheffield University Management School, University of Sheffield, United Kingdom; Giulia Priolo, Department of Psychology and Cognitive Science, University of Trento, Italy. Department of Psychology and Behavioural Sciences, Aarhus University, Denmark

Research goals. Safety at work is a key concern in today's workplace. Associations between risk perception and safety behaviours have been established in several sectors, but results are mixed, and a broad understanding of this association is lacking. Nevertheless, better understanding this relationship and its determinant is paramount from both a theoretical and practical levels, for instance in terms of the creating of more effective training in which risks are discussed not only from an engineering perspective, but also from a psychological one. Using three different theoretical frameworks combined, we aim to explore a) how risk perception is defined; b) whether risk perception is associated with safety behaviours and c) which role contextual factors (e.g., safety climate) play in this association.

Theoretical background. Risk perception has been defined as "a person's subjective judgment or appraisal of risk" (Slovic, 1987; p. 8) and it refers to a complex and multi-dimensional construct composed by three main aspects: probability, the severity of consequences and emotions (Siegrist & Árvai, 2020; Slovic et al., 2002, 2004). According to Christian's (2009) integrative model of workplace safety (2009), risk perception is associated with two different types of behaviours: safety participation and safety compliance. In order to better understand this association, the IGLO model developed by Nielsen and colleagues (2018) has been used.

Design/Methodology. Using the PRISMA method, we conducted a comprehensive literature search looking for peer-reviewed papers published in the last 20 years only in English, having "risk perception" and/or "safety behaviour" in the title, keyword or abstract. Eligibility criteria also referred to; being the participants first-line workers employed in high-risk sectors for physical risk (e.g., construction).

Results. Our search resulted in 92 papers. Results show that most of the studies selected have been conducted in the construction sector and in Asia. Only one-third of the papers include a definition of risk perception. Moreover, we found that the majority of the papers mostly measured only the probability dimension of risk perception, and only a small amount of papers correctly investigated the three dimensions of the construct (probability, severity of consequences, and emotions). Concerning the relationship between risk perception and safety behaviours, the analysis held mixed results since both positive and negative associations, as well as null effects, were detected. The variety and inconsistency of the methods and conceptualization used to assess risk perception might explain these findings and make the interpretation of the association between the two constructs very complex. Moreover, we found that most of the safety behaviours have been investigated in terms of compliance (and not participation). Considering the IGLO model, results showed that the most investigated factors related to risk perception are the individual ones (e.g. knowledge, demographics) and the organizational ones (e.g. safety climate, training).

Limitations. Due to the difficulty to retrieve relevant information (especially on the association between risk perception and behaviours), we focused only on quantitative studies and not qualitative ones. Moreover, we focused only on high-risk front-line workers, thus our results might not be generalisable to supervisors or workers employed in low-risk sectors.

Conclusions. Most studies focused on the cognitive dimension of risk perception while failing to consider its emotional one. This narrow conceptualization of risk perception might explain the mixed results. Moreover, a crucial effect of contextual factors such as safety climate was detected. Guidelines for a more comprehensive assessment of risk perception in the workplace are outlined for future studies. This study contributes to the risk perception and safety literature by clarifying the construct of risk perception and the relationship between risk perception and safety behaviours. As a practical implication, the results of this study could enhance how risk perception is managed in organisations, as a better understanding of the role of risk perception, in both its cognitive and emotional dimensions, in shaping safety behaviours is pivotal to developing efficient training on non-technical skills able to increase safety and decrease injuries and fatalities.

Relevance to the Congress Theme: The world of work is rapidly changing and there still are important issues related to the safety and health of workers that are urgent and cannot wait to be addressed and solved to enhance the quality of the working conditions for all workers.

Relevant UN SDGs: Results of this study are relevant to at least three UN SDGs: Good health and well-being; Decent work and economic growth and Industry; Innovation and Infrastructure.

Keywords: risk perception, safety behaviours, high-risk workers

Paper 2

Engage in Safety, Stay Safe! – Evidence for the impact of Safety Training Engagement and Motivation on the Transfer of Training

Marco Giovanni Mariani, Department of Psychology "Renzo Canestrari", University of Bologna, Italy; Dina Guglielmi, Department of Education Studies "Giovanni Maria Bertin", University of Bologna, Italy; Michela Vignoli, Department of Psychology and Cognitive Science, University of Trento, Italy; Gerardo Petruzziello, Department of Psychology "Renzo Canestrari", University of Bologna, Italy

Research goal. This study aims at testing the relationships between Safety Training Engagement (STE), Motivation towards training, intention to transfer and real transfer of training, among Italian workers in the chemical industry. Testing such relationships is a valuable addition to the literature. Indeed, it draws on the call to further address and articulate psychological factors enhancing the effectiveness of the training methods. In a practical sense, our results suggest ways to design and carry out safety training interventions.

Theoretical background. STE is understood as a combination of two psychological states pertaining to safety training, namely dedication (meaningfulness and enthusiasm) and absorption (focus and concentration on the training tasks). This study addresses the mediation mechanisms through which STE determines the actual transfer of the knowledge and skills acquired during safety training in real work activities. In line with the previous research, it could be argued that being engaged represents a starting point for motivation to apply what is learnt during a training programme, because trainees may see this application as a means to protect themselves (autonomous motivation) and that it bodes well for better performance and recognition (controlled motivation). In turn, we expect motivation to inform the intention to transfer, in line with a consistent body of literature. Eventually, as the intention is a close predictor of behaviours, we also expect that it predicts the actual transfer of training. We combined these hypothesised relationships in a serial mediation model, where STE predicts the actual transfer indirectly through the mediation of Motivation (autonomous and controlled) and intention to transfer.

Methodology. We adopted a two-wave research design, recruiting employees from a large chemical company in the north of Italy. STE, Motivation (autonomous and controlled) and intention to transfer were collected at the end of a training section of a broader safety training program (Wave 1). Actual transfer was measured after three weeks (Wave 2). Participants have assured confidentiality and acknowledged the right to participate upon informed consent and withdraw at any time. The final sample comprised 125 participants with a mean age of 42.40 years (SD = 11.90), mostly Men (90%).

Results. We tested two serial mediation models (one for each form of motivation) with the SPSS macro Process software. The results confirmed our serial mediation hypothesis. Although small, the effects found confirm the cognitive process linking STE and transfer.

Limitations. This study has some limitations; two are the mains. In our opinion, first, the samples involved only workers of chemical plants that attended courses on non-technical skills. Such homogeneous samples may have some drawbacks in terms of external validity. The second is that we have measured the actual transfer based on only worker perceptions and not considered a different assessor.

Conclusions - Research and practical implications. The evidence confirms the serial mediation model where STE predicts the actual transfer indirectly through the mediation of Motivation (autonomous and controlled) and intention to transfer. The research suggests future keys to developing effective training programs in the occupational health field. The main theoretical and practical implications regard the constructs of Safety Training Engagement: how we can monitor it and how the training engagement can be used to enhance the training transfer.

Relevance to the Congress Theme. The research focuses on strategies for improving Safety through training. So we are at the center of the urgent topic of sustainability.

Relevant UN SDGs. The results of this symposium focus on UN SDGs as Good health and well-being, Decent work and economic growth, and Industry and Innovation and Infrastructure.

Keywords: safety, training, engagement

Paper 3

Safety Integrated Model-training (SIM-t) and its evaluation: A safety training proposal for mechanical companies

Federico Ricci, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Italy; Massimo Nucci, Department of General Psychology, University of Padova, Italy

Research goals. In the EU, the number of occupational accidents is still too high, with serious social and economic consequences. We have devised an intervention called Safety Integrated Model-training (SIM-t) with the aim of unifying the most effective training methods for adults in a single proposal. Beyond presenting the SIM-t, this research aims to contribute to this knowledge through evaluation of the effects of an intervention delivered with the SIM-t method for workers at mechanical companies.

Theoretical background. The SIM-t is a training methodology designed according to a constructivist approach, with reference to Kolb's (1984) experiential learning model. That method traces the acquisition of new knowledge, skills, and attitudes to four modalities: concrete experience, reflective

observation, abstract conceptualization, and active experimentation. The framework of reference offered by experiential learning is necessary for designing in an appropriate and integrated training pathway that combines the main principles of andragogy: examples, videos, a participative approach, and reinforcement in daily practice.

Design/Methodology. SIM-t involves the use of ad hoc audiovisual materials, a participatory approach, and regular and lasting reinforcement in daily practice. The training intervention is divided into several sessions over several weeks. For its evaluation, we conducted a longitudinal study (September 2017–April 2018), with the participation of workers (n = 185) from mechanical companies in northern Italy.

Results. Overall, the participants' average safety performance at the end of the training was significantly better than the initial level. In particular, knowledge showed a significant improvement and a substantial effect size ($F = 455.3$; $p < 0.001$; $\eta^2_G = 0.49$). Similarly, the behaviours showed a significant growth pattern and an adequate effect size ($F = 108.5$; $p < 0.001$; $\eta^2_G = 0.32$). The contents that emerged from the study suggest extending this training intervention and the evaluation of its effectiveness to different contexts.

Limitations. Given the nature of the ecological study, the training and data collection involved a convenience sample of companies that cannot be considered representative. However, bearing in mind the necessary caution in generalizing the results, all the workers employed in the chosen departments participated in the longitudinal study.

Conclusions. The results of this study confirm the importance of delivering training according to actual needs of participants, via the use of effective methods for adult learning. The SIM-t methodology aligns with these principles exactly and allows us to achieve favourable lasting outcomes regarding knowledge improvement, implementation of safe behaviours, and an increase in safety performance.

Relevance to the Congress Theme: The future is now! For safety training means that those interested in delivering effective training, with the intention of designing safer systems, should think not only about quantity but also quality. Training interventions that focus on content (the object of

the training) are destined to fail if they do not shift their attention toward the best methods (how to do the training).

Relevant UN SDGs: Results of this study are relevant to at least three UN SDGs: Good health and well-being; Decent work and economic growth; Industry, Innovation and Infrastructure.

Keywords: safety behaviours, safety training, training evaluation

Paper 4

Factors influencing Safety Performance: the impact of Knowledge and Safety culture on Safety Compliance after a training

Federico Ricci, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Italy; Annalisa Pelosi, Department of Medicine and Surgery, University of Parma, Italy; Chiara Panari, Department of Economics and Management, University of Parma, Italy

Research goals. This work aimed to examine the precursors of safety compliance whilst focusing on organizational factors (the management's safety climate, as well as colleagues' safety climate) and individual factors (safety knowledge and attitude). In particular, we tested different models to measure the impact of the above four precursors on safety compliance, both individually (H1) and in combination (each precursor was tested added to each other, without hypothesizing their interaction, H2) or in interaction with each other (H3), so as to identify the most predictive factors of safe behaviour.

Theoretical background. The literature about the effectiveness of safety training showed results that are not entirely clear and this is often due to the use of objective indicators, such as injuries and accidents, referring to a concept of safety as the absence of negative events (Robson et al., 2012). Quite the opposite, the Safety-II perspective (Hollnagel et al., 2015) assumes that, while accidents clearly indicate the absence of safety, a lack of accidents cannot necessarily be used to infer a low probability of harm. In this framework, safety compliance can contribute to the implementation of adaptive safety performance for the organization (Griffin and Neal, 2000). Literature focused on antecedents of safety compliance underlined the importance of safety knowledge (Christian et al., 2009) and attitude (Clarke et al., 2006), on an individual level, and studies on the effectiveness of safety training are now clearly focused on assessing the changes concerning knowledge and attitudes after safety training has been conducted (Robson et al., 2012; Ricci et al., 2016). Furthermore, a recent systematic review (Kalteh et al., 2021) concluded that increasing the level of safety climate and safety culture could be effective in reducing incidents and improving safety performance indicators

Design/Methodology A sample of mechanical Italian workers (n = 109) was involved in a safety training intervention. Before and after safety training, intervention data concerning the four precursors affecting safety-related behaviours, measured through observed objective behaviours, were collected. A model class of competing general linear models was built to determine the best model for predicting safety-related behaviours. Akaike's information criterion corrected was used as an indicator of incremental fit to estimate the residual variance of the model corrected for the number of predictors. Models with an Akaike's weight approximately equal to 10% of the weight of the best model were included in the confidence set.

Results. The results showed that knowledge combined with themanagement safety climate, not in interaction, effectively predictsafety compliance ($R2 = 0.283$, $R2adj = 0.269$; $F [2,106] = 20.76$, $p<0.001$). This model had the best Akaike's weight (= 0.524).

Particularly, the knowledge of the rules, regulations, procedures, and roles of the prevention system and unsafe behaviours defines what each worker must know to be able to act safely and these elements are critical to safety performance. Furthermore, management's safety climate contributed to the workers' safe behaviour, demonstrating that the workers' perception that safety was indeed a

priority of the company management, increasing the positive effect of knowledge on the production of safety compliance.

Limitations. The study involved a non-representative convenience sample, and the choice of measures depended on the agreement with the companies involved, with the cultural level of the participants, and with their familiarity with social research.

Conclusion. Crucial implications concern the effectiveness of active teaching methods, and the importance of the involvement of the management in giving relevance and constructing a safety culture. Firstly, the intervention could help to effectively link cognitive processes, behaviour, external environment, and measurable results, facilitating learning by action. Secondly, this research emphasised the importance of continuous training. Finally, this study showed the prominent role of supervisors and top managers in giving further relevance through their actions to the need to respect the company's rules and procedures. Increased managerial safety commitment, could directly motivate workers to contribute to safety.

Relevance to the Congress Theme. This study places emphasis on the theme of workers' safety and health considering that despite the largest decreases in incidence rates of fatal and non-fatal accidents, in the last years there are still too many events that cause serious or irreparable damage to workers.

Relevant UN SDGs. The results of this study are relevant to at least three UN SDGs: Good health and well-being; Decent work and economic growth and Industry; Industry, Innovation and Infrastructure.

Keywords: safety compliance, safety training, safety climate

Paper 5

The safety bowl. An accident investigation model for fostering safety culture

Fabrizio Bracco, Department of Education Science, University of Genoa, Italy

Research goal

This research aims at the development of an accident investigation model and a related tools which have the characteristics of effectively representing accident dynamics, of being easy to implement for safety managers and accident investigators, and of providing trainers and safety managers with a metaphor that can be shared across the whole organization, for promoting safety culture.

Theoretical background

Accident causation models could be accurate in representing the dynamics of accidents (accuracy) and easy to use for safety managers and accident investigators (usability). However, in addition to accuracy and usability, a good accident causation model should also allow for the shareability of analysis across the organization, as the culture of safety is primarily based on a common view of system dynamics. The safety bowl model is proposed, which aims to provide a depiction of complex interactions between the elements of a system and a clear metaphor, easy to understand and share with workers in safety training programs. The model, inspired by the principles of resilience engineering, enables shareability because it graphically represents abstract and complex concepts like “emergent property”, “systemic approach”, and “functional resonance”. For the sake of accuracy and usability, the model is accompanied by a tool for collecting data concerning the various elements of the system and their interactions (the safety bowl checklist) and a tool for mapping these interactions (the safety bowl grid).

Methodology

Opinions on the model were collected by safety experts in various sociotechnical systems (N=19) via online questionnaire and investigated:

The knowledge and frequency of use of some of the main accident investigation models (root cause analysis, fault tree, Ishikawa model, FMEA/FMECA, Bow Tie, Swiss Cheese, Accimap, STAMP/CAST, FRAM) ranging from traditional, simplistic, and easy-to-use models, to sophisticated and less easy to adopt models.

The perceived accuracy, usability, and shareability of the safety bowl model

The ratings ranged from -2 (worse than the other methods) to + 2 (better than the other methods). A final open-ended question was posed to get free comments on the model.

Results

The results demonstrated that the safety managers and trainers do not know the most recent and sophisticated models (e.g., Accimap, STAMP/CAST, FRAM), and when they know these models, they do not use them. These models are very accurate in analysing accidents but, as expected, they are perceived as being difficult to adopt. The most known and used model is the fault tree model, followed by the Swiss Cheese. Again, the participants seem to prefer simpler (and simplistic) models.

Concerning the opinion about the safety bowl model, all the rating were positive (mean score: 1,1). This means that the safety bowl has been rated better that the other models concerning the three properties of accuracy, usability, and shareability.

Limitations

This is a pilot study conducted with a small sample. The sample size was due to the small number of practitioners who already knew and adopted the safety bowl model. Future research should involve a wider sample with mixed methods (e.g., interviews, and field observations).

Research and practical implications

Shareability does not seem to be the core property of many accident causation models, revealing how the development of these methods have been driven mainly by the views and needs of sophisticated scholars (tending towards the accuracy of analysis) and practice-oriented safety managers (tending towards the usability of the tool). The safety bowl model aims at balancing the three characteristics of accuracy, usability and shareability. Safety is an emergent property of a system where the most flexible elements are the people operating within and around it. If they can share a common perspective on a system's dynamics and can understand how accidents occurred in the past, they can learn from experience and foster resilience.

Relevance to the Congress Theme

The future is now: the complexity of accidents in socio-technical systems can be tackled thanks to effective and accurate models, but these models must leave the ivory tower of scientific journals and academic domains, otherwise practitioners will continue to use simpler and more simplistic models for accident investigations. In addition, if we want safety to become a common ground among all the members of the organization, a simple and shareable metaphor for representing safety issues is needed.

Relevant UN SDGs

This study provides results that are relevant to at least three UN SDGs: Good health and well-being; Decent work and economic growth and Industry; Innovation and Infrastructure.

Keywords: Accident causation model, resilience, accuracy, usability, shareability

Symposium S112

Safety culture and safety performance (II)

Francisco J. Gracia & Mario Martínez-Córcoles | IDOCAL. University of Valencia

science_practice

What will be covered and why (including the contribution of any discussant)

Safety culture and safety performance have been considerably studied over the last two decades, as they are main triggers of safety outcomes. However, despite the existing numerous studies, safety culture and safety performance are still somewhat controversial, complex, and ambiguous concepts that need further theoretical and empirical elaboration. This Symposium aims to 1) dig deeper into the appropriateness of current assessment methods of nuclear safety culture and propose new directions, and 2) analyze other key antecedents of safety performance (e.g. leadership, safety climate, etc.).

More specifically, Schöbel analyzes the safety culture assessment methods proposed in the nuclear industry nowadays. Martínez-Córcoles tests the validity of the Harmonized Safety Culture Model designed by the International Atomic Energy Agency, and Clarke proposes a novel conceptual model of safety culture for the UK nuclear industry. Besides, Seitkanova tests the mechanisms through which empowering leadership impacts on the ability to anticipate and contain unexpected events in air traffic control, and Jackson explores the group and individual-level antecedents of safety performance in heavy mobile plant drivers.

Relevance to the Congress Theme

Safety accidents lead to undesired social, environmental and economic consequences. Further research on enhancing organizations' safety capability is crucial to prevent accidents and to achieve more adaptive and sustainable operations.

Research/Practical Implications

This Symposium provides novel contributions to the field of safety culture and safety performance in organizations. Particularly, it will contribute to existing research on 1) examining, reflecting, and re-formulating new ways of measuring safety culture in high-risk organizations, and 2) exploring additional antecedents and influential mechanisms of safety performance.

Furthermore, this Symposium will cover critical areas of safety in organizations, and will give insights on how to measure safety culture and why, what other aspects (besides safety culture) should be considered to improve safety performance, etc. Therefore, agencies, regulators, and organizations pursuing safety performance could be benefited from the Symposium contributions

Overall conclusions

The main conclusions of the present Symposium are the following:

Assessment of safety culture might have repercussions on safety outcomes. Therefore, current assessments are reviewed, analyzed, tested, and re-formulated.

Empowering leaders impact on the organization's safety capability. The mechanisms by means of which they do so are highlighted.

Group and individual-level antecedents influence safety performance. These (cross-level) relationships are explored.

Keywords: Safety culture; Safety performance; Safety management

Paper 1

The 5-Safety Performance Questionnaire (5-SPQ): Theoretical model and empirical validation.

Francisco J. Gracia, IDOCAL-University of Valencia (Spain); Alena Mezentseva, University of Valencia (Spain); Inmaculada Silla & Mario Martínez-Córcoles | IDOCAL-University of Valencia (Spain)

Research goals and why the work was worth doing

In this paper, we propose a new model of safety performance and develop and validate an instrument for its operationalization, the five-safety performance questionnaire (5-SPQ). Safety performance refers to employees' behaviors related to safety. As a meta-analysis revealed, the relevance of safety performance is due to the fact that it is the main antecedent of safety outcomes (Christian et al., 2009). Through their behaviors, employees contribute to safety outcomes. Hence the relevance of a more complete understanding of what safety performance involves and the different ways the employees can contribute to safety outcomes through their behaviors.

Theoretical background

The most acknowledged model of safety performance distinguishes between safety compliance and safety participation, or intra and extra-role behaviors related to safety (Neal & Griffin, 2006). Another proposal includes a third dimension of safety performance, risky behaviors or counterproductive behaviors related to safety (Martínez-Córcoles et al., 2013). Van Dyne et al. (1995) distinguish between affiliative and challenging extra-role behaviors, and other authors have identified different behaviors under the umbrella of safety citizenship behaviors (Curcuruto and Griffin, 2018). Finally, Holnagell (2014) in his Safety-II paradigm speaks of the importance of employees "adapting" their behavior to guarantee safety. Our proposal is based on these previous contributions of literature and include five dimensions for safety performance: intra-role safety behaviors, affiliative extra-role safety behaviors, risky behaviors, challenging extra-role safety behaviors, and adaptative safety behaviors.

Methodology

555 employees from a nuclear power plant answered to our questionnaire.

Results

Reliability values were satisfactory for the five subscales: intra-role safety behaviors (α= .75; rho= .76), affiliative extra-role safety behaviors (α= .82; rho= .83), risky behaviors (α= .87; rho= .87), challenging extra-role safety behaviors (α= .89; rho= .89), and adaptative safety behaviors (α= .81; rho= .82).

Regarding validity we obtained some evidence based on internal structure. Confirmatory factor analysis revealed that the goodness-of-fit of the proposed five-factor model fit the data adequately ($\chi2$= 262.312, df= 160, p < .001; RMSEA= .035; NNFI= .995; CFI= .995). By contrast, the one factor solution provided a poorer fit to the data ($\chi2$= 2332.949, df=170, p <.01; RMSEA= .154; NNFI= .891; CFI= .903). Moreover, differences between the fit of the five- and one-factor models were relevant from a practical point of view (ΔNNFI= .104, ΔCFI = .092 and ΔRMSEA = .119). Thus, the five-factor model proposed by the authors was empirically supported. All factor loadings were statistically significant (p <.01) and high enough according to the standards (> .60). Average factor loadings were

.84, ranging from .62 to .95, thus supporting convergent validity. All correlation coefficients among the five dimensions of the questionnaire are high, but did not exceed the accepted criterion, thus supporting factor discrimination. All of them show significant and positive correlations among them, ranging from .26 to .65, but significant and negative correlations with risky behaviours, ranging from -.17 to -.42. These correlations show that the five dimensions represent highly interrelated components of safety performance.

Furthermore, we obtained some validity evidence based on relationships with external variables. Pearson correlations between each of the five dimensions of the 5-SPQ and safety culture, organizational safety climate and team safety climate were calculated. All correlation coefficients are statistically significant ($p < .01$) and exhibit the correct sign. Safety culture, organizational safety climate, and team safety climate were negatively related to risky behaviors and positively with the other four dimensions of safety performance.

Conclusions – research and or practical implications

This study advances scientific knowledge through the proposal of a new model of safety performance that includes five different dimensions. Furthermore, it develops a scale for its operationalization and provides empirical evidence of validity. This instrument can be used in high-risk industries to detect those behaviors that should be reinforced and improved to enhance employees' contributions to safety outcomes.

Limitations

Although the nuclear power sector is well suited to test a safety performance measure, we do not know if our results can be generalized to other industries.

Relevance to the Congress Theme

A constantly changing work environment poses a great threat and challenge for all those organizations that cannot afford to fail and where safety is critical (eg nuclear energy sector). In this context, extra-role safety related behaviors and adaptative safety behaviors acquires higher relevance to achieve excellent safety outcomes.

Relevant UN SDGs

Our study contributes to the following UN SDGs: 3, 7, 11 and 13.

Keywords: safety performance, theoretical model, scale development

Paper 2

The Role of Empowering Leadership, Safety Culture and Safety Climate in the Prediction of Mindful Organizing in an Air Traffic Management Company

Francisco J. Gracia, Mario Martínez-Córcoles & Inmaculada Silla | IDOCAL-University of Valencia (Spain); Alena Mezentseva, University of Valencia (Spain)

Research goals and why the work was worth doing

The purpose of this study was to add to our understanding of the conditions necessary to develop mindful organising in high-reliability organisations (HROs). Namely, we explored a moderated-mediation model of antecedents of mindful organising (MO) in an Air Traffic Management company. The model evaluated whether safety climate mediates the relationship between empowering leadership and MO and whether safety culture moderates the effect of empowering leadership on safety climate. The concept of MO summarises the key features of HRO, which allow them to anticipate and quickly recover from unexpected events (Renecle et al., 2020). Because failures in this type of organisation can cost hundreds of people's lives, studying factors of their sustained performance is crucial for maintaining safe and flawless operations.

Theoretical background

The central concept of our study is MO, as it was coined and developed in Weick's work (1999). It encompasses behaviours, reactions, and norms that appear in the actions and interactions of HROs members and result in almost faultless operation. Such reliability in performance is possible due to five interrelated processes that create the basis of mindful infrastructure: preoccupation with failure/error, reluctance to simplify interpretations, sensitivity to operations, commitment to resilience, and deference to expertise (Vogus & Sutcliffe, 2012; Weick et al., 1999; Weick & Sutcliffe, 2015).

Research explores antecedents of MO and connects it to other safety variables. Renecle and colleagues (2020) showed that MO is related to safety culture and climate, but it only partially overlaps with these concepts. Further research discovered that group safety climate leads to MO, and MO mediates the relationship between safety climate and employees' behaviours related to safety (Renecle et al., 2021). It also has been found that MO mediates the relationship between empowering leadership and safety behaviour (Callari et al., 2019). Mindful organising theory and existing empirical findings create the background for the present investigation.

Methodology

73 employees from an Air Traffic Management company answered our questionnaire.

Results

First, we tested a simple mediation model with a safety climate as a mediator between empowering leadership and MO. The regression analysis results indicated that the model explains 62.0% of the total variance of the dependent variable ($R2 = .62$, $p < .001$). The direct effect of empowering leadership on MO was significantly different from zero ($c' = .31$, $p < .01$), providing evidence that empowering leadership is positively related to MO. Empowering leadership was positively associated with safety climate ($a = .57$, $p < .001$), and safety climate was positively related to MO when controlling for empowering leadership ($b = .51$, $p < .001$). Finally, the bias-corrected bootstrap

confidence interval for the indirect effect (ab = .29) was above zero (95% confidence interval = .03–.63), indicating that our findings supported the hypothesis about the mediating role of safety climate.

Next, the moderated mediation model was tested to provide evidence supporting the moderating role of safety culture. The bias-corrected bootstrap confidence interval for the index of moderated mediation included 0 (95% confidence interval = -.15–.04), which indicated that the research findings testified against moderated mediation.

To summarise, the results showed that a strong safety climate was a significant predictor of MO. Moreover, empowering leadership influenced MO indirectly through a positive effect on the safety climate in a work unit. However, the moderating role of safety culture still needs to be confirmed.

Limitations

The study sample is relatively small and comprises employees from only one ATC company. It limited the complexity of the model we could test and the generalisation of the results.

Conclusions – research and or practical implications

The present research continues the research line on mindful organising and examines antecedents of mindful organising in the new organisational context of air traffic management. From a practical point of view, research findings help build a safe environment in high-hazard organisations by providing recommendations on changing HR and managerial practices to improve collective mindfulness and sustainable operation.

Relevance to the Congress Theme

Mindful organising is one of the conditions of sustainable performance under hazardous and unpredictable settings, so investigating its antecedents and outcomes is highly important. The results can help organisations function in a constantly changing world.

Relevant UN SDGs

Our study contributes to the following UN SDGs: 3 and 8.

Keywords: mindful organizing, empowering leadership, safety culture

Paper 3

Investigating the role of technology in telephone triage safety performance

Jill Poots, Jim Morgan & Matteo Curcuruto | Leeds Beckett University (UK)

Research goals and why the work was worth doing:

Telephone triage services (which assess patients' symptoms via telephone) serve as an entry point to the healthcare system in many countries. These systems have been described as 'complex sociotechnical systems' due to a heightened reliance on technology and onus on callers to report symptoms accurately, relative to face-to-face care. Despite widespread adoption and use, telephone triage services have been implicated in patient death and malpractice claims (Ernesäter et al., 2014; Rees et al., 2017), and research investigating their safety is lacking (Lake et al., 2017). During the COVID-19 pandemic, telephone triage was adopted rapidly to help curb its spread, by offering an alternative to face-to-face healthcare and the use of these services is set to remain at a high level post-pandemic. It therefore seems paramount to understand the myriad of factors affecting the safety of telephone triage. This study aims to investigate the role of telephone triage technology on safety performance.

Theoretical Background

Since 2000, there has been a call to understand the many interacting factors across entire healthcare systems which can affect healthcare safety performance, to improve patient outcomes (Donaldson et al., 2000; Holden et al., 2013). Previous research suggests Computer Decision Support Systems (CDSS) – decision-making software commonly used in telephone triage – can cause communication issues which may lead to unintended and undesirable safety consequences for patients, such as failure to disclose underlying illnesses or misunderstanding worsening advice, which could result in harm to patients (Morgan & Muskett, 2020; Murdoch et al., 2015). Additionally, usability issues can increase cognitive burden (Tariq et al., 2017), create 'hidden labour' for users (Murdoch et al., 2015) and increase the likelihood of human error and adverse events. An earlier interview study by the current authors exploring risks to patients in a telephone triage system found 'workarounds' – whereby workers deviate from designed protocols to complete tasks – are readily used by telephone triage professionals to counter usability issues. It is unclear how these adaptive behaviours may affect safety performance so further study is warranted.

Approach

There are problems with using interview findings to investigate usability of technology since they may be susceptible to bias (Tariq et al., 2017). Research methods such as naturalistic observations may enhance the ecological validity of technology research (Kushniruk et al., 2013). This study aims to replicate and extend research by Tariq et al. (2017) which used Nielsen's ten usability heuristics (1994) to understand how the design of a CDSS may affect safety performance in a similar telephone triage setting. Three observers will apply ten usability heuristics to a CDSS used by both non-clinical staff providing telephone triage in one contact centre in England during normal working hours over a two-day period. Workaround details will also be noted. Frequencies will be counted and severities will be estimated in line with the heuristic evaluation technique.

Results

A pilot study aiming to test the suitability of the usability heuristics noted violations across all ten usability heuristics, most frequently, 'visibility of system status' and 'mismatch between the system and the real world'. Many workarounds were noted e.g. the use of external websites where insufficient details are provided by callers/patients, and deviations in the language used by telephone triage professionals to help callers' understanding. Final results will be available at the Congress.

Limitations

Not all telephone triage systems utilise CDSS, meaning the findings may not be generalisable to all triage settings. Observations will take place during office hours. Workarounds may differ during out-of-hours due to differences in service availability.

Conclusions

Findings will inform recommendations for improvements to the design of software and patient safety. This study will be used to inform the design of a contributory factors framework for telephone triage to improve incident investigation and organisational learning.

Relevance to Congress Themes

This safety performance research is relevant to the congress theme as healthcare professionals' work recently and rapidly moved away from face to face care to remote care, with little understanding of the implications for safety.

Relevance to UN SDGs

UN SDG 3 – Good Health and Wellbeing. Most notably, concerns have been raised over the suitability of telephone triage for children following adverse events (Rees et al., 2017) and SDG 3.1 calls for improvements to preventable deaths in young children.

Keywords: safety performance, patient safety culture, patient safety outcomes

Paper 4

System-Intelligent Human Factors for Promoting Safety in the Chemical industry

Anna Maria Teperi, Finish Institute of Occupational Health, Helsinki (Finland); Riita Juvonen, Aalto University, Espoo (Finland)

Aim

This study aims to create knowhow for proactive safety management in the chemical industry. The chemical industry is a typically complex sociotechnical system in which humans, technology, and organizations are constantly intertwined. This systemic interaction has already been studied and the HF approach applied in other safety-critical industries such as the nuclear and transport industries. Several accidents in the chemical industry, including that in Bhopal in 1984, have shown how critical the human contribution is to safety. Several organizational factors, work characteristics, and performance of teams and individuals affect the success of production and the safety of processes. However, we do not currently know whether the HF approach has been implemented in the safety management practices of chemical industry workplaces.

Theoretical background

We use Systemic Human Factors (HF) and Systems Intelligence (SI) to evaluate the current state and areas in need of development through HF implementation in the chemical industry. In previous studies, the HF Tool has efficiently improved safety thinking and procedures by considering human contribution in a holistic, participative, positive, and solution-based manner. However, the use of the HF Tool has not yet been researched in the chemical industry nor combined with other lines of research. SI describes human experience and interaction within a system. It also describes succeeding in systems, and SI-metrics have been found to work well as indicators of learning organization and well-being at work. In this study, we combine HF and SI into a synergized framework called 'System Intelligent HF (SIHF)'.

The current phase in safety research calls for adaptive measures to improve safety in complex, dynamic circumstances by deliberating the role of human variability in a mindful manner. Safety management and HF approaches have evolved from being individual-, risk- and error-prone to being more systemic, proactive, and success-based. The focus is on improving the enablers of resilient performance from anticipation to recovery, analysis, and on learning from everyday operations. However, we have a wealth of knowledge on HF, but availability of means to tackle HF issues in the reality of all workplace levels is far from ideal. Earlier studies have shown that in other safety-critical fields, HF has been successfully implemented by utilizing a holistic, solution-based, and participative HF approach with practical models. In practice, this means several years of stepwise development processes, during which the actors themselves become the subjects of change and learn measures to implement HF in safety practices. HF activities take place before accidents or incidents happen and require understanding and competence to facilitate resilient performance from the bottom up, not through top-down actions and compliance targets. Thus, we need more conceptual and practical power to understand how the people themselves see the system from the inside, and how they feel about their work and safety. We aim for this by combining the SI framework and the HF approach (SIHF), highlighting the subjective experience and reflecting on the skills essential for improving safety in organizations.

Methodology

Four companies are participating in the study, representing four different chemical industry sectors: oil and gas, paint manufacturing, tall oil refining, and plastics and rubber. We conduct interviews (n=36), 12 workshops, and analyze 89 documents to assess the current state of SIHF in the studied companies. In 2022 we have already developed and conducted a survey with ten items (n=210). SIHF models and practical tools for preventive safety management will be developed on the basis of the collected data.

Results

The preliminary results of the survey and interviews show that the HF concept is still narrowly understood, which indicates a clear need to expand the concept and competence related to it. The HF Tool for chemical industry purposes will be renewed using SI, and an SIHF model will be produced to help supervisors and managers lead safety culture. The results will be finalized in 2023–2024.

Limitations

This variety of chemical industry companies provides a good basis for our research. However, it is important to carefully consider how the results are disseminated to ensure that they are widely available and applicable in the multifaceted field of chemical industry.

Relevance to Congress Theme

This study utilizes knowledge of work and organizational psychology and creates new safety culture theory and practice for industry and academia.

Relevant UN SDGs

Our SDGs are safety, health, and well-being. We believe that our study findings will facilitate workplaces' future climate actions.

Keywords: safety management, human factor, safety performance

Symposium S066

The future under construction

Taina Eriksson, University of Turku

science_practice

State of the art

Even though the construction industry includes a lot of traditional manual labor, work is changing also there. Mobile digital tools - systems, apps and platforms used with mobile devices - are becoming an integral part of everyday operations on the construction site. Digital technologies have been part of site managers' job for some years already. Mobile technologies and the effects of their use reach increasingly also the employees in site managers' teams. Thus far, the change has been somewhat superficial, and the underlying processes and structures have not yet been affected.

Construction industry is characterized by a strong focus on projects, each done with a unique combination of partners. The actors in a project are tightly connected to each other due to the interdependence between different tasks. On the other hand, site managers have a lot of freedom in deciding how exactly their project is carried out to achieve the desired outcome.

All of the aforementioned characteristics have important implications on the digital transformation starting to take a shape in the industry.

Novel insights

The complexities of digitalization, which is a prerequisite for digital transformation, are not well understood in the systemic, project-based context of construction. The presentations combine academic and practitioner knowledge to create impactful insight into the development of work and the role of people and technology in these developments.

The symposium focuses on small and medium-sized enterprises (SMEs), since they are an important part of European economies and tend to be more agile than large corporations. In addition, SMEs have less legacy load in terms of digital tools.

Theoretical and managerial contributions

The presentations contribute to the academic discussion on the implications of the digitalization of work. The contribution stems on one hand from the conceptualization of the employee attitudes and experiences through self-determination theory (Deci & Ryan). This provides new knowledge on the areas of importance for employee motivation in the digitalizing work which has traditionally been characterized by craftsmanship.

On the other hand, the symposium adds to the understanding of employee surveillance as a dimension of the use of mobile technologies. The use of mobile technologies has numerous benefits as they for instance offer real-time visibility to the progress on the site or hints on the well-being of the employee. However, there are also numerous potential threats and the symposium raises the ethical aspects into the discussion.

Finally, the symposium adds to academic research at the intersection of digitalization and professional pride in a setting where emotions are typically not discussed and hence not routinely acknowledged. It is important that professional pride is examined in different contexts, and on multiple levels of analysis.

The symposium presents and discusses findings mainly from qualitative empirical research among SMEs in the construction industry. Also quantitative survey data is used to grasp the attitudes towards technology.

From a managerial perspective, the research findings offer perspectives into the management of digital transformation. There is a lot of literature on the most advanced technological tools and their applications in construction. Nonetheless, the adoption of advanced technologies lags far behind. Particularly the SMEs are only beginning to adopt mobile solutions to be used on-site. Thus, there is a need to understand better the realities of mobile technology adoption in the construction context, both the inhibiting and advancing factors.

Relevance to the congress themes

Digitalization is typically treated as a technological process, but we argue for the importance of the human aspect. The symposium looks into the adoption and use of technology as fundamentally human-oriented processes and hence brings an important lens to the discussion of the use of mobile technologies in construction work.

Keywords: technology, construction industry, digitalization

Paper 1

Technology, attitudes & changing work

Titiana Ertiö, Aino Saaristo, University of Turku

Background & Goals

The goal of the research was to gauge construction workers' attitudes towards the use of technology at work. It is well established that intention to use a particular technology is dependent on both skills and motivation; however, the topic of motivation has been tackled rather generically whereas in this study we focus on using technologies at work in the construction industry.

Design & Methodology

We surveyed construction workers to understand their attitudes related to using technology at work. In the survey, the affinity for technology interaction (ATI) and techno-work engagement scale (TechnoWES) both measured on 9 items each were used to understand how attitudes toward the advent of technology in the workplace unfold. The investment of effort and time construction workers set aside to familiarize themselves with new technology speaks to their motivation and interest to pursue their use in their daily activities. We triangulate data with interviews conducted with 31 site-managers from two medium-sized Finnish construction companies. The semi-structured interviews covered themes of e.g. well-being and technology-use at work.

Results

The initial interview results reveal site-managers' motivations to use technology in their work and perceptions of their usefulness - some interviewees recognized how technology had made their work easier whereas for others, technology was a source of frustration or indifference. In addition, the interviews reveal different degrees of concerns about technology and how it is used.

To date, preliminary results from the survey show that more than one third of respondents are content with knowing the basic functionalities of mobile technologies, while about 30% are very enthusiastic about using mobile technologies at work.

Together, the qualitative and quantitative evidence gathered this far suggests that attitudes towards the use of technology in the construction industry are rather intricate, exhibiting the complexities and sometimes contradictions of what perceived benefits these technologies might bring.

Relevance & Limitations

Our study contributes to the changing nature of work, particularly manual labour, in the context of accelerated digitalization. We anticipate that in the future, it will be less relevant to know how to use a particular digital tool but rather to own digital meta-skills that allow to adapt previous knowledge to new (digital) contexts. Managers can help construction workers gain interest and build basic skills which can be then expanded upon.

Finland is a particularly interesting case-study setting as it consistently tops different rankings in digitalisation. In 2022, Finland ranked 1st in the Digital Economy and Society Index and 2nd in the UN E-government survey. We recognize, this is also a limitation of the study in terms of sample size and representativeness.

Keywords: technology, attitudes, construction industry

Paper 2

Mobile digital tools, employee surveillance & ethical questions

Juho Vaiste, University of Turku

Research goals & theoretical approach

The construction industry is increasingly applying smartphone applications in its reporting and management tasks. While the digitalization of construction sites offers excellent opportunities, it is crucial to consider the ethical risks and challenges which might arise from such applications. A primary ethical consideration focuses on how these applications enable a powerful platform for employee surveillance. This article examines this ethical risk: How easy and feasible is it to enable advanced tracking of employees – both technically and managerially?

The ethical risk of employee surveillance arises from tracking and analyzing an employee's movements and acts. Although a smartphone application would be considered only to ease reporting, find relevant information, and communicate the progress of job tasks while operating at a construction site, a technical and actual capability to track and follow an employee is always present. The applications examined in this research potentially fulfill at least three of the surveillance targets defined by the European Union's report Electronic Monitoring and Surveillance in the Workplace (Ball, 2021).

The management and organization literature has raised an emergent discussion of workplace surveillance. For example, Manley & Williams (2022) critically assess the effects of broadening surveillance: they analyze enhanced visibility, increasing regulation and control within an organization, and interpreting inaccessible data results. Though employee tracking and analytics may sound useful and might indeed introduce good use cases, implementing those kinds of methods must always meet "reasonable expectations" of privacy considerations, as formulated by Doberstein et al. (2022). The concern over amplifying workplace surveillance is not only an academic worry, but also lately recognized by BBC (2022) and The Harvard Business Review (2022).

The research builds on three research questions: Does a smartphone application technically possess the capability to track an employee? How feasible would it be managerially to implement these capabilities into practice? What kind of gatekeepers are there to protect employees from these capabilities? In addition to the underlying ethical debates, the research aims to contribute to research questions from a managerial perspective. All three questions represent topical and potentially tricky puzzles that a modern leader involved in technology implementation should be able to answer in depth. By answering these three questions with practical and concrete sense, the research clings to the heated debate in the ethics of technology and artificial intelligence: how to make ethical principles and guidelines worthy (Munn, 2022).

Methodology

The methodological approach of the research is an impact assessment based on the extended framework of the PAPA model (Vermanen et al., 2021). The PAPA model (Mason, 1986) is a traditional approach to considering ethical question points related to information technology, formulating examination around privacy, accuracy, property and accessibility. The extended PAPA model adds security, motivation and autonomy to the consideration. In addition to existing literature

and ethical argumentation, the impact assessment is supported by an interview-based case study, approaching research questions from the perspective of a technology vendor.

Preliminary results & contributions

The expected result of the study is a concrete assessment of which level tracking and analytics capabilities are acceptable and feasible in the mobile management application of construction industry. The results will be available in March 2023. The major limitation of the research is the perpetual nature of all three: ethics, impact assessment of technology – and justified limits of organizational surveillance (see e.g., Iedema & Rhodes, 2010).

Relevancy

The construction industry has been recognized as a field that could have nearly the most unexploited benefits of digitalization, but the effects of this transformation are still understudied.

Keywords: technology, surveillance, construction industry

Paper 3

Professional pride in site managers' work in construction industry amid digital transformation – A qualitative study

Anni Paalumäki, Taina Eriksson & Juho Vaiste | University of Turku

Research goals & theoretical approach

This study explores experiences and meanings of professional pride in site managers' work in construction industry. We ask: 1) how is professional pride involved in site managers work and their interactions with each other, with their designated workers, their supervisors, and sub-contractors? 2) How does professional pride come into play when new digital technologies are introduced to the construction site?

Our basic assumption is that construction is an emotionally-charged environment (see e.g. Lindebaum & Fielden, 2010). Construction is characterized as a complex system with high uncertainty and unpredictability, as well as operational interdependence of various sub-systems, technologies, trades and professionals to take coordinated local action (Dubois & Gadde, 2002). Moreover, in recent years technological advancement, digitalization and automation have challenged the traditional ways of working, and there is a push towards even more rapid transformation for the coming years to improve productivity, quality and sustainability. All this constitutes a work environment with high demands of temporal strains, occupational stress and psychological burden, resulting in the display of various emotions and emotional interactions between construction professionals as well as the need to regulate emotions appropriately.

Pride at work in general is referred to as a positive affect related to being responsible of achieving socially or personally valued good or virtuous outcomes in one's work or profession (e.g. Ritzenhöfer et al. 2019). Our attention here lies mainly on pride as a group level phenomenon (see De Hooge & Van Osch 2021 for review). Thus, we focus on affects related to the social group which people identify themselves with. As De Hooge and Van Osch (2021) point out, group level pride is related to the degree a person is identified with the group, shares the affect with the group and contributes to the collective maintenance and regulation of the affect in question.

Methodology

This presentation is based on thematic analysis of 12 qualitative interviews with 31 site managers in 2 small and medium-sized construction companies in 7 construction sites around Finland.

Preliminary results & contributions

Site managers described their work as something done in all possible conditions from freezing cold to extreme heat. Moreover, they pointed out several factors causing work-related strain, such as dealing with delays and uncertainties due to the lack or poor quality of information and overall reliance on the progress of other professionals' work to be able to complete one's own.

Yet at the same time, the site managers expressed their content and even pride towards their work and profession. They described themselves as a group of professionals in contrast to "those who have once built a children's playhouse and considered themselves as masters of construction afterwards." In that way construction work is comparable to any other profession, they point out. Professional pride is about doing your best and being able to participate in the completion of the

building together with your colleagues. In addition, distinction was made between “old” and “new” ways of leading the people. Mangers in charge took pride in leading the workers by “soft” ways, by walking around, talking to people and listening to their worries, with humor and encouraging everyone to participate coffee breaks and lunches in contrast to yelling and using fear for control.

However, the use of new digital applications and particularly extensive monitoring of work was often experienced as unnecessarily control of work. From the perspective of professional pride, new technology was regarded as means to question their professional skills and the quality of their work, even their integrity as professionals. Digital applications used in quality measurements were considered as an additional burden to their actual “real” construction work. This was the case particularly with older site managers, often lacking skills to use the new technology. In contrast, it seems, that to some younger tech-savvy site managers their knowledge of the new technology gave a possibility to help others, thus giving new importance to their role in their work community.

From a practical perspective we argue that understanding the role of professional pride can help SMEs and their management to plan and introduce appropriate ways to bring new technology to construction work. The results can help to deal with negative consequences of technological stress by different support initiatives and interventions.

As a limitation of the qualitative study, we are not able to generalize the findings to all SMEs. In addition, construction in Finland as a work context limits generalization to other nations in Europe and elsewhere.

Symposium S088

Hybrid Work: Between Flexibility and Isolation – How to reap the benefits of working from home and working from the office?

Franzisca Fastje, University of Groningen; Ann Sophie Lauterbach, University of Konstanz, Germany; Alejandro Hermida Carrillo, LMU Munich School of Management, Germany, Human Capital Management Institute

science

Theme and Relevance of the Symposium

Hybrid work, the practice of splitting work time between working from home (WFH) and working from the office (WFO), is emerging as the dominant work format worldwide (Wigert, 2022). In the offshoots of the Covid-19 pandemic, more and more companies decide to transition from remote work to hybrid work – out of necessity or the need to reunite their workforce. Despite the widespread consensus that hybrid work is here to stay, scholars and practitioners are debating whether hybrid work can reap the benefits of both WFH (i.e., increased flexibility) and WFO (i.e., reduced feelings of isolation) or if it is doomed to lead to the complete opposite. To provide preliminary insights, this symposium considers three main aspects that may foster or hinder the effectiveness of hybrid work:

Individual-other congruence in work-from-home intensity

Workspace design

The home environment and segmentation preferences

Relevance to the Congress Theme

The Covid-19 pandemic has undoubtedly changed our working lives and the way in which we think and operate. Although forced remote work during the Covid-19 pandemic largely disrupted how we work (de Vries et al., 2021), it also made us rethink the effectiveness and suitability of traditional work arrangements. Given the many benefits of WFH on the individual (e.g., better work-life balance, Franken et al., 2021) and organizational level (e.g., improved operational cost-effectiveness, ILO, 2020), most employees and organizations want to continue WFH 2-3 days a week (Bloom, 2021). Nevertheless, the past 2 years also exposed us to two major drawbacks of WFH: Feelings of isolation and work-home conflict (ILO, 2020; Leroy et al., 2021). Given its novelty, scholars and practitioners have to cumulatively assess (a) How much of the traditional and forced remote work settings are desirable in the future and (b) What changes are needed and/or essential to turn hybrid work into a success story. These questions align nicely with the conference theme “The Future is Now: The Changing World of Work”.

Research/Practical Implications

Cumulatively, these symposiums´ contributions provide a starting point for how individual-and department-level factors (i.e., WFH intensities, segmentation preference) affect the effectiveness of hybrid work arrangements and how workspaces can be designed to help build a culture of healthy interaction during office days.

Overall Conclusions

With our symposium, we offer insights into some preliminary findings relating to how the work and home environment impact the shape and effectiveness of hybrid work. More specifically, the first contribution advances our understanding of how knowledge workers' social contexts shape the impact of WFH on their perception of social isolation. The second contribution provides insights into designing office workspace to foster a culture of healthy human interaction. Lastly, the third contribution examines employees´ private lives to shed light on why some individuals struggled while others thrived amidst forced remote work and what we can learn from this regarding WFH-WFO preferences moving forward.

Paper 1

Reconceptualizing Working From Home: The Impact of Individual-Other Congruence on Social Isolation

Franzisca Fastje, University of Groningen

Research Goal

The COVID-19 pandemic facilitated working from home (WFH) across a large portion of the workforce, leading to fundamental changes in how knowledge workers interact and connect. We propose that a better understanding of today's WFH arrangements requires careful consideration of the WFH behaviors in an individual's larger social context (i.e., workgroup). Specifically, we examine the complex interplay between individuals' and others' WFH intensity in predicting knowledge workers' perceived social isolation and emotional exhaustion at work. Our findings highlight the importance of examining knowledge workers' own WFH intensity and that of others in their workgroup and add to the debate about whether previous findings are generalizable to contemporary WFH arrangements.

Theoretical Background

Existing studies assumed that higher WFH intensities put knowledge workers at risk of feeling disconnected from others at the workplace (i.e., "out-of-sight, out-of-mind"; Sewell & Taskin, 2015, p. 1508) and deprived of social resources (e.g., informal talk, support; Cooper & Kurland, 2002; Golden et al., 2008). However, it remains unclear how specific levels of WFH intensity relate to social isolation and its downstream consequences (e.g., emotional exhaustion; Sahai et al., 2021). Building on recent studies, knowledge workers tend to vary in their WFH intensity levels (e.g., between 0-60 hours/week; cf. Barrero et al., 2021), which creates large uncertainties around "who will be in, and who won´t, on any particular day" (Parker, 2020, p.2). Indeed, it may be more difficult nowadays to establish predictable and meaningful work relationships at moderate WFH intensities (e.g., 20 hours/week) in comparison to very high WFH intensities where advances in the quality and availability of virtual communication tools may help to prevent isolation (Parker & Grote, 2022; Standaert et al., 2022). Following, we argue for a curvilinear relationship between WFH intensity and social isolation.

Additionally, the shift towards WFH has fundamentally changed focal workers' social context by changing the WFH intensity of others in their direct environment. While a sizable amount of literature has explored WFH intensity as a salient antecedent of isolation, we know little about how individual and other department members' WFH intensities interact in eliciting isolation. However, the WFH intensities of other group members may critically shape a knowledge worker's experience of social isolation because it shapes peoples' availability for meaningful interactions and social support (Cooper & Kurland, 2002; Pyöriä, 2011). Therefore, we argue for a shift from a purely individual-level focus to considering WFH configurations that specify how a knowledge worker's WFH intensity and the WFH intensity of the other workgroup members jointly predict isolation.

Drawing from conservation of resources theory (COR; Hobfoll, et al., 1989), we argue that social isolation is lowest when a knowledge worker and others in the group adopt higher or lower WFH intensities (i.e., mainly virtual or mainly in-person scenarios). In contrast, we expect social isolation to be highest when the focal worker and the other group members adopt moderate WFH intensities – a more hybrid work setting. Our theorizing contradicts the emerging belief that flexibly splitting

time between WFH and the WFO combines the "best of both worlds" (e.g., Choudhury et al., 2022, p. 16) and suggests that more hybrid WFH scenarios deplete knowledge workers of important social resources. Building on research showing that social isolation is related to emotional exhaustion (Bentein et al., 2017; Bentley et al., 2016), we further predict that a focal worker's WFH intensity will also indirectly relate to emotional exhaustion, depending on others' WFH intensity.

Methodology

To test our propositions, we build on a longitudinal dataset of 2,413 knowledge workers nested in 95 units within a large research-focused organization in the Netherlands. Data collection at Time 1 took place when government-mandated COVID-19-related restrictions eased in mid-2021, thus granting knowledge workers in our sample to choose when and how often to WFH freely. As such, variation in WFH intensities was relatively common within our sample, offering an ideal setting to study how individual knowledge workers' WFH intensities. The Time 2 survey was administered in the fall of 2022, mainly to examine how contemporary WFH arrangements affected knowledge workers' long-term well-being (i.e., emotional exhaustion). To examine the joint and indirect effect of an individual's own and other group members' WFH intensity on social isolation and emotional exhaustion, we used multilevel polynomial regression and response surface analyses (Edwards, 2002; Edwards & Cable, 2009).

Preliminary Results

The results from our multilevel polynomial regression and response surface analyses indicate support for a curvilinear congruence effect, implying that work settings where one's own and others' WFH intensity are both lower or higher, respectively (i.e., mainly virtual or mainly in-person) are associated with lower perceptions of social isolation. In contrast, when a knowledge worker and other group members worked from home to a moderate extent (i.e., more hybrid scenarios), feelings of social isolation were significantly higher. Finally, we found that individual-other WFH intensities indirectly and positively affected emotional exhaustion, as mediated by social isolation.

Conclusion

Although past research has already investigated how WFH relates to feelings of isolation (for an overview, see Gajendran & Harrison, 2007), we identified two shortcomings of past WFH research: (a) individual-focused conceptualization of WFH and (b) ignorance of the WFH intensity of others in close social proximity to a focal worker. To alleviate these shortcomings, we collected data from individuals nested in work groups and used multilevel polynomial regression analysis to better understand different WFH configurations among work group members and individuals' experiences of social isolation and emotional isolation exhaustion. Findings suggest that mainly virtual or mainly in-person settings result in lower perceptions of social isolation, while more hybrid scenarios may lead to higher feelings of social isolation. We hope that our theory and results motivate scholars to explore further how knowledge workers' social contexts shape the impact of WFH on their work outcomes.

Paper 2

Coming Back to the Office – What is Needed for a Culture of Healthy Interaction and Cohesion?

Ann Sophie Lauterbach, University of Konstanz, Future of Work Lab

Research Goal

During the wind-down of the Covid-19 pandemic, many companies decide to gradually bring their office staff back into the existing office buildings (Farre, 2021). A disconnect between employers' offers and employees' needs is more profound than most employers believe. A spike in attrition and disengagement due to the lack of interaction and a feeling of belonging may be imminent (Smet et al., 2021; Sull et al., 2022). Office space design plays a crucial role in positive collaboration and connection, but many traditional offices dedicate more than two-thirds of their space to individual, heads-down workspaces (Wineman & Barnes, 2018). We have to rethink these office layouts when it comes to hybrid workspace. What new designs help provide flexibility and collaboration? This mixed-methods study explores whether we can achieve a culture of interaction and cohesion by offering adequate physical workspace for hybrid work.

Theoretical Background

Spatial hybridity changes the nature of work, organization, and management across domestic and organizational space (Halford, 2005). A hybrid workspace can be defined as individuals working at home and engaging in embodied organizational space wherein the office workspace acts as a meeting hub for the dispersed team (Halford, 2005; Hosemann, 2021). Previous studies have shown that physical proximity and visibility influence information sharing (e.g., Appel-Meulenbroek et al., 2016; Coradi et al., 2015), trust (e.g., Wohlers & Hertel, 2018), and social relations (e.g., Brennan et al., 2002; Oldham & Brass, 1979). Cellular offices (i.e., private rooms enclosed by walls) are well suited to promote undisturbed and private working, allowing employees to concentrate on their tasks. However, they do not support communication and interaction among colleagues (Allen & Gerstberger, 1973; Kaarlela-Tuomaala et al., 2009). Hybrid workspaces come with new challenges, as employees might experience their time spent at the office now more relationship-focused than before. Therefore, we argue that more physical workspace dedicated to formal and informal interaction might improve the feeling of cohesion and healthy interaction among employees.

Methodology

We investigated interaction and psychological well-being-related variables among 120 white-collar workers within two groups with a baseline survey and measurements after 10 and 20 months. The two groups were explicitly selected based on comparable tasks in cooperation with the company to ensure a high degree of comparability. After working remotely over the last two years, the treatment group moved into a new workspace while the control group returned to the previous conventional office building. The new campus includes modern activity-based spaces, flexible desks, and informal meeting rooms. Physical meetings, personal and creative exchange, and team building are the focus of the new campus. In comparison, the conventional office consists primarily of one- to two-person cell offices with few rooms for interaction. The data is collected in three waves: During remote work setting in June 2021, in the hybrid work environment in April 2022, and one year later, continuing in the hybrid format. In addition, we gain qualitative insights by examining open questions at the end of each survey.

Preliminary Results

Preliminary results show that the treatment and control groups differ in their experience of peer interaction. The treatment group in the innovative campus reports more inspiration from and interaction with their colleagues than their peers in the control group. The results also showed better self-reported psychological well-being due to interaction among colleagues – more substantial in the treatment than in the control group. Transitioning from remote to hybrid work led to less conflict among team members in both groups and more cohesion in the treatment group. Employees' answers to the open survey questions indicated that they value informal interaction and appreciative communication in meetings, e.g., by being open-minded and approachable, grabbing lunch or coffee together, or encouraging and praising colleagues in on-site and online meetings.

Conclusion

In sum, this working paper explores whether we can achieve a culture of healthy interaction by offering adequate physical workspace for hybrid work. Our results indicate that an office layout that prioritizes formal and informal meeting spaces might help to build a culture of healthy interaction. Therefore, it provides us with insights on how to design hybrid workspaces. Combined with the practical need to examine the shift to hybrid work, our research approach substantially contributes by combining the research strings of the built workplace design and organizational psychology.

Keywords: Hybrid Work; Workspace Design; Healthy Interaction

Paper 3

Alone Together – A Family Systems Approach to Home Boundaries and Loneliness During Remote Work

Alejandro Hermida Carrillo, LMU Munich School of Management

Research Goal

Individual attitudes, personalities, and values interact with those of their co-workers and managers in a systemic way to explain well-being and performance at work (Kristof-Brown et al., 2005). But what happens when work takes place in one's own living room, far away from the office? We propose that interactions within the family system become critical to predicting individual outcomes. Specifically, (in)congruence among employee and romantic partner attitudes plays a critical role in understanding experiences of work-to-home conflict (WHC) and loneliness, especially when working from home (WFH). We provide insights useful for individuals choosing their preferred WFH deals in the new world of hybrid work.

Theoretical Background

While some individuals prefer to keep the psychological boundaries between the work and home domains permeable (i.e., to integrate), at the other side of the continuum lie people who erect thick walls to separate these domains (i.e., to segment; Ashforth et al., 2000). These segmentation preferences do not act in isolation to explain individual outcomes but are activated by the work environment. For example, Rothbard et al. (2005) found that integrators (vs. segmentors) respond with lower job satisfaction when offered flextime, a segmenting policy, and higher job satisfaction as a response to onsite childcare, an integrating policy. Yet, although boundaries are proposed to be co-created by individuals and close others (Kreiner et al., 2009), both the role of romantic partners in boundary construction as well as the consequences of these boundary dynamics have received scarce scholar attention.
