The system view to families proposes that attitudes, emotions, and inclinations of romantic couples interact to create "a living, growing, super-personality" (Smith & Hamon, 2012, p.152). Consequently, it is the boundary configuration of the couple, and not the preferences of the individual partners, that determines how members react to outside stressors (Olson, 2000). Building on boundary theory (Kreiner et al., 2009), we posit that home boundary systems are co-constructed through the level of congruence (fit) in segmentation preferences among romantic couples. First, we hypothesize that misfit in preferences increases individual experiences of WHC. Then, following balance and family systems theories, we predict that fit is not equally beneficial across the whole continuum; the more individuals and their partners agree on segmentation (vs. integration), the more rigid the boundaries of the home system, and the higher the experience of WHC of individual dyad members. We forecast that both effects (fit and misfit) should be most pronounced for dyad members working at high levels of WFH intensity. We finally expect that, when individuals experience WHC, they remain trapped in their work roles, incapable of connecting with their loved ones. Thus, the individual experience of WHC stemming from the interplay of boundary configurations and WFH intensity will result in heightened experiences of loneliness for both the individuals and their partners.

Methodology and Results

In study 1, we test our theoretical model on a unique dataset of dual-earner couples living in Munich, Germany, acquired through a two-step random procedure in two waves. Wave 1 (N = 170 dyads; May - June, 2020) measured WFH intensity and WHC, and wave 2 (N = 107 dyads; July - August, 2020) loneliness at home. Using dyadic response surface analysis (Schönbrodt et al., 2018), we find that fit in integration (vs. integration) relates to lower WHC at high WFH intensity, and that incongruence is harmful for males but surprisingly beneficial for females. WHC mediates the effects of boundary configurations in individual loneliness at home. In study 2, we use a higher-powered sample of dual-earner couples (N = 1,561 dyads; 2019) to replicate our effects of employee WHC on employee loneliness and to test the crossover effects on partners' loneliness. We find strong evidence for both effects.

Conclusion

Prompted by the offset of the COVID-19 pandemic, millions of workers were pushed to work from home regardless of their preferences. Why some suffered from the new conditions while some thrived has been a puzzling question for researchers and organizations alike. The findings of this study indicate that part of the answer might lie in the joint work of attitudes and emotions of romantic couples. Our findings showed that incongruence differentially affected females and males, leaving more questions than answers. A robust WHC and loneliness-decreasing pattern emerged for members of couples who agree on integration rather than segmentation, especially at high WFH intensity. Individuals are advised to reflect on the environment at home when choosing their preferred WFH deals. Insights from this study are relevant for a future in which "…a lot of companies will no longer have [office] space to return to." (Herd, 2021).

HYBRID WORKING: CURRENT ISSUES AND EMERGING CHALLENGES FOR WORK AND ORGANISATIONAL PSYCHOLOGISTS

Juliette Stéphan, CRTD-LISE/CEET, CNAM, Paris; Marc-Éric BOBILLIER CHAUMON, CRTD, CNAM Paris; Corinne Gaudart, LISE/CEET, CNAM Paris; Pauline Crouzat, CRTD, CNAM, Paris

science_practice

Modern organisations offer an increasingly unpredictable work environments that challenge work collectives and established organisational routines. By suddenly bringing a great number of employees to experience remote working, the Covid-19 pandemic further accelerated this trend (Rigotti & al., 2021). Today, there seem to be an agreement among, both academics and practitioners on the "transformative potential" of the Covid19 crisis on work and workplaces. The pandemic brought forward fundamental changes on the way we live and work that the public media refer to as "the new normal". Critical in such a complex environment is our ability as Work and Organisational Psychologists, to elaborate on these practices and engage a dialogue on work and work-related issues (for instance health, wellness, policies, design, management) with the practitioners in the field.

This symposium gathers academics and practitioners in Work and Organisational Psychology and intends to open up a stimulating theoretical, methodological and empirical discussion on what consultants, management and employees refer to as hybrid workplaces or hybrid working . In many organisations, these latter terms appear to cover a combination of in-office and remote days of work that is agreed upon by the employer, the employees and the employees' representatives of an organisation. They also increasingly include the implementation of activity-based offices, that is to say workplaces with non-attributed desks, an extensive set of office design to support different kinds of activities such as collaboration, innovation, concentration and so on (Ianeva & al, 2017).

Whether it is an activity-based office or a formal telecommuting agreement, these flexible work arrangements raise important issues for management, employees and work psychologists. While indeed there is a significant amount of research in work and organizational psychology on remote work practices (Van Zoonen & Sivunen, 2021), existing knowledge can be questioned in the context of pandemic restrictions and even more, in the post-pandemic "new normal". Furthermore, from a practical point of view, mandatory work from home and virtual teams during the crises gave rise to team-level experimentations that need to be elaborated on a collective and organisational level.

Each of the contributions of our symposium highlight different aspects of hybrid working and bring forward the lessons learned from the crisis. They also emphasize on a paradox: hybrid work requires the production and/or the re-negociation of existing rules and procedures in order to coordinate multi-located work while promoting autonomy and flexibility. In the same vein, as remote mediated work (RMW) distributes work in space and time, it also contributes to the sociospatial invisibility of work. The additional need of coordination comes with another requirement, that of producing the indicators needed to "see" work (Leigh Star & Strauss, 1999).

What are the psychosocial impacts of the shift towards these new remote mediated work arrangements? How hybrid work practices – as a complex organizational, sociomaterial and psychological phenomenon - impede on building common corporate culture, workplace integration and teamwork?

Activity-based offices are another growing trend in today's hybrid workplaces as companies are acknowledging multi-location work and are therefore reducing office space. How are activity-based

workplaces to be designed in order to support (rather than hinder) work activities? How to trigger and maintain an activity-cantered design process that takes into account employees' activities?

Addressing these issues is expected provide the ground for a stimulating and meaningful dialogue on hybrid working as well as to bring forward a better understanding of the way Work and Organisational Psychologists, both academics and practitioners, navigate the post-pandemic "new normal".

Keywords: Hybrid working, work and organisational psychology, flexibility

Paper 1

HYBRID WORKING, WORK COLLECTIVES AND CORPORATE CULTURE: THE CASE OF A TELECOMMUNICATION COMPANY

Maria Ianeva, Marc-Éric Bobillier-Chaumon, Emmanuel Poussard, Bénédicte Leygues | CRTD, CNAM Paris

Research objectives

Over the past three years, the Covid-19 crisis has sped up workplace transformations. During the crisis, companies were forced to redesign their organizational processes and to rapidly implement digital technologies in order to keep up the good work. For many organisations, the post-pandemic "new normal" included redefining and extending telework agreements as well as implementing new flexible working policies (Ianeva & al., 2021). It also triggered numerous questions such as: What does hybrid working actually mean in practice? How does it bear upon corporate culture, work collectives or workplace learning? What are the lessons learnt from the crisis? What processes, practices, tools are worth continuing and developing?

Our research project

Our contribution draws upon a one-year collaborative research project initiated in September 2022 by a telecommunication company's internal "think tank" which aims to deliver insights on strategic work-related issues through the collaboration with research teams. It includes both management and employees' representatives as well as external experts.

The main objective of the project is to address post-pandemic hybrid work practices. While these practices became rather widespread within the company during the Covid-19 crisis, their implementation and consequences were not elaborated by the management and the employees. The institute's governing body of representatives and experts felt that there was a lack of awareness and understanding of the potentials risks and pitfalls of hybrid working. In particular, there was a growing concern on how hybrid work practices – as a complex organizational, sociomaterial and psychological phenomenon - impede on building common corporate culture, workplace integration and teamwork.

Theoretical background

The research proposal that we have submitted to the organisation is built upon both situated (Suchman, 1987; Lave, 1988) and transformative approaches of work and cognition (Clot, 1999; Bobilier-Chaumon & al., 2018). As such, we bring forward two different perspectives on fieldwork (Schein, 1976): a clinical and an ethnographic perspective. Both these perspectives highlight different features of the organizational dynamics, changing work practices and processes. The clinical or transformative perspective on fieldwork relies on careful analysis of the way organisational members and the clinician relate to each other. The ethnographic or ecological perspective emphasize the need to understand activities as they unfold in context. In the case of this research project, we consider ourselves involved in a short-term or "focused" ethnography (Knoblauch, 2005; Pink & Morgan, 2013) that is characterized by short-term field visits as well as in the gathering and analysis of artefacts and documents in use in the field.

Design/Methodology/Approach/Intervention

The initial stage of the project involves an interview survey with management and employees of the company (N=30) as well as field observations. The second stage includes 4 to 6 meetings with two different groups of practitioners (a group of managers and a group of employees that have a similar work position and fulfill the same tasks). Participants of both of these groups will be recruited on a voluntary basis.

Expected results and contribution to the symposium

Results are expected to be available in the beginning of 2023. This study results from a “science-practice” collaborative project and provides a valuable empirical contribution to the “Hybrid working: current issues and emerging challenges for WOP” symposium.

Limitations and future work

The clinical and ethnographic perspectives on fieldwork build on different assumptions and mind-set. Therefore, their articulation needs to be managed and carefully arranged in practice and that in an uncertain and changing corporate environment.

Keywords: Hybrid working, clinic of activity, work collective

Paper 2

PRESCRIPTION OF THE FLEXIBILITY OF HYBRID WORK, PSYCHOSOCIAL ISSUES OF OVER-COMMITMENT TO WORK?

Nadia Barville-Deromas, GRePS Laboratory, Lyon 2 University

Research objectives and challenges of the work carried out

Aware of the link between quality of work and performance for health, an energy purchase and resale company is implementing, in 2019, a new collective organization of work based on a collective reflection around hybrid work. The stated objective is to develop work processes that take professional needs into account while integrating flexibility and productivity criteria. Professionals got involved in this participatory project. The Covid situation has shaken up the schedule by imposing forced telework and the implementation of hybrid working methods without any real prior elaboration. How did professionals take up this new organization of work? What were the effects on individual and collective activity?

Theoretical frame

Hybrid working brings together different working methods that combine remote working (institutionalized or nomadic teleworking), on site or at home, synchronously or asynchronously, using communication technologies (Barville, 2020; Bobillier-Chaumon, 2021; Vayre, 2019). The modification of temporal markers (now or later) and geographical markers (here or elsewhere, with family, on professional site or on the move) induce flexibility at all levels for professionals to carry out their work: organizational flexibility (working in different projects), time flexibility (knowing how to work at different times depending on professional and personal constraints and possible connections), interactional flexibility (knowing how to manage exchanges with different people, on different communication tools, concerning different projects), professional flexibility (knowing how to articulate one's professional practice with colleagues who are not in the same profession), organizational flexibility (integrating changes to regular processes or organizations) (Barville, 2020). Flexibility is also personal (doing part of the work in the family sphere) and social (taking into account health or other hazards and reshaping practices in the situation. The literature reports an increase in the workload during this transitional health crisis management period.

Approach/intervention/methodology

From a clinical and situated approach to uses (Bobillier Chaumon, 2013) resulting from the contributions of Vygotsky's clinical psychology, we seek to understand the effect of a prescription for hybrid work on activity. The individual, collective, professional and organizational dimensions of the activity are appreciated to provide a detailed reading of the psychosocial issues.

The qualitative method combines 13 semi-structured video interviews (1.5 hours) involving 3 men, 10 women, 1 top manager, 3 middle manager, 8 employees, 1 service provider. The objective is to understand the effects of remote work. 2 face-to-face collective interviews of 3 hours recorded (discussion of work constraints). Thematic analysis was performed using NVIVO software.

Results obtained or expected

Managing multiple news feeds (What'sApp, Team, emails, calendars) takes up all day. The activity is reconfigured to give a very important part to the management of the poor quality of the information

transmitted: " At work there is a good word and if we do not use the good word, we do not pass the same thing ".

The fact of no longer being together in a common space removes informal and affective information which proves to be fundamental for regulating individual activity (knowing whether the choices made are coherent) and collective activity (knowing how to act and help each other collectively) : " You don't know where the people are if they are available you dare less to look for interaction. There is Teams, there is WhatsApp but it's not the same" . An important part of the activity consists of strategies for analysing digital traces and emotional availability to build future collaborations.

Collective regulations, prescribed and standardized by necessity (collective regulatory daily meetings, rituals of conviviality such as "e-cafés", meetings for sharing emotions at the start of the day, meetings for technical regulations and meeting objectives, meeting of projects, management meetings) we maintained a good level of conviviality. On the other hand, the professional arbitrations, usually discussed at the collective level have been postponed to the top management level, which weakens the collaborative dynamics and the feeling of belonging: "W e don't have the time to devote to wanting to share".

Limits

Situated study not allowing a generalization of the results

Conclusions - practical and theoretical contributions

The highly situated nature of the approach makes it possible to better understand the dimensions of the activity impacted by this change in the organization of work and to grasp the possible positive and negative effects on health.

Relevance to the theme of the congress

Provide a situated reading of the effects of the prescription of flexibility inherent in hybrid work

Keywords: prescription, flexibility, hybrid work

Paper 3

TOWARDS SUPPORTING THE DESIGN OF ACTIVITY-BASED WORK ENVIRONMENTS: LESSONS FROM A RESEARCH-INDUSTRY COLLABORATION

Chiara Lai, Colliers International France R&D / CRTD, CNAM Paris; Maria Ianeva, CRTD, CNAM Paris; Audrey Abitan, Colliers International France R&D; Marc-Éric Bobillier-Chaumon, CRTD, CNAM Paris

Research objectives

This research is the result of a three-year industrial research agreement with the Research and Development (R&D) department of a real estate consulting company. This company designs and implements new flexible workspaces (flex office, activity-based workspaces (ABW)) for their clients. Spatial arrangements such as activity-based workspaces enable companies to cope with an increasingly uncertain economic environment and to meet the growing demand in hybrid working. In this context, many organisations implement new work organisation methods that are expected to support the autonomy and flexibility of workers as well as the re-articulation of the spatio-temporal boundaries of work. Thus, the designers of these workspaces aim at conceiving a spatial artefact which will have a certain impact on the work practices of its users. Flexibles offices are supposed to engage the employees of a given company in the transformation of their practices to meet new organisational requirements (collaboration, knowledge-sharing, innovation and so on).

Our collaboration with design professionals aimed at engaging and accompanying them in the elaboration of the relationship between workspaces and work activity. How are activity-based workplaces to be designed in order to support (rather than hinder) work activities? How to trigger and maintain an activity-centered design process that takes into account employees' activities? This partnership resulted in the co-design of a design workshop for simulating the activity of future users, based on the recontextualisation of work practices and their rearticulation in a new spatial context.

Theoretical background

Our objective is to focus on the relation between space and activity, in order to understand how workspace is constructed by the subjects through their practices. The situated cognition approach (Lave, 1988) connects the organisation of human action with the artefactual environment in which it takes place. This approach brings to the fore how practices are constructed through everyday action. Central to this understanding of practices as ongoing achievement is the distinction between the arena , the spatial environment in which workers act, and the setting , which refers to the reorganisation of this environment by the subject's activity. It is through this work of reorganisation of the arena that we can grasp the way in which individuals manage to transform what is "given" or incorporated into their environment into resources for action.

Our previous work on the appropriation processes of activity-based workplaces (Lai et al., 2021) reveals how subjects navigate flexible and hybrid workplaces and what meaning and functionalities they give to workspaces in practice. Results clearly showed that what makes workplaces great places to work is not so much a matter of functional design or additional services but offering to employees means and occasions to individually and collectively redesign their work environment. This requires a careful analysis and a deep understanding of work practices as they occur.

Methodological approach

Following our theoretical framework, we mobilised the simulation process (Van Belleghem, 2020) to put a group of designers to work on the central question of the relationship between space and activity, thanks to the design of a workshop that they could then deploy during design projects. We mobilised a group composed of each design profession (two Workspace Consultants, a Change Management Consultant and an Architect), as well as two internal researchers around a series of seven co-construction workshops lasting an average of 2.5 hours.

Five of these sessions were recorded, and their partial transcription is in progress.

Presentation of results

The main result of this approach is a workshop "arrangement" which can be used by designers with future users. We note that this tool and the reflection that led to its conception guided the designers towards a better understanding of the relationship between space and activity in the reconstruction and development of work situations by the workers. The designers apprehended the spatial object in a moving and developmental dimension, better able to guide them in the design and in the making and argumentation of certain architectural choices.

Limitations of the study and future directions

This workshop was tested by the consultants with 2 clients in June 2022 and has been only recently included to the consultancy company offers to clients (September 2022). We expect to have more data on the actual deployment of this tool with clients by the end of the year. This will help us better understand its impact on future users and their appropriation of their space.

Relevance to the conference theme

Our study explores how workplaces are impacted by post-pandemic flexible and hybrid working. In particular, we focus on the design process of work environments that effectively support these new work practices. We argue that design should be anchored in the situated activity of the users/professionals.

Paper 4

THE ROLE OF RECOGNITION IN THE ACCEPTANCE OF NEW REMOTE MEDIATED WORK

Juliette Stéphan, (CRTD-LISE/CEET, CNAM, Paris); Marc-Éric Bobillier-Chaumon (CRTD, CNAM, Paris); Corinne Gaudart (LISE/CEET, CNAM Paris)

Research objective and issues

The introduction of technological artefacts in professional environments has led to the emergence of new organisational devices - such as telework, nomadic work, itinerant work (Craipeau & Marot, 1983; Taskin, 2003; Vayre, 2019) - allowing for a flexibilisation of work times and spaces. The Covid 19 global pandemic had a considerable impact on the way people practice and experience remote working. During the past three years, remote work arrangements gradually became a common feature of today's hybrid workplaces .

The research work undertaken aims to analyse in detail the psychosocial impacts of the shift towards these new remote mediated work arrangements. In order to study these transformations, we rely on the case of professionals who had to suddenly submit to the telework system in response to the exceptional measures put in place during the covid-19 pandemic. The health crisis situation illustrates the rapid, unexpected and unpredictable changes that can characterise the professional world today. The study of its consequences offers an opportunity to design new arrangements to anticipate and cope with future developments (Fischer, Lundin & Lindbergn, 2020). Our attention is focused more particularly on the issues at stake in these transformations in terms of occupational health and, in particular, the recognition of work, the pillar of professional identity (Dejours, 1993).

Theoretical framework

Today, work activity is marked by a multiplicity of places and temporalities (Vayre & Vonthron, 2019) made possible by the introduction of technologies: we speak of remote mediated work (RMW). These technological tools lead to a transformation of the professional's action and to a modification of his or her relationship with the object of his or her work (Rabardel, 1995). In parallel with technological changes, the question of recognition at and through work is emerging within the digitalised organisations that are being transformed (Andonova & Vacher, 2009, Bigi & al., 2015). Recognition is a "constructive and dynamic reaction" that has a dual character:

(i) in the possibility of recognising oneself in one's work and finding meaning in it (Clot, 2008)

(ii) through the recognition of others through judgements (Dejours, 1993)

Like contemporary work, recognition at a distance is mediated by technological tools. The means of recognising oneself and being recognised through work are therefore closely linked to the use of technologies and evolve according to them.

Approach/intervention/methodology

The research field is the French subsidiary of an international company that designs, manufactures and distributes audio-visual equipment for professionals. Before March 2020, the work of these marketing and international trade professionals was characterised by a high degree of mobility around the world (nomadic and mobile workers). They experienced the sudden switch to teleworking as a restriction of their possibilities of action. The aim of our ex-post study of these changes was to understand the psychosocial impact of the sudden transition to a new RMW arrangement.

The qualitative method in this research field includes five semi-structured interviews and three group interviews. We wanted to organise the collective reflections around three axes: organisational changes, new professional practices and the impact on recognition. These areas were the subject of three collective interviews. In this case, activity simulation methods (Bobillier Chaumon, Rouat, Laneyrie and Cuvillier, 2018) were used, such as the organisational frieze, the technical object method or the projective method.

Results obtained or expected

All the material has not yet been fully exploited. From the data processing already carried out we were able to observe that:

- In this particular configuration of mediated remote work, recognition is exercised as meta-labour, i.e. work on work that consists of additional tasks in order to better coordinate and be better recognised in work systems that tend to become more invisible, fragmented and individualised. This is known as "recognition activity".

- the appropriation of the new telework system is undermined when the managerial line alone designs and dictates the "good conduct" to be observed in its use. In order to promote the appropriation of this new work organisation by professionals, it seems necessary that the transition be designed in such a way that workers find meaning in it. Recognition "by others" (Dejours, 1993) in remote work also, and above all, requires recognition of the appropriation of the devices by the professionals.

Limitation

Qualitative approach situated in an unprecedented context of health crisis

Conclusion

This study allows us to study recognition as a condition for the acceptance of new organisational measures.

Relevance to the conference theme

Study of the psychosocial impact of new hybrid work arrangements.

Keywords: recognition, remote mediated work, clinic of work

Symposium S119

From Acronym to Action: Advancements in DEI Measurement and Methods

Rebecca Harmata

science_practice

Workplace diversity has become an undeniable fact, leading to an exponential rise of organizational diversity, equity, and inclusion (DEI) initiatives. Indeed, Culture Amp's 2022 Workplace DEI Report revealed that 81% of organizations surveyed are already implementing DEI initiatives. Not only are organizations continuing to develop DEI initiatives, they are also responding to the changing workforce demography by including identity groups beyond traditional mandatory reporting groups, such as neurodiversity and political orientation (CITATION). Despite the increased focus on understanding the experiences of employees with diverse backgrounds and lived experiences, organizations are ill-equipped to develop action-oriented strategies due to lack of resources regarding data collection, action-oriented DEI measures, and accountability (Corrigan, 2022). Indeed, the emphasis on DEI scorecards within organizations presents an unsustainable effort to manage organizational DEI. Some even argue that the scorecard approach inhibits structural change by providing the organization with a superficial scaffold rather than a systems approach to integrating DEI throughout the organization (Melaku & Winkler, 2022). Organizations must shift from a frequency and descriptive approach to DEI to understanding the employee experiences. As such, the goal of this symposium is to bring together four papers that highlight new organizational measures that not only capture the employee perspective through behavioral and self-report methods, but also are tailored toward accountability and action. The present symposium corresponds to the conference theme, The Future is Now: The Changing World of Work, by presenting four new measures to empower organizations to address the increase need to create evidence-based solutions to the changing workforce demography.

In the first paper, Jordan and Deal discuss the development and use of a new scale, DEI Elevated that not only expands the definition of organizational diversity from traditional reporting groups (e.g., race, ethnicity, age) to include political and religious diversity, neurodiversity, and disability status, but also emphasizes the importance of employee perspectives of organizational DEI initiatives. Specifically, the DEI Elevated measure consists of seven categories: Diversity, workplace injustices, safety, inclusion, supportive culture, policy, and DEI training. These categories were specifically developed to practically measure employee perspectives of DEI practices and organizational culture, as employee perceptions inform organizations about the impact of DEI practices on employee experiences.

In the second paper, Harmata and colleagues argue that an identity agnostic microaggressions measure would help mitigate organizational issues regarding tokenism, employee privacy, and intersectionality. As legislation and organizational policies continue to ban explicit discrimination (e.g., CROWN Act), interpersonal discrimination is becoming more subtle and discreet. Indeed, research has shown that microaggressions are just as harmful as overt forms of discrimination (Jones et al., 2013), yet organizations are ill-equipped to measure and act upon such instances due to the siloed nature of current microaggression measures. Building upon employee perceptions and an extended definition of workplace diversity, Harmata and colleagues present novel work regarding the development of an identity agnostic microaggressions at work measure.

Next, Feitosa, Khoobchandani and Davis address an important gap in DEI literature and measurement by presenting a complete validation study of an original scale, the Measure of Equity in the

Workplace (MEW). Feitosa and colleagues identified three key dimensions within organizational equity: Recognizing Inequity, Actively Dismantling, and Leading to Absence of Differences. The MEW empowers organizations to measure perceptions of equity in the workplace in a way that promotes accountability and action.

Finally, Kim moves beyond self-report measures of employee experience and developed a situational judgement test (SJT) to better understand microaggressions against East Asian Americans (EEA). Specifically, Kim aims to identify the attitudes of those who perpetrate discriminatory behaviors for the purpose of developing behavioral interventions. Using 35 scenarios on a sample of 400 participants, a three-factor solution was identified: Challenging, Ambivalent, and Reinforcing (α = .92 - .95).

Together, these papers highlight practical and meaningful measures to incorporate into current organizational DEI strategies for the purpose of understanding the employee experience and developing actionable DEI solutions. These measures will not only promote peace, justice, and strong institutions by reducing workplace inequalities, but also sustainably increase the overall health and wellbeing of employees.

Keywords: Employee Perspective, Diversity Equity and Inclusion, Scale Development

Paper 1

The Development and Use of DEI Elevated

Caroline Deal, University of South Florida; Cassidy Jordan, University of Tulsa

Introduction

Theoretical background and Purpose

As diversity, equity, and inclusion (DEI) rises to the forefront of organizational goals, so too should the measurement of effective DEI initiatives (Romansky et al., 2021). Organizations must promote policies and practices that support its diverse workforce to maintain their competitive edge (Downey et al., 2015). Historically, DEI include some of the most difficult metrics to measure in an organization (Romansky et al., 2021). Although DEI policies and diverse representation provide some information regarding the prominence of DEI initiatives, there is a disconnect between organizational and employee perceptions regarding DEI. As such, Workforce Lifecycle Analytics developed a measure to assess employee experiences and perspectives of DEI practices and policies within their organization.

Employee perceptions are vital to any type of organizational change, as they inform leaders of potential successes and failures in new or existing policy. Romansky et al. (2021) stated that employee feedback serves as the most salient method for measuring inclusion. Additionally, Katsaros et al. (2014) identified several moderators of employee perceptions, including but not limited to, organizational commitment, job satisfaction, and autonomy. While it is not in the scope of this paper to explore the factors relating to employee perceptions, these key moderators are critical to understanding why certain DEI initiatives may be effective for employees.

Although organizational diversity has primarily targeted gender and race, calls for expanding the social categories included within DEI initiatives can be seen in both academia and industry. For example, Cletus et al. (2018) defined diversity to not only include additional social categories such as sexual orientation, political and religious beliefs, but also disability and lifestyle choices. Clouder et al. (2020) included neurodiversity, which refers to different behavioral and learning functions and traits. As such, the current measure included neurodiversity, as well as racial, ethnic, religious, sexual, and political diversity.

Scale Development

Content Validation

First, various words associated with diversity, equity, and inclusion (i.e., acceptance, belonging, inclusion, justice, representation, etc.) were identified. Then, subject matter experts (N = 2) sorted the words into various clusters, separating those with different nuances from those that were essentially synonyms (i.e., cluster types included diversity, workplace injustices, inclusion, supportive culture, and justice/equity). Next, 11 current DEI surveys were reviewed to determine areas that could have been missed and re-evaluate current clusters. Other I-O psychologists to review the items and determine any potential changes.

Originally, the survey consisted of 6 categories with 54 items total. Throughout the content validation, 7 categories were ultimately included at this stage: diversity, workplace injustices, safety, inclusion, supportive culture, policy, and DEI training. A total of 94 items measured these categories, and each main category included 3-5 subcategories.

Refining the Scale

The next stage of scale development was to refine the items. The first step was to edit or delete any double-barreled items. Once double-barreled items were eliminated, the scale developers did a detailed review of the remaining items and attempted to identify which items fit the categories and their definitions the best. The scale developers flagged items that did not fit in the intended category and proposed edits. Some items were removed as the scale developers did not feel that they were measuring employee perceptions or the overall DEI culture. Definitions were edited to better capture the constructs. Additionally, other scales measuring DEI were reviewed again to determine if gaps existed; items were written as needed. A gap regarding involvement with community DEI activities was identified. Multiple items were added during the refinement process to target community involvement which was meant to target the organization's involvement with DEI initiatives in the community. Content validation was addressed through the conceptual analysis of matching items to their intended category and definition, but the scale required further validation efforts.

Validation Efforts

After the refinement process was completed and the scale developers agreed on the scale, they moved on to validation efforts. The first stage of validating the scale was a sorting task. The task created included 113 items as well as the main category names and their definitions. The sorting task was sent out to the scale developers, as well as colleagues (with experience in item sorting). Once the results were received, the responses were combined and summed. The cut-off for retainable items was set at four, as that was two-thirds of the six sorters. Many items that did not make the sort were due to definition overlap. The category definitions were further refined to be more specific to the construct; additionally, items were edited to fit their intended categories better, and new items were added as well. After refinement, the scale was left with six main categories and 157 items. Further validation efforts will include administering a pilot survey. Currently the data collection process has not started but is expected to start in the year 2023. Data from the pilot study will be used to run item analyses to further refine the scale and assess the structural validity.

Practical Implications

By measuring employees' perspectives of DEI practices and organizational culture, the implementing organization can get a better idea of how their employees feel about current DEI efforts and reconcile those practices that are not effective. This survey gives employees the opportunity to use their voice which could increase many positive organizational outcomes. Additionally, by capturing multiple domains of diversity, results can encompass more than the practices surrounding DEI in terms of race/ethnicity and give all employees an opportunity to feel included and valued.

Limitations

The main limitation of our survey up to date is that we are limited in terms of establishing validity. Although efforts are still in progress, it does limit our ability to promote a valid DEI measurement instrument until proper validity is established. Further, we have identified construct overlap during the validation process that must be addressed to ensure clear construct measurement.

Conclusion

Not only do DEI practices benefit the valued employees — they benefit the implementing organization as well. The implementation of DEI practices can result in a variety of positive

organizational outcomes such as “increased profitability, creativity, flexibility, successful adjustment to fluctuations in the market, and overall individual and organizational growth” (Thomas & Ely, 1996).

It is our hope that this survey will give organizations the information needed to identify and implement meaningful DEI practices that contribute to positive employee perceptions, as well as enhance their overall organizational culture so that employees can have a more positive experience at work.

Keywords: scale development, employee perceptions, organizational culture

Paper 2

Developing a Microaggressions at Work Scale: An Identity Agnostic Approach

Rebecca Harmata; Arturia Melson-Silimon; Jorge Lumbreras; Hannah Marriaga

Project Purpose

With the exponential increase of organizational diversity, equity, and inclusion (DEI) initiatives, a need exists to accurately measure DEI-related employee experiences in an actionable manner. Although organizations are well-equipped to measure overt forms of interpersonal discrimination such as racism and sexism via annual climate surveys, rarely do these surveys include measures to quantify the rate of subtle discrimination, such as microaggressions. Despite the subtle nature of microaggressions, microaggressions have been found to be as harmful as overt forms of discrimination (Jones et al., 2013). As such, the purpose of the present project is to develop a validated scale of identity-agnostic microaggressions at work that not only educates key organizational stakeholders, but also provides pathways for effective interventions.

Theoretical Rationale

Microaggressions are defined as daily verbal, nonverbal, or environmental slights, regardless of intentionality, and can manifest in several forms, including micro-assaults (i.e., intentional explicit derogatory remarks and/or behaviors), micro-insults (i.e., unintentional subtle derogatory remarks and/or behaviors), and micro-invalidations (i.e., ostracizing remarks and/or behaviors; Sue et al., 2007). The microaggression literature initially focused on covert racism directed toward people of color (Pierce, 1970; Sue et al., 2007). Since then, microaggressions have been expanded to not only describe the experiences of people of color, but also the experiences of disabled people (Conover et al., 2017), in addition to sexual (e.g., Galupo & Resnick, 2016), gender (e.g., Owens et al., 2010) and religious (e.g., Pagano, 2015) minorities.

Despite the progress in delineating microaggressions of specific communities, the siloed nature of current microaggression measures is impractical for organizational use. The low representation of marginalized identity groups and issues regarding disclosure directly implicate the privacy of identity holders and risk tokenizing already marginalized identities. In addition, approaching microaggressions through an identity siloed lens fails to consider the intersectionality of identities.

Not only do microaggressions at work contribute to increased perceptions of a hostile work environment (Galupo & Resnick, 2016), evidence suggests that microaggressions also negatively impact the psychological well-being of individuals. Specifically, experiencing microaggressions result in psychological distress (Livingston, 2017) and depression (Fattoracci et al., 2021). In addition, research on workplace incivility suggests workplace deviant behaviors also impact bystanders by increasing perceptions of interactional injustice (Andersson & Pearson, 1999).

Research Methodology

Item Generation

A literature search was conducted to review existing microaggression scales, resulting in an initial list of 33 unique microaggression measures, 132 unique themes, and 836 microaggression items. Microaggression scales were retained if the items referred to an individual's personal experience (e.g., frequency, magnitude) with microaggressions. Translated microaggression scales (e.g., Spanish

translation of the Racial Microaggressions Scale; S-RMAS) and microaggression scales measuring an individual's endorsement of microaggressions (e.g., Acceptability of Racial Microaggressions Scale) were excluded. The remaining 126 identity specific themes were coded by subject matter experts (SME; N = 4) into 15 identity agnostic themes and definitions based on Williams et al. (2020). Then, SMEs conducted a redundancy coding procedure to eliminate duplicate items and generated additional items for themes with few unique items (e.g., Myth of Meritocracy, Avoidance).

Proposed Content Validation

A total of 30 SME's will be surveyed for face and content validity of the initial identity agnostic microaggressions at work list for relevance to the overall theme and the workplace. Participants will be recruited via convenience sampling through listservs (e.g., APAEMGS) and networking with research lab contacts. Participants will report tenure in their respective field (e.g., social psychology; industrial organizational psychology) and length of time engaging with the microaggression literature. Participants will be entered into a raffle pool for the chance to receive one of two $30 gift cards.

Proposed Structural Validation

Based on Guadagnoli and Velicer's (1988) recommendation for appropriate sample sizes for exploratory factor analyses (EFA), a total of 350 full-time working adults with diverse categorial identities within the United States will be recruited via Prolific to complete a 20-minute Qualtrics survey. Participants will be compensated based on Prolific's recommendation of $8/hour, resulting in $2.67 per 20-minute survey, totaling $934.5.

Proposed Analytic Procedures

An exploratory factor analysis (EFA) will be conducted using the R (2021) package lavaan (Rosseel, 2012) to investigate the structural integrity of the identity agnostic microaggressions at work measure.

Keywords: Microaggressions, scale development, employee experience

Paper 3

A Measure of Equity in the Workplace (MEW): Scale Development and Validation

Jennifer Feitosa; Nishka Khoobchandani; Alicia Davis

There has been substantial research that highlights how companies with increased equity, diversity, and inclusion (EDI) produce greater financial returns – companies who actively spearhead these strategies are 35% more likely to achieve above-average returns and have their business performance increase by 31% (Hunt, 2015). Recently, a more intentional focus on organizational social justice pushed organizations to re-evaluate their missions, create policies and procedures focused on respecting differences and treating others with dignity, and more importantly include accountability for equity in the workplace.

Developing an equitable environment can increase happiness, belonging, productivity, and more (Mousa, 2020). Additionally, when employees perceive the workplace as equitable, they will be more likely to remain engaged and less likely to show burnout signs (Sharma & Sharma, 2015). Even with the current organizational interest and the accumulating evidence of its importance, equity's conceptualization and measurement remain nebulous. Currently, equity work has evolved to go beyond a comparison of input and output (Adams, 1965) to actually identifying the barriers and properly dismantling them (Hagman, 2021). To respond to these societal pressures, we follow Hinkin's (1998) steps to define equity and develop a Measure of Equity in the Workplace (MEW) that represents a more robust conceptualization. Ultimately, the goal is to have a multi-item, self-report scale that is concise, assesses different types of equity, and is versatile enough to be applied across settings.

Method and Results

Table 1 shows details of the studies and samples used for the development and validation of the MEW. First, in the item development phase, we draw from Hagman's (2021) definition of (1) acknowledging the (both visible and invisible) barriers to success that some may face and (2) working to dismantle such barriers; and complement them with a third dimension that is actually (3) achieving the absence of avoidable or remediable differences. With this in mind, we developed 45 items after consulting other measures (e.g., Keleher, 2014; Mousa et al., 2020) and came up with our own set of items. Our DEI subject matter experts (SMEs) were asked the extent to which they agree that each specific item was conceptually consistent with the above definition. After reviewing the quantitative results as well as the qualitative information (e.g., organizations' reported data was more related to diversity than equity), items were eliminated and new items were generated, resulting in 30 items.

In the content adequacy phase, these 30 items divided across the three dimensions of equity went through extensive scrutiny. Naïve participants and workers alike rejected the idea that these items were part of a three-dimensional construct; but only two out of the 31 items were properly categorized in Study 2, and the three-dimensional model had a very poor fit in Study 3 (RMSEA=.056 [.051-.060], TLI=.17, CFI=.24). This study shed some light regarding convergence and discriminant validity results (Table 2 for details). Next, we consulted another set of experts in Study 4 to review the items, which then were edited accordingly to a total of 21 items.

During phase III, the dimensionality was further clarified by showing that participants were really unable to classify any of the items into the dimensions (Study 5). Furthermore, another sample rated

all 21 revised items as meeting the criteria regarding whether they captured the definition of equity in Study 6. We then picked the 10 items with the highest agreement, see Table 3 for the final items.

Lastly, participants read a vignette describing a workplace with low, medium, or high levels of equity and rated the workplace on the ten, which then was further reduced to four final items (MEW-S). In the final nomological network phase, we show that the one-factor model shows a good fit (Table 4), it shows statistically significant differences when the equity in the context shifts ($F(2,304) = 533.42$, $p < .001$, $\eta^2 = .79$; Figure 1), and is related to criteria such as performance, $r(305)= .49$, and turnover, $r(305)= -.83$, as expected (Table 5).

Discussion and Conclusion

We have built evidence for the four-item MEW with concise, valid, and reliable proprieties. Additionally, precisely establishing equity's conceptual realm in relation to other constructs such as justice, diversity, and equality is key as attention to EDI continues to grow in the workplace. To strengthen these remarks, the next steps include performing cross-validation, multigroup comparisons, and field samples. Overall, MEW can quickly inform perceptions of organizational climate related to their commitment to equity.

Keywords: Equity, scale development, organizational accountability

Paper 4

Measuring Prejudice: The Development and Validation of the East Asian American Situational Judgment Test

Emily Kim, Virginia Tech

Research Goals : In 2020, there was an escalation of bias, xenophobia, racism, and violence against the Asian American community, especially due to COVID-19. The goal of this study was to develop and validate a scale to improve our measurement of prejudice, particularly against East Asian Americans (EAAs).

Background : Many racial bias measures for Asian Americans and other races are designed to evaluate perceived discrimination and are only directed towards members of their respective minority groups. While understanding the perspectives of those who experience prejudice are valid, it is equally important to identify the attitudes of those who perpetrate discriminatory behaviors to better combat these issues.

Although theoretical understanding of bias has improved, psychometric measurement scales and methods of assessments have continued to rely almost exclusively on self-reports of cognitions and affective reactions to a target group. This study uses a situational judgment test (SJT) to measure prejudice towards EAAs based on behavioral expectations.

SJTs are assessments composed of brief scenarios and a fixed set of responses where respondents are asked to imagine they are in a certain situation and indicate the likelihood of engaging in each response. The underlying logic for using SJTs is based on the behavioral component of the tripartite model of attitudes (Bagozzi et al., 1979). Shifting focus to behavioral-based measurement strategies provides the benefit of potentially reducing social desirability responding (Kanning & Kuhne, 2006), as well as improving predictions of behavioral outcomes compared to cognitive/affective scales (Peus et al., 2013; Teng et al., 2020).

Methods : The initial item pool for the EAA-SJT consisted of 35 scenarios depicting microaggressive situations directed towards EAAs. The structure of the response options primarily draws from the results of the Diversity Engagement Test II (DivETII; Sturdivant et al., 2017). The DivETII identified three emergent factors: Challenging (likely to engage or confront those who commit microaggressions), Ambivalence (likely to shift focus away from the microaggression), and Reinforcement (likely to support or rationalize the microaggression). In the development of the EAA-SJT, the Challenging and Ambivalent dimensions remained the same, but the Reinforcing dimension was bifurcated into Negative Reinforcing (NR) and to Positive Reinforcing (PR) dimensions. NR response options were designed to reflect behaviors that reinforced the negative aspects of anti-EAA bias and PR response options were designed to reflect faux complimentary behaviors that are likely to be viewed as offensive by EAAs.

Participants were asked to complete a 20-minute survey consisting of an informed consent form, demographic questionnaire, and five measures: EAA-SJT, Asian American Stereotypes Scale (AAS), Marlowe-Crowne Social Desirability Scale (MCSD), and two locally developed criterion measures, the East Asian Cultural Knowledge Test (CKT) and the Asian American Microaggression Behavior Checklist (MBC).

Results : Data were collected from 400 participants through the Qualtrics market research panel. Participants were 49% female, 57% White, and had average age of 52.5 (SD =17.9). After iterative exploratory factor analyses for the EAA-SJT, results supported a three-factor solution composed of Challenging, Ambivalent, and Reinforcing, with PR and NR not emerging as separate factors. Convergent validity was assessed with the AAS with moderate, significant correlations. Discriminant validity was assessed with the MCSD, and social desirability response bias was not found to be a meaningful problem for the EAA-SJT. Criterion-related validity was assessed by regressing the CKT and MBC on EAA-SJT scores; results indicated that Reinforcing was the only dimension that significantly predicted both measures (CKT: $t(396)=-5.26$, $p<.001$, partial $\eta 2 = .07$; MBC: $396)=6.02$, $p<.001$, partial $\eta 2 = .08$.). Reinforcing scores also provided significant incremental variance over AAS scores for both the CKT and MBC.

Discussion : Overall, these results suggest that the initial evidence for the EAA-SJT is promising. The use of behavioral-based measurement strategies may provide benefits in reducing social desirability bias in responding and improving predictions of behavioral outcomes over more commonly used cognitive/affective measures. However, results are limited due to the initial exploratory stage of this research. Confirmatory factor analyses and subsequent validation strategies must be conducted to truly identify the benefit of this measurement.

Later results may have varying workplace implications such as predicting performance in diversity programs and expanding our understanding of microaggression response profiles.

Relevance : As the world continues down a path of increasing globalization, it is increasingly important to address DEI in the workplace. With a better understanding of bias and prejudice through improved measurement strategies, we can work toward the UN SDG goal of reducing inequality at work.

Symposium S120

Adapting Assessment Centres for Virtual Delivery – Experience and Best Practice

Baron Helen, Independent

The arrival of Covid-19 disrupted many processes in organisations and assessment processes were no exception. Assessment centres, by their nature, involve the interaction of quite a large group of people, many of whom have never met before, exactly the kind of scenario likely to spread the virus. Employers were faced with the need to find ways of assessing candidates that did not require face-to-face encounters. This practical symposium reviews the experiences of a number of psychologists whose role included the design and delivery of assessment centres, how they responded to this challenge and what they learned from the process. The organisations are all in the public sector from both the UK and Ireland. These organisations typically faced increasing demands as a result of the virus and therefore were under substantial pressure to not just maintain their assessments for selection purposes, but often to increase their productivity. The papers discuss topics such as different approaches to redesigning exercises, assessor training and support, security and remote invigilation as well as the impact on candidates of using a virtual delivery. While there are challenges in working in the virtual environment, many of the innovations introduced out of necessity were received very positively and some are likely to be maintained even when face to face assessment becomes possible again. Others needed some reworking before they were deemed effective. The final paper provides an overview of guidelines designed to support effective design and delivery of virtual assessments providing a framework for evaluating the practical solutions these organisations found.

Keywords: Assessment Centre, Virtual, Standards, Selection

Paper 1

Redesigning Exercises for Remote Delivery

Gray Aine, An Garda Síochána; Lyons Aoife, Public Appointments Service

The Public Appointments Service (PAS) is the centralised recruiter for the Civil and Public Service in Ireland. PAS recruits for a wide range of Public Sector roles, with applications of up to 30,000 candidates for some of our large volume general service roles.

When, due to Covid, a nationwide lockdown was announced, PAS had to explore how recruitment could carry on in a context where candidate travel to our Dublin Office for Assessment Centres was impossible. A number of criteria were applied to determine the best course of action:

Urgency of filling the posts – many of our roles are critical particularly due to Covid;

Impact of changes on the validity of the assessment process;

Impact of changes on candidates and their ability to perform to a high standard;

Ability of Assessors to assess using new techniques and technology;

Impact of changes on cost, timescales and staff resources required;

Security of test materials;

In addition, a key consideration was to avoid simply replicating what we were doing in-person online, but rather to revisit each of our processes to determine how best to assess the required competencies remotely.

This paper will review 2 specific assessments used by PAS as part of promotion to Inspector and Sergeant in the Irish police service (An Garda Síochána). The Irish police service is a national one and has a staff complement of approximately 17,000 and a budget of approximately €2bn.

Inspector Briefing Exercise

The first exercise that was adapted for on-line delivery was an analysis presentation exercise used for Inspector roles. In delivering this type of exercise previously, candidates would have been supervised reviewing a detailed brief and asked to present it to assessors. It would have been very challenging to maintain the security of the brief and very resource intensive to adopt this approach remotely.

Following a review of the competencies and the potential assessment options, an alternative approach was developed. This involved streamlining the volume of content given to candidates and the development of a series of parallel exercises to be used on different days. In addition, a sample exercise (of similar length) was developed to familiarise candidates with the approach and to maximise the perceived fairness of the process.

In determining whether this new model is better than the existing one, there are a number of areas where there is evidence to support the ongoing use of this model, in particular the very positive candidate and assessor feedback. Compared to the previous approach, more evidence on the competencies came from the question and answer session which followed the initial response of the candidate to the assessment material so it felt like a more dynamic engagement than the previous more formal presentation. Assessors particularly commented on how each candidate brought something unique and different to the exercise based on their previous experience. Ongoing

monitoring is required to ensure this approach continues to work, e.g. no evidence of collaboration in preparing the presentation and ongoing review of the performance of the successful candidates.

Sergeant Online Tests

The second assessment process adapted as a result of the pandemic was on-line multiple choice critical reasoning tests and a bespoke situational judgement exercise used at the first stage of the Sergeant promotion process. Typically, 1,500 to 3.000 candidates apply for promotion at this level.

This is a very high stakes process so in order to safeguard the security of the material it was decided that live remote invigilation was the optimum approach. An alternative approach would have been to use a "record and review" approach to invigilation which involves the testing session being recorded and a sample of the completed tests being reviewed later by invigilators. The live invigilation was used because issues can be addressed as they arise and it was more credible for the applicant population. Because of the security concerns, it was decided that the ideal ratio of invigilators to candidates was one invigilator to five candidates.

In summary, the key learning for PAS was how quickly we could change our assessment models in light of the new situation. While we have made changes and improvements to many of our initial approaches, in particular related to scoring, the flexibility and need to innovate quickly gave us the courage to try new things. There are areas where further data is required to fully understand the potential longer-term implications of the changes made during the pandemic, but on balance, we feel the new approaches we used are improvements on previous practices and will continue in the future.

Keywords: Assessment & Recruitment, Public Sector, Remote Invigilation

Paper 2

Improving consistency in assessor scoring for an online assessment process

Louise Meade, Matthew Humphries & Howard Clemence | College of Policing

The College of Policing were asked to rapidly design and implement an online assessment process to allow police recruitment to continue regardless of the significant restrictions imposed by the COVID-19 pandemic. Both historical assessments and assessor training had previously been delivered face to face. One facet of this project was to design and deliver online assessor training to 600+ assessors in a limited period of time to a high standard.An initial assessor package was put in place to support roll out of the online assessment process which was aligned with best practice and contemporary research. Once the process was live evidence was collated which identified opportunities to enhance consistency in assessor performance and overall reliability of the assessment process. The evidence base consisted of an inter-rater reliability study, speaking to psychologists, quality assurance team and assessors to identify areas to develop. It was identified that the below areas could be developed:

Further practice materials – including benchmark content

Further clarity on how to use a behavioural anchored rating scale to rate individual behavioural indicators and overall exercise marks

Preference for increased interaction with trainer

Further develop a quality assurance performance management framework to highlight inconsistencies in assessor performance which further training can help address.

Evaluation evidence identified additional training and guidance that could be developed. These included:

Information leaflet – highlighting areas that could quickly be addressed and generate immediate results

Skills Development Workshop - provided a platform to cover areas of performance that needed addressing whilst allowing assessors to interact with the organisation and ask questions on the process/training

Additional benchmark training – assessors identified as underperforming in the quality assurance performance management framework are supplied with additional benchmark training. This provides the assessors with further practice aimed at increasing consistency of their scoring.

In order to keep a direct communication between the organisation and assessors, drop in webinars are being carried out each month to help answer queries and address any issues which may be attributing to assessor performance.

Aligned with the British Psychological Society standards assessor performance is continually monitored through a quality assurance process, the recent results since the additional training had been introduced highlight an increase in consistency of assessor scoring across three online exercises.

Overall conclusions from this project were that the online assessment process has been effective for high volume recruitment with promising outcomes for minority ethnic candidates. Another conclusion is that e-learning training is most effective when a range of support tools are put in place. By providing delegates with training through different mediums this can help facilitate for a wider

variety of learning styles. Limited practice can affect performance, therefore optimising benchmarking content is important to help aid consistent performance and provide a good understanding of the assessment rating criteria. Important to continuously monitor performance and address any trends or inconsistencies found.

Keywords: Assessor Consistency, Online Assessment, COVID Response

Paper 3

Responding to the Pandemic - Delivering Virtual Assessment: Civil Service Fast Stream and Emerging Talent

Phil Wilson, Sonia Pawson | Cabinet Office

1. Goals

This paper outlines the transition from a face to face graduate Assessment Centre (AC) and Final Selection Board, in a public sector context, to a virtual delivery format. This conversion was driven, above all, by Covid-19 restrictions and the need to shape a user friendly but compelling alternative assessment. The AC design involved replacing an existing iPad tablet-based app, that was run face to face, with a fully virtual experience - administered remotely.

The shortlisting stages of the graduate assessment process, prior to the AC stage, had been online for a number of years, comprising online tests, work based scenarios and a video interview. The virtual AC app was therefore a continuation of an online candidate experience.

The assessment design was also shaped by a number of strategic objectives:

Identifying candidates with the highest potential for future senior leadership.

Strengthening the flow of diverse talent into the pipeline for senior leadership roles that reflects UK society.

Providing fast, flexible, and more modern, graduate assessments.

Offering an engaging and positive candidate experience using multimedia elements.

Improving scheme retention.

A digital agency was secured to support the AC update. This agency had originally been commissioned to create the previous iPad app, which they were then contracted to adapt for virtual provision.

2. Theoretical background

The assessment process was developed by occupational psychologists, according to best practice and aligned with the UK's British Psychological Society's Standards on Assessment Centres (2015), the International Taskforce on Assessment Centre Guidance (1989), and the International Test Commission's (2005) International Guidelines on Computer-Based and Internet Delivered Testing.

3. Method

The assessment process itself comprised:

A leadership roleplay exercise conducted with a 'colleague' (played by the assessor) – with information presented via the app, and with the discussion on Google Meets.

A group stakeholder exercise within a fictitious scenario – again presented via the app, with the discussion on Google Meets.

A written analysis exercise, presented on the app, requiring the generation of ideas around an initiative – with the response recorded on a computer by the candidate.

A Final Selection Board virtual interview, following the AC.

The creation of the virtual app involved a series of digital and non-digital user trials to learn about candidate experience and build quick prototypes to test hypotheses. Web analytics and other data was used to enhance understanding of any emerging user/accessibility issues.

The assessment experience – supported by a fully trained operational team - was evolved in a number of ways, by providing:

The capacity to easily activate exercises for candidates in an accessible way.

A virtual candidate common room, allowing real time updates and support during the process.

An easy to use tutorial for candidates; a preview of exercises; exercise instructions and password access.

Ability to browse exercise items with easy navigation; a note and highlight facility; an FAQ Help screen; capacity to lock exercises and allow candidates to offer feedback about their exercise experience, including incorporation of reasonable adjustments.

4. Results

The virtual assessment was delivered to 3,449 candidates. In developing the app, user (candidate) testing offered positive metrics:

Leadership Exercise:

'I found the app easy to use overall in the exercise': 91% positive.

'I preferred doing the exercise on the app compared to paper version': 82% positive

Group Exercise:

'I found the app easy to use overall in the exercise': 89% positive.

'I preferred doing the exercise on the app compared to paper version': 83% positive

Written Exercise:

'I found the app easy to use overall in the exercise': 91% positive.

'I preferred doing the exercise on the app compared to paper version': 82% positive

Candidate satisfaction data during the live virtual process was also positive:

Leadership Exercise: 91%

Group Exercise: 87.6%.

Written Exercise: 90%

Assessor testimonial included: 'It was really impressive how arrangements were made so effectively to support online assessments'.

In addition, diversity outcomes exceeded previous year metrics, including for the Final Selection Board (Commercial Fast Stream):

Female: 45% (4% increase on 2020)

Ethnic minority: 28.2% (120% increase)

Lower socio-economic background: 6.7% (34% increase)

Disability: 27.8% (63% increase)

5. Conclusions

The case study provides an example of a successful transition of a volume assessment centre process to a virtual delivery format. Candidate reaction and diversity outcomes were positive. Future assessment plans will build on this experience, with new, even more diversity focused content, utilising similar virtual architecture.

Keywords: Virtual, Online, Multimedia, Assessment centre

Paper 4

The BPS Guidelines on the Design & Delivery of Virtual Assessment Centres

Baron Helen, Independent; Choi Max, Quest Partnership; Eyre Charlie, Workspheres Ltd; Thomas Natalia, Shell

In 2015, the British Psychological Society (BPS) released its Standard for the Design and Delivery of Assessment Centres (British Psychological Society, 2015). Drawing heavily on the Assessment Centre literature as well as the insights of highly experienced practitioners, the Standard has been subsequently used internationally as a means of supporting practitioners in both the preparation and implementation of assessment centres. While the original standard made some reference to virtual delivery, its primary focus was on the face-to-face delivery of assessment centres. The extensive and unexpected changes to global working patterns which resulted from the Covid pandemic in 2020 required many organisations to rapidly review and adapt their delivery models for assessment centres. Against this backdrop, the BPS Assessment Standards working group recognised that practitioners were often having to attempt this transition with limited guidance or models for how this might be implemented.

While existing literature provides some useful advice on the practicalities of incorporating technology into assessment centres (e.g. Guidelines and Ethical Considerations for Assessment Center Operations, 2015), it was felt that further detail would be advantageous for practitioners seeking to make the switch to full virtual / online delivery.

The presenters drew together key themes within the guidance through their own practitioner experience of transferring online assessment centres to online format, and also through consultation with practitioners across the UK with recent experience in this area. The broad themes around which the guidelines are structured relate to design issues, technical issues, exercises, assessors, participants, validity and fairness. The guidelines are due to be made freely available to practitioners through the BPS website.

The paper provides an overview of the new guidelines, and how they can be used by practitioners. This will be linked to the specific practical experiences of virtual assessment centre delivery cited by other presenters within this symposium.

The guidelines are intended for all practitioners planning to deliver Assessment Centres in virtual formats, and particularly those who are switching from face-to-face to virtual format. The presenters will provide an overview of the guidelines, explain how they relate to the 2015 BPS Standard for the Design and Delivery of Assessment Centres, and how they might be used across a range of assessment and development centre applications. They will also be relevant to converting other assessment processes, such as stand-alone interviews, for virtual delivery

The guidelines offer an additional resource for practitioners and academics focussing specifically on the factors to be considered when implementing a virtual assessment centre. This will complement the extensive guidance provided by the standard.

Symposium S116

Vales-based HRM in times of multi emergencies

Nuno Rebelo dos Santos, Research Centre in Education and Psychology (CIEP-UÉ), School of SocialSciences, Universidade de Évora, Portugal

science_practice

What will be covered and why?

The United Nations Sustainable Development Goals are imperative due to environmental, social, and economic emergencies leading to dangerous social tension. Everyone is challenged to participate in pursuing those goals, regardless of the role he or she has within society. As collective agents (with social structures and processes), organisations also have a relevant role in pursuing those goals. The symposium focuses on Human Resources Management (HRM) practices and policies to meet some of the values behind the United Nations' sustainable development goals.

The first paper reports empirical knowledge about the relationship between several personal and work-related demands/resources and psychophysiological recovery in Spain and Portugal. Therefore, it is related to workers' well-being and decent work.

The second paper proposes a framework to guide values-based interventions in the work, organizational and personnel psychology (WOPP) field. In the current multi-emergencies times, values can be a stable compass to guide the practice in this field. That framework is also an instrument to implement, monitor and evaluate such interventions.

The third paper using documentary analysis of 40 reports made by adherent organizations to the United Nations Global Compact (UNGC), identifies types of actions related to HRM practices through the lens of decent work. Those actions are framed in a typology that characterizes different ways of meeting the values behind the UNGC.

The fourth paper frames HRM and employment relationships in the wider society and proposes several statements and guidelines for research and practice based on literature reviews. Those statements and guidelines try to prevent or fix the low quality of employment relationships, making it possible to design interventions within the scope of HRM beyond its internal organizational impacts.

Finally, we will present a general framework of understanding, joining together the several contributions of the individual papers.

It is increasingly essential to include universal human values in the policy and practice of HRM since every agent, both collective and individual, has a role in redesigning it. Responding to emergencies requires all social agents to play their role in that endeavour. Some ideas come from practice, and others from theory and previous research. We include here those ideas, statements, and guidelines in a general framework of understanding. That framework is helpful for new research and practitioners to guide that kind of innovation in HRM.

Overall conclusions

The relevance of approaching HRM beyond the internal organizational impacts is a response to the call that comes from current times' social, economic, and environmental emergencies. The universal values expressed in Decent Work's concept, and in the UNGC, is a good choice confirmed here. An

essential endeavour to pursue is to innovate by joining together workers' well-being, decent work, and effective human resources management.

Relevance to the Congress theme

The innovative approaches in HRM and decent work presented in this Symposium meet the challenging, demanding and changing times we live in, particularly in the labour context.

Research/Practical Implications

The approaches, frameworks and perspectives presented in the Symposium suit well the required standards to guide HRM practitioners in their innovations, and researchers in developing new measures and further research approaches. The inclusion of guiding values, decent work, and the consideration of societal impacts of HRM policies and practices are remarkable.

Paper 1

The work-life-flow of Spanish and Portuguese employees: Preferences, sleep, recovery, and influencing factors

Rita Berger, University of Barcelona, Spain; Nuno Rebelo dos Santos, Research Centre in Education and Psychology (CIEP-UÉ), School of SocialSciences, Universidade de Évora, Portugal; John S. G. Wells, WellsSchool of Health Sciences, South East Technological University, Ireland; Florian Scheibein, School of Health Sciences, South East Technological University, Ireland; Leonor Pais, Center for Research in Neuropsychology and Cognitive and Behavioral Intervention (CINEICC), Faculty of Psychology and Education Sciences, University of Coimbra, Coimbra, Portugal; Jan Philipp Czakert, University of Barcelona, Spain

Research goals and why the work was worth doing:

The main research goal was to obtain and to cross-culturally compare empirical knowledge about the relationship between various personal and work-related demands/resources and psychophysiological recovery in Spain and Portugal.

Increased remote work and new (inter-)national regulations during the ongoing COVID-19 pandemic show the growing importance of the work-nonwork interface, work-life flow (WLF), and its relation to wellbeing. The forced integration of the work and nonwork areas means increasingly blurred boundaries between both areas. This calls for a more holistic view of employee well-being across the entire work-life system, including work, nonwork, recovery and sleep. As for the nonwork area and the work-nonwork interface (WNWI) as the linking pin between the two broad domains, more research is needed to uncover underlying mechanisms. Specifically, more empirical research is needed for WNWI-preferences, emotional experiences, and how they relate to crucial recovery experiences, e.g., psychological detachment and sleep.

Theoretical background:

The concept of WLF means a re-conceptualization effort of the rather traditional concept of work-life balance. A positive psychology approach that does not neglect potential incompatibility issues but also focuses on enriching resource-based processes seems needed. WLF integrates the elements of flow, boundary, and resource-demands based theories (Czakert et al., 2022).

The WNWI can be referred to as 'the interaction of employee work experiences and [nonwork] lives' (Allen, 2012, p. 1163), where spillover effects can happen in various forms. In other words, behaviours and affects from the work domain could easily transmit to the life domain and vice versa. For example, work-related stressors could affect more easily important recovery experiences and the whole process across the WNWI and well-being, and vice versa.

Following boundary theory, people vary in preferences for segmenting or integrating aspects of work and home (Ashforth et al., 2000). Yet, less is known about how distributed this variation actually is or if a majority of people prefer segmentation or integration rather in general.

Although with the recent advent of emotion research, recovery research and research of the WNWI, the nonwork domain was also integrated into employee wellbeing research, more research needs to be done cross-culturally to understand related influencing factors at organizational and personal levels.

Design/Methodology/Approach/Intervention :

The cross-sectional online survey named “Study on Work-Life-Flow” including a multi-scale battery of established scales, was distributed via snowballing sampling in Portugal (n = 590) and Spain (n = 1536) in 2022. The study is part of the Erasmus+-funded Strategic Partnership Project "Excellence based profiling to identify and apply tools and trainings for a better and sustainable Work-Life-Flow" (Project Number: 2020-1-ES01-KA203-083282). The project has been approved by the Institutional Review Board (IRB00003099) and the IRB of the University of Coimbra, “Ethics and Deontology Committee of Research in Psychology” (CEDI/FPCEUC: 53-7-21-08-2021).

Results obtained:

The big majority of our two samples preferred to separate work from nonwork and vice versa and can be categorized as segmenters (Spain = 61.9%; Portugal = 63.8%). In contrast, only few participants can be categorized as integrators (Spain = 9%; Portugal = 8.1%) which prefer to combine roles in both domains.

Perceived sleep quality, psychological detachment, and frequency of related experienced emotions such as feelings of exhaustion, recovery, and burnout all correlated significantly with perceived organizational culture, perceived leadership, and perceived emotion regulation and optimism. Correlation coefficients were similar for Spain and Portugal.

Limitations:

1) The cross-sectional design precludes causal inferences. Future research should use intensive longitudinal data to depict real-world phenomena. 2) We relied on self-perception measures only, which are subject to common method bias and do not measure organizational behaviour itself. Future studies should apply a multi-method design, including observer ratings for work conditions or objective measures such as email traffic outside working hours.

Research/Practical Implications:

Theoretically, we propose WLF as an integrated concept across the WNWI and highlight the importance of recovery and emotions for employee wellbeing, especially in hyperconnected work-life systems. Practically, this implies to reflect on mental health policies and interventions regarding their impact on nonwork-based recovery.

Relevance to the Congress Theme:

The future is now. Contribution . Informing Human Resources for training and organizational development.

Relevant UN SDGs:

UN SDGs 3 and 8 reflect the interface, growing relevance and attention to employee wellbeing.

Keywords: work-life-flow, cross cultural, work-related demands and resources

Paper 2

Values-based interventions: Designing and undertaking interventions in turbulent times

Pereira Susana Alves, Universidade da Maia, Portugal; Nuno Rebelo dos Santos, Research Centre in Education and Psychology (CIEP-UÉ), School of SocialSciences, Universidade de Évora, Portugal; Pais Leonor, Center for Research in Neuropsychology and Cognitive and Behavioral Intervention (CINEICC), Faculty of Psychology and Education Sciences, University of Coimbra, Portugal

Research goals:

Organizations worldwide entered an emergency model during the multi-emergence times, thoroughly transforming the labour market. This study proposes a framework to design and evaluate interventions to improve the real and effective translation of values into practice.

Theoretical background:

The COVID-19 pandemic changed the nature of the world of work and consequently has unhinged the workers' lives across the globe. From the perspective of people at work, this ongoing pandemic has posed unprecedented challenges to organisations. Other emergencies have arisen, such as climate and environmental extreme changes, social tension and conflict escalating and economic poverty of so many people. In seeking solutions, values can offer a stable compass that helps people in general and decision-makers, in particular, to deal with overwhelming times.

The concept of decent work (DW) is a values-oriented concept that expresses this concern based on four fundamental values: freedom, equity, security and human dignity. Thus, DW offers, in the field of work, organizational and personnel psychology, an approach that contributes to overcoming the overwhelming demands of the current labour field.

Design/Methodology /Approach/Intervention:

By reviewing the existing literature on WOPP interventions, we propose a framework to design and guide values-based interventions suitable to deal with the current turbulent times.

Results:

A framework is presented suitable to guide values-based WOPP interventions design and implement, monitor and evaluate such interventions.

Limitations:

The intention of offering a transcultural framework was not tested yet, and some cultural specificities can hamper its applicability worldwide.

Research/Practical Implications:

Offering a framework for values-based interventions, we stimulate research and practice. Practitioners can apply the framework to their professional practice, Researchers can evaluate values-based interventions, and cross-cultural comparisons can be undertaken as much as the framework was applied worldwide.

Originality/Value:

To our knowledge, no prior study proposed a values-based framework for WOPP interventions. Such a framework is worth to be adopted to innovate work-related conditions, contents and contexts.

Relevance to the Congress Theme:

It is relevant to make available useful conceptual tools that can be applied to innovate in work-related interventions.

Relevant UN SDGs:

The United Nations Sustainable Development Goal number 8 expresses decent work, and economic growth is at the core of the framework presented in this presentation.

Keywords: Values-based intervention, Organizational-change management, Framework

Paper 3

The integration of Decent Work concept in HRM: a documentary analysis of United Nations Global Compact annual reports of Portuguese organizations

Anabela Magalhães, Faculty of Psychology and Education Sciences, University of Coimbra, Portugal; Nuno Rebelo dos Santos, Research Centre in Education and Psychology (CIEP-UÉ), School of SocialSciences, Universidade de Évora, Portugal; Leonor Pais, Center for Research in Neuropsychology and Cognitive and Behavioral Intervention (CINEICC), Faculty of Psychology and Education Sciences, University of Coimbra, Portugal

Theoretical background:

We assisted in the last two decades to the emergence of Corporate Social Responsibility initiatives by organizations. Business organizations want to communicate their active role in pursuing societal overall goals and contributing to sustainable economic growth. How are they incorporating these concerns in actions targeted at their employees? How can Human Resource Management (HRM) research orient practitioners' work in designing and implementing HR practices and systems that incorporate these goals? In the field of work, organizational and personnel psychology, one might find various studies covering the relationship of HRM with organizational performance, productivity, employee commitment and work motivation, as well as the role played by ethical leaders and the integration of human rights concerns in HRM. Corporate sustainable initiatives such as the United Nations Global Compact (UNGC) can guide and support organizations to consider the long-term impacts of their activities by focusing on socially responsible actions. Since 2016, in addition to the protection of labour and human rights universal principles, the UNGC also asks their members to guide their actions in alignment with SDGs, being the eighth Goal, “Decent Work and Economic Growth”.

As a comprehensive concept, decent work (DW) has been studied by various scholars in the area of work, organizational and personnel psychology. The DW integrates the four strategic objectives of the International Labour Organization (ILO): the promotion of rights at work; employment; social protection; and social dialogue, providing a worldwide common language to integrate the discussion about labour rights and conditions.

Research goals:

The main objective of our study was to analyse, describe, and characterize to what extent HRM of the organizations enrolled in UNGC incorporates the concept of DW, leading to a typology of progressive maturity.

Design/Methodology /Approach/Intervention:

Through a documentary analysis of 40 annual reports of Portuguese organizations enrolled in the UNGC, we characterized their HRM practices considering the concept of Decent Work. Qualitative content analysis and cluster analysis based on coding similarity were performed using Nvivo.

Results:

The adhesion of companies to UNGC expresses an intention however, the translation of the intention into HRM practices is a step-by-step process. One output of this research is the design of a maturity typology of adhesion to the UNCG. Furthermore, we present several conceptual

propositions focused on the role played by HRM policy and practices and DW in the company and society.

Research/Practical Implications:

The UNGC, the world´s largest corporate sustainability initiative, aims to improve responsible practices in organizations in alignment with labour and human rights principles, promoting decent work for all. The field of HRM in the last decades has addressed not only its impacts on organizational outcomes but also ethical issues and other fundamental values at work, as it is underlined in the DW concept. This research reflects HRM's concerns with employees' well-being and conditions. It may support the design of future research and interventions leading to more responsible and ethical HRM practices.

Limitations:

As a study based on a documentary qualitative analysis, further empirical investigation, namely using a multi-source assessment of DW dimensions and HRM practices, can enlarge this field of knowledge.

Originality/Value:

To our knowledge, this is the first study discussing the relationships between HRM and the Decent Work concept in the context of UNGC.

Relevance to the Congress Theme:

The knowledge of the practices adopted by organizations in attempting to pursue the values expressed in the UNGC can be helpful in innovative initiatives to be undertaken by corporations in the future. Furthermore, the maturity typology can be an excellent guiding compass that helps organizations in those interventions.

Relevant UN SDGs:

The United Nations Sustainable Development Goal number 8 combines decent work and economic growth, being the most related to the paper's content.

Keywords: Decent Work, Human Resources practices, United Nations Global Compact

Paper 4

Work and organizational psychology and changes in the employment relationship

Keating José, CIPSI, Escola de Psicologia, University of Minho, Braga, Portugal

Research goals and why the work was worth doing:

Some main interactions between psychological science and business practice occur within human resource management (HRM) systems. As the objectives, orientations and methods of HRM systems change, so must change the objectives, orientations and methods of work and organizational psychologists if they are to continue giving relevant input into these organizational processes.

Because some of these changes may negatively affect the quality of the employment relationship and the psychological well-being of employees, the question arises of how work and organizational psychologists can deal with these changes. This research aims to clarify HRM practices that can take into account and obviate the negative effects of these changes in the employment relationship.

Theoretical background

The financial crisis of 2008 brought to the fore the negative consequences of corporate-level decisions on the quality of life in general, and at work, of ordinary citizens. The impacts of this crisis on the employment relationship were profound, persisting even as national economies recover: unemployment and its consequences on the intrinsic value of human resources; the incidence of precarious work and its consequences for work motivation and engagement; and the financialization of the employment relationship predated but were heightened in the financial crisis aftermath. The economic and social crisis, as well as the forced experiments in remote and other alternative forms of work resulting from the COVID-19 pandemic, will likely maintain and reinforce these trends towards a merely transactional and very asymmetric employment relationship.

These corporate strategies and the work experiences they induce have consequences, not always positive, in how people lead their lives. It is relevant, therefore, to examine the consequences of these kinds of jobs on the psychological well-being of the workers involved. Because such consequences, due to the nature of the changes under examination, affect the relationship of individuals to their livelihoods, it makes sense that this examination includes how the societies where these corporate practices take place are affected. The problem, however, is that HRM theories and models are notoriously blind in what concerns the lives and well-being of workers beyond the duration of their involvement in some corporate endeavour.

Design

The results of systematic literature reviews about different areas identified as relevant in this exploration will be presented. The areas explored include (i) the psychological effects of precarious work and unemployment experiences; (ii) the effects of these experiences on citizenship behaviours; (iii) how management and HRM practices may exacerbate, compensate for or attenuate such effects and; (iv) the conditions needed for the implementation of compensating practices.

Results obtained or expected

The complete set of reviews will be finished by December 2022. Work so far suggests abundant literature on the negative effects of the ongoing changes in the employment relationship and a paucity of research on the extra-organizational effects of intra-organizational practices.

Limitations

As a review of the literature, the usefulness of this research is limited by the scarcity of research on the effects of intra-organizational practices on extra-organizational behaviours.

Research/Practical Implications

Identifying practices that modify the effects of changes in the employment relationship is a meaningful contribution to psychological practice in and around organizations. The research gaps identified, particularly how specific interventions may counteract the deleterious effects of changed employment relationships, may be a fruitful area of research.

Originality/Value

The psychological literature on HRM is typically limited because HRM models restrict themselves to the intra-organizational effects of HRM options. A better understanding of management and human resource management options and an awareness of how deep and wide this gap is, is a useful contribution to work and organizational psychology. Widening the scope of the problem to extra-organizational issues may contribute to understanding under what conditions HRM may evolve into a value-based management practice.

Relevance to the Congress Theme:

The review presented in this paper adds a systematization of knowledge on innovation at work, HRM, and managing turbulent contexts.

Relevant UN SDGs:

The present paper focuses on the United Nations Sustainable Development Goal number 8.

Keywords: Human resource practices, Work and organizational psychology, Citizenship

Symposium S118

Workplace bullying: From risk-factor identification to research-based interventions

Gamian-Wilk Małgorzata, SWPS University of Social Sciences and Humanities, Institute of Psychology

science_practice

Workplace bullying is a well-known and clearly defined phenomenon (e.g., D'Cruz & Noronha, 2021; Einarsen et al., 2011), which involves negative behaviour (harassing, offending, socially excluding) occurring regularly and over a period of time. The phenomenon has been related to a variety of negative outcomes both on individual (e.g., Conway et al., 2021; Hansen et al., 2021) and organizational (e.g., Hogh et al., 2021; Salin & Hoel, 2020) levels. Although workplace bullying has been the subject of research for almost four decades, there is a continuous need for evidence-based interventions. By knowing the extent to which organizational and individual factors contribute to bullying escalation, it would be easier to create effective intervention programmes (D'Cruz et al., 2021). In this symposium, we put together five empirical studies to examine the predictors underlying the effective prevention of workplace bullying. The symposium is within the scope of the EAWOP theme as it helps to cope with stress and dysfunction (Topic 15).

In the first study, researchers focus on organizational features being possibly responsible for increased workplace bullying during pandemics. They hypothesized that 1) professional isolation was related to exposure to workplace bullying, 2) isolation via workplace bullying impaired psychological well-being, and 3) psychosocial safety climate moderated this relationship. The results of an online survey (N=1039) revealed that the positive relationship between professional isolation and workplace bullying was indeed strengthened when psychosocial safety climate was low, and vice versa. Moreover, it was found that the negative impact of workplace bullying on well-being was significant only when psychosocial safety climate was low. The researchers conclude that, to develop effective anti-bullying interventions and to promote employees' well-being, organizations need to endorse psychosocial safety climates.

The second study by researchers aims at examining the relationship between both the work environment and vulnerability hypotheses. In a full two-wave panel study (N=253), they have shown that generally the vulnerability hypothesis was not confirmed. Contrarily, the shifts in personality traits (increase in neuroticism and decrease in agreeableness, in extraversion, and in openness to experience) resulted from exposure to workplace bullying. In line with the work environment hypothesis poor workplace conditions predicted exposure to bullying. The study underscores that, to create effective anti-bullying programmes, it is reasonable to focus on limiting organizational risk factors which trigger bullying.

The third study pays attention to the importance of gathering evidence on anti-bullying intervention effectiveness. The researchers conducted a series of intervention evaluation case studies using a mixed-methods approach. A qualitative review was carried out to examine enablers and barriers to effective interventions. The findings highlight contextual and process factors that are significant to intervention design. The researchers' findings provide crucial information on the challenges of evaluating workplace bullying intervention programmes.

The next group of researchers concentrates on the role of bystanders in a preventive intervention. Researchers conducted an intervention project using a full RCT design (N=1500). The findings suggest that intervention was positively evaluated by the participants, yet somewhat less so by bullying victims. However, those bystanders with experience of intervening in bullying situations were even more positive than others.

The final paper provides a good illustration of the urge to focus on organizational interventions, thereby neatly and coherently bringing together all the previous papers which make up this symposium, researchers conducted a systematic review and meta-analysis of 10 studies (N=2014) on the effectiveness of workplace bullying interventions. The results indicate that, although all the interventions studied in the inquiries constituting the meta-analysis were targeting the employee, significant effects following training related to decreasing negative organizational outcomes, instead of individual outcomes. Therefore, it is crucial to create contextual-oriented workplace bullying interventions.

Taken together, all the papers included in the symposium focus on broadening knowledge on improving anti-bullying strategies to prevent organizational bullying risk factors. Importantly, the conclusion from all the five research studies, using diverse methodologies (cross-sectional and longitudinal study, qualitative case studies and meta-analysis), is straightforward: to prepare effective anti-bullying programmes, organizations need to concentrate on eliminating harmful contextual, organizational factors. The five studies included in the symposium will help both researchers and practitioners understand and manage workplace bullying more effectively.

Keywords: workplace bullying, intervention, risk factors

Paper 1

Psychosocial Safety Climate, Prevalence of Workplace bullying, Isolation and Well-being During COVID-19 Pandemic

Nguyen Diep & Teo Stephen T.T. | Northumbria University; Bentley Tim, Edith Cowan University

Research goals and theoretical background: Workplace bullying is a longstanding organizational issue that needs the commitment and involvement of management in protecting workers from health impairment by bullying exposure (Tuckey et al., 2022). Workplace bullying has risen during the pandemic due to role conflicts, limited access to resources, the lack of face-to-face interactions, blurring workplace boundaries, and ambiguity of instructions and supervision (Calderone & Karunakar, 2020; York, 2022). We contend that this situation could be more prevalent in workers who have a state of professional isolation during the lockdowns. One possibility is that these workers could not effectively manage interpersonal relationships and face-to-face interactions with others due to social distancing and lockdown directives (van Zoonen & Sivunen, 2022), similar to the work experience of remote workers (Golden et al., 2008). Another reason could be the rapid shift to flexible practices in organizations, leading to increased pressures, miscommunication, and ambiguity of job tasks and demands (Koch & Schermuly, 2021). Such uncertain changes in work are critical factors that encourage workplace bullying incidents (Nielsen & Einarsen, 2018). However, the existing literature has not shown adequate evidence of these assumptions, although the report from the Workplace Bullying Institute (2021) has flagged an increase in working bullying during the COVID-19 pandemic.

It is pertinent to consider the drivers of workplace bullying and anti-bullying strategies to prevent this psychosocial hazard within a context of professional isolation. Specifically, we will explore whether a professional isolation state is associated with exposure to workplace bullying. Next, we will provide additional evidence on how professional isolation via workplace bullying exposure impairs the psychological well-being (PWB) of employees. Lastly, what is more, we will use the theory of psychosocial safety climate (PSC, Dollard et al., 2017) allows us to understand the moderation effects of PSC in attenuating the adverse impacts of professional isolation and workplace bullying on PWB of employees who may have a state of professional isolation. In doing so, we contribute to the existing knowledge of anti-bullying strategies and PSC by giving empirical evidence of how organizations can protect PWB of employees who may experience mistreatment from others during the global health crisis.

Methods: We collected data during the first wave of Australia's COVID-19 pandemic lockdown in 2020 via the assistance of an online research panel company. An online survey was distributed to Australian white-collar workers from New South Wales. Of the respondents, 1,039 respondents identified themselves as being flexible workers who engaged in some form of working from home during this period. Approximately 21% (N=279) did not work in a flexible capacity. There was an equal number of male-female respondents.

This study adopted previously validated scales. We used the 12-item PSC scale from Hall et al. (2010). Workplace bullying exposure was measured with the short-form Negative Acts Questionnaire (NAQ) by Notelaers et al. (2019). Professional isolation was measured with the scale from Golden et al. (2008). PWB was operationalized with a four-item scale from Brunetto et al. (20112).

Results: Data analysis was conducted using model 59 of Hayes (2016) Process Macro within IBM SPSS v27. We found a significant moderation effect of PSC on the relationship between professional isolation and workplace bullying (β=.04, p<.05), such that the positive relationship between professional isolation and workplace bullying is strengthened when PSC is low, and vice versa. We found that the negative impact of workplace bullying on PWB is significant when PSC is low (β=-.16, p<.001), but not at high PSC.

Discussion and Implications: We argue that a hybrid work design could be the new normal of working lives. Consistent with PSC theory (Dollard et al., 2017), we found support for PSC acting as a buffer of psychosocial risks on PWB in the new normal era. Our study highlights the critical of PSC as the effective anti-bullying strategy to protect PWB of employees. Therefore, organizations need to develop and enact PSC to thwart workplace bullying and enhance PWB of employees. Future studies could validate the findings using a longitudinal design and multiple sources of respondents.

Keywords: workplace bullying, intervention, organisational climate

Paper 2

Vulnerability versus work environment in workplace bullying: Personality traits and organizational features as predictors or outcomes of being exposed

Małgorzata Gamian-Wilk, SWPS University of Social Sciences and Humanities, Institute of Psychology, Faculty in Wroclaw, Social Behavior Research Center; Stale Einarsen, Department of Psychosocial Science, University of Bergen; Agata Gąsiorowska, SWPS University, Institute of Psychology; Eva Gemzøe Mikkelsen, University of Southern Denmark, Department of Psychology; Brita Bjorkelo, Norwegian Police College University / Oslo New University College; Premilla D'Cruz, Organizational Behaviour, IIM Ahmedabad

Research goals and why the work was worth doing: The present research aims to examine the relation between both work environment and vulnerability hypotheses.

Theoretical background: Research on workplace bullying, defined as the prolonged and systematic exposure to negative acts against which the targeted individuals cannot defend themselves (D'Cruz & Noronha, 2021; Einarsen et al., 2020; Yamada et al., 2018), has focused on its consequences for individual health and well-being (Mikkelsen et al., 2020; Conway et al., 2021; Hansen et al., 2021; van Heugten et al., 2021) and its effects on organizational productivity and efficiency (Hogh et al., 2021; Salin & Hoel, 2020). The research on the antecedents of workplace bullying has mostly been focused on investigating the impact of organizational factors (the work environment hypothesis, Hauge et al., 2011; Leymann, 1996) and the personalities of bullying targets (the vulnerability hypothesis, Bowling & Beehr, 2006). Despite the large body of literature on both the work environment and vulnerability hypotheses, there remain important questions that still lack empirical verification (Nielsen & Einarsen, 2018). Importantly, the majority of studies have investigated bullying exclusively within either the work environment paradigm or the vulnerability paradigm. It is essential to include both these two complementary explanations in a single model to test which of the two hypotheses (the work environment hypothesis or the vulnerability hypothesis) better explains exposure to workplace bullying. The present study examines therefore both targeted employees' personality traits and organizational factors (e.g., role conflict) within a single longitudinal study.

Design/Methodology/Approach/Intervention: A complete two-wave panel study was conducted, with a time lag of approximately six months between each wave. Data were collected among 253 employees from several private and public corporations (33.1%), including working students.

Results: Generally, the vulnerability hypothesis was not confirmed, with one exception: high extraversion predicted exposure to bullying. The cross-lagged structural path analyses revealed that exposure to bullying led to increase in neuroticism and decrease in agreeableness, in extraversion and in openness to experience. In line with the work environment hypothesis, the reversed causation model was confirmed, suggesting that bad workplace conditions predict exposure to bullying.

Limitations: The study sample was relatively small. Future research should focus on replicating the findings among larger and more representative samples.

Conclusions – research and or practical implications/Originality/Value: The present research is a test of two complementary hypotheses, the work environment hypothesis and the vulnerability hypothesis. The findings indicate that a drop in extraversion, in openness, in agreeableness and a rise in neuroticism result from the trauma of being bullied. Taking the antecedents and outcomes of

workplace bullying into consideration, we may think of a vicious circle, where affective and behavioural consequences influence back the affective event and its antecedents.

Relevance to the Congress Theme: Our topic is relevant to theme No4: Diversity and Inclusion and theme No14: Stress and Dysfunctions

Relevant UN SDGs: Our research concentrates on such UN Sustainable Development Goals as Good health and well-being at workplace and Reduced inequalities at workplace.

Keywords: workplace bullying, vulnerability hypothesis, work environment hypothesis

Paper 3

A critical reflection on approaches to evaluating workplace bullying interventions: lessons learned from multiple case studies

Charlotte Emmerson, Madeline Carter, Neill J. Thompson|Northumbria University

Research goals and why the work was worth doing: Workplace bullying is recognised as an issue across most organisations, resulting in widespread consequences for individual employees, team performance and the overall functioning of the organisation. A repeated call within the literature is the need to develop evidence-based interventions, however, there remains a lack of published research on interventions.

This paper provides reflexive insights from the authors following their experiences of undertaking several projects that incorporated an evaluation of some form of workplace bullying intervention. The study aims to identify enablers and barriers to the success of workplace bullying interventions and associated evaluations and to present lessons learned.

Theoretical background: Workplace bullying is a persistent problem in organisations (Hoel & Cooper, 2000; Nielsen & Einarsen, 2018). The economic cost to organisations can be significant when taking into account reduced performance, absence and turnover (Giga, Hoel & Lewis, 2008; Kline & Lewis, 2019). The damage to individuals, teams and organisations is widespread resulting in detrimental effects to individual health and performance (Bourdrias et al., 2020; Nielsen & Einarsen, 2012).

A diverse array of workplace bullying interventions are used in practice (Caponecchia et al., 2020) but there remains a disconnect between academia and practice with a lack of robust evidence on interventions (Branch et al., 2021). Research has highlighted the need for evidence-based interventions and stronger theoretical foundations to better inform prospective change programmes (Hodgins et al., 2014).

Systematic reviews carried out on the current state of evidence have identified only a few studies that met high standards of rigour in design (Escartin, 2017; Gillen et al., 2017; Illing et al., 2013).

Overall, there is a lack of documented evidence on interventions (Escartin, 2016), resulting in calls for increased understanding of the practice and efficacy of interventions in greater granularity (Branch et al., 2019; Escartin, 2016).

This paper will illustrate the challenges of conducting workplace bullying intervention evaluation through a review of case studies from applied examples. Building on the work of Mikkelsen et al. (2011), the results will draw upon contextual and process factors that are critical to intervention design (Nielsen & Miraglia, 2017; Pawson et al., 2005). Enablers and barriers to success and lessons learned from these author experiences will be explored.

Methodology: A series of intervention evaluation case studies have been carried out by the authors using mixed-methods approaches. Interventions were designed as training approaches to tackle workplace bullying and incivility. A realistic review was also carried out to examine the existing evidence base. Qualitative reflections from the authors, stakeholders and participants have been collated and reviewed across the cases in order to understand contextual and process issues. These factors can act as potential barriers and enablers in the implementation of interventions and the

undertaking of evaluations that when better understood can provide important learning for future study design.

Results obtained: The results describe the multi-level challenges of evaluating workplace bullying interventions and focus on defining outcomes, evaluation design, stakeholder relationships, data management, process factors and the wider implications of contextual factors. Lessons learned from these themes will be reported with recommendations for improving the design of interventions and evaluation.

Limitations: Data is drawn from the authors' own reflections of involvement in a range of intervention studies, although supported by evidence from participants and stakeholders.

Conclusions: This paper aims to develop a greater understanding of the challenges that researchers face when attempting to evaluate real-world organisational interventions such as those designed to address workplace bullying. This paper will also consider the practitioner perspective, to inform future interventions.

There is a lack of research exploring the contextual and process challenges of evaluating workplace bullying interventions. Furthermore, the call for evidence-based interventions often fails to acknowledge the complexity and challenge of undertaking intervention evaluation research. This paper will help to guide both the design and development of evaluation frameworks and help to inform researchers. It will also aid practitioners involved in intervention delivery to consider how they can build effective evaluation into their design.

Relevance to UN SDGs: This paper is directly relevant to the 'UN Strategic Development Goal 8: Decent Work and Economic Growth' in seeking to promote safe and secure working environments. It also relates to the conference theme facet of the 'future is now'. As workplace bullying is widely acknowledge as an essential change needed at work, we discuss issues on how to deliver on such a change.

Intended audience: Both academic and practitioner

Keywords: workplace bullying, intervention, evaluation

Paper 4

Workplace intervention against workplace bullying and harassment: A bystander approach

Einarsen Kari, Department of Psychosocial Science, University of Bergen / Department of Leadership and Organizational Behaviour, BI Norwegian Business School; Nielsen Morten Birkeland, Department of Psychosocial Science, University of Bergen / National Institute of Occupational Health; Hetland Jørn, Department of Psychosocial Science, University of Bergen; Olsen Olav Kjellevold, Department of Psychosocial Science, University of Bergen / Department of Leadership and Organizational Behaviour, BI Norwegian Business School; Zahlquist Lena, Department of Psychosocial Science, University of Bergen; Mikkelsen Eva Gemzøe, Department of Psychology, University of Southern Denmark; Koløen Justine, Department of Psychosocial Science, University of Bergen / Aker Solutions; Einarsen Ståle Valvatne, Department of Psychosocial Science, University of Bergen

Research goals: Workplace bullying (WB) is an important and prevalent risk factor for health impairment, reduced workability and lowered efficiency among targets and observers. Development and tests of effective organizational intervention strategies is thus highly important. This abstract presents an overview of a bystander intervention and the participants satisfaction evaluation of the intervention. The intervention is a cluster randomized controlled trial evaluating the effectiveness of an organization-wide intervention on preventing WB that focus on promoting active and constructive bystander involvement. The main goal is to develop an easy-to-use organizational intervention based on theory and research on bystanders' role in bullying situations.

Theoretical background: The intervention is based on existing literature and empirical research on bystander behavior (e.g. Paull, etal, 2012; Ng, etal, 2019). The main theoretical assumption is that the actions of bystanders in situations where coworkers are exposed to acts of WB, can either escalate or reduce WB. Hence, stimulating early, active, and constructive involvement by bystanders should prevent further escalation and possibly create an anti–bullying climate.

Thus, the theoretical hypothesis of the intervention is that

1) if bystanders intervene constructively in bullying situation, such intervening will then potentially eliminate further escalation of bullying situations, and

2) if bystanders start intervening constructively in bullying situations, then such intervening will have a preventive effect on counterproductive behavior, i.e. bullying behavior in the organization.

Thus, developing a psychosocial climate in the organization where the norms welcome positive bystander behavior, and at the same time enhance the employees' perceived bystander behavior control, is crucial in combating WB in organizations.

Method: Using a full RCT design, this intervention project empirically tests the outcomes of an intervention program targeting bullying as the main distal outcomes and perceived behavioral control and helping behavior among bystanders as the main proximal outcome. A one-year cluster randomized controlled design is utilized, in which controls also receive the intervention. About 1500 workers from two different locations of an industrial company are randomized into one intervention group and two control groups with at least 400 workers in each group. A survey based on the theory of planned behavior (Ajzen, 1991) are conducted electronically totally three times. Thus, the data collections take place at baseline, completion of the intervention and at four months follow-up. Also,

a survey evaluating the participants satisfaction with the intervention are sent out immediately after their participation in the group sessions (i.e. the intervention).

The intervention is based on an existing workplace intervention developed by researchers and practitioners in Denmark (Mikkelsen & Hogh, 2019). The present intervention is customized to a Norwegian industrial setting by the authors, representing both researchers and practitioners. The intervention program contains a planning meeting, and a three-hour group session.

Results: The preliminary results show that the intervention was positively evaluated by the participants, yet somewhat less so by bullying victims. However, those bystanders with experience of intervening in bullying situations were even more positive than others.

Limitations: The survey instruments are all self-report measures, and the project is thus subject to limitations specific to self-report instruments such as response-set tendencies. The survey data are also measured from the same source, yet at different timepoints. As such, common method variance may inflate the relations between constructs somewhat (Podsakoff, et al. 2003).

Research: This study primarily aims to develop, implement, and evaluate an intervention based on the abovementioned features with the aim of reducing the prevalence of WB, by focusing on bystanders. The preliminary result of the intervention shows that there are some factors predicting the satisfaction of the intervention; being a bullying victim, and prior experiences as an intervening bystander in bullying situations. Given the scarcity of evidence on effective interventions for preventing and managing workplace bullying, this study is important and timely, and may enhance our knowledge on how organizations may focus their efforts and resources in combating workplace bullying.

Originality: This project address important knowledge gaps in research on workplace interventions against workplace bullying, focusing on the role of bystanders in a preventive intervention. By examining mediating and moderating variables in the relationship between perceived bystander behavior control and outcomes, this project will generate novel knowledge important for extending and developing the theoretical basis of our understanding of bystander behavior.

Keywords: workplace bullying, intervention, bystanders

Paper 5

Effectiveness of Workplace Harassment Interventions: A Meta-Analysis

Iván Sánchez-Iglesias & Mirko Antino | Universidad Complutense de Madrid; William Fernando Duran, Pontificia Universidad Javeriana; Alfredo Rodríguez-Muñoz, Universidad Complutense de Madrid

Research goals and why the work was worth doing: A large literature examines the antecedents and effects of harassment in the workplace. However, research on interventions to prevent or mitigate the effects of bullying is less abundant. We conducted a meta-analysis of studies on the effectiveness of workplace harassment at work.

Theoretical background: Despite the crucial role of interventions in preventing harassment at work, this field has many limitations. For example, the interventions delivered in workplaces often vary in terms of content, dose, and method used. Similarly, the conceptualization of harassment changes between interventions (e.g., workplace bullying, incivility, social exclusion, etc). The result is a heterogeneous number of studies.

Design/Methodology/Approach/Intervention: We provide a systematic review (for the period of 1980-–2022) of the published and unpublished literature, in ProQuest, Pubmed, Scopus, Cochrane Library, and WHO International Clinical Trials Register. Meta-effect estimates (Hedge's g) were computed using data from 10 studies (N=2014).

Results obtained: All the interventions included in the study were targeting the person (100%), not the environment, with a variety of contents (e.g., cognitive reappraisals, expressive writing, or mindfulness-based intervention). Preliminary results indicate significant effects following training for decreasing negative organizational outcomes ($p<0.05$), but not for individual outcomes.

Limitations: The small number of studies included, that some of them did not provide detail about attrition, and that follow-up was not always reported either, may potentially limit the scope of this study.

Research/Practical Implications: Based on our study, it is clear more organisational interventions are needed to alleviate this problem. This is particularly important if we take into account that the main antecedents of harassment are contextual, and all interventions are employee oriented.

Relevance to the Congress Theme: Our research is in line with the congress delivery line. How do we mitigate harassment? Is it effective?

Relevant UN SDGs: This research relates to the UN Sustainable Development Goal of decent work and economic growth.

Keywords: workplace bullying, intervention, meta-analysis

Fair Judgement and CV Evaluations: The Impact of a Nudging System on Cognitive Biases amongst Recruiters

Julia Lotova, HR Practitioner; Vincent Cassar, University of Malta

science&practice

Despite being an indispensable tool in hiring, the process of CV evaluation appears to be highly biased. This research had two main goals – analysing the extent to which recruiters engage in cognitive bias when evaluating CVs and whether nudging could improve the judgement reliability of recruiters.

The literature on CV evaluation points towards two core issues: firstly, the CV as a selection tool does not provide the necessary insights into predicting the future performance of the candidate, and secondly, recruiters are highly biased when assessing resumes. The hiring recommendation is often subject to error because of biases like Anchorism which does not allow the recruiter to take a fair and reasonable assessment of the applicants' qualities which are relevant to the job. Looking at the large body of empirical evidence, it appears that nudges mainly work in situations where the decision-maker has limited access to information or short attention spans (Löfgren and Nordblom, 2020). Nudges are therefore techniques that aim at using heuristics from System 1 Thinking (Tversky and Kahneman, 1974; Kahneman, 2003) to alter the decisions in a subtle way, leading to a more rational reconsideration of choice.

The experimental design implemented for this study collected data from experienced professionals in the field of HR and Recruitment. After splitting the participants into a control and an experimental group, the efficacy of the nudge was tested. Participants of the experimental group were asked to review CVs with the help of our nudging instrument, which was essentially a 'Candidate Checklist' that gave fair weighting to a wide set of elements deemed by job experts as important for the job.

Overall, the results suggest that recruiters in both research groups are likely to engage in cognitive bias, however, this is seemingly less, although not excessively, amongst participants exposed to the nudge. Furthermore, this study suggests that the nudge can improve the perceived suitability of applicants by cueing recruiters to consider more CV deducible qualities. Keeping all aspects constant, results strongly suggest that a nudge can enhance the selection process and quality decision of the recruiter.

Given the short time frame of this study, the window for participation was limited and recruitment of participants was difficult. Moreover, this experiment was conducted under non-laboratory conditions – the materials were sent to participants via email and there was no control over whether the participants of the experimental group used the checklist as instructed or not.

The nudge seems to interfere in the CV evaluation process by diverting the focus of the recruiter towards job-relevant information on the resume, resulting in a more rational judgement. The concept of nudging in CV evaluation also contributes to a structured procedure of CV review.

The practical implications of this study are relevant for all hiring professionals since the nudge can be introduced as a minor intervention in their daily routine.

This research incorporates several topics in one. Firstly, the impact of new technologies on the recruitment process – to what extent can automated systems reduce error and decision risk as well as improve decision-making in hiring? Secondly, the research contributes to a more uniform and structured selection process, creating a fairer environment for applicants to be judged, based on their qualifications rather than non-job-related attributes.

Keywords: Decision-making and control, Person-job fit, Candidate Perceptions

Poster P002

EMPLOYABILITY, CAREER ADAPTABILITY AND PSYCHOLOGICAL CAPITAL AMONGST NON-DEGREED YOUTH AT AN EDUCATIONAL INSTITUTION

Rudolf M Oosthuizen, Jean Van Vuuren & Linda Steyn | University of South Africa

science

Research goals: The study investigated the relationship between employability, career adaptability and psychological capital amongst non-degreed youth at an educational institution.

Theoretical background: The world of work is evolving and dominated by the demands of the fourth industrial revolution (4IR) and ever-faster technological developments. Employability, rather than just finding employment, is required today. Consequently, employees, but increasingly so, the youth, needs to adapt and adjust their skills, knowledge, and behaviour to maintain employability in our contemporary work context. To remain employable, people must adopt a protean career by adapting to their circumstances and updating their skills and knowledge to stay relevant in the 4IR work environment and contribute to their employer's success.

Research Design, Approach and Method: This study used a cross-sectional quantitative, non-experimental research approach to evaluate the interrelatedness of variables. A biographical questionnaire, Employability Attributes Scale (EAS), Career Adapt-Abilities Scale (CAAS) and Psychological Capital Questionnaire (PCQ-24) were utilised to collect data. A non-probability approach was followed to select the participants, using a convenience sampling method. There were 263 participants in the sample group. Descriptive statistics and correlation statistics were used to analyse the data.

Results: The results demonstrated a strong positive significant relationship between employability and career adaptability, employability and psychological capital and career adaptability and psychological capital. The relationship between employability and career adaptability was more substantial than the relationship between employability and psychological capital. There was also statistical evidence of significant statistical differences at a demographic level.

Limitations: A longitudinal study is recommended to investigate the changes in perceived employability, career adaptability and psychological capital over time given the influence of technological advancement and what the possible causal links may be.

Research/Practical Implications: The contemporary work environment is volatile due to the pressures of the 4IR. Therefore, there is an ever-increasing need to equip youths and new entry workers with the attributes that ensure employability and the know-how to adjust their careers according to the demands of the work environment. There is also a need to aid them in strengthening their psycho-social career resources to help them cope with changes in their career and to help them maintain employability.

Relevance to the Congress Theme: The results of the study suggest that developing youth in educational institution's employability attributes as well as their career adaptability factors, together with psychological support factors such as resilience and efficacy, may strengthen their self-perceived employability and how well they adjust their careers to a changing 4IR world of work.

Relevant UN SDGs: The research is meaningful in its value as it contributes to the Sustainable Development Goal of Decent work and economic growth regarding how employability, career adaptability and psychological capital relate to each other. It is also a study focusing on a South

African view on this combination of variables and how professionals can use it to the advantage of South African youth.

Keywords: career adaptability, employability, psychological capital, psycho-social career resources, fourth industrial revolution

Poster P003

Empowerment of Women Leaders in the Fourth Industrial Revolution

Rudolf M Oosthuizen, University of South Africa

science

Research goals: The aim of the study is to explore the empowerment of women leaders in the Fourth Industrial Revolution (4IR).

Theoretical background: Leaders require a certain set of proficiencies to effectively lead organisations and to be aligned with the 4IR. Research has shown that women leaders recognise the need to be empowered in a rapidly changing technological environment. Compared to previous industrial revolutions, the 4IR is evolving at an exponential rather than a linear pace. It is important to shape the 4IR to ensure that it is empowering and life-centred instead of divisive and dehumanising. This is the work of leadership. To deal with the complex challenges of the 21st century, new ways of knowing and leading will be increasingly important. In the 4IR, leaders will need to be more agile, human-centric and adapted to a highly volatile, uncertain, complex, and ambiguous world. Ultimately, the challenges of the 4IR may empower women leaders to connect more readily with the wisdom of knowledge and facilitate the change and transformation needed to ensure a sustainable future.

Research Design, Approach and Method: The critical review of the research literature entailed a broad systematic review of contemporary research on the empowerment of women leaders in the 4IR. A qualitative approach was followed which enabled the author to evaluate documented research on the empowerment of women leaders in the 4IR.

Results: Empowered women leaders exhibit high levels of human intelligence, which are made up of the four types of intelligence (strategic, emotional, inspired, and somatic) that determine 4IR-Intelligence. Empowerment of women leaders in a VUCA world are highlighted that help build employees' psychological capital as a reliable source of competitive edge during the 4IR.

Limitations: Potential publication bias could be viewed as a limitation of the study.

Research/Practical Implications: Future research could focus on the narratives of successful empowered women that navigated this arduous journey in a VUCA world that requires certain mindsets and behaviours from women leaders that are different from those required in the past.

Relevance to the Congress Theme: Owing to the ever-changing 4IR world of work and evolving 4IR technologies, a creative approach to leadership is crucial. The study highlights the empowerment of women leaders that embrace 4IR leadership essential for success in this 4IR world. This necessitates the incorporation of the principal concepts of a transformation attitude.

Relevant UN SDGs: The research is meaningful in its value as it contributes to the 2030 Agenda for Sustainable Development, with the Sustainable Development Goal of Decent work and economic growth. Women leaders applying 4IR intelligence in their day-to-day operational tasks is a key competence to deliver results and promote advancement in addition to the competence to motivate employees to aspire to the vision and mission of an organisation.

Keywords: Women's empowerment, Leadership, Transformation, Women leaders, Fourth Industrial Revolution

Poster P007

Telework demands/resources and burnout: The mediating role of work-life conflict

Rodanthi Lemonaki, HELLENIC TELECOMMUNICATIONS AND POST COMMISSION

science&practice

Purpose : Following the covid-19 pandemic, a considerable proportion of employees continue to work from home, as telework became the norm for many jobs that it was technically feasible (tele-workable jobs). This leads to blurred boundaries between work and personal life. The aim of this research was to explore how specific telework demands and resources relate to the core dimensions of burnout (exhaustion and disengagement), via their association with work-life conflict.

Theoretical background: Based on the job demands–resources model, it is argued that telework demands and resources relate positively/negatively to work–life conflict. Moreover, COR theory proposes that work–life conflict may lead to a wide variety of stress reactions (i.e. exhaustion, disengagement), because valued resources are lost in the process of management both work and personal life roles. In line with these assumptions, it is hypothesized that telework demands/resources have an indirect positive/negative relationship with the core dimensions of burnout (exhaustion/disengagement) via their association with work-life conflict.

Methodology : One-hundred thirty-one employees of a Greek Independent Administrative Authority participated in the study. Employees, assessed via self-reports telework demands/resources, work life conflict exhaustion and disengagement. Hypotheses were tested by means of path analysis with manifest variables using the AMOS v.26 software package. A model with paths from job demands/resources to work life conflict and to exhaustion/disengagement respectively fit to the data. Moreover, the hypothesized model included paths from work life conflict to exhaustion/disengagement respectively. This model was a fully saturated model and as such had a perfect fit to the data.

Results : All examined telework demands (continuous availability/connectivity, boundaryless working hours, intensive use of ICT) and telework resources (flexible working hours, saving time on commuting to work and job autonomy), have been found to significantly associate with work life conflict (Hypothesis 1 & Hypothesis 2). Work life conflict was, in turn, significantly associated with employees' exhaustion and disengagement (Hypothesis 3 & Hypothesis 4). Particularly, work life conflict mediated the relationship between telework demands/resources and exhaustion/disengagement link (Hypothesis 5 & 6).

Limitations: The research used data collected from a self-report questionnaire developed for practitioner's research. As such, there is a risk of misunderstanding of questions and subjectivity in the interpretation of the scales. Moreover, this study is based on cross-sectional survey data which inhibits causal inferences of the investigated relationships.

Research/Practical Implications . For a successfully telework related wellbeing, organizations need to focus on decreasing high telework demands (e.g., boundaryless working hours, intensive use of ICT) and increasing telework resources (e.g., flexible working hours, job autonomy). Organizations should strive to educate their managers to support work-life balance and offer a variety of programs that meet the exact needs of their employees, maintaining with this way, good levels of work-life balance, which consequently leads to low levels of exhaustion and disengagement.

Originality/Value. Results shed light on the psychological processes that may underlie the association between telework demands/resources and exhaustion/disengagement link.

Keywords: burnout, telework demands/resources, work life conflict

Poster P008

Relationship between work–family conflict and life outcomes: does position matter?

Tadas Vadvilavičius & Aurelija Stelmokienė | Vytautas Magnus University

science

The aim of this research is to analyze how does a position in organization (leading vs. following) moderate the relationship between work–family conflict and different life outcomes: happiness, life satisfaction, job satisfaction, and subjective general health. The ongoing debate about desirable leadership position in mass media and the lack of unambiguous insights from scientists on this topic was the main trigger for the research.

Theoretical background: Studies have found that work–family conflict may lead to various negative consequences, e.g., lower job/family/life satisfaction (Kossek et al., 2011; Zhao et al., 2020). However, what kind of effect does a position in organization have on the relationship between work–family conflict and different life outcomes is barely analyzed. Leader`s position is perceived as the most important position in organization that can lead any organization to success or failure (Antonakis & Day, 2017; Chemin, 2021). Therefore, this important role is often related with higher resources and higher demands, as well. The question remains – higher demands or higher resources win, especially when we talk about work-family conflict and its negative outcomes.

Methodology : European social survey (ESS) data (Round 10, year 2020-2022; v1.0) was used for the analysis. Data from 10 European countries (n=18060) was used. 3826 participants from the sample were supervising other employees. There were 9960 females, from which 1747 were leaders. Average age of employees was 51.99 (SD=17.45), while average age of leaders was 53.56 (SD=16.36). Average years of full-time education completed for employees was 12.88 (SD=3.52) and for leaders - 14.61 (SD=3.60). Finally, average number of employees leader has/had – 10.24 (SD=49.19). Work–family conflict was measured using three-item scale developed for ESS (α=.77), while happiness, job and life satisfaction, and subjective general health were measured using one-item each.

Results : Analysis revealed significant difference between leaders and non-leaders in: work-family conflict, subjective happiness, subjective satisfaction in life, subjective general health, and subjective job satisfaction. Leaders perceived higher work-family conflict, felt more happiness, were more satisfied with life and job and had better health in comparison with employees. Moderation analysis revealed that position in organization moderated (-.26, CI 95% [-.38; -.15]) only the relationship between work–family conflict and subjective job satisfaction (R 2 =.11, F=370.98, p<.001), meaning that having an employee position weakens the negative relationship between work–family conflict and job satisfaction (more conflict, less satisfaction).

Limitations: Although ESS provides methodologically very valuable and comparable data, majority of variables are being tested using only one item/question, which often is a debate if a single item is enough to measure the construct.

Research/Practical Implications : Future studies need further and deeper investigation of differences between leaders` and follower`s perceived job demands and resources and how do they affect work–family interaction. Meanwhile, practitioners should pay more attention to leaders` perceived work–family conflict and finding ways to help them manage both work and family duties. In most cases, leaders are perceived as resources to help employees manage work and family life, however less attention is paid to them.

Keywords: work-family conflict, life outcomes, position

Poster P009

Reduction of time and performance pressure - Five fields of action

Anika Schulz-Dadaczynski, Federal Institute for Occupational Safety and Health

science&practice

Research goals and why the work was worth doing

Many employees have to deal with time and performance pressure (TPP) in their everyday work. Research shows that TPP is a relevant risk factor for employee's health and well-being. Therefore, work design to reduce TPP and to foster a good coping with TPP is a key requirement for companies. Nevertheless, companies and occupational health and safety stakeholders are often overwhelmed by this requirement and are reaching their limits. Against the background of current work design knowledge, five fields of action for the reduction of TPP were identified which could give guidance to companies and their stakeholders.

Theoretical background

The five fields of action to reduce TPP are based on the results of several research projects which took place from 2012 to 2022. They covered different theoretical backgrounds relevant for the demand of TPP, such as the job-demand-control-model or the job demands-resources model but also more current models like the demand-induced strain compensation model.

Design/Methodology/Approach/Intervention

Data and results of several prior research projects concerning work design to reduce TPP or to cope better with existing TPP were reviewed and processed in an overarching manner. In addition, an expertise was commissioned to prepare the current state of knowledge on work design measures to reduce TPP. Based on the analysis of all results five thematic fields of action were derived.

Results obtained or expected

The five thematic fields of action for the reduction of TPP are: 1) to obtain a balance between demands and resources, 2) to create transparency and smooth workflows, 3) to ensure necessary autonomy at and over work, 4) to develop, communicate and live a realistic and health-compatible performance culture and 5) to create a caring climate in the company and to live mutual care. The five fields of action contain both condition-related as well as behavior-oriented measures to reach the aims. They address different design levels from the organizational level to the team and task level down to the level of individual employees.

Limitations

The current work design knowledge for the reduction of TPP was prepared only for the context of service and knowledge work, mainly for German companies. The transferability of the five fields of action to other contexts and companies needs to be assessed.

Research/Practical Implications

The five fields of action could guide work design processes in companies with the aim of reducing the important demand of TPP. The integration of the five fields of action in an action aid for companies is planned and subject of a current research and development project.

Relevance to the Congress Theme

The reduction of TPP plays a central role for employees' health and well-being. Therefore, orientation and guidance for companies to reach this aim is necessary.

Relevant UN SDGs

The research contributes to the aim of health and well-being as well as to the aim of decent work.

Keywords: time and performance pressure, work design, psychosocial risk management

Poster P011

Effort-Reward-Imbalance within a PhD Student Population: Development and Validation of the Effort-Reward-Imbalance Scale for Doctoral Students

Melanie Vilser, Dieter Frey & Irmgard Mausz | Ludwig-Maximilians-University Munich

science

Theoretical background: Many studies show that high stress is common during gaining a PhD degree. Nevertheless, there is no common standardized instrument to measure work stress of PhD students and explain the adverse health effects of stressful work experiences.

Research goals: To capture work stress, we adopted the Effort-Reward-Imbalance (ERI) Scale for doctoral students and tested it in a sample of PhD students gaining a doctoral degree in Germany.

Design: We calculated Item-total correlations and Cronbach´s alpha to assess the internal consistency and used exploratory and confirmatory factor analysis to test the theoretical structure of the tool. Criterion validity was demonstrated by investigating the association of the PhD-ERI with respondents' burnout.

Expected Results: We expect that our calculations in August 2022 are going to show, that the PhD-ERI questionnaire has good overall validity and reliability and that the ERI differs according to sociodemographic factors. Also, it is assumed that a high level of burnout is associated with a high ERI.

Limitations: The study focuses on PhD students, which gain a doctoral degree at German universities.

Implications & Conclusion: It will be assessed whether the PhD version of the ERI questionnaire is a valid and reliable new instrument for assessing the psychosocial work environment of PhD students. As this current study is the first of this kind further analyses are needed with an international doctoral sample.

Relevance to the Congress Theme: Considering current debates about the working conditions and the academic contract law there is a need for a discussion and implementation for a healthy working environment among PhD students.

Keywords: Effort-Reward-Imbalance, Burnout, PhD students

Poster P012

Effort-Reward-Imbalance in Judges

Melanie Vilser, Irmgard Mausz & Dieter Frey | Ludwig-Maximilians-University Munich

science&practice

Theoretical background: Judges state a lot of different burdens in their professional work due to very high job demands, such as highly emotional cases, high time pressure and workload. At the same time rewards are perceived very little leading to the feeling of a lack of social reciprocity between the effort given into the job and the reward gained. We propose, that the Effort-Reward-Imbalance model (ERI) and its additional component overcommitment (OC), a well-known model to explain work stress and occupational health, might explain judges' work stress. However, the exact relations between ERI and OC have not been cleared up so far. Originally an interaction hypothesis between ERI and OC was proposed, but many studies failed to support the hypothesis (Siegrist & Li, 2016). Recent studies recommend using OC as a mediator within the framework of the ERI model. This study is one of the first to follow this recommendation proposing OC, defined as exessive motivation to expose oneself to demanding work, to mediate the relationship between ERI and well-being. Additionally, we assumed self-efficacy to buffer negative consequences as it is proven to be a valuable protective factor in the stressor-strain relationship.

Research goals: In the present study we shed light on the relationship between effort-reward-imbalance and well-being over time in the highly demanding profession of judges. Key indicators of well-being (perceived stress and job satisfaction) were examined. Furthermore, we proposed the process in which overcommitment is a potentially harmful coping mechanism by mediating the forenamed relationship. A protective factor on the individual level (self-efficacy) was identified.

Design: In a survey 713 judges in Germany participated in a two-part online study (time lag of 8 weeks). To test this study's hypotheses we calculated two parallel moderated-mediation analysis run with the PROCESS macro for IBM SPSS Version 24.

Results: As hypothesized, ERI predicted both a reduction in job satisfaction and an increase in perceived stress over time through increased OC. However, when the judges showed self-efficacy to a high degree, the mediation with job satisfaction dissolved. No moderated mediation was found for the model with perceived stress as an outcome.

Limitations: We have obtained our data through self-reports which may have caused common method bias. Additionally, due to our research design, we were not able to draw casual conclusions and therefore reversed causality is possible for our line of arguments.

Implication & Conclusion: We addressed a gap in the literature analyzing the process in which OC is mediating the relationship between ERI and judges' well-being and job satisfaction. The results of this study help to gain a better understanding of the detrimental role of ERI as well as OC on judges' well-being over time. Furthermore, by identifying self-efficacy as a protective factor in the ERI process, that is open to change, the present study brings along important implications for practice.

Relevance to Congress Theme: We followed a call for research to test the mediation hypothesis linking the ERI model with occupational well-being at work via OC. We have added further value through our specific target group of judges, which, to the best of our knowledge, has not yet been considered in the context of the ERI model. By introducing the protective factor of self-efficacy into the ERI model, we also contributed to practice.

Keywords: Effort-reward-imbalance, overcommitment, well-being

Poster P013

Does Off-Work Volunteering Promote Work Creativity? A Lab Experiment

SinHui Chong, Richelle Adarsh, Dawnn Xingyi Lim & Amanda Chia | Nanyang Technological University, Singapore

science

Volunteerism cultivates aÂ cohesive societal foundation for commercial companies to thrive, but welfare organizations often face volunteer shortage. Adults often cite formal job responsibilities for not volunteering, but this research suggests that off-work volunteering can promote work creativity. The findings will show how contributing to societal good via volunteering can benefit volunteers and their formal employers too.

Based on construal level theory, we hypothesize that volunteering for causes more psychologically distant exposes one to diversity, which expands oneâ€™s tendency to accept inconsistencies (dialectical thinking). This will promote creativity in oneâ€™s formal job, especially if one focuses on the broad meaning as opposed to specific features of volunteering (high construal level) as they will recognize and integrate the inconsistencies more effectively.

A lab experiment was conducted. Undergraduate participants reported their trait construal level before engaging in aÂ volunteering task to help someone who is psychologically close or distant. They reported their state dialectical thinking before completing aÂ creativity task to develop ideas for aÂ school-related issue. Trained research assistants blind to the hypotheses would rate the creativity of these ideas.

Data collection and analyses are ongoing, and results will be presented at the EAWOP Congress. We expect the creativity ratings of participants in the high construal level Ă— high psychological distance condition to be significantly higher than those in the low construal level Ă— low psychological distance condition.

The experimental design might have low fidelity, thus we plan to follow up with aÂ field study using full-time employees who volunteer during their off-work hours.

This research aligns with the congress theme because it explores the novel idea that individuals may possess multiple work identities straddling paid and unpaid domains. It also looks at how to integrate beneficial spillovers from the social sector (volunteering) to the commercial sector (formal job).

This research contributes to UN SDG #11 (Sustainable Cities and Communities) that emphasizes inclusive and resilient communities. Our findings offer insights into how unpaid volunteering that benefits the marginalized in society can also benefit employees and their employers.

The third, fourth, and fifth authors contributed equally and are listed by alphabetical order of first names.

Keywords: volunteering, creativity, dialectical thinking

Poster P014

A systematic review of the link between process factors and outcomes in work-wellbeing interventions for healthcare staff

Ella Hatton, University of Sheffield/Arden University; Karina Nielsen, Cristian Vasquez & Ray Randall |University of Sheffield

science&practice

Consideration of how work-related wellbeing can be enhanced through interventions for healthcare workers is of utmost importance for multiple reasons, not least the relationship between work wellbeing and patient safety (Hall et al., 2016).

Process factors are gaining more traction in being paramount to evaluating organisational interventions, including those focused on work-wellbeing, in order to understand why and how such interventions can change outcomes. These can include factors pertaining to; intervention factors, such as implementation strategy; and mental models, including organisational readiness for change; and context, such as barriers and facilitators to implementation (Nielsen & Randall, 2012).

It is important to consider how intervention process factors can influence the outcomes of such interventions, outside of the intervention content itself. However, a recent systematic review of quantitative measures of process factors found that a limited number of studies investigated the relationship between process factors and intervention outcomes, such as wellbeing (Nielsen et al., 2022). There is a current lack of systematic reviews that investigate relationships between process factors and wellbeing outcomes in studies using qualitative and mixed-methods approaches, as well as limited reviews concerning process evaluation within work wellbeing interventions in healthcare staff. This systematic review will therefore address this gap by addressing the research question 'How do process factors affect outcomes in work-wellbeing interventions for healthcare staff?'.

This review will consist of results from searching databases including APA PsycINFO, MEDLINE and CINAHL, using search terms that pertain to 'organisational intervention', 'healthcare staff' and 'process evaluation'. Studies are included if; they report on an organisational wellbeing intervention; participants are any kind of physical or mental health worker that work directly with service-users; report on least one process factors and how they affect work-wellbeing outcomes; primary outcomes are related to work wellbeing, including physical and psychological; a qualitative and/or quantitative methodology is employed; they are published in peer-reviewed journals. Limitations of publications written in English language and those published between 2012 and 2022 are applied to the search. Results will be synthesised using a narrative approach as opposed to a meta-analysis, due to the inclusion of quantitative, qualitative and mixed-method research; lack of ability to account for the diversity of organisational settings within healthcare (Blamey & McKenzie, 2007); as well as the participatory process that may be utilised within included studies (Nielsen & Miraglia, 2017).

Anticipated implications of the systematic review will include informing on relevant process factors, such as multi-level contexts, that should be considered in the design of participatory organisational approaches that aim to enhance the work wellbeing of healthcare staff.

Keywords: Wellbeing interventions, process evaluation, healthcare staff

Value creation in the modern organizational context: A systematic overwatch of its' antecedents, mechanisms and consequences

Christodoulos Katsaitis, Undergraduate student

science

The multidimensionality of value is not an easy concept to grasp. As a concept, it is interdisciplinary by nature, since it has made its appearances on sociology, philosophy and at last, psychology, where it is conceptualized as an influential and malleable mental structure, that enjoys special implementation in the workplace, serving a multitude of beneficial mental functions for the individual. While it also has being defined differently throughout the centuries, its' solid theoretical background has led us to the conclusion that It is not limited to an economic aspect, but can take many other forms, respective to each individual's motives, with our focusing being on Lackeus' conceptualization of value as a reference point, which includes social, influential, enjoyment, harmony and economic value. Value can be created and maintained through psychological mechanisms that influence the outcome of the effect of certain organizational factors, otherwise commonplace in the organizational context, with the most prominent ones being commitment, creativity, motivation, productivity, human and social capital, certain organizational cultures, fulfillment of psychological contract and opportunity capitalization. After being created, a new dichotomy seems to be evident in the literature: value can either be captured, ostensibly staying within the context of the same organization that created her in the first place, or slipping outside of its borders. On the latter case, the organization seems to lose the strategic advantage it possessed by creating a specific kind of value. Therefore, our literature review explored the previously under-researched field of organizational value creation and its' outcomes.

Keywords: value creation, value capture, value slippage

The people practitioner of the future: Identity, role and contribution

Dieter Veldsman, AIHR

science&practice

The transformation of the technology-enabled workplace has a significant impact on the future professional roles, services and capabilities of both the human resource professional (HRP) and industrial/organisational psychologist (IOP). The present study aimed to identify the intersecting professional personas and capabilities that speak to both the HRP and IOP as people practitioners of the digital era.

The study builds upon two previous research papers. The first focused on the key employer perspective of what the people practitioner of the future role should be, while the second provided a thematic overview of four digitally-dexterous capabilities proficiency domains and six professional personas relevant to the technology-enabled working environment. In this paper, we utilize these insights to further explore the people practitioner capabilities required in the future through an integrated perspective. First, we discuss the professional in the context of professional identity, and the contribution towards organizations and society; next we discuss the people function of the future and last, we propose 3 future scenarios impacting the people practitioner of the future.

The study adds to the research literature on the shifting roles and capabilities of IOPs and HRP as future people practitioners in technology-enabled hybrid and virtualised work environments.

Keywords: skills, people practitioner, competency

Conceptualisation of Hybrid Work: Where, When and How Do We Work in the Future?

Johanna Bernhardt, Pascale Le Blanc & Anna-Sophie Ulfert | Eindhoven University of Technology

science&practice

Purpose : Due to the recent pandemic and accelerated digitalisation, organisations are forced to adopt new ways of working. Employees have more flexibility in where, when, and how they work, which is often referred to as hybrid work. However, there is not yet a formal definition. Therefore, the purpose of this research is to provide a conceptualisation of hybrid work and identify factors that influence employees' choice of their work arrangement.

Theoretical background : So far no scientific conceptualisation of hybrid work has been established. Research has been conducted on relating concepts, for example, telework and Flexible Work Arrangements (FWA) focusing mainly on remote work and time-spatial flexibility. However, the aspect of how we collaborate with co-workers, i.e. via Information and Communication Technology (ICT) or face-to-face, has not yet been taken into consideration. To bring these elements of hybrid work together this research will focus on three dimensions: place of work, working time, and virtuality. Additionally, factors influencing the decision employees take when choosing their work arrangement will be identified.

Design : A case-study design with a leading food & beverage organisation will be used to validate and expand the three proposed hybrid work dimensions through literature review and qualitative interviews. Therefore, semi-structured interviews will be conducted with knowledge workers currently working in a hybrid work environment. A random sample of employees (N=12) from different functions (Supply Chain, Sales, Marketing, Enabling Services), level, age and tenure will be interviewed on their hybrid work routines as well as preferences and needs. The interviews will take place end of 2022/ beginning of 2023 and first results will be available to present at the EAWOP conference.

Results expected : Considering the recent changes in ways of working, it is expected that hybrid work will differ from relating concepts. The conceptualisation of each of the mentioned dimensions is not expected to be different from earlier research, but rather that their extent and their availability varies depending on organisational policies and employees' personal circumstances and preferences.

Limitations : Generalisability will be limited due to focusing only on one global organisation with specific processes and culture. Additionally, will the interviews be conducted at a certain point in time. As employees are still adapting to hybrid work and their approach and preferences change over time, this is also a limitation.

Research/Practical Implications : Through conceptualising hybrid work this research will provide a basis for further research on future work arrangements and it will support organisations by providing a better understanding of hybrid work and its implementation.

Relevance to the Congress Theme : This research relates to EAWOP by focusing on the changing world of work and exploring how employees will work in the future.

Relevant UN SDGs : By focusing on how employees will work in the future and identifying their preferences and needs, this project is in line with the UN sustainable development goals number 3 ('Good Health and Wellbeing') and 8 ('Decent Work and Economic Growth').

Keywords: Hybrid Work

Poster P018

Organizations as non-human, abstract attachment partners – How are general and organizational attachment related?

Tammo Straatmann, Anna Maria Engel, Marina Schefer & Patrick Hofschröer | Osnabrueck University, Germany

science&practice

Attachment theory has become increasingly recognized in the organizational context (Yip et al., 2018). Yet, the growing body of research has mostly focused either on general attachment (e.g., Klohnen et. al., 2005) or on relationship-specific attachment (e.g., towards the supervisor: Game, 2008; towards other people at work: Leiter et al., 2015; or towards the organization itself: Feeney et al., 2020). The purpose of the present study is to extend existing research by empirically examining relationships between general attachment and the newly developed relationship-specific organizational attachment scale (Feeney et al., 2020).

Attachment theory proposes that human behavior in relationships is influenced by two dimensions of attachment – namely attachment avoidance and anxiety (for a review, see Brennan et al., 1998). Attachment avoidance refers to doubts about the trustworthiness of the attachment figure (cf., Brennan et al., 1998) and attachment anxiety is concerned with negative expectations of self-worthiness in the relationship (cf., Bartholomew, & Horowitz, 1991). Whereas general attachment develops based on the history of relationships with diverse others (e.g., Klohnen et al., 2005), relationship-specific attachment reflects unique dynamics tied to a specific attachment partner (e.g., Game, 2008). In the case of organizational attachment, the attachment partner is the organization (Yip et al., 2018). Yet, little is known about the extent to which general attachment and attachment to a non-human entity, as in organizational attachment, are related.

Data were collected via online panel including 253 employees in Germany. The survey included a short version of the German equivalent of the ECR-R for assessing general attachment (BoBi; Neumann et al., 2007) and the Organization Attachment Survey (OAS) for measuring organizational attachment (Feeney et al., 2020). Structural equation modeling was used to test relationships between general and organizational attachment.

Organizational attachment avoidance was positively and moderately related to general attachment avoidance, as were organizational attachment anxiety and general attachment anxiety. Moreover, correlations across the attachment dimensions were significant, showing a small positive effect. Lastly, while no significant correlation was found between the general attachment dimensions, organizational attachment dimensions were correlated.

Using self-report measures may potentially result in common-method bias and the cross-sectional design prevents inferences about causality.

Results show that organizational attachment is not independent of, but also not completely determined by employees' general attachment. Hence, results suggest considering both in organizational contexts. Specifically, more research is needed to explore how positive attachment-relevant experiences influence organizational attachment beyond general attachment. Moreover, it seems useful to offer training programs to raise the awareness of managers, supervisors or HR for general and specific attachment needs of their employees.

With organizational attachment being just recently acknowledged, this study is an early contribution to a better understanding of the relationships between organizational attachment and general attachment as well as the resulting responsibility of HR to shape a sustainable workforce.

Keywords: Organizational attachment, Human Resources, Attachment theory

iJobs – an internet intervention for the unemployed: A feasibility and acceptability study

Alexandra Bodnaru, West University of Timisoara; Roland W.B. Blonk, Tilburg University; Dragoș Iliescu, University of Bucharest; Delia Vîrgă & Andrei Rusu | West University of Timisoara

practice

Background: The unemployment rate is still elevated (e.g, 6.2% in the EU), but a more alarming feature is its highly asymmetrical distribution, even across the same country, such as Romania (Statista, 2022). Unemployment has significant individual repercussions, being associated with mental health impairment (Paul & Moser, 2009). Therefore, evidence-based intervention programs for increasing employment are highly needed. JOBS II (Curran et al., 1999) is one of those programs. It comprises five elements: Job-search skills, Active learning, Inoculation against setbacks, Social support, and Trainer referent power and combines principles from behavioral and social sciences (i.e., self-efficacy theory, theory of planned behavior, coping theory). JOBS II was and is still being adapted in different countries (e.g., the US, Finland, South Africa, and Germany), but only in a face-to-face format. An online adaptation of this intervention has several advantages: is asynchronous, highly scalable, allows self-administration, and has reduced costs. The relevance of these advantages became even more evident in the recent period of lockdown used for mitigating the COVID-19 pandemic, the context in which the current study emerged.

Aim: The current study aimed to test the feasibility and acceptability of iJobs, an online adaptation of the JOBS II program.

Design: We conducted an open-label trial, with an uncontrolled, within-group, pre-posttest, and follow-up design.

Intervention: iJobs is a two-week asynchronous intervention with five modules that focus on identifying job skills, dealing with obstacles to employment, finding job openings, analyzing resumes, exercising different types of interviews, and planning for setbacks. The content is only text-type. After each module, participants received personalized written feedback on the web platform.

Participants: Out of the 56 participants allocated to the intervention, 36 completed (Mage=25 years; 57.1% females) the post-test (36% dropout), and 34 the three months follow-up.

Results: The quality of module completion was high among the protocol-compliant participants (mean above 4 points out of 5 for each module). The online platform's usability was high (84.86 points out of 100). Participants reported increased overall satisfaction with the program.

After iJobs, inoculation against setbacks (d = .64), job search self-efficacy (d = .50), and self-esteem (d = .28) increased significantly, while future career anxiety in the COVID-19 context decreased significantly (d = .34).

Three months after iJobs 55.9% of the participants found employment, while 5.9% were in a job selection process, and 38.2% were unemployed. Job satisfaction was high among the employed.

Discussion: Our results showed that iJobs is a feasible intervention and was accepted by its beneficiaries. Even though the results are promising, the trial design does not allow causal inferences regarding the program's efficacy or effectiveness. The sample characteristics (young, highly educated, with a short period of unemployment) restrict the findings' generalization. Moreover, social support facilitated by the interaction between participants, a central component of JOBS II is

almost absent in iJobs. After further testing its efficacy in an RCT that will address those limitations, iJobs has the potential to become a cost-free, easily accessible, and highly scalable resource for the unemployed.

Keywords: unemployment, JOBS II program, internet intervention

Poster P020

The attitudes towards Augmented Decision Making (ADM) Scale: Development and an initial validation

Kees Maton, Philippe van de Calseyde, Pascale Le Blanc & Anna-Sophie Ulfert-Blank | Eindhoven University of Technology

science

Purpose: Organizations increasingly use (AI) decision-support systems. Research shows that the highest decision-making performance is achieved when humans intensively collaborate with such systems in a complementary manner, a process also referred to as augmented decision-making (ADM). Although portrayed as ideal, ADM typically fails to deliver added value, as employees are unwilling to collaborate with these systems. In Technological Acceptance Models (TAM) attitudes predict a person's willingness to use technology. Researchers recently showed that attitudes consist of cognitive instrumental and affective experiential components. As TAM was typically intended to research traditional, passive tool technologies, it gives primacy to human agency. Therefore, based on the premise that people will use their usage to extrinsic rewards, TAM research has predominantly focused on instrumental evaluations, neglecting employee experiences. However, in ADM, also decision-support systems have agency, and employees may experience a transfer of agency, rights and responsibilities that may also impact their willingness to collaborate with these systems. Therefore, to better predict behavior, we need to broaden our scope in conceptualizing and assessment of attitudes towards ADM, by also assessing their experiential evaluations. A scale that can assess such attitudes may give organizations insights into factors that can enhance ADM performance from a human perspective.

Design: We have performed an interdisciplinary literature review, to conceptualize employee experiences of ADM and define our dimensions. Semi-structured interviews based on the critical incidence technique were used to triangulate our findings stemming from the literature. On this basis, items will be developed, and evaluated by subject-matter experts, and by actual users through cognitive interviewing. Lastly, Exploratory Factor Analyses will be performed among employees that currently collaborate with such systems, to quantitatively extract dimensions and reduce redundant items.

Results: The Scale will be developed in March, and pre-tested at the beginning of April 2023. Validation of the items will take place at the beginning of May 2023.

Limitations and Future Research: The generalizability of the scale may be limited due to the sample solely consisting of employees working in the forecast planning domain. Future research should test the applicability of the scale in other domains in which ADM takes place as well as performing extensive reliability, and validity tests. Subsequently, future research should explore the relationship between these attitudes (or dimensions) and employee system usage behaviors.

Practical Implications: Organizations need to adopt a more comprehensive view of employee attitudes toward ADM, to optimize the collaboration between humans and AI decision-support systems, thereby enhancing both employee well-being, and decision-making performance.

Relevance for Congress: Given our focus on ADM that will increasingly be applied in work-settings, our research is clearly related to the ' The Future is Now: The Changing World of Work ' theme.

Relevant UN goals: This article provides insights into designing satisfactorily augmented decision-making processes, to optimize employee behavior and facilitate increased ADM, contributing to the UN sustainable development goals 'Decent Work and Economic Growth' and 'Industry, Innovation, and Infrastructure.

Keywords: Artificial Intelligent, shared decision-making, attitudes

University employees' psychological wellbeing profiles in Lithuania: a person-centered approach

Aurelija Stelmokienė, Giedrė Genevičiūtė-Janonė, Kristina Kovalčikienė, Loreta Gustainienė

science

Different perspectives propose a variety of employees' well-being indicators. However, only a few research is using a person-centered approach to understanding multiple dimensions of employees' well-being. The current study aimed to identify clusters of university employees who shared common configuration of perceived health (stress, burnout) and positive attitudes (job satisfaction, organizational commitment and work engagement) at work. Selected indicators represent both eudemonic (pursuit of meaning) and hedonic (pursuit of pleasure) approach of well-being (Grant, McGhee, 2021; Giuntoli et al., 2021; Bartels, Peterson, Reina, 2019; Diener et al., 2010).

Cross-sectional survey in three Lithuanian universities involved 451 employees (31 percent males and 67 percent females; 57 percent academic staff, 22 percent non-academic staff and 20 percent doing both academic and administrative tasks). Two scales from COPSOQII (National Centre for the Working Environment, 2007) about stress and burnout, short scale of job satisfaction based on the Spector model (1985), Organizational commitment questionnaire (Meyer et al., 1993) and UWES (Schaufeli, Bakker, 2003) were used as the main questionnaires.

Results of the cluster analysis showed that in the flourishing group of employees (57 percent of the sample) stress and burnout were perceived as low and job satisfaction, organizational commitment and work engagement were rated as high. An opposite situation was in the group of languishing employees (43 percent of the sample): more health problems, less positive attitudes. Further analysis of group comparison and identification of significant demographic factors as predictors of profile membership is on the go.

As Grant and McGhee (2021) pointed out and our research showed, integration of eudemonic and hedonic approach was the best solution for understanding employees' well-being. Moreover, a person-centered perspective applied in this research added knowledge about well-being to still dominating a variable-centered perspective (Cheung, 2016). Nevertheless, longitudinal research in the field would be a useful future direction for determining the stability and transition patterns of well-being profiles over time. The main message for practitioners – HRM intervention programs in universities should be based on the needs of particular groups of employees that perceive the changing world of work differently.

Keywords: well-being, eudemonic and hedonic approach, cluster analysis

Poster P023

Virtual Teams: supporting collaboration, productivity and wellbeing in virtual teams and remote workers

Evie Michailidis, Vicky Charalambous, Panagiotis Kosmas, Charalambos Vrasidas

science&practice

Research goals and why the work was worth doing:

The main purpose of this study was to explore the challenges and needs of team leaders who work remotely. This study was conducted in the framework of the Virtual Teams project, an Erasmus plus funded project that aims to support Team Leaders operating in SMEs across the EU to acquire the appropriate competencies, to manage their Team's productivity and wellbeing better while working remotely, and at the same time enrich their capacity to use the appropriate technological tools.

Theoretical background:

The nature of work has undergone profound changes driven by technological progress, macroeconomic fluctuations, other internal and external factors, and recent COVID pandemic. The number of workers who identify as "Remote/virtual workers" is increasing dramatically. Managers who lead remote/virtual teams not only face the usual leadership dilemmas but also have to adapt to these challenges in an environment where the practices have changed. Managing virtual teams requires a different approach. It means developing new skills, communication methodologies and techniques to get the best out of teams and improve organisational and personal performance (Grant et al.,2013).

Design/Methodology/Approach/Intervention

A focus group and a questionnaire to team leaders, from all the partner countries (Cyprus, Greek, France, Ireland, Slovenia and Spain) were conducted with the aim to help the consortium address the needs of the primary target group. By utilising the findings from this primary research the consortium then designed and developed a step by step toolkit for effective management of Virtual Teams for enhanced employee engagement, wellbeing and productivity.

Results obtained

A total of 128 team leaders from the 6 partner countries completed the questionnaire. Findings indicated that their main challenges are to build trust with their team members, keep their members motivated and engaged and ensure team's connectedness and communication. A total of 49 participants took part in the focus groups. Findings indicated that some of the key challenges that team leaders face include dealing with mental health Issues of their team members, staying connected with remote team members, helping remote workers maintain a healthy work life balance, managing performance and finally dealing with technical issues.

Limitations

Cross-sectional nature of study, self-reported data and relative small sample size.

Conclusions – research and or practical implications/Originality/Value

Through the survey and focus group, the consortium gathered information that assisted them in the development of a toolkit, and currently a training course and other free material with the aim to benefit both the team leaders and their team members are being developed.

Relevance to the Congress Theme

The study is relevant to the Congress Theme “The Future is Now: the changing world of work”, as an increasing number of leaders in the future will be asked to manage remote teams.

Relevant UN SDGs

The topic is relevant to the Sustainable Development Goals (SDGs) and especially to the goal for good health and wellbeing.

Keywords: Virtual teams, remote working, team leaders

Poster P026

Job Crafting put into context: Can proactive people benefit from their job design?

Eleni Georganta, Technical University of Munich, Lisa Handke, Freie University of Berlin

science

Research goals

Job crafting - the process by which individuals actively shape their work to enhance a sense of meaning - has been a focal research topic over the past decades. Various studies have shown that job crafting is influenced by personal traits and thereby supports work outcomes. Nevertheless, evidence on the boundary conditions impacting the role of job crafting is missing. The goal of the present study is to provide insight into the contextual conditions (autonomy, skill variety) that shape job crafting and its relationship to antecedents (proactive personality) and outcomes (work engagement).

Theoretical Background

On the basis of the job demands–resources model, we investigate whether proactive personality predicts job crafting and in turn, work engagement. Building on the job characteristics model, we also explore whether the mediating relationship between proactive personality, job crafting and work engagement is stronger at higher levels of autonomy and skill variety at work.

Methodology

Three hundred and forty-four employees from different organizations participated in a two-wave study. Using online questionnaires, we first measured proactive personality and job characteristics (autonomy, skill variety). One day later, we assessed job crafting and work engagement. We used two time points to clearly capture the directionality of effects (with personality and job characteristics predicting job crafting and work engagement).

Results

As expected, job crafting mediated the relationship between proactive personality and work engagement. However, our findings did not confirm that both autonomy and skill variety moderated the relationship between proactive personality and job crafting. Instead, autonomy and skill variety had a direct and positive impact on job crafting.

Limitations

Our study has some limitations that should be considered when interpreting our findings. Specifically, we only assessed employees' perceptions regarding job crafting and not their actual behavior. Furthermore, we collected our data during the pandemic and may thus not have captured 'typical' manifestations of autonomy and skill variety at work, factors that possibly impacted our findings.

Practical/Research Implications

Our findings provide support for the multilevel nature of work (re-)design by suggesting that there are two independent mechanisms that support job crafting: personal, i.e., bottom-up (proactive personality) and organizational, i.e., top-down (job characteristics). We suggest future research to explore whether high manifestation of one mechanism is enough to engage in job crafting behaviors.

Such insight will help organizations to promote job crafting either by selecting employees with high proactive personality or by shaping their job characteristics.

Relevance to the Congress Theme

In an effort to provide first evidence on the boundary conditions impacting the role of job crating, a mechanism which is becoming extremely valuable given the changing nature of work, we found that both personal and organizational mechanisms are supportive for job crafting. With our study, we combined top-down characteristics (job characteristics) and bottom-up processes (job crafting) as recently called for.

Relevant UN SDGs

We adopt a human-centered approach and combine top-down characteristics (job characteristics) and bottom-up processes (job crafting) to decent work and economic growth.

Keywords: Job crafting, job characteristics, proactive personality

Poster P027

Deepening the Job Demands-Resources Model applied to safety: The role of hope and job dedication

Simona Margheritti, University of Milan-Bicocca; Sílvia Agostinho da Silva, Business Research Unit-ISCTE; Alessia Negrini, Institut de recherche Robert-Sauvé en santé et en sécurité du travail (IRSST)

science&practice

Most of the safety studies focused on safety prevention, investigating the factors leading workers to incur or not in accidents and injuries. However, the absence of these adverse safety outcomes does not provide evidence of safety. Following the safety promotion perspective, this study focuses on promoting safety participation, defined as proactive and voluntary behaviours that are not mandated by the worker's role (e.g., assisting colleagues in hazardous conditions) (Griffin and Neal, 2000). Safety participation decreases the probability of accidents and injuries by directly creating a safer work environment. Several studies have analysed its antecedents. However, only a few have explored its role within the motivational process of the Job Demands-Resources Model (JD-R Model; Bakker and Demerouti, 2001;2017). Expanding this model applied to safety (Nahrgang et al., 2011), this study aims to understand the role of job demand (i.e., workload), two job resources (i.e., autonomy and supervisor support), a personal resource (i.e., hope), and job dedication in promoting safety participation. This objective results into the following research hypotheses: job resources help workers to have goal-directed and planned goals (hope). This allows workers to provide the willingness (job dedication) to reach goals and behave more frequently in safety participation. Job demands, instead, could adversely affect this virtuous process. To test these hypotheses, a cross-sectional study was conducted involving 225 people working for a multinational corporation. Half of the sample were female (53%) and almost half were aged 30–39. Data were analysed using SPSS with the Bootstrap method. Model 87 (Hayes, 2017) was performed for testing moderated serial mediations. Results showed that autonomy (1) and supervisor support (2) were associated with safety participation through two serial mediators, such as hope and job dedication (β1=.04, SE=.02, CI [.01;.07]; β2=.02, SE=.01, CI [.01;.05]). At the same time, workload moderated the relationship between job dedication and safety performance (β=-.16, SE=.06, p <.01), indicating that a high workload weakened the favourable connection between job dedication and safety participation, rendering job dedication insufficient to achieve safety participation. These results showed that workers were hopeful and more dedicated when they felt resourceful. Consequently, experiencing hope and being dedicated at work made workers implement positive safety behaviours, such as safety participation. At the same time, being exposed to job demands makes dedicated workers not behave safely. Thus, their resources could be focused on coping with job demands and cannot be available to achieve safe, voluntary behaviours. The research is not without limitations. The data were collected through a cross-sectional study and self-report measurement scales. Future research should use longitudinal study designs and incorporate objective measures (e.g., micro-accident rates). Our results allow for deepening the JD-R Model applied to safety by including the role of hope. In addition, they suggest the need to supplement mandatory training with pathways aimed at developing personal resources and attitudes to improve safety performance.

Keywords: Safety at work, safety promotion, JD-R

Poster P029

Mixed Feelings and Creative Minds: A Leader-Follower Crossover Mechanism

SinHui Chong, Nanyang Technological University, Singapore; Riguang Gao, Jiangxi University of Finance and Economics, China; Shamira Banu & Tong Wu | Nanyang Technological University, Singapore

science

With diverse responsibilities and challenges, leaders readily experience emotional ups and downs at work, making them likely to express a mix of emotions to followers. This offers an ideal opportunity to understand how mixed emotions shape creative processes in an organized setting. This study aims to investigate how leaders' emotional complexity shapes followers' dialectical thinking and creativity. We shed light on a novel and complex crossover (from leader to follower) and spillover (from affective to cognitive) mechanism underlying employee creativity.

Based on emotions-as-social-information theory, we hypothesize that leader emotional complexity sends signals of ambiguity, thus positively predicting follower dialectical thinking (i.e., tendency to identify and accept inconsistencies), especially in followers with higher emotional intelligence who are able to recognize others' emotions effectively. We expect dialectical thinking to predict creativity, especially if there is stronger error management climate that regards risky creative endeavors as learning opportunities.

We conducted a lab experiment for Study 1 in which 120 undergraduates rated their emotional intelligence, watched a video of a student leader expressing either high or low leader emotional complexity, reported their state dialectical thinking, and created a poster for the creativity task. Trained research assistants blind to the hypotheses rated the posters. In Study 2, a lagged-wave, multisource study is conducted on 132 leaders with 392 followers.

Results demonstrated that leader emotional complexity expression positively predicts follower dialectical thinking more in employees with high (vs. low) emotional intelligence, and dialectical thinking positively predicts creative work behaviors if the work unit has a weaker error management climate.

There are several limitations, for example in Study 1, we manipulated only leader emotional complexity expression but not follower trait emotional intelligence, thus compromising on the controlled environment of the lab experiment. We encourage future research to explore rigorous ways to manipulate trait emotional intelligence.

Future work requires employees to work creatively and adaptively with burgeoning technologies to meet fluid market demands. This study aligns with the congress theme because it explores the novel idea of how leader emotional complexity can be leveraged to benefit follower dialectical thinking and creativity.

This research contributes to UN SDG #9 (Industry, Innovation and Infrastructure) that emphasizes innovation facilitation because we shed light on a potential way to promote creativity in the workplace.

Keywords: emotional complexity, dialectical thinking, creativity

Poster P030

TELEWORK SATISFACTION AND WELLBEING DURING COVID-19 LOCKDOWN IN SPAIN: ARE CHILDREN A RESOURCE OR A DEMAND?

Esther García-Buades, Joanna Blahopoulou, Silvia Ortiz-Bonnin, Gema Torrens Espinosa & Maribel Montañez-Juan, Universidad de las Islas Baleares

science&practic

Research goals and why the work was worth doing

The research goal is to study telework satisfaction in a context where the main advantages of teleworking (e.g., less work interruptions) were missing, and to analyse its effects on subjective wellbeing during the COVID-19 lockdown.

This work is worthwhile because we evaluate the level of satisfaction with telework using a specific set of items. Furthermore, our longitudinal design supports the causal interpretation of the effects moving forward from previous cross-sectional research.

Theoretical background

According to the spill-over hypothesis (Bakker & Demerouti, 2013), job satisfaction is one of the determinants of subjective wellbeing because positive experiences at work can influence other life spheres, which enhance wellbeing. We extend these arguments to telework satisfaction.

Design/Methodology

Our longitudinal study explores the relationship between telework satisfaction (time 1) and subjective wellbeing (time 2) during the COVID-19 lockdown, with a time lag of one month. Data were collected through an online survey in Spain (N=111).

Building on Staples et al.'s work (1999), we measured telework satisfaction through a nine-item scale (i.e. facets like organization of working hours, possibility to concentrate without interruptions, supervisors' support, availability of ICT). Cronbach's alpha was .84.

We measured subjective wellbeing through the WHO-5 (World Health Organization - Five Wellbeing Index) in its Spanish version (Topp et al., 2015). Cronbach's alpha was .84.

Results obtained

Telework satisfaction ($b = .26$, $p < .01$) and the control variable 'children under 18 years old' ($b = .21$, $p < .05$) had significant positive effects on subjective wellbeing. Further, telework satisfaction and 'having children under 18 years old' were significantly negatively correlated ($r = -.34$; $p < .01$). Interestingly, employees with children felt less telework satisfaction but higher subjective wellbeing. Having children at home while teleworking is likely to be both a "resource" (compensating loss of social relationships at workplace) and a "demand" (increases home demands and workload; Shockley et al., 2021).

Limitations

The generalization of the results is limited because of a highly feminized (80%) snowball sample. Furthermore, our data allowed studying only short-term effects of satisfactory telework.

Research/Practical Implications

Future telework studies should explore further outcomes of telework satisfaction in crisis and non-crisis times, measuring long-term effects (with children at home) and contributing to the validation of the telework satisfaction scale.

Furthermore, we send a clear message to practitioners: Organisations can improve employees telework experience. The effort will not be in vain: Teleworking is here to stay, thus designing adequate telework conditions will prepare organizations for the Post-Covid-19 era.

Relevance to the Congress Theme

The sudden and extensive adoption of telework since the outbreak of the pandemic has changed peoples work but also family life in a radical way. Our research aims to contribute to a meaningful adaptation of working conditions.

Relevant UN SDGs

The UN Sustainable Development Goals (2015) that apply to my paper are: “Good health and wellbeing” and “Decent work and economic growth”.

Keywords: telework, wellbeing, children

Poster P031

The effects of executive coaching on behaviors, attitudes, and personal characteristics: a meta-analysis of randomized control trial studies

Andreea Gabriela Nicolau & Ad Kleingeld | Human Performance Management Group, Department of Industrial Engineering and Innovation Sciences Eindhoven University of Technology

science

Coaching is widely used in organizations to create cultural and well-being change (cf. O'Connor & Cavanagh, 2013). A growing number of studies emphasize executive coaching as an effective developmental tool. Yet, the existing literature suggests a large variety of processes and outcomes and generally lacks clarity on the main dimensions impacted by executive coaching. The current meta-analysis aims to shed light on the most impacted outcomes by executive coaching.

Reviewing 18 studies with a rigorous methodological design that used control trials and pre-post tests, this meta-analysis examined the effectiveness of coaching for three theoretically and practically relevant individual-outcome dimensions: behaviors, attitudes, and personal characteristics. The results indicate a significant and positive effect of executive coaching on behaviors (Hedges' $g = 0.86$, $k = 12$), attitudes (Hedges' $g = 0.34$, $k = 11$), and person characteristics (Hedges' $g = 0.53$, $k = 15$) with the strongest relationship with behavioral coaching outcomes. Moreover, we found significant and positive effects for specific outcomes such as self-efficacy (Hedges' $g = 0.31$), goal attainment (Hedges' $g = 1.32$), psychological capital (Hedges' $g = 0.83$), and resilience (Hedges' $g = 0.57$). The aggregated effect size for job satisfaction was positive but not significant (Hedges' $g = 0.36$). The results show no differences regarding the length of the coaching program, the number of sessions, the background of the coach, and the coaching method. Our findings suggest that executive coaching is an effective intervention, and behavioral, attitude, and person characteristic change is likely to occur due to coaching interventions. As an implication for practice, we suggest that coaches take a more systemic approach and facilitate the alignment of the manager's goals with the organization's strategy to enhance their positive attitudes toward the organization and, thus, the motivation and engagement in achieving their goals. Designing coaching interventions to provide frequent feedback from coaches and encourage executives to reflect on positive changes in their relationships at work could have important consequences on the organizational level (cf. O'Connor & Cavanagh, 2013).

This meta-analysis contributes to the existing coaching literature in three different ways. First, we have included only the studies on executive coaching in organizational settings with high methodological rigor and design that allow for causal conclusions. Second, we shed light on what dimensions are most impacted by executive coaching. This furthers our understanding of what resources executive coaching may enable and how these may contribute to the employee's optimal functioning, allowing both the employee and the organization to flourish. Third, we explored what factors moderate the coaching outcomes. These findings contribute to supporting the effectiveness of coaching and help coaches and clients to strive for the coaching outcomes that contribute the most to clients' performance.

Future research might explore dimensions not covered here, such as cognitions and intentions, which we could not analyze due to a lack of studies.

Keywords: executive coaching, coaching effectiveness, organizational performance

Impulsitivity as a Personal Demand - Toward Complementation of the Job Demands- Job Resources Theory

Bohdan Rożnowski, John Paul II Catholic University of Lublin; Antonii Wontorczyk, Jagiellonian University

science

The study took up the idea of adding a new component to the Job Demands - Resources Theory (Bakker & Demerouti, 2018), which should be called “personal demands”. As an example of personal demands, the construct of Impulsivity was studied. A cross-sectional questionnaire was conducted. A total of 394 (Female = 59.6%) workers were surveyed. The standardized survey questionnaires were used in the study, i.e. The Utrecht Work Engagement Scale (UWES-9), Life Roles Self-Efficacy Scale (LRSES) and UPPS-P Impulsive Behaviour Scale. The obtained results indicate, that Impulsivity correlates negatively with Work Engagement. In addition, Positive Urgency, which is one of dimension of impulsivity, moderates the relation between Self-efficacy and Work Engagement, in line with theory. This confirmed the fact, that impulsivity should be included in the JDR theory as a personal demand.

Keywords: Job Demands Job Resources Theory, work engagement, impulsivity

Toxic Leadership Style: Relationships with Work Motivation and Work Engagement

Tiiu Kamdron, Tallinn University of Technology, School of Business and Governance, Lecturer; Liina Randmann, Tallinn University of Technology, School of Business and Governance, Senior Lecturer

science&practice

Research Goals . The purpose of this study is to investigate relationships between immediate manager's toxic leadership style and subordinates' work motivation and job engagement.

Theoretical Background. Blumen (2009) defines toxic leadership as: "a process in which leaders, by dint of their destructive behavior and/or dysfunctional personal characteristics generate a serious and enduring poisonous effect on the individuals, families, organizations, communities, and even entire societies they lead" (p. 29). Piecing together the various definitions, we find two elements that define toxic leadership. First of all, toxic leaders' behavior harms (directly or indirectly) individuals within the organization. And second, their behavior results in systemic damage to the effectiveness of the organization. The dimensions of toxic leadership are: Abusive Supervision, Authoritarian Leadership, Narcissism, Self-Promotion and Unpredictability (Schmidt, 2008).

Design/Methodology . A cross-sectional survey design was used with a convenience sample (N=263) of Estonian employees. Toxic Leadership Scale (Schmidt, 2008 34 items); The Multidimensional Work Motivation Scale (MWMS with 24 items); The Work-Related Basic Need Satisfaction Scale (W-BNS with 18 items) and Utrecht Work Engagement Scale was used in this study. 6-point scale for assessment was used in all questionnaires.

Results. Toxic leadership style is negatively related with all subscales of motivation, especially with identified and intrinsic motivation. The only significantly positive relationship is with amotivation. Narcissism subscale show somewhat different results compared to other toxic leadership subscales: weak positive correlation with amotivation and weak negative correlations with only identified and intrinsic motivation. Extrinsic material motivation has weak negative correlations only with abusive supervision and self-promotion subscales. Absorption is negatively related with self-promotion and authoritarian toxic leadership subscales. Vigor and dedication subscales have negative relationships with all subscales of toxic leadership. Dedication subscale show the higher negative correlations with work motivation compared to other work engagement subscales. Multiple regression analysis, where intrinsic motivation was as dependent variable and vigor, dedication and toxic leadership were independent variables shows a good fit: $F(3, 193) = 44.172$, $p < .0001$ and $R^2 = .411$.

Limitations. The small sample size and use of cross-sectional design are limitations of these study.

Practical Implications. Our study clearly shows the negative consequences of toxic leadership on employee motivation, especially intrinsic motivation. Somewhat less impact has toxic leadership only on extrinsic material motivation. Toxic leadership shows negative consequences to work engagement, especially when it comes to dedication.

Relevance to the Congress Theme. Our study is connected mainly with decent work and economic growth theme of congress.

Keywords: Abusive Leadership, Self-Determination Theory of Work Motivation, Work Engagement

Poster P034

Workplace Bullying among Brazilian Urban Public Transportation Workers

Sorina Naidin, University of Bucharest

science

Workplace Bullying is a process in which abusive, hostile, and humiliating behavior occurs repeatedly and frequently. The psychosocial approach to understanding this kind of violence associates it with individual and relational factors. It is a collective situation that includes work organization managers and society, which establishes the rules of human relations in its context. It is a psychosocial risk factor, which generates negative implications, causes suffering, and damages the health of those involved.In Brazil, there is a lack of studies showing the incidence of this kind of violence. This study identified the occurrence and characterized workplace bullying among urban public transport workers. A total of 382 workers from a capital city in the South Region of Brazil participated in the study. Participants answered a socio-professional questionnaire, the Escala Laboral de Assédio Moral - ELAM (Workplace Bullying Scale), and questions related to violence at work. Descriptive and inferential statistical analyses were performed. Results showed a difference between the number of workers identified by ELAM items as targets of bullying (48.6%) and those who recognize themselves in this situation (33.7%). It was found that work conditions and organization are conducive to situations of workplace bullying; most of the hostile acts described are related to a deterioration of work conditions, attacks on human dignity, and humiliation; and direct bosses are the main bullies, reflecting a reality of abuse of power. In addition, single individuals [$H(2) = 8.96$; $p = 0.01$], bus collectors [$H(2) = 8.77$; $p = 0.01$], and individuals who had a higher workload [$H(2) = 9.35$; $p < 0.001$] had higher scores on the scale, meaning they were exposed to bullying situations more often. There was a weak and negative association between participants' age and ELAM's total score ($r = -0.217$, $p < 0.001$), showing that younger workers had higher scores on the scale. The main limitations of the study were: the use of a self-report instrument, with potential biases; a convenience sample, which increases the possibility of biased data, as probably only workers willing to discuss the subject participated; and the fact that, as this is a cross-sectional study, it is not possible to reach conclusions on causal relationships. By specifically approaching the professional occupation of urban public transport workers, it was possible to observe exclusive aspects of this sector. The study identified the occurrence and described the characteristics of this kind of violence, which allowed the unveiling of variables that contribute to its occurrence. The data point to the need for efforts by organizations and unions to implement actions that can prevent this kind of violence, aimed mainly at supervisory positions, as well as inform and prepare workers to recognize real bullying situations. This topic adheres to the UN's 2030 Agenda for Sustainable Development, as the discussion on workplace violence has contributed to the dissemination of information, which is the first step to mitigating this kind of behavior and establishing well-being practices and decent work in the different professional categories.

Keywords: Workplace Bullying, Urban Collective Transport, Working Conditions

Poster P036

The relationship between organizational safety climate and driving style of Lithuanian professional drivers

Aukse Endriulaitiene, Justina Slavinskiene | Vytautas Magnus University

science

Theoretical background . Drivers in occupational settings are frequently provided with inconsistent demands for work performance (long working hours, speeding for timely delivery of goods vs. following safety rules in traffic and avoiding accidents). This compromises safety and might lead to crashes that account for between 20% and 40% of work-related accidents in industrial countries. Organizational safety climate is an important predictor of employees' safe performance at work helping drivers to manage their job demands, remain focused, avoid fatigue, and maintain good reaction time while driving. Still, data on how safety climate might be related to habitual driving style of professional drivers is limited. So, the current study is aimed to explore the relationship between organizational safety climate and different driving styles of Lithuanian professional drivers.

Methodology. Eighty-two professional drivers (51 male, 31 female; the mean driving experience – 15.8 years) from different Lithuanian organizations participated in cross-sectional study. Organizational safety climate (OSC) (Brondino et.al., 2011) was used to measure their evaluation of organizational safety systems, safety training, safety communication and safety values. The multidimensional driving style inventory (Taubman-Ben-Ari et.al., 2004) was used to evaluate four driving styles - anxious, reckless/careless, hostile/angry and careful/patient.

Results . Female professional drivers reported more anxious driving style than male professional drivers. No significant gender differences were found in perceptions of organizational safety climate. Significant negative correlation was found among driving experience and perceptions of safety communication and safety training. Age was not statistically correlated to any organizational safety climate. Contrary to expectations more frequent safety communication in organization was related to more hostile driving style among professional drivers. While higher scores on safety training and safety values were correlated to more reckless driving style. Anxious and careful driving styles were not related to perceptions of organizational safety climate.

Limitations . Small sample size and self-reported data limit the reliability and generalizability of results. Lack of information about the type of organizations where participants work (e.g. delivery, passenger transportation etc.) does not allow to control additional variables that might be related to organizational safety climate.

Conclusions . Unexpectedly, perceived organizational safety climate did not contribute significantly to safe driving style. On the contrary, present results indicate that higher scores in perceived organizational safety climate provoke professional drivers' to be more irresponsible and to take higher risk by driving recklessly or in a hostile way. So, further studies should focus on investigating psychological mechanisms or other organizational characteristics, explaining why safety climate does not operate in the expected way in this specific sample.

Research/Practical Implications. These results indicate that when professional drivers believe that their work environment is safe and their organizations take care of safety, they might tend to drive in more dangerous way while performing their work. So, organizations who employ drivers should look for additional means to ensure safety, not only emphasizing safety rules, values or training.

Keywords: organizational safety climate, driving style, professional drivers

Poster P037

Home Office and Its Impact on the Job Performance

Lucie Ottova, Palacky University Olomouc

science&practice

There is currently an increase in the use of flexible work arrangements by knowledge workers, based onthe experience gained during the covid epidemic.

Measures to limit the spread of the Covid-19 epidemic have suddenly changed the working conditons of many people, especially in regard to working hours and work location.

There has been an increase in the use of home office work among knowledge workers and the researchers show that the transition to working from home has had a significant impact on their work-life balance. Currently, organisations have to decide how to deal with the home office in the post-pandemic period.

Research published so far shows that employers will continue to use the home office. It is necessary to define the optimal home office setup taking into account the employer's interest and the impact on job performance.

This research aims to determine the impact of work-from-home on job performance with a consideration of personality.
According to the results of the literature review, this topic has not yet been sufficiently researched. I set the hypothesis on the basis of available knowledge:
H:An individual's personality influences their work performance when they work from home.
The research is realized in two parts.

For the implementation of the survey, I chose a questionnaire and a qualitative method in the form of structured interview. In the first part, employees are interviewed by questionnaire survey. In the second part, the method of structured interviews with supervisors is used.
The research starts in 2023 and will be completed in 2024.

The respondents are employees of an international company in the Czech Republic - 150 persons, both men and women. The selection of respondents was done by the method of purposive sampling. The research sample includes respondents who have specific experience of working from home, which means that they currently use work from home.

This new knowledge and the subsequent use of the results by employers can help to optimally adjust the use of the home office with consideration of the employee's personality and to address the worklife balance of knowledge workers and their work performance. This can be used in attracting and retaining talented knowledge workers.

The reserch will be presented by e-Poster only.

Keywords: Flexible working arrangements, Job Performance, Work-life balance

Poster P038

A better understanding of Occupational Well-Being using NLP techniques

Laurențiu P. Maricuțoiu, PhD & Eusebiu Ștefancu, PhD Student | Department of Psychology, West University of Timișoara, Romania

science

Occupational Well-being represents a well-known field of study, which is usually related to Health Psychology and mainly, it represents a valuable component of Organizational Psychology. Natural language processing (NLP) is regarded as the most promising method for developing new knowledge, but it is also the most challenging to acquire. This is because of the technological advancements that have occurred in this field. Some of these include the development of computational linguistics and digital information technologies. On the one hand, NLP is a subfield of linguistics and artificial intelligence. It focuses on the development of systems that can understand and improve the grammar and structure of natural human languages. On the other hand, besides being able to improve the grammar and structure of natural human languages, NLP can also be used to describe and measure the subjective states of people. Types of text that are commonly used in this field include interviews' transcripts, dialogs, narratives, answers to open ended questions, as well as clinical notes and social media messages.

Natural language processing has become a popular tool for detecting and analyzing the expressions of sentiment in text. The goal of this process is to identify the words (i.e., positive, negative, or neutral words), or phrases that the author uses to describe a particular topic. It can be used to perform various tasks such as sentiment analysis and information extraction. One of the most common tasks that can be performed by this technology is to detect the subjective state of a person in a text. The concept of the subjective level refers to the various aspects of a person's life, such as happiness, well-being, and satisfaction.

There is currently a lack of methods that can capture the psychological constructs that are commonly used in language analysis. However, computational methods are being used in social sciences to perform this task. The use of semantic measures is offering a better description of the construct, which can help differentiate them from other similar constructs. In daily life, individuals tend to communicate their thoughts and feelings using words instead of numbers and scales. They tend to give open-ended answers when it comes to asking someone how they feel or think.

First, this approach is different from the rating scale method, which requires the respondent to perform a brief mental analysis of their natural responses and select the best answer option that would fit from the given scale. Second, instead of forcing the respondent to use numerical rating scales, they are encouraged to provide open answers. Lastly, the construct measured is then interpreted by the respondents and they can provide fitting answers according to their attitudes, emotions, and thoughts.

So far in psychology, machine learning can be used to train models identifying certain features that are associated with a given task or psychometric scale. This method can then predict a score without requiring any traditional measurement. New technologies that can improve the measurement and intervention of well-being are expected to have a significant impact on the scientific understanding of this field. It is widely believed that the use of certain machine learning technologies can evaluate a person's well-being.

Laboratory Design Methodology for Deception Detection Research in Job Interviews: A case study

Petra Hypšová, Martin Seitl & Stanislav Popelka | Palacký University Olomouc, Faculty of Arts, Department of Psychology

science

Research goals and why the work was worth doing: Numerous requirements for job applicants increase the likelihood of deception in personnel selection processes. Lie detection is still an unsolved riddle, but increasing technological advances allow researchers to noninvasively study the physiological and behavioural changes during lie and truth production to determine whether the person was honest or not. Our main objective is to present a case study describing the methodology of laboratory setup for conducting deception detection experiments by using non-contact technology as facial infrared thermal imaging, eye tracking, remote photoplethysmography, and behavioural analysis in personnel selection simulations.

Theoretical background: Deceptive behaviour is an undeniable part of a person's life. The average person lies at least 1-2 times a day. In situations where the stakes are high, such as a job interview, this frequency can be even higher. For example, up to 90% of job applicants fraudulently change at least one answer to be more successful. As a result, research has begun to focus on detecting deception not only in litigation, but also in job interviews. A technology-based approach to lie detection relies mainly on contact polygraphy for its accuracy. However, contact polygraphy can easily introduce bias into the basic interaction, which is particularly problematic in personnel selection, where non-invasive tools seem more promising. However, the study of deception in the context of job interviews under experimental conditions using the aforementioned non-invasive technology is still in its infancy, and there is no existing laboratory methodology for conducting these experiments.

Design/Methodology/Approach/Intervention: To achieve the goal of the study, a within-subject experimental design was conducted. Above-mentioned non-invasive technologies were used. Independent variables included baseline condition and prepared and spontaneous truthful and deceptive scenarios. A system of PC codes was developed in Esri ArcGIS Pro software for thermal face data selection. All measures were carried out in the experimental laboratory of the Department of Psychology of Palacký University in Olomouc.

Results obtained or expected (if not available, it must be made clear when they will be) : A final methodological design was prepared and tested in a pilot experiment. Mixed-effects regression models revealed a statistically significant effect of prepared scenarios on most of our variables. Our data showed no significant effect of general deceptive behaviour on any variable except the number of eye-fixation measurements.

Limitations : Because this is a laboratory study, the results cannot be generalised to regular conditions of personnel selection procedures.

Research/Practical Implications : The methodological approach could be used and re-evaluated in future laboratory studies of non-invasive deception detection in job interview simulations. The results pave the way for further application of non-invasive technology in lie detection which could overcome the ongoing problems with contact-based measurements.

Keywords: non-invasive deception detection, personnel selection, psychophysiological experiment

Poster P042

Animal ethics committees all around the world

Julia Bastian & Wolfram Hötzenecker | Johannes Kepler University Linz

science&practice

Millions of animals are used each year for scientific purposes. Often life-saving treatments without alternatives for performing research on a complete living being are implemented. In animal experimentation medical treatments are developed, drug toxity is determined as well as product safety, biomedical or other health care processes for humans is checked. Often animal rights-activists or groups describe animal experimentation as cruel and inhumane and insist on alternatives for replacement. So, animal ethics committees play a very important role in order to discuss if a special animal experiment is necessary or can be replaced, reduced or refined according to the 3 R´s of Russel & Burch (1959).

In a mapped review scientific articles about animal ethics committees all around the world were found. Veterinarians are the most important experts in evaluating the animal welfare in animal experiments. Despite, this group of experts are in most countries not the only members but animal-rights activists or simply laypersons are members of animal ethics committees also that are part of the population of a country as well.

In the results the methodological procedure will be outlined. Starting with the appropriate search string, then presenting the chosen data bases in showing a prisma flow diagram and finally constituting the in- and excluded criteria of the review will be part of the process.

A scientific report of every country in the world is difficult to receive. Looking at continents most literature is published in the European countries. Grey literature is an important additional source of information which especially in conference proceedings and institutional working papers can be achieved.

In a changing world and at a time of war people all around the world reflect about the dealing with animals. On the one hand animals are our best friends as pets and on the other hand humans are using them as food, for experiments or as spare parts stores.

Most animal ethics committees around the world are composed of a mixture of experts and laypersons. The quality of education is different in the groups of members in order to represent the population more as a whole and not only the experts as a special part of the population who may be more in favor of being for animal experimentation. In reducing inequalities while decision making processes pro or contra animal experimentation, experts and laypersons have the equality of votes.

Keywords: animal ethics committee, ethics of animal experimentation

Poster P045

How demands of flexible work relate to employee engagement and emotional exhaustion. The mediating role of (mal)adaptive regulation

Gordon Adami & Jan Dettmers | University Hagen, Faculty for Psychology

science

The goal of this study was to investigate whether and to what extent high job autonomy might strain employees. This aligns with meta-theoretical reasoning (e.g., Warr, 2017). However, only inconsistent evidence supports this theorizing (Kubicek et al., 2014; Dettmers & Bredehöft, 2020). Theoreticall y, we combined research on Job Design Demands (JDD) (Dettmers & Bredehöft, 2020) and on Cognitive Demands of flexible work (CODE) (Prem et al., 2021). The JDD and CODE scales were developed to capture demand-like features that might emerge from job autonomy. We focused on the task and process domain. Examples include development, planning demands and demands to regulate effort (JDD subscales) and demands for coordinating with others (CODE subscale). Theoretically, e.g., coordinating, and planning might involve the expenditure of (mental) effort. Hence, employees might experience e.g., more fatigue or less detachment. However, dealing with JDD and CODE might simultaneously foster work motivation, or cognitively flexibility (Kubicek et al., 2021). Against expectations many employees seem to experience resource gains, rather than losses, when dealing with JDD and CODE (Dettmers & Bredehöft, 2021; Kubicek et al., 2021; Kubicek et al., 2022; Uhlig et al., 2022). To further investigate these assumptions, we combined the JDD and CODE scale with (mal)adaptive regulation. Regarding adaptive regulation, we assume that many employees will use increasing JDD and CODE to better align their jobs with their strengths (Job crafting towards strengths). Regarding maladaptive regulation, we assumed that many employees would prolong their working hours when dealing with JDD and CODE. Thus, when JDD and CODE (T1) promote both adaptive and maladaptive regulation (T2), this should lead to both more exhaustion and more engagement (T3). We conducted a three-wave lagged design, with 130 heterogeneous participants and three measurement points at an interval of four weeks. Preliminary results of hierarchical multiple regression analyses show that only development demands predicted both prolonged working hours and engagement. Against, our expectations planning demands showed negative relationships with exhaustion, while, as expected, showing positive relationships with job crafting towards strengths and engagement. Furthermore, demands to regulate effort showed only a positive relationship with exhaustion, while coordinating with others was unrelated to outcome variables. Finally, no expected mediation effects were found. Our main limitation is the self-assessment of cognitive demands that in many cases might occur rather unconsciously (Rau et al., 2020). Practically our findings might indicate that demands emerging from unstructured work are very unlikely to strain the average employee. We urge future research to focus on (un)favorable boundary conditions that might amplify potentially straining and motivating autonomy-outcomes (Van Veldhoven et al., 2020). Our study aligns with conference's topic (changing world of work) and the UN SDGs (decent work and economic growth). Empirically, the changing face of work, seem to contradict only partially the unambiguously health promoting nature of job autonomy (e.g., Warr, 2017). Instead, contradiction-free autonomy might be an ever more important prerequisite for proactivity and value creation, as well es for adaptive regulation and well-being.

Keywords: Flexible work, cognitive demands, job strain

Poster P046

Development of a digital situational judgment test for social and emotional competences in medical assistants

Markus Peters, Julia Raecke & Sebastian Konheiser | Federal Institute for Vocational Education and Training (BIBB, Germany)

science

Research goals

The mental wellbeing of people working in the health care sector has been a widely discussed topic during the Covid-19 pandemic. Medical assistants (MAs) work in doctors' offices and perform tasks both in patient management and treatment assistance. For these tasks they not only need healthcare skills, but also social-emotional competences, for example for calming down agitated patients. However, instruments to assess general social competences often do not reflect the specific competences needed by MAs. We therefore further developed a situational judgment test specifically targeted at the social and emotional competences of MAs in training.

Theoretical background

According to Monnier et al. (2016), the central social and emotional competences MAs need in their daily work are emotion regulation, perspective coordination and communication strategies. For operationalising emotion regulation, we resorted to the works of McRae and Gross (2020) on the use of different strategies in dealing with emotions. Perspective coordination was defined following Selman's (1986) research on the ability to coordinate different perspectives in interpersonal conflicts. The operationalisation of communication strategies is based on Rosenberg's (2015) approach to nonviolent communication. Resorting to these theoretical foundations, we developed rating schemes for open format questions on all three competences.

Methodology

The computer-based assessment instrument is designed as a (kind of) situational judgment test (Ployhart & MacKenzie, 2011). There are three parallel versions of the test, each comprising 12 interaction situations identified in requirements analyses with MAs and doctors by Critical Incident Technique (Flanagan, 1954). The situations are presented as short video clips, filmed from a first-person angle, followed by open-format questions addressing the three competences.

We are currently piloting the test with 200 apprentices in their second year of training to become MAs.

Results expected

Firstly, we will present sample test items. Secondly, we will describe the development of the rating schemes for participants' answers. Thirdly, we will present psychometric properties of the current test versions like interrater-reliabilities, internal consistencies and factor loadings based on the data collected in the piloting phase in autumn 2022.

Limitations

Preliminary data analyses indicate that test-taking takes longer than expected and that participants might progressively reduce their effort, which in turn may result in varying amounts of information available for rating the answers.

Implications

We developed a theoretically founded test for occupation-specific competences that could not be assessed properly so far. The test will be used for research purposes like evaluating the effectiveness of trainings. Additionally, teachers and trainers could use the tests to assess competence levels in their classes to inform them on their apprentices' needs for support in this area. The test could also be adapted to other professions with similar social-emotional demands.

Relevance to Congress Theme

To maintain a functioning healthcare system, not least during the COVID-19 pandemic, MAs need social-emotional competences now in order to stay healthy themselves and do a good job in supporting doctors in their practices in the future. To foster these competences successfully, we first need to develop instruments that assess them reliably.

Keywords: Social-emotional competences, medical assistants, computer-based testing

Poster P050

Relationships between leaders' and followers' views on the effectiveness of teamwork

Slavka Silberg, Constantine the Philosopher University in Nitra, Faculty of Education, Dražovská 4, 949 01 Nitra, Slovak Republic; Palacky University Olomouc, Faculty of Arts, Department of Psychology, Křížkovského 10, 779 00 Olomouc, Czech Republic; Luděk Stehlík, independent researcher, Czech Republic

science&practice

Research goals: Our research aims to better understand the relationship between team leaders' and team members' views of teamwork effectiveness. Discrepancies in perceptions can have a negative impact on engagement, participation and job satisfaction, because these factors play an important role in team/organisational performance, development and innovation, and employee well-being.

Theoretical background: The effectiveness of teamwork can be hindered by many factors. Research of related studies has confirmed the importance of focusing on teamwork effectiveness as it increases organisational resilience, agility and the ability to innovate. This was partly examined in Studies I and II (2021). Study I proved evidence about discrepancies in perceptions of teamwork effectiveness between teams and leaders. Study II shows that to significant factors influencing team performance and innovation include clear mission, diverse talents and decision-making power.

Methodology: We are interested in the nature of the relationship between team leaders' and team members' views on teamwork effectiveness, as team leaders' views may be causally related to those of team members. The sample of 85 work teams (75 team leaders, 11 team superiors and their 740 followers, and 9 participants in the team role „Others") was surveyed from 12/2014 to 3/2021 using the online questionnaire TAS-II. Our first step is to estimate the direction and strength of the relationship between team leaders' mean scores and team members' scores on the 8 main scales of TAS-II (Context, Mission, Talent, Norms, Buy-in, Power, Morale and Results). For this purpose, we used the Bayesian hierarchical regression model with the skewed normal response distribution, the identity linkage function and the default priors. Team members' and average team leaders' scores were used as response variable and independent variable, respectively. Team IDs and TAS-II scales were used as grouping variables, as we can assume that the available observations within the same teams and on the same scales are more similar.

Results: The resulting 95% credible interval for the population-level effect of independent variables includes values between 0.14 and 0.26, indicating a relatively weak positive relationship between team leaders' and team members' views on teamwork effectiveness. When examining specific TAS-II scales, the strongest effects are observed for the Morale, Mission, and Buy-In scales and the weakest effects in the case of Results, Talent and Power scales.

Limitations: The study is only correlational in nature and therefore provides only weak evidence for the existence of a causal relationship between the views of team leaders and team members on the effectiveness of teamwork. The TAS-II questionnaire has not yet been localised for Slovakia.

Research/practical implications: Our study offers new insights into the potential mechanisms of the influence of the leader's perception of teamwork effectiveness on teamwork/followers in the team. We discuss the implications of the findings. The findings are useful not only for academics but especially for practitioners. Eliminating discrepancies and communicating regularly about moral values and shared mission are helpful in enhancing performance, commitment and job satisfaction as

well as innovation, and in helping individuals, teams and organisations to progress in a highly competitive environment. This work was supported by KEGA 005/UKF4/2021 and IGA FF 2023/001.

Keywords: TAS-II, teamwork effectiveness, team L&D

Poster P051

Days When Mothers Work from Home: Interferences, Coworker Incivility, and Work Vigor

SinHui Chong & Tong Wu | Nanyang Technological University, Singapore

science&practice

Hybrid work arrangement (HWA) offers employees the options of working in office on some days and at home on others. It has become a contemporary work norm after Covid-19, and has been lauded for offering employees greater flexibility in juggling their work and personal demands. Some advocating it as a solution for increasing women's participation in the workforce. This research challenges the notion that HWA is beneficial for women. Integrating theories of gender roles and biases with workplace incivility, we hypothesize:

On days when they work from home (vs. office), employees will experience greater daily work-family interference (WFI) and family-work interference (FWI).

The daily positive relations of working from home with WFI and FWI will be stronger for women, especially women with children.

Daily WFI and FWI will be positively related to the daily incivility employees receive from their coworkers.

Daily incivility will be negatively related to next-day work vigor, but this will be weakened if employees perceive general ease of communicating with their coworkers virtually (vs. in-person).

We conducted an experience-sampling study on 117 full-time employees who were in a HWA (i.e., at least 50% split between home and office). The completed a baseline survey and two daily surveys for ten consecutive workdays. We received and matched 1104 daily observations. In the baseline survey, they reported their gender, whether they had children, and the general ease of virtual communication with coworkers (e.g., "In general, it is more tedious exchanging information with my supervisor/coworkers online than in-person (reverse)"). In the midday survey, they reported whether they worked from home (vs. office) on that day, family-work interference, work-family interference, and workplace incivility experienced so far that day. In the end-of-day survey, they reported their work vigor projected for the next day (e.g., "I look forward to getting up the next morning to start work"). We conducted multilevel modelling in Mplus.

The results showed that on days when they worked from home, women, especially those with children, experienced greater FWI (but not WFI) than men and women without children. Both daily FWI and FWI were positively related to daily incivility from coworkers. Interestingly, daily coworker incivility was positively related to next-day work vigor in employees who perceived greater ease of virtual communication with coworkers.

The research used ratings from a single source. Future studies could consider other-source ratings for variables like FWI, WFI, and incivility.

The research poignantly demonstrated that women with children experienced greater FWI when working from home and their coworkers penalized them with incivility. This suggests that even if HWA could encourage women's participation in the workforce, women with children might experience unpleasant treatment from their coworkers when they take up HWA.

This research contributes jointly to the congress theme and the UN SDG #5 (Gender Equality). We identify a vulnerable group who may be disadvantaged by the contemporary HWA and suggest that

this detriment could be reduced by strengthening online communication mechanisms in the organization.

Keywords: hybrid work arrangement, workplace incivility, interferences

Poster P052

Applying a job crafting intervention in a higher education context

Lorena Körner, Aalen University; Timo Kortsch, IU Internationale Hochschule

science&practice

Higher education (HE) students are a growing part of the overall population and of great importance to the growth of a country's economy (Auerbach et al., 2018; Wörfel et al., 2016). At the same time, HE students report high levels of exhaustion and burnout is even higher during study than during work (Robins et al., 2018). For this reason, universities should offer interventions to counteract this.

Lesener et al. (2020) introduced the study demands-resources framework (SD-R) and confirmed the core assumptions of the of the JD-R model (Demerouti et al., 2001) for the HE context. Job crafting—within the JD-R model—describes the proactive adjustment of employees' resources and demands with the goal of better matching work to personal needs and abilities (Tims & Bakker, 2010). Due to the positive effects of job crafting, interventions have been introduced to foster this behavior in the work context. The concept study crafting has also recently been examined in the HE context; however, no interventions have yet been introduced to foster study crafting.

Therefore, this study evaluated two brief (two weeks) online interventions aimed at (1) increasing resources, or (2) reducing demands. Based on findings from the work context, it was hypothesized that the resources-intervention would increase resources and the demands-intervention would reduce demands. Furthermore, it was hypothesized that both interventions would increase study crafting and thereby increase engagement and reduce exhaustion.

The study was a randomized controlled trial with a waiting-list control group. The final sample consisted of 205 participants divided among the resource-intervention group (n = 64), the demands-intervention group (n = 70), and the waiting-list control group (n = 71). All participants completed a questionnaire before (T1) and after (T2) the intervention and at the 8-week follow-up (T3).

Results showed that the resource mindfulness, the study crafting strategies increasing structural resources and increasing challenging demands increased in the resoures-intervention group after the intervention and at follow-up compared with the control group and compared with the pre-intervention level, while exhaustion decreased. The demand procrastination and the study crafting strategy increasing structural resources increased in the demands-intervention group after the intervention and at follow-up compared with the control group and compared with the pre-intervention level, while exhaustion decreased.

Several limitations need to be mentioned: The study was conducted at only one university and female students were overrepresented, limiting generalizability. In addition, the data were collected exclusively as self-reports.

Our study confirms that job crafting interventions can be effective in other contexts—in this case, the HE context. Therefore, universities should be aware of the potential of (study) crafting interventions as a cheap and effective intervention that can be an important component of student health management, but also support the successful application of study crafting strategies.

The relevance of our poster is that it presents an effective intervention to promote well-being and reduce burnout in the important group of HE students.

Keywords: study crafting, engagement, burnout

Trickle-around effects of injustice amidst the COVID-19 pandemic

Marc Ohana, Kedge Business School; Marcello Russo, University of Bologna; Constanze Eib, Uppsala University

science

Research goals and why the work was worth doing:

Covid-19 has been an unprecedent shock that dramatically hit a myriad of stakeholders, including governments, organizations, families, and individuals. The Covid-19 pandemic has undoubtedly raised justice problems and different perceptions of inequality in the treatment and benefits received from employers that could have nurtured feelings of anger and resentment towards organizations. In this study, we propose a trickle-around effect of injustice during the Covid-19 pandemic. Specifically, we expected an indirect relationship between employees' overall injustice perceptions stemming from employers and incivility at work directed towards colleagues via employees' anger states. Moreover, we consider Covid-19 anxiety and moral obligation as potential boundary conditions of these relationships.

Theoretical background:

The Stressor-Emotion Model of Counterproductive Work Behaviors by Spector and Fox (2005) suggests that when an environmental factor such as injustice perceptions is perceived as a stressor, it can elicit a strong negative emotional response (e.g. anger), which, in turn, can trigger a behavioral action. We also propose that anger towards organizational representatives can trigger the behavioral action of incivility at work.

Additionally, relying on uncertainty management theory (van den Bos & Lind, 2002), we consider individual's Covid-19 anxiety as an individual factor that can moderate the relationship between individuals' perception of overall injustice and anger towards the organization.

Finally, we expect that moral obligations helps prevent individuals in engaging in uncivil acts and behaviors towards their colleagues.

Methodology:

We collected our data during the COVID-19 pandemic (May, 2020) in the United States. We used a three-wave survey design.Participants were recruited from Cloudresearch, an online sample provider. We obtained 156 complete and valid answers.

Results obtained:

We tested our model through structural equation modeling with Mplus. The results confirm the hypotheses of mediation of anger between justice and incivility and moderating role of both Covid-19 anxiety and moral obligation

Limitations:

Even if the data was collected in three waves, we cannot exclude reverse causation or assume causal relationships. Longitudinal and/or experimental studies can further provide empirical evidence for our proposed model.

Research/ practical implications:

We demonstrate how a significant and massive external shock can shape employees' organizational justice perceptions and their incivility behaviors at work – generating a trickle-around effect from actions of organizational representatives to employee's actions towards colleagues. We also focus on two important individual characteristics that can moderate the effects of overall justice perceptions, namely Covid-19 anxiety and moral obligation. Practically, results suggest that organizations do not get a free pass during a pandemic.

Relevance to the Congress Theme:

Our study adds to our understanding of how organization's actions towards employees during the first pandemic in recent times affected employees' state of mind and their behaviors towards their colleagues. Results help us to evaluate organization's responses and consequences of the pandemic, which can hopefully prepare us all better for the future pandemics and crises.

Keywords: justice, covid anxiety, incivility

Generational Differences in Work Values: Fact or Myth?

Barbara Stiglbauer, Bernad Batinic & Marlene Penz | Johannes Kepler University Linz

science&practice

Research goals: Whether, how, and to what extent employees from different generations (i.e., Babyboomer, Generation X, Generation Y, or Generation Z) differ with regard to their work-related expectations, attitudes, values, or behaviors has become a frequently discussed topic in the popular media. The goal of the present research therefore was to shed more light upon this topic by developing a short, valid measurement instrument to assess work values and by examining potential generational differences in those work values in a representative online sample.

Theoretical background: Previous scientific research has provided limited or very mixed support for generational differences in work values. However, those findings are restricted with regard to sample characteristics (e.g., convenience sample / not representative of the population) or work values (e.g., some general values assessed but other more work-specific values missing).

Methodology: In a first step, we developed and validated (n = 316) a short scale that allows to measure a broad range of work values. In a second step, we collected data within a representative online sample (n = 956) to test for generational differences in these work values.

Results: Results provided support fort he validity of our newly developed measurement instrument. We also found some statistically significant generational differences in work values, which, however were well explainable from an employee lifecycle perspective. For example, younger generations valued career or social aspects more strongly than older generations, whereas older generations valued stability/structure more strongly than the younger generations. On the other hand, generations did not differ significantly in values concerning sustainable organizational development, basic needs, or intrinsic work characteristics (e.g., autonomy or meaning).

Limitations: As we applied a newly developed scale, more research is neccessary to further prove its validity. Furthermore, this study is limited by the shortcomings that generally hold for generational research (e.g., age-period cohort effects).

Research/Practical Implications: Our newly developed scale can be used by practitioners as well as reserachers within the context of employer branding, recruitment, and employee retention. Furthermore, our results highlight the relevance of an employee lifecycle-perspective (rather than a foucs on generational differences). We therefore strongly reccommend to incorporate employee lifecycle strategies within organizations.

Keywords: work values, generations, employer branding

Poster P055

The Perception of Skills in Organizational Psychology: The construction of a measure

Silvia Amorim, Clara Dolabella & Caroline Campos | Universidade Federal de Minas Gerais

science&practice

The role of the psychologist in the organizational and work context involves preparation to intervene in transformation processes, but also in a context in which the old coexists with the new and the management models are hybrid.

Considering the needs of the field, the Brazilian Association of Organizational and Work Psychology built a reference for training and professional qualification in WOP in Brazil. The document considered technical primary competences, basic for any interventions (analysis of demands and needs, assessment and diagnosis, planning, intervention, evaluation and communication), in addition to a set of primary personal competences, which consist of personal traits, attitudes facing their own career and relational skills (continuous professional development, self-assessment, creativity, innovation and entrepreneurship, working in multidisciplinary teams, communication, political vision and team articulation and leadership).

Although the manual, there was a gap in measures for the assessment of these competencies. Therefore, the objective of this work is to present the construction of an instrument on the perception of competences to work in organizational psychology, aimed at the public of psychology students inserted in internships, in addition to newly psychologists.

For the development of the instrument, the Skills Manual for Working in WOP was analyzed, together with the mapping of skills necessary for the performance of trainees in people management, carried out by Ramos, Costa and Feitosa (2017). From this analysis, an instrument with 13 dimensions and 41 items emerged, covering personal and technical skills. The first version of the instrument will be sent to eight judges selected for being specialists in competences and in the construction of instruments and for composing the target audience of the instrument. In a second moment, a pre-test will be carried out with about 70 students from a public university, in order to verify the initial psychometric behavior.

As results, it is expected that the judges' analysis and the pre-test present an initial structure of the instrument from its validity evidence, to be presented at the congress, along with the construction process. Such results will then enable a large-scale collection that represents a validation at the national level, planned for later stages of the project.

We emphasize that the construction process already has limitations, such as the use of only two national references, which restricts competences to the Brazilian context. After the stages of construction and validation for this context, it is expected that the instrument can be expanded and adapted to other realities.

Despite this, it is believed that the proposal has the potential to build scientific knowledge that can improve academic and professional practices. The application of the instrument should provide greater knowledge about the skills necessary for the performance of students and professionals involved in the WOP area, as well as the possibilities for professional development. It is believed that the instrument contributes to psychology as a science and profession, based on the advancement of the necessary skills for this performance. The work expands the discussion about the psychologist's

career and its potential and limitations, in addition to generating technical support for this discussion, which can be used in different situations.

Keywords: Skills, Organizational Psychology, Measurement

Poster P056

Development of competencies for work in organizational and work psychology: An intervention model

Silvia Amorim, Clara Dolabella & Caroline Campos |Universidade Federal de Minas Gerais

practice

The objective of this work is to present an intervention model aimed at the development of competences for the work in WOP of psychology students and recently graduated psychologists, inserted in the area. The performance in these spaces is considered complex, involving not only the preparation to intervene in transformation processes, but also in a context in which the old coexists with the new and the management models are hybrid. Despite the great insertion in the area and the constant search for training, some studies demonstrate the need for professional development for this activity, based on gaps in the necessary skills to work with interns and psychologists at the beginning of their careers.

To develop the method, the assumptions of individual and on-the-job learning were considered, anchored in the concepts of Training, Development and Education, which seeks to create environments that facilitate learning at work and that consider the internal and external conditions existing in the environments. In these processes, it is necessary to carry out in-depth needs analysis and planning and execution, in addition to evaluating the results based on pre- and post-tests, based on the competencies and expected impacts. As a theoretical reference, we used the manual for training and professional qualification in WOP in Brazil developed by the Brazilian Association of Organizational and Work Psychology (SBPOT), which considers primary technical and personal skills.

The intervention proposal consists of holding open workshops offered based on the needs analysis carried out previously, based on an instrument developed for this purpose. The activity will take place on a monthly basis, in remote or hybrid format, lasting approximately three hours. The schedule of the workshops will be defined from the initial assessment, approaching the topics that present the greatest need in the assessment of competences.

As results, until the congress, it is expected that at least five workshops will have already been carried out and evaluated, with the presentation of the initial model and its results, in addition to the analysis of needs, being expected. The presentation of these results will enable the exchange of experiences and improvement of the project, so that it can be applied in its entirety.

It is considered that training cycles, based on practical needs and experiences, can provide direct benefits to workshop participants, by creating a space for training and improvement that represents an impact on performance and, therefore, on their careers. It is also believed in the potential for promoting the necessary dialogue between academia and the practical environment, by establishing a constructive dialogue with the organizational environment. The possibility of academic training and dissemination of scientific knowledge should strengthen healthy and ethical organizational practices, contributing to the development of the POT area.

Despite its limitations, especially as it represents an initial model that requires an assessment of feasibility and impacts, in our view, the model already represents an important contribution. It can enrich the discussions offered by EAWOP and offer support to students and educators in the area, based on the advancement of the necessary skills for this activity.

The Predictive Effects of Personality and Gender on Leader Emergence in Groups

Julia Grgic, EBS Universität für Wirtschaft und Recht

science&practice

Aim & Theoretical Background. Despite women increasingly entering leadership positions in organizations, inequalities in career advancement continue to exist (Sczesny et al., 2007). While past research focused mostly on contextual and organizational factors to explain disproportional leadership emergence of men and women, the current study contributes to this discourse by examining the role of individual-level traits and behaviors in predicting leader emergence of men and women. Specifically, the current study aims to understand how the mechanisms underlying the well-established relationship between extraversion and leader emergence (Judge et al., 2002) may differ between men and women. I predict that the assertiveness facet of extraversion, as manifested in the construct dominant behavior, mediates the positive effect of extraversion on leader emergence. Based on social role theory (Eagly, 1987) and gender stereotypes (Costa et al., 2001), female group members showing dominant behavior might be evaluated less favorably than men, undermining the positive effect of extraversion on leader emergence. Thus, I expect a moderating effect of gender on the relationship between dominant behavior and leader emergence.

Methodology. Data was gathered from 98 participants and was analyzed using a moderated mediation analysis in PROCESS, with extraversion as independent variable and leader emergence as dependent variable. Dominant behavior was the mediator between extraversion and leader emergence and gender the moderator of the effect of dominant behavior on leader emergence.

Results. As expected, extraversion and leader emergence were positively related . This relationship was full y mediated by dominant behavior. In contrast to my hypothesis, gender did not moderate the effect of dominant behavior on leader emergence. However, significant mean differences were found in dominant behavior and leader emergence, with men displaying more dominant behavior and emerging more frequently as leaders.

Implications. The findings contribute to our understanding of gender differences in leader emergence in three ways. First, results support previous findings on the predictive effect of extraversion while revealing that the assertiveness facet is highly relevant for leader emergenc e. Second, the positive effect of dominant behavior on leader emergence does not seem to differ for men and women , suggesting that dominant behavior is equally rewarded and predicts leader emergence across gender. Third, however, women, on average, seem to engage less in dominant behavior, contracting the positive effects of extraversion on the acquirement of leadership roles and hence restricting their access to those.

Limitations. Future studies should make use of experimental designs to further increase the generalizability of the results and establish the direction of causality. Additionally, a group setting would allow to assess all group members and investigate the effects of group composition in terms of gender and group-level extraversion. Alternative measures of leader emergence should be included to test if any moderating effects of gender exist for other operationalizations.

Relevance. This research is in line with the congress topic areas of leadership as well as diversity and inclusion and primarily addresses UN SDG5 (gender equality) and SDG10 (reduced inequalities).

Keywords: leader emergence, leadership, gender differences

Poster P060

Leadership – The Role of Your Life? The Influence of Leadership Motivation on the Team, Mediated by Role Satisfaction in China and Germany

Stephan Braun, Goethe University Frankfurt

science

Research goals and why the work was worth doing

Our research goals were (1) to introduce role satisfaction with the leadership role as mediator of the effects of different motivation-to-lead types and (2) to show that cultural background is an important boundary condition for the relationships.

Theoretical background

The motivation to lead (MTL) paradigm in its German version (FüMo, Felfe et al., 2012; based on Chan & Drasgow, 2001) distinguishes three different types of motivation for a leadership position: affective (aMTL, enjoyment of leadership itself, intrinsic), normative (nMTL, leadership as social norm and responsibility; extrinsic) and calculative (cMTL, motivated by personal benefits, extrinsic). Badura et al. (2020) show in a meta-analysis positive effects of aMTL and nMTL and negative effects of cMTL on work-related attitudes and behaviors.

We complement this research by integrating role satisfaction with the leadership role as one important mechanism for these effects of MTL on team effectiveness and team climate and adding culture as a boundary condition for positive effects of nMTL.

Design/Methodology/Approach/Intervention

We collected online questionnaire in three different samples: a German leader sample (N = 129), a German follower sample (N = 104) and a Chinese follower sample (N = 164). Items were related to the participant him*herself (in the leadership sample) or the direct leader (followership samples), and the participant's team.

Results obtained

We found that MTL influences team effectiveness and team climate. The strengths and direction of this influence depends on the type of MTL. Role satisfaction mediates this effect, especially regarding aMTL. Additionally, we found cultural differences. aMTL is always positively related to role satisfaction and team outcomes. In contrast, nMTL has positive effects in China, but not in Germany. cMTL is especially negative from a German follower perspective, while Chinese followers perceive it somewhere between neutral and positive.

Limitations

Because the data is cross sectional, we can not draw conclusions about the causality of the relationships.

Research/Practical Implications

We draw the conclusion from our results that the way in which a leader is motivated for his or her leadership position is strongly connected to team outcomes. Therefore, it is important for organizations to take motivation to lead into account when filling a leadership position. Additionally,

our data shows that in practice as well as in research it is highly important to consider the cultural background when working with MTL.

Relevance to the Congress Theme

In a rapidly changing world of work where complexity is increasing, it is important that leaders are motivated in a way that they feel satisfied with their role and thus can guide and positively influence their followers.

Relevant UN SDGs

This research contributes to the UN SDGs of good health and wellbeing as well as to decent work and economic growth. We show that motivation to lead is an important factor for the satisfaction of leaders as well as for the effectiveness and the climate of their team. These variables are important for the wellbeing as well as for decent work conditions of leaders and their followers.

Keywords: motivation to lead, role satisfaction, cultural influence

Poster P061

Organizational factors determining workaholism: the results of a systematic review

Modesta Morkevičiūtė & Auksė Endriulaitienė | Vytautas Magnus University

science

Research goals and why the work was worth doing. As the majority of research focused on describing, rather than explaining workaholism, antecedents are probably the least understood aspect of it. The existing reviews did not generate a comprehensive discussion around the theme of workplace aspects predicting workaholism. Therefore, the aim of this review was to systematically review scientific literature on the relationship between organizational factors and employees' workaholism.

Theoretical background. Keeping in mind the fact that organizations often appreciate hardworking employees, the authors suggested that organizational factors (the aspects of work itself, the organizational environment, as well as interpersonal communication) play an important role in the development and maintenance of workaholism behaviors. However, the data of the previous research are still scattered and far from consistent.

Methodology. Computer-based literature searches were conducted through September, 2020. Five online databases were used to search for scientific papers. The key terms used in a literature search (with their synonyms and closely related words) were "workaholism" and "organization". The relevance of the studies was determined by screening the titles, abstracts and full texts. Studies that met the following criteria were considered eligible: research was quantitative; the focus was on the role of organizational factors in predicting employees' workaholism.

Results. The results of the 24 studies in this review show that workaholism is influenced by a wide variety of organizational factors. However, the overall construct of job demands (as well as two specific types thereof that are referred to as emotional and cognitive demands) was confirmed as the most important factor predicting the increased levels of workaholism. Some conflicting information was also found. For instance, although the phenomenon of social support at the workplace was a commonly measured factor in predicting workaholism throughout the studies and although the authors expected social support provided by a manager and co-workers (and overall organizational support) to be the factor decreasing employees' workaholism, however, all of them reported controversial results.

Limitations. The primary limitation concerns publication bias.Taking into consideration the exclusion criteria used during the process of study selection, we did not analyze all the relevant scientific literature in this field. Second, all studies included were cross-sectional in design, limiting the interpretations of cause-effect relationships.

Research Implications. Our systematic review is (to the best of our knowledge) the first to summarize the existing knowledge of the effects of organizational factors on the levels of employees' workaholism. Hence, the present review expands the knowledge of the field and lends highly necessary support to the claims of a link between organizational factors and workaholism.

Relevance to the Congress Theme and UN SDGs. The current review helps to disclose the organization-related factors strengthening workaholism and simultaniously leads to consider how this health-damaging phenomenon can be addressed from organizational level.

Keywords: Workaholism, organization, antecedents

Poster P062

Defining the border between workaholism and work addiction: the results of a systematic review

Modesta Morkevičiūtė & Auksė Endriulaitienė | Vytautas Magnus University

science

Research goals and why the work was worth doing. There was a long period of confusion as to the conceptualization of both forms of excessive work (workaholism and work addiction). We strongly believe that subsuming different types of work-related behaviors under the same heading is not a very good strategy because this "blurs" the meaning of possibly different phenomena. Therefore, the aim of this review was to define the conceptual border between workaholism and work addiction.

Theoretical background. The primary scientific debate is now focused on the juxtaposition of work addiction with workaholism. These terms were often used interchangeably, leading to a lack of conceptual and empirical clarity. It left many questions unanswered such as whether workaholism could be separated from work addiction or maybe both of them could be merged into a single phenomenon and used as synonyms.

Methodology. The purpose of a current study was achieved by performing a systematic search of scientific literature. The search was limited to references published from 2007 onwards. Five online databases were used to search for scientific papers. Since "workaholism" was traditionally used in the literature as a general term to indicate related phenomena (including work addiction), the former was regarded as the general keyword throughout the search. The relevance of the studies was determined by screening the titles, abstracts and full texts. Both authors performed a study selection independently. Only those papers that did not include any established exclusion criteria and that met all the inclusion criteria were analyzed.

Results. A systematic review included a total of 79 studies. Most authors who attributed workaholism to the group of addictions described it as a state of being overly concerned about work, driven by an uncontrollable work motivation and investing much time and effort into work, which leads to negative consequences. Seven clinical criteria (salience, tolerance, mood modification, conflict, withdrawal, relapse and problems) were proposed as key aspects comprising the phenomenon. The authors who named workaholism as a behavioral pattern or a personal characteristic, defined it mainly as the obsessive, irresistible inner drive to work excessively hard and explained the phenomenon in terms of the aspects of excessive and compulsive work.

Limitations. The primary limitation concerns publication bias. It is possible that the validity of the present review was influenced by publication bias due to the exclusion of gray literature, unpublished studies and non-English publications.

Research Implications. This review contributes to literature by integrating current divergent opinions on the conceptualizations of workaholism and work addiction and guiding future research. By reducing the "blurred" boundaries between the similar constructs, our review addressed the issue of the conceptual confusion that hindered theoretical and empirical progress on a field. We suggest that the term "work addiction" should be used to denote merely the genuine addiction and the term "workaholism" - to denote anything related to too high involvement in work.

Relevance to the Congress Theme and UN SDGs. The present study provides a first quantitative summary of differences between workaholism and work addiction, which is a highly important step towards the necessary changes in studying and managing these constructs of employee well-being.

Keywords: Workaholism, work addiction, concept

Poster P063

From training to transfer: a qualitative study on the implementation of motivational counseling by public health insurance practitioners.

Isha Rymenans, KU Leuven

science&practice

BACKGROUND AND PURPOSE - Absence from work due to sickness is an increasing societal problem. Return to work (RTW) can be seen as a complex decision-making process which involves biomedical, psychological and social factors. Personal coaching is needed to facilitate the RTW of work disabled patients. Important stakeholders are public health insurance practitioners who have a dual task: evaluating the eligibility of the sickness benefits but also providing their patients with advice and guidance.

Because of the controlling aspect that is inherently present in these consultations, we suggest that adopting a more positive and need-supportive communication can benefit work disabled patients' well-being. Furthermore, since motivation is an important predictor of RTW, practitioners should focus on enhancing patients' motivation and stimulate them to take charge of their own RTW process. Therefore we developed an innovative counseling method (i.e. motivational counseling) that integrates both the techniques of motivational interviewing and the principles of the self-determination theory.

The purpose of this qualitative study is to explore the experiences of health insurance practitioners who are trying to implement motivational counseling (MC) in their daily practice. This will allow us to provide recommendations for further training and implementation of motivational counseling which in turn can promote the RTW of work disabled patients in the future. Besides these advantages for practice, this study also contributes to expanding the knowledge on transfer of trainings based on motivational interviewing.

METHODS – We used the intervention mapping protocol to develop our motivational counseling training program. This protocol consists of 6 steps: 1) problem analysis, 2) determining change objectives and 3) identifying theory-based methods to address these, 4) practical application into an organized training program, 5) adoption and implementation plan and 6) evaluation plan to conduct effect and process evaluations. 32 public health insurance practitioners (advising physicians, paramedics and RTW-coordinators) will receive a 10-hour training in motivational counseling. One month after we will conduct a focus group with each participating health insurance fund in order to perform a process evaluation of the implementation. A total of 7 online focus groups will be audio-recorded, transcribed and analyzed through thematic analysis. The Medical Research Council (MRC) process evaluation framework will be taken into account for the interview guide and the coding process of the collected data.

RESULTS - The qualitative results are expected to be obtained in December 2022 and analyzed by early 2023.

LIMITATIONS – Our results will only be applicable for the Belgian social security context.

RELEVANCE TO THE CONGRESS THEME AND UN SDG's – This study will contribute to improving the practice of health insurance practitioners and may therefore also benefit their well-being at work. A more long-term goal of this research project is to promote work disabled patients' well-being and

facilitate their process of a sustainable return to qualitative work. Therefore this study relates to the UN SDG's of 'good health and well-being' and 'decent work and economic growth'.

Keywords: sickness absence, training implementation, self-determination theory

Poster P064

Internet addiction, studyholism, and exhaustion: a moderated mediation with optimism

Domenico Sanseverino, Università degli Studi di Torino

science

Research Goals: Understanding the psychological wellbeing of university students by investigating the role of study load and internet addiction as demands and optimism as a personal resource.

Theoretical Background: University students during the COVID-19 emergency experienced increased stress, anxiety, study obsession (studyholism) (Aristovnik et al., 2020; Loscalzo & Giannini, 2021), ICT use for learning and problematic internet usage, related to decreased psychological wellbeing (Gavurora et al., 2022). Study load and Internet addiction (IA) are positively related to academic burnout (Tasso et al, 2021; Zhu et al., 2022). Studyholism is related to stress, sleep problems, and negative affect (Loscalzo, 2021) and it may be considered an early form of workaholism (Atroszko, 2016). Compulsive internet use has been linked with workaholism (Quinones et al., 2016), but this relationship is less investigated in students. However, the presence of personal resources such as PsyCap, of which optimism is a dimension (Luthans & Youssef, 2004), can protect against the risk of adopting maladaptive coping strategies, such as internet and study or work addiction.

Methodology: The study has been conducted during the second lockdown of the COVID-19 pandemic in Italy, involving 10298 participants from 11 universities (70.8% females, mean age 24.25 years; SD= 6.13). Participants gave their informed consent to fill in an online questionnaire on various aspects of academic and personal life. SPSS 26 and R were used to perform descriptive analyses and test a moderated mediation model.

Results: The moderated mediation was conducted including study load and IA as independent variables, optimism as a moderator, studyholism as a mediator and emotional exhaustion as dependent variable. I controlled for age, gender, broad scientific area, and being on par with exams. Both study load and IA were positively associated with studyholism, which partially mediates the relationship between the two IV and exhaustion. Optimism is a protective factor against studyholism, although the interaction effects are positive, showing that the two IV have a stronger effect on studyholism and indirectly with exhaustion for higher level of optimism. The first regression model explains 41% of variance, the second 43%.

Limitations: The study uses a cross-sectional design and self-reported data, increasing the likelihood of common method variance, and excluding causal inferences. There are no systematic pre-pandemic analyses on these dimensions in this population, preventing comparisons.

Research/Practical implications: This research offers some insight about the nature of studyholism and contributes to the notion that study addiction may stem from a combination of personal and contextual resources and demands. The results show that the compulsive use of internet and excessive study load lead to study addiction with negative consequences on well-being.

Relevance to the Congress Theme: Internet addiction and overworking are increasingly common problems, which may originate early; investigating students' wellbeing is important to reflect on what kind of work environments we will shape in the future.

Relevant UN SDGs: Good health and wellbeing, Quality education

Keywords: studyholism, internet addiction, student wellbeing

Poster P065

The longitudinal influence of job and off-job crafting on well-being among school principals: The role of basic psychological need satisfaction

Hiroyuki Toyama, Katariina Salmela-Aro, Lauri Hietajärvi & Katja Upadyaya | University of Helsinki

science

Goal and Theoretical background: The stress of the COVID-19 crisis is clearly taking a toll on school principals, who are already dealing with a large workload (Lien et al., 2022). It is important to take into account their well-being, as they play a crucial role in their school and beyond. Job and off-job crafting may be a promising strategy for principals to adapt to the increasingly dynamic work environment. Job crafting is the process of changing one's job duties or responsibilities in order to improve one's work experience (Tims et al., 2012), while off-job crafting is the process of shaping one's off-job life in a way to meet psychological needs (Kujanpää et al., 2022). Both job and off-job crafting can contribute to well-being (Tims et al., 2013; Kujanpää et al., 2022). However, it is not well understood whether these two types of crafting have unique contributions to well-being when both are simultaneously considered in a single framework. Moreover, the common mediating factors underlying the relationships are not much explored in the literature. This study aims to address these gaps by examining how job and off-job crafting is associated with work engagement and perceived health (fitness and depressive symptoms), and whether need satisfaction mediates these relationships. Combining crafting theories (de Bloom et al., 2020; Times et al., 2012) and self-determination theory (Ryan & Deci, 2008), we propose that an increase in job and off-job crafting contributes to an increase in need satisfaction, which, in turn, predicts desirable changes in well-being.

Methodology: The data was collected from Finnish school principals in the Spring of 2021 and one year later via an online survey platform (Qualtrics). Participants assessed their own job and off-job crafting, need satisfaction, work engagement, fitness, and depressive symptoms. For this study, longitudinal data from 205 principals were used, and hypotheses were tested using path analysis in AMOS 28, with missing data complemented by multiple imputation.

Results: The increase in job and off-job crafting predicted the increase in need satisfaction. The increase in job crafting contributed to the increase in work engagement. The increase in need satisfaction predicted an increase in work engagement and fitness and a decrease in depressive symptoms. Need satisfaction mediated the relationship between crafting and well-being outcomes: the increase in job and off-job crafting contributed to the increase in work engagement and fitness and the decrease in depressive symptoms via the increase in need satisfaction.

Limitations: The main limitation of this study is a small sample size and the risk of common method bias due to the exclusive reliance on self-reporting for the measurement approach.

Implications: The results of this study suggest that increasing job crafting and off-job crafting leads to an increase in need satisfaction, which ultimately predicts desirable changes in well-being. School principals are therefore encouraged to engage in both job crafting and off-job crafting.

Relevance to the congress theme: Accelerating social change and the protracted unforeseen crisis have imposed enormous demands and pressures on school principals, which puts their well-being at risk. Therefore, an effective means for maintaining their well-being is urgently needed. This study suggests that by crafting the job and off-job activities, principals may be able to manage their well-being in a proactive manner.

Keywords: Job crafting, off-job crafting, need satisfaction

Poster P068

Intersectionality at Work: An Investigation of Ethnicity and Sexual Orientation Perceptions

Neslihan Turnalar-Çetinkaya, MEF University; Serin İşiaçık, Işık University

science

Estimating Turkey's cultural nature (i.e., collectivistic, House et al., 2004), identities falling outside the dominant social identities (i.e., Turkish and heterosexual, Özatalay & Doğuç, 2018) may be more likely to be stereotyped and discriminated in work setting (e.g., Strinić et al., 2021). As intersectionality theory (Crenshaw, 1989) emphasized, since people have multiple identities, the possible intersection of these identities can provide diverse insights. Likewise, double or multiple jeopardy theory (Chappell & Havens, 1980; Nelson & Probst, 2004) argued that belonging to more than one outgroup simultaneously can increase the severity of discrimination.

Based on the gap in the literature and grounded in intersectionality theory (Cole, 2009), our study's aim was to explore others' competence/warmth perceptions and preference to have others as colleagues and managers regarding their ethnicity, sexual orientation, and their intersection in the business context.

We adopted a descriptive research methodology. We had different profiles indicating ethnicity (Kurdish/Turkish), sexual orientation (Homosexual/Unspecified), and interaction of them. We asked university students to rate the profiles on their level of warmth and competencies by deploying the Warmth/Competence Survey of Cuddy et al. (2009). We also asked whether others would like to be colleagues with them and would like to have them as their managers. Our sample consisted of 451 university students (87.1% Turkish, 82.3% Women).

We conducted a MANOVA to check grouping variables' possible effects on warmth and competence perceptions and preference for being a colleague or a manager. The results revealed that the grouping variable explained 12% of the variance in competence ($F = 70.97$, $p < .001$), 7% in warmth ($F = 39.25$, $p < .001$), 15% in colleague preference ($F = 93.65$, $p < .001$), and 20% in manager preference ($F = 130.35$, $p < .001$). Tamhane's T2 analyses revealed that the Turkish category was rated significantly warmer than Kurdish and other categories, including homosexuality. Compared with TurkishxHomosexual, KurdishxHomosexual was evaluated as significantly less warm. The Homosexual category did not significantly differ from the Kurdish. The analysis also showed that Turkish was evaluated as the most competent and significantly more competent than all other categories except UnspecifiedxKurdish. On the other hand, HomosexualxKurdish was evaluated as significantly less competent among all categories but Homosexual. Regarding the preference to be a colleague, Homosexual was significantly less preferred than HomosexualxTurkish. On the other hand, Kurdish was rated less preferred than HomosexualxKurdish. The TurkishxHomosexual category was rated over the Homosexual and HomosexualxKurdish. Regarding the preference for a manager, the categories including homosexuality were significantly less preferred than ethnicity and unspecified only, and unspecified x ethnicity categories. While Kurdish was less preferred than Unspecified, Turkish was more preferred than Unspecified.

Some limitations include a sample dominated by women and people who identify themselves as Turkish. Yet, as students will soon be part of the workforce, it draws attention to the fact that organizational decisions are vulnerable to societal perceptions. Thus, practitioners should cultivate practices to hinder latent biases while researchers focus on different identity elements and empirically test the phenomenon.

Keywords: intersectionality, social content model, organizations

Poster P069

Social well-being profiles: Associations with trust in managers and colleagues, job satisfaction, and intention to leave

Marita Heyns, Ian Rothmann & Eugeny Hennicks | Optentia, North-West University, South Africa

science&practice

Recent research (2023) increasingly shows that the quality of working relationships is the single most important factor that affects employees' well-being. It is thus essential that social scientists pay more attention to this aspect of well-being to form a better understanding of how it can support employees from diverse backgrounds to equally thrive within work and organizational contexts.

Existing research shows that interdependence among employees is crucial due to information, resources and social support that flow though networks. The workforce composition has also become more diverse and calls for a nuanced understanding of the factors that may influence employees' sense of social inclusion, belonging and connectedness to others – factors that influence their motivation and access to equal opportunities and decent work.

Using a positive psychology framework as point of departure, well-being can be understood as a multidimensional, context specific construct which reflects an individual's subjective state of feeling good (emotional well-being) and positive functioning (psychological and social well-being). Previous studies focused relatively more on the emotional- and psychological components while less is known about employees' social well-being.

This study challenged homogeneity of social well-being among members of a diverse workforce. It employed a cross-sectional survey design and a person-centered approach to identify social well-being profiles and to examine differences between the profiles in terms of trust in managers and colleagues, job satisfaction, intention to leave, and demographic variables.

The study is situated in a developing country context and targets permanently employed individuals of a utility organization which is critical to the South African economy (N=403). The Social Well-being Scale, Workplace Trust Survey, and Job Satisfaction and Turnover Intention Scales were administered. Mplus version 8.6 was used to analyse data. Three profiles of social well-being were identified: the socially well, socially withdrawn, and superficially socially well. The first two profiles demonstrated either relatively high or relatively low scores on five dimensions of social well-being (contribution, integration, acceptance, actualization, and coherence). The superficially socially well profile showed above-average social contribution and integration, but below-average social acceptance, actualization, and coherence. The socially well profile was associated with trust in managers and colleagues, job satisfaction, and low intention to leave. The opposite patterns were found for the socially withdrawn profile. Two demographic variables, namely, age and service years, were associated with profile membership. The associations between age, job satisfaction, and intention to leave were more significant in specific social well-being profiles.

The originality of this research stemmed from methodically identifying and comparing specific subgroups of employees both in terms of their individual social well-being configurations and how these patterns related to trust relationships at work and complexities as influenced by a demographically diverse workforce composition. Recommendations were made regarding ways in which the social well-being of specific sub-populations within the sample group could be supported

Keywords: social well-being; trust; latent profile analysis

Speaking without words: A meta-analysis of over 70 years of research on the power of nonverbal cues in job interviews

Michelle Martin-Raugh, The University of Texas at Arlington; Cristina Anguiano-Carrasco, ACT; Justin Banfi, University of Albany, SUNY; Jason Randall, University of Albany, SUNY; Harrison Kell, Educational Testing Service

science&practice

Interviews are the most popular method of personnel selection (Posthuma et al., 2002). Prior research shows that evaluations of interview performance are affected by both the verbal content of job candidates' responses to interviewers' questions (Burnett & Motowidlo, 1998; Krajewski et al., 2006) and by the nonverbal cues, behavior and characteristics beyond speech content, displayed within the interview (e.g., Fox & Spector, 2000). Moreover, people's nonverbal cues influence interviewers' judgments even after accounting for the content of interviewees' responses (Burnett & Motowidlo, 1998).

Yet, it remains unclear which cues most influence interviewers' judgments. Often hampered by small sample sizes and a limited number of cues, studies have produced inconsistent results. However, meta-analytic research may resolve the uncertainty produced by inconsistent results by aggregating results across multiple studies, allowing for the estimation of true, underlying effects by sifting the "signals" of those effects from the "noise" often contributed by small, underpowered studies (Schmidt & Hunter, 2015). Although many meta-analyses have focused on the employment interview (e.g., Huffcutt et al., 1996; Levashina et al., 2014), no meta-analytic research to date has been dedicated to examining the impact of specific nonverbal cues on interview performance.

The purpose of this investigation is to conduct the first comprehensive meta-analysis of the relationship between specific nonverbal cues and job interview performance. To do so, we integrated findings across 63 studies (total $N = 4,868$) for inclusion in our meta-analysis. The nonverbal cues demonstrating the strongest association with employment interview performance were professional appearance ($\rho = .62$), eye contact ($\rho = .45$), and head movement ($\rho = .43$). Only two of the five moderators examined (interview modality, structure, duration, gender, interview type, and study design) explained meaningful variance in the relationship between nonverbal cues and interview performance.

Gender of the interviewee played an important role on the effect of most, but not all, nonverbal cues on interview performance. Samples with more women than men demonstrated stronger effects of kinesics, professional appearance, facial expressions, and overall dynamic cues on interview ratings, but no effect on stigmatized appearance, vocalics, static overall, and nonverbal overall cue categories. Thus, women may be rewarded in their interview ratings more than men for how they dress (professional appearance) and for displaying dynamic nonverbal cues in the kinesics category, which includes facial expressions (eye contact and smiling), head movements, haptics, hand gestures, and posture. Second, the effect of nonverbal cues on interview performance is stronger in experimental studies than in correlational studies. This may have occurred because many experimental studies use simulated interviews in low stakes settings where motivation to effectively respond may be lacking (e.g., Woodzicka, 2008), which could artificially inflate the effect of nonverbal cues on interview performance.

Overall, results suggest nonverbal cues and characteristics are an important influence on job applicants' success in employment interviews. These findings imply that applicants may be able to improve their interview performance by honing some of their nonverbal skills.

How much is too much? Reconceptualizing and Measuring Information Overload and Communication Overload

David Schischke, Rebecca Müller, Conny H. Antoni & Benedikt Graf | Trier University

science

Research goals/Relevance : Due to employees working from home, there has been a surge in the use of Information and Communication Technologies (ICTs) at work. Studies show that communicating via ICTs differs from face-to-face interaction and that collaborating via ICTs is related to adversarial outcomes. To improve understanding of these outcomes, this study aims at 1) re-defining two central constructs, namely Information Overload (IO) and Communication Overload (CO) and 2) developing short scales that enable researchers and practitioners to measure both IO and CO efficiently.

Theoretical Background : IO and CO are two central constructs of Technology Overload. Meta-analyses indicate the negative impact of the constructs on e.g. employee's well-being. However, most research confounds the concepts of IO and CO, e.g. by using measures of IO to measure CO or vice versa.

While IO and CO are correlated, both can exist independently. IO develops mainly due to the contents of an information, which can be explained using Cognitive Load Theory. CO develops mainly due to the number of messages, as explained by the experienced Social Load and the perceived Normative Response Pressure. This is in line with meta-analytical findings that IO is more strongly affected by Information Quality than Quantity.

Methodology : Based on existing literature, definitions for IO and CO are derived. In a second step, new measurements for IO and CO are generated. Two samples will be collected, sampling professionals working at least 20h/week, whose work requires the usage of ICTs. The scale development will be done using EFA on the first and CFA on the second sample.

Expected Results : Data collection is ongoing (First sample N = 127, Second sample currently at N = 78). We aim at developing short-scales for both IO and CO, that fulfil both discriminant and convergent validity requirements. Predictive validity will be tested by predicting Technostress, work-related burnout and well-being. Construct validity will be evaluated using adapted measures from the NASA-TLX to measure Cognitive and Social Load. Exploratory factor analyses from the first sample indicate that IO and CO are distinct constructs that can be measured with the developed instrument.

Research/Practical Implications : The refined concepts will enable future research to evaluate the negative outcomes of ICT usage at the workplace more precisely. The developed scales will enable practitioners to monitor the overload of employees and avoid long-term negative consequences such as burnout. They can also be used for longitudinal field studies in organizations.

Limitations : Because we aim at developing short scales, the statistical properties of the scales are likely not going to be ideal compared to longer instruments.

Relevance to the Congress Theme : The refined concepts help understanding new sources of strain in the changing world of work. Measuring them can help employers to avoid adversarial outcomes for their employees.

Keywords: Cognitive Load, Computer Mediated Communication, Technostress

Poster P073

Does work-related rumination (affective, problem-solving pondering) or burnout predict psychiatric morbidity?

Zoe Clothier & Mark Cropley | University of Surrey

science

Research goals and why the work was worth doing:

Burnout has been associated with poor health and work-related outcomes, especially among health professionals. Health professionals are regularly exposed to excessive high-stress conditions, particularly throughout the COVID pandemic, which has contributed towards increased higher reported burnout within this occupational group.

The aim of this study were to examine the association between work-related rumination, burnout, with psychiatric morbidity among health professionals.

Theoretical background:

The association between burnout and psychiatric morbidity has been well-established in previous literature. Especially among health professionals, there is a high prevalence of psychological distress, and this seems to be related to high rates of occupational burnout in this profession.

Furthermore, research suggests that the role of unwinding from work is critical for several aspects of wellbeing. Work-related rumination (the inability to mentally unwind and switch off from work) is detrimental to health and is associated with several health problems, such as depression, anxiety, diminished executive function, and occupational burnout. Affective rumination is a form of negative thinking involving intrusive, repetitive thoughts about work during non-work time. Problem-solving pondering is typified by prolonged thinking about a specific problem, or evaluation of previous work to see how it can be improved. It is not necessarily negative, however, as many people enjoy the act of evaluating their work performance.

Design: This was a cross-sectional questionnaire study. The questionnaire included questions taken from the Maslach Burnout Inventory (Maslach & Jackson, 1981), the affective rumination and problem-solving pondering subscales of the Work-Related Rumination Questionnaire (Cropley et al., 2012), and the General Health Questionnaire-12 (Goldberg & Williams, 1988).

Results: Correlational analyses showed a significant positive association between emotional exhaustion and problem-solving pondering (.453, $p < .001$), and emotional exhaustion and affective rumination (.740, $p < .001$). There was a negative significant correlation between emotional exhaustion and personal accomplishment (-.352, $p < .001$).

The main research question was tested using a multiple regression. Control variables (age, gender) were entered in step 1, burnout (emotional exhaustion, personal accomplishment, depersonalisation) in step 2, and work-related rumination (affective rumination, problem-solving pondering) in step 3. The control variables accounted for 1.3% of the variance and were not significant. Burnout contributed significantly to the model, explaining 38.2% of the variance ($R^2 = .411$, $F(5,105) = 13.97$, $p < .001$). After controlling for burnout, work-related rumination contributed significantly to the model, explaining 50.8% of the variance ($R^2 = .541$, $F(6,105) = 16.51$, $p < .001$). Affective rumination accounted for 32% of the variance, and problem-solving pondering accounted for 19% of the variance within the model.

Limitations: These findings are based on cross-sectional data, thus causation cannot be determined. The sample is also small (N=106) and biased towards pharmacists (86.7% of the sample).

Research/practical implications: These preliminary results reiterate the importance of being able to mentally switch off from work, and highlight the need to provide support with achieving this successfully.

Keywords: Rumination, burnout, wellbeing

Poster P074

Evidence-based approach for categorizing change projects to guide practitioners on their investment decisions for organizational change management

Kerstin Schroeter, SAP Deutschland SE & Co. KG; Oliver Kohnke, University of Mannheim

science&practice

Research Goals

The need to deal with simultaneous changes has become the new normal in organizations. Even if potential negative consequences of poorly managed changes on employees' wellbeing and health are well known (e.g., Oreg et al. 2011) budget for change-management (CM) is scarce, underestimating its importance (Creasey et al., 2018). Hence, practitioners ask for an evidence-based tool to justify their OCM-investments. This research developed and validated a tool that aims to help demonstrating the need for CM.

Theory

Nadler et al. (1995) defined 4 types of organizational changes (Tuning, Adaptation, Reorganization, Recreation) by combining the two dimensions continuity (incremental vs. discontinuous change) and timing (anticipatory vs. reactive change). This research builds upon the assumption of Nadler et al. (1995) that the change-categories (CCs) differ in their intensity of change and the associated need for CM-resources.

Hypothesis 1 assumes ordered mean differences in CCs for (H1a) subjective-change-impact (SCI, Caldwell et al., 2004) and for (H1b) stress (Oreg et al., 2018) in the following order: [low SCI/ stress] Tuning < Adaptation < Reorientation < Recreation [high SCI/ stress], investigating content respectively criterion validity.

Hypothesis 2 addresses the assumed interaction of CCs and CM-practices (e.g., communications). While more intense changes lead to higher SCI and stress levels, CM-practices aim to reduce negative consequences (Jong et al., 2016; Morin et al., 2016). The latter relation is expected to be stronger for more intense CCs.

Methodology

The two change dimensions were adapted from Nadler et al. (1995) and assessed with self-developed items to build the 4 CCs. Other scales (SCI, stress, CM-practices) were obtained from previous research (Caldwell et al., 2004; Oreg et al., 2018; Straatmann et al., 2016). Data were collected via an online-survey (cross-sectional). Sample: 773 persons M(age) = 39.3 years (52.6% female) from a financial institution impacted by various organizational changes. Hypotheses were tested using the statistical tool R, "successive-difference-contrast-testing" and linear regression modelling.

Results

Results mainly support hypotheses, showing a main effect of CCs on SCI (H1a) $F(3, 769) = 19.51$, $p < .01$, $n_p^2 = .067$ and on stress levels (H1b) $F(3, 769) = 10.33$, $p < .01$, $n_p^2 = .035$ with most means differing between CCs in the assumed order. However, not all mean category differences are significant. Testing for interactions (H2) shows support for some CM-practices, yet not reaching significance in model comparisons. For more intense CCs, better CM-practices show stronger relations to reduced levels of SCI and stress compared to less intense CCs.

Limitations & Implications

Being aware of limitations (e.g., correlational design, self-report measures bearing the risk of common-method-bias, employees from one organization) the tool demonstrates its usefulness by showing expected differences in outcome variables across CCs. Partially significant interactions also tend to support H2, indicating that CM may be more important in more intensive CCs. For CM-practitioners the tool might be a fruitful way to further support their CM-investment decisions. Being able to demonstrate decision makers the type of change employees are facing, together with potential negative risks, opens the stage for earlier and likely more successful negotiations on budget for CM.

Keywords: Organizational Change Management, Type of Change, Stress

Poster P075

Only who has will be given more? A panel analysis on the psychology of economic inequality, financial inclusion, and future investments in Germany

Robin Bachmann & Ilka Gleibs | London School of Economics and Political Science

science

Research goals and why the work was worth doing: Economic elites generate much of their income from capital. However, even in countries such as Germany with relatively high income and savings, most households do not invest their money to generate additional income, better prepare for retirement or accumulate wealth. In face of aging societies, social spending restraints and high investments needs required for a green transformation of economies in Europa, households need to invest more privately. Our research aims at a better understanding of social psychological factors that influence financial decisions and might influence public financial policies.

Theoretical background: Economic research struggles to explain low Capital Market Participation (CMP). This is true for research based on classic economic models (Haliassos et al., 1995) but also research from behavioral economic models including psychological factors (Barberis et al., 2003). Based on more recent research on decision-making under different socioeconomic life conditions (Haushofer et al., 2014), we investigated psychological factors for capital market participation and focus on how they differ considerably between Socio-Economic Status (SES) groups.

Design/Methodology/Approach/Intervention: We analyzed four waves of German Socio-Economic Panel (GSOEP) data spanning around 20 years and including around 13,000 household heads. We estimated the association of risk attitude, patience, control beliefs, political orientation, social trust and sociability with CMP in different SES groups as well as the overall interaction of these variables with a latent SES factor and its components (income, education level and occupational status). We regressed on CMP in the respective year but also on CMP over the years based on a Latent Growth Class Analysis (LGCA).

Results obtained or expected (if not available, it must be made clear when they will be): We found that risk attitude and right political orientation (and negatively also patience) were strong CMP predictors for higher SES, while control, trust and sociability were stronger CMP predictors for lower SES. We also analyzed different dimensions of sociability.

Limitations: Findings are based on associations between self-reported measures. The binominal measurement of CMP and especially its stability over time made it difficult to analyze within-person association of CMP and psychological variables. However, the panel data provided a unique opportunity to analyze differences across a full range of socioeconomic groups as well as to take a longitudinal perspective based on the LGCA.

Research/Practical Implications: Financial policy makers and investment product designers might need to focus less on different risk profiles to increase CMP and financial inclusion, but instead on control and trust perception as well as social identities in relation to financial decisions, especially in lower SES groups. Estimated effect sizes and assumed change levels suggested that psychological interventions might have equal impact as direct monetary payments.

Relevance to the Congress Theme: “The Future is Now.” Despite the feeling of being overwhelmed by current crises, households need to regain a sense of control, social trust and future optimism.

They need to make NOW financial – but also non-financial - investments for THEIR FUTURE and the future of THEIR SOCIETIES.

Keywords: Economic inequality, financial decisions, socioeconomic status

Poster P076

Work readiness in student nurses voluntarily supporting NHS during COVID-19 pandemic. A mixed methods investigation into students' experiences.

Ethan Shapiro & Barbara Piotrowska | Edinburgh Napier University

science&practice

This study explored the experiences of student nurses who responded to Covid-19 crisis to understand the impact of this early transition to the clinical workforce. This study was important to do as it provided evidence for how to improve training for nursing students as they transitioned to professional practice.

Previous research has shown high turnover rates of graduate nurses within the first year of their work (e.g., Kovner et al., 2014; MacKusick & Minick, 2010; Shi et al., 2016). Nursing graduates have been previously shown to be overwhelmed and stressed during the transition from student to clinical practice (Duchscher, 2009; Flinkman, Isopahkala-Bouret, Salantera. 2013; Hofler & Thomas, 2016). The transition period has been recognised as a particularly stressful time due to issues of "reality shock" as nurses fully immerse themselves into the work environment. Kramer put forward Theory of Reality Shock (1974) which described this difficulty experienced by new graduate nurses.

This was a mixed methods study that incorporated quantitative and qualitative methods. The first part of the study we utilised the Work Readiness Scale (WRS-GN; Walker et al., 2015) to measure participants' self-perceived readiness to work at the beginning of their COVID-19 placements. In the second part of the study interviews were conducted. Themes were drawn from the data and used to support the development of an interview schedule for the second part of the study. There were seven interviews conducted lasting between 45-60 minutes. These interviews were Thematically Analysed (Braun & Clarke, 2006).

Overall readiness scores were at a relatively high level (M= 7.04 on a scale from 1 to 10) with the aspects of personal work characteristics perceived as the lowest (M= 3.87). There were five themes that emerged from the analysis of interviews. These themes were: coordination of support, drivers to take part, identified gaps in clinical knowledge, and developing into the role. These themes highlighted the importance in understanding the transitional experience as nursing students prepare for clinical practice.

This study has implications for how to improve training for nursing students as they transition to professional practice by informing undergraduate curricula of the dynamic experiences of this process. This is an important consideration as nursing students have highlighted through this study areas in their education that has not prepared them for clinical work as well as support that would be instrumental in the process of transition.

The pandemic brought forth an overwhelming demand on healthcare system. Therefore there is a need for understanding of experiences and dynamic processes of people's transition to professional practice. This study contributes to our understanding of how we can support our nursing students' development and transition to the hugely demanding and ever-changing work. This is imperative in dealing with current and future healthcare crises, which speaks to the themes of Contribution and Urgency.

Keywords: Qualitative, Healthcare, Training

Work-related stress and Burnout in high school teachers: development and evaluation of an online training for stress-reduction

Marlene Penz, Bernad Batinic & Anna Katharina Pöcksteiner | Johannes Kepler University Linz

science&practice

Research goals: Based on the increased need for e-mental health interventions, that became especially apparent during the Covid-19 pandemic, we aimed to develop a brief online-based mindfulness-based stress reduction (MBSR) program, that supports high school teachers in developing positive coping skills to reduce stress and prevent burnout.

Theoretical background: High school teachers experience a high amount of work load embedded in a socially demanding work environment. They belong therefore to a professional group that is especially prone to experience burnout symptoms, such as emotional exhaustion. Work-related stress and burnout are not just considered as a challenge for mental but also for physical health, which highlights the importance of "teaching" teachers stress-reductive coping skills.

Design: The whole faculty of a local Austrian school was invited to participate (N = 60). Participants provided questionnaire date regarding work-related stress (effort reward imbalance/ERI) and burnout (MBI-GS) as well as about physical (SF-36) and mental (GHQ-12) health, at two time points before (N = 33) and after (N = 29) the intervention. Further, salivary cortisol (cortisol awakening response/CAR) was assessed as an additional stress marker at both time points (N = 10). The MBSR intervention included four evening online meetings, 60 minutes per session, combining traditional MBSR elements with skill training.

Results: There was a significant negative relationship between work-related stress/ERI and mental health/GHQ-12 ($r_{(32,28)} = -0.45$) at both assessment points as well as with self-reported physical health (e.g., "vitality": $r_{(32,28)} = -0.44/-0.48$). Similar but even stronger relationships were found regarding burnout symptomatology/MBI-GS (e.g., SF-36: vitality": $r_{(32)} = -0.72$). No significant stress-reductive effect could be detected, neither based on self-report, nor by changes in cortisol levels.

Limitations: Due to a surprisingly low rate of participation in the MBSR intervention (N = 8), results regarding the evaluation of the intervention can only be considered as preliminary which might also explain the lack of an intervention effect.

Practical implications: Considering the reported associations between perceived stress and health in teachers, we suggest to implement the training of health-preserving coping skills into the training of high school teachers. We further aim to sensitize in general for the health-imperiling effect of work-related stress.

Keywords: teacher burnout, work-related stress, MBSR

Poster P078

Negative Effects of the Exposure to Sexism on Women's Performance and Job Satisfaction: a multi-group analysis between STEM and non-STEM workplace

Martina Morando & Silvia Platania | Psychology Section, University of Catania

science

Research goal

The gender gap is a highly topical issue, of universal nature and imbuing the culture, science, economy and all formal and informal social groups. Sexist assumptions about women and men, manifested as gender stereotypes, are partially responsible for these inequalities, and negatively affecting performance, sense of belonging, mental health and job satisfaction.

The aim of this study is to examine the impact that sexism could have on performance and job satisfaction in a sample of female workers in STEM and non-STEM sectors.

Theoretical background

The theory of ambivalent sexism introduced by Glick and Fiske (1996, 1999) claims that sexist attitudes include substantial ambivalence from each gender to the other. Hostile sexism refers to explicitly antagonistic sexist attitudes, while benevolent sexism refers to apparently positive but implicitly devilish attitudes (Acar & Sumer, 2018). Studies revealed that benevolent sexism was detrimental to women's personal and professional well-being (Rubin et al., 2019; Moya et al. 2007), implied lower career aspiration levels and impacted on task performance.

Click et al.(2000) showed that significant correlations between levels of benevolence and hostility could be considered indices of gender inequality.

Methodology

Three-hundred-and-sixty-four women were enrolled to participate in the study. They agreed to complete a survey on google platform, measuring as predictors Work Engagement, Psychological Capital and Organisational Support; as Moderators the Ambivalent Sexism toward Women and the Hostile Sexism toward Men, and as outcomes Task Performance and Job Satisfaction. For the moderation hypothesis it was used SEM, whereas for estimating the difference between STEM and non-STEM workplaces it was applied invariance tests and multigroup analyses.

Results

The results showed that benevolent sexism towards women (ASI) and hostile sexism towards men (AMI) had a significant direct negative effect on task performance and job satisfaction. Furthermore, benevolent sexism dampened the positive relationship between Psycap and Task Performance and between Organisational Support and Task Performance. Whereas hostile sexism only dampened the positive relationship between Work Engagement and Job Satisfaction. A significant difference emerged in relation to the effect of the work context (STEM vs. non-STEM), supporting the greater impact of sexism in traditional male-dominated contexts.

Pratical Implication

The results suggested that the perception and exposure to sexism affected work outcomes and counteracted the resources held such as psychological capital and work engagement or perceived organisational support. These findings provide insight into the effect of sexism on personal and

occupational wellbeing and suggest that empowering personal and organisational resources could be a functional strategy.

Relevance to the Congress Theme

The topic of gender job equality is currently central to the international debate in the field of counselling and organisational psychology, and its promotion is one of the priority goals of the Agenda for Sustainable Development. Furthermore, equality and equal opportunities between men and women is one of the most reliable and effective tools for combating poverty and social exclusion, and thereby contributes to the guarantee a decent work for all and to important economic growth and development.

Relevant UN SDGs

Gender equality, Decent work and economic growth

Keywords: gender equality, sexism, workplace

Poster P079

Development of a measure for the Behavioral Assessment of Telework Strategies (BATS)

Gavril Rad & Laurențiu Maricuțoiu | West University of Timișoara

science&practice

The present work started from the qualitative review of previous literature through which we extracted a series of behaviors that people use when working from home, with the aim of building a questionnaire that quantitatively evaluates the behavioral strategies of this type of work. The main objective of the present study is to develop and validate the Behavioral Assessment of Telework Strategies Questionnaire (BATS). Secondary objectives address the internal and external validity of the BATS questionnaire.

The work-family boundary management literature states that people create, maintain, or change boundaries to simplify and categorize the world around them (Ashforth et al., 2000). Boundaries reffer to space and time, and individuals are cathegorised into segmenters or integrators when they separate or mix family and professional roles (Nippert-Eng, 1996). Clark (2000) argues that people create psychological boundaries alongside physical and temporal boundaries that can be flexible or permeable. Individuals may also impose physical, cognitive, and behavioral boundaries with the implication that they may shift from one role to another multiple times during a day. Based on boundary management theories, the boundary work tactics model was created. This model posits that individuals adopt behavioral, physical, temporal, and communicative strategies to manage the conflict between family and work roles as effectively as possible (Kreiner et al., 2009).

The methodology includes content validity, factorial structure, construct validity and replicability of the BATS questionnaire. The data were collected in two samples, an internal sample (N=374), population from Romania and an external sample (N=342), population from the USA. To analyze the data and the factorial structure of the BATS questionnaire, we applied the method of confirmatory factor analysis, using the R statistical computing platform.

The results of the confirmatory factor analysis on the internal sample demonstrated a model of the BATS questionnaire having 24 items related to 6 factors (physical, behavioral, temporal, communicative, me-time and role mixing). The scale has obtained adequate model fit and residual evaluation indices and good internal consistency, both for the entire scale and separately for each dimension. Regarding the external sample, the results of the confirmatory factor analysis were similar to the results obtained in the internal sample, both in terms of internal consistency and in terms of fit indices, which denotes a good evidence of replicability.

One of the limitations of this study may be the fact that the data was collected immediately after the cancellation of the restrictions due to the pandemic context, the data may be somewhat unnatural because many of the respondents were forced to work from home for the first time.

The present study brings theoretical improvements to the literature aimed at managing role boundaries by adding two distinct complementary strategies to the tactics proposed by Kreiner and his collaborators (2009), as well as practical implications by developing and validating the BATS questionnaire. We believe that this telework behavioral assessment tool can be useful in managing the boundaries between professional and family roles, potentially benefiting both individuals and organizations.

Keywords: boundary management strategies, telework

Tell me a different story! Storytelling, reflective practice and self-awareness: A case study

Marco Peña Jimenez, University Paris Nanterre; Sabine Pohl, Free University of Brussels; Daria Mariangeli, Nexteria; Luis Caramagna, Nexteria; Letizia Dal Santo, University of Verona

Aim: The purpose of this case study was to test the role played by storytelling and reflective practices in promoting self-awareness at work. More in detail, by focusing on individual reflectiveness, we aim to explore how constructing, giving sense and sharing stories may contribute to individuals' self-awareness (Boyatzis, 2009, 2019).

Theoretical background: According to the narrative, to the reflective approach (Robert & Ola, 2021) and particularly to the storytelling intervention model (Mirvis, 2019), individuals can develop their self-awareness through practices, which allow them to make sense of their work experiences from different perspectives.

Method and Intervention: 10 managers of an Italian company (outsourcing and consulting sector) participated in a 12 month program. In the first part (3 months), participants were asked to tell some stories about their work life. In the second part (5 months), managers were involved in reflective sessions, where they recaptured their prior experiences, used reflexivity and evaluated them by taking different perspectives. In the third part of the program (4 months), participants narrated again their stories, by using a different sense meaning. All stories were collected and a content analysis based on thematic coding was conducted (Braun & Clarke, 2016, 2019).

Results: The coded themes were: "Myself at work", "My relations with others" and "My relationship with time". Regarding the first theme, participants described their emotions and thoughts as personal "perturbations", which interfere with their professional attitudes. Regarding the second theme, colleagues and clients were split into "good people" and "bad people". Concerning the relation with time, stories were categorized as "Losing time" and "Running against time". Then, after the reflective sessions, the main themes took different meanings. Emotions appeared as "natural components", which may contribute to better understanding the context. Thoughts were divided into "mental loops" to be stopped and "reflective thoughts" to be developed. Relations with others were reinterpreted by using others' points of view, so that people's attitude and behaviors could assume different nuances. The relationship with time was described as an emerging chance to "Sparing time", that is to adopt a proactive attitude toward the temporal dimension and to try to create "empty times" to better think and to choose how to use time more properly.

Implications: Managers' development programs (e.g., mentorship, coaching) may consider using storytelling and reflective practices to develop self-awareness and a better understanding of others' actions. Moreover, reflexivity can contribute towards developing thinking skills and proactive attitudes.

Relevance to congress themes: Developing leaders' self-awareness can be beneficial for both themselves and their subordinates. Thus, in a context of changes in the world of work that are generating phenomena such as the "Big Quit", reflection practices might develop meaningful jobs in the workplace (UN SD Goal 3).

Limitation: This study was focused on exploring how managers reinterpret their meaningful work experiences by developing their self-awareness. Therefore, future studies ought to be conducted in different and controlled settings, with different measurement tools, to evaluate the effectiveness of the intervention protocol based on reflection activities.

Keywords: storytelling, reflectiveness, self-awareness

The role of leadership during implementation of robots in elderly care

Maria Forsgren, Susanne Tafvelin & Aandreas Stenling | Umeå University, Department of Psychology; Ulrika Haake, Umeå University, Department of Pedagogy

science

Research goals & contribution

Due to the demographic development the social services in Sweden are, to an increasing extent, implementing automation as a strategy to meet demands for welfare services. This has generated many questions from both practice and academia, and today we know little about how these types of welfare technologies best are implemented, and what the consequences are for employees and users. The overarching aim of the study is to contribute with knowledge on how managers in social services successfully can support implementation of automation. This will be done by studying an implementation of medical dispensers. The study will explore meanings assigned to the role of leadership and perceptions of what managers have done to support the implementation.

Theoretical background

To explore leadership in relation to implementation of the robot this project will foremost build on theories of leadership, including implementation leadership. The implementation framework of CFIR (Consolidated Framework for Implementation Research) describing factors that may explain implementation outcomes serves as a background. Empirical findings are assembled from various fields of research related to implementation of the technologies in focus.

Design, method & results

This study is a qualitative interview study involving elderly-care within two municipalities in Sweden. Semi-structured individual interviews will be conducted with professionals who have been influenced by or involved in the implementation of digital medical dispensers. A purposeful sampling will be used including key informants involved in the implementation as well as aiming at covering varying perspectives. Being dependent on the cooperation with key persons to assist with sampling in practice, is regarded as a limitation.

Reflexive thematic analysis will be used to develop inductive, and data driven themes developed from codes, following the coding of the whole data set. Using a reflexive approach means recognizing coding as a profoundly subjective process. This means bringing theoretical assumptions to the surface as well as embracing personal experience of the coder as a resource in the process.

30 - 35 interviews will be conducted and analyzed during spring 2023. The Poster will contain early results exemplify and illustrate insights to some aspects of the cases.

Practical Implications

Medical dispensers are designed to help people take the right medication at the right time without medical supervision. These technologies are envisioned to create smarter, more qualified work and result in better quality care, empowering clients. The two municipalities are in different stages of implementation, both having several dispensers in full use. As time passes new users will enroll using

dispensers making it important for the project to contribute with knowledge, to the municipalities studied, and to other contexts where findings seem to be of value.

Keywords: Implementation, Automation, Elderly-care

Poster P082

Towards sustainable careers in retail: Job demands, job resources and personal resources as predictors of work-related and health-related outcomes

Philip Ström, Magnus Sverke, Constanze Leineweber, Jacobus Pienaar & Helena Falkenberg | Stockholm University

science

Research goals

Employing close to one out of ten workers in Europe, the retail industry is a major force in the European economy. It has undergone major structural changes related to consumer behaviours, global competition and digitalization, and is projected to continue doing so. There is limited knowledge available about how these changes affect working conditions and, thus, mental health, attitudes and behaviours. Taking the Job Demands-Resources model as point of departure, the aim of this study is to investigate how a) job demands (e.g., emotional demands, job insecurity and physical workload), b) job resources (e.g., control, leadership and learning opportunities) and c) personal resources (e.g., employability and coping) associate with employee mental health (burnout), attitudes (job satisfaction) and behaviour (turnover intention) among retail workers in Sweden.

Background

Many young workers with lower education are employed in retail. Here, they often experience a work situation characterized by alternative employment forms in order to meet flexibility needs, as well as customer interactions and evolving competence demands. Recent studies on retail workers have reported challenges related to lack of support and sense of security, especially for young workers.

Associations between work environment factors and outcomes are well established in the existing literature. Less is known, however, about how these associations can be applied to outcomes among retail workers, especially considering job demands and job resources in the retail industry. Previous literature has called upon further investigation of the customer–employee interaction as well as factors related to high levels of flexibility and insecurity, physical workload and evolving competence demands.

Methods

Cross-sectional survey data were collected through the nationally representative Swedish Longitudinal Occupational Survey of Health [SLOSH] in the 2020 wave. A sub-sample representing individuals with employment in the retail sector will be selected (preliminary N = 765) based on occupational codes as applied in previous studies. The research questions will be investigated through hierarchical multiple linear regression with burnout, job satisfaction and turnover intention as the outcome variables. Step 1 will be demographic controls (e.g., gender, age and education). Step 2 adds job demands and Step 3 job resources to the model. In Step 4, personal resources will be added. The study has been approved by the Swedish Ethical Review Authority (ref.no. 2022-02880-01 and 2022-03845-02).

Expected results

Data analysis is planned to be completed by spring 2023.

Limitations

Studies based on cross-sectional data are always exposed to potential risks of common method variance and do not allow for causal inferences. The data was collected in Sweden and during a time where the ongoing COVID-19 pandemic might have imposed unknown effects on the study variables.

Implications

The results will provide insights on key factors for employers and policy makers to craft attractive, healthy and sustainable careers in retail.

Relevance to the Congress theme

A similar development to that of the retail industry is likely to take place also in other industries as the world of work becomes increasingly complex and volatile. As such, retail serves as an interesting context for investigating work- and health-related outcomes both in itself and as a prototype for the future of work.

Work Meaning During the College-to-Work Transition: A Two-Year Follow-Up

Tirza Willner, Itamar Gati & Yuliya Lipshits-Braziler | Hebrew University of Jerusalem

science

The college-to-work transition is critical for successful integration into the labor market. In today's changing labor market, there is an increasing need to find purpose in one's work (Hirschi, 2018). Dick and Duffy (2009) have emphasized the importance of focusing on work meaning to increase awareness of one's purpose in life. The goal of the present study was to test the development of the purpose of work during the college-to-work transition. Using the multidimensional Work Orientations Questionnaire (WOQ; Willner et al., 2020) we elicited the purpose students give to their future work: calling (prosocial value), job (financial benefits), social embeddedness (belongingness), career (advancement and influence), and busyness (filling ones' time with activity).

The present study aimed to test whether and how work orientations change during the college-to-work transition. In a 2-year follow-up study, we first tested the work orientations of 674 Israeli college seniors (60% women) at the end of their last semester in college (Time 1). We sent out a follow-up questionnaire after one year (Time 2; N = 224) and two years (Time 3; N = 145), in which we tested students` work orientations.

The results of Pearson correlations revealed that the one-year stability of three of the five work orientations was greater between T2 and T3 (after the transition to work) than during the transition year (between T1 and T2). Specifically, for calling (r T1-T2 =.52, r T2-T3 =.71), job (r T1-T2 =.63, r T2-T3 = .72) and social embeddedness (r T1-T2 =.39, r T2-T3 =.51) orientations. The stability of the career (r T1-T2 =.47, r T2-T3 =.45) and busyness (r T1-T2 =.65, r T2-T3 =.58) orientations slightly decreased after the transition. The ipsative stability, estimated using the within-person Spearman rank-order correlation, revealed that the relative salience of the pattern of orientations remained quite high; however, it was greater between T2 and T3 (median r s = .87, inter-quartile range = .53-.90) than during the transition, i.e., between T1 and T2 (median r s = .70, inter-quartile range = .41-.90). Interestingly, it was higher between T2-T3 than between T1 and T2 for 60% of the participants with data at all 3 points. To further test the nature of the changes in graduates` work orientations, we performed a series of paired t-tests. The results revealed that during the college-to-work transition (from T1 to T2) four of the orientations decreased: calling (d =-0.20), social embeddedness (d =-0.44), career (d =-0.43), and busyness (d =-0.26). However, a year after the transition no such changes emerged.

The results revealed the developmental nature of the purpose of work and how volatile it may be during the college-to-work transition. Thus, they have implications to career counseling. Specifically, career counselors, helping individuals navigate this challenging transition, may focus on identifying the purpose that individuals are seeking in their work, and thus possible work environments that will fit their orientations. Since the present study focused only on the few years after the transition from college, the long-term implications are yet to be uncovered. However, the study illuminates the possible impact of the changing world of work on the purpose individuals seek in their work. Individuals in today's work world are taking on increasing numbers of career transitions, and the college-to-work transition can be used as a case study to investigate this larger phenomenon.

The mediating role of leadership style in the relationship between span of supervision and multiple outcomes in business setting

Per-Magnus Thompson, Norwegian Business School; Geir Thompson, NLA University College; Robert Buch, Oslo Metropolitan University

science

Research goals and why the work was worth doing

While early research primarily focused on size, i.e., optimal span of supervision (Davison, 2003), more recent studies are investigating various consequences of span of supervision. While the link between wider span of supervision and various outcomes has been documented in numerous studies, research focusing on mechanisms causing these effects has received little attention (Zoller & Muldoon, 2020). Researchers have recently suggested that leadership activities, that may help or hinder functioning in larger teams, should be an area of exploration for future research. The present study aims to expand on existing research using leadership as a potential mediator between a novel antecedent, that is, span supervision in relation to various outcomes through leadership behaviors.

Theoretical background

Social scientists have identified various outcomes of increased span of supervision such as physical proximity between leaders and followers facilitates the communication process and quality of exchange (Yammarino and Bass, 1990). In contrast, with larger span of control leaders can appear distant to followers and maintain infrequent contact. Furthermore, leaders, with a wide span of supervision, have more constraints on their time than do leaders with fewer followers (Schriesheim et al., 2000; Anand, Vidyarthi, & Park, 2016) Larger span of supervision can also limit leaders' opportunities to display supportive behavior, to respond positively when followers experience setbacks, to offer help and assistance, and to advise how to overcome specific difficult situations. In accordance with social exchange theory, when leaders maintain infrequent contact with followers, treat them in an interpersonally less sensitive manner (Antonakis & Atwater, 2002), and limit their directive and supportive behavior.

Design/Methodology/Approach/Intervention

Our data comprised of actual pay provided by the organization, as well as survey data provided by the employees at two points in time. At Time 1 (N = 237), we collected data on controlling effects and informational effects. Of these, 163 employees (69%) also responded at Time 2, where they provided data on their intrinsic motivation. The company provided actual data for several control variables. Regression analyses was used the test the hypotheses.

Results obtained

Specifically, (1) the present study found how span of supervision of various sizes influence the extent to which leaders actively engage in supportive and directive behaviors. Larger span of supervision limits leaders' capability to calibrate their directive actions to elicit the desired response from their followers. In addition, larger span of supervision reduces leaders' opportunities to display supportive behavior such as provide help and assistance and give positive feedback. As such, span of supervision changes the dynamics of the influencing process between leader and followers, which fluctuate with the size of span of supervision. Furthermore, (2) our study found support for the notion that large

span of supervision limits leaders' ability to perform supportive leadership behavior, with decreased follower performance, increased social loafing as well as increased propensity to quit as outcomes.

Keywords: Span of supervision, leadership behavior, performance

Focused attention meditation and well-being: tapping into relative strength, timing, and changes in effects

Justine Van de Velde, Katia Levecque | Ghent University

science&practice

Research goals and theoretical background: This study aims to answer three research questions: does focused attention meditation affect different dimensions of employee well-being differently? When do these effects occur and do they change over time?

Meditation practice can be categorized as a personal resource within the Job Demands-Resources Model (Demerouti et al., 2001) explaining employee well-being. Although the study of meditation and employee well-being is on the rise, there are still multiple knowledge gaps this study aims to fill. First, focused attention meditation has received less research attention than popular mindfulness meditation. Both represent different techniques that produce different neurofunctional and cognitive outcomes (Fox et al., 2016; Lippelt et al., 2014). Focused attention meditation is considered a starting point for meditation novices, while mindfulness meditation is more advanced. Second, by adopting a multidimensional approach to well-being, we disentangle the potentially different meditation effects on different dimensions of well-being. Third, our time window of six months allows for investigating the timing and changes in longer-term meditation effects, while most studies only examine the presence of short-term effects.

Intervention/Design: The meditation technique was taught online as COVID-19 inhibited on-campus training. Participants practised meditation with their pupils for a few minutes every school day. A six-month longitudinal, three-wave study was conducted, and latent growth modelling was used to monitor changes in teacher well-being in comparison to a waitlist control group.

Results: Meditation practice lead to well-being improvements in intervention group participants: emotional exhaustion, negative affect, concentration problems, and musculoskeletal problems decreased, and positive affect increased. Waitlist control group participants consistently reported opposite evolutions (i.e., increases in emotional exhaustion, negative affect, concentration problems, and musculoskeletal problems, and a decrease in positive affect). No effect was found for sleep problems. The strongest effect was found for concentration problems, followed by negative affect, emotional exhaustion, musculoskeletal problems, and positive affect in order of decreasing effect size. The effects were observed after three months of meditation for each of the well-being dimensions. Emotional exhaustion, positive and negative affect continued to improve during the last three months of the study. For concentration and musculoskeletal problems, the last three months of meditation only preserved the increased level of well-being that was already reached.

Limitations: Attrition rates were high, but additional analyses showed no attrition bias. The self-selection of participants might have an impact on the generalizability of our findings to work contexts in which meditation practices are not voluntary but imposed.

Implications: Three months of focused attention meditation practice produces benefits for different dimensions of well-being. Benefits are preserved or even expanded in case of prolonged practice. Focused attention meditation is an accessible, quickly implemented and low-cost intervention that enhances employee well-being.

Keywords: meditation,well-being,longitudinal

Balance is not something you find, it's something you create: The development of a work-life balance intervention

Whitney Van den Brande, 1. IDEWE, External Service for Prevention and Protection at work; 2. Research Department Work and Organisation Studies, KU Leuven; 3. Research Group Work, Organisational and Personnel Psychology, KU Leuven; Sofie Vandenbroeck,

science&practice

INTRODUCTION: Work-life balance, defined as the individual perception that work and non-work related activities can be combined, is a topic that can no longer be ignored in today's society. Scientific studies show that a poor work-life balance has negative consequences for employees (e.g., lower job satisfaction), organisations (e.g., more absenteeism), and society (e.g., costs related to absenteeism). Scholars argue for interventions that support employees in creating work-life balance and stimulate employers to create policies facilitating work-life balance. To our knowledge, todays interventions mainly focus on either individual-, team- or organisation level. However, it is important to develop interventions at all levels of an organisation. The overall aim of this study was therefore to develop a multi-level intervention that contributes to creating a good work-life balance. The Job Demands Resources model is used as theoretical framework for the development of the intervention, and explains the causes (e.g. role overload, low autonomy) and consequences of a poor work-life balance.

METHODOLOGY: The intervention was developed thriving on the PATHS-principle of Buunk and colleague's, and the Human Design Thinking approach. In order to define the needs of Flemish employees and identify the causes of a good work-life balance, qualitative and quantitative data were collected on three different manners (i.e., methodological triangulation) among Flemish employees in 2019: two focus groups with seven participants, 21 semi-structured interviews, and an online questionnaire completed by 142 employees. Data were analysed using qualitative methods (i.e. clustering and identifying themes) and using quantitative methods (i.e. correlational associations).

RESULTS: The results showed the need for an overall service that focuses on optimising employees' work-life balance: the focus groups and interviews suggest both offline and online services that focus on the level of the individual (i.e., coaching sessions and online training tool), the team (i.e., team coaching) and the organisation (i.e., clear policy, group report regarding work-life balance). Via co-creation workshops (i.e., prototyping and testing), a service was developed consisting of several elements: workshops on "work-life balance" policy, employee needs analysis, awareness materials, online training tool, group coaching and individual coaching sessions.

LIMITATIONS: Although the intervention was developed based on different types of data, its effectiveness has not yet been proven through an intervention study. Therefore, the next step within this project will focus on testing the effectiveness of the developed service regarding work-life balance by means of an experimental research design (e.g. RCT).

RESEARCH/PRATICAL IMPICATIONS: Through the BalanceCrafter service, work is done to achieve a good work-life balance at the level of the organisation, the team and the individual. In follow-up research, it is important to measure the impact of this service through an experimental research design.

Keywords: Work-Life Balance, Intervention, Human Design Thinking Approach

Poster P088

Team Adaptability in the Context of Human-Autonomy-Teaming: A Theoretical Framework

Tilman Nols, Josette Gevers & Anna-Sophie Ulfert-Blank | Eindhoven University of Technology

science&practice

Fast-paced developments within Industry 4.0, particularly in Artificial Intelligence (AI), encourage the increasing application of so-called Human-Autonomy-Teams (HATs) in the near future. These systems represent a paradigm shift from technology as a sole tool to technology occupying the role of a formal teammate. Accordingly, AI takes up specific tasks and responsibilities which are interdependently embedded in the overall team activities while maintaining a degree of agency, characterized by independence and proactivity of actions.

Although recent research has started to highlight factors that influence the effectiveness of HATs, its insights remain bounded to static settings and thereby its transfer to real-life applications is hampered. Furthermore, HATs are often constrained by technological issues such as design or function allocation to only work effectively across a limited span of scenarios. However, since it is expected that the application of such systems progresses into inherently dynamic contexts (e.g., health care, aviation, or military), HATs may suffer from rigidity, inflexible coordination patterns, and subsequently, lack of adaptability when confronted with changes to the task environment. Considering the domains of applications and the associated costs of not being able to maintain effectiveness when routinized actions are not appropriate anymore, it is crucial to guide research into a more ecological valid direction by acknowledging the significance of adaptability.

In the present paper, we try to tackle this gap and develop a framework for team adaptability in the context of HATs by building on findings from all-human teams and integrating research from different research areas, including ergonomics, human-AI interaction, and psychology. We begin by reviewing the theoretical background of HATs in general, then specify what it means for AI to function as a teammate and make adaptability possible and further discuss specific requirements for AI development. Following this, we transfer the Team Adaptation Cycle (Burke et al., 2006) to HATs and simultaneously elaborate on multilevel influences from the perspective of an Input-Mediator-Output Model.

We envision to finalize the framework in Spring 2023 to provide testable propositions for interdisciplinary future research which further can help to inform practice on how to apply robust and effective HATs. Although the framework represents a first step towards projecting HATs in a dynamic environment, the approach still needs to be transferred to the real-world and further validated, including tests of its generalizability.

With the forthcoming presentation, we contribute to research revolving around the changing world of work by acknowledging and strategizing about future technological developments and their interaction with humans. Consequently, we do not only contribute to Sustainable Development Goals (SDGs) which encompass high-quality work (SDG 8 and 9) but also allow more successful partnerships to achieve other SDGs by enabling advanced synergies between AI and humans (SDG 17).

Keywords: Human-Autonomy-Teaming, Team Adaptability, Artificial Intelligence

Poster P089

Vigorous or happy worker? A Diary Study on the Interaction Between Vigor and Positive Affect on Job Performance

Johanna Blume, FernUniversität in Hagen

science

Research goals and why the work was worth doing/ Theoretical background

Job performance can be considered a dynamic construct, which fluctuates within persons on a daily base. Research has shown that daily internal states such as vigor can predict daily fluctuations in job performance. The substitution hypothesis of conservation of resources theory postulates that personal resources are substitutable for one another (Hobfoll, Freedy, Lane & Geller, 1990). However, the literature's focus has been dominated by research on the impact of single personal resources on work outcomes. This study includes both employee's daily vigor and positive affect to test their separate effects on daily self-reported task performance. Most importantly, however, we investigate a potential compensation effect between the two personal resources.

Design/Methodology/Approach/Intervention

We conducted an online diary study on ten consecutive workdays with 110 participants. Directly at the end of the workday, participants had to indicate their state vigor and affect at the workplace and additionally estimated their task performance.

Results obtained or expected (if not available, it must be made clear when they will be)

Multilevel analyses showed that daily vigor positively predicts self-reported task performance. The negative interaction between vigor and positive affect was significant. Results indicate that high positive affect can compensate for low energetic states – and vice versa.

Limitations

Common method variance might confound the results because all variables were self-reported and measured at the same time same measurement point.

Research/Practical Implications

Looking at the interplay between personal resources at work might offer a valuable starting point for individual - tailored interventions that allow people to unfold their full potential.

Keywords: dynamic performance, vigor, positive affect

Poster P090

Sustainability of work in the life cycle: a research project in a manufacturary plant in Italy

Giulia Bacci, Sara Viotti, Ilaria Sottimano, Gloria Guidetti & Daniela Converso | University of Turin

science&practice

The issue of work sustainability takes on even greater importance when one considers the progressive aging of the workforce, and the amount of time individuals spend at work. This challenge is critical, not only for businesses, but also for society.

Over the past decade, sustainability has increasingly been understood not only in terms of the ecological and socioeconomic environment, but also in terms of improving the quality of life of each individual. The perspective of sustainability and resource conservation in the context of working life underscores the fact that work should not „wear out" individuals in the long run, but should guarantee workers to maintain their health status, preserve (if not improve) their motivation/satisfaction, balance work and personal life, and keep their skills from becoming obsolete.

The qualitative data will be collected in November 2022 and will refer to all employees of a northern Italian manufacturing company in the automotive sector. The qualitative data will be collected through interviews, conducted by PhD student responsible of the project, during working hours, aiming to investigate workplace sustainability, critical aspects of workplace sustainability both from a psychological and physical point of view, and to identify which factors can be considered as risk factors and protective measures for work sustainability both from a personal and organizational point of view. Will be conducted approximately 25 interviews with employees with different task in the company.

The expected outcomes of this project relate to the creation a questionnaire that will investigate of a map of risk factors (as work shifts or physical demands) and protections of well-being and work ability (as reward or support from superiors), and the development of a questionnaire to further explore perceptions of work sustainability from a primary prevention perspective in this organizational context. From a general perspective, the expectation is to test a monitoring system that is fully operational in the factory and can be exported to other organizational contexts in the future.

Regarding the limitations of this study, we must point out that it was conducted in a manufacturing context, so generalization to other contexts may require further study

The implications of this study concern the possibility of creating a monitoring system that can be used to evaluate the effectiveness of ordinary and extraordinary interventions for labor sustainability, which could be exported to other contexts with the appropriate measures.

Keywords: Work sustainability

Poster P092

Work Intensification and Its Effects on Mental Health: The Role of Workplace Curiosity

Luis Manuel Blanco-Donoso, Autonomous University of Madrid; Bettina Kubicek, University of Graz; Jose Luis Cifri, Autonomous University of Madrid; Isabel Carmona-Cobo, University of Jaén; Eva Garrosa, Autonomous University of Madrid

science

Work intensification is a psychosocial risk that has been increasing in recent decades and may have been accentuated after the COVID-19 pandemic. Its effects on health are negative, but they can be moderated by contextual and personal factors. The aim of this study was twofold: to analyze the effect of work intensification on workers' stress, anxiety, and depression and to explore the role of workplace curiosity in these relationships. The study design was cross-sectional, and a total of 766 Spanish workers (58.9% female) with different occupations completed the survey. The results showed that work intensification was associated with the symptomatology of stress, anxiety, and depression, with a medium effect size. Women workers showed higher work intensification, but its association with mental health was equally strong for both genders. Workers with higher levels of the workplace curiosity dimension "stress tolerance" showed less impaired mental health in the presence of work intensification. However, workers with higher levels of the workplace curiosity dimension "deprivation sensitivity" showed more symptoms of stress, anxiety, and depression when faced with high work intensification. The results were discussed in terms of their contributions to the field of study of work intensification, the future research they could inspire, and the prevention and intervention measures they could motivate.

Keywords: Work Intensification, Workplace Curiosity, Mental Health

Self-Actualization: A Systematic Review and Meta-Analysis of Work-Related Findings

Lucas Maunz & Jürgen Glaser | University of Innsbruck

science

Relevance, goals, background. Self-actualization is a popular concept in academia and culture, often referring to people's experience of realizing their potentials (Maslow, 1943). It has had a rich history of empirical research as a work concept because the workplace is one of the primary domains where people can actualize and apply their talents (Baumeister, 1991). With almost 80 years of research, the literature on self-actualization is still growing and has branched out into different fields. Within disciplines that are concerned with work, such as leadership, human resource management, nursing, and education, a variety of research has been published. Thus, findings are now scattered in different fields and information about relations to other concepts is cluttered. A systematic overview of quantitative findings is missing. This study aimed to provide a systematic overview of findings and knowledge gaps.

Design, methodology . We conducted a systematic literature review following PRISMA guidelines (Page et al., 2021). We searched the databases: Scopus, Web of Science, Pubmed, PsycINFO, and Proquest Dissertations for the keywords: self-actualization, self-fulfillment, and self-realization, and additional keywords that ensured capturing work-related studies. We reviewed 92 articles, which provided 276 effect sizes. With good interrater agreement (κ = .84), we grouped effect sizes into 27 synthetic constructs and performed separate two- or three-level random effect meta-analyses for each construct with different robust variance estimation procedures (Pustejovsky, 2022).

Results. Self-actualization was significantly, positively related to (1) age, (2) job position, (3) leadership characteristics, (4) social support at work, (5) social relations at work, (6) job resources, (7) job satisfaction, (8) mental health, (9) flourishing, (10) individual and group performance, and (11) job retention. In addition, self-actualization was significantly negatively related to (12) burnout.

Limitations. The meta-analysis is limited by our choices to aggregate the constructs. Some constructs were grouped from the same concept, but others were grouped of related concepts or sub-dimensions, which may limit the generalization of results and explain the overall high heterogeneity. The explorative review approach limits the ability to demonstrate directions of effects and make causal claims. Finally, systemic publication biases might have confounded the true effect sizes.

Conclusions. The quantitative review documented a rich body of research that extends our knowledge of relations of self-actualization. We conclude that work offers ample opportunities for employees to actualize talents and abilities. Moreover, self-actualization is related to several important psychological, health, and performance constructs and thus has positive implications for employees and organizations.

Relevance to SDG. Self-actualization is an essential component of the concept of eudaimonic well-being (Ryff, 2018), it is also related to several important psychological and health concepts and therefore an important indicator for the SDG Good Health and Well-Being.

Relevance to congress theme. Organizations that improve the conditions for experiencing self-actualization at work provide meaningful goods to individuals and society. Self-actualized employees

engage in personally meaningful and health-promoting activities, which is a desirable state for contemporary workplaces.

Keywords: self-actualization, systematic review, meta-analysis

Digital Work: Theoretical model and Questionnaire Validation in the Field of Public Administration

Julia Kaesmayr, University of Applied Science Ludwigsburg; Michael Schorn, Institut for Economic and Politic Research, Cologne; Anna Steidle, University of Applied Science Ludwigsburg

science&practice

Digitalization transforms the conditions, nature and experience of work at an increasing rate. To describe the ongoing transformations and quantify and explain their impact on humans at work, we need a model of digitalized work. The aim of the present research was to conceptualize digital work and develop a respective measure using the example of public administration.Hertel et al. (2017) summarized five core characteristics of internet-based work: (1) accessibility of information within organizations and beyond, (2) interactivity of communication, respectively direct interaction with other users including other multi-directional interaction, (3) reprocessability of information, (4) automatization and (5) boundary crossing. Utilizing dialectic inquiry (Berniker & McNabb, 2006) we fused these characteristics with the e-government maturity stages information, communication, transaction, integration and political participation enriched by horizontal and vertical integration (Hiller & Bélanger, 2001; Layne & Lee, 2001) into a five-dimensional construct, namely information, interaction, integration, data processing, and transaction (Kaesmayr, Schorn, & Steidle, 2021).85 items were derived according to Rossiter's (2008) approach, assessing the degree of availability and use of analog and digital work tools, i. e. technology. They were content validated by expert interviews. 518 public agents answered the questionnaire in a version adapted to administrative work. For 17 aspects of non to digital work e. g. interactions with customers, a single index was computed. This was achieved by using contrast-coding on objective technical digital criteria derived from communication, information security, and semantic processing concepts. The resulting indices of digital work aspects were then assorted to their corresponding dimension and averaged.Exploratory factor analyses indicated a five-factorial structure, showing slight variations opposed to the theorized dimensions which confirmatory factor analysis supported. The assessment of digital work in the examined agencies painted a heterogenous picture. The dimensions information and interaction showed promising efforts of progress while the dimensions integration, data processing and transaction were lacking behind considerably. Reliability of the construct was sufficient. Item difficulty and homogeneity showed satisfying results.The instrument is yet only available for administrative action. Seizing self-administration and restricting application to the state of Baden-Wuerttemberg, Germany with a focus on municipalities however, posed a calculated risk which was remedied by adapting the application to different types of agencies.The proposed measure of degree of digitization of administrative action is expected to predict administrative outcomes by shaping public servants' work and consequently their work behavior. Given the evidence of such predictive validity, long-term research could provide additional practical insight into public servants' job demands and resources. This research endeavor adds to insights into internet-based work (Hertel et al., 2017) and job demands and resources (Demerouti et al., 2001) research in the field of public administration. The results contribute to the body of literature of behavioral public administration (Grimmelikhuijsen et al., 2017).By combining internet-based work and administrative action, ramifications of digitalization can be incorporated and balanced.

Keywords: digital work, instrument, validation

Poster P098

A theory of not-so quiet quitting and Firing: a Psychological Contract and Leader-Member Exchange perspective.

Francesca Murdocco, Xavier Caroff & Xavier Borteyrou |Université Paris Cité, Laboratoire de Psychologie et Ergonomie Appliqué (LaPea)

science

Research goals

As quiet quitting and firing gain relevance in the media as new perceptions and attitudes towards work of employees, no scientific publication has tried to operationalize them.

Here, we propose a study to try and translate these two concepts by using already known concepts in the work and organizational psychology literature.

Moreover, we propose to investigate whether the two phenomena are complementary by trying to verify if following a feeling of being “quietly fired” employees reacts with the “quiet quitting” of their jobs.

Theoretical background

Quiet firing is defined by the media as the perception of the employee of a lack of appreciation, support and rewards from managers and company, this feeling could be translated by two concepts: Psychological contract breach (PCB) and the quality of Leader-Member Exchange (LMX).

Quiet quitting on the other hand is an attitude of the employee corresponding to doing ‘the bare minimum’, refusing to do more than what he/she is rewarded for. This perception might correspond to a transactional psychological contract, which includes a narrowed view of tasks and responsibility (Rousseau & McLean Parks, 1993).

Both quiet quitting and quiet firing seem to have a lowering of work engagement and an increase of turnover intentions consequently.

Methodology

Based on the proposed theoretical background, our variables of interest are LMX, measured with the LMX-7 (Scandura & Graen, 1984 ; Graen & Uhl-Bien, 1995), PCB measured with Robinson & Morrison's (2000) scale, Work Engagement as measured by the UWES (Schaufeli et al., 2002), turnover intentions as measured by the TIS-6 (Bothma & Roodt, 2013) and an adaptation of the PCI (Rousseau, 2000) to measure transactional psychological contract expectations.

The study will be carried out between March and February 2023, we aim to collect cross-sectional data from approximatively 300 French white collar workers from different sectors.

The data will be analysed through structural equation modelling to allow a better view of the overall model and assess indirect effects.

Expected Results

Since both quiet quitting and firing seem to have as a consequence a loss in engagement and an increase of turnover intentions, we expect to find that a low LMX quality will lead to feelings of PCB (Hill et al., 2016) which in turn will lead to lower engagement and higher turnover intentions (Bal et al., 2013). We further propose that transactional psychological contract beliefs will moderate the

effect on work engagement and turnover intentions: transactional beliefs might in fact intervene as a defence following breach, a posture the employee takes in order to be able to stay in the job.

Limitations

The present study stems from concepts not yet researched scientifically and represents an attempt at translating them into research terms.

Research Implications

However, the present research might offer a first base of comparability in the event that fellow researchers decide to codify quiet quitting and firing in a psychometric scale.

Relevance to the Congress Theme

This research aims to better understand the current trends in the changing work relationship. An enhanced awareness of employees of their value in the world of work demands for organizations to change how they see the work relationship, to create a better work environment that fosters not only economic growth but also employee flourishing.

UN SDGs : Decent work and economic growth

Keywords: Psychological Contract, Leader-Member Exchange, Work Engagement

Poster 099

Does One Size Fit All? Individual Differences and Reactions to Feedback: A Meta-Analysis

Sergiu-Mihail Condrea, University of Bucharest

science

One of the organizational processes relevant to those who are particularly interested in increasing efficiency in the organizational environment is feedback (Rummler & Brache, 2012). Research has focused on both internal and external factors that could have a major impact on individualsâ€™ reactions to feedback. In terms of external factors, extensive research has been conducted on the valence of feedback (Brett & Atwater, 2001; Elicker et al., 2006), the characteristics of those who provide feedback, participation in the feedback process, and time of receiving feedback (Elicker et al., 2006; Nathan et al., 1991; Lechermeier & Fassnacht, 2018). Regarding internal factors, in his seminal feedback reaction model, Ilgen (1979) emphasized that feedback is also influenced by internal variables (â€śrecipient's frame of reference or personalityâ€ť; Ilgen et al., 1979, p. 355). Studies show that personality traits (e.g., Five Factor Model), demographic variables, and other individual differences (e.g., feedback orientation) influence individualsâ€™ response to feedback (Corwin et al., 2019).

Even though there are various empirical studies that attempted to explore the relationship between individual differences and feedback reactions, to our knowledge, no research aimed to quantitatively analyze the results of these studies. Therefore, the current study (i.e., being grounded in feedback reaction model; Ilgen, 1979) will meta-analytically investigate the relationship between individual differences and reactions to feedback (e.g., both positive and negative perceptions, intentions, emotions, and behaviors). Our search strategy resulted in a total of 5.741 articles. After the removal of duplicates and screening, 56 reports, with 72 independent samples/studies were included.

The results section of the paper is in progress (we estimate that it will be completed by the end of November 2022). Even so, at the moment some of the results have been analyzed. In our meta-analysis, we found significant medium effect sizes between: self-efficacy ($g = .536$; $p < .001$), learning goal orientation ($g = .508$; $p < .001$), feedback orientation ($g = .614$, $p < .001$), and positive feedback reactions. Further, we found significant small effect sizes between: self-esteem ($g = .436$, $p < .01$), agreeableness ($g = .477$, $p < .01$), conscientiousness ($g = .357$, $p < .001$), openness to experience ($g = .265$, $p < .05$), and positive feedback reactions; self-esteem ($g = -.273$, $p < .05$), narcissism ($g = .296$, $p <.001$), and negative feedback reactions. From a theoretical standpoint, our study will consolidate an important tenet of the feedback reaction model (i.e., feedback reactions are influenced by recipientsâ€™ individual differences).Â From a practical standpoint, if individual differences are related to recipientsâ€™ feedback reactions, practitioners should consider both the person and the situation when developing feedback interventions.Â This study also has some limitations: the low number of samples for some relationships (hindering the performing of subgroup analyses), the reactions to feedback conceptualized dichotomously as positive and negative.Â

This study is relevant for the facets mentioned in the congress theme. Whether we are talking about Contribution (e.g., we can develop new competences and collaborate using feedback as an important leverage), Urgency, Delivery, the intersection of these will have feedback as an important tool in the world of work.

Keywords: feedback, individual differences, feedback reactions

The relationship between team leader coaching behaviours and collective efficacy: evidence for explanatory mechanisms

Lucia Ratiu & Corina Vele | Babes-Bolyai University

science&practice

Coaching as a development intervention has been increasing rapidly aiming at higher performance and well-being not only in employees, but also in teams and entire organisation. There is growing empirical scientific evidence that team leader behaviours play a critical role in team outcomes. However, a lack of clarity remains as to how team leader coaching behaviours (TLCB) predict team dynamics. Also, collective efficacy has been often studied as a mediator or predictor for performance and effectiveness in working teams. This study provides new empirical evidence about the influence of TLCB on team processes - according to the conceptualisation by Marks et al. (2001) - and collective efficacy. In addition we aim at testing if team size matters in the level of collective efficacy. A random sample of 46 teams consisting of 202 employees participated in the study. The following scales for data collection were used: TLCB scale developed by Rousseau et al. (2013); team processes scale develop by Mathieu et al. (2019) and collective efficacy scale develop by Salanova et al. (2003). Individual data were aggregated at the team level and the indices met the cutoff criteria for agreement and consistency. Data analyses were conducted with the macro PROCESS v4.1. (Hayes, 2022). The findings reveal that the paths from TLCB to collective efficacy through team coordination as an action process was statistically significant (Rsquare = 433, p <. 001). The moderation analyses indicate that the high number of team members decrease the association between TLCB and collective efficacy. However, the team size does not affect the relationship between TLCB and team coordination. Following the same conceptualization of team processes, we a posteriori explored the mediating role of other team action processes and we found support for monitoring progress towards goals as a mediator between TLCB and collective efficacy. The statistically nonsignificant direct effect of TLCB on collective efficacy show that team members, following their coaching interactions with their team leader take on the task of coordinating and their perception of the team's ability to achieve a certain task also increases. Consequently, when the team takes on one of the functions of a leader (i.e. team coordination which is especially vital for teams with high interdependence), it becomes a motivating phenomenon for teamwork and leads to positive perceptions of the team's ability to fulfil its tasks. Furthermore, the team leader can "handle" other activities and develop strategic capabilities in the team. This preliminary evidence sheds light on the importance of TLCB in team dynamics, namely, team coordination and monitoring and shared motivation in teams. The study also provides suggestions for research on team dynamics and team management.

Keywords: coaching; collective efficacy; team processes

The influence of leadership on employee's work-nonwork interface and wellbeing: A scoping review

Rita Berger & Jan Philipp Czakert |Universitat de Barcelona

science

Research goals and why the work was worth doing: Employee wellbeing (EWB) is pivotal for individuals and for business and societal concerns, including sustainable development. Leadership (LS) is core for EWB. Existing research focuses mainly on narrowed EWB at work. A dynamic process-perspective inherent to current working conditions with blurred boundaries between work and nonwork is often missing. EWB needs to expand to a more holistic perspective, including employees' work-nonwork interface (WNWI). Research goals: Firstly, get an insight in concepts and mechanisms that relate positive and negative LS to sustainable EWB focusing on the dynamic WNWI, including spillover and recovery. Secondly, expand the understanding of the LS-EWB relationship, including the nonwork area, and shaping the EWB concept towards sustainability. Thirdly, analyze limitations of the applied methodologies. Finally, to provide recommendations for future scholarly work.

Theoretical background : Sustainable EWB may be defined as feelings of pleasure and/or experiencing fulfillment and purpose related to work that can be sustained over time (Di Fabio, 2017; Sonnentag, 2015) . Leaders have a significant impact on EWB, especially in times of crisis (Rudolph et al., 2021). LS behavior must manage the WNWI and related dynamic processes of physical energy, dynamic recovery, and emotions for a sustainable EWB. The WNWI can be referred to as 'the interaction of employee work experiences and [nonwork] lives' (Allen, 2012, p. 1163), where positive and negative spillover effects can happen in various forms. So, adverse impacts of one domain may come with pervasive impact across the entire work-life system.

Design/Methodology/Approach/Intervention : Following the PRISMA Extension for Scoping Reviews and building on recent LS-EWB reviews and emerging trends in recovery and emotion research, we apply a narrative synthesis to organize the 21 selected studies and integrate them across the WNWI.

Results obtained: The review of 21 articles shows that LS plays a dominant role in sustainable EWB representing perhaps the most impactful contextual macro variable. We (1) provide a framework consisting of LS, EWB, and WNWI approaches to cluster theoretical approaches used. We identify two categories of investigated mechanisms: bolstering/hampering and buffering/ strengthening. We (2) identified limitations of the used methods e.g., selective samples, incentives affecting data quality, and (3) offer recommendations for future research.

Limitations: We examined only empirical published manuscripts. This did not allow us to analyze unpublished studies. Our results are only up to date as of February 2021.

Research/Practical Implications:

We propose the circumplex model of affect (Russell, 1980) as a starting point for integrated (EWB, LS, WNWI) theory development.

We recommend theorizing LS as a stand-alone factor that influences job characteristics using the job demands-resources-recovery model (JD-R-R; Kinnunen et al., 2011) representing a situational perspective.

We reinforce calls for studies researching resources when investigating LS and dynamic sustainable EWB.

We call for research on the influence of passive forms of negative LS on employees' WNWI and dynamic sustainable EWB.

Relevance to the Congress Theme: The contribution is: Informing Human Resources for leadership training and development.

Keywords: Leadership, Work-Nonwork Interface, Wellbeing

Presence and Learning in VR: What can Human Behavior Tell?

Andreas Winklbauer, Department of Work- Organizational- and Media Psychology/ Robopsychology Lab, JKU Linz; Bernad Batinic & Barbara Stiglbauer | Department of Work-, Organizational- and Media Psychology, JKU Linz

science&practice

The market for virtual reality applications in education and workplace learning is growing rapidly. According to the Cognitive Affective Model of Immersive Learning (CAMIL) presence, the feeling of „being there", is a psychological affordance of learning in virtual reality-based education and training lessons (Makranski & Petersen, 2021). Therefore, to ensure training success, it is essential to detect or even predict users' presence . Using additional sensory hardware (eye-tracking, hand-tracking), virtual reality applications can record users' behavior in detail. It is to be assumed that behavior changes when users feel present in the environment vs. when they do not. Therefore, behavioral indicators could be suitable to surveil and predict users' presence. The current study tries to answer two main questions: can behavioral data prior to a task (exploration and tutorial phase) predict users' presence? Can users' behavior during a task (task-sequences) explain differences in presence? One hundred and twenty-four participants first explored a virtual factory environment in a test room (exploration phase), then played through a tutorial followed up by three task-sequences in different rooms, during which participants had to interpret signaling of different collaborative robots (cobots), in randomized order. To test our hypotheses, the following predictors were calculated: eye-movement indicators (which objects participants looked at), spatial movement indicators (how much and how far participants moved), hand usage indicators (how much participants' hands got used) and head rotation indicators (how much participants moved their head). The relationship between behavioral predictors and presence was analyzed using regression analysis and mixed effect models. Results suggest that behavioral data (specifically head-rotation) can be linked to presence. Current research can act as impetus for future research analyzing objective behavioral data. If presence can be detected using behavioral indicators, educational- and workplace- learning applications will get more adaptable. Our article fits into the conference theme in multiple aspects. One is that the implementation of virtual reality applications into education and workplace learning is a great example of how the world of work is changing. Additionally, in order to allow future usage of learning applications in vr, research has to be done now (the future is now). This work was funded by the Austrian Research Funding Agency FFG under grant number 872590 (CoBot Studio).

Keywords: virtual reality, presence, behavioral data

Poster P103

Role of Technostress in Work Engagement and Job Satisfaction in People Working with Information and Communication Technologies

PAWEŁ KOT, The John Paul II Catholic University of Lublin

science

Today's working environment becomes very stressful due to the rapidly changing information and communication technologies (ICT) used in the work process. As part of this survey, measures were taken to verify the relationship between technostress creators and technostress inhibitors, and job satisfaction and work engagement of employees. To this end, 349 employees using ICT at work were surveyed. Polish versions of the following scales were used in the survey namely Technostress Creators and Technostress Inhibitors Scale (Kot, 2022), Job Satisfaction Scale (2003) and Utrecht Work Engagement Scale (Schaufeli at al., 2006). The survey used the method of Structural Equation Modelling to find the relation between the analyzed variables: Technostress creators, Technostress inhibitors and job satisfaction and work engagement. The results have revealed a relation between technostress creators and technostress inhibitors. Additionally, these variables turned out to be important for shaping job satisfaction, and ultimately also for explaining employee work engagement. Technostress may have a negative effect on employee satisfaction and work engagement, so action should be taken to reduce technostress creators in the workplace and to support technostress inhibitors.

Keywords: Technostress, Job satisfaction, Work engagement

Poster P105

The Dark Core at Work: Development and Validation of a Contextualized Measure

Isaiah Hipel, Kevin Kelloway & Lanxi Wang | Saint Mary's University

science

The aim of this project is to develop and validate a measure of the Dark Core for use in a work specific context. The Dark Factor of Personality (D) has been a recent topic that has arisen in dark trait literature and has received little attention in organizational contexts. Many negatively connoted personality traits (often termed “dark traits”) have been introduced to account for ethically, morally, and socially questionable behavior. D is the basic tendency underlying dark traits. Specifically, D captures individual differences in the tendency to maximize one’s individual utility—accepting, disregarding, or malevolently provoking disutility for others—accompanied by beliefs that serve as justifications for these actions. The current research has three objectives. Based on previous research the current study is developing a measure of the Dark Core based on a five-factor model comprised of callousness, vindictiveness, narcissistic entitlement, deceitfulness, and sadism. Therefore, the first objective of this study is to validate the structure of the new scale and correlate scores on the scale with another measure of the Dark Core and organizational outcomes (e.g., counter-productive work behaviours). The second objective is to establish a relationship between leaders’ scores on the Dark Core at Work scale and important organizationally relevant outcomes related to leaders (e.g., toxic leadership). The third objective of this study was to assess whether the Dark Core at Work scale provides incremental prediction in organizationally relevant outcomes compared to the other personality measures (e.g., Dark Tetrad at Work, Big-Five). The study is recruiting participants through Prolific, an online survey platform. The current study expects that the Dark Core at Work measure will be comprised of 5-factors (callousness, deceitfulness, vindictiveness, sadism, and narcissistic entitlement) and be positively related to negative organizational outcomes (e.g., toxic leadership, counter productive work behaviours, bullying). It is also expected that the Dark Core at work measure will provide incremental prediction of organizationally relevant outcomes over the Dark Tetrad at Work measure. Results for the study should be obtained in December 2022. The current study is limited in that data is collected solely from an online source which relies on self-report data. This may distort the results due to socially desirable responding. Establishing a context specific measure of the Dark Core provides researchers of workplace behaviour with a measure to assess traits of the Dark Core at work. By screening individuals who have elevated levels of the Dark Core, organizations can create more productive and healthy working environments with less risk of violent behaviours, bullying and toxic leadership. Additionally, by using this workplace-specific scale, organizations would not have to worry about the inappropriate and potentially jarring items relating to sexual preferences (e.g., psychopathy: I enjoy having sex with people I hardly know) or religious beliefs (e.g., I would like to make some people suffer, even if it meant that I would go to hell with them) that are currently in other measures of the Dark Core.

Keywords: Extreme Personalities, Psychometric Tests, Abusive Leadership

Poster P106

Dance-movement therapy as the holistic body-mind approach in organizational practice: Building the foundation for expressive therapeutic interventions

Olga Válková Tarasova, Prague University of Economics and Buisness, Faculty of Buisness Administration, Department of Managerial Psychology and Sociology

science

A study in a phase of a progressed literature review aims to determine whether dance-movement therapy (DMT) or other body-mind interventions are viable for stress management and the general well-being of the staff. The underlying research focuses on enhancing stress management programs in organizations and supporting HR managers in building more in-depth well-being-related interventions at the workplace. We believe that bringing more body-mind-focused interventions can enrich the importance of employees' well-being, especially managers and leaders because emotional intelligence is also critical in the field of management (Ashkanasy & Daus, 2002).

DMT is defined by the American Dance Therapy Association (ADTA) as the psychotherapeutic use of movement to promote the individual's emotional, social, cognitive, and physical integration to improve health and well-being. The DMT is one core approach that focuses on body-mind interventions, stress management, and stress reduction (Bräuninger, 2014; Wiedenhofer & Koch, 2017). Supporting stress management allows one to orient in life roles, find work/life balance, understand stressors and defense mechanisms to express affect safely, learn to understand coping mechanisms (Richardson & Rothstein, 2008), and discover new and healthy ones. That all builds personal stress management and prevents burnout (Shaufeli, Desart, & Witte, 2020), which again has a positive impact on organizational performance (Bräuninger, 2014; S. Koch, Kunz, Lykou, & Cruz, 2014; Mala, Karkou, & Meekums, 2021).

The most extensive survey of the arts therapies submitted by (Millard, Medlicott, Cardona, Priebe, & Carr, 2021) done by National Health Services in the UK shows that 60% of respondents of the survey would be interested in group arts therapies with expectations of enjoyment, helpfulness, impact on mood and social interaction. However, only 2,8% of the general population sample tried DMT, and 16,3% preferred other art therapies (Millard et al., 2021).

The approach at this initial stage is a systematic literature review focused on the studies from 2012-2022, which aims to narrow down the evidence for using body-mind therapeutic intervention, especially DMT, in organizational practice. The core findings will be highlighted in the EAWOP congress 2023.

The review of resources and theories shows an immense amount of literature relevant to the general topic of workplace well-being and related body-mind approaches. However, not so many intersections with DMT. So the main limitation is the small number of studies meeting the inclusion and exclusion criteria and the lack of rigorous empirical data on using the DMT intervention as part of stress management and/or self-development programs in the workplace.

The main research implications are a theoretical contribution by including DMT as a therapeutical intervention in the workplace, that at the current state of the art, seems to be a missing piece that will be validated by experimental research. The practical implication is resulting tool allows the use of DMT in the workplace by practitioners from the field of managerial psychology.

We believe that current and future workplaces will largely benefit from enhanced stress-management programs based on DMT and other holistic therapeutic body-mind interventions.

Keywords: Dance movement therapy, body-mind intervention, workplace well-being

Poster P108

Financial implications of perceived unfairness in selection

ANDREEA BUTUCESCU, University of Bucharest; DELIA VIRGA, West University of Timisoara; ANDREEA CORBEANU & DRAGOS ILIESCU | University of Bucharest

science&practice

Importance

The organizational literature is abundant in questions of accountability, and the request for more accountability has never been stronger in society, also putting pressure on other domains, such as school/educational psychology. Simply stating that a phenomenon has an impact is no longer accepted enough; not even effect sizes continue to appease critics - researchers are expected to articulate clear links between a phenomenon or practice and individual or organizational performance and this articulation is subsumed under the heading of utility analysis. We will follow this important call by investigating the financial impact of perceived unfairness during the assessment process under the precepts of utility analysis. We argue, in consensus with Cascio&Boudreau (2011) that measurement of a phenomenon (in this case concern about perceived unfairness)is only valuable if it improves decisions, and that such an objective "requires not simply more or better measures, but an integrated approach that combines those measures with logic, analytics, and knowledge processes" (p. xvi).

We will therefore draw on the LAMP framework for econometric analysis and outline logic diagrams to explain the links between fairness perceptions, employee behaviors, and operational and financial outcomes at the organizational level.

Objective

we will conduct a utility analysis by constructing a logic diagram for the utility analysis of candidate reactions. To this end, we will use the LAMP framework (Cascio & Boudreau,2011), which has been previously used with significant success for econometric analyses in applied psychology in general and the human resources literature specifically. The LAMP framework emphasizes the importance of the 4 components of logic, analytics, measures, and process in utility analysis. We will therefore draw on insights from psychology, sociology, economics, accounting, and finance to construct the logic diagram, outline the analytics, delineate the measures (actual formulas), and describe the process needed for a lucid communication of results to decision makers or policymakers in the organization.

Methodology

We will follow this route by first establishing a defendable theory-driven mechanism through which to evaluate how unfairness reactions produce financial costs. This will reflect in a formula constructed based on the principles of the LAMP model (Cascio & Boudreau, 2011). We will then use that model in order to conduct Monte Carlo simulations on the formula, updating the variance of the various variables according to the principles of Bayesian inference, i.e. based on evidence-informed lower- and upper-bound estimations of marginal likelihood (i.e., model evidence). Simulated data will be generated with the simTool package in R, and Monte Carlo simulations will be conducted with the Monte-Carlo package in R.

Expected results

This work is in progress and will be finished by the end of the year. We expect that the econometry utility study will offer logical (and science-driven) descriptions of the mechanisms through which a psychological phenomenon impacts a business and reflects in Return on Investment (ROI) - and ultimately in business profit, as a function of relative costs and gains.

We believe that this research is related to at least two objectives from UN Sustainable Development Goals (2015): Justice and Partnerships for the goals.

Keywords: financial implications, perceived unfairness, selection

„Alexa, how do we break the glass ceiling?" How voice assistants affect gender stereotypes about career and family

Anna Aumüller, Bernad Batinic & Martina Mara | JKU Linz

science

This study aims to lay a foundation for research on how technologies like voice assistants can affect users' gender stereotypes, especially in the business context, and how to subsequently use technology as a tool to break the glass ceiling for women.According to the "Computers are Social Actors" paradigm, people often treat computers the same way they treat other human beings. This includes perceiving technology as male or female, depending on its features like design or voice, and ascribing different traits and competences to female- or male-connotated technologies. According to Eagly's biosocial-role-theory, gender stereotypes do not only mirror biological differences, but mostly social role perceptions of women and men. Studies show that automatic stereotypes can be reduced when people are being exposed to counter-stereotypes. Therefore, perceiving more women working as financial advisors, which is a rather male-dominated occupation, should help reduce the gender bias in financial consulting.To combine the findings regarding the biosocial-role-theory, the effectiveness of counter-stereotypes and gender attributions to voice assistants, two voice assistants of different gender were used to examine to what extent counter-stereotypic voice assistants can reduce participants' gender-career stereotypes. A quantitative online experiment with 259 participants was conducted, with the intervention consisting of two conditions: in the counter-stereotypical participants listened to a female voice assistant, allegedly being employed as a business consultant and giving workshops about investment strategies, whereas the control group listened to a male voice assistant in the same position. At first, the extent of people assigning gender-stereotypic characteristics to the voice assistant was measured. Implicit association tests before and after the intervention were used to measure associations between gender and career. The results showed no significant effect of the voice assistant's gender on the implicit associations between gender and career after the intervention compared to before and no moderating effect of the gender-stereotypic traits of the voice assistant. Furthermore, the implicit associations had no significant effect on the intention to use the technology. However, people who had listened to the female voice assistant showed significantly lower implicit gender associations after the intervention than people who had listened to the male voice assistant. Moreover, results showed that implicit associations between gender and career still exist today.The main limitations were that the study only measured a short-term effect, the counter-stereotype only consisted of a female voice and people did not attribute gender-stereotypical characteristics to the female voice.Practical implications include to end the practice of making voice assistants female by default and to track the gender balance of AI devices in companies. Future research should include severalinterventions and measurement times and a more interdisciplinary approach, e.g. developmental psychology, by addressing the influence on children, who grow up with such devices from early on.Implementing new technologies in the work context and breaking the glass ceiling for women are both topics, which are highly relevant in the changing world of work. The study also contributes to the SDG of promoting gender equality.

Keywords: voice assistant, glass ceiling, gender roles

Poster P110

The link between work engagement and job performance: a meta-analysis

Andreea Corbeanu, University of Bucharest

science

This study addresses the link between WE, task and contextual performance, providing a systematic review of our knowledge on the topic of WE and JP. Firstly, it paints a complete picture of JP, by addressing both contextual and task performance. Secondly, we also focus on the two main measures that are habitually used to measure the job engagement: the Utrecht Work Engagement Scale (UWES), versus the Job Engagement Scale (JES). By comparing the two measures directly, this paper investigates whether the JES is a viable alternative to UWES, to be used in organisational practice, and examines some of the theory around the conceptual models on which the two scales are built.

Thirdly, by including participant occupation as a moderator we reveal whether the relationship between WE and JP could be different for customer-facing versus non-customer facing roles. The burnout literature suggests that employees who have to deal with emotional demands on their jobs, such as facing irate customers, or having to caretake a number of patients while faking positive emotions are more vulnerable towards developing burnout. Given that some authors view WE as a direct opposite of burnout we investigate whether these assumptions hold true for the positive end of the spectrum as well. Following a systematic literature review, we identified 174 unique studies. Studies had to be set in an organizational environment, to include a measure of WE, an objective or subjective measure of performance and offer information concerning the link between WE and JP, irrespective of whether it was the main aim of the study or not. Following a random-effects model, we obtained meta-analytic correlations of $r = .36$ ($N = 33$ independent samples), $r = .36$ ($N = 26$ independent samples), $r = .38$ ($N = 29$ independent samples) between vigour, dedication, absorption and job performance, respectively. For the overall WE and JP, we report a correlation of $r = .37$ ($N = 166$ independent samples). Further, potential moderators were examined. The findings highlight the importance of WE research, for improving organizational performance.

The main limitation of the current meta-analysis is tributary to the nature of this kind of study design and refers to it unavoidably taking over some of the limitations of the primary studies included in the analysis. Because these articles included cross-sectional designs, we cannot draw any causal inferences from our findings. A valuable contribution of this paper lies in the importance of the examined moderators. By examining the average correlations among the WE facets for both measures, we found that only the link between dedication and vigour (and not any of the JES scales) was statistically significant, yielding a very high correlation coefficient ($r = .91$). The type of participant occupation is another promising moderator that we considered. We have pursued the expectation that WE is boosted by the immediate feedback one gets from human interactions, and therefore would be more strongly associated with client-facing roles. Our findings seem to oppose that, as we found stronger associations for non-client-facing roles, in the case of absorption.

In the context of The Future is Now, our paper is relevant to the Changing World of Work as it provides an overview of our current knowledge on the WE and JP literature, which could be used by both academics and practitioners as a starting point to subsequently better tackle this phenomenon in the workplace.

Keywords: work engagement, job performance, meta-analysis

Poster P111

Work Environment and Stress – Moderating Role of Extraversion and Emotional Stability

Viviana Maria Fen-Loi & Lenka Duranova | University of Applied Sciences Schmalkalden

science&practice

Research goals and why the work was worth doing

Currently, increased health issues due to stress at work are being recorded. Particularly, the context of work environment has become more important since the outbreak of the COVID-19 pandemic, with more knowledge workers having to relocate from the office to the home office, assuming that home working ratio will not decline to pre-pandemic levels (Bogenstahl & Peters, 2021). Stressful environmental conditions may result in different stress perceptions due to different coping mechanisms. There is an empirical evidence that working at home is associated with additional stress (Oakman, Kinsman, Stuckey, Graham & Weale, 2020; Palumbo, 2020) on the one hand, but also with relief (Rothe et al., 2017). The present study aims to shed more light on the interaction between work environments (office vs. home office) and personality traits (extraversion vs. emotional stability) in order to better understand individual stress perceptions at work. Our study contributes to the development of targeted and tailored interventions for improving employee health.

Theoretical background

Based on the differential reactivity model of Bolger and Zuckerman (1995), the present study posits a moderating role of extraversion and emotional stability (low neuroticism) in the relationship between work environment and stress.

Methodology

Using a cross-sectional design, our data were collected online from German full-time office workers (N = 82). To test our hypotheses, we conducted hierarchical regression analyses controlling for children and other persons in household.

Results

The empirical tests partially confirmed our hypotheses. Emotionally unstable workers perceived lower stress in their home office compared to the office. Emotionally stable workers showed an opposite pattern: Their stress level was higher in the home office. Furthermore, they perceived lower stress than emotionally unstable individuals in both examined work environments. Contrary to our expectations, we did not find any moderation effect of extraversion.

Limitations

The survey data were collected at a single point in time and therefore, fluctuations in stress perceptions over time cannot be considered. The validity of the work environment instrument needs further examination.

Research and practical implications

The need to integrate hybrid working into the future work models is indispensable for modern organisations (Vartiainen, 2021). The present study contributes to the knowledge of interactions between personality differences and environmental stressors. The findings suggest working at home vs. in the office having more negative effects for some employees. Future research should shed more light on the long-term consequences of working at home compared with the office.

Relevance to the congress theme and relevant UN SDGs

This study is designed to supplement approaches for promoting health and well-being of office workers by increasing the person-environment fit from a psychological perspective. This does not only benefit the individuals, but also companies that possibly can count on a lower absenteeism rate due to illness among employees. Furthermore, working at home saves office space, reduces general costs and technical services, increases flexibility in office use, and also the flexibility to reach employees geographically (Grunau et al., 2019).

Keywords: Work Design, Home Office, Personality

Poster P112

A Piece of Humble Pie: The Role of Relational Humility on Performance and Leadership (Emergence and Effectiveness)

Erin Newkirk, Chockalingam Viswesvaran & Laura Heron | Florida International University

science

While humility has been investigated since the early 2000s, relational humility (RH) has only recently been introduced to the literature. RH can be deconstructed into three components: a) global humility b) superiority and c) accurate view of self. Thus far, the association of RH with organizational variables is largely unknown. The present study addressed existing gaps by investigating the relationship between RH and several well-known organizational variables including leader emergence, leader effectiveness, organizational citizenship behaviors directed towards individuals (OCB-Is), and counterproductive workplace behaviors directed towards individuals (CWB-Is). Thus, the present study provides a novel contribution that establishes the beginnings of a nomological network for understanding the role that RH plays in the workplace.

We searched the extant literature regarding humility to inform our hypotheses. To summarize: those who are low in humility tend to be less likely to be perceived as leaders (leader emergence). Humble leaders are more likely to create bonds with their teams through social exchange theory, whereby teams may respond with stronger commitment and performance (leader effectiveness). Further, humility is linked to generosity and being kinder to others, including enemies (OCB-Is). Finally, there is ample evidence that those who score low on humility are more inclined to engage in harmful behaviors, like cheating, stealing, and sexual harassment (CWB-Is).

Given the nature of RH as a perceived character judgment, we gathered other-report data from 556 undergraduate students who were randomly assigned to answer questions based on their most (n = 285) or least humble coworker (n = 271). This experimental manipulation ensured variability in levels of relational humility. Two-step hierarchical regressions demonstrated that RH is indeed a key contributor to leader emergence, leader effectiveness, OCB-Is, and CWB-Is.

Study limitations included: 1) the use of student samples which may impact the external validity of the study, though we determined our sample had robust work experience prior to participating, and 2) the fact that participants placed in the least humble condition may select an individual who is more humble than the colleague chosen by a participant placed in the most humble condition, though we partially addressed this with random assignment.

By increasing our understanding of the role that RH plays in the workplace, the present findings have significant implications for organizations looking to develop effective leaders, promote OCB-Is, and reduce CWB-Is. Thus, this submission is relevant to this year's theme in that high RH in the workplace leads to more emergent and effective leaders, as well as a kinder, more cohesive environment (increased OCB-Is, decreased CWB-Is), which may be especially important as we negotiate a new normal in the workplace after the pandemic. RH is a trait that makes organizations a more friendly, positive place to be – especially following a period of isolation and loss of human connection. Thus, we align this paper with the UN SDG of peace, justice, and strong institutions.

Keywords: relational humility, leadership, organizational citizenship behaviors

Poster P113

Are All Craving for Appreciation? A Cross-Lagged Analysis of Leaders' Appreciation at Work and its Interplay with Employee Well-Being

Laura Schlegel & Kathleen Otto | University of Marburg

science

Research goals: Since employees spend a great part of their daily life at work, the effects of work conditions on health should not be underestimated. As it is central to maintain employee health and well-being, resources need to be identified to do so. One promising approach might be to focus on appreciation; a construct which has found little attention in the past and which was mainly analysed as part of other constructs (e.g. social support). Appreciation at work is more than positive feedback or positive reinforcement, as appreciation "implies recognition of one's qualities and achievements, signals acceptance, and acknowledgment, and thus responds to the need to belong and boosts self-esteem" (Pfister et al., 2020, p. 63). Recent research confirms that appreciation is worth to be researched on its own (Semmer et al., 2019). Thus, this study analyses which effects leaders' appreciation has on employee well-being and moreover raises the question if this relation should be regarded as a one-way street.

Theory: Stress-as-Offense-to-Self theory (Semmer et al., 2019) outline that appreciation at work is an important resource for employee health and well-being. Missing appreciation can result in a threat to self which, in turn, can result in stress or depressive mood. On the other hand, research could reveal positive effects of perceived appreciation on job satisfaction and well-being (Pohrt et al., 2022; Stocker et al., 2019). Commonly in occupational health psychology, job resources are seen as influencing factors shaping employee well-being (Bakker & Demerouti, 2007). But Ford et al. (2014) could show multidirectional effects in their meta-analysis: Not only work conditions can affect well-being, well-being can influence conditions at work and employees' perceptions of these as well. Regarding appreciation, reversed effects might occur because generally people prefer to interact with people high in well-being and they appear more efficient and in control to them. Therefore, this study focuses on the multidirectional effects of appreciation and well-being.

Methodology : A two-wave study with a time lag of six weeks is carried out among German employees (expected n = 120). Leaders' appreciation and well-being, i.e. job satisfaction, will be analysed via cross-lagged paths.

Results: Results will be available in March 23. The analysis is expected to reveal multidirectional effects, that leaders' appreciation (T1) can shape job satisfaction (T2; regular causation), but also that job satisfaction (T1) determines if employees are vulnerable to the effects of leaders' appreciation (T2; reversed causation).

Limitations and implications: This study only focuses on leaders as sources of appreciation and does not distinguish between different forms (e.g. praising, saying thank you). Given that appreciation is easy to show and trainable, it is a low budget but effective resource to promote employee well-being.

Relevance to congress theme : In a world where employee health and well-being is coming to the fore as the numbers of psychical-health-related absences are increasing and employees are facing new challenges (e.g. Covid), it is important to identify resources for employee well-being. Granting and receiving appreciation at work can be seen as a promising approach.

Relevant UN SDGs: Our study aims to clarify the role of appreciation at work which might be an effective resource to facilitate and maintain good health and well-being.

Keywords: Appreciation, Well-Being, Multidirectional Effects

Poster P114

Associations of job demands and burnout symptoms at baseline with adherence in a web-based cognitive ergonomics intervention

Heidi Lahti, Finnish Institute of Occupational Health; Tuula Oksanen & Piia Kauhanen |University of Eastern Finland; Kia Gluschkoff & Virpi Kalakoski | Finnish Institute of Occupational Health

science&practice

Research goals: Online platforms are increasingly used in workplace learning and development activities. However, adherence to online interventions is often poor and attrition rates are high. Current research has not widely studied which factors are associated with continued participation in web-based workplace interventions. The aim of this study was to examine whether contextual factors related to self-reported demands of work and burnout symptoms are associated with adherence in a web-based intervention.

Theoretical background: Previous literature has shown that process evaluation is necessary in the evaluation of complex workplace interventions as it helps to understand why an intervention succeeded or failed in achieving the desired outcomes. One key area of focus in process evaluations is intervention context, which refers to anything external to the intervention that might affect its implementation or effects. In this study, we focused on the associations of certain contextual factors with online adherence.

Design: The data were derived from an intervention study that sought to improve cognitive ergonomics at work. The 73 participants from three public sector organizations worked in various specialist jobs. Before the intervention, a baseline survey with questions about job demands and burnout symptoms was conducted. In the intervention phase, the participants completed an online coaching programme that lasted for 10 weeks. After the intervention, each participant's activity on the online platform was examined from three perspectives (number of modules completed, number of days with visits, number of comments and likes). Quasi-Poisson regression analyses were used to study if the frequency of five cognitive demands (learning, unclear instructions, distractors, multitasking, and time pressure) and indices of quantitative job demands and burnout (COPSOQ-II) at baseline predicted the three measures of adherence in the intervention phase.

Results: Quantitative job demands (IRR 0.86, 95% CI 0.77–0.96, $p < .01$) and the frequency of time pressure (IRR 0.88, 95% CI 0.79–0.98 $p < .05$) and distractors (IRR 0.88, 95% CI 0.79–0.99 $p < .05$) at baseline were associated with less modules completed during the intervention. Predictions based on these models indicated that there was a difference of about one completed module for low and high (±1 SD) quantitative job demands, time pressure and distractors (1.2, 1.0 and 1.0, respectively). Burnout symptoms were not associated with the measures of adherence.

Limitations: The main limitations of the study are the small sample size and the focus on specialist work in office environments, which limit the generalizability of the findings.

Practical Implications: Our results indicate that high job demands may form a barrier to adherence. To improve adherence, and thus the effectiveness, of web-based workplace interventions, these demands need to be considered, and sufficient time for completing the intervention needs to be ensured.

Relevance to the Congress Theme: The study is highly relevant as workplace learning and development activities are increasingly carried out online and means for improving adherence in

these activities are needed. Furthermore, the studied intervention targeted improving work practices and conditions that relate to digitalization, intensification, and fragmentation of work, all of which are common phenomena in the changing world of work.

Keywords: online intervention, adherence, context

Poster P115

On Being Open to Change the World: Boundary Conditions for the Relationship between Openness and Performance

Raluca Dutu & Dragos Iliescu | Faculty of Psychology and Educational Sciences, University of Bucharest

science

Research goals

This study addresses a relatively understudied topic in personality and work psychology: the processes through which openness to experience and workplace context predict distinct facets of work performance.

Theoretical background

Openness to experience has been shown to predict performance criteria only inconsistently. However, previous meta-analytical studies emphasized that openness might be of great importance for a new category of organizational citizenship behaviors: change-oriented citizenship. By and large, there is limited empirical evidence on this topic. In addition, the results were inconsistent, leaving enough room for moderators. Drawing on Trait Activation and Situation Strength theories, this study proposes that two variables (organizational climate and innovation requirements) simultaneously moderate the relationship between openness as a predictor and the two criteria of task performance and change-oriented citizenship.

We propose the following hypotheses:

H1: Openness to experience will be a better predictor for change-oriented citizenship.

H2: The relationship between openness and change-oriented citizenship behavior will be jointly moderated by climate for initiative and requirements for innovation, such that change-oriented citizenship behavior will be highest when all three (i.e., openness, climate for initiative, and innovation requirements) are high.

H3: The relationship between openness and task performance will be jointly moderated by climate for initiative and requirements for innovation, such that task performance will be highest when all three (i.e., openness, climate for initiative, and innovation requirements) are high.

Method

The foreseen end of the project is on April 2023. For the current study, a cross-level design was used. The final sample will include approximately 200 participants. The targeted population consisted of employees and their direct supervisors. The only criteria for inclusion were the employment status and the duration of the employee-supervisor relationship. The employees assessed their personality traits and their jobs in terms of creativity requirements and participative climate. The supervisors provided performance ratings for their employees (task and change-oriented citizenship).

Results expected

Relationships of different magnitudes are expected between openness and the two facets of performance, and these relationships might change depending on situational cues.

Limitations

Some limitations need to be acknowledged. The cross-sectional design impedes causal inferences. The moderating variables are based on self-report and thus represent a subjective perspective on situational cues.

Research/Practical implications

The present study adds to our understanding regarding the association between openness and performance, and (a) makes a clear distinction between two facets of performance, and (b) specifies some situational cues that change the link between openness and performance, simultaneously. Understanding how situational cues within the organization imprint the link between openness and performance provides a powerful tool by which organizations could facilitate desirable outcomes.

Relevance to the congress theme

Change-oriented citizenship is a key concept in this study and it shows how employees can actually change the world of work.

Keywords: openness to experience, organizational climate, change-oriented citizenship behavior

Poster P116

Exploring Generational Stereotypes in the United States and China: Comparing Millennials and Bailinghou

Cody Cox, Zecong Ma & Marisol Moreno | St. Mary's University

science&practice

Research goals

Generational stereotypes are pervasive despite consistent empirical evidence that generational differences tend to be overstated (Costanza & Finkelstein, 2015). The use of generational stereotypes may lead employees to seek employment elsewhere. Further, there has been little research comparing generational perceptions between cultures. For example, China has a considerably larger population of Millennials (i.e., the bailinghou). The purpose of this study is to explore perceptions and stereotypes of Millennials in the United States and China and to see if the prevalence of these stereotypes in the workplace turnover intentions in both populations.

Theoretical background

Generational stereotypes in the United States can negatively impact stigmatized workers (Cox, Young, Guardia, & Bohmann, 2017). While these results have demonstrated some impacts on American employees, it is important to note that generational labels exist in other cultures as well. In particular, China labels the generation born after 1980 as being “Bailinghou.” Whether these stereotypes are similar in China and whether they negatively impact Chinese Millennials has yet to be explored.

Design

Using MTurk and other survey tools, 800 working individuals from across a range of industries (400 in China and 400 in the United States) are being recruited. All measures are established and validated.

Results

Data collection is currently underway and 150 responses from the United States have been collected.

Our factor analysis indicated an eight factor solution that accounted for 75% of the variance best fit the data. Millennials in the United States are viewed as privileged, idealistic, materialistic, distrusting, expressive, eco-friendly, sociable, and immature.

Our data indicates that perceived discrimination towards Millennials is actually associated with greater organizational commitment and job satisfaction in our sample. However, Millennials perceived more Millennial discrimination, $t(81) = 1.80$, $p = .04$, and had greater intention to turnover, $t(92) = 2.09$, $p = .04$. Further, perceived discrimination fully mediated the relationship between Millennial status and intention to turnover. This provided some evidence that the presence of these stereotypes in the workplace can lead employees to seek work elsewhere.

Limitations

The data is all self-reported and cross-sectional, which raises issues of common method bias. However, our findings with regards to age (i.e., Millennial status) should be less susceptible to this bias as age is an objective measure.

Conclusions

This is the first study to demonstrate that generational labels in the workplace can lead to individuals leaving the organization. Second, our findings suggest that stereotypes about Millennials are complex. Millennials are viewed as entitled, casual, uncommitted and self-expressive. Finally, our findings will include the first examination of stereotypes of Chinese Millennials and whether these stereotypes impact workplace experiences.

Relevance to the Congress Theme

This work is most relevant to the fourth theme, Diversity and Inclusion.

Relevant UN SDGs

This work is most relevant to decent work and economic growth as well as peace, justice, and strong institutions.

Keywords: Millennials, stereotypes, bias

Poster P120

Company's Cyberexposition and the Employees' risk propensity.

Zofia Przymus, Karolina Małagocka & Krzysztof Przybyszewski | Kozminski Univeristy

science&practice

Aims of the project:

The increasing number of attacks exploiting the human factor has been observed due to the fact that breaking through technological barriers becomes a resource-intensive process, because of their cumulative complexity and sophistication (Ani, He & Tiwari, 2019). Our studies were aimed at finding how companies are exposed to cyberthreats by employees' remote working habits. In study 1 the scale based upon Fishbein's (1967) expectancy model of attitudes towards actions was constructed. Study 2 was aimed at testing the hypothesis of the influence of employees' individual risk propensity on the company's exposition to the cyberthreats.

Results:

The list of 26 items - potentially risky habits elicited in preliminary qualitative studies - was subjected to factor analysis, (principal components, Varimax rotation, N=548). The analysis revealed three factors accountable for 67% of variance explained. The employees's habits may be categorised as posing (1) the environmental threats, (2) the credentials -related threats, and (3) the behavioural threats on the company's cybersecurity. The expectancy model we applied allows to calculate the indices of risk posed by the employee's habits on the company's cybersecurity.

In study 2. DOSPERT (Weber, Blais & Betz, 2002) scale was used to measure the individual's propensities towards taking risk in various domains together with our cyberexposure scale. The preliminary results show that cyberexposure correlates with financial and ethical but not with social risk taking.

Practical Implications:

The cyberexposure scale measures separately two parameters of the habits/behaviours related to cybersecurity: (a) the valence i.e. severity of a threat posed and (b) the probability of being performed. This expectancy based approach allows the users to separately assess the cybersecurity beliefs/knowledge of the employees, their habits and the overall value of the risk posed by the employees. The severity of the behaviours may as well as the subjective probability of being performed may perceived as lower or higher, which produces four types of cyberexposure attitudes: low perceived threat and low probability of doing, low perceived threat and high probability of doing, high perceived threat and - low probability of doing, and high perceived threat together with high probability of doing. As can be seen, this approach allows the cybersecurity officers to adjust their policies: sometimes the education on severity of threats will be effective (low perceived threat) but sometimes, in high threat cases, the different policies will be not needed.

Keywords: Cyberexposition, Risk propensity, Cyberthreats

Poster P121

Women's Careers: The influence of Resources on Resilience to achieve Subjective Success.

Alice Zenari, Alma Mater Studiorum- Università di Bologna; Isabel Rodriguez, Universitat de Valencia; Rita Chiesa, Alma Mater Studiorum- Università di Bologna

science&practice

The aim of this research is to explore resources that can boost women's career development in light of the gender inequalities which still persist in today's work environment. Firstly, we are interested in identifying what leads women to face career challenges and achieve their career ambitions. We look into the influence of both personal and contextual resources on women's resilience in overcoming career setbacks. Secondly, we delve into the concept of resilience and its impact on achieving subjective success. Thirdly, we deepen the relationship between resources, resilience, and subjective success, investigating a mediation between them. This research is important as the role of resilience is still missing in studies on women's careers (Jogulu et al., 2022).

The research findings can inform both researchers and practitioners concerned with equity and inclusion to better support women in their professional development. Using the conservation of resources theory (Hobfoll, 1989) as a theoretical lens, lack of support is a career-related stressor in a shared social context. The theory posits that resources allow individuals to increase their coping capabilities. The insights of modern career theories are also considered in this research. Specifically, Savickas' (2005) career construction theory delves into individuals' successful adaptation to their environment by considering personal resources in persisting towards setbacks (i.e., career adaptability).

The research sample consists of Italian women having a work career. We used a cross-sectional design with snowball sampling. Data were collected with a survey, using measures from previous research on career satisfaction. Data collection and analyses will be finished by the end of 2022.

The results of this research include the distinction between personal and contextual resources needed for overcoming career barriers. In addition, the results highlight women's resilience and its relationship with achieving subjective success. In exploring the results, the importance of certain forms of support is deepened when considering women's achievement of their career goals. Some limitations that need to be considered in this research include the cross-sectional design, the measures used and the convenience sampling.

This research has implications for fostering career resilience leading to subjective career success. It contributes to the expansion of knowledge regarding the role of resilience in women's career development, and it provides further insights into women's subjective success. The research also has practical implications for companies, especially in developing support strategies and creating a safe environment of sharing and networking for women.

In line with the congress theme, this research delves into women's careers as they are still discriminated against in work environments. This study invites scholars and practitioners to essentially act in implementing solutions and interventions that benefit the achievement of women's career ambitions.

This research contributes to Sustainable Development Goal 5, Gender Equality, highlighting the different contextual resources women and men have in workplaces, and to Sustainable Development

Goal 8, Decent Work and Economic Growth, in light of the projected global unemployment rate that disproportionately impacts women.

Keywords: women, subjective career success, career resilience

Poster P122

A mixed-method investigation of workload and job satisfaction among air traffic controllers: the key roles of work-family interface and resilience

Chiara Bernuzzi, University of Pavia, Department of Brain and Behavioural Sciences; Department of Law; Ilaria Setti, University of Pavia, Department of Brain and Behavioural Sciences; Deirdre O'Shea, University of Limerick, Kemmy Business School

science&practice

Research goals. The travel restrictions introduced by European countries to contain the spread of the COVID-19 virus have severely affected international air traffic demand (ICAO, 2021). Italian airlines have witnessed alterations in air traffic volumes, resulting in substantial changes in workload. Nevertheless, little is known about the psychological challenges that Italian air traffic controllers (ATCOs) faced during the pandemic. This research aimed to examine whether workload would be directly and indirectly (through work-family conflict) related to job satisfaction among ATCOs and whether this relationship could be conditional on resilience levels.

Theoretical background. Workload is one of the main causes of stress among ATCOs (Triyanti et al., 2020) and has adverse effects on work-related outcomes, including job satisfaction (Jou et al., 2013). Job dissatisfaction can threaten ATCOs' productivity (Qureshi et al., 2019) and team cooperation (Kuang et al., 2020), which may increase the risk of compromising the efficiency and safety of air traffic management (Kuang et al., 2020). Thus, it is crucial to analyse how and when workload can be negatively related to job satisfaction.

Design. A total of 168 ATCOs operating throughout the Italian territory completed questionnaires that measured workload, work-family conflict, job satisfaction, resilience, and Covid-19-related exposure. Descriptive statistics and moderated mediation analyses were performed. To deepen the quantitative results, ten semi-structured interviews were conducted and analysed using thematic analysis.

Results . When ATCOs perceived a high workload, they were more likely to develop work-family conflict. As a result, they became less satisfied with their work. Resilience buffered this relationship, suggesting that ATCOs with high and moderate resilience levels were at lower risk of experiencing job dissatisfaction related to work-family conflict under heavy workload conditions than those with low resilience. Six core themes were identified from the interviews: the impact of the Covid-19 pandemic; double-edged job characteristics; job-related risks stressors; protective resources; work-life interface; and consequences.

Limitations. The cross-sectional study merely relied on self-report measurements.

Research/Practical Implications. By addressing the call for more research on the workload-job satisfaction link (Inegbedion et al., 2020), this study suggests the need for flexible work arrangements and family-friendly policies to allow ATCOs better managing workload and balancing work and family demands. Additionally, given the protective role of resilience, organizations could provide ATCOs with psychological resilience training. These programs could be integrated with courses on coping skills on how to balance work and personal life (e.g., time management strategies) and on how to set boundaries between these two domains (e.g., cognitive-emotional segmentation strategies).

Relevance to the Congress Theme. This study deepens the topic of wellbeing by revealing how and when workload is related to job satisfaction among ATCOs.

Relevant UN SDGs . Good health and wellbeing.

Keywords: Job satisfaction, work-family interface, resilience

Poster P123

Development of a Framework to Examine Expectations in Human-AI-teamwork

Mira Kaut, Claudia Peus & Eleni Georganta | Technical University Munich

science

Research Goals

The current literature discussing AI in Teams is mostly concerned with questions of how an artificial agent should be designed to be positively perceived by humans. However, little research has been done into what humans expect from AI colleagues compared to human colleagues. There seems to be something inherently different in how AI agents compared to humans are perceived, especially with regard to expectations. Therefore, the goal of the present work is twofold: first, to show that AI colleagues are perceived differently from human colleagues; second, to examine if expectations towards an AI colleague can be managed.

Theoretical Background

Applying the Expectation States Theory to the context of human-agent teams, we first propose that the status characteristic of being human compared to AI (i.e., nature) might result in different expectations towards a colleague and thereby to differences in team-related factors such as trust. Building on the Expectation Disconfirmation Theory, which has been widely used to study the relationship between expectations towards a technology, we then propose how to manage and alter these different expectations towards AI colleagues and in turn improve collaboration and satisfaction.

Method

To do so, we start by investigating differences in perceptions between having a human and an AI colleague. Specifically, we recruited 106 subjects for an online between-subjects experiment. Participants were assigned either to a human or an AI colleague as part of a medical team. Then, they read different team scenarios and rated the extent to which they perceived their colleague to be a teammate and a tool.

Results

Preliminary results showed that participants in the AI-colleague condition perceived their colleague more as a tool and less as a teammate than those in the human-colleague condition.

Limitations

Despite the importance of these first findings, the present study has some limitations, such as the use of scenarios instead of real-world teamwork situations. Future studies should overcome this issue and continue investigating differences in expectations associated with the characteristic nature and how they can be managed to enable the integration of AI into teams.

Implications

Our results indicate that while all other factors remained equal (role, skills, experience), the perception of the colleague changed depending on its nature (AI vs. human). Even though the nature of the colleague was not pertinent to a specific task or situation, it led to differences in perceptions. This indicates that the status characteristic “nature” exists, is salient, and can impact the perceptions of humans when integrating an AI as a colleague. This might also indicate that expectations about a

colleague's performance differ when the characteristic nature is salient, resulting in differences in team dynamics.

Relevance to the Congress Theme

For companies who seek to introduce AI as part of a team, this means that they will first need to change the expectations associated with a colleague when being artificial. This is especially important, as the world of work is changing rapidly and the integration of AI into the workplace is becoming a reality.

Relevant UN SDGs

We adopt a human-centred perspective of human-AI teamwork that can help to sustainably and ethically introduce AI into the workplace, improve working conditions and promote economic growth while simultaneously relieving the human workforce.

Keywords: artificial intelligence, teamwork, expectations

Poster P124

The interplay of meaningfulness and money in momentary work performance: an experimental approach

Aleksandra Penza, SWPS University; Samantha Heintzelman, Rutgers University; Ewelina Smoktunowicz, Aleksandra Kosiarczyk & Katarzyna Cantarero |SWPS University

science&practice

We tested how task meaningfulness affects performance, using a novel online procedure that built upon previous studies (Ariely, Kamenica, & Prelec, 2008; Chandler & Kapelner, 2013). Participants were asked to either count white dots on a black background, or, in the meaningful condition, to count stars on sky maps as part of an alleged program that monitors illumination pollution. Participants could decide on how many tasks they wanted to complete. We conducted three pre-registered studies (N = 471) where we showed that counting stars was perceived as a more meaningful task. In the first two studies we paid participants a fixed amount of money regardless of the time spent on the task. We found no main effect of experimental manipulation on the number of tasks. We found an exploratory indirect effect in that task meaningfulness played the role of the mediator. In the third study we offered additional remuneration for every completed sky map/photo. The payoff dropped after each task. We found that individuals performed more tasks in the meaningful condition. There was no significant indirect effect through subjective task meaningfulness. These results suggest that when performance is not rewarded with external benefits, subjective meaning ascribed to a task can drive the performance. Interestingly, even slight financial reward per task boosts performance in the meaningful condition. Taken together, the findings suggest that the interplay between meaning and money may be not only compensatory, but also complementary.

Keywords: work meaningfulness, performance, work engagement

Older workers' decisions to stay at work: The role of self-efficacy and perceived occupational opportunities

Maaike Schellaert & Eva Derous |Ghent University; Donald Truxillo, Deirdre OShea & Gemma McCarthy | University of Limerick

science&practice

Research Goals and Theoretical Background. Recently, the Covid-19 pandemic has drastically changed working environments, which could cause uncertainty among (older) workers and affect work-related outcomes, like retirement. Despite the societal importance to prolong working lives, previous research indeed showed an increase in the number of (early) retirees during the Covid-19 pandemic (Davis, 2021).

According to the uncertainty regulation model (Griffin & Grote, 2022), endogenous/perceived uncertainty (i.e., uncertainty over which individuals have control) is affected by personal and environmental factors (Downey & Slocum, 1975), which can influence decision-making. Individuals who have more perceived control over their retirement decisions, for example, have stronger retirement intentions (van Dam et al., 2009). Further, opening behaviors, which are actions directed towards new goals (e.g., focusing on new occupational goals), can affect endogenous uncertainty. In this study, we focused on self-efficacy to work longer (i.e., until the legal retirement age) as endogenous uncertainty, and we investigated whether there is a positive relationship between older workers' self-efficacy and intentions to work longer. Further, we investigated whether perceived occupational opportunities (as opening behavior) mediates this relationship. Finally, since leadership support is an important factor in retirement decisions (Woźniak et al., 2022), we investigated whether the effect of self-efficacy on intentions to work longer via perceived occupational opportunities differs depending on levels of leadership support (i.e., moderated mediation).

Methods. A longitudinal study was conducted among employees aged 50 years or older that worked in a large Western-European government organization. Data include participants from the fourth and fifth wave (N total = 967; M ageT4 = 55.0, SD ageT4 = 3.4; 67% women).

Results. First, a mediation analysis using PROCESS macro (Hayes, 2013) showed a significant direct effect (β =.31, p <.001) of self-efficacy on intentions to work longer, R 2 =.12, F (2, 964)=65.89, p <.001, as well as a significant indirect effect via perceived occupational opportunities, 95% CI [.01, .04]. However, a moderated mediation analyses showed no moderation effect of leadership support (p =.22) on the relationship between self-efficacy and perceived occupational opportunities. The overall moderated mediation model was not supported, index=.00, 95% CI [-.02, .00].

Limitations. First, this study focused on intentions, but did not capture actual retirement behavior. However, this study is part of a larger longitudinal research project, hence, we will accommodate this limitation with additional analyses. Further, we focused on leadership support and perceived occupational opportunities. No effect was found of leadership support; other work (like work complexity) and personal characteristics (like health) might have a stronger impact on older workers' uncertainties and push them to retirement.

Research/practical Implications. Uncertainty among older workers and how it affects retirement decisions is underresearched. Organizations might focus on older workers' self-efficacy and occupational goals, for example by organizing coaching sessions, to motivate older workers to work longer.

Relevance to the Congress Theme. Given global aging and shortages in the labor market, it is highly relevant to investigate uncertainties older workers may experience.

Keywords: Retirement, self-efficacy, occupational opportunities

Poster P128

South African Organisations on the Couch. Exploring unconscious dynamics in organisations. A post pandemic view

Louise Tonelli, Michelle S May, Calum McComb & Frans Cilliers | University of South Africa

science&practice

Research goals and why the work was worth doing

This longitudinal study argues that the present conscious and rational discourse on the identity of South Africa and its organisations, denies the underlying, deeper roots and causes, irrational and unconscious manifestations in the collective system. We realise that this could be because of the country's painful past and the difficulty to talk about such overly sensitive matters. Therefore, the approach suggested by this study is to imagine South African organisations on the metaphorical Freudian couch to study its systemic psychodynamic behaviour. Hopefully, this will provide an awareness and understanding of the nature and intensity of the underlying collective anxiety, as well as its manifesting defensive structures.

Theoretical Background

Systems Psychodynamics (SP) is conceived as a systems theory through which one understands the universe as a hierarchy of systems (Cilliers & Henning, 2014). SP originated at the Tavistock Institute for Human Relations in London and functions as a depth psychology organisational theory, consultancy stance and research domain (Cardona, 2020). SP studies organisations as consisting of complex micro, meso and macro systems with cognitive, affective, motivational, and relational behaviours manifesting consciously and unconsciously (Armstrong, 2005).

Design/Methodology/Approach/Intervention

Hermeneutic Phenomenology (Kafle, 2013) allowed for an emerging qualitative approach within an interpretive framework (Creswell & Poth, 2018). The research approach was orientated towards exploring participants lived experiences of being members of South African organisations and interpreting the context (Creswell & Poth, 2018).

A Listening Post (LP) (Long, 2013) served as the data gathering approach. Listening posts are centrally associated with OPUS (Organisation for Promoting Understanding in Society) in the United Kingdom. An unstructured group method based on the notion that a group of people (8-12) convening to study the unconscious behaviour of a system, act as a representation the larger system.

Results obtained or expected

Results of this research are currently being refined to be presented in journal articles in 2023.

Preliminary results obtained from three LP convened in 2020 and 2022 are integrated to reveal the following themes:

Metaphor – Rhinoceros and Tom and Jerry (cartoon).

Survival – personal, organisational, and societal.

Government – not taking care of citizens, threatening citizens.

Coping mechanisms – smoking and alcohol during prohibition.

Hypervigialism

Post traumatic experiences after Covid-19 restrictions lifted

Disconnection, dissociation

Control – Leaders and followers

Limitations

The researchers were aware that the LP as a qualitative instrument, does not require a stratified random sample of employees of South African organisations. It served as a snapshot (Khaleelee and Stapley, 2018) of unconscious dynamics which may be manifesting in some organisations at a particular point in time.

Research/Practical implications

Behavioural Practitioners in organisations are made aware of members of organisations lived experiences of the prevailing climate and culture. Based on LP findings practitioners may develop their own hypotheses of conscious and unconscious dynamics manifesting in their work groups and the organisations

Keywords: Covid-19, Listening Post, Systems Psychodynamics

Poster P130

How to support the realization of sustainability preferences in self-service online investments? – An integrative literature review on digital nudges

Jan-Philip Schumacher, Britta Hülsmann, Fabia Hettler & Tammo Straatmann | Osnabrueck University

science

Research goals and why the work was worth doing – The growing emergence of online-based financial self-service platforms provides new access to investment opportunities for individual investors (Chaudhry & Kulkarni, 2021; Graham & Henman, 2019). Simultaneously, these platforms offer a new approach to strengthen funding for sustainable projects and organizations (Horn et al., 2020). However, individual investors are subject to behavioral biases (Sahi et al., 2013) often prohibiting effective translation of sustainable preferences into congruent behavior (Alemanni, 2022). Hence, the choice architecture available to the individual plays an important role in the decision-making process (Pilaj, 2017). Organizations and platform designers should pay close attention to include supportive mechanisms for guiding individuals towards preference fulfillment. For identifying potential support mechanisms an integrative literature review is conducted aiming to provide an overview of existing digital nudging mechanisms and their potential to support individual decision making.

Theoretical background – Decision making in online contexts is significantly dependent on informational and physical design aspects and affected by implicit cognitive and emotional processes (Michalek et al., 2015). Hence, the choice architecture available to the individual and associated biases substantially affect the decision-making process (Kahneman, 2012, Smith & DeCoster, 2000). Nudging can change the way in which choice relevant information is presented to individuals (Thaler & Sunstein, 2008). By altering interface design elements via digital nudges decision making can be subtly guided towards individual preference fulfillment (Weinmann et al., 2015).

Design/Methodology/Approach/Intervention – The integrative literature review was conducted based on 643 sources of which 82 were considered for an in-depth analysis of digital nudges in online decision-making contexts which were systemized based on outcome and type of behavior change (Oinas-Kukkonen, 2013).

Results obtained – The resulting conceptual framework consists of 42 digital nudges in 15 online decision-making contexts. The digital nudges differ in terms of their goals regarding the outcome (act of compliance, behavior change, attitude change) and type of behavior change (forming, altering, reinforcing).

Limitations – Besides typical limitations arising from the methodological approach of the review, the study specifically focused on digital nudges in online decision-making contexts. This focus limits the amount of nudges which could have been identified by including broader nudging research from other contexts .

Research/Practical Implications – This study contributes to research on the effect of choice architecture and interface design on the ability to promote sustainable decision making in line with individual preferences. For practice this review provides a systematic overview of digital nudges and their potential to aid specific types of behavior change.

Relevance to the Congress Theme – The study relates to the changing world of work in investigating the impact of different forms of online presentation on sustainable decision-making which can be particularly valuable in the area of public relations and influencing skills.

Relevant UN SDGs – The study investigates digital nudges as a means to support sustainable consumption and production patterns via individual investment, thus promoting sustainable economic growth.

Keywords: Sustainability; Digital Nudge

Towards an integrative approach to work-life flow and wellbeing: a systematic review of stable and dynamic influencing factors

Rita Berger & Jan Philipp Czakert | Universitat de Barcelona; John Wells & Florian Scheibein | South East Technological University; Nuno Rebelo dos Santos, University of Evora; Paolo Nogueira Ramos, University of Coimbra

science

Research goals and why the work was worth doing : Work-life balance and flow (WLF) is important for wellbeing (WB) at work. The COVID-19 pandemic created new hybrid working conditions impacting on employees' WLF and WB. As hybrid work in ongoing post pandemic times is further present, its impact on the work-nonwork Interaction (WNWI) and WB remains important. There is nearly no research on a comparison between pre- and pandemic research on this field but a need. The research goal is collect, analyze and compare information on pre- and pandemic research.

Theoretical background: This review builds a theoretical framework, with two organisational behavior theories: Human System Audit and IGLO Model, and four theories explaining WNWI: Job Demand-Resource Model, Role Theory, Work-Family Spill Over and Boundary Theory. It compiles the literature search, coding scheme, inclusion criteria, and data extraction, with the subsequent quality of evidence, including the high and moderate results. We classify protective resources and risk factors/stressors from work from home (WFH) in a VUCA environment at all organizational levels that contribute to employee WB and WLF.

Method: Article compilation was done by two independent researchers based on PRISMA (Bossuyt et al., 2020) using the following databases: CINAHL Complete, MEDLINE, APA PsycInfo, APA PsycArticles and keywords: work-life* OR work-9 nonwork* OR work-home* OR work-family AND flow* OR balance* OR conflict OR enrichment OR enhancement OR depletion AND remote work or virtual work or telework or WFH or telecommuting or virtual office or remote employees. The first level of inclusion criteria was: articles published between 2020-2021, peer-reviewed, full text available, written in English. A total of 113 articles were screened in this first level. At a second level of inclusion criteria a coding scheme was introduced. Once all articles were classified, those who had assigned the numbers 1, 2 and 3 were revised. 27 articles were included. A measure of internal reliability of the process of literature search was computed using Fleiss' Kappa. Data extraction criteria noted author, year, methods used, variables studied, results and limitations of each article. Methodological parameters concerned target group, sample size, location of work and study design. Variables studied concerned the theory framework, resources, stressors, and the perspective regarding WNWI, classified as balanced, negative, or positive (Beigi et al. 2019). Lastly, the impact on positive and negative WB was included. After data extraction, a quality appraisal was made using Grade Approach.

Results: Dominant topic is the approach to WFH as a tool for positive WLF and helping to improve WB, autonomy, flexibility a frequently found resource helping to reconcile work and nonwork responsibilities. The integration of roles arises stressors, resulting in a negative impact on WNWI. Pandemic studies faced the issue of the abnormality of events raising concerns about the extrapolation of results.

Limitation : Our systematic review does not include more years of pre-pandemic research.

Conclusions : We contribute with important information on working conditions and their impact on pre- and pandemic WFL. Main limitation of reviewed articles is the subjectiveness of measures as data was self-reported and based on perception rather than actual behaviors. Future research is required on psychosocial processes (leader, group level) relevant to WB.

Keywords: Work-life flow, COVID working conditions, Systematic Review

Poster P132

How parents' subjective economic situation affects their environmental uncertainty perceptions across Slovakia, Germany and Great Britain

Jaroslava Babjáková, University of Presov, Faculty of Arts, Institute of Psychology; Kathleen Otto, Philipps-Universität Marburg, Faculty of Psychology, Work and Organizational Psychology; Peter Babinčák, University of Presov, Faculty of Arts, Institute of Psychology; Emily Kleszewski, Philipps-Universität Marburg, Faculty of Psychology, Work and Organizational Psychology; Christina Pranjic, Philipps-Universität Marburg, Faculty of Psychology, Work and Organizational Psychology; Andre Baumann, Philipps-Universität Marburg, Faculty of Psychology, Work and Organizational Psychology

science

The study aimed to verify how parents´ subjective economic situation, and objective demographic variables (gender, country, number of children, employment status) contributed to their enviromental uncertainty perceptions, namely job insecurity, fear of Covid-19 and parents´ subjective assumptions of childrens´ quality of life across Slovakia, Germany and Great Britain. The mental health of parents during Covid-19 were studied in many countries among those in Slovakia (Vargová et al., 2022), Germany (Christner et al., 2021) and the United Kingdom (Cheng et al., 2021). Many children and parents experienced lockdown-related stress during the Covid-19 pandemic (Christner et al., 2021), and working parents, in particular, had worse mental health and experienced financial insecurity (Cheng et al., 2021). The caring of parents for their children because of Covid-19 and their own difficulties doing or keeping their job (job loss) went sometimes along with a lower income (Anant & Gassman-Pines, 2020).

Data of parents aged at least 18 with at least one child aged from 4 to 24, for which the parents are financially responsible were collected online from August to October 2022. The final sample consisted of 499 parents (353 women, 146 men). Job insecurity scale (De Witte, 2000) contained four items (Cronbach's alpha = .859). The fear of Covid-19 and parents´ subjective assumptions of quality of life of children were measured each with one question. We conducted multiple hierarchical linear regression analyses separately for each dependent variable (job insecurity, fear of Covid-19 and quality of life of children) in SPSS 23.0. Independent variables were divided into two blocks and dummy-coded: in Step 1, gender (men, women), country (Slovakia, Germany, Great Britain), the number of children (one, two, three and more), and employment status (part-time, full-time, other) were entered, then in Step 2, the subjective economic situation (without difficulties, some difficulties, difficult/very difficult) was introduced. At first, we found stronger job insecurity in parents living in Slovakia and lower job insecurity was experienced by those evaluating their economic situation as without difficulties or with only some difficulties. Secondly, parents with part-time jobs experienced greater fear of Covid-19. Finally, fathers, parents living in Slovakia and those without economic difficulties subjective evaluated their children's quality of life to be better. In contrast, parents with difficult/very difficult economic situations subjective evaluated their children's quality of life as worse.

Our study clearly demonstrates the significant role of the subjective economic situation in terms of job insecurity and the parents´ subjective evaluation of their children' life. The employment status was only significant in fear of Covid-19 whereas gender was important in terms of the parents´ subjective evaluation of the quality of life of children.

The lower number of fathers in our research sample as well as the sole use of self-reported data might be seen as limitations. Overall, our findings contribute to clarifying antecedents of job

insecurity, fear of Covid-19 and evaluation of children's quality of life of employed parents. Poverty might be a serious threat to parents and families modifying perceptions of one‘s present environmental conditions and future options.

This study was supported by APVV-20-0319 and VEGA 1/0719/20.

Keywords: job insecurity, fear of Covid-19, subjective assumptions of employed parents of children´s quality of life

Poster P133

"I like you, AI, but I don't want to work with you!" - A closer examination of the effect of AI-assisted feedback on work engagement

Regina Rockinger, Matthias Hudecek & Peter Fischer | Department of Experimental Psychology, University of Regensburg

science

Research goals Artificial intelligence (AI) is an increasingly important topic in organisational context. 64% of more than 8000 respondents prefer a robot over their own supervisor, according to a study by Oracle (2019). These results stress the emerging importance of technologies like AI in the workplace, specifically in leadership positions. Thus, the goal of our study is to examine the underlying psychological mechanisms that contribute to the cooperation of employees with an AI in a managerial role.

Theoretical background In 2022 we aimed to further examine the perception and acceptance of artificial intelligence in an organisational context. Our experimental design focused on assessing the effect of feedback given by either an AI versus a human manager on employees´ work engagement. Our research group found that feedback from human managers leads to a higher work engagement than the same feedback from an AI. This poster takes a closer look at possible mechanisms related to this effect. Specifically, the focus is on whether the subjects´ attitudes towards AI, affinity for technology and previous experiences with AI and human managers moderate the relationship between the source of feedback (AI vs. human manager) and work engagement.

Design In a 2x2 online-based study, participants (n=357) were asked to imagine a work-related scenario, in which they had held the leading position of an important project in their company. After its completion, the participants were now to receive feedback on their performance, which was presented to them randomly varied in source (AI vs. human manager) of feedback. Afterwards, individual work engagement was assessed as a dependent variable. Furthermore, the aforementioned moderator variables were surveyed.

Results A moderation analysis was conducted to determine whether the interaction between the moderator variables and the independent variable source of feedback significantly predicts work engagement. Results show that the effect between source of feedback and work engagement was not significantly moderated by affinity for technology ($p = .512$), attitude towards AI ($p = .815$), previous experiences with AI ($p = .761$) or previous experiences with human managers ($p = .577$).

Limitations As our study was based on an imagination-based scenario, the results might lack external validity. A replication in real-life organisational context could be beneficial to verify the results.

Conclusion As shown in our study, receiving feedback from a human manager leads to more work engagement than receiving the exact same feedback from an AI. Subjects´ high affinity for technology, positive attitude towards AI, positive experiences with AI or negative experiences with human managers did not mediate this effect. This indicates that even subjects that had a more positive opinion on AI technology did not benefit from AI feedback in terms of their work engagement. Thus, it might be beneficial to rely on human feedback rather than AI technology due to its detrimental effect on work engagement.

Relevance to theme “The changing world of work” is going to involve various advanced technologies, such as AI. Even though many participants of the Oracle study (2019) would rather work with “robots” than human supervisors, AI is not always superior to traditional leadership.

Keywords: artificial intelligence, employee communications, human-machine systems

Poster P136

Be mindful=be able to handle critical incidents: A mixed-method study among Italian air traffic controllers

Valentina Sommovigo, Sapienza, University of Rome, Department of Psychology; Ilaria Setti, University of Pavia, Department of Brain and Behavioural Sciences; Deirdre O'Shea, Kemmy Business School, University of Limerick; Chiara Bernuzzi, University of Pavia, Department of Brain and Behavioural Sciences, Department of Law

science&practice

Research goals. Air traffic controllers (ATCOs) are among the most high-risk groups for critical incidents (CIs). Facing such incidents may hinder professional activity, undermine affected individuals' well-being and cause company financial losses. Shedding light on how and when ATCOs feel capable of managing CIs is crucial to formulate preventive measures that help companies reduce future incidents. This study aims to examine the mediating processes – i.e., problem-focused coping tendencies – and boundary conditions – i.e., previous experience with CIs and training on CI management – associated with the impact of mindfulness on self-efficacy in managing CIs.

Theoretical background. Mindfulness – the intentional and non-judgmental attention to present events (Brown et al., 2007) – is a personal resource for ATCOs (Kearney et al., 2016) as it enables them to make timely decisions (Li et al., 2018), be aware of and attentive to ICs (Li et al., 2014) to find solutions to address them (Liang et al., 2022). Although the link between mindfulness practices and self-efficacy has been proven (Charoensukmongkol, 2013), little is known about the factors enhancing self-efficacy in managing CIs among ATCOs. Based on the social cognitive theory (Bandura, 1989), prior experience with ICs and training in CI management are mastery experiences that can foster self-efficacy.

Design. A total of 168 Italian ATCOs completed questionnaires that measured mindfulness, self-efficacy in assessing and deciding about critical incidents, problem-focused coping tendencies, prior experience with CIs, training on CI management, and COVID-19-related experience variables. Descriptive statistics and moderated mediation analyses were performed. To deepen the quantitative results, ten semi-structured interviews were conducted and analysed using thematic analysis.

Results. High-mindful ATCOs were more problem-oriented and then self-confident about their ability to manage CIs, especially when they had prior experience with CIs and received training on CI management. Three core themes were identified from the interviews: decision-making as a core job aspect; environmental facilitators (training, social support); personal resources (prior experience, coping strategies, situational awareness).

Limitations. This cross-sectional study merely relied on self-report measurements.

Research/practical implications. This study moves a step forward in both the air traffic management and mindfulness literature, as it is the first to clarify how and when mindfulness can promote self-efficacy in managing CIs in the understudied population of ATCOs during the pandemic. ATCOs could benefit from on-the-spot mindfulness interventions, CI management, and problem-focused coping strategies training. Mentoring and sharing sessions could also help less experienced aviation personnel build skills.

Relevance to the Congress Theme. This study sheds new light on the personal and environmental factors that promote ATCOs' beliefs in their ability to manage ICs. This has implications for ATCOs' and air passengers' well-being and security.

Relevant UN SDGs . Good health and well-being.

Keywords: Air traffic controller, mindfulness, critical incident management

Poster P138

Untying attachment and commitment relationships in dual study programmes – A longitudinal investigation

Jutta Bloem, Anna Engel & Tammo Straatmann | Osnabrück University, Osnabrück, Germany

science&practice

Research goals: Developing strong commitment ties with dual students is of great interest to cooperating companies, as commitment is associated with lower turnover intentions and lower actual turnover (e.g., Meyer et al., 2002). However, dual students are newcomers in their cooperating companies and research has shown that commitment of newcomers is quite easily lost (e.g., Vandenberg & Self, 1993; Maia, Bastos & Solinger, 2016). We suggest that an attachment perspective building on the „propensity of human beings to make strong affectional bonds" (Bowlby, 1977, p. 201) can offer a conceptual lens to better understand the formation of commitment over time. Following calls for greater emphasis on individual factors, multi-target-approaches, and longitudinal designs for a deeper understanding of commitment (e.g., van Rossenberg, Cross & Swart, 2022), the study aims to examine the relationship of attachment and commitment of dual students in their first year of study and employment.

Theoretical background: A growing body of research has taken the route of applying an attachment perspective in the organisational context and analysing attachment avoidance and anxiety as antecedents of commitment (e.g., St. Clair, 2010; Yip et al., 2018; Feeney et al., 2020). Therefore, this study builds on the attachment theory of Bowlby (1969) and on Meyer and Allen's (1991) 3-component model of commitment. Employing a multi-target-approach (e.g., Reichers, 1985), both the cooperating company and the in-company trainer are important targets for dual students' attachment and commitment. We assume that relationship-specific attachment to these targets will affect the commitment of dual students. More specifically, we will distinguish how both central attachment dimensions (Bartholomew, 1990), namely attachment avoidance (model of the target) and attachment anxiety (model of the self) will have an influence on how dual students experience commitment.

Design and methodology: A three-wave panel design was used to collect data from dual students in their first year of study and employment. We employed the Organisational Attachment Scale (Engel & Straatmann, 2017) for measuring organisational attachment, a short version of the Experience in Close Relationships Scale (Brennan, Clark & Shaver; 1998) to capture in-company trainer attachment, and the COMMIT Scale (Felfe & Franke, 2012) to assess commitment.

Results: The results will be presented at the conference.

Limitations: Despite careful measures, the reliance on self-report data holds the potential of common-method variance.

Research and practical implication: The results are expected to advance our understanding of the interrelationship of attachment and commitment by clarifying the ambiguity about changes in commitment over time and the direction of influence between attachment and commitment. Further, the results may enhance dual study training practice by providing insights to develop initiatives for increasing the commitment of newcomers.

Relevance to the congress theme: The results are likely to lift the curtain on how cooperating companies and in-company trainers can better respond to the attachment needs of dual students to support the formation of beneficial relationships in a changing world of work.

Keywords: Commitment, attachment theory, dual study programmes

Poster P139

Predictors and outcomes of Decent Work among non-European migrants

Maha Yomn Sbaa, University of Bologna

science&practice

Over the last decade, an increasing number of migrants has been arriving in Europe looking for better opportunities (Migration Governance Indicators Profile, 2020). However, they tend to work in low or unskilled jobs that are insecure (EUROSTAT, 2018; Piper et al., 2017) with unfair pay and undesirable work hours (Binggeli et al., 2013; de Castro et al., 2006; Marfleet & Blustein, 2011). For this reason, this research project aims to investigate the Decent Work (DW) experiences of non-European migrant workers. Based on the International Labor Organization's standards, Duffy et al.(2016) developed the Psychology of Working Theory which focuses on the experiences of people who are marginalized in the workplace. The theory highlights the importance of considering the broader social, economic, and political contexts in which people work, as well as the individual's own psychological experiences and development. For this reason, migrant workers are an important and relevant population in this framework due to their vulnerable status in society. Three studies are outlined to achieve the research goals. First, a qualitative study in Italy will investigate migrant workers' experiences from different stakeholders' perspectives through semi-structured interviews with migrant workers (individual level), employers (organisational level), and experts (national level). Second, a comparative study will explore the DW experiences of migrant workers in two European national contexts (Italy and Germany) through an online survey which will be disseminated in both countries. This study will include specific demographic variables that are related to the migrant group population (e.g., residency status), as well as work-related variables such as DW Questionnaire (Ferraro et al., 2018), Organizational Justice Perceptions (Moliner, 2004), Employee Performance (Koopmans et al., 2014) and Employee wellbeing (Bartels et al., 2019). Finally, a quantitative longitudinal study (3 waves) will be conducted in Italy through a questionnaire to investigate differences in the predictors and outcomes of decent work between migrant and Italian workers operating in the same company. Variables included in this study will be further specified, and studied in depth, in a later stage, following the results of the interviews conducted in study 1. The qualitative study results may be available in June 2023 (study 1), and the comparative survey's results (study 2) in May 2023. The longitudinal study in a company will be conducted next year. One limitation of the research project is that Study 2 uses a cross-sectional design that does not perfectly fit the PWT model. However, the project has several implications: Study 1 will offer important insights for employers and Civil Society Organizations in the region to improve DW conditions for migrant workers. The cross-country comparison of decent work in Italy and Germany (Study 2) highlights the importance of contextual factors (e.g., national legislation). Finally, Study 3 situates migrant workers' perceptions of DW with respect to their Italian (local) coworkers. This will reveal any potential disparities between both groups and call for organizational interventions to reduce such inequality. Migrant workers are often underrepresented in the WOP scholarship and research. This project answers the urgency aspect of the congress: "The future is now!" by addressing the SDG on Decent work and economic growth for all- migrants included.

Not too few, not too many – A validation of the situational judgment test measuring five key leadership competencies

Antun Palanović, Mitja Ružojčić, Nikola Erceg, Zvonimir Galić & Maja Parmač Kovačić | University of Zagreb

science&practice

Research goals and why the work was worth doing

Situational judgment tests (SJTs) can be a useful tool for selection and development of leaders. However, most traditional leadership SJTs have questionable construct validity. At the same time, newer, construct-driven SJTs might not be as appealing to practitioners and candidates as they can be long and assess a large number of overlapping dimensions. The goal of our research was to design a leadership SJT that would be both construct based and appealing to HR practitioners and leaders.

Theoretical background

Based on critical incidents methodology, literature review and interviews with managers, and guided by the "not too few, not too many" principle we identified five key leadership competencies that appeared across all sources: motivating subordinates (MS), developing subordinates (DS), teamwork management (TM), relationship management (RM) and decision-making (DM).

Next, we developed a construct-driven SJT to measure the procedural knowledge (Motowidlo et al., 2006) related to these competencies. The content of our item responses draws on three well-known psychological constructs that conceptually align with the five competencies – transformational leadership (MS and DS), political skill (RM and TM) and actively open-minded thinking (DM). Each competency was assessed with four situations each having three response alternatives that reflected different levels of a specific competency.

Design/Methodology/Approach/Intervention

To validate the SJT, we conducted an online survey of 197 supervisors (46.5% female) with the average of 9.25 years of supervising experience (SD = 6.83). The participants completed the SJT and self-reports of declarative knowledge related to the five competencies, transformational leadership, political skill, actively open-minded thinking and the Big 5. We also obtained data from their subordinates (on average, 3 subordinates per supervisor) who rated their supervisor's transformational leadership and work performance and completed self-reports of burnout, psychological safety and perceived organizational support.

Results obtained

Monotrait-heteromethod correlations between supervisors' SJT scores and declarative knowledge of the five competencies showed partial support for the convergent validity of the SJT-MS, SJT-TM and SJT-DM. When it comes to related constructs, only SJT-DM had a significant correlation with actively open-minded thinking. SJT-MS was the only dimension that predicted higher subordinate ratings of supervisors' transformational leadership and work performance as well as their psychological safety after controlling for supervisors' self-reported transformational leadership, political skill and personality.

Limitations

Internal consistencies of SJT dimensions were below the acceptable level.

Conclusions – research and or practical implications/Originality/Value

Our SJT aims to walk a fine line between the traditional and purely construct-based SJTs. The validation results are promising when it comes to dimensions of motivating subordinates and decision-making, but warrant further refinement of the test.

Relevance to the Congress Theme

Good bosses are leaders - they motivate employees, help them develop their talents and make important decisions. These leadership competencies, as well as their assessment will only become more important in the future dynamic work environment.

Applicant reactions to selection methods in Romania: Fairness of the artificial intelligence-based interviews compared to other selection methods

Claudia Lenuța Rus & Sabina Ramona Trif | Department of Psychology and Work and Organizational Psychology Research Center, Babeș-Bolyai University, Cluj-Napoca, Romania

science

The rapid adoption of artificial intelligence in organizational staffing practices amplifies the importance of applicant reactions, in general, and reactions to artificial intelligence-based assessments and interviews, in particular. In this context, our study compared artificial intelligence-based interviews (AI-based interviews) to other 21 selection methods (e.g., traditional interviews, curriculum vitae, work samples, general mental ability tests, online information, and others) in terms of process favorability and procedural fairness.

Although literature comprises numerous empirical and theoretical works on applicant perspectives and reactions, our study concentrates upon a relatively newer digital selection procedure for organizational staffing, and extends the knowledge about applicant reactions to digital interviews and AI-based interviews. Our study can contribute to a more fine-grained understanding of the generalizability and situational specificity in applicant reactions to selection methods, mainly in Eastern Europe. In addition, this study can inform the improvement of the AI-based interviews use as an assessment tool in selection.

This study builds on the large body of applicant reactions, in general, and on Steiner and Gilliland's (1996) selection fairness theoretical framework and research, in particular. In this framework, process favorability refers to how fairly people think they have been treated using a particular assessment method, while procedural justice includes the following seven dimensions: face validity, scientific evidence, opportunity to perform, interpersonal treatment, propriety of questions, invasion of privacy, and widespread use of the assessment method. These dimensions are believed to form the basis for fairness perceptions.

Our sample comprised 427 undergraduates enrolled in a semester course on work and personnel psychology. Thereof, 22.01% were also employees. Data was collected online with an adapted version of Phillips and Gully's (2002) questionnaire.

We expect that AI-based interview will have a significantly lower process favorability compared to most of the selection methods (e.g., interview, situational judgment tests). It will be more favorable only than graphology and ethnicity and similar to personal contacts and unproctored Internet testing. On all seven procedural justice dimensions, AI-based interviews will be a significantly less fair method than most of the selection methods examined.

As limitations, we did not differentiate between types of AI-based interviews (with and without a human-like avatar). Not all the participants were human resource professionals or employees. Data collected were cross-sectional.

This study extends the relatively small and inconsistent body of knowledge on applicant reactions to AI-based interviews using a well-established methodology to investigate applicant reactions that permits us to maximize the comparisons between our findings and those of the previous studies. Our findings signal that organizations should pay attention to how to use AI-based interviews in selection processes and manage applicant reactions.

Our study investigated the fairness of a relatively new selection method that transformed the landscape of today's personnel selection. As AI-based interviews might threaten the fairness of personnel selection, this topic is relevant for the future of work, in particular, for staffing sustainable organizations.

Keywords: process favorability, procedural justice, artificial intelligence-based interviews

Psychological Capital and Creativity in the Workplace: Gaming habits as an antecedent

Maxence Mercier, Todd Lubart | Université Paris-Cité

science

Research goals

Video games play a big part in many people's lives, and adults are not exempt. This begs the question of the potential effects of playing video games. Here, we examine whether playing more video games leads to higher Psychological Capital (PsyCap) and higher creativity in the workplace.

Theoretical background

PsyCap can be defined as a higher-order construct consisting of four positive psychological resources: hope, efficacy, resilience and optimism. Creativity corresponds to the ability to achieve a production that is both original and adapted to the context in which it occurs. Creativity can be applied to various domains and settings, the workplace being of particular importance.

PsyCap is a strong predictor of creativity in the workplace, as all components have been linked to it. For instance, creative endeavors are difficult and often lead to failures or setbacks. Resilient individuals are likely better equipped to pursue creative goals. Optimism also helps in that way, as optimistic individuals are less likely to give up and more likely to persevere through adversity.

Playing video games requires, as well, a certain mindset, as encountering adversity is a core aspect of the game experience. In games, people are often faced with difficulty and loss, and it can be tempting to just give up. Being optimistic is helpful in this sort of situation, as optimism helps see negative events as temporary and thus surmountable. Hope and resilience are also highly required to play and go through many video games.

Video games have also been linked to creativity, in many populations and ages, although no study has examined creativity in the workplace specifically.

We hypothesized that playing more video games would lead to higher PsyCap and higher creativity in the workplace. Furthermore, we hypothesized that the relationship between video games habits and creativity in the workplace would be mediated by PsyCap.

Design/Methodology

Using a questionnaire-based online study (N = 370), we measured whether participants played video games, the amount of time players dedicated to video games, PsyCap, and Creativity in the Workplace. PsyCap was measured using the French version of the PCQ, and Creativity in the Workplace was measured with a 13-item self-report scale.

Results

Video game frequency of play correlated positively with three components of PsyCap: efficacy, resiliency, and optimism; it correlated with overall PsyCap as well. Furthermore, creativity correlated positively with gaming frequency, albeit to a lower degree. PsyCap correlated with creativity, as expected. After performing a mediation analysis, our results indicated a full mediation of the effects of gaming frequency on creativity, through overall PsyCap.

Limitations

The main limitation concerns the use of self-report measures for creativity, which can be debated. We argue their use was justified in this study, as they can yield satisfactory and valid results. Future studies could implement creativity rating by superiors or colleagues, or more objective measures such as divergent and convergent thinking tasks.

Conclusions & Relevance to the Congress Theme

This study furthers the idea that video games have positive effects, and is among the first to link video game habits with PsyCap and creativity in the workplace. These results suggest that video games could prove to be an interesting and effective avenue to help develop creativity in the workplace, possibly through PsyCap improvement.

Keywords: video games, creativity in the workplace, psychological capital

How much psychology can you find in cybersecurity research? A scientometric analysis of the field

Nida ul Habib Bajwa, Cornelius J. König & Stefan Kenst | Universität des Saarlandes

science

Research Goals:

Many organizations have reported cyber-attacks, particularly by fraudster and scammers who try to breach organizational security mechanisms to extort money. There has been an increase in research in the last years that tries to better understand end-users' cybersecurity perceptions and their use of cyber-safe systems. Whilst it seems obvious that the involvement of experts of human behavior (i.e., psychologists), is key to research that tries to understand human behavior, many studies in the field of cybersecurity seem to be conducted by computer scientists only who borrow psychological methods and theories. More recently, some psychology researchers have been drawn to this research field, but there is no systematic understanding of the characteristics of psychologists interested in this work and of the ways how psychological models and theories inform the field of cybersecurity. Therefore, this study takes a data-driven approach of systematically exploring the role of psychologists in cybersecurity through conducting a scientometric analysis over 200.000 papers.

Theoretical background:

Whilst in the past organizations focused on primarily trying to protect themselves from cyber-attacks by improving their technological solutions, it has become increasingly evident that such a perspective has its limitations, as systems are only as safe as their users. Therefore, organizations and researchers alike have understood that mitigating cyber-risks necessitates to involve focusing on human behaviors when using digital systems. For human-centered cybersecurity research questions psychological theories (e.g., theory of planned behavior) are increasingly being used and are likely to help to work towards a better understanding of human behavior. Nevertheless, there is need for a more systematic understanding of how psychology and cybersecurity are linked.

Methodology:

We conduct a scientometric analysis, using a dataset of more than 200.000 journal and conference articles related to cybersecurity. Abstracts of these articles are scanned using psychological keywords to identify psychological topics, theories and methods. Furthermore, we analyze authors' affiliations and augment the data by looking up CVs of authors in order to assess whether the number of psychologists in this research field as well as their characteristics.

Results obtained:

A comparatively low amount of research articles were found to be specifically related to human security aspects in cybersecurity. Psychologists represent a tiny fraction of researchers who publish in most of the high impact cybersecurity journals and conferences. Furthermore, the field seems to be dominated by WEIRD populations (White, Educated, Industrialized, Rich, and Democratic), creating a challenge for the generalizability of findings.

Limitations:

We focus on high impact journals and conferences solely.

Research/Practical implications:

There is a need for more psychologists engaging in human factors related cybersecurity research.

Relevance to the Congress Theme

Cybersecurity is a key challenge of the 21 st century and has a strong impact on the future of digital work.

Keywords: cybersecurity, IT security, human security

Poster P146

What does transformation look like at a Group Relations Conferences: A South African case study

Louise Tonelli, University of South Africa; Michelle S May, University of South Africa

Research goals and why the work was worth doing

Transformational Group Relations Conferences provide adult learners opportunities to study above and below the surface dynamics of organisational and community life. An effective pedagogy in developing complex world views when exploring challenges of managing different social systems. The literature suggested there is a hatred of learning by experience and lack of faith in such learning. What prompted this research was to study experiential learning and transformation at GRC.

Theoretical Background

Systems Psychodynamics (SP) integrates social, cultural, and historical factors at a conscious level, yielding information about unconscious motivations and defences (van Eeden, 2010), revealing the function of dysfunction (Petriglieri & Petriglieri, 2015). The focus is on the interplay between psychological and social forces that shape organisations and the experiences of people within them, taking phantasies seriously as products of unconscious wishes which open the possibility of an alternative to conformity and resistance (Petriglieri, 2020).

Design/Methodology/Approach/Intervention

Hermeneutic Phenomenology allowed for emerging qualitative approach applied within an interpretive framework, in the meta theoretical post-positivistic paradigm of Critical Realism. A non-probability sampling strategy enabled a multi-method research strategy of face-to-face interviews and a focus group (Interactive Qualitative Analysis). To analyse the data, the Braun and Clarke six-step thematic analysis method and IQA were applied.

Results obtained

A hidden story of working at the edge of knowing and not knowing emerged, where a multitude of defences against learning by experience informed how much awareness and attention participants paid to truth/reality in the here and now. In defence against knowing there was a wish from some for the container to break so it could be escaped from. For others, the defence against knowing manifested in experiencing adulation and narcissistic omnipotence of the self (de Goldstein, 2015) in a safe container. Yet some risked working uncontained in a good enough container trusting the container to hold experiences allowing for choice to transform or to transmogrify.

Dynamics manifested as above the surface dynamics when some participants allowed themselves to not feel excessively contained, experience some loss and not defending against thought and development. Participants transformed in a known, discernible, and planned way. Participants who worked with the unknown and complexity, tolerated feeling uncontained, risked annihilation seemed to transmogrify.

Limitations

The concept of transmogrification in the social sciences is extremely limited. The use of this model requires Industrial and Organisational psychologists, psychologists, and consultants to understand the below the surface unconscious dynamics of groups. Further research is required to test whether it can be operationalised.

Research/Practical implications

A new concept of preservation, transformation and transmogrification was conceptualised to extend the body of knowledge of what transformation may look like at GRC. The conceptual model of transmogrification is new in Psychology, Industrial and Organisational Psychology and Group Relations Conferences, which can used to work with psychodynamic material. The model can be used as a coaching and consultation framework for leaders to learn about dynamics in organisations.

Keywords: Group Dynamics, Transformation, Systems Psychodynamics

A qualitative investigation of teleworking during Covid-19 times through the lenses of supervisors and subordinates

Lucia Ratiu, Daniel Metz, Tudor Irimias, Sabina Trif & Loredana Mihalca | Babes-Bolyai University

science

The Covid-19 pandemic brought difficulties, uncertainty, and worries, challenging the working life of both supervisors and employees in organizations. Following the preventative measures imposed by governments, employees at all levels had to rapidly cope with teleworking in order to ensure the activity in companies. Despite the growing use of telework, an effort to understand the phenomenon from different perspectives – supervisors and employees - is welcome. Using a social constructivist approach, this study investigates how employees at different hierarchical levels experienced challenges associated with teleworking during the Covid-19 context. How did the changes shape the virtual work characteristics and what are the mechanisms underlying the performance during telework?

A sample of sixty-two employees in an IT company was included in this study. The participants were almost evenly distributed into three categories: supervisors, full teleworkers, and partial teleworkers. Semi-structured interviews were conducted to reach an in-depth understanding of work-related changes of the participants during the first months of the Covid-19 pandemic. Transcribed data were analyzed using thematic analysis and content analysis following both inductive and deductive approaches. Two independent coders analyzed the data and the values of interrater reliability met the cutoff criteria. The findings revealed that employees reported changes during the Covid-19 pandemic in terms of communication (i. e. quality, frequency) with other employees and clients, social isolation, individual differences regarding telework, work conditions, social support, informal learning, work productivity, coping with telework, self-management skills, and job characteristics. Overall, the endeavor to maintain the level of productivity was mentioned by all participants. Furthermore, participants showed concern regarding their professional development (i.e. mentoring, formal learning) which had to be reconsidered. Social isolation, lack of provocative tasks, and voluntary overtime emerged as negative aspects of telework. In addition, the lack of technical equipment or task interdependence impaired the performance while teleworking. Despite the difficulties reported by the participants, the remote support provided by the organization buffered the impact of the pandemic context on the work outcomes.

At the supervisors' level where work pressure is usually higher, telework has been experienced significantly differently on a few dimensions. Supervisors' expectations regarding telework and adaptation to telework were seen as more important by the supervisors than the employees. However, unlike the employees, supervisors referred less to tasks suitable for office work, social isolation, task-focused communication, delay in problem-solving, and monotonous tasks.

By providing in-depth views into how supervisors and employees experienced teleworking during the Covid-19 pandemic, the results offer avenues for further research on the factors influencing not only

performance but the quality of working life while teleworking. With regard to practical implications, the study guides the implementation of flexible working arrangements in the future.

Keywords: teleworking, Covid-19, work conditions

Poster P156

Mindfulness and Psychological Capital to Reduce Workers' Stress and Enhance Health and Well-being

Israel Sánchez-Cardona, Edwin Trejo Rivera & Tyler Collette |Kennesaw State University; Camille Vélez Álamo, Grupo Nexos; Eric A. Rivera-Colón, University of Puerto Rico; Lili Sardiñas, Grupo Nexos

science&practice

This study aims to test the combined effect of mindfulness and psychological capital (PsyCap) on reducing stress, burnout, and improved perception of health (psychological and physical). While developing PsyCap has shown effectiveness for workers, some evidence suggests that its effect on positive health and well-being outcomes may be stronger if PsyCap is combined with self-regulatory resource strategies, such as mindfulness (Roche & Haar, 2019). Based on the JD-R model assumption of personal resources as a key aspect to preventing stress and promoting health through the mobilization of resources (Bakker & DeVries, 2021), and drawing on the COR theory elements of "resources caravans," we consider mindfulness a condition for resources sustenance, buffers the relationship between PsyCap and stress and burnout, and enhances the effect on the perceptions of health. Mindfulness equips individuals with a healthy cognitive process and emotional regulatory strategies that allow individuals to remain resilient (Tomlinson et al., 2018). Therefore, we argue that mindfulness is a key resource to understanding the effect of PsyCap in reducing negative health outcomes and improving positive health outcomes. We hypothesized that individuals with higher levels of PsyCap and mindfulness would show reduced stress and burnout and improved perception of health.

To test our hypothesis, we used a sample of 398 workers (94.5% females; (M age = 44.29, SD = 11.07) from a public organization in Puerto Rico dedicated to providing services to families and their children as part of an occupational health assessment with an online survey (61% response rate). The questionnaire was available for four consecutive weeks; participants received an incentive of a $30 gift card to complete the survey. We performed a series of moderated regression analyses using PROCESS with SPSS to test our hypothesis.

Results indicate that mindfulness was related to stress (b =-.587, p <.001) and burnout (b =-.539, p <.001), but not PsyCap (stress: b =-.132, p =.074; burnout: b =-.063, p =.353). The interaction effect of mindfulness and PsyCap on stress (b =-.259, p =.016) and burnout (b =-.184, p =.013) was significant, indicating that a high level of mindfulness and PsyCap reduces burnout and stress. Mindfulness and PsyCap were positively related to physical (Mindfulness: b =.634, p <.001; PsyCap: b =.345, p =.001) and psychological health perceptions (Mindfulness: b =.087, p <.001; PsyCap: b =.202, p =.031). The interaction effect was also significant for psychological health (b =.231, p =.003), but not for physical health (b =.154, p =.05).

These results suggest that mindfulness provides the necessary condition that fosters mobilization of other personal resources (i.e., PsyCap) during stressful situations, instigating actions toward greater well-being. In addition, the study highlights the multiplicative effect of personal resources on stress and health. Future intervention strategies should consider combining various personal resources to increase their effectiveness in reducing stress and promoting well-being. The study was conducted in one organization with mostly females, thereby limiting our ability to speculate on the interactions of mindfulness and PsyCap in male workers.

This project aligns with the sustainable development goal of ensuring healthy lives and promoting well-being by identifying mechanisms that promote psychological and physical health.

Keywords: psychological capital, mindfulness, interaction effect

Poster P157

Testing the Theory of Good Thinking and Deciding in Organizational Setting: Some Benefits of Leader's Actively Open-minded Thinking

Nikola Erceg, Anđela Buljan Šiber, Zvonimir Galić | University of Zagreb

science

Research goals

Decision-making is one of the core things a manager does and one of the core skills he or she must possess (e.g. Bartram, 2005; Hogan Assessment Systems, 2009; Tett, Guterman, Bleier & Murphy, 2000). Yet, research shows that managers are notoriously bad at decision-making (e.g. Nutt, 2002). The errors leaders make when making decisions generally fall under three categories: a) rushing to conclusions without considering wide enough array of possibilities or evidence; b) searching for and overweighting evidence that is in line with favorite position or idea, while simultaneously avoiding and downplaying evidence that counters it; c) overconfidence in one's own conclusions and decisions (Ketchen & Craighead, 2022; Nutt, 2002; Sibony, 2020).

Theoretical background

According to Baron (2000) who developed the theory, AOT describes what a good thinking should look like, and it consists of three things:a) search of information that is sufficient and thorough in proportion to the importance of the questionb) active search for and fair treatment of possibilities other than the one decision-maker initially favorsc) confidence that is appropriate for the amount and quality (direction) of thinking done.From this definition of AOT, it is immediately clear that this kind of thinking is the direct antidote to the three mistakes in managers' thinking that underpin majority of bad strategic decisions. Our goal was, thus, to test this theory in an organizational setting by examining whether the leaders' AOT would be reflected in their subordinates' perceptions of their decision-making quality (DMQ), intellectual humility (IH), and performance in leadership role (PLR).

Methodology

We recruited a sample of N = 177 managers (49% female; Mage = 42.86, SDage = 7.38) with the average of 9.14 years of supervising experience (SD = 7.00). Among other things, they completed AOT self-report questionnaire and IPIP-50 and were also rated by their subordinates (on average, three subordinates per manager) on disposition to think in AOT way, DMQ, IH and PLR.

Results

Managers' AOT was significantly correlated with subordinate ratings of managers' propensity to think in AOT way (r = .22), indicating that managers' AOT is reflected in their behavior and thus perceived by their subordinates. Furthermore, managers' AOT was positively correlated with ratings of their IH (r = .17) and PLR (r = .17), while its correlation with perceived DMQ did not reach significance (r = .10). At the same time, the five personality dimensions were practically unrelated with measured outcomes, except for agreeableness which correlated significantly with perceptions of IH (r = .21).

Limitations

There are two notable limitations: this was a cross-sectional study, preventing us from making any conclusions about causality, and AOT is a self-report measure susceptible to socially desirable responding which skews its distribution and limits its response range.

Conclusion

While the obtained correlations were not spectacularly high, results indicated that AOT is a desirable leader characteristic that could be related to many beneficial individual and organizational outcomes. We hope our results would motivate further investigation of AOT in organizations, currently missing from the literature.

Relevance to the Congress Theme

In the future dynamic work environment, good leadership will be of utmost importance. Decision-making is one of the key leadership tasks, and AOT underpins good decision-making.

Keywords: leadership, decision-making, actively open-minded thinking

Poster P158

HUMAN RESOURCE (HR) SYSTEMS IMPLEMENTATION FROM A RESOURCE ORCHESTRATION PERSPECTIVE: DO TOP AND MIDDLE MANAGERS' HR PHILOSOPHIES MATTER?

Per-Magnus Thompson, BI Norwegian Business School; David Guest, King's College London; Jeffrey B. Arthur, Pamplin College of Business; Anders Dysvik, Bård Kuvaas & Invild Andersen | BI Norwegian Business School

science

Why the work is worth doing : Researchers are increasingly recognizing that successful implementation is a necessary condition for a relationship between HR and firm performance as, if not well implemented, good HR policies and practices can still get bad results. Although the recognition of the importance of effective implementation for the bottom line is increasing and research on the topic is on the rise, the nature of HR implementation and how HR content on the books is implemented, remains poorly understood. To gain a deeper understanding of how HR practices are implemented, we need to grasp the mechanisms through which espoused HR policies are translated into actual practices.

Theoretical background : Drawing on Sirmon et al.'s (2011) Resource Orchestration Model , that successful HR implementation requires consensus and commitment across organizational levels, we examined the roles and values of top and middle managers. Specifically, we tested whether top and middle managers' HR philosophies influenced HR implementation as perceived by employees. In addition, we explored the boundary conditions under which HR philosophy may more strongly affect implementation of HR practices and systems.

Methodology : Organizations were recruited through Proff Forvalt, a database containing information about Norwegian companies in private and public sector. 5.7% of the companies that received our invitation to participate provided us with data from all three levels of the organization, hence being included in our final dataset. At T1, CEOs from 30 organizations and 218 middle managers reported on commitment-oriented HR philosophy. At T2, 647 employees reported on commitment HR system . Data was analyzed using multilevel polynomial regression and response surface analysis.

Results: Data showed that top and middle managers' HR philosophies in isolation had limited effect on how well commitment HR systems were implemented, while increasing consensus between the two levels was associated with greater HR implementation. Furthermore, the effect of consensus varied across sectors, with a significant effect in private sectors, while no effect in public sector was found.

Limitation/future direction : First, this study was conducted in Norway and the results may not be generalized to other contexts. Second, top management response rate was low, reducing the number of organizations included in the study. Third, future research should also explore the roles of other actors (HR specialists, senior professionals, and trade unions) in the effectiveness of implementation, and in particular any potential role conflicts between them.

Practical Implications : One obvious implication is that top managers considering implementation of HR systems should ensure support and commitment across organizational levels. Another implication is the importance of selection of middle managers.

Originality/Value : The extant HR implementation literature has been gravitated toward a single managerial level, exclusively focusing on middle managers as key actors in HR implementation, known as “the middle management perspective”. Our study highlights the importance of consensus between top and middle managers and its impact on HR implementation.

Keywords: Strategy Implementation, HR Systems, Resource Orchestration Perspective

Poster P159

Closeness or close-Bias?: Work-family conflict and the importance of parental proximity for children's physical health in Germany, the United Kingdom

Christina Pranjic, Kathleen Otto, Andre Baumann & Emily Kleszewski | University of Marburg; Jaroslava Babjáková, University of Presov

science

The aim of the study was to find out cross-culturally which occupational context-related variables influence the child's health status of working parents. In addition, it was explored to what extent parents' proximity to the child favors the connection.

So far numerous studies have already shown that work-family conflict has a significant impact on parents' physical and mental health. However, very limited research has been conducted on the effects of work-family conflict (WFC) on children. Moreover, previous parent-child studies have focused only on the relationship between work-family conflict and children's mental health (e.g., the Australian sample of Dinh, Cooklin, Leach, Westrupp, Nicholson & Strazdins (2017)). Little attention, however, was paid to children's physical health or even psychosomatic problems.

In a Portuguese sample, it was also shown that the parent-child relationship plays a supportive role in the association between WFC and behavioral problems characterized by internalizing and externalizing behaviors (Vieira, Matias, Ferreira, Lopez & Matos, 2016).

Since proximity to the child is considered a crucial feature of the parent-child relationship, this study raises the question of whether proximity to the child should be attributed a mediating role between WFC and the child's physical health status in different cultures.

Second, it raises the question of whether the relationship between parental proximity and child physical health status is further mediated by child mental health.

Our sample consisted of 498 employees. Of these, 148 were from Germany, 200 from the United Kingdom, and 150 from Slovakia. Data were collected online from August to October 2022. Variables were collected using the Work-Family Conflict Scale (Carlson et al., 2000) and the Child-Parent Relationship Scale (Driscoll & Pianta, 2011). The child's physical and mental health status was assessed with one item. Data were analyzed using SPSS 23.0. Regression analyzes were calculated to test the mediation hypotheses. The results showed significant cultural differences: While an indirect and a total effect were found for the first question in the Slovak sample, only the total and the direct effect could be confirmed in the German sample. In the English sample, there was neither a direct nor an indirect nor a total effect. The mediating effect of mental health on the association between parental proximity and physical health could be determined by an indirect and a total effect in both the Slovak and German samples. In the English sample, there was also an indirect and a total effect, but also a direct effect of parental proximity on children's physical health.

The results show that especially in the Slovak culture, which is characterized by a high family orientation, WFC negatively influences parent-child closeness, which in turn has a significant impact on the child's mental health and, consequently, physical health. Limitations of the study (e.g., cross-sectional study design, sample size, age of children, and questionnaires) and future research opportunities are critically discussed. The study contributes to explaining which measures are useful in which country to combine occupational and family well-being in a meaningful way.

Keywords: work-family conflict, closeness, children's mental and physical health

Poster P160

For the sake of safety: Towards pinpointing day-to-day leadership behaviors that matter in relation to employee safety behaviors

Amanda Ulfdotter Samuelsson, Martin Grill & Pernilla Larsman | Gothenburg University

science&practice

Research goals & value

This study investigates the importance of four categories of managerial leadership behaviors (i.e., planning, safety priority, safety positive feedback, and active listening) for three categories of employee safety behaviors (i.e., compliance, participation, and voice), both cross-sectionally and longitudinally.

Theoretical background

The construction industry is affected by severe occupational accidents, and the leadership of site managers has been identified as critical in relation to safety. Most of the literature in this field is cross-sectional and concerns broadly defined meta-categories of behaviors. The theory of operant learning is a well-established theoretical framework for understanding, influencing, and predicting behavior. Leadership can be defined as the management of behavioral contingencies in work settings (Komaki, 1998; Podsakoff et al., 2006); involving both antecedent and consequential leadership behaviors (Gravina et al., 2017; 2018; 2019; 2021; Komaki, 1998; Komaki et al., 2011). Change initiatives based on this approach involve identifying, analyzing, and modifying environmental stimuli that influence the targeted behaviors (Choi & Johnson, 2021; Gravina et al., 2021; Tuncel et al., 2006; Vance et al., 2022; Wilder et al., 2009; Wilder et al., 2019).

Design/Methodology/Approach

A two-wave longitudinal study with 4 months between the waves was conducted among construction site employees in Sweden. Employees rated their managers' leadership behaviors and their own safety behaviors on two occasions using an electronic questionnaire. Data was analyzed cross-sectionally as well as longitudinally (n = 123). Three cross-lagged panel models were tested, one for each category of employee safety behaviors.

Result

The cross-sectional results support positive associations between all categories of leadership behaviors and employee safety behaviors, with bivariate correlation coefficients ranging between .25 and .55. The longitudinal data support a prospective influence of safety priority leadership behaviors on employee safety voice behaviors (r = .34, p = .05), but do not support prospective influence on employee safety behaviors for planning, safety-specific positive feedback, or active listening leadership behaviors. Indications of reversed causality were found, as employee safety compliance behaviors predicted managerial listening behaviors.

Limitations (main)

Common method bias. Several circumstances may have contributed to masking the hypothesized prospective effects (e.g. time interval, magnitude of employees' exposure to their managers' leadership, the organizational safety contingency system).

Conclusions

The cross-sectional results support positive associations between all categories of leadership behaviors and employee safety behaviors. The longitudinal data support a prospective influence of safety priority leadership behaviors on employee safety voice behaviors, but not for the rest of the behaviors investigated. Several circumstances may have contributed to masking the hypothesized prospective effects. Indications of reversed causality were found, as employee safety compliance behaviors predicted managerial listening behaviors.

Relevance

Safety-leadership is a key component for organizations to maintain high occupational safety and long-term overall success. Understanding what specific day-to-day leadership behaviors matters for employee safety is vital.

Keywords: leadership, leadership behavior, occupational safety

Poster P162

The relative importance of predictors of turnover intention

Israel Sánchez-Cardona, Kristin Horan & Edwin Trejo-Rivera | Kennesaw State University; Zulmarie De Pedro Serbiá, Grupo Nexos; Eric A. Rivera Colón, University of Puerto Rico; María Vera, Universidad Plablo de Olavide

science&practice

Understanding reasons for job turnover has been a crucial research area for applied psychology. Several theoretical models propose distal (e.g., job characteristics) and attitudinal antecedents (e.g., job satisfaction) of turnover (Hom et al., 2012). Research has identified numerous predictors such as organizational context variables (e.g., support), job characteristics (e.g., workload), job attitudes (e.g., job satisfaction), individual attributes (e.g., tenure), and other personal conditions such as stress, engagement, or coping (Rubenstein et al., 2018). Despite progress, no previous study has examined the relative importance of these predictors on turnover intentions beyond determining effect sizes with meta-analytical techniques. Examining standardized coefficients alone provides misguided interpretations of the relative importance of predictors. This study applied a dominance analysis (DA) technique to elucidate the relative importance of job demands, resources, attitudes, and well-being indicators on turnover intention.

The sample included 1379 employees (77% female) from a public child welfare agency in Puerto Rico. Participants completed a paper-and-pencil organizational assessment. Most reported having a permanent position (91%) with a mean tenure of 18.05 years (SD =8.09). Employees were highly educated (80% completed a bachelor's or graduate degree).

We measured the following variables: Time pressure (5 items, α=.81; Potter et al., 2016); Role clarity (3 items, α = .84, Salanova et al., 2012); Role conflict (3 items, α = .69; Salanova et al., 2012); Organizational support climate (4 items, α =.83; Gonzalez Romá et al., 2009); Transformational leadership (15 items, α =.95; Rafferty & Griffin 2004); Job satisfaction (1 item; Moncada et al., 2014); Organizational commitment (3 items, α =.65; Salanova et al. 2012); Organizational justice (4 items, α =.85, Moncada et al., 2014); Exhaustion (5 items; α =.76), Cynicism (4 items; α=.94) and Efficacy (6 items; α=.94) (Salanova et al., 2000); and Turnover intention (3 items, α =.86; Cho & Song, 2017).

Overall, 37.2% of the variance in Turnover is explained by the MLR model. DA revealed that exhaustion (.101 [.077,.123]), cynicism (.094 [.073, .123]), and job satisfaction (.050 [.032,.083]) have the highest influence on turnover. These predictors showed complete dominance over transformational leadership (.018 [.012, .029]), organizational support climate (.023 [.013,.037]), organizational justice (.013 [.008, .019]), conflict (.010 [.005, .020]), clarity (.012 [.007,.022]), and efficacy (.005 [.003, .010]) suggesting the incremental validity was always higher for exhaustion, cynicism, and job satisfaction across all possible subset models.

These results offer theoretical contributions suggesting the need to incorporate well-being factors in the path process to explain turnover. Practically, this study implies that interventions to reduce burnout and improve well-being constitute relevant building blocks to prevent turnover intentions. Despite the contributions of this study implementing a novel analytical technique with a large sample, the results need further cross-validation across different organizational sectors.

This project aligns with the sustainable development goal of employment and decent work. We identify key factors to promote safe and secure working environments and decent job creation that retains and stimulate workers' quality of life.

Keywords: turnover intention, dominance analysis

Qualitative assessment of job experiences for support to self-development

Bo Strangert, Communication Research unit (ArbOrg.se); Christine Strangert, ArbOrg Utveckling AB

science&practice

Goal. Consulting on workplace development needs valid and sensitive methods to assess individual differences in the process to support effective coping with job demands. This study tested a simple qualitative assessment technique as part of a project about how individuals can recall and use their job experiences to value and cope with challenges at work.

The theoretical purpose was to elaborate on the concept of personal coping. This study explored how individuals' systematic reflections and qualitative judgements of significant personal job experiences were related to their reports concerning coping with challenging job demands.

Methodology. In the first testing phase, 25 professional business and public service participants rated their present job experiences on 5-point bipolar scales of mental workload, task difficulty, control, and general job satisfaction. Next, in the main session, each participant recalled and briefly noted the most significant experiences of four work states: mental workload, task difficulty, organisational change, and innovative demands. For each state, the participant then judged the occurrence of expectancies (the risk of psychological stress and the possibility of an engaging task) and moods (intense negative pressure and positive emotions). At the end of each tested work state, the participant reflected and reported spontaneously whether it was coped with and how. Two independent judges categorised states' judgements in binary terms (yes/no) and the reports of coping by binary categories of eight attributes.

The Results to be presented in the e-Poster:

substantiate how quantitative ratings of work conditions can be supplemented and interpreted by the simple qualitative assessment technique,

show that networks of reported associations between experienced states, expectancies and moods can suitably represent the diversity among participants,

include alternative ways of categorising attributes of perceived coping.

Limitations . The sample of participants was from a population of people 25-55 years old with various professional jobs and enrolled on an introductory university course in applied Work and Organisation Psychology. None worked in the same workplace as any other in the sample.

Research and practical implications. Focusing on reflection about the previous coping at work indicates that qualitative methodology is suitable when individual diversity is crucial. This assessment technique can be a simple but valuable tool for consulting when it involves individuals deeply in work environment problems and development.

Relevance to the Congress Theme : Research Methods (Qualitative methods). Well-being (Coping and social support).

Relevance UN SDGs: Good health and well-being. Decent work and economic growth.

Keywords: Qualitative methods, Job experiences, Coping

Are We a Good Temporal Fit? Examining Synchrony Preference Fit Between Supervisors and Supervisees on Temporal Outcomes

Tianyi Zhang, The Pennsylvania State University; Songqi Liu, Georgia State University; Robert Melloy, Culture Amp; Susan Mohammed, The Pennsylvania State University

science

How well do supervisees and supervisors match? This question matters because person-supervisor (PS) fit positively predicts key outcomes like performance and job satisfaction. Whereas previous research has examined fit on values, personality, and goals, PS fit studies generally ignore time. This omission is regrettable because poor temporal fit between supervisors and supervisees can cause coordination breakdowns, missed deadlines, and unfinished tasks. To fill this gap, we examine PS temporal fit in terms of synchrony preference: the tendency to adjust one's temporal rhythm to match that of others. Synchrony preference has been shown to positively predict flexible pacing, interpersonal facilitation, and job dedication. Despite its importance, synchrony preference has received little research attention. Based on social entrainment theory, supervisees often adapt to the pace of their supervisor. However, the consequences of such adaptation are understudied. For example, how does the synchrony preference of the supervisor interact with that of the supervisee? Does fit or misfit affect supervisees' confidence in their ability to complete tasks on time (higher temporal self-efficacy)? In addition, does temporal efficacy reduce time pressure?

Drawing from social entrainment and PS fit theories, we examine the effect of synchrony preference fit between supervisor and supervisees on temporal efficacy and subsequent time pressure, as moderated by two contextual variables: coordinative complexity (the degree to which information from each of the steps in a task must be applied to other steps in the task) and temporal ambiguity (uncertainty regarding the time frame to finish tasks). We expect that supervisee temporal efficacy will be lower when levels of synchrony preference are similar. The PS synchrony preference-temporal efficacy relationship will be stronger when supervisees have higher synchrony preference than supervisors. Temporal self-efficacy will negatively predict time pressure, and the higher the coordinative complexity and temporal ambiguity, the stronger the negative relationship.

Dyadic-level data were collected from 23 supervisors and 255 supervisees in the Chinese banking industry. We will examine immediate and subsequent outcomes of synchrony preference PS fit using polynomial regression and mediation analyses. Analyses will be completed in spring 2023, before EAWOP. Although using dyadic-level data is a strength, it would be ideal to survey across different time points instead of just one. Also, future research should test these relationships beyond one Chinese organization.

This study expands the PS fit literature base to include how supervisees and supervisors fit temporally regarding synchrony preference. We also expand synchrony preference research from the individual level to supervisor-supervisee dyads. Building on social entrainment theory, we also examine two contextual influences of the temporal efficacy-time pressure relationship that can serve as intervention points for practitioners to increase temporal efficacy and decrease perceived time pressure. The results of temporal PS fit have the potential to inform supervisor-supervisee working relationships with implications across domains like selection, mentorship, and managerial practice.

Keywords: Person-Supervisor Fit, Synchrony Preference, Temporal Self-Efficacy

A Pedagogy of Empowerment in the Mexican Educational System

Nathan Iverson, California Baptist University

science&practice

The paper shares the qualitative discovery of the Education System in Mexico taking particular interest in the UNESCO-awarded efforts of the Instituto Nacional para la Educación de los Adultos (INEA) which has made incredible strides over the past century to build and sustain high rates of adult literacy in Mexico and the influence of Paulo Friere upon this system for what is described as transformational learning . Mexico has grown 300% in literacy over the past 100 years which is a higher rate of growth than any other nation in Latin America. This study shares key findings and themes of empowerment from interviews with teachers and students in INEA. The goal of the researchers is to generalize the themes to Latinos in the American University system to raise Latino gratuation rates by orientation of new students and training of professors. The gap between Latino and White graduation rates in the USA, California, and many Hispanic Serving Instutions are respectively 8.9%, 10.5%, and 20%. Similiar retention challenges are seen among communities of color in the American workplace particualtly in higher education. Generalizing the themes of empowerment to a global context, the researchers hope to empower communities of color using new employee/student orientation and manager/professor training integrating the same themes shown to be effective in the collectivist context of Latin America.

Keywords: education, empowerment, latino, retention

Poster P167

Are Risk Takers More Likely to be Self-Employed?

Simon Toms & Geoff Trickey | Psychological Consultancy Ltd

science&practice

Research goals

The current research sought to explore if and how aspects of personality relevant to risk taking could predict participants' likelihood to be self-employed.

Theoretical background

Why do people choose to be self-employed? The opportunity to work unsupervised outside an organisational structure may feel exhilarating and liberating. For others, the increase in risk and uncertainty will prove too daunting. As personality psychologists, we were interested in the following question: Are there elements of personality that predict these preferences and influence the decision to pursue self-employment?

Chan et al. (2015) recruited two Undergraduate samples to explore whether personality could predict those who are motivated or aspire towards entrepreneurial careers. The analysis incorporated risk-related traits, the Big Five, and a 'proactive personality' construct.

The analysis found that risk-related traits, the Big Five (primarily Openness to Experience and Extraversion), and proactive personality predicted participants' desire for entrepreneurial careers. Conversely, increased risk aversion predicted reduced interest in an entrepreneurial career path.

Research like this provides an intriguing insight into the aspects of our personality that are likely to predict a desire to be self-employed. However, reliance on student samples can limit generalisability to working populations. Will these findings translate to the working population?

Design

The research obtained access to participants who had completed the Risk Type Compass (RTC) personality assessment. The RTC incorporates risk-relevant elements of the Big Five to predict how individuals perceive, react to and manage risk. Participants are placed into one of eight 'Risk Types' using data from twenty personality 'subthemes'. Participants were divided into two groups dependent on whether they indicated they were self-employed (n = 596) or non-self-employed (approximate n = 20k).

Results

Analysis demonstrated clear and significant differences in the prevalence of personality traits between the self-employed and non-self-employed samples. 'Excitable' Risk Types, who demonstrate a preference for spontaneity and flexibility, were 50% more likely to reside in the self-employed sample. At subtheme level, the largest difference could be found in the 'conforming' facet, indicating that self-employed participants were less likely to conform to rules and procedures compared to the non-self-employed sample.

Limitations

The research design did not determine whether participants resided in self-employment due to choice, which is something future research could address.

Implications

In conclusion, personality has a clear impact on the preference for being self-employed. Risk Types predict a preference for the stability that organisations provide and a greater need for 'permission to act' that can be fulfilled by managers and supervisors. In contrast, Risk Types lower on the desire for stability are more likely to crave the flexibility and autonomy afforded by self-employment and may be more negatively impacted in job roles that fail to provide this.

Understanding these personality-driven propensities may shed light on professional discomfort and identify alternatives more strongly aligned with individuals' underlying tendencies and preferences.

Relevance to the Congress Theme

The form of work has changed significantly since 2020. Understanding the role personality plays in individuals' response is crucial.

Keywords: Personality, Self-Employed, Risk-Taking

Poster P168

Strengths Use at Work: A Meta-Analysis

Jack C Friedrich & Cort W Rudolph | Saint Louis University; Hannes Zacher, Leipzig University; Ryszard J Koziel, Saint Louis University

science

Research goals

Research on strengths use at work has rapidly accumulated over the last decade. Despite the construct's increasing popularity, we lack a quantitative synthesis of research on strengths use at work. Such a synthesis could inform the (re)development of theory, future research, and the implementation of interventions to encourage strengths use in the workplace.

Theoretical background:

Character strengths refer to the idea that individuals possess relatively stable patterns of different positive unique traits, characteristics, and abilities, such as creativity, zest, or self-regulation. Awareness of one's strengths is distinct from their use, which is thought to be energizing and promotive of wellbeing and other positive outcomes. Numerous interventions and programs have been designed with the goal of promoting strengths knowledge and use, reasoning that optimal development occurs through investment in an individual's strengths rather than a focus on their shortcomings.

Methodology:

We conducted a meta-analysis ($K = 89$ independent samples; total sample $N = 34,163$) examining the relationships between strengths use and relevant workplace outcomes.

Resulted obtained:

We found significant meta-analytic relationships ($p < .05$) between strengths use and wellbeing ($rxy = .59$), performance ($rxy = .45$), and work-engagement ($rxy = .56$).

Limitations

Importantly, the results summarized above include only measures of strengths use assessing the construct generally (i.e., with items such as "I always play to my strengths") rather than those assessing the use of individual strengths. As this project is ongoing, findings including these additional measures will be available by the time this poster is presented.

Research / Practical Implications

These initial results support assertions that strengths use is closely linked to important work outcomes and, from a practical perspective, are a valuable starting point for employee development.

Moreover, these results have implications for the continued development of this research. Our next steps for this project include meta-analyzing additional strengths use relationships (e.g., with work-related flow), elaborating on relationships between strengths use and subdimensions of our outcomes (e.g., burnout subdimensions), exploring the relationship between different strengths use measures and our constructs of interest, and the inclusion of additional non-published findings and correlations received from contacted authors.

Next steps beyond the scope of the current project include synthesizing research on strengths use interventions, exploring the boundary conditions of strengths use (e.g., when and for who is it most effective), and exploring what individual strengths may matter the most for workplace outcomes.

Relevance to the Congress Theme

This meta-analysis is relevant to the conference theme of "the future is now: the changing world of work." It offers a contribution insofar as our findings highlight the relevance of strengths use for employee wellbeing and performance. In terms of urgency , our results suggest that focusing on strengths may help promote employee wellbeing, performance, and motivational outcomes. Finally, in terms of delivery, this work suggests that in the future emphasis should be placed on employees' strengths at work, rather than their deficits.

UN SDGs

- Good health and wellbeing

Keywords: Strengths, Wellbeing, Performance

Artificial intelligence at universities - a qualitative and quantitative study regarding the use of humanoid robots

Lisa Drescher, Westcoast University of Applied Sciences

science&practice

Goals

In recent years, incredible progress has been made in the field of artificial intelligence. Digitization is bringing about a multitude of changes that are also reflected in higher education (Barton & Müller, 2019). Digital and alternative learning formats, as well as individualized student support, are becoming increasingly important. This raises the question of what the university of the future might look like (Dittler & Kreidl, 2017). Humanoid robots could provide added value through their ability to interact socially by supporting teachers and also students in different areas. The goal was to identify possible areas of application for a humanoid robot in higher education by means of a qualitative and quantitative study, as well as to adapt the technology acceptance model with regard to the factors influencing acceptance.

Theoretical background

The special feature of humanoid robots is that they can establish an interpersonal relationship on the basis of language, gestures and facial expressions due to their human-like shape and the possibility of social interaction (Dautenhahn, 2007). The use of humanoid robots has so far been primarily investigated in the marketing sector as well as in the healthcare sector. In the field of adult education, only a few studies have been found so far. When using new technologies, technology acceptance is also of great importance. For the following studies, the technology acceptance model (Davis, 1989) was adapted. The working model includes perceived usefulness, intention to use, and was supplemented by other potential influencing factors.

Design

The qualitative survey was conducted in the form of semi-structured interviews supported by an interview guide that included open exploratory questions. A total of 24 students from different disciplines were interviewed. In addition to a task analysis, potential areas of use and students concerns about use were recorded. Based on this, a quantitative survey in the form of a questionnaire study was conducted with 183 students. With regard to the areas of use, various cases of use were derived from the qualitative study and evaluated with validated scales in terms of their perceived usefulness and intention to use. Potential influencing factors such as scales on concerns and technology affinity were also surveyed.

Results

The qualitative study was evaluated using IPA. It was found that students can imagine humanoid robots in different areas of use. This was confirmed in the quantitative survey and it was possible to further differentiate the application areas. Students could imagine a humanoid robot as an organizational assistant, as a trainer and personal assistant, and in the library. This also showed that a humanoid robot in an assistance function is perceived as more useful than a robot that replaces complete human activities. In addition, it was possible to evaluate various factors (privacy concerns, social interaction, equal treatment, ...) influencing technology acceptance.

Limitations

The technology acceptance model also includes other variables such as perceived ease of use and actual use. These could not be taken into account within the studies, as no actual application took place in practice.

Research

The combination of the qualitative and quantitative approach has already yielded a great increase in information. It would make sense to carry out a field study in the next step in order to be able to check the practice-related variables as well.

Keywords: artificial intelligence, humanoide robots, technology acceptance

Corporate Stakeholder Responsibility in Germany: A Translation and Validation of a Measure

Sophia Angelika Kohlenberg, WHU - Otto Beisheim School of Management; Jürgen Deller, Leuphana Universität Lüneburg; Marlene Gruber, Wirtschaftsuniversität Wien; Tilman Nols, Eindhoven University of Technology

science

Research on Corporate Social Responsibility (CSR) disproportionally neglected the employee's role over the past decades. As members of an organization, employees perceive and react to CSR and thereby contribute to the overall success of CSR practices. How employees evaluate CSR serves as the ultimate antecedent to how they are affected by organizational activities. Due to the acknowledgment that CSR also needs a micro-foundational perspective, authors increasingly published suitable measurement instruments to account for that deficit. However, these research streams are predominantly tested in English-speaking countries, leading to a lack of comparability between different nations. Testing the micro-foundational differences of CSR across countries may help to delineate why some cultures are more engaged with CSR than others. The lack of comparability slows down CSR research and measuring constructs in a non-native language introduces a risk of biased assessment, leading to a need for valid and comprehensive scales in other languages.Therefore, the present study translates and validates the corporate stakeholder holder responsibility (CStR) scale originally proposed by El Akremi et al. (2018) in German to enable a more thorough analysis of CSR in other countries. We committed to a German translation since German is one of the most prevailing languages across Europe, trying to establish its forerunner role in CSR despite evident local differences in CSR appreciation and implementation. Considering CSR from the stakeholder theory perspective structures CSR around a framework of activities that impact entities with high value to the organization, both internal (e.g., employees) and external (e.g., community). Accordingly, CStR is not narrowed down to a purely environmental dimension but considers the distinguishable focus on human and social aspects through a multi-dimensional concept. The proposed second-order construct establishes how employees generally perceive and evaluate CSR activity in companies by considering diverse stakeholder groups related to an organization.

Within a longitudinal study across two time points, we established the validity of the multi-dimensional construct as a German version of the Corporate Stakeholder Responsibility Scale (CStR-G). The scale consists of six subdimensions considering different stakeholder groups of an organization, including community, natural environment, employee, supplier, customer and shareholder. Using 412 participants from a diverse sample from companies across Germany, we tested the psychometric quality of our questionnaire. We derived satisfactory internal reliability using Cronbach's alpha. In addition, we found adequate convergent and discriminant validity utilizing multiple CFAs and concurrent and predictive validity through regression analyses. Despite promising results, we found mixed results for the hypothesized second-order structure of the construct which we discuss considering the statistical evidence. However, the Corona pandemic and the Ukraine-Russia conflict limited our data collection. Companies were increasingly expected to act more socially responsibly. Nevertheless, our research contributes to how employees judge their corporate contributions to Sustainable Development Goals through CSR by illuminating the importance of different stakeholder groups. By offering a CSR scale in German, we provide a crucial step for more cross-cultural research on the individual level.

Keywords: CSR, micro-foundations, psychometrics

Poster P173

The impact of servant and authentic leadership on job embeddedness: the moderated mediation of job crafting and overall justice

Ana Margarida Graca, Henley Business School, University of Reading; Muhammad Ali Awais Ali , Kingston University

science&practice

Research goals and why the work was worth doing

This study aims to examine the relationship between servant leadership and authentic leadership as predictors of job embeddedness through the mediating role of job crafting. Besides, the study examines the moderating role of organizational justice - an individual's perceived fairness in the organization - in the underlying linkage. By doing so, we thoroughly investigate the impact of the conditions and underlying mechanisms of contextual and individual job characteristics on the relationships between leaders and employees.

Theoretical background

The study theoretically integrates servant and authentic leadership, the job demands-resources model and the social exchange theory, often disconnected theories, to predict the studied relationships. Prior studies corroborate that servant leadership offers more desired outcomes than authentic leadership, in particular in the job context. This is because servant leadership engenders autonomy to subordinates with respect to their jobs, ultimately influencing job crafting and job embeddedness. In addition, the study investigates the role of overall justice as a moderator variable, as justice and autonomy are intertwined.

Design/Methodology/Approach/Intervention

The study collects data using a cross-sectional design from employees working in the banking sector in Pakistan. A total of 217 completely filled questionnaires were used.

Results obtained

The findings suggest that both types of leadership positively influence job embeddedness. In addition, the impact of servant leadership on job embeddedness is more significant than that of authentic leadership on job embeddedness. Furthermore, the study finds the significant mediating role of job crafting in the underlying linkage. The moderating role of overall justice is not significant.

Limitations

The study uses a cross-sectional research design. However, it brings really interesting results on underexplored relationships. The study was also conducted in the Pakistani context, characterized by high-power distance and collectivism, so findings should take this into consideration. Nevertheless, the focus on non-Western countries significantly contributes to the literature in this area.

Research/Practical Implications

First, the study examines the distinctive role of Servant Leadership being more pronounced than Authentic Leadership on job embeddedness. This shows that if employees are given autonomy from their supervisors to control the facets of the job embeddedness, their staying intentions will more likely be enhanced.

Second, the study examines the understudied mediating role of job crafting in this relationship, showing that with the proactive support of their supervisors, employees are more likely to foster augmented levels of job embeddedness.

The study suggests that organizations should conduct leadership training by first focusing on employees' needs, and fostering a culture of autonomy in which employees are given the freedom to craft their jobs to enhance their embeddedness.

Relevance to the Congress Theme

Job embeddedness and job crafting are pillars in "future and changing way of working" themes, contributing to giving autonomy to employees in emergent crises and unexpected situations. These pillars can only be elevated by servant and authentic forms of leadership where leaders are close to their teams and communities and put the employee's needs first.

Keywords: authentic leadership; servant leadership; job embeddedness

Poster P174

Perceptions of the Functionality of Face-to-Face versus Virtual Formats in Medical Multidisciplinary Decision Teams

Ian Bushnell, Mark Danton & Mhairi McGinley | University of Glasgow

science&practice

Objectives: Following COVID-19, Multidisciplinary Decisionmaking Team meetings (MDTs) have increasingly been conducted online. However, the shift from face-to-face (F2F) to Virtual conferencing (VC) formats may influence MDT processes including the ability to share clinical data, view imaging and the group processes of discussion & collective decision-making. This study aimed to compare F2F versus VC for MDT functionality using a mixed-methods design.

Methods: An online mixed-method questionnaire was employed. In-house clinicians, BCCA and SCTS members were contacted, and 78 participants completed the questionnaire: 57 Surgeons, 12 Cardiologists and 9 Other allied specialties. Eleven questions were answered on a 7-point Likert scale regarding pros and cons of VC compared to F2F on key aspects of the MDT process. Thematic analysis was used to analyse open-ended questionnaire responses regarding opinions on MDT format.

Results: Opportunity to attend and MDT efficiency were perceived as improved with virtual formats. Sharing clinical information and viewing imaging (Echo, Cross-section, and Catheter) was rated inferior with VC. Group processes of discussion, interaction, being listened to and contributing to decision-making were balanced between F2F and VC. Thematic analysis of responses developed six themes: attendance, efficacy, equality of participation, group dynamics and technology. These were perceived as important factors impacted by MDT format.

Conclusion: Virtual MDTs have the advantage of access but are compromised by inferior image quality when viewing clinical scans. Compared to face-to-face MDT, participation online creates structurally different group discussion and engagement. Appreciating these differences, with appropriate modification together with technology advance may address some current limitations of virtual MDT. However, future research is warranted to build upon current findings and importantly assess decision-making quality before online MDT can be recommended.

Keywords: Decision-making, medical, Zoom

Poster P175

The mediating effect of Personality on Impostor Phenomenon and Organizational Commitment

Mohit Jain & Angeli Santos | University of Nottingham; Simon Toms, Psychological Consultancy Limited

science&practice

Title: The mediating effect of Personality on Impostor Phenomenon and Organizational Commitment

This study aimed to understand how the impostor phenomenon, neuroticism, and organizational commitment are related.

Note: T he term neuroticism in the context of a non-clinical personality factor is incorporated in a personality psychometric that is a Registered Test with the British Psychological Society.

Impostor phenomenon (IP) and Organizational commitment (OC) have recently attracted the attention of researchers who are eager to delve deeper into the topic. Previous findings show that employee turnover and organizational commitment are correlated, meaning that less committed employees are more likely to leave the company (Kelly, 2015).

This study discussed these two important questions:

1. What is the relationship between the Impostor phenomenon and Organizational Commitment?

2. Do neuroticism mediate the relationship between the Impostor phenomenon and Organisational Commitment?

Methods

To ascertain and explore correlations among variables, a quantitative study and experimental research design are used. This research study especially focuses on young working professionals. To conduct the surveys, it was given to private sector organizations in India. We contacted organizations and young working professionals through personal contacts. Psy-Key (PCL platform) and JISC (Nottingham Surveys) questionnaires were used to obtain the data. A portion of the questionnaire was sent using the online platforms & Psy-Key from Psychological Consultancy Limited (PCL) and JISC Online Surveys (JOS).

Results

Research has demonstrated that young working professionals have a higher tendency for the imposter phenomenon. This study investigated the imposter phenomenon in the workplace and discovered that it is positively correlated with continuance commitment. The results of the correlation analysis showed a statistically significant moderately positive association between the continuance commitment and the imposter phenomenon (.338). It can also be inferred that high career instability among impostors motivates them to demonstrate greater dedication to their current position. The findings show that the imposter phenomenon plays a critical role in the formation of organizational commitment

Limitations

Because our data was gathered by questionnaires and the metrics employed were self-report, the results could be biased. Our findings might partially reflect under-reporting effects because

impostors tend to lower themselves given the characteristics of our key research variable (Vergauwe et al., 2015).

Cross-sectional studies are unable to examine changes over time. It does not determine cause and effect relationship. It has been suggested that a sample of participants for cross-sectional studies must frequently be chosen from a sizable and diverse study population.

Relevance

Impostor phenomenon and neuroticism may hinder professional advancement. As a result, it is crucial to study and raise awareness among individuals and organizations. Even if a corporation may give its employees organizational tools, it typically finds that there is a high percentage of employee turnover (Barza et al., 2022). The research is relevant to SDG 8 “Decent work and economic growth” and the future of work. Understanding the dynamics of personality and employee commitment works as a key factor for employee retention in the workplace.

Keywords: Impostor, Personality, Organisational Commitment

Poster P176

Investigating stereotype threat in developmental dyslexia: Implications for job selection processes.

Barbara Piotrowska, Edinburgh Napier University; John Barratt, University of Leicester

science

Theoretical background and research goals

Stereotype threat is a phenomenon that leads to decreased test performance and occurs when one deals with added pressure of being judged on the basis of their group membership. The effect has been previously investigated in many contexts but not in individuals with developmental dyslexia (DD) who are often stereotyped as less intelligent. Prevalent use of intelligence tests in job selection processes and employment gap between people with dyslexia and those without warrants this investigation. We aimed to investigate if stereotype threat extends to people with dyslexia. This investigation is important as understanding of this phenomenon would allow practitioners to design recruitment process in a way that would not trigger stereotype threat.

Methodology

Sixty-three participants (30 with DD and 33 without DD; mean age = 33.7; SD =13.7; 47 F, 13 M, 3 non-binary) were asked to complete intelligence test typically used in selection processes. Participants in both groups were randomly assigned to one of three test instruction conditions: 1) they were told the test was diagnostic of their intelligence (stereotype threat); 2) test was a measure of their problem-solving skills (reduced threat); 3) or they were simply asked to take the test (control).

Results

Results showed that participants with DD in stereotype threat condition performed statistically significantly poorer than those in other conditions and those in the same condition who did not have DD. This study provides evidence for diminishing effects of stereotype threat in DD and recommends job recruiters to use strategies to reduce it to assure fairness and inclusion.

Limitations

The sample size was relatively small which did not allow for more detailed analyses of the impact of educational level, occupational status, gender and dyslexia comorbidities (e.g., ADHD) on test performance. Further research is needed.

Research/Practical Implications

Research on use of intelligence tests for job recruitment processes should consider impact of situational factors such as what test instructions are used and whether stereotyped groups, such as people with developmental dyslexia, are included.

Practitioners designing selection processes should think through and pilot instructions that are to be used while administering intelligence tests making sure that they offer minimal instructions or frame the tests as measuring learnable skills rather than stable intellectual abilities. This will assure fairness of the assessment.

Relevance to the Congress Theme

As our future is indeed created by many professionals, we need to ensure that our practices are inclusive and that we recruit best people for the jobs. Individuals with dyslexia are often credited with many strengths (e.g., being able to see the 'big picture', being creative and 'out of box' thinkers, good problems-solvers; Nicolson & Fawcett, 2015; Reid & Kirk, 2001) that are highly valued in today's workplaces. By engaging in fair recruitment processes we stand a better chance in highly competitive market. Also, in ever-changing work environment and with multiple crises we need creative and novel solutions. This speaks to the themes of Contribution and Urgency.

Keywords: equal opportunities, neurodiversity, recruitment

Work-family relationship in remote workers differing with regard to social support and hours worked per week

Patrycja Siemiginowska, Jagiellonian University, Krakow, Poland; Irena Iskra-Golec, SWPS University of Social Sciences and Humanities, Faculty in Poznan, Poland

science

The purpose of this cross-sectional study was to examine the work-family relationship with regard to the number of hours worked per week and perceived social support in employees who had to switch to remote work due to outbreak of COVID-19 pandemic. Work-family relationship has been addressed in numerous studies (i.e. Allen et al. 2019). COVID-19 pandemic has been proven to be stressful and detrimental to health (Patel et al., 2022). There is however a great need of studying work-family interface in this context. The role of social support as a stress buffer has been widely documented (i.e. Ditzen, Heinrichs, 2014). It's combined effect with number of hours worked per week has been examined.

635 workers (19 to 70 y.o., M=37,24 years, SD=11,02 years) took part in the online study. They had to have been working remotely for at least three months. There were 438 women (69%) and 197 men (31%). 6 groups of employees have been distinguished: (1)low social support and working less than 40 hours per week (N=77, aged 20-68, M=38,60 years; SD=13,24 years, 70% female), (2)low social support and working full time (40 hours per week; N=144, aged: 19-67, M=36,21 years, SD=8,94 years, 67% female), (3)low social support and working overtime (more than 40 hours per week; N=123; aged: 21-64 years, M=36,23 years; SD=8,96 years, 67% female), (4)high social support and working less than 40 hours per week (N=73; aged: 20-69 years, M=39,48 years, SD=14,29 years, 62% female), (5)high social support and working full time (N=118, aged: 22-70 years, M=36,31 years, SD=10,98 years, 74% female), (6)high social support and working overtime (N= 100, aged: 20-66 years, M=38,39 ears, SD=11,30 years, 73% female). Work-family interface was measured by 12-item scale comprising of 4 subscales: work-family facilitation-WFF, work-family conflict-WFC, family-work facilitation-FWF, family-work conflict-FWC (Cronbach's alphas: 0,709; 0,801; 0,821 and 0,768 respectively). Social Support was measured by Polish adaptation of Multidimensional Scale of Perceived Social Support (Zimet et.al., Polish adaptation: Buszman, Przybyła-Basista, 2017). The Cronbach's alpha of the general result was 0,956. One-way AVOVA analyses were performed. Statistically significant differences in average WFC ($F(5,629)=7,041$; $p<0,001$), WFF ($F(5,629)=13,331$; $p<,001$), FWC ($F(5,629)=4,717$; $p<,001$) and FWF ($F(5,629)=30,055$; $p<,001$) were found. Post-hoc analyses revealed that WFF was higher in the group of workers who had more social support regardless of working hours. The lowest WFF was experienced by employees working overtime and having low social support. Similar results were obtained with regard to FWF, however lowest FWF was observed in employees working less than 40 hours per week and experiencing low social support. Highest WFC and FWC were experienced by employees working overtime with low social support. Lowest WFC and FWC were reported by full time workers experiencing high social support. Limitation of this study is that there was uneven distribution of men and women in this study.

Remote work, although present in the job market before the Covid-19 pandemic, has become a reality for many people not used to it. Researching this area is very important as remote work can have both beneficial and detrimental effects on employees' health and wellbeing.

The results of this study contribute to better understanding of remote employees wellbeing and their health which is in line with UN SDGs.

Keywords: work-family relationship, social support, telework

Poster P178

Stress perception in remote workers differing with regard to social support and hours worked per week

Patrycja Siemiginowska, Jagiellonian University, Krakow, Poland; Irena Iskra-Golec, SWPS University of Social Sciences and Humanities, Faculty in Poznan, Poland

science

The goal of this research was to study perception of work stressors with regard to social support and hours worked per week in employees who had to start working remotely after the outbreak of COVID-19. Although telework has been known for decades, the coronavirus pandemic forced many employees to work remotely without training or preparation. This sudden change in working conditions was a serious stressor.

635 workers aged 19 to 70 years old (M=37,24 years, SD=11,02 years) took part in the online study. They had to have been working remotely for at least 3 months. There were 438 women (69%) and 197 men (31%). They were either working less than 40 hours per week (N=150), full time (40 hours per week, N=262) or more than 40 hours per week (overtime, N=223). Based on social support results (Polish adaptation of Zimet's scale, Buszman, Przybyła-Basista, 2017, Cronbach's alpha: 0,956) the workers were split into 2 groups: workers with high social support (N=291) and workers with low social support (N=344). Six groups of employees have been distinguished: (1) low social support and working less than 40 hours per week (N=77, aged 20-68, M=38,60 years; SD=13,24 years, 70% female), (2) low social support and working full time (40 hours per week; N=144, aged: 19-67, M=36,21 years, SD=8,94 years, 67% female), (3) low social support and working overtime (more than 40 hours per week; N=123; aged: 21-64 years, M=36,23 years; SD=8,96 years, 67% female), (4) high social support and working less than 40 hours per week (N=73; aged: 20-69 years, M=39,48 years, SD=14,29 years, 62% female), (5) high social support and working full time (N=118, aged: 22-70 years, M=36,31 years, SD=10,98 years, 74% female), (6) high social support and working overtime (N= 100, aged: 20-66 years, M=38,39 ears, SD=11,30 years, 73% female). Stressors investigated were: exertion, mental burden of work, and the right to take up decisions.

One-way AVOVA analyses were performed. Statistically significant differences in average exertion ($F(5,629)=9,053$; $p<0,001$) as well as mental burden of work ($F(5,629)=7,977$; $p<0,001$) and the right to take up decisions ($F(5,629)=3,117$; $p=0,009$) were found. The exertion was highest in the group of employees working overtime with high social support when compared to other groups of employees. Mental burden of work was highest in employees working overtime regardless of social support. The right to take up decisions was highest in employees who were working less than 40 hours per week and experienced high social support. Mental burden of work was highest in employees working overtime regardless of social support.

Preliminary findings suggest limited role of social support in reducing the stress of remote work. It might mean that the stress of telework can only partially be buffered by perceived social support. Even employees with high social support were very stressed when compared to those experiencing low social support, especially when working overtime. The results of this study suggest that social support can be a stress buffer only in limited capacity in remote employees during the pandemic. Hours worked per week should be taken into account as one of the factors contributing to stress perception in remote workers. Further examination of these phenomena is needed. The specificity of remote work may be an important factor to be investigated closely in future research.

This study is relevant UN SDG: good health and wellbeing.

Keywords: stress perception, social support, telework

Poster P179

Wellbeing, sleep and health assessments in remote due to Covid pandemic workers depending on hours worked and gender - a prospective study

Irena Iskra-Golec, SWPS University of Social Sciences and Humanities, Faculty in Poznan, Poland;
Patrycja Siemiginowska, Institute of Applied Psychologu, Jagiellonian University, Krakow, Poland

science

A goal of this prospective study was to examine the dynamics of the impact of remote due to pandemic working arrangements on wellbeing, sleep problems, and physical health perception in a representative sample of remote due to pandemic workers in Poland. The outbreak of Covid pandemic resulting in implementation of remote work on a larger than earlier scale has a potential of creating not only the new opportunities but the new work stressors and their outcomes as well. The research have already showed negative impact of remote working during pandemic on wellbeing, sleep and health (Patel, Robertson, Kwong, Griffith, Willan, Green, et al. 2022). The question is whether and which of these effects change in the course of time of working remotely in times of pandemic.

The participants of the two wave study (n=477; women=311; men=166) aged 19 to 70 years (M=37,24; SD=11,02 years) filled in online surveys two times, the first in January and the second in May of 2021. They were divided into 6 groups on the basis of hours worked per week (below 40h, 40h, more than 40h) and gender. The groups were as follows: (1) women > 40h per week (N=67, M=36.62 years; SD=11.11years), (2) women and 40h (N=133, M=37.23 years, SD=9.54year), (3) women and < 40h (N=111, M=39.86 years; SD=10.47 years), (4) men and > 40hours per week (N=46, M=45.22 years; SD=13.49 years), (5) men and 40h (N=72, M=40.32 years; SD=10.42 years), (6) men and <40h (N=48, M=39.54 years; SD=9.17 years,).

Well-being was assessed by WHO-5 Well-being Index (WHO, 1998), sleep problems were evaluated by usage of Athens Insomnia Scale (Soldatos, Dikeos, Paparrigopoulos, 2000), and subjective health was assessed by questions derived from Short Form Health Survey SF-36 (Ware, Sherbourne, 1992). Analysis of variance was performed on the data to find out differences in dependent variables between the first and the second measurement time in groups of workers differing with regard to hours worked per week and gender. Main effect of time of measurement was found on wellbeing assessment ($F(1, 471)=355,6$; $p<001$). There was a higher assessment of wellbeing in the first study at the beginning of pandemic than after four months of remote working during pandemic (x=16.52, SD=5.07; x=11.97, SD=5.06, respectively). Main effect of time of measurement at the level of tendency have been found in a number of complaints about discomfort and pain felt in different parts of body ($F(1, 471)=2.774$, $p=.096$). There was an increasing trend in a number of complaints on discomfort and pain from the first to the second measurement time (x=5.41, SD=1.75; x=5.50, SD=1.73, respectively). There was not found statistically significant difference between the first and the second measurement in sleep problems and physical health assessment in the groups of participants.

The limitation of this study is too small amount of men when compared to women in the studied groups. There is a high relevance to the subject of Congress theme because working remotely may create new work stressors, which may increase a risk for health and wellbeing of the workers, especially when they work remotely for long periods.

Practical implications of the research findings is drawing attention to hazards of working remotely and a need for monitoring wellbeing of remote workers and when necessary undertaking actions

aimed at improvement of well-being of remote workers. By indicating these this presentation contributes to SDGs (Good health and wellbeing).

A week-level study examining the mediating role of mood regulation in the relationship between work-related perseverative thinking and work performanc

Abbas Firoozabadi, Ferdowsi University of Mashhad; Fred Zijlstra & Sjir Uitdewilligen | Maastricht University

science

In this study, we investigated how two types of work-related perseverative thinking (i.e. affective rumination and problem-solving pondering) during the weekend are related to job performance-related outcomes (i.e. compensatory effort and task performance) through their relationships with mood regulation in the workplace during the subsequent working week. Participants responded to weekly web-based surveys at the beginning (i.e. on Mondays) and at the end (i.e. on Fridays) on six consecutive working weeks. The data (N = 107; 490-568 week-level data points) were then analyzed using Multilevel Structural Equation Modeling (MSEM). The results revealed that affective rumination during the weekend was indirectly related to a higher level of compensatory effort and a lower level of task performance during the subsequent working week via its negative relationship with mood regulation. Problem-solving pondering was not significantly related to mood regulation, nor to compensatory effort and task performance at the within-person level. Testing a dynamic model of weekly fluctuations, the findings of this study provide empirical evidence to support that affective rumination has a stronger emotional straining effect than problem-solving pondering.

Keywords: weekend, recovery, rumination, problem-solving, mood regulation, job performance

Poster P184

Development of emotional exhaustion and secondary traumatic stress in healthcare workers during the second wave of COVID-19 in Spain.

Mercedes Hernandez Hurtado, PhD student at Universidad Autonoma de Madrid, Spain

science

Goals: Exploring job and personal demands and resources of healthcare workers that have influenced the development of emotional exhaustion (EE) and secondary traumatic stress (STS) during 2nd wave of pandemic in Spain.

Background: The Job Demands-Resources Model considers EE and STS in healthcare workers as the result of managing difficulties in a demanding stage (high workload, fear of contagion), and establishes that job and personal resources (hardiness and posttraumatic growth (PG)) could lessen negative psychological consequences. EE is experienced when emotional resources and the ability to cope with difficulties decrease, while STS combines symptoms derived from indirect exposure to others' trauma. Regarding resources, Hardiness involves a perception of control, commitment and challenge in stressful situations, while PG promotes succesful coping and includes 5 dimensions (relations, possibilities, strength, spirituality, appreciation of life). These variables are closely linked to COVID-19 evolution. The growth of patients increased workload and fear of contagion at overcrowded hospitals. This experience became traumatic for many professionals, and resulted in EE and STS.

Methodology: This is a cross-sectional study that evaluated 172 Spanish healthcare workers on job demands, lack of job resources, Hardiness, PG, EE and STS. Snowball sampling method was used and professionals were evaluated throughout December 2020 (2nd wave in Spain).

Results: Firstly, descriptive analyses reveal high level of job demands and Hardiness, and moderate levels of EE, STS, lack of job resources, and PG. Secondly, we calculated mean differences depending on job position, and observed that assistants have less access to job resources, but, at the same time, show higher PG. Finally, regression analyses suggest that EE is positively related to fear of contagion and negatively related to "relations" (PG), while STS is positively related to job demands, lack of resources and "apreciation of life" (PG).

Limitations: This is a cross-sectional study, so it is not possible to build a global picture of pandemic and its impact on healthcare workers. Moreover, the sample is not representative of men and certain job positions. Additionaly, social desirability could be present, due to self-report measures.

Implications: This research sheds light over PG and Hardiness as personal resources that could prevent from negative psychological consequences. "Relations" (PG) protects against EE. This highlights the importance of perceived social support on wellbeing. "Appreciation of life" is possitively associated with STS, and this involves that some dimensions of PG could be more useful than others when confronting hazardous situations. Hardiness does not work as a protective resource in this analysis, as psychological distance from the trauma could be neccesary to provide the experience a new meaning. These findings are meaningful for designing preventive programs based on the improvement of social networks at organizations, the provision of enough human and material resources, and the strengthening of psychological strategies to deal with challenging work demands.

Relevance to the Congress Theme: This study discusses issues associated to new competences that could be trained by professionals (contribution), provides solutions for the mental health crisis that has been derived from COVID-19 (urgency), and stresses changes for the improvement of working conditions (delivery).

Keywords: COVID-19, emotional exhaustion, secondary traumatic stress

Is remote working suitable for managers? The Study on Managers' attitudes toward working from home.

Grzegorz Kowalski & Katarzyna Ślebarska | Institute of Psychology, University of Silesia in Katowice

science&practice

Currently, job duties are massively transferred from in-person to remote working. Existing knowledge on remote working is mainly based on employees' assessment. However, the manager's perspective is crucial in organizations that turned into remote work for the first time facing sudden circumstances, i.e., SARS-CoV-2 pandemic. The main aim of the first measurement of this study was to analyze remote work effectiveness perceived by managers (N = 141) referring to three crucial aspects, i.e., manager, team, and external cooperation. We assumed the perceived benefits, limitations, and online working frequency as predictors of remote work effectiveness. Further, we analyzed the possible differences in remote work perception referring to different management levels (i.e., middle-level and lower-level). Our findings revealed a significant relationship between the benefits and effectiveness of managers and external cooperation, specifically among lower-level managers. Limitations, particularly technical and communication issues, predicted team and external cooperation effectiveness. The results showed remote work assessment as being socially diverse at the management level. In order to rule out the impact of pandemic stress and its effect on effectiveness, it is necessary to repeat the study after the epidemiological threat has ceased. If home-office information on a management level is available, and if a comparison during and after the coronavirus crisis is possible, we can learn whether COVID-19 has contributed to a substantial structural change. Without a doubt, remote work has become an inherent work system, and the challenge today is to maintain or indicate maximum efficiency.

Supporting the Next Generation of WO Psychologists: Evaluation of the 'Emerging Occ Psychs' Initiative

Simon Toms, Simon Gander, Eloise Mason, David Biggs, Hardeep Virdi, Nikita Mikhailov | PsychologyAtWork.Blog

practice

Occupational Psychology represents a popular field of study, with over two-dozen MSc courses in the UK alone. However, graduates frequently report difficulties in transitioning from their degree programmes into professional roles that are relevant to their qualifications.

The 'Emerging Occ Psychs' (EOP) initiative was launched in 2020 to provide mentoring and support to graduates of MSc programmes in Occupational Psychology (and related fields). The goal of the initiative was to increase graduates' engagement with their desired profession by pairing them with a mentor who possessed experience in relevant areas of the industry.

The current research project sought to evaluate the EOP's ability to increase the professional engagement of mentees taking part in the second cohort of the EOP, which ran from Autumn 2021 through to Summer 2022.

Research methodology

Prospective mentees were given a questionnaire that formed the basis of their application to the EOP initiative. In addition to asking questions relevant to their mentor pairing preferences, mentees were administered several variables relevant to their engagement with, and transition into, the occupational psychology industry. These variables included perceived employability (Berntson & Marklund, 2007), career planning confidence (McAuliffe, Jurgens, Pickering, Calliotte, Macera, & Zerwas, 2006), and self-esteem (Robins, Hendin, & Trzesniewski, 2001).

At the evaluation stage of the research nine months later, these variables were re-administered alongside additional questions relevant to the EOP's evaluation. This would enable the research to determine whether improvements between the application and evaluation questionnaire could be measured. Mentees were also offered the opportunity to complete an interview with the researcher about their experience of the EOP. This resulted in a longitudinal mixed-methods study.

Findings

The research concluded with 34 of the 104 applicants completing the evaluation questionnaire, six of which also completed a further interview to supplement their survey data. Analysis of the resulting data identified significant improvement across the majority of variables administered in the surveys. Mentees' perceived employability increased by 34.3%, Self Esteem increased by 24.0%, and Career Planning Confidence increased by 11.0%.

Thematic analysis of the interviews highlighted various themes of note. Greater professional engagement was reported by mentees, as the EOP enabled them to engage with a wider community of experienced professionals, peers, and potential employers. Improvements in perceived employability and networking were also cited. Benefits of mentoring included greater awareness of the industry and improvement to key skills relevant to career progression. Analyses highlighted various recommendations for the EOP organisers and future mentors.

Implications

The provision of mentoring had a clear and positive impact on various aspects relevant to mentees' engagement with the profession. This demonstrates the important role the EOP, or similar initiative, could play in facilitating the transition of fresh talent into the profession. This will also have clear relevance to the universities that offer MSc programmes, as transition into suitable employment is an important goal. Finally, the research provided some useful guidance for mentors interested in enhancing their effectiveness in supporting graduates.

Poster P187

Lost in translation: Expectations and employment among refugees and immigrants in the U.S. versus Spain. A replication study.

Vickie Coleman Gallagher, Eva Garrosa, Sorin Valcea, Laura Torio

science

Employment is a central resettlement factor for refugees in the United States (U.S.), in addition to needing to learn a new language. As noted by Baran, Valcea, Porter and Gallagher (2018), resettlement involves "a complex trajectory of expectations, adversity, turning points, and status changes". Underemployment, job dissatisfaction, and the like are work and life stressors. Based on Psychological Contract Theory, the results showed that refugees came to the U.S. with high expectations that didnt match the reality and they experienced underemployment, which resulted in lower life and job satisfaction (Baran et al., 2018). Low job satisfaction was a significant reason for many refugees to abandon the American dreamâ€ť and to wish to return home. Study variables included are: sociodemographic data, core self-evaluations, perseverance, underemployment, psychological contract, past U.S. perceptions, current U.S. perceptions, job and life satisfaction, and thoughts of returning home.

Since Baran et al., (2018) data was collected in 2016, there have been numerous changes: a different U.S. president, a decline in refugee resettlement after 2016, an increase in U.S resettlement since 2021, and a world-wide pandemic. As such, our study will replicate the findings in the U.S. (with the same variables), to compare the earlier findings with those of the refugee experience during these last few years. In addition, our study will be extended to Spain, in order to compare the differences in attitudes and feelings in both countries. Spain in particular is uniquely relevant to understanding the migration and refugee population due to Spains southern location and proximity to North Africa, as well as their historical relationship with Latin America. Other potential differences that may be observed between the U.S. and Spain may be due to variations in tolerance and cultural values, their health care systems, among other differences, that would subsequently alter perceptions of Psychological Contract breaches. For example, health care availability in Spain may contribute to higher perceptions of life satisfaction while job opportunities may be more prevalent in the U.S. leading to higher job satisfaction.

In addition to our conceptual considerations noted above, our goal is to obtain a larger sample of more than 100 refugees, with about half living in the U.S. and half living in Spain. We seek to collect the data during February and March of 2023. We currently have about 10 respondents and are seeking IRB approval to offer a gift card drawing incentive to increase the response rate. The previous study had a number of other limitations, such as an entirely male sample. We aim to acquire a more diverse sample in the U.S. and Spain, with a variety of countries of origin, a mix of males and females, etc.

Future research should supplement our survey with qualitative interviews, explore other countries of resettlement, and continue to explore diversity of sample in order to obtain deeper insights into our hypotheses and findings.

Plan for equality between women and men, adaptation of state law to the reality of a public hospital

Ruth Maria Martón Sobredo, Sabina Sales Reid; Hospital Universitario Son Espases (Balearic Islands, Spain)

science&practice

Objectives of the research :

The objectives are several:

to comply with a legal obligation at both European and national level on the implementation of equality plans in all companies.

To find out the real situation regarding equality in a specific environment.

To analyse how the situation affects the working environment and individual comfort.

To take measures to correct the inequalities detected in order to increase job satisfaction and, therefore, confidence in the company.

To achieve the natural integration of equality in the culture of the organisation as something positive for the mental health of the company and its employees.

To promote the feeling of belonging to the organisation as the employee feels identified with the institutional policy.

Theoretical background .

Inequality between men and women is an issue as old as mankind.

In the last century, the situation has become legally equal, but much more slowly at the organisational level, since socially and culturally women continue to take care of the family and the home, especially in the Mediterranean family environment, and the role of men in these tasks has not been sufficiently corrected to achieve a balance between the genders.

This is why it has become necessary to make laws that promote this cultural and business change to improve the mental and physical well-being of women workers by implementing measures that allow them to combine their tasks without stress and in an equitable way.

The data of the global gender gap report 2022 of the world economic forum shows that Spain is in 17th place in the world ranking in terms of gender GAP.

The 2030 agenda of the united nations includes in its No. 5 the importance of promoting gender policies from the institutions.

At the European level, the question has been promoted by legislating with the 2006 directive on the involvement of the principle of equal opportunities and equal treatment between men and women in matters of employment and occupation.

Subsequently, the European gender equality strategy 2020-2025 and Community action plans are being developed.

Design / Method / Intervention.

Based on the general guidelines set out in the state law, LO 3/2007, for the development of an equality plan in all companies in Spain, the Hospital has followed the following steps:

-Creation of a commission made up of social agents and members of the company and training them in the matter to work on the development of the plan:

Situation diagnosis was carried out with data broken down by gender:

-Professional classification

-Training

-Professional promotion

-Working conditions.

-Salary Audit

-Family reconciliation and work.

-Prevention of sexual and occupational harassment.

-Analysis of the results of the diagnosis and elaboration of an improvement action plan in areas where it is needed.

Follow-up and evaluation.

Results.

Corrective actions put in place:

- Training courses on equality with a positive impact on a personal level and also on a work level as they are taken into account for promotion in the company.

- Facilities for work-life balance and professional promotion with very good results in terms of workers' well-being.

-Surveys on the perception of the situation and expectations regarding equality in the company.

-Creation of an internal forum for employee contributions to the equality plan.

-Implementation of a harassment protocol, the application of which has proved to be ideal for the cases to be dealt with.

Conclusions: Value

An equality plan can be an instrument that allows: balance and improve the work conditions, build sustainability and impact on community as a part of the Institutional Social Responsibility.

Include gender perspective in every hospital area.

Create a data system that allows having an accurate image of gender situation.

Improve the well-being of the worker who sees increased confidence in the institution, thus improving their productivity and motivating their sense of belonging.

Keywords: Gender equality, balance and working conditions, Institutional Social Responsibility

Poster P192

Is job crafting able to build up our mental health? Validation of the job crafting scale

Kristýna Cetkovská, Ivana Šípová | Charles University

science

Research goals and why the work was worth doing

My conference contribution presents a validation of the job crafting scale on the Czech population. The ultimate aim of this project is to explore job crafting behaviour in the Czech working population together with mental health factors and to validate the existing job crafting scale. This validation has never been conducted on such national population before which places the project into a key role of raising the awareness of the job crafting concept in the field of Czech research and further.

Theoretical background

There are many facets out there aiming to strengthen our mental health. However, few of them can be directly placed in our working environment and especially the working behaviour. Wrzesniewski and Dutton (2001) introduced a concept called job crafting. Job crafting can be defined as " the physical and cognitive changes individuals make in the task or relational boundaries of their work." (Wrzesniewski & Dutton, 2001). In other words, a job crafter is an employee who proactively shapes his work activities or relationships into the form where he feels good and satisfactory. This concept shows thus positive corelation with work engagement (Frederick & VanderWeele, 2020) and also has extended the original Job Demands-Resources Model (Demerouti, Bakker & Xanthopoulou, 2017). It is undoubtedly a complex phenomenon, nevertheless, job crafting has ultimately the potential to strengthen our mental health at work, as well as anywhere else (Boehnlein & Baum, 2018). In order to examine job crafting behaviour, Tims, Bakker and Derks (2011) developed and validated job crafting scale. This measuring instrument laid the basis for our project where we focus on the Czech population. The Czech Republic belongs among post-communist countries and the population have tendency to maintain rigid and punctual (work) behaviour (Hofstede Insights, 2022) which puts this project into an interesting perspective.

Methodology

Quantitative research design was implemented to explore the job crafting behaviour and mental health factors on the Czech population. The project starts with a scale translation and back-translation from English into the Czech language. Online survey has been chosen as a research method administrated via research agency in order to ensure representativeness of the study sample. The survey consists of job crafting scale, mental health continuum and Utrecht work engagement scale (UWES).

Expected results

The results are not available yet and will be compiled in early spring 2023. We hypothesize that mental health and work engagement is positively correlated with all four dimensions of job crafting scale (increasing social job resources, increasing structural job resources, increasing challenging job demands, and decreasing hindering job demands). The hypothesis will be tested using linear regression.

Limitations

Limitations of this study are mostly connected with limitations that surveys bring in general. Since we apply only quantitative design, we miss the contextual level of gathered data and can rely solely on respondent's answers at the time of administration.

Conclusions

The results would clarify job crafting tendencies and possible determination of employee's mental health. Furthermore, and more importantly, the project is another potential step to raise awareness of this phenomenon within the Czech environment. Since mental health at workplace is coming to the fore more and more, it is crucial to look for ways and instruments that would help to grasp this topic better.

Relevance to the congress theme

The project is in line with the congress theme since working behaviour of ours is very much in a transforming stage due to all (post-)pandemic consequences. The working behaviour together with mental health belongs among the most crucial topics that organizations currently deal with and will possibly deal in the future.

Keywords: Job crafting, mental health, Czech Republic

Poster P193

ASSOCIATIONS AMONG PATIENT EXPERIENCES, ORGANISATIONAL CLIMATE FACTORS AND PATIENT OUTCOMES: A SYSTEMATIC REVIEW

SETH ADDO, ESPEN OLSEN & REIDAR MYKLETUN | UNIVERSITY OF STAVANGER BUSINESS SCHOOL

science

Research goals: Patient experience is an essential indicator for assessing hospital performance. The increasing attention on patient experience has also yielded research on its relationships with patient outcomes as well as organisational factors. In previous reviews, it was concluded that evidence of associations between organisational climate and patient variables is inconclusive, indicating a need for more research. Considering the years that have elapsed, and the increasing attention on patient experience from researchers, there is the need for a systematic review to draw adequate conclusions on whether there has been some changes in the associations between these variables in the general body of literature. The overarching goal is to make a qualitative synthesis of studies among the variables to draw informed conclusions on the general directions and theoretical underpinnings.

Theoretical background: The review focuses on and defines three main concepts; organisational climate factors, patient experiences, and patient outcomes.

Methodology/Approach: The study involved a search for literature in PubMed, PsychINFO, Medline, CINAHL, Academic Search Premier, Scopus and Web of Science between 2007 and 2022. The search was limited to English language and to human adult inpatients. The search was also done with the guidance of a librarian. Articles were screened first on title and abstract, and then on fulltexts. Quality assessments such as risk of bias assessments were done on remaining articles. Data was extracted from articles that met the inclusion criteria and passed the checks. Any discrepancy during the study was addressed through discussions or engaging a neutral expert in systematic review. The review also focused on both foundational climates such as the broad workplace environment, and specific climates, such as safety climate and service climate. Patient outcomes that were sought included both subjective (eg. patient satisfaction) and objective (eg. accidents) outcomes.

Results: The search identified 11570 records that were checked for duplications. After removing duplicates, 7361 records were eligible for the two phases of screening. The eligibility criteria were used in selecting articles for inclusion. A final list of 224 articles were included for the qualitative synthesis. Similarities and differences were drawn on the variables and findings in the included studies and presented under five broad themes: variables and factors, overview of associations, group comparisons, forms of interventions, and theoretical overview. Results showed that the relationships among patient experiences, organisational climate factors and patient outcomes were more conclusive and generally positive rather than negative. The review however showed areas that required more attention such as an encompassing quality-oriented care climate theory, validation of patient-reported instruments, and longitudinal studies linking subjective patient outcomes to objective patient outcomes.

Limitations: The review limited its search to quantitative studies or studies that employed mainly quantitative tools to assess associations or changes. Secondly, only peer-reviewed articles were included in the review. Also, a clear distinction was made between some related concepts, for example, between organisational climate and organisational culture, where the latter was excluded.

Conclusions/Implications: First, there is the need for an encompassing theory or framework that captures the care climate in hospitals, taking cognizance the different perspectives of employees and

patients as well as the complexities and interrelationships among organisational factors and patient-related factors. Secondly, although most of the longitudinal studies also show positive influences of favourable organisational factors on patient variables, there is still the need for more studies on concrete changes and trends in the associations of these variables. More studies are also needed towards linking subjective patient outcomes or experiences to objective outcomes especially for longitudinal studies. Furthermore, there should be more best practice examples in improving the experiences and outcomes of patients by way of interventions based on reports from patients. This also means increased collaboration between researchers and hospitals to know actual issues that need intervention for improved patient experience. Lastly, there is the need for more studies to validate instruments that are used to gather periodic data on patient-reported variables to ensure that adequate and accurate data is always gathered from patients.

Originality: This review provides thorough evidence of conclusive relationships among the concepts across a 15-year span in research.

Relevance to the congress theme: This study sets the tone for future research that focuses on increased collaboration between hospital workers and researchers thereby influence how work is organised in hospitals.

Keywords: patient centeredness, hospital factors, systematic review

Poster P194

Sex Differences in the Hierarchy : An Experimental Study on Nonverbal Communication Behavior Adaptability.

Phebe Driebergen & Marianne Schmid Mast | HEC Lausanne

science

Our goal was to address gaps in the existing research on Behavioral Adaptability (BA), the ability to change one's verbal and nonverbal interpersonal behavior in a non-random way according to the needs and preferences of different interaction partners (Schmid Mast & Hall, 2018). Preliminary evidence suggests that individuals who adapt their interaction style have better interaction outcomes and most of the results emerged for nonverbal BA. Existing studies have only investigated BA display in people of high-power and it is not clear whether previous results are specific to people of high-power or if BA display is related to power at all . We would expect that low-power individuals would be more likely to display BA when interacting with high-power individuals than vice versa based on the Social Distance Theory of Power (Magee & Smith, 2013) and Communication Accommodation Theory (Giles et al., 1988). We also explored if self-reported sex or sex of the interaction partner affects the link between an individual's power position and BA.

To assess BA, 4 interaction targets were chosen based on their previous pretested (fast or slow) articulation rates. In this online study, participants were asked to imagine taking part in a hypothetical values workshop to help establish the core values of their organization and were given a description of their role and an organizational chart that showed their position as well as the interaction targets position in the company. Participants made a baseline audio recording where they talked about their 3 most important values and then listened and responded to the interaction targets sharing their top 3 values resulting in 12 recordings per participant. The 306 participants (49% women) were recruited via Prolific and were randomly assigned to one of the 3 experimental conditions following a 3 (power level: low, equal, high) by 2 (target gender: women vs. men) between-subject design. BA was operationalized as the extent to which participants adapted their articulation rate to each of the targets' articulation rates.

Mixed-effects modeling showed that power, as such, did not affect BA display. However, self-reported sex did, as women showed more BA than men. Women were equally likely to display BA towards both female and male targets. Men showed similar amounts of BA when interacting with male targets and with high-power female targets but showed significantly less BA towards low-power or equal-power female targets.

Social Role Theory (Eagly, 1987) can explain the gender differences we found, which suggests that women would be more socialized to display BA compared to men. We suspect that men's BA display might be more status driven and are thus less motivated to display BA towards female targets except if they are explicitly described as high status. While the power manipulation was effective, future studies could manipulate "real" power and use an experimental design that allows for real-time exchanges. BA operationalization could be expanded to include more than one nonverbal channel.

This study focuses on interpersonal communicative behavior within hierarchical interactions and advances our understanding of how people interact in organizational settings. Moreover, this is additionally relevant to the "the future is now" theme and the "Partnerships for the goals" UN SDG as it investigates BA, an interpersonal skill that affects various interaction outcomes such as collaboration.

Keywords: Behavioral Adaptability, Interpersonal Communication, Hierarchical Relations

Poster P195

Intention to Leave and Commitment to the Legal Profession: What Future for Canadian Lawyers?

Eveline Morin, Martine Gingues, Jean Cadieux & Nathalie Cadieux | Université de Sherbrooke

science

Research goals. This study assesses whether professional commitment mediates the relationship between job demands/job resources and intention to leave the profession.

Theoretical background. Canada's aging population has created a labour shortage, and as a result, retention has become an issue. A key lever for retention is workplace health and wellbeing. Unfortunately, some professionals are particularly affected by mental health issues, including lawyers (Krill et al., 2016; Skead et al., 2018). One study found that 59.4% of Canadian jurists experience psychological distress (Cadieux et al., 2022). Yet, the literature has shown that mental health influences work attitudes such as professional commitment and intention to leave the profession (e.g., Chênevert et al., 2021). Again, according to Cadieux et al. (2022), 54.2% of jurists stated that they would be inclined to accept another occupation at the same remuneration level if an opportunity were offered to them. Many factors can influence intention to leave, including working conditions. Since the human being is a multifactorial whole whose reality cannot be explained by a simple stimulus-response model, it also seems relevant to consider the mediating role of professional commitment, which is an important predictor of the intention to leave the profession (Lee et al., 2000). Professional turnover has important consequences for society and for the profession itself, particularly in terms of the loss of skills (Parry, 2008). When voluntary professional turnover and intention to leave are high, they may be a symptom of a profession in poor shape. Studying intent to leave is essential to 1) understanding how to ensure a happy and fulfilled professional succession and 2) retaining experienced professionals who can be a lever for knowledge transfer.

Methodology. Data were collected via a self-reported questionnaire. A pre-test with 29 English and 35 French speakers was conducted to validate the measurement scales. The final sample was composed of 2,352 lawyers, 29.63% of whom were men. The average age was 40.44 years. To test the mediation, hierarchical multiple regressions (Baron & Kenny, 1986) were conducted along with bootstrap analyses (Hayes & Little, 2018; Preacher & Hayes, 2008) to increase the reliability of the results.

Results. Data analysis is not yet finalized. Preliminary results suggest that professional commitment mediates the relationship between several job demands and resources (i.e., workplace incivility, decision authority, skill utilization, and support from colleagues) and intention to leave the profession.

Limitations. Results should be interpreted with caution since the data are from a cross-sectional research design.

Conclusion. Few studies have examined the indirect effect of working conditions on intention to leave the profession. This study provides food for thought for professional associations that wish to ensure the outreach and sustainability of their profession.

Relevance to the Congress Theme. The study highlights the need to think collectively about how to change workplaces so that they become healthy and adapted to the next generation of professionals. Without this enthusiastic and motivated succession, the future is at risk.

Relevant UN SDGs. The research encourages organizations to change their practices and implement working conditions that are more beneficial to mental health and wellness.

Keywords: Intention to leave the profession, professional commitment, lawyers

Individual resistance to organisational change and practical implications

Ezequiel Frydman, Erasmus Mundus Joint Master Degree (EMJMD) in Work, Organizational and Personnel Psychology - Universitat de Barcelona; Antonio Luiz Marques, Erasmus Mundus Joint Master Degree (EMJMD) in Work, Organizational and Personnel Psychology - Universitat de Barcelona

science

Research goals and why the work was worth doing: Constant change in the world of work makes transformation a fundamental part of organisational life and long-term success. In this sense, individual resistance to change is an inherent part of transformations and an important source of information that can be used to improve these processes. Thus, this study seeks for the most important sources of resistance in different types of transformations in order to suggest evidence-based practices that can improve organisational change.

Theoretical background: In order to understand the phenomenon of organisational change more precisely, this case study distinguishes between changes that focus on processes, those that are structural and those that pursue cultural change. In terms of the sources of resistance to organisational change, individual variables such as the degree of understanding of organisational change are analysed. At the same time, the world of work is facing the oldest workforce in history and little research has been done on the influence of age and seniority on resistance to change. While some of the literature says that older generations are more resilient, others claim that organisations are acting biased against older age groups. This is why age and seniority are analysed as individual variables. Group variables are also included in relation to social life and peer pressure in work teams, and organisational variables linked to leadership style and previous organisational changes.

Design/Methodology: The study has a cross-sectional design that evaluates the relation between indecision and inconclusiveness, threat to social life at work, group pressure, organisational inconsistency and previous experience with unsuccessful change with individual resistance to organisational change. Age and seniority were studied as independent and moderating variables. All 96 participants experienced changes in the organisation where they worked in the last 5 years.

Results obtained: The sample analysed perceived high levels of cooperation in general terms. However, individual indecision and inconclusiveness and organisational inconsistency emerged as the strongest correlations with individual resistance. As for age and seniority, it is important to highlight that there is neither a statistically significant direct correlation nor a significant moderation.

Limitations: This study uses a cross-sectional design and the sample size could be bigger.

Conclusions and practical implications: This investigation details how to take forward evidence-based practices to address the variables most correlated with individual resistance to organisational change. These include improving communication in organizations, increasing organisational consistency and implementing active employee participation plans.

Relevance to the Congress Theme: It is understood that there is a call to action that is now. In this sense, this research makes it possible to link the scientific literature with different interventions for action at the workplace level.

Relevant SDGs: In a world pursuing decent work and economic growth, organisations cannot forget the worker as a key player. Continuous changes are implemented to increase productivity, apply new technologies and innovate and this is why this research seeks to promote development-oriented policies that focus on the well-being and continuous growth not only of organisations, but also of the people who make them up.

Ethnography of the activity: the case of a transport company in fear of loss of knowledge

Cassandre Seyve, GRePS, Sabrina Rouat, Bruno Cuvillier

science&practice

Following World War II, some European countries experienced a rapid increase in their birth rate. This is called a “baby boom”. The massive retirement of an entire generation represents a considerable challenge in terms of the transmission of knowledge. These departures are being more complex due to the changing world of work that organizations are experiencing, such as premature resignations, increased competition or the scarcity of labour, etc. Nevertheless, this transmission experiences a paradox: despite the risk of loss of knowledge which could jeopardize the performance, occupational health and sustainability of companies; current working conditions contribute to the reduction of discussion times and the destruction of the collectives on which this transmission is based (Thébault & al. 2014).

Moreover, the process by which new members must learn to see the organizational world as the more experienced ones do is called organizational socialization. Even if it represents an important theoretical resource for the transmission of experiential knowledge, we think that it does not sufficiently develop the concrete activity of workers. Thus, in activity analysis, we retain two relevant approaches. The first one is professional didactics, which made it possible to demonstrate the formative power of the activity (Pastré, 2002). And the second one is the clinic of activity, which aims to understand real work (Clot, 2008). These approaches complement each other, but we think that they don’t develop enough one of the purposes of the transmission of knowledge, its appropriation.

Therefore, the present communication aims to study a phenomenon made more complex by changes in work, the transmission and appropriation of experiential knowledge. This work proposes an approach that focuses on the reality of the individuals’ activity, but which also and above all tries to combine knowledge development and organizational development through the clinic of activity.

To study this, our methodology is divided threefold, and takes place within our thesis field, namely a temperature-controlled road freight transport company. First of all, the first axis concerns the ethnography of the activity that we carried out for five months. We deep dived into a work situation, conducted interviews and observed for long periods of time. The objective was to understand the activity of managers and employees, to understand their expectations and to analyze their demand. The second axis relates to the realization of nine focus groups carried out on the nine subsidiaries in our scope. By means of a simulation of the activity, the objective is to identify the work situations that are problematic and those that are self-evident in the daily lives of workers. We will also seek to identify each of the strategies implemented by workers during a working day. Our third axis originates from these analyses. Indeed, based on the situations identified in the previous step, we will go into a work situation to set up simple and cross self-confrontations on a pilot subsidiary. Thus, the ultimate goal is to optimize the current training processes before the retirement of workers.

We have not yet obtained results during our study, but our methodology is in progress and will be finished in April 2023. Therefore, we will have the results at the time of the congress. Ultimately, we believe that our subject is aligned to the theme of the congress. Indeed, our thesis work studies one of the consequences of changes in work, the transmission of knowledge from experience. Our work aims to try to limit the harmful consequences that companies could experience following the loss of their experienced staff. We seek to promote a healthy future to ensure the competitiveness of companies, but also the increase in the individual and collective skills of workers.

The main and original contributions of our research are the association of the ethnography of activity and the clinic of activity to support a process favorable to the transmission of knowledge in the professional environment; and the participatory approach by associating the actors in the field to guarantee the sustainability of the action.

Keywords: Activity; transmission of knowledge; clinic of activity

Poster P204

The impact of a brief gratitude intervention on the cardiovascular response to an acute laboratory-stressor.

Brian Leavy, Maynooth University

science

Research goals and value

Health is an important resource at the individual, organizational and societal level (Cartwright & Cooper, 2014). Research indicates that work-related stress can lead to poor health outcomes (Li et al., 2016; Rose et al., 2017). Gratitude interventions have been explored as low-cost well-being interventions which have been shown to reduce work-related stress (Cheng et al., 2015). A review has identified work-related stress as a significant predictor of cardiovascular disease (Kivimäki & Kawachi, 2015). Some studies have estimated that cardiovascular diseases costs $127 billion dollars per year in lost productivity. Furthermore, a recent survey of employers in the UK identified work-related stress as the main health concern among staff (Tu, Maguire & Shanmugarasa, 2021).

Research suggests that gratitude interventions have the potential to improve cardiovascular health outcomes (Cousin et al., 2021). Building on this, recent research has examined gratitude may act as a possible buffer to the development of cardiovascular disease (Ginty et al., 2020). This research extends this and utilises a randomized-control trial design to explore how gratitude impacts the cardiovascular response to acute psychological stress.

Theoretical background

The magnitude of the cardiovascular response to stress is typically labelled cardiovascular reactivity. Increased reactivity been associated with negative health outcomes such as coronary heath disease mortality and myocardial infarction (Carroll et al., 2012; Phillips & Hughes, 2011; Yuenyongchaiwat, 2015). Recent research has shown how gratitude has an inverse relationship with reactivity, implying gratitude to play an important role in buffering the effects of stress on cardiovascular stress. (Gallagher et al., 2020; Ginty et al., 2020).

Gratitude's apparent cardio-protective effects are consistent with the broaden-and-build model of positive emotions (Fredrickson, 2001), which postulates that positive emotions like gratitude broaden the repertoire of thoughts, actions, and attention (Le Nguyen & Fredrickson, 2018). This is also coherent with the stress-appraisal theory of stress which posits that one's internal resources are important influences on how one copes with stress (Folkman, 2008). For example, gratitude expressions are correlated with coping actions such as reappraisal (Bryan et al., 2018), as well as planning and goal-directed strategies which reduce the frequency and intensity of stress (Wood et al., 2007).

As such, it is unsurprising that gratitude's effect on stress has been proposed as a potential mechanism by which gratitude impacts cardiovascular health (Gallagher et al., 2020).

Method

This research uses an experimental design to examine how a short gratitude intervention impacts the cardiovascular response to stress in a laboratory stress-task. 128 healthy young adults underwent a standardised stress-testing protocol. Blood pressure and heart rate were measured throughout. This incorporated a 20-minute acclimization period, 10-minute baseline, 8-minute intervention, and a

12-minute stress period. The experimental intervention included writing a gratitude letter where the participant thanked someone in their life they had not thanked before. The control intervention included describing the laboratory in which the study was carried out. The stress tasks included both a mental arithmetic task and a public speaking task. This was followed by a 10-minute recovery period.

Results

Results will be analysed using a multi-level growth curve modelling approach. While data-collection will be fully completed in November 2022, it is expected that the gratitude intervention will decrease the cardiovascular response to stress for systolic blood pressure, diastolic blood pressure and heart rate.

Research implications/Limitations

This study will help further elucidate the effects that gratitude have on the cardiovascular response to stress. This will further help inform practitioners, both in a workplace and clinical context, as the value of short gratitude interventions for physical health. While this study takes place in a laboratory setting, which has the advantage of being very well-controlled, it would be beneficial to explore this relationship using an employee sample in a workplace context.

Novelty

To our knowledge, is the first study to examine the impact of gratitude on the cardiovascular response to stress in a randomised control trial context.

Relevance to the congress theme

With the American Heart Association suggesting that the burden of cardiovascular disease is set to triple by 2030 (Heidenreich et al., 2011), exploring how low-cost workplace well-being interventions can improve cardiovascular health is will be important in the years to come.

This study has been funded by the BIAL foundation.

Keywords: Gratitude, health, well-being

Distant learning for leadership training: A systematic review of theoretical foundations, design, and evaluations of web-based leadership training

JOSÉ MARÍA PEIRÓ SILLA, IDOCAL- UNIVERSITAT DE VALENCIA & IVIE-INSTITUTO VALENCIANO DE INVESTIGACIONES ECONÓMICAS; NURIA TORDERA SANTAMATILDE & ALEXANDRA PUENTES SUÁREZ | IDOCAL- UNIVERSITAT DE VALENCIA

science&practice

Research objective.

The development of digital and digitalized competencies has become a central issue in many organizations, and especially for leadership positions (Peiró & Martinez-Tur, in press). The rapid technological advances offer a wide variety of alternatives for leadership training in companies, that might replace or support the traditional methods of training delivery with more practical and cost-effective approaches (Kim et al. 2018; Bosman et al., 2019). The evidence provided by previous systematic reviews and meta-analyses on leadership training (Avolio et al., 2009; Lacerenza, et al., 2020), has shown that, in general terms, leadership training and development interventions have been successful in improving leadership in organizations. This research also points out differences in the results achieved depending on the theoretical basis of the interventions, the characteristics of design and delivery of the training, and the type of outcomes considered to evaluate the programs. However, these studies have not specifically addressed leadership development web-based training and its impact on organizational outcomes. Taking into account the exponential increase of web-based programs for leadership development, it is peremptory to address this issue. In the present work, we develop a systematic review aimed to identify the challenges in the design, implementation and/or evaluation of web-based training programs for leadership development.

Theoretical background.

We consider the Kirkpatrick (1994) four-level training evaluation model to analyze the extent to which each of the programs reported significant impacts on reactions to training, learning, transfer, and organizational outcomes. In accordance with Kraiger, et al. (1993), we also consider the multidimensional nature of learning, attending to cognitive, affective, and skills capacities.

Methodology.

This review focuses on the analysis of empirical articles and doctoral theses published in PsycInfo, Scopus, Proquest, Web of Science, ERIC and Google Scholar databases, during the years 2000 - 2022, following the PRISMA methodology. In our preliminary search we found eight articles that present online or web-based leadership training programs. We plan to keep on refining the search in the forthcoming months. The analysis of the information is done with the NVivo software. The systematic review focuses in analyzing topics such as: aims of the study, characteristics of the sample and work setting, the theoretical foundations of the program, research design and results, and evaluation methods used.

Results.

The preliminary results show that out of the eight articles analyzed, four ground the training programs on experiential learning theory, one on constructivism, and another on the principles of behavioral learning; Two do not explain the basis of the learning theory. In terms of training design, two of the studies have a practical part (with equipment) and a web-based training part, two use

simulation games, and the other four rely on training platforms. The evaluation is carried out through questionnaires, two studies apply measures before and after training, and two studies use interviews to learn about the participants' experience. Additional analysis will focus on the extent to which each of the training programs contributed to learning, transfer, and results in the organizational settings.

Limitations.

There is little published evidence on leadership training based on the web or app, proportional to the online programs that already exist; very few report their evaluations in research.

Conclusion.

Rapid technological advances offer a wide variety of alternatives for training leaders through online education. So far, the systematic review shows that research in this area needs to develop further efforts in the analysis of the effectiveness and efficiency of those programs.

Relevance to the theme of the congress.

This review allows for presenting conclusions so that organizations recognize what changes and adaptations are necessary for the training processes mediated by information and communication technologies.

Relevance for the SDGs.

The review is framed in the SDGs: Decent Work and Economic Growth, and Quality Education. It allows organizations to support decision-making for the design and development of leadership training processes, making use of technological innovation.

Keywords: systematic review, leadership training, training evaluation

Poster P207

“There once on a ship…”. The quality of life onboard among Italian seafarers

Francesco Buscema, University of Turin; Clarissa Cricenti, University of Rome Sapienza; Lara Colombo, University of Turin

science

Research goal and why the work was worth doing

This study analyses psychosocial risks in Italian seafarers during their time on board and ashore, using an online questionnaire based on the Job Demands-Resources Model (JD-R) (Bakker & Demerouti, 2007). The JD-R is an occupational stress model that suggests burnout is a response to an imbalance between job demands and job resources. The purpose of this study is to identify the predictors of burnout using a hierarchical regression model. Since there are few studies that focus on the quality of life of seafarers Carter, 2005; De La Campa Portela & Pérez, 2016; Mellbye & Carter, 2017)., this study is an interesting contribution that fills this gap.

Theoretical background

The literature describes seafaring as a high-risk occupation for physical and mental health (Brooks & Greenberg, 2022; Oldenburg et al., 2010). During their careers, seafarers often face serious events that can impact the quality of life on board (Jensen & Oldenburg, 2019). In addition, the workload on board is very high, intensified by forced cohabitation over a long period of time and distance from family.

Design/Methodology/Approach/Intervention

An online tailor-made questionnaire that investigated job demand, job and personal resources related to life on board was sent to a random sample. The questionnaire collected: sociodemographic and occupational characteristics, job demands (workload, cognitive demands, negative work environment, physical characteristics of the work environment), job resources (quality of work, social support), and personal resources (humour at work, resilience, recovery). The data refer to 213 participants (91.5% male, 39.9 years old, all Italian). The research design, data collection procedure, and confidentiality were approved by the Bioethics Committee of the University of Turin.

Results obtained or expected (if not available, it must be made clear when they will be)

The results (IBM SPSS V.28.0.1.1.) of the hierarchical regression model (Adj-R 2 =.442, F=13.91, p=.001) are interesting: among job demands, workload and negative work environment increase burnout; among job resources, social support and quality of work decrease burnout; among personal resources, resilience decreases burnout.

Limitations

Limitations of this study relate to participants' confidence in privacy and willingness to cooperate in the distribution of the questionnaire. In addition, this is a cross-sectional study that cannot show causality between variables.

Conclusions – research and or practical implications/Originality/Value

The results of this study are partial because the administration of the questionnaire is still in progress. However, the initial results of the study are interesting: regression was used to determine which demands and resources are likely to impact seafarer burnout. The results show the importance

of intervening in workload, quality of the work environment, relationships, and the individual's ability to adapt to job demands and the work environment.

Relevance to the Congress Theme

This study aims to break new ground in research on the maritime industry, focusing on the health of seafarers in the workplace. The goal is to spread the word about the importance of wellness in the maritime sector by networking with companies and unions.

Keywords: Seafarers, psychosocial risks

Poster P208

Developing systems and services for the digital transformation of SMEs, public sector, and professionals: The DANTE Project

Patrik Pluchino, Human Inspired Technologies (HIT) Research Centre - Department of General Psychology - University of Padova; Pietro Aldo Siciliano, Institute for Microelectronics and Microsystems (IMM-CNR); Marcello Dorian Donzella, National Technological Cluster on "Smart Living Technologies" (SMILE)

science&practice

Currently, social and demographic modifications in our society brought into evidence the need for an overall digital transformation for organizations in the industrial and public sectors and at the individual level for professionals. The Covid-19 pandemic exacerbated the situation requiring rapid countermeasures linked to the innovation of digital systems/infrastructures and services to make them more resilient, accessible, and inclusive. These actions aim at improving people's quality of private and working life in all living environments, especially for the elderly and people with disabilities.

DANTE project is a European Digital Innovation Hub (EDIH) with the primary objective of supporting and fostering the digital transition for Small and Medium Enterprises (SMEs), Public Organizations, and professionals in the domain of healthy and active aging, Ambient Assisted Living, and Intelligent environments. On the one hand, the project will adopt a user-centered approach to design and develop digital-based tools and services to support the elderly and people with disabilities in their daily activities. It will provide professional and non-professional caregivers with digital knowledge, skills, and instruments to speed up the care processes and improve the quality of the Health System services, e.g., increasing the de-hospitalization and ameliorating the patients' diagnosis and treatment. On the other hand, the project will work on supporting the connections between the health and social policies of the Public Administration at the regional, national, and European levels and the citizenship, professionals, and companies in the domain of healthy and active aging in smart and sustainable environments. DANTE will work to fill the digital knowledge gap and boost the ability of professionals and organizations to implement digital innovations also based on increased collaboration among relevant players across Europe. One of the main strengths of the project is providing the stakeholders with the opportunity of trying its advanced digital services (e.g., test-before-invest solutions, based and advanced "skills and training" programs, etc.) and living labs equipped with cutting-edge and emerging technologies.

Keywords: Digital Transformation, Advanced tools and services, Innovation

Ongoing research: Does mobile phone behavior in social contexts at work have implications for the psychosocial work environment?

Sara Thomée, PhD, Department of Psychology, University of Gothenburg, Gothenburg, Sweden; Maria Spante, PhD, School of Business, Economics and IT, Division of Informatics, University West, Trollhättan, Sweden; Per Martinsson, MSc, Department of Psychology, University of Gothenburg, Gothenburg, Sweden

science

Research goals

Phubbing (from phone and snubbing) is the phenomenon of interacting with one's smartphone rather than with physically present persons. The research project explores the occurrence of phubbing in social contexts at workplaces, e.g., in the breakrooms, and how phubbing at work is perceived on different levels in the organization. Further, the project examines if phubbing at work is associated with psychosocial factors such as organizational commitment and social support, including stress, and whether phubbing at work is an issue that needs to be addressed.

Why the work is worth doing

In pilot interviews with safety representatives in the electrical trade, concerns were raised that preoccupation with smartphones in the breakrooms contributed to reduced social communication among co-workers, impaired communication about work tasks, less commitment to work, and reduced access to social support. These are factors that by extension may have significance for occupational safety and health, occupational learning, productivity, and turnover. Only few studies have examined phubbing at work and its potential implications.

The research project Phubbing at work: A study of mobile phone behavior in social contexts at work and associations with the psychosocial work environment is granted by the Swedish Research Council for Health, Working Life and Welfare.

Theoretical background

The smartphone promotes multitasking and makes it easy to be mentally elsewhere or in communication with others rather than where one physically is. This means changed behaviors also in traditionally social contexts at work. Breaks at work gives an opportunity to recover, but also to chat and socialize with co-workers – a social exchange that seems to be positive for developing collegial cohesion and trust and facilitates access to collegial social support. On the other hand, studies have shown that being exposed to phubbing, i.e., being ignored because the other is preoccupied with their smartphone, is associated with feelings of exclusion and an experience of lower quality communication and relationship. In work life context, employees who were “phubbed” by their managers reported lower work engagement and trust (Roberts & David 2017; 2020).

Methodology

The project is partly exploratory and combines qualitative and quantitative methods.

Ongoing studies:

1) Exploratory survey study in 4 workplaces in the electrical trade and 4 in health care and dentistry, including a pilot study in various occupations (n=320). Maps mobile phone behaviors during the workday, policies regarding phone use, and psychosocial factors at work.

2) Qualitative interview study with electricians and health care and dentistry workers (n=25). Maps phone behaviors in social contexts at work and explores perceptions about these behaviors, causes and consequences, and norms and policies.

3) Qualitative interview study with managers and HR in the above trades (n=approx. 25). Explores the organizational and managerial perspective on mobile phone behavior at the workplace.

4) Cross-sectional survey to members of the Swedish Electrical worker union (n=800). Maps phone behaviors in social contexts at work and examines associations with psychosocial factors.

5) Longitudinal survey study in a representative sample of the Swedish working population (n=approx. 750 at T2). Examines associations between phubbing in the breakrooms and psychosocial factors including stress and need for recovery, at baseline and after 6 months.

Results

Preliminary results from ongoing studies:

Study 1) A scale for phubbing at work has been developed and tested.

Study 2) Phubbing occurs at work and can be seen to be age-related, a means of escape, and a potential obstacle for social exhange and productivity.

Study 3) Managers and HR seem to identify co-worker phubbing more as a matter of individual misconduct than an organizational climate issue.

Study 4) Preliminary analyses shows associations between levels of perceived phubbing and psychosocial factors at work.

Study 5) is currently being launched. Preliminary results from the baseline survey can be presented at the conference.

Limitations

Studies 1-4 are in mainly two trades. Survey methodology can raise questions about validity and reliability of measures. Low response rates can lead to participation bias and decreased generalizabilty.

Conclusions/Discussion/Implications

This is an ongoing research project. Preliminary results indicate that mobile phone behaviors such as ”phubbing” in social contexts at work may have implications for the psychosocial work environment. Varying norms seem to be at play and could be a relevant topic for discussions at the workplace.

Relevance to the Conference Theme

Smartphones are part of the changing world of work and imply changed behaviors in social contexts at the workplace. Mobile phone behaviors such as phubbing and its potential implications for the psychosocial work environment is a contempory issue.

Keywords: smartphones, psychosocial work environment, mixed methods

Poster P214

The future of Work after COVID-19: qualitative and quantitative analysis

Andrea Fontes, ISCTE

science&practice

Research goals

This research intended to investigate the impacts of confinement on job satisfaction and work life balance and the future perspectives of work.

Theoretical background

The pandemic forced many companies to adopt new work methods and come up with more flexible work arrangements, such as working from home. Recent research about the impact of COVID-19 on Job satisfaction and Work Life Balance (WLB) evidenced the reduction of boundaries between life and work (Anwer, 2020; Schieman et al., 2021). Additionally, research have shown that women were more affected in their WLB during this pandemic and still bearing the burden of "hildrearing and household labor in industrialized countries" (Hjálmsdóttir & Bjarnadóttir, 2020; p. 2)

In a different perspective, a crisis can be seen as a turning point and an opportunity for new development and reflection has proved to be a good tool to face pessimism with (Jacobsen, 2006). Based on the goal setting theory (Locke & Latham, 1990), goal establishment imply a motivational impulse, that stimulates the identification of cognitive strategies towards goal attainment (Fontes & Dello Russo, 2020; Seijts & Latham, 2005). Our study intended to investigate:

RQ1: What reflections are reported during the confinement period regarding the professional context?

RQ2: Where does the work life balance topic stand within the objectives defined as a result of reflections made during the confinement?

H1: Do Job Satisfaction and WLB present significant differences during the locked down, when compared to the period before the lockdown.

H2: The differences between job satisfaction and work-life balance before and during confinement are moderated by remote work and demographic variables (gender, number and age of children)

H3: The differences found in job satisfaction and work-life balance, before and during confinement are moderated by reflection about the future (those who reflect about their future goals will present a higher Job Satisfaction and WLB in comparison to those who don´t reflect)

Method

Data was collected during May 2020) via Linked. A total of 260 participants started the questionnaire and 171 fully completed it.

Qualitative data: With an open question, participants were asked to reflect on the impact the pandemic was having on how they viewed their life (personal, family, social, and work).

Quantitative data: A second semi-open question was presented: "Thinking about a post-epidemic scenario, do you intend to change any of your behaviors? A list of areas was displayed.

Job satisfaction and WLB scales were asked to be evaluated in two moments:

1)how they recall it before the pandemic and 2) at the present moment?

Results

RQ1: Looking into the reflections during confinement we found that the majority has a positive nature. Improved WLF and competences development were the most mentioned.

RQ2: Work Life balance goals are the main change participants intend to implement.

H1: Job satisfaction presented significant differences during vs before locked down and WLB presents nearly significant differences.

H2: Remote work attenuates the decrease of job satisfaction during the pandemic but does not have the same significant effect in WLB. Gender evidence a nearly significant effect in the evolution of WLB.

H3: Goal setting for future changes moderates the negative effects of the pandemic in both job satisfaction and work life balance. Gender also works as a moderator together with the goal setting in the case of work life balance.

Our findings evidenced that remote work positively contributes to job satisfaction and women seem to be taking more advantage of the current situation, increasing their work life balance.

The main outcome is related with the reflection and goal setting process, that eventhough not necessary work related contributes positively for job satisfaction and work life balance, working as a buffer for the pandemic effects.

Limitations and Future Studies

Longitudinal analysis would be necessary to access the maintenance of the results over time. The use of a reflection scale should allow for more robust analysis.

Practical Implications

For companies to build a more satisfied workforce they need to, first, listen to their employees and assess what best suits their needs in terms of work-life balance and second, they should invest in developing their employees' positive focus in the future.

Originality/Value

This study does more than measuring the effects of the pandemic, it takes a step further to assess future intentions of employees after the confinement. And we consider this to be powerful information that companies need to be made aware of.

Keywords: work-life balance, reflection, job satisfaction

Poster P218

The effect of leader's transgression for the procrastination and anxiety of employee's: the role of psychological safety

Milena Gojny-Zbierowska, University of Economics

science

The research goals:

The two years of the Covid-19 pandemic resulted in deterioration of the mental health and increased anxiety. On the other hand we live in a VAST World that requires to be daring, fast-acting and responsive, which is the opposite of procrastinating and being anxious. In an attempt to reduce anxiety and procrastination we look at the its determinants. The purpose of the paper is to investigate the direct effect of leader's transgression on follower's procrastination and anxiety as well as indirect effect mediated by the psychological safety.

Theoretical background:

Current research indicates an increase in mental health issues such as anxiety disorder, depression, post-traumatic stress disorder and psychological distress, which are caused by increased fear, and a loss of a sense of psychological safety and control in a time of Covid-19 (GUS, 2020; Heitzman, 2020; Pierce et al., 2021). The other thing that is maladaptive work behavior is procrastination which involves delaying work-related activities and engaging in non-work-related actions at worktime (Metin, Taris, & Peeters, 2016). Procrastination lowers well-being and self-efficacy (Çelik & Odaci, 2020; Metin, Peeters, & Taris, 2018), and raises fatigue, psychological detachment, job stress, job boredom and unemployment (Metin et al., 2018). A counterbalance to the unpredictable outside world and the resulting sense of danger can be a predictable and safe workplace (Heitzman, 2020).

The work environment is modelling both: procrastination (Reijseger et al., 2012) and anxiety (Heitzman, 2020), and I assume that the organizational factor such as psychological safety is decreasing them but also that the leader behaviour may play a role. Psychological safety is a cognitive state that is the result of assessment of the surroundings as accepting and friendly, an environment in which it is safe to take risks, e.g. interpersonal risk, in which making a mistake does not result in social ostracism (Edmondson, 1999). Research shows the relation between the feeling of safety and positive organisational behaviours, such as thriving (Jiang et al., 2019), identification with the organisation (Liu et al., 2015), effectiveness (Obrenovic et al., 2020), innovativeness (Sun and Huang, 2019), creativity and knowledge sharing (Wang, Liu and Zhu, 2018). Safety gives employees the courage to undertake activities (Chen et al., 2019), engage in voice behaviours (Xu et al., 2019), come up with ideas (Wang, Liu and Zhu, 2018) and put them into practice (Agarwal and Ferndale, 2017). Therefore I assume that psychological safety decreases the feeling of anxiety and the attempt to avoid the action.

We also already know that the leader might be a key factor in shaping the follower behaviour, attitudes and emotions. Harmful behaviour may rise this both negative outcomes and lower psychological safety. Leader transgression is defined as a (dysfunctional) behaviour contrary to the accepted societal principles, norms and practices in a given organisation (Shapiro et al., 2011). The effects of transgression are, among others, the intention to leave, withdrawal (Shapiro et al., 2011), loss of trust towards the leader and damage to employee well-being (Byrne, Barling and Dupre, 2014).

Design:

I use the data from daily diary study of 60 dyads of leader-follower (120 respondents, 10 observations per respondent) and apply multilevel modelling to test the hypotheses.

Results:

The results confirmed that transgressive leader behaviour reduces psychological safety of the follower and rises the procrastination and anxiety of the followers. The effect of the transgression on procrastination and anxiety is mediated by psychological safety in a way that psychological safety lower the level of both consequences. Conclusions and implications:

This research contributes to the body of literature on psychological safety, procrastination and anxiety but it is also a voice in a dispute on the impact of leader's certain behavior on employee's perception, emotions and behavior. In a changing world of work the feeling of safety is more important than ever because it enables employee to meet the requirements and to work without procrastinating and anxiety. The role of the leader is crucial in here. Leader must remember that through transgressive behavior is depriving employee's psychological safety and at the same time pushing them into procrastinating and feel of anxiety.

Relevance to the Congress Theme:

The idea of that research was driven by the rapidly changing World. Anxiety and procrastination caused by these changes exist alongside the requirements to be reactive and fast acting. This contradiction is creating a tense and the research questions are dealing with that and try to find a factor within the organization that may be a resolution.

The Questionnaire 4EF: collective effectiveness as a broader perspective for measuring team effectiveness

Anita Pollak & Barbara Kożusznik | Institute of Psychology, University of Silesia, Katowice, Poland;
Philip Gouverneur, Department of Medical Informatics, University of Lübeck, Germany

science

The effectiveness of virtual collaboration remains a challenge, which is particularly important because companies need to stay competitive in the face of recent crises (pandemic, war). In addition to economic parameters, most previous research on virtual teams has focused on non-economic parameters and variables, such as trust, cultural differences, communication, social skills, clarity of mission and goals, rewards, and recognition. As a result, the context of virtual teamwork is broad and varied. However, the team members' interdependence and the role of their individual and collective experiences have not been addressed so far in the context of efficiency. Our study comprehensively analyzes existing methods of measuring virtual team effectiveness before proposing a new one. The first phase of our research involved analyzing interviews with virtual team members (N = 87). Respondent's written statements addressed their understanding of team effectiveness, techniques for effective work, and methods for evaluating virtual team performance. We analyzed the interviews using machine learning methods to understand the respondents' opinions better, looking for trends and patterns.

The second phase of the work involves to set up a new method. We analyzed the methods presented in the literature and used in the research to evaluate the effectiveness of virtual teams. Based on the collected information and conclusions of the first part of study, we have prepared a set of statements. We are currently collecting data to validate our proposal. The questionnaire has four dimensions that assess the performance of a virtual team, such as characteristics of the tasks performed [task performance], voluntary activities that go beyond duties and contribute to a good team atmosphere [extra-role performance], commitment to a common goal and teamwork [collective performance], and creative behavior [creative performance]. The results of the study are expected in March 2023. The outcome of the study will be an updated method with validated psychometric values.

The volume of the method (currently 20 items), due to its many aspects and the long execution time, can be viewed as the research's limitations. This is in contrast to the search for methods that require less workload on respondents. In addition, self-reporting measurements can be subject to response errors due to social desirability and individual answering tendencies.

Globalization and the increasing digitization of the workplace, as well as other factors such as pandemics, climate change, and the need to conserve resources, are forcing virtual teams to work more efficiently. Organizations and companies are facing these modern challenges, causing the development of a new, customized tool that considers both quantitative and qualitative methods of evaluating the effectiveness of virtual teams. For the above reasons and its innovative analytical approach, this study fits well with the conference theme „The Future is Now: the Changing World of Work."

Keywords: virtual team, team effectiveness, collective effectiveness

The Efficacy of Servant Leadership with Hospital Employees

Kristine Olson, Utah Tech University; Mitchell Cloward, Intermountain St George Regional Hospital; Joelle Jacobsen, Intermountain St George Regional Hospital; Erin Ortiz, Utah Tech University

science&practice

In the United States, over 41,000 healthcare facilities utilize the Press-Ganey ® (2022) Engagement and Safety Survey as a national benchmarking device for comparing healthcare worker attitudes across hospitals. Considering the national interest among healthcare administrators in assessing caregiver job engagement, it is critical to understand which specific leadership behaviors are associated with employee job engagement. One leadership method associated with fostering positive employee workplace attitudes is servant leadership--a practice whereby leaders serve their subordinates by providing information, resources, and career growth opportunities. Further, social exchange theory (Cropanzano & Mitchell, 2005) suggests that employees are inclined to exert positive attitudes and behaviors at work as a social "exchange response" when leaders provide material and socioemotional support. Indeed, research has provided some evidence that servant leadership behaviors are related to employee job engagement (i.e., sense of energy; e.g., Ozturk et al., 2021). Moreover, engaged employees experience less job overload and turnover intentions, as well as greater job satisfaction and organizational commitment (Coetzer et al., 2017).

Given hospital administrators' interest in employee engagement, we test a theoretical model (within the context of a hospital that trains servant leadership principles) whereby hospital caregiver job engagement serves as a mediator between specific servant leadership behaviors and job attitudes among hospital caregivers.

H1 : Servant leadership will be positively related to job engagement.

H2 : Job engagement will be positively related to job satisfaction and job commitment, and negatively related to job overload and turnover intentions.

H3 : Job engagement will mediate the relationship between servant leadership and employee job attitudes.

Method

Survey responses included 377 (72% women, 90% Caucasian) caregivers from a single hospital in the United States in 2021.

Servant leadership factors including emotional healing, helping subordinates succeed, putting subordinates first, empowerment, and stewardship (Liden et al., 2008; van Dierendonck & Nuijten, 2011) were the independent variables. Dependent variables were work engagement (Schaufeli et al., 2019), job satisfaction, work overload (Cammann et al., 1983), organizational commitment (Cook & Wall, 1980), and turnover intentions (Boroff, & Lewin, 1997).

Results

A structural equation mediation model was created to test the hypotheses, (χ 2 (17)=23.31, $p > .01$, CFI=0.99, RMSEA=0.03, SRMR=0.05) using MPlus (Muthen & Muthen, 2007).

H1 (partially supported): Putting subordinates first (β=.19, t =2.90, $p < .01$), and stewardship (β=.22, t =2.76, $p < .01$) were significantly related to job engagement.

H2 (supported): job engagement had a significant relationship with job satisfaction (β=.68, t =17.83, p <.01), organizational commitment (β=.62, t =15.22, p <.01), and job overload (β=-.55, t =-12.70, p <.01) and turnover intentions (β=-.21, t =-4.05, p <01).

H3 (partially supported): Job engagement significantly mediated the relationship between stewardship and organizational communication (indirect effect=.12, SE =.05, p =.02), putting subordinates first and organizational commitment (indirect effect=.12, SE =.04, p =.01), stewardship and turnover intentions (indirect effect=-.11, SE =.05, p =.02), putting subordinates first and turnover intentions (indirect effect=-.10, SE =.04, p =.01), stewardship and job satisfaction (indirect effect=.11, SE =.06, p =.02), putting subordinates first and job satisfaction (indirect effect=.14, SE =.05, p =.01).

Discussion

Though using cross-sectional data from a single source that limits generalizability, the results provide evidence that servant leadership, when explicitly trained, is significantly related to employee job attitudes through employee job engagement. Based on the significant mediation paths in our theoretical model, we suggest several practical courses of action for human resource managers. Training managers on stewardship and putting subordinates first servant leader behaviors may help hospitals bolster employee perceptions and positively affect national benchmarking goals. While technical skills are critical for managers, interpersonal skills such as meeting employee work needs and referring employees to workplace resources are important.

Congress Theme and UN SDGs

Future is Now. Contribution and Delivery . Servant leadership can engage hospital caregivers while also fostering positive employee attitudes while mitigating employee job overload and turnover intentions. Given the positive effects, managers should be trained on servant leadership.

Good Health/Wellbeing : The enactment of servant leadership behavior is related to positive attitudes among hospital caregivers.

Partnerships/Goals . This research was conducted via a partnership between a public university and a hospital to promote hospital employee well-being and academic advancement.

Keywords: servant leadership, engagement,

The Functional Resonance Analysis Method (FRAM): An approach to complex socio-technical systems

Marc Wiesener, Thomas Mühlbradt, FOM Hochschule für Oekonomie und Management

science&practice

Work-systems are increasingly understood and described in research as complex socio-technical systems (Mühlbradt, Shajek & Hartmann, 2022). This is accompanied by the need for new methodological approaches to such systems. One such approach ist the Functional Resonance Analysis Method (FRAM) (Hollnagel, 2012). The presentation of results of a FRAM is usually prominently displayed and communicated in the form of a network representation of the process under investigation. This might give the impression that FRAM is just another method from the business process modeling toolbox. However, FRAM is a qualitative research method that is essentially based on guided interviews. This fact makes it interesting for numerous applications in work- and organizational psychology.

In our joint research project, FRAM is therefore being used for the first time in the context of health services research in two hospitals. In this contribution the essential steps of a FRAM are presented and experiences from the practicala application to clinical processes are reported. From a systems theory perspective, there are interesting cross-connections to the postulates on Qualitative Research formulated by Mayring (2015). These ties are discussed with a focus on the phenomenon of complexity in the world of work.

The proposed contribution has a high and direct relevance to the conference theme „Changing world of work“ because it adresses the change towards complexity. The contribution also relates to the UN Sustainable Development Goal „Decent work and economic growth“ because FRAM uses a participative approach to encourage compence development und reduce stress. It also refers to „Good health and wellbeing“ because it adresses matters of patient safety in complex health care environments in a new and promising way (McGill et al., 2022).

Keywords: complex socio-technical systems, qualitative research, healthcare

Changing of organizational roles and functions during the war in the area of active hostilities

Polina Tetska, Department of Special Faculty of Organizational Psychology
of the Institute of Applied Psychology "Humanitarian Center" / "Fitoria"

Problem: Many people left Ukraine because of the war. As a result, organizations are faced with a shortage of employees and a large number of responsibilities that there is no one to perform. There was a need for a global restructuring to continue the operation of the enterprise. First of all, this is due to a change in the structure of duties. These processes occur spontaneously and are highly dependent on the personalities of workers and their willingness to take on additional responsibility. It was important for us to trace the factors that influence the process of restructuring and the reasons for the distribution of organizational roles in conditions of active hostilities.

Purpose: to clarify and track changes in the structure of organizational roles and functions in the Ukrainian organization during the war on the example of a manufacturing enterprise in Kharkov which was in active hostilities from February 24, 2022 to August 24, 2022. Determine what causes the fact that people independently occupy certain roles.

Methods: To collect data, we use the method of participant observation, semi-structured interview, which was conducted with each employee once a week and consisted of 9 open-ended questions and analysis of job descriptions, which include 4 sections (basic duties, additional duties, regulations, description of general requirements for the performance of duties). The study was conducted by the owner of the company from February 24, 2022 to August 24, 2022. The organization has existed for 23 years and is engaged in the development and production of extracts, dietary supplements and skin care cosmetics.

Results: The results of observations and interviews of 13 employees of the organization were obtained, who continued to work after the start of the war. 112 interview recordings and 56 hours of observations were received. It was found that the structure of duties has changed for all employees. The roles were distributed: the production worker took the role of production manager, the administrator took the role of retail manager, the commercial director took the role of deputy owner. This was due to high loyalty to the organization, personal initiative and willingness to learn.

Conclusions**:** In conditions of active hostilities and threats to life, we observed a natural and spontaneous restructuring of organizational roles, which helped to stabilize the organization and facilitated adaptation to new conditions.

Poster P232

Getting Workers to Engage in Organizational Citizenship Behaviors and Decrease Their Intention to Quit: A sequential mediation process model

Audrey Babic, University of Liège; Elodie Baijot, PwC Luxembourg

science&practice

Some researchers have investigated the relationship between justice at work and congruence (e.g., Çelik & Damar, 2017). Others have also highlighted a positive relationship between values congruence and organizational identification (e.g., Cable & Derue, 2002; Kristof-Brown, Zimmerman, & Johnson, 2005). Other studies have shown a relationship between organizational identification and affective commitment (e.g., Marzucco, Marique, Stinglhamber, De Roeck, & Hansez, 2014). Previously, relationships were found between organizational commitment, OCB, and intention to quit (e.g., Gurbuz, 2009; Haque, Fernando & Caputi, 2017). Relationships between these concepts seem established. However, most of the time, they were investigated separately. In fact, to the best of our knowledge, no previous study focuses on these concepts within an integrated model, despite the theoretical framework that supports its relevance (e.g., self-categorization and social identity theory, Tajfel & Turner, 1986; social exchange theory, Blau, 1964; norm of reciprocity, Gouldner, 1960). Therefore, the objective of this research is to shed light on the mechanisms leading workers to adopt/engage in extra-role behaviors, such as organizational citizenship behavior (OCB), and to intent to quit the organization employing them. More specifically, the aim is to investigate a mediation in sequence linking global justice, values congruence, organizational identification, affective commitment, OCB, and intention to quit. A self-reported questionnaire was diffused through an online survey. This study was carried out on an all-round sample. 193 people responded to the questionnaire. Analyses were performed using Mplus 6 (Muthén & Muthén, 1998-2010). We found that the perception of overall justice generates a feeling of congruence between the values of workers and those of their organization. This feeling in turn generates the development of a feeling of oneness with the organization, which, coupled with a feeling of obligation of reciprocity, allow the development of an emotional and affective attachment to the organization. This attachment subsequently results in a desire to implement positive and beneficial behaviors towards the organization such as organizational citizenship behaviors directed towards the organization, as well as a decrease in the intention to quit. Our study has several limitations, leading us to interpret the findings with caution. The first major limitation is the cross-sectional design, which precludes any inference of causality among the variables. A second limitation concerns our sample. Although a heterogeneous sample can have many advantages, it is undoubtedly a potential source of bias. In fact, the individuals composing our sample come from many different organizations. Although we have included some covariates (i.e., diploma, seniority in the company, seniority in the function, managerial responsibilities, and company size), other factors specific to organizations, such as organizational climate or human resources practices, could have influenced the investigated associations, making it impossible to guarantee that the relationships were isolated from spurious influences (Bollen, 1989). Thirdly, as we used self-reported data, common method variance may have biased our results (Podsakoff, MacKenzie, & Podsakoff, 2012). Nevertheless, considering that the single-factor model showed a poor fit to the data, this common method bias was partially treated (i.e. Harman's single-factor test; Podsakoff et al., 2012). Despite these limitations, our research also has several strengths. The first is that we tested a triple mediation model never investigated in the literature before. Our study extends previous research focusing on OCB and intention to quit by proposing a more comprehensive model. The second is that our study is in line with theories/models largely acknowledged in the literature (e.g., the self-categorization and social identity theory, Tajfel &

Turner, 1986; social exchange theory, Blau, 1964; norm of reciprocity, Gouldner, 1960). The third, is the fact that our study responds to the call for more research based on holistic and systemic visions of justice and examination of the effect of overall justice on workplace outcomes (e.g., Mohammad, Quoquab, Idris, Al Jabari, Wishah, 2019; Rodell, Colquitt & Baer, 2017).

Keywords: Organizational citizenship behavior; Intention to quit; sequential mediation process

Poster P236

A Computational Approach to Understand Social Flow and Its Role in Interpersonal Relationships in Virtual Teams

Corinna Peifer, Department of Psychology, University of LÄĽbeck, Germany; Adrian Pyszka, Department of Human Resource Management, University of Economics Katowice, Poland; Olaf Flak, Faculty of Law and Social Sciences, Jan Kochanowski University

science

With the increasing possibilities to work remotely in virtual compared to in-person collaborations, employees are confronted with new challenges to build and maintain positive social connections with their team members. A concept that could possibly serve as a protective factor is social flow, the joyful experience of being absorbed in an optimally challenging social activity. As previous research demonstrates, the shared experience of social flow might promote indicators of positive relationships among team members, such as team cohesion. However, there is little consensus about what the term social flow actually describes and several other names such as group flow or team flow are used interchangeably or with slightly different meanings. Consequently, one goal of the current study is to narrow down the construct of social flow and disentangle its preconditions or behavioural correlates from the experience itself. Furthermore, as to our knowledge there is no study that investigated social flow in the context of online collaboration, we aim to explore how social flow can occur in virtual teams depending on the number of interaction partners (dyads vs. groups) and different synchronous and asynchronous communication media. Finally, we determine the relevance of experiences of social flow for team relationships by examining interpersonal perceptions such as liking and interpersonal closeness. To address this research gap, we plan to conduct a cross-sectional field study in the form of an online survey, in which we will assess qualitative and quantitative data of N = 400 German and Polish employees working in virtual teams. Three open questions will be asked to identify typical situations, in which social flow in virtual teams is experienced, as well as fostering and hindering conditions. Furthermore, the participants will complete a series of questionnaires including a personality scale, several flow scales and ratings on their relationship with other team members. The qualitative data will be pre-processed with the help of text-mining tools and analysed by using latent semantic analyses to identify relevant components of social flow experience and its antecedents in virtual teams. As a second step, the resulting components will be combined with other questionnaire data and related to social flow with the help of machine learning models. Further analyses will be conducted by using a mixed-design ANCOVA and regression models. Results are expected for March 2023. We discuss how our findings contribute to a better understanding of social flow and its role within the cooperation of virtual teams, and critically evaluate possible limitations of our study.

Relevance to congress theme: The present study addresses recent developments of the increasing virtual collaboration, which will enable organizations to cope with modern challenges brought on by globalization as well as crisis such as pandemics and climate change. Moreover, we follow an innovative analytic approach by relying on text mining and machine learning algorithms. By tackling these future-oriented topics, our study fits in well with the congress theme The Future is Now.

Keywords: flow experience, interpersonal processes, virtual teams

Transferring production plant practices in times of war and increased danger to a safe location using the competence center method

Tetiana Sverdlenko, hr of Triol Poland R&D company, Institute of Applied Psychology “Humanitarian center”, Kharkov, Ukraine

Problem - in warfare and high-risk situations, there is a need to relocate business, and quickly transfer and recreate competencies for productive operation of the plant at the new location. The particularity of the production is a complex product; high requirements for product quality, which meets international standards; critical consequences in case of errors in equipment operation. Currently, there is no proven and described method for such a transfer of competencies, provided no specialists and no supply chain for components; there is no prepared production area; new financial rules and labour laws.

Objective is to develop, adapt and practically verify, in a short time, a method making it possible to reproduction competences, for further productive performance of industrial plant in relocating circumstances

Method. We have developed a special method, the competence center method, which consists of several steps:

1. Selection of productive employees, carriers of core competencies for the full production cycle.

2. Relocating employees.

3. Establishing competence centers out (which supplies dynamic competence transferring, adaptation, and solves practical problems at the intersection of areas of responsibility; adapts competencies to current conditions).

4. Recruiting of newcomers from local candidates. Mentoring by competence bearers - do-it-like-me mentoring.

5. Practical activities (error correction and approbation).

The result - using the competence center method, it was possible to transfer all competences which are required for the production of the complete plant product cycle: technical product development; production competences of employees; planning; purchasing; recruitment; economic; commercial.

1.The peculiarity of the employee selection stage was the need to include managers in the assessment of necessary and sufficient competencies for the full actual production cycle.

2.The employee relocation phase worked partly because of the high risk conditions and the impossibility to leave the country.

3.The main difficulty of the competence center formation stage was the awareness and acceptance by employees that only necessary tasks should be done now, it express in stress and unpreparedness of workers to start work on such terms.

4.The recruitment and practical activity phases were completed. The negative features of the practical activity stage were the cultural differences, which became apparent in getting feedback, understanding the evaluation in real work.

The method has been verified in practice, allowed to solve the problem, can be used in the transfer of the production plant of the complete cycle of production.

Conclusion - the key resource that enabled the transfer of practices was the people who had a set of competencies; the physical presence of these people in a safe location and contact with the tasks.

Poster P238

Stress at work on oil rigs in Poland in the perspective of 20 years of research. Time as a determinant of the dynamics of stress at work

Irena Leszczyńska, WSB University in Gdansk

science&practice

Introduction: Adaptation to stress at work in difficult conditions is a complex process, involving various cognitive, emotional evaluations, also depends on the objective situation related to working conditions. It is a kind of variable interaction, the result of the employee's perception of objective conditions, the relationship between this perception and the experience of stress, and between this experience and changes in behavior, physiological functions and health (Cox, 2006, Dudek,1999, Karasek, 1990). Many studies of stress at work have been accused of a static understanding of the process, poorly chosen research procedures, and single-level research (Segestrom, O'Connor, 2012).

Method. Each of 167 oil rig workers in Poland, (average age 42), working in the same jobs and in a company with a more or less constant organizational structure, was surveyed several times over a 20-year period (1993-2014). According to the principle of triangulation, stress was studied from three sources: a. opinions on objective stress obtained from experts, b. study of subjective stress through questionnaires and surveys, c. data on physical health and mental well-being. Psychosocial burden and a wide range of demographic and individual variables were also examined.

Results. The 20-year study made it possible to distinguish 3 groups of employees differing in the level of declared subjective stress : 1-“Stress Resisting”, “SR”, 2 – “Stress Sensitizing”, “SS” and 3 – “Flexible Group”, “FG” . Intra-group variability was also shown: employees in the „RS” group are characterized by high stress at the outset, and declare a systematic decrease over 20 years. The „SS” group is characterized by an initial low level of stress, and declares a systematic increase over 20 years. Employees in the third group „FG” adapt to stress flexibly, depending on the real situation. Employees in the „RS” group, after 20 years, are characterized by worse health (number and type of ailments) than the „FG” group, in whom stress is variable and who activate, in addition to task-based, emotional coping strategies. If the results were to be developed in a cross-sectional model, one could conclude that declared subjective stress is not related to health indicators, to individual variables and perceived psychosocial burdens. The result obtained related to a single measure and in no way reflects the dynamics of stress. The results obtained in the prospective procedure also show that subjective stress is significantly lower than objective stress, which, on the one hand, may indicate a well-chosen professional group in terms of coping skills, the positive impact of occupational stress on its subjective perception, or a specific defensive attitude, characteristic of this professional group (the stereotype of the strong man).

Conclusions. Only longitudinal studies with diverse research methods reaching three measures of stress (objective, subjective and health consequences) can show the mechanisms of stress-related processes in cause-effect terms. The prospective nature of the study and the principle of triangulation showed a picture of a dynamic rather than static picture of stress, coping and individual health from the perspective of work conditions.

Keywords: dynamics of stress at work, longitudinal study, wellbeing in work

Employee retention in the manufacturing industry: a key factor in Mexican organisations

Elsy Guadalupe Parada Ruiz & Geovana Elizabeth Armenta Borgo | Universidad de Sonora

science

The objective of this research is to identify and analyse the variables that affect employee retention in the manufacturing industry in Sonora, Mexico. Manufacturing is key to the economic development of the northern region of the country due to its strategic geographic location that facilitates trade with several countries. Mexico has one of the largest economies in the world, but this has not been enough to maintain strong growth. Evidence suggests as a key problem the decline in productivity and as one of its main causes, the high rate of employee turnover that increases the costs of recruitment, selection, hiring, and training, decreasing productivity and profitability, also impacting the quality of life of employees. In Mexico, employees in the manufacturing industry tend to leave their jobs within a few months of joining. This turnover is partly influenced by migration, violence, and low involvement of women, as well as low investment in public infrastructure that hampers living conditions, however, it is essential to analyse the underlying labour factors. Some variables were identified as predictors of intention to quit such as job satisfaction and immersion, organisational commitment, work-life balance, information, and working conditions. A non-experimental, causal, quantitative approach research is being conducted by applying questionnaires to employees from the manufacturing industry in the region of Sonora, Mexico. To date, 49 questionnaires have been applied to operative employees. The research is expected to be completed within three months, considering the necessary availability and permissions. Lack of cooperation from organisations in research is a major limitation, as well as the fear of workers expressing their opinions. The present study is a significant contribution to the scarce research on this subject. Some of the preliminary results were low satisfaction with promotions and financial rewards, low levels of challenge and perception of ergonomic problems, poor cleaning conditions, and inadequate temperature in the facilities. The induction process is lengthy and the time is not properly used for training. Workers express insecurity when returning home. Lack of information related to the company's mission and objectives inhibits organisational commitment. Higher work-family conflict and difficulties with work flexibility have been detected in employees with children; young workers expressed dissatisfaction with the information provided by their employers. Variables with low satisfaction indices were found to have a significant impact on intention to quit. Based on the preliminary results obtained, it is proposed to implement a programme of interventions that include incentives, promotions, hiring more female personnel, implementation of a life and career plan, improvement of facilities and working conditions, greater flexibility, and job information. The dynamics and working conditions in Latin American organisations require strategies to adapt to demographic, social, and competitive changes and to adjust the needs of employees to promote their retention. This research aims to contribute to the UN SDGs: Decent Work and Economic Growth and Good Health and Well-Being, providing knowledge on industrial manufacturing organisations to implement interventions for a better quality of life and well-being of their employees and economic growth of organisations and nations.

Systemic leadership - how does it differ from other leadership constructs?

Vera Simone Göllner, German Police University / FOM University of Applied Sciences; Kai Externbrink, WHS Westphalian University of Applied Sciences; Christine Sutter, German Police University; Sandra Sülzenbrück, FOM University of Applied Science

science

Research goals

This paper examines how systemic leadership, as a new construct in leadership research, differs from other leadership styles. A measurement instrument has only recently been developed (Systemic Leadership Inventory Revised, SLI-R, Göllner, et al., 2019). To date, there is little empirical research potentially due to the lack of a measurement tool.

Theoretical background

Leadership is one of the most important determinants of a company's success or failure (Al Khajeh, 2018; Felfe & van Dick, 2016). How leaders behave toward their employees is of particular importance. Distinct hierarchies and rigid leadership constructs, as they (still) prevail in most companies, lack the adaptability to quickly respond to changes. Leadership theories therefore need to shift to new perspectives that meet the complex adaptive needs of organizations. The systemic leadership approach provides a framework for leadership behaviors that are more likely to address these complex needs.

Design

In two cross-sectional online survey studies (currently running) employees from various professional backgrounds assess their leaders in systemic, transformational, transactional, ethical, authentic, servant as well as laissez-faire leadership and abusive supervision. Study 1 includes a criterion validity survey, study 2 measures incremental validity.

Results expected

Based on the evidence found in the literature, parallels are suspected between systemic, ethical, authentic, and servant leadership. The unique selling point of systemic leadership could be the holistic approach, which goes beyond the boundaries of the own company and recognizes and uses interdependencies. (Studies will run until end of November, with initial results expected in December)

Limitations

There may be measurement errors due to external assessments. It is essential to include the leaders' perspective in future research. Drawing firm causal conclusions about predictive validity is impossible because our data were collected in two cross-sectional surveys. Future research should use longitudinal designs to verify this.

Conclusions

Research using an entirely new measurement instrument, as well as validity testing, represents a completely new approach to leadership research. The results present similarities and differences of the leadership styles shown. They can be used to present suitable leadership styles to companies and to point out special characteristics and differences. Trainings can be designed.

Relevance to the Congress Theme

Due to the increasing complexity, fast pace and dynamism in everyday business life, traditional leadership approaches no longer seem to be up to date. Analogous to this environment, the field of leadership research has also evolved in a diverse and dynamic way (Felfe, 2015). Therefore, it is no longer time to highlight the purely property-theoretical, behavior-theoretical, and situational approaches to leadership, but the systemic approach, which aims to understand and grasp the growing complexity in organizations and their environments.

Relevant UN SDGs

A positive leadership and work climate contributes to health. Research to date show that systemic leadership has a positive impact on employee health. Furthermore, the lived diversity in a team of systemic leaders contributes to gender equality. Systemic leadership and thus our research should contribute to decent work, economic growth and innovation as a new approach in (positive) leadership research is explored.

Keywords: systemic leadership, system theory, incremental validity

Digital Disconnection: a grey zone between right and wrong? A qualitative study amongst mid-career employees

author: Alice Verlinden, sender: Lore Geldof & author: Elfi Baillien | KU Leuven

science_practice

Introduction

This study aims to gain in-depth insights into the why, how, and when of employee digital disconnection. To date, research on digital disconnection has theoretically developed along the lines of work-related technostress. From identifying notable negative consequences of staying always 'on' through digital media (e.g., e-mails, instant messaging…) – such as for example anxiety, irritability, difficulties with concentration, headaches as well as absenteeism (Sanderlin, 2004) – recent voices have called for a more balanced usage of digital media as workers. Digital disconnection encompasses this by setting – both short and long term – limits on digital connectivity with the goal of improving health, productivity, and wellbeing (Vanden Abeele, 2021). While practical interventions to digitally disconnect as employees are booming rapidly, scientific knowledge about the drivers behind disconnecting (why), the strategies employees deploy to disconnect (how), and the moments in which they experience a need for disconnection (when) is grandly lacking. As a consequence, current practical initiatives lack an evidence-based ground, and may risk failure.

Methodology

In an in-depth, qualitative study consisting of semi-structured interviews with nine employees – knowledge workers highly depending on digital media in their job – belonging to different organisations, we gathered insights on why, how, and when employees digitally disconnect. Our participants were recruited as subject matter experts: they were those scoring highest on an assessment of digital disconnection behaviours – part from another, quantitative study – and who had agreed to participate in further research by providing the principal investigator with their email address. For our current study, we specifically selected mid-career employees as a particularly valuable group in providing us information on digital disconnection. First, given their job and career tenure they may have installed more conscious habits on digital disconnection. Second, this group of employees is typically more challenged in their work-life balance by taking care of children or family members. The interviews were recorded, transcribed, and analysed using Nvivo.

Results

The rich information we collected, was integrated into a disconnection model, which incorporates the relation between disconnection at work and various influencing individual and organisational characteristics. Central to the model is the balance between connection and disconnection. This balance as well as how, why, and when employees disconnect, are influenced by both variable situational aspects (e.g., the urge of a certain interaction or the person with whom one collaborates), as well as (relatively) stable aspects (e.g. personal preferences and organisational expectations). Furthermore, why and how employees digitally disconnect is linked to when they do this. At work, the participants disconnected to improve focus. When not at work, they disconnected to psychologically detach from work. Our interviews reveal that the participants either disconnected in a direct way by eliminating digital devices (disconnection-by-device), or by limiting functions such as notifications (disconnection-by-function). Alternatively, disconnection can also be supported in an indirect way, through communication about one's (un)availability, management of communication

streams at work, or leisure time. In all, the proposed model portrays the various influences on the connection-disconnection balance, while it simultaneously shows that multiple factors are at play, which complicates or even limit the possibility to disconnect or improve (digital) wellbeing.

Limitations

While valuable in building in-depth insights on digital disconnection by investigating subject matter experts, we have only looked at a specific age group in our current study. Future research could thus benefit from comparing our findings to those of digital natives (i.e., younger generation) and digital immigrants (i.e. older generation) at work.

Conclusions

Our study can inspire follow-up scientific research on digital disconnection by employees, for example by quantitatively testing our model's pathways. From a practical angle, this research portrays how digital disconnection is of importance for employees' health and wellbeing, however, related to a balance with being connected. As such, organisations may see to facilitate digital disconnection (e.g. informal agreement), rather than imposing organisation wide regulations (e.g. shutting down server).

Keywords: Digital disconnection, digital wellbeing, information and communication technology (ICT)

Poster P190

Relationships Between Immediate Manager's Leadership Style, Work Motivation and Psychological Resilience

sender: Tiiu Kamdron, Lecturer, Liina Randmann | Tallinn University of Technology, School of Business and Governance

science_practice

Research Goals . The purpose of our study is to investigate relationships between leadership style, work motivation and psychological resilience.

Theoretical Background. The approach where transformational and transactional leadership styles are distinguished (Bass, 1985) was used in this study. Transformational leadership theories predict followers' emotional attachment to the leader and emotional and motivational arousal of followers as a consequence of the leader's behavior while transactional leadership theories assume exchange processes take place between the leader and subordinates.

One the other hand self-determination theory about the work motivation (Deci & Ryan, 2000) was used to explain motivation type. There are three basic needs for workers: need for competence, autonomy and relatedness. The self-determination continuum includes six types of motivation.

Resilience refers to positive adaptation, or the ability to maintain or regain mental health, despite experiencing adversity (Wald & Asmundson et al., 2006). The level of resilience is influenced by personal and environmental factors, including organizational level factors. Psychological resilience an important construct in understanding how individuals respond to workplace stressors and appears to be a major determinant of whether or not certain unfavourable outcomes such as burnout, compassion fatigue, anxiety, or depression ensue. Some studies have found that resilience can be fostered through the provision of workplace support (e.g., Grant, Curtayne, & Burton, 2009).

We have evidence that these constructs may be related in organizational behaviour.

Design/Methodology . A cross-sectional survey design was used with a convenience sample (N=263) of Estonian employees. The Multidimensional Work Motivation Scale (MWMS with 24 items), The Work-Related Basic Need Satisfaction Scale (W-BNS with18 items), Resilience Scale (CD-RISK) (Connor & Davidson, 2003 with 10 items) and Multifactor Leadership Questionnaire (MLQ short form with 36 items, Bass & Avolio, 1995) were used in the study. Six-point assessment scale was used in all questionnaires.

Results. The results show significant relationships between different leadership styles and subordinates' work motivation. Transformational leadership (TR) has positive medium size correlations with identified and intrinsic motivation and negative correlation with amotivation.TR has also weak positive correlations with extrinsic social and material motivation. All five subscales of TR show the similar correlations with work motivation types. Transactional leadership (TA) has positive correlations with amotivation and extrinsic material motivation. Passive leadership (PL) and TA have both weak positive correlations with amotivation. PL has no positive correlations with extrinsic and intrinsic motivation types. IL has weak positive correlations with satisfied need for relatedness and medium size positive correlations with satisfied autonomy need, but no correlations with satisfied competency need. PL has negative correlations with satisfied autonomy and relatedness needs. TA has negative correlation with autonomy need satisfaction. Satisfied need for autonomy (SA) has positive correlations with identified and intrinsic motivation. Resilience (RES) is positively correlated

with autonomy, relatedness and competency need satisfaction and with identified and intrinsic motivation. From the other side resilience is highly positively correlated with TR. Multiple regression analysis with intrinsic motivation as dependent variable and IL, SA and RES as independent variables shows a good fit: $F(3,191) = 23.106$, $p < .001$, $R^2 = .266$.

Limitations. The small sample size and use of cross-sectional design are limitations of these study.

Practical Implications. Our study shows that transformational leadership style is preferred as a generator of intrinsic motivation and satisfier of relatedness and autonomy needs. It also has a strong positive relationship with psychological resilience. At the same time use of transactional style has, depending on the situation, an impact on extrinsic material motivation.

Relevance to the Congress Theme. Our study is connected mainly with decent work and economic growth theme of congress.

Keywords: Leadership Style, Self-Determination Theory, Basic Psychological Needs

Teleworking components and scientific productivity in Spanish ERC-granted teams: The mediating role of climate and well-being

Nuria Tordera; sender: Guido Martinolli, IDOCAL - University of Valencia

science_practice

Background - The COVID-19 pandemic has forced a massive and unprecedented use of teleworking in several work fields. Despite such new way of working was forced due to force majeure , it has resulted in increased productivity and most importantly highly appreciated by employees. This to the point that, today, offering flexible or remote work solutions and practices represent a competitive advantage when retaining and hiring talents. Due to the recency of this global phenomenon, the reasons that empirically explain why teleworking, and which of its specific components, play such a relevant role on workers' well-being and productivity remain partially unclear. In regard, Lunde and colleagues (2022) highlight that the literature explaining this relationship is scarce and makes it difficult for practitioners and HR managers to make adequate decisions about how to best implement this relevant practice. Furthermore, Beckel and Fisher (2022) point out also the scarcity of research that explores how the different components that characterize the practice of teleworking, such as its duration, frequency, voluntariness, need for justification, and flexibility, are related to other outcome variables, as for example well-being or productivity. Under the theoretical framework proposed by Ostroff and Bowen, justifying the origin of climates through HR practices, the present study further explores, with a more granular approach, the relationship between the practice of teleworking, and its components, and scientific productivity, and considers the climate for well-being and well-being as relevant mediating variables.

Method - A sample of 358 participants working in the research sector distributed across 48 ERC-granted research teams belonging to different Spanish universities and research centers were involved in the study. The sample responded to an online survey measuring teleworking time, frequency, flexibility, voluntariness, need for justification, climate for well-being, perceived well-being, and objective performance indicators for the academic sector both at the individual and team level. The research design is cross-sectional.

Results – At the individual level, a direct link was found between telework quantity and scientific productivity ($\beta = 0.25$, $p < 0.001$), while among the considered teleworking components, only flexibility was found to have a positive relationship with climate for well-being ($\beta = 0.24$, $p < 0.001$). Climate for well-being was found to have a direct relationship with all four well-being outcomes: 1. Job satisfaction, $\beta = 0.57$, $p < 0.001$; 2. Positive emotions, $\beta = 0.59$, $p < 0.001$; 3. Negative emotions, $\beta = -0.53$, $p < 0.001$; 4. Eudaemonic well-being, $\beta = 0.59$, $p < 0.001$. Finally, negative emotions and eudaemonic well-being were directly linked to scientific productivity, respectively $\beta = 0.12$, ($p < 0.01$) and $\beta = 0.24$ ($p < 0.001$).

At the team level, a direct link was found between the components of quantity and frequency and team scientific productivity; respectively $\beta = 0.17$ ($p < 0.001$) and ($\beta = -0.98$, $p < 0.001$). Among the considered teleworking components, only telework voluntariness and flexibility were found to have a positive relationship with the climate for well-being, respectively $\beta = -0.44$ ($p < 0.001$) and $\beta = 0.68$ ($p < 0.001$). In addition, climate for well-being was found to have a direct relationship with all four well-being outcomes: 1. Job satisfaction, $\beta = 0.77$, $p < 0.001$; 2. Positive emotions, $\beta = 0.72$, $p < 0.001$; 3. Negative emotions, $\beta = -0.58$, $p < 0.001$; 4. Eudaemonic well-being, $\beta = 0.55$, $p < 0.001$.

Finally, and contrary to what was found at the individual level, none of the well-being outcomes were found to have a relationship with the team's scientific productivity.

Discussion – Relevant insights are provided about how to best handle and manage the practice of teleworking in the context of ERC-granted research teams. Specific teleworking components are pointed out to play a relevant role while others not. The climate for well-being and some well-being outcomes are identified as relevant mediators between the variables of teleworking components and scientific productivity. Differences are highlighted between the individual and team levels of analysis. Relevant insights are thus provided on how to redesign workplaces and work spaces to facilitate the achievement of "Good health and well-being" in scientific research centers.

Limitations – The present study was carried out according to a cross-sectional research design, hence not allowing to draw causal conclusions. Also, the number of teams (n. = 48) should be greater for guaranteeing more power to the study.

Keywords: Teleworking components; team climate; scientific productivity

Poster 241

Zooming in on the Experience of Administrative Tasks in the Public Sector: A Day Reconstruction Study among Dutch Detectives

Lina Lioba Rachow, Piet van Gool & Sonja Rispens | Human Performance Management group, Eindhoven University of Technology

science&practice

Research Aim

Engaging in administrative tasks experienced as red tape (i.e., pointless yet burdensome; DeHart-Davis & Pandey, 2005) negatively affects employee outcomes (e.g., decreased autonomy, increased powerlessness; Quratulain & Khan, 2015), ultimately decreasing organizational performance (Bloom & Labovich, 2020). The red tape problem is pervasive and so far it has been difficult to remedy it (George et al., 2020), especially because subjective differences between individuals' perception of red tape have not been addressed sufficiently (Brewer & Walker, 2009). Therefore, in this study we investigate whether the experience of red tape depends on individuals' personal and job characteristics.

Theoretical Background

Based on the "stress-as-offense-to-self"-perspective, being engaged in red tape tasks is expected to lower employees' self-esteem, leading to a poor work evaluation (Semmer et al., 2007). In line with that, the JD-R theory implicates that experiencing red tape (i.e., job demand) can evoke negative emotions (e.g., sadness, dissatisfaction, and annoyance). We examine whether the interactive role of job and personal resources (i.e., autonomy, meaningfulness) and job demands (i.e., time pressure) will weaken or intensify this effect respectively.

Methodology

Using the Day-Reconstruction-Method, 1615 Dutch detectives filled in questionnaires to reconstruct their workdays (e.g., time spent on work activities such as administrative tasks, perceived red tape doing those tasks, and several emotions for every half hour, job characteristics daily) for five

consecutive workdays. The DRM allowed us to capture detectives' experiences, record those in a precise way, and investigate differences between participants (Kahneman et al., 2004).

Results

Preliminary results indicate detectives spent on average 30,1% of their workdays on red tape tasks (e.g., transferring information between registration systems or handling a seizure). Further, when an activity was experienced as red tape, detectives indicated the feeling 'annoyance' more often ($r=0.43$, $p=0.00$); whilst they indicated the feeling 'enthusiasm' more often when a work activity was not experienced as red tape ($r=0.26$, $p=0.00$). We are currently running a multilevel analysis, testing several interaction effects. Thorough results will be available at the end of November 2022.

Limitations and Future Research

Because we collected data within one organization (i.e., the Dutch police) it may limit generalizability of the results. Hence, future research should investigate employees' experiences from different governmental organizations.

Research & Practical Implications

When our expectations come true, this study adds to the literature on job design, that both job and personal resources are part of the solution to diminish the experience of red tape. An important practical implication is that organizational managers and employees' themselves can create more (job and personal) resources to balance the experience of red tape (e.g., offering job crafting training, empowering leadership).

Relevance for Congress

Since rules and guidelines are permanently increasing in current democratic societies (Kaufmann & van Witteloostuijn, 2018), red tape is a pressing issue in the modern working world. We aim to provide insights how to reduce employees' experience of red tape at work, contributing to design better jobs, and hence to EAWOPS' congress theme: ' The Future is Now: The Changing World of Work '.

Keywords: DRM, Red Tape, Job and Personal Characteristics

7-minute science 7M85

A social support and resource drain exploration of the bright and dark sides of teachers' organizational citizenship behaviors

Arcadius Muntean, Babes Bolyai University

science&practice

Organizational citizenship behaviors (OCBs) are important antecedents of work related outcomes in a wider variety of domains, including education. Next to the benefits of engaging in OCB, teachers also incur costs as OCBs are helping behaviors performed on top of the prescribed work roles. Our study tests in a sample of 1229 teachers two mechanisms that explain the cost-benefit interplay of OCB in relation to work performance (WP) and maladaptive work outcomes (MWO, stress and burnout).

Organizational Citizenship Behavior (OCB) reflect one's engagement in supportive extra role behaviors that are beneficial for teacher and overall school performance (Belogolovsky & Somech, 2010; Oplatka, 2006). More recent OCB conceptualizations, based on role theories argue that an excessive engagement in extra-role behaviors can be resource draining for employees (Jolly, Kong, & Kim, 2020). Therefore, an important question arises whether teachers' engagement in OCBs, a construct depicted as having important benefits for work outcomes (one of the most prototypical positive organizational behavior components see Bolino et al., 2013; Organ, 2018), also have detrimental effects in schools? We set out to answer this question by using a framework in which we investigate the mediating role of relational benefits of OCB (reciprocated social support received from peers and supervisors) and its costs (workload) in the relation between OCB and teachers' work-related outcomes (performance, exhaustion and stress).

Although OCB behaviors were clustered in multiple ways, meta-analytic Confirmatory Factor Analysis of the OCB dimensions has supported the bi-dimensional structure of the OCB as targeted towards the organization OCB-O (including conscientiousness, sportsmanship and civic virtue) and towards individuals OCB-I (including courtesy and altruism) (Hoffman, Blair, Meriac & Woehr, 2007). Moreover, in an integrative perspective on OCB research, Spitzmuller and colleagues argue "that a simple conceptual framework that contrasts types of OCB based on intended beneficiary (OCB-I and OCB-O) would provide focus and help researchers integrate and consolidate research findings." (Spitzmuller, Van Dyne & Ilies, 2008, p.115).

First, we argue that different types of OCBs influence differently the benefits and costs, such that workload is rather tied to OCB-O, while social support to OCB-I. Second, we claim that the balance between costs and benefits is influenced by the intensity of engaging in OCB such that the relational benefits emerge swiftly upon engaging in OCB, while the costs are tied especially to high levels of OCBs.

On the one hand we show that workload explains the association between OCB, WP and MWO for high rather than low levels of OCB, while social support explains the association irrespective of the OCB level. On the other hand, our results show that the association between organizational OCB, WP and MWO is mediated by workload, while the association between individual OCB, WP and MWO is mediated by social support.

These results show that both the type and level of OCB should be jointly considered when trying to understand the costs and benefits of OCB for work related outcomes.

Next to its contributions, our study has also important limitations. Data was collected from a single source, CMB is likely to have influenced our results. Second, because our study was cross-sectional, we cannot draw definite causal claims.

Keywords: : organizational citizenship behavior, teachers, work performance

Flexible work arrangements – do they differ? A comparison of employees with flexible working times and flexible location

Rita Jakštienė, Arunas Ziedelis, Jurgita Lazauskaite-Zabielske & Ieva Urbanaviciute | Vilnius University

science

Research goals. When the literature talks about flexibility at work, quite often everything is taken into account, including choice of working time and different locations (Wessels et al., 2019). However, there is a lack of information about how those different aspects of flexibility are associated with crucial employee outcomes such as job satisfaction, team belonging and extra-role behaviour. In this study, we will investigate how different flexibilities are associated with these different employee outcomes.

Theoretical background. Flexible work arrangements, including choice of working place or non-standardized working time are associated with the possibility to better align work needs to personal needs (Thompson et al., 2021). This flexibility is often treated as a job resource and a type of autonomy that a person can use to one's benefit. However, the literature also shows that flexibility is not a one-size-fits-all construct, and that different aspects of flexibility may have differential effects (Wessels et al., 2019). Job autonomy (that is inherent in flexible work arrangements) is often positively associated with job satisfaction and extra-role behaviour. On the other hand, flexible work arrangements (both, in terms of working time and location) receive criticism that they may create a feeling of loneliness and challenge team-cooperation (Wang et al, 2021).

Methodology. The study is based on the 10 th wave of the European social survey. Data from a representative sample of employed individuals in a European country were used for the analysis. ANCOVA test was applied for a set of variables covering remote work arrangements and flexible working time.

Results. Results showed that different flexible arrangements were associated with different outcomes. Work start/finish flexibility is bringing significantly different positive associations with job satisfaction, extra-work responsibilities and belonging depending on the level of flexibility. Workers who had full autonomy towards their work start/finish time were the most satisfied, willing to take extra-responsibilities, and feeling part of the team. A different pattern of results was observed for location-related flexibility. Most satisfied with work and willing to take extra responsibilities were those workers who were somewhere in the middle – neither fully, nor never working from home or other preferred location. There were no significant differences between feelings of belonging to the team and work location.

Limitations. The results should be generalised with caution due to the use of data from only one country. As single-item construct evaluations were used, the study is suggesting a direction for further research.

Conclusions. When discussing flexible work arrangements, we should notice that there is no one-size-fits-all solution. It is important to take into account nuances, that can make the difference about employees' satisfaction and extra-role behaviour.

Relevance to the Congress Theme. This study showed that future of work will require a deeper look into areas (i.e., flexible work) that are often treated as well-known.

Relevant UN SDGs . Results of this study show that various flexible work arrangements could be related to job satisfaction, hence showing an opportunity to contribute to work-personal life alignment, which is relevant to the 3 rd UN SDG (Good health and well-being).

Keywords: Flexible work; job design; job satisfaction

Intentions to stay: Examining expatriate adjustment in a host country according to time-dependent factors and cultural distance.

Anouk Jasmine Albien & Peter Hilpert | University of Lausanne

science

Expatriates or highly skilled migrants represent anincreasing number of employees around the world, and follow a time-based cross-border movement driven by the underlying intention of gaining better professional opportunities in the face of unstable economic opportunities. Expatriates are essential for the Swiss economy with approximately 70,000 highly skilled adults entering Switzerland yearly. The research study aimed to assess if repatriation intentions were predicted by expatriate adjustment (EA) among three groups of expatriates according to time spent in Switzerland (Group 1 = 1-5 years, Group 2 = 6-10 years, Group 3 = 11-15 years). Additionally, cultural distance was included as a moderator in the EA process. Various inconsistencies exist in EA research, with cross-cultural adaptation, and acculturation being used interchangeably to refer to the EA process and outcomes. Expatriate studies have focused on indicators of work outcomes such as work productivity and job satisfaction, which were positively predicted by EA, but non-work variables have been overlooked. A recently developed EA theory and assessment was utilised in this study to assess changes experienced in ten diverse EA facets. Specific domains were selected namely: “work environment”,“job characteristics”, “work-life balance, “family life”, “local friendships”, and “contact to those left behind” in this cross-sectional quantitative research design. Expatriates in German-speaking Switzerland (N= 266) completed an online survey. The following measures were used: demographic questions; Expatriate adjustment scale (Hippler et al., 2014); Cultural distance (Chen et al., 2010); and Repatriation intentions (Cao et al., 2013). The multi-group model showed good fit indices. In group one, there were significant findings on all domains, except local friendships ($p > .05$). In group two, there was a significant result in the work environment domain and interaction effect between family life and cultural distance ($p > 0.01$). In the third group there were significant results in work life balance and local friendship domains, and the interaction effect persisted ($p > .01$).This means that EA issues change according to time spent in a host country, but that EA issues remained. Also, the effect of cultural distance is reduced by existing social support structures, but more research is needed to see how career trajectories and well-being is affected. Limitations include the cross-sectional approach and that the data was only collected in the German-speaking Swiss regions. Future research should consider a longitudinal approach to assess how time lags affect EA processes and other Swiss regions included. The originality of this study is the inter ali examination of EA trajectories according to time-dependent groups in the absence of longitudinal data. These results are informative to develop the EA literature base and create effective human resource management approaches and interventions for improving EA.The current research relates to the conference themes of Careers and the Labour market and Diversity and inclusion, because of an ever-increasing globalised and diverse workforce, resulting in the need for work environments that manage and incorporate diversity well. The 2030 Agenda for Sustainable Development is supported by including the relevant goals of decent work and economic growth and reduced inequalities, by creating inclusive work environments supporting EA processes.

Keywords: expatriate adjustment, cultural distance, repatriation intentions

“LIVING AND WORKING TOGETHER” IN FAMILY BUSINESS DURING GENERATIONAL TRANSITIONS

Carlotta Morozzi & Diletta Gazzaroli | Catholic University of the Sacred Heart

science

Within the current scenario, statistics report that in Europe approximately 8 out of 10 businesses are family-run, and only 2 go beyond the third generation (Family Business Yearbook,2017). Moreover, literature on family businesses seems to be more focused on economic aspects, rather than the psychological ones (Corbetta & Quarato,2021). Regarding this, Living and working together in organizations perspective (LWTOP) could provide an insightful framework. LWTOP assumes that – within a specific organizational culture, which informs about implicit assumptions related to diversity – the relational quality between generations impact in terms of well-being and performance during the handover (Gozzoli,2016). Consequently, LWTOP could help to better understanding how relational dynamincs impact on managing the balance between individuality/conformity (group dynamics) and on the generational changeover (careeres and labour market).

Using a qualitative approach, the present study aims to intercept the LWTO styles and their implications on the generational transition in 5 Italian family-businesses, where this process is taking place. For each business, senior and junior family members with managerial roles were involved.

Data were collected using semi-structured interviews. Analyses were conducted via paper and pencil, using both theory-driven categories and categories emerging from the data. Specifically, during the top-down phase, a direct content analysis was applied in accordance with the LWTO categories; during the bottom-up phase, a conventional content analysis was applied to identify specific micro-categories related to handover process factors. Results show that in all organisations, regardless of the LWTO style, there are common processes related to (re)defining functions and roles: division of tasks, how the junior joined the company, the representation of the senior figure, the giving back of positive feedback. However, it is the specific LWTO style that impacts on how this happens in terms of quality. Thus, where the generational diversity can find a symbolic space to be faced, a better relational quality between generations can be developed and, consequently, the turnover process is generative. Vice versa, when the generational diversity cannot find a symbolic space, the turnover process is infertile.

Since this is an initial exploratory survey, some limits should be highlighted. Future research should consider two other categories of participants: other family members working in the same company, for a better understanding of relationship dynamics; employees to define a more complex picture of LWTO representations.

In conclusion, results support the assumption that the generational transition in family business does not only concern technical and factual aspects (such as the entrepreneurial status, the family history and corporate assets), but also symbolic ones. In fact, the turnover needs an “ Otherness” space in which generational differences could and should take form to support a whole organizational development. Analysing psychological aspects based on the LWTOP seems to be an added value both to support practitioners and develop literature. In fact, LWTO allows to pursue a dialogue between generations – which is the actual heart of the 'familiar' in family businesses (Cigoli, 2006) – by holding together psychological, technical and procedural dimensions.

Keywords: Family business, Generational transition, Relational dynamics

"Taking longer and better lunch breaks?" Effects of nudging and break activity interventions on recovery during the lunch break

Jan Sinner & Verena C. Haun | Julius-Maximilians-Universität Würzburg

science

Research goals

Recovery during the lunch break is important to maintain energy and performance during the workday. However, many employees cut their lunch breaks short or engage in activities that are not optimal for recovery during breaks, especially when time pressure at work is high. Thus, the present study aims to investigate whether it is possible to support employees in (1) taking sufficient time for their lunch breaks despite high time pressure and (2) using their lunch break for recovery enhancing activities. To address these questions, we implement a daily diary design with (1) two nudging interventions (i.e., social comparison and default option) to prolong lunch break length and (2) two break activity interventions (active and mindful breaks) to improve employees' recovery strategies during lunch breaks.

Theoretical background

Building on the notion of the Recovery Paradox (Sonnentag, 2018), we hypothesized that on days of high time pressure, employees tend to take less time for their lunch breaks although recovery would be particularly needed. To counter this harmful tendency, we leverage the principle of nudging interventions which aim at positively changing behaviour without any restrictions or rules by changing the choice architecture (Sunstein & Thaler, 2008). Specifically, we assume that the nudging interventions (descriptive social comparison and default option) prolong lunch breaks and prevent cutting lunch breaks short by making the decision to take longer lunch breaks more likely. Drawing from the Effort-Recovery Model (Meijman & Mulder, 1998) and the Conservation of Resources Theory (Hobfoll, 1989), we argue that longer lunch breaks should result in better recovery outcomes (i.e., increased positive affect and work engagement and decreased negative affect) as longer breaks offer more time to unwind from job demands. Further, given that mindfulness and engaging in physical activities allow employees to get a break from their work demands and generate new resources, we propose that on days when employees participate in either an active break intervention (with light physical activities) or a mindful break intervention (with mindfulness exercises), recovery at the end of the workday should be better and employees should benefit more from longer lunch breaks.

Method

We conducted a diary study over three workweeks with an experimental intervention design. Forty-six employees from one company filled in one daily survey at the end of the workday. The first week was used as baseline week without any interventions. During the second and third week, participants were randomly allocated to receive a nudging intervention (descriptive social comparison, default option or control group) and to participate in a lunch break intervention (active break, mindful break or control group).

Results

Results of multilevel analyses showed that on days with a higher time pressure participants took shorter lunch breaks. However, lunch break length was not associated with recovery indicators at the

end of the workday. The nudging interventions did not prolong the lunch breaks, nor did they reduce the negative effect of the workload on lunch break length. On days the employees participated in the active or the mindful break interventions, they reported increased positive and decreased negative affect, but no increases in their work engagement. Participation in break interventions did not strengthen the association between break length and recovery indicators.

Conclusions

Our study shows that it is possible to enhance lunch break recovery by participating in active and mindful break activities. In the current study, nudging interventions were not effective in preventing employees from cutting their lunch break short on stressful days. However, since lunch break length was not associated with recovery indicators at the end of the day, focusing on increasing break quality, rather than break quantity might be more important to optimize lunch break recovery.

Limitations

As the sample size of our study was small and all employees came from only one organization, the generalizability of our results may be limited. Further, the average length of lunch breaks over all three weeks was rather high (M = 38.6 minutes); hence, there was little room for improvement regarding break length.

Relevance to the Congress Theme & Relevant UN SDGs

Our study contributes further insights into the topic " The changing world of work " by investigating new possibilities to improve lunch break recovery. In a changing world of work with increasing and intensifying demands, knowledge about effective recovery is essential for sustaining employees' good health and well-being.

Keywords: Recovery, Nudging, Breaks

“What Do I Want to Do Next?” The Phenomenon of Task Rotation at the Workplace

Yingyue Luan & Yeun Joon Kim | Cambridge Judge Business School

science

Organizations have touted and implemented task and job rotations at the workplace because they anticipate various benefits from rotations such as greater job satisfaction and an increase in performance due to lower monotony and higher flexibility. However, because of organizations’ strong belief in their advantages, their adoption of task and job rotations have left with no autonomy to the employees. As a result, it is hard to distinguish if employees truly appreciate the opportunity and benefit from rotating and switching tasks at the workplace. We focus on task rotation in this study which refers to the switching between tasks within a job that requires different skills and responsibilities. We draw on both inertia and effort-recovery literature to explain why individuals refuse or prefer task switching at work. Across three studies (an online cross-sectional study (N=115), an experience sampling study (N=1047, number of participants=163, number of waves=7), and a lab experiment (N=195), we found that individuals in general showed no intention to switch to a different task from their current task (Study 1-3). The preference was especially strong when individuals who have been working on creativity tasks were asked if they want to switch; they expressed no interest in rotating to a routine (non-creativity) task. Furthermore, their performance on the routine task after switching showed no difference compared with the baseline condition (Study 3). However, when individuals who have been working on routine tasks were asked, they showed mixed preferences between continuing working on routine tasks or switching to a creativity task, mediated by boredom and information learning (Study 2). Our study contributes to the task rotation literature highlighting the employee’s agentic role in task rotation interventions and encourages organizations to reconsider their intended influence and outcomes of the concrete deign of rotation practice. Our findings also have implication for the utilization of AI at work. Organizations can consider introducing AI tools to handle repetitive and routine tasks so that employees can focus on generating creative ideas and solutions.

Keywords: Task rotation, Creativity, Boredom

„Everything is important“ – Testing rating scales for a differentiated value measurement in organisational research

Svenja Schumacher, University of Osnabrueck; Karsten Mueller, University of Osnabrueck; Regina Kempen, Aalen University of Applied Sciences; Lena Schmeiduch, University of Osnabrueck

science

Research goals: Although organisational values are extremely important in organisations, their reliable and valid measurement remains challenging. When measuring values, typical distributional difficulties such as left-skewness occur. This study aims to test alternative response scales for measuring organisational values. In previous research by the authors, a substantive impact of response scale labelling on distributional properties was found. Building on these results, we expect a moderate and moderate-extreme response scale to result in more appropriate distributional parameters than a standard or an extreme response scale.

Theoretical background: Organisational values play a key role in organisational research and practice (e.g., Bourne & Jenkins, 2013). Hence, the reliable and valid measurement of values is important (Jung et al., 2009). However, as respondents consider values to be ideals, differentiation in the ranking of value importance is usually low (McCarthy & Shrum, 2007). Consequently, value measurement in organisational settings faces typical distributional difficulties (e.g., pronounced skewness, non-normality) limiting its informational value. Thus, rating scales with approx. equidistant verbal labels are needed as an alternative to alleviate the difficulties in organisational value measurement.

Design: Organisational values were measured with the German version of the Organisational Culture Profile (OCP). 406 participants took part in an experiment with four conditions, which differed in the presented response scale varying the extremeness of the verbal labels. A categorisation of these verbal labels has been developed in previous work. Affective commitment, turnover intention, and job satisfaction were measured as external criteria. Differences in variance, value means, normal distribution, intraindividual variance and the prediction of organisational value-related variables were analysed.

Results: Results showed lower value means for all three alternative rating scales compared to the standard scale. While no significant differences between the conditions emerged for value variance, the response distribution of two of the alternative response scales conformed to a normal distribution. The value distribution for one of the alternative response scales was significantly less skewed than the standard scale. Predictive validity of the values did not differ between the conditions.

Limitations: The present study uses panel data. Thus, incentivized participation potentially affects responses. However, data quality was monitored via control items and analysis of reckless responding.

Implications: Research on organisational values relies on reliable and valid measurement. This study offers response scales solving distributional issues of value measurement. The results advise future research on organisational values on how to create reliable, valid, and useful response scales. The developed rating scales enable the measurement of normally distributed and highly differentiated value ratings, thus improving the quality of future research in this context. Further, results of this study underline the importance of considering the specific subject area in which rating

scales are employed. Sophisticated development of response scale labelling is crucial for the remedy of distributional issues.

Relevance to Congress Theme – To assess changes and their consequences in the working world, organisational research requires reliable scales.

Keywords: organisational values, value measurement, response scale

A cross-sectional study about nurses´ profiles in workplace incivility: the effect of sexism on employment

Esther Lopez-Zafra, Isabel Carmona-Cobo & Manuel Pulido-Martos | Universidad de Jaén (Spain)

science

Research goals: Drawing upon role congruity theory, this study aims to analyse how uncivil nurse leaders are perceived in the feminine nursing context by their counterparts (nursing workers) and which are the consequences they predict.

Theoretical background: Nursing is still perceived in a feminine context. Despite current advances in gender equality, gender stereotypes remain evident nowadays. Furthermore, leadership characteristics have been traditionally associated with agentic characteristics (Vial & Napier, 2018). Thus, in this context we could wonder whether to being a nurse and acting in an agentic way, could be perceived as (in)congruent and (un)civil. In fact, recent research reports a high prevalence of incivility among nurses. Research about incivility in the nursing context has mainly focused on victims and less on bystanders. Moreover, less is known about how sexist perceptions can affect the perceived consequences of an uncivil situation. In sum, addressing incivility in the workplace is essential not only for the benefit of the nursing profession but also for quality healthcare outcomes including safety.

Design/Methodology: In a Quasi-experimental cross-sectional survey 557 nurses (63% women) were asked to read a scene in a hospital describing an episode of incivility from a nurse leader toward a nurse employee.

Results: Nurses are low in sexism in this working context, but two clusters emerged showing two distinct profiles: high sensitized nurses, who were higher in awareness and lower in tolerance for incivility; and medium sensitized nurses, who were lower in awareness and higher intolerance for incivility. Moreover, medium-sensitized nurses were significantly higher in sexism on employment affecting their evaluation of the incivility situation.

Limitations: All the participants pertained to the same culture and to different positions in the nursing context. Moreover, the levels of sexism in nursing participants were low, and generalization is limited. It would be also of interest to further explore whether in other cultures (i.e. masculine or feminine) the levels of sexism differ. Furthermore, comparing specific contexts of nursing (i.e. specialities or healthcare centres) could help to acknowledge the context influence.

Conclusions – research and or practical implications/Originality/Value: Despite most nurses being sensitized to incivility, slight higher sexism makes a difference in the perception and tolerance of an uncivil episode by bystanders. Therefore, it is yet necessary to train nurses, especially men, in the awareness of incivility. Enhancing the awareness of these behaviours could reduce this source of stress and negative consequences among nurses.

Relevance to the Congress Theme: The relevance of this study derives from the need of making work environments less uncivil and stereotypes context. The "future is now" implies solving gender problems in working contexts.

Keywords: nursing, sexism, workplace incivility

A gender-role perspective of employee wellbeing and resilience

Tinkuma Edafioghor, University of the West of England

science&practice

Research goals and why the work was worth doing

The existing literature suggests that wellbeing plays an essential role in establishing a ground for resilience (Steel et al., 2008; Athota, 2019) and potential relation between resilience, wellbeing and gender (Purvanova and Muros, 2010). Women in particular have been found to score lower on measures of resilience (Stratta et al., 2013). Employee wellbeing and resilience appear to be associated with specific organisational and cultural contexts. For example, Huang et al. (2019) found that gender plays an important role on employee wellbeing in the Chinese retail sector. However, research on wellbeing and resilience from a gender perspective in the UK is scare.

The aim of this research is to examine the relationship between resilience and employee wellbeing from a gender perspective. The research seeks to address the following research questions:

Are UK retail employees' reaction to exceptional job demands different in respect to their gender?

Could any relation be established between resilience and wellbeing and the reaction to these demands?

What is the implication for HRM practices in the UK retail sector?

Theoretical background

This research draws on the Job Demands-Resources model as it provides a useful theoretical framework that organizations can use to understand the well-being of employees and improve their health at work, whilst at same time improving performance of the organization. The model argues that there is a tendency for every occupation to have specific risk factors linked with job stress, which can be grouped into two overarching categories of job demands and job resources (Bakker & Demerouti, 2007). Job demands are potential initiators of a health impairment process and may include workload and emotional demand while job resources are factors that can initiate a motivational process and include interpersonal relations, job security, and participation in decision-making (Bakker et al., 2004; Crawford et al., 2010). Accordingly, Crawford et al. (2010) argue that these two general categories can have significant effect on the well-being of employees. The current research focuses on these two overarching categories especially as hard work and the need for emotional management in delivering satisfactory customer service are associated with retail sector jobs (Bakker & Demerouti, 2007; Huang et al., 2019) and interpersonal relations, job security, and participation in decision-making influence employees in the retail industry (Huang & Gamble (2011).

Design/Methodology/Approach

The methodological paradigm chosen for this project is empirical-quantitative research which requires the development of hypotheses based on extant literature. Survey data will be produced through an online questionnaire via Qualtrics from 1000 frontline employees of 10 large retail stores (supermarkets) in Bristol, United Kingdom. The survey questionnaire will be based on a deductive theoretical framework aimed at examining the extent to which respondents regard the influence of job demands and resources on their own wellbeing.

Results expected

it is expected that the effect of workload, emotional demands, job security, employee participation in decision making on employee wellbeing will differ by gender

Limitations

This research has some limitations that provide opportunities for future research. for example, a cross-sectional design is used. Future research can address this by adopting a longitudinal design to understand the relationships employee wellbeing and resilience and the role played by gender

Conclusions

This research has important implications. First, the findings will provide organisations and in particular, those in the retail sector with a better understanding of frontline employees and hence, help inform HR policies designed to increase wellbeing and resilience. In this regard, I will offer consultancy services to organisations in the retail sector and organize webinars and online workshops. Second, this study extends prior research which focuses on emerging economy context, by showing the role of gender in the relationship between employee wellbeing and resilience.

Relevance to the Congress Theme

This research is relevant to the congress theme - the Future is now: the changing world of work shares critical links with employee resilience and wellbeing. Also, employee resilience have been identified through empirical research to substantially improve employee wellbeing (Cooper et al., 2014; Tonkin et al., 2018)

Relevant UN SDGs

This research is relevant to good health and wellbeing, decent work and economic growth and gender equality.

Keywords: employee wellbeing, resilience, gender

7-minute science 7M10

Training transfer: a nexus between formal and informal learning

Giuliano Cataldo Gemmano, Maria Luisa Giancaspro & Amelia Manuti |University of Bari (Italy)

Training transfer: a nexus between formal and informal learning

The present study aims to investigate the relationships between formal and informal learning processes at work and their interaction effect on transfer of training. The challenges posed by the current working contexts have highlighted the crucial role played by workplace learning to continuously adapt job skills, however, most companies still focus only on formal training programmes losing valuable opportunities from the integration between formal and informal learning processes (Manuti et al., 2015).

Workplace learning is the process engaging individuals in training programmes as well as experiential learning for the purpose of implementing competences (Jacobs & Parks, 2009). Therefore, it consists of both formal and informal learning dynamics. Formal learning is traditionally referred to training courses, characterised by a prescribed learning framework and specific objectives (Eraut, 2000). Informal learning occurs in the actual work setting because of evolving activities, it is mainly experiential and characterised by individual reflection and relational exchanges (Marsick & Watkins, 1997). The effectiveness of the formal learning processes is often evaluated in terms of transfer of training - the extent to which the learning acquirements resulting from a training experience might transfer to the job – but transfer needs experiential informal learning for generalization and retention (Baldwin et al., 2017). Despite a large theoretical consensus on the importance of a variety of learning opportunities, few studies focused on linking formal and informal learning processes (Ford et al., 2018).

An online survey was administrated to 119 employees investigating perceptions of HRM practices referred to formal training, individual evaluation of the formal training, organization's learning culture, informal learning behaviours, and transfer of training. A path analysis was conducted to investigate direct and indirect relationships and explore the interaction effect between formal training evaluation and informal learning behaviours on transfer.

Results showed that HRM practices were related to training evaluation. Organizational learning culture was related to informal learning behaviours. Training evaluation and informal learning behaviours were both related to training transfer and showed a significant interaction effect suggesting that the relationship between training evaluation and transfer intention was stronger for those employees who adopt more informal learning behaviours.

The cross-sectional nature of the study and the self-report measures do not allow strict causal conclusions.

Research and practical implications of the study suggest that formal and informal dimensions of learning need to be seen as interdependent rather than separate processes. Specifically, high-quality training courses may result in higher levels of transfer if they are complemented by informal learning behaviours, which are promoted by organizational learning culture. Therefore, a learning culture should be widespread at all organizational levels since it has a crucial role in promoting informal behaviours that contribute to the effectiveness of formal training. Organizations that consider closely the virtuous circle between formal and informal learning dimensions may benefit in terms of return on investment in training and employees development.

Congress Theme of training and development.

UN SDGs: goal 8

Keywords: Transfer of training, Informal Learning, Learning Organization

Openness or closedness to experience – what protects better bullied employee's mental health?

Anna Skuzińska, Academy of Applied Medical and Social Sciences in Elblag; Wojciech Plopa, University of Economics and Human Sciences in Warsaw

The aim of the current study was to better understand the role that openness to experience plays in the relationship between mobbing and employee mental health. Psychosocial stressors, and mobbing in particular, are important risk factors in the workplace. Mobbing is a specific stressor which comprises hostile social interactions and ambiguous workplace communication (Einarsen & Nielsen, 2015). High openness to experience involves tolerance of uncertainty, more liberal social attitudes, adaptation to change, and divergent thinking (McCrae, 1996). Employees with high openness to experience more frequently appraise stressors as challenges rather than threats (Penley & Tomaka, 2002). Thus, they may be able to better cope with negative workplace acts (mobbing).

We carried out an anonymous, cross-sectional study of n = 695 employees (nurses, public servants, and police officers). We used Goldberg and Williams' GHQ-28, Diener et al.'s Satisfaction With Life Scale, Costa and McCrae's NEO-FFI, and Einarsen and Raknes' Negative Acts Questionnaire. Contrary to expectations, lower rather than higher openness to experience protected employee mental health against negative workplace acts, particularly anxiety and insomnia, social dysfunction, and physical symptoms. This paradoxical effect may explained by the impenetrable cognitive set and the need for closure characteristic of individuals with low openness to experience. It may motivate them to make surface-level interpretations of others' behaviors and not seek alternative, "deeper" explanations. On the other hand, these results may also be explained by an interaction between closedness and workplace environment. In highly structured workplace environments, individuals who are closed to experience are better able to cope with conventional tasks than individuals who are open to experience. Through its relation to a low amplitude of experienced emotions, low openness to experience may have a protective role for the mental health of employees experiencing intensive negative workplace acts.

These conclusions are suggested tentatively due to the study's cross-sectional and self-descriptive character. In sum, it seems that those characteristics of closedness to experience which seemingly make individuals more vulnerable to stressors actually have a protective role in the context of mobbing. The role of openness to experience appears more complex and interesting than previously thought. Future studies on mobbing should explore these surprising effects caused by well-known factors and their interactions. Studying protective factors for mental health in the workplace is in line with one of the United Nations' Sustainable Development Goals - good health and well-being.

A Meta-Analytical Review on Negative and Positive Crossover at the Work-Family Interface in Couples

Rebekka Simone Steiner, University of Neuchâtel; Laurenz Linus Meier, University of Neuchâtel; Franciska Krings, University of Lausanne; Andreas Hirschi, University of Bern; Mina Westman, Emeritus in Coller School of Management; Denise Messerli, University of Neuchâtel

science

Research goals and why the work was worth doing

Crossover refers to a dyadic or interpersonal transmission, whereby stressors and resources are transmitted between closely related persons, such as life partners, across the work and family domains (e.g., Westman, 2001).

Two recent meta-analyses on crossover among life partners contributed in important ways to our understanding about crossover from work to family. At the same time, these meta-analyses mainly focused on crossover of stressors from work to family. Yet, besides stressors, also resources are powerful determinants of work- and family outcomes, not only for the focal employee but also for the life partner at home. Hence, also positive crossover (i.e., crossover of resources) between life partners can occur. Further, existing meta-analyses only focused on the crossover from work to family; however, crossover among life partners is considered a bi-directional phenomenon that also includes crossover from family to work. In addition, more knowledge is needed with respect to the underlying mechanisms through which crossover at the work-family interface unfolds. Finally, as work and family tend to remain highly gender-segmented, at least in heterosexual couples, further knowledge is needed of whether gender differences exist in crossover effects at the work-family interface.

We aim to address the identified gaps, by providing a quantitative summary of negative and positive crossover from work to family and from family to work among life partners, as well as the underlying processes and boundary conditions of these crossover effects. Thereby, we contribute in several ways to work-family crossover research. First, by investigating—besides crossover of demands—crossover effects of resources, and crossover from family to work, we contribute to a more complete picture on crossover effects at the work-family interface among life partners. Second, by investigating theoretical assumptions about the underlying mechanisms of crossover, we contribute new knowledge about how crossover among life partners unfolds. Third, by investigating gender differences in crossover effects, we provide new insights into potential boundary conditions of crossover effects.

Theoretical background

According to the work-home resource model (e.g., Brummelhuis & Bakker, 2012), stressors/resources in one domain deplete/increase resources and impede/facilitate accomplishments in the other domain. As in couples, the work and family domains tend to be highly intertwined, according to crossover theory, stressors and resources in different life domains have not only implications for the job incumbent but also for their life partner.

Design/Methodology/Approach/Intervention

We conducted a computer search, using the PsycINFO, Web of Science, and Scopus databases. We combined the following search terms work-family , work-home , work-life , each paired with each of the following search terms crossover , dyadic , couple , spouse .

We applied the following inclusion criteria: First, studies had to investigate cross-domain crossover. That is, stressors or resources that the job incumbent faces in one domain cross over to affect an outcome of the life partner in the other life domain. Second, to be included, measures of both spouses had to be reported. Finally, we included empirical quantitative studies that were published in English. Based on these inclusion criteria, we identified 113 articles as relevant for our meta-analysis.

Results obtained or expected

Preliminary analyses indicate that besides stressors, also resources have crossover effects on the life partner. In addition, preliminary results indicate crossover effects occur in both direction, that is, from work to family and from family to home. The final results, as well as the results for the underlying processes and gender differences in crossover effects, will be ready to be presented at the conference in May 2023.

Limitations

We limited our meta-analytical investigations to crossover across life domains (i.e., cross-domain crossover) in heterosexual couples.

Conclusions: Research/Practical Implications /Originality/Value

We add to previous meta-analytical findings by showing that besides work stressors, also work resources have important effects for the life partner. Further, we provide evidence that crossover occurs not only from work to family, but that also factors at home impact on the partner at work.

Relevance to the Congress Theme

Increasing rates of telework will increase the interconnection of work and family for many people, making crossover in couples more likely to occur. Hence, understanding how stressors and resources in the two life domains affect not only focal employees but also their partner seems increasingly crucial.

Keywords: Crossover, work-family, couples

Adaptation of Self-Perceived Employability Scale and Psychological Predictors of Young Adult's Employability

Piotr Mamcarz, Katolicki Uniwersytet Lubelski Jana Pawła II; Andrew Rothwell, Loughborough University; Agnieszka Fudali-Czyż, Uniwersytet Pedagogiczny w Krakowie; Klaudia Martynowska, Katolicki Uniwersytet Lubelski Jana Pawła II; Ewa Domagała-Zyśk, Katolicki Uniwersytet Lubelski Jana Pawła II

science

Research goals:

The main aim is to explore Polish University students' employability and its psychological predictors. Many studies suggest that employability is positively correlated with job-seeking, self - efficacy and is the crucial factor in graduates' transition to the labor market (Paulos, Valadas, Almeida, 2021; João, Gamboa, Paixão, 2019). The research goals are focused on:

To examine the relationship between self-perceived employability and procrastination, personality, and hope for success;

To establish the psychometric properties of the adapted, polish version of Self Perceived Employability Scale;

To make recommendations for curriculum and policy initiatives relevant to Universities, career counselors, and managers in organizations.

Theoretical background:

Employability in a traditional view has been understood as a set of skills that is likely to give a graduate secure employment (Rothwell & Rothwell, 2016). This type of thinking focused on short-term employment outcomes – on initial graduate destinations. However, a more appropriate approach might be to facilitate skill development to help individuals sustain their careers in labor markets where continuous life-long employment has not been the norm for some time. In more recent times, employability understood more as the ability to attain sustainable employment appropriate to one's qualification level, has been perceived on four different levels (Vargas et al., 2018).

Design

Ethics committee approval was obtained for the research conducted following APA requirements. Our study is based on a survey of 1200 first-year students at a Polish University. Survey instruments include the Self Perceived Employability Scale, Academic Procrastination Scale Hope For Success Questionnaire, and personality traits were measured using the Ten Item Personality Inventory. Socio-demographic data were also obtained.

Results

A two factors structure was chosen, which explained 47.6%. The internal consistency obtained in our research was lower (for the 8-item scale it was .779, for internal employability .754, and for external employability .741) than the reliability of the original version. Our findings are similar to the Spanish researchers who tested a two-factor model. Their model explained less variance (44.28%), and more items had higher factorial loadings. Finally, they received a higher reliability index in external

employability (Factor 1 – .81) but a lower reliability level in internal employability (Factor 2 – .64). The stability of the scale assessed at an interval of 4 weeks was rs = .759, p < .001 for external factor, rs = .650, p < .001 for internal and rs = .769, p < .001 for the general score which is at the satisfactory level. The CFA showed that x2 value is not significant(p > 0.05) and the chi-square/df ratio is < 3 indicating a great value (chi2 == 39.53; df = 17). The other model fit indices are good: CFI = 0.984; NFI=0.973; RMSEA = 0.047; PCLOSE=0.570. The results also showed that employability was predicted by personality, procrastination, and hope for success. Hence, the research reveals an understanding of the relative importance of antecedents that determine employability.

Limitations

Some limitations set a basis for future research directions. Firstly, reliance on self-report measurement raises concerns over construct validity due to response distortions, among others. Secondly, the sample was derived from a single university and focused on a simple measure of self-perceived employability in this specific context. Additionally, the follow-up study could take into account possible socio-economic changes resulting from the specific global situation.

Conclusions

Perceived employability may be considered an important variable – from the economic, educational, and individual perspectives. However, following the career development of graduates in Poland – and graduates of our university in particular – it can be noted that for a number of them, their employability skills are not solid enough to enable them to find a good job and feel competent players in the job market. This observation underlines a gap in the employability perception of students and reality after graduation. More importantly, it calls for implications for university study programs: they should incorporate not only subject knowledge but also courses on developing student's manage-rial, communication, and career development skills.

Relevance to the Congress Theme

Our concern is regarding the work-readiness of the graduate workforce, their sustainable livelihoods, as well as their ability to engage proactively with the world of work from a basis of sound psychological health.

Keywords: Employability, job-seeking, personality

Adapting Mindfulness-Based Programmes to the Workplace: An exploratory Case Study

Anne Macdonald, University of Edinburgh

science&practice

According to the World Health Organisation, 8% of the global disease from depression is currently attributed to workplace risks (Prüss-Ustün & Corvalan, 2006). In recent years, the pace of demand for making the wellbeing benefits of mindfulness-based programmes in clinical settings available in more mainstream settings such as the workplace, has outstripped the pace of research. There is both a need for more knowledge on the process of adapting mindfulness-based programmes (MBPs) without compromising their integrity and effectiveness (Crane et al., 2016), as well as a need to explore the outcomes and process of adapted programmes, (i.e., what works and why, e.g., Lomas et al., 2017).

Underpinned by a pragmatic research philosophy and using a case study design, this series of studies aimed to address these needs. A phased approach to adapting an MBP to a retail workplace setting is outlined, with two studies exploring the scoping phase and one single-case design intervention study investigating the implementation and evaluation phase.

The overall findings contribute to the fledgling body of knowledge on adapting MBPs in two ways, both of which offer advances to professional mindfulness teaching practice. Firstly, the adaptation process used provides a platform for developing a “compass” for mindfulness teachers to use whilst adapting programmes and protecting their integrity. Secondly, the intervention study findings strengthen the case for workplace MBPs being a facilitator of mental wellbeing and other useful employee behaviour benefits (e.g., interpersonal skills, ability to focus). The programme theory of change and associated theory of action elicited offer a clear support to mindfulness teachers in their articulation of how and why MBPS can benefit a prospective organisation.

Whilst the case study approach limits the generalisability of the findings, it paves the way for future research to refine both the adaptation process and the use of a specific theory of change and theory of action for workplace programmes.

AI, will you hire me? Perception of AI-assisted recruiting systems in the context of assessment centers

Matthias F. C. Hudecek, Department of Experimental Psychology, University of Regensburg, Germany; Eva Lermer, Department of Business Psychology, University of Applied Sciences Augsburg, Germany and Center for Leadership and People

science&practice

Research goals and why the work was worth doing

Artificial intelligence (AI) will become increasingly important in the organizational context in the near future. However, psychological research on this topic is still scarce. Thus, our scenario-based study examined the perception of AI-assisted feedback in the context of assessment centers (AC).

Theoretical background

Previous studies have shown that people have concerns about using AI in recruiting. Concerns are expressed about usefulness (Araujo et al., 2020), fairness (Acikgoz et al., 2019), or emotional creepiness (Köchling et al., 2022). Based on construal level theory (Lermer et al., 2015), we examine the extent to which the degree of individual involvement influences the perception of AI-assisted recruiting as there is evidence from the medical context that people prefer the advice of human doctors rather than AI when it comes to their own situation (Hudecek et al., 2022).

Design/Methodology/Approach/Intervention

We conducted a preregistered (osf: https://tinyurl.com/42v2xeyp) study with a 2x2x2 between-subjects design. Participants (N=379) were asked to imagine that they vs. an average German citizen (condition perspective) have recently applied for a senior lead position in a medium-sized company. They (vs. the person) have successfully completed the first phase of the selection process. After a personal interview, they (vs. the person) are now invited to a one-day AC. Here, participants were then randomly assigned to either human recruiters or the AI HireBot (condition source of feedback). Next, all participants received randomly either a positive or a negative feedback and evaluation of their performance (condition decision). The feedback and decision were communicated to them by human recruiters or HireBot, respectively.

Results

Results show that people prefer the feedback from human recruiters rather than from HireBot. Feedback resulting in a positive hiring decision was perceived as more accurate and trustworthy. Negative hiring decisions communicated by HireBot were perceived as the worst. Accordingly, there were statistically significant main effects for source of feedback ($\eta 2=0.12$) and decision ($\eta 2=0.23$). No main effect was found for perspective (i.e., self vs. average German citizen). Thus, participants perceived feedback and evaluation in the same way regardless of whether it was about themselves or an average person.

Limitations

We used a scenario-based design which might affect the validity of results. Future studies should therefore replicate the design in a more realistic setting.

Conclusions

Contrary to research in other settings (e.g., medical advice), participants' perception was independent of whether the scenario involved themselves or an average person. In general, AI-assisted recruiting processes were perceived as critical by applicants. Especially when it comes to a negative hiring decision, it is highly recommended that feedback is provided by human recruiters.

Relevance to the Congress Theme

As AI will be of increasing importance for the organizational context, it is crucial to learn more about psychological effects to design work environments in a human way.

Relevant UN SDGs

Decent work for all requires that we use technological development in a way that meets human needs and ensures fair cooperation between humans and machines based on humanistic values. In this context, our research provides insights for the responsible use of AI in recruiting.

Keywords: artificial intelligence, recruiting, assessment center

All that glitters is not gold: Self-efficacy enhances the negative consequences of illegitimate tasks for health and job engagement

Maria U. Kottwitz, Achim Elfering, Norbert K. Semmer, Yannik Faes & Wolfgang Kälin | University of Bern

science&practice

Research goals: Believing in ones own capacity to accomplish tasks is a powerful resource. As such, this self-efficacy is known to enhance performance and personal well-being, and can buffer negative consequences of stressors. But what if the task is not worth it? Illegitimate tasks are tasks that are not consistent with the individual's occupational role because they are perceived as unnecessary or unreasonable. This study addresses the question if especially individuals with a high level of self-efficacy are impaired in health and job engagement by illegitimate tasks.

Theoretical background: Based on the Stress-as-Offense-to-Self theory, employees seek affirmation of their occupational identity. Illegitimate tasks are known for disregarding this need and thus threaten self-esteem. Previous research has shown that such tasks can impairboth health and job engagement. In general, dealing with work tasks requires effort. Personal resources, such as self-efficacy, help individuals to regulate decision-making and effort accordingly. Yet, apart from the effort to complete illegitimate tasks, they distract from pursuing more meaningful tasks. Especially when individuals believe in their abilities, a mismatch arises between needs and supplies of the work situation. Thus, we propose that higher levels of self-efficacy enhance the negative association of illegitimate tasks on general health and job engagement.

Design/Methodology: We tested our hypotheses in two Swiss longitudinal samples. In Study 1, we examined the association of illegitimate tasks and general health using data from the last two measurement points (2010, 2014) of the first cohort of the Swiss Transition from Education to Employment (TREE) study. The final sample consisted of 1'031 employees (61% female), aged 25 to 29 years. Study 2 serves to replicate these findings in a large-scale Swiss employee survey, the Job Stress Index (JSI) Study. In addition, we examined the relationship between illegitimate tasks and job engagement. A total of 368 employees (40% female) participated in both surveys (2018, 2020), aged 18 to 63 years. Data were analyzed using a cross-lagged structural equation model with a latent interaction term between illegitimate tasks and self-efficacy (Mplus 8.8), controlling for sex, age and job change.

Results: Study 1 showed a negative association between illegitimate tasks and general health. This relationship was strengthened at higher levels of self-efficacy. In study 2 no main effect of illegitimate tasks occurred, but we also found a significant interaction with respect to general health and job engagement.

Limitations: Our results are based on self-reports. Future research should include, for example, sick leave and bio-physiological indicators of health.

Conclusions: Organizations benefit from high self-efficacious employees, when opportunities to confirm one’s occupational identity are available. Therefore, organizations should take care to promote meaningful tasks in the workplace.

Relevance to the Congress Theme: A high degree of personal responsibility in shaping and redefining one's own work is attributed to the individual, but should an individual be left with the

responsibility for such tasks? Social sustainability of work also requires sustainable task design, which focuses on the social message of tasks assigned.

UN SDGs: Our study aims to promote decent work and economic growth, as well as health and well-being, as part of social sustainability.

Keywords: self-efficacy, illegitimate tasks, well-being

Applying psychometric rigour in the development of a game-based assessment

Sabia Akram & Victor Ellingsen| SHL

science&practice

There is an increasing interest in assessments with game elements as a way of improving the applicant experience and safeguarding against cheating. The initial work of this project was to redevelop an existing static assessment by adopting five key principles that a game-based assessment will address:

1) interactive and engaging, to improve applicant engagement with the recruitment process

2) dynamic to mitigate against test leakage

3) intuitive design to remove the need for written instructions

4) ensure device equivalence

5) job relevance

There is little literature on the practical development of an assessment with game-based elements in a way that is psychometrically robust. This work sets out the detailed steps in designing such an assessment and hopes to inform this area of psychometrics and invite further considerations.

We first undertook a literature review of the cognitive constructs of attention and vigilance and looked into the engineering field to explore key components of process monitoring. From this work we translated an existing static assessment, that was used as a selection tool for control room operators, into a 3-stage model. We presented this model to new and existing clients and from their feedback, scoped out the initial elements of the assessment. Key design considerations were:

How many elements?

How do we ensure measurement equivalence across devices?

How do we train the candidates in the rules of the "game"?

Should candidates be able to review the rules during the assessment?

We developed 5 moving elements each with its own distinct set of rules defining when each element is either "safe" (requiring no action), or in an "alarm state" (requiring some action). We focussed on ensuring that all elements can be measured in a psychometric sense. We devised a clearly defined sequence of events, at a second-by-second level, such that each element had specified windows of time that constituted where an applicant can be awarded credit for a response. Timing of events and responses would inform the scoring. This 2-minute sequence constituted one block and the aim was to build multiple, equivalent blocks to dynamically construct an assessment.

The first block will be trialled in November. The trialling will inform further block construction and scoring methodology, namely: Was the trial block complex enough/too complex? What is the response behaviour to the "alarm" states of the elements? Do we award partial credit to responses? How do we ensure device equivalence?

A separate criterion-related validity study will also be conducted in December to validate the assessment with existing job roles.

One of the limitations of our approach is the resource intensive nature of constructing a block. We are currently doing this manually in order to maintain full psychometric control given the novel nature of the assessment, but a future approach could be to automate the block generation subject to pre-defined constraints.

This research offers a practical blueprint for ensuring psychometric principles are kept at the forefront of the development of a game-based assessment.

Increasing globalization and the pandemic disruption has meant organisations have had to adapt to working in different ways, which inevitably means recruitment assessments need to be:

Convenient (remote, mobile-enabled)

Predictive

Engaging

Provide a realistic job preview which is what our new game-based assessment sets out to do.

Keywords: psychometrics, game-based assessment

Association of Systems Intelligence and Job Performance: A Three-Wave Longitudinal Study

Sidra Liaquat, University of Barcelona, Spain; Jacqueline Coyle-Shapiro, The London School of Economics and Political Science, UK; Dr. Jordi Escartín, University of Barcelona, Spain

science&practice

In today's dynamic world, employees need to adapt to changing demands to achieve goals in their personal & social life, especially at the workplace. Systems intelligence refers to behaving intelligently in complex systems based on the interaction and feedback mechanism of the environment (Hämäläinen & Saarinen, 2004). A person's level of systems intelligence reflects his/her ability to think, adapt and act effectively by understanding the basic features of relevant systems. Individuals within a system are interconnected, they act according to their mindset, and get feedback from the system. Both system and individual are affected by each other. This study investigates the association between systems intelligence and job performance, job crafting, job stress, and job autonomy. Drawing on the job demand-resource model, we argue that human skills such as systems intelligence will affect Job performance. Specifically, job resources (job autonomy), personal resources (job crafting), and job demands (job stress) will mediate the relationship between systems intelligence and job performance. We have conducted a three-wave study (time lag mediation design) with a one-month time lag (Robledo et al., 2019) and administered self-report measures the same for each lag (Miragila et al., 2017) for three months. By following the job demand-resource model (Bakker, Demerouti, 2007), we assumed that human skills such as SI (measured at T1) lead to outcomes like Job performance (measured at T3). Whereas job resources (job crafting and job autonomy) and job demands (job stress) mediate the relationship between systems intelligence T1 and job performance T3. Measures of control variables will be done at T1. Using a three-wave longitudinal study, we test these relationships. The first time lag of data collection was completed in April 2021 (n= 405), the second in May 2021 (n=312), and the third wave was done in June 2021. Data were analyzed by SPSS and Smart PLS 0.3. Bivariate correlation indicate positive correlation of systems intelligence with job autonomy (r = .196**), positive correlation with job crafting (r = .434**), job stress (r= -.038) job performance (r = .683**). Job performance is positively correlated with job autonomy(r= .262**), job crafting(r= .230**) and job stress (.155**). Job stress is negatively correlated with job autonomy (r= -.307**) and job crafting(r= -.139**). The statistics indicate that SI has a significant effect on Job performance (β = .639, p<0.000***). We assumed emotional intelligence as a control variable which has also a significant effect on job performance (β =.119, p<.01*). Other significant predictor of job performance are; Job autonomy (β = .100, P<.013), job crafting (β = .164, p<.001), and job stress (β = .138, p<.001). Findings of the study indicate that Job position (β = -.480, P=.05) is a significant moderator, whereas gender (β = -.063, P > .790) is not a significant moderator between the relationship of systems intelligence and job performance. We hypothesized that Job crafting, job stress, and job autonomy (at T2) will positively mediate the association between systems intelligence (at T1) and job performance (at T3) over time. The mediational model was analyzed by mediational path model bootstrap in smartPLS0.3. Statistics indicate significant partial mediation of job autonomy and stress between systems intelligence and job performance. Whereas job crafting is a significant positive mediator between systems intelligence and job performance. The findings of the study will help to understand the utility of systems intelligence in organizations and the antecedents of job performance at the workplace. Future research should explain the association of work-related factors such as motivation, leadership, commitment, and success.

Authenticity at Work: Comparing Perceptions of People with and without a Mental Illness

Anouk Jasmine Albien, University of Lausanne; Teresa Maria Sgaramella & Lea Ferrari | University of Padua

science

One billion people worldwide were reported to be have a mental disorder, according to the World Mental Health Report (WHO, 2022), and 15% of working-age adults had a mental illness. An observed 25% increase in anxiety and depression was reported to be triggered by the COVID-A9 pandemic, and the global shortage of mental health resources was highlighted, with governments budgeting approximately 2% on mental health resources (WHO, 2022). In a work arena, wider societal issues are amplified that negatively affect mental health, which include discrimination, bullying, bossing or mobbing. The promotion of mental health and well-being at workplaces, together with reduction of stigma, discrimination and integration, is recognized as crucial by many national and international organizations for social and work inclusion of people who experience mental conditions (WHO Regional Office for Europe, 2010). Authenticity at work was recently explored as a set of perceptions and feelings that allows an individual to express him/herself in accordance with his/her True Self. Although, authenticity at work is related with positive job outcomes, it is dependent on organizational policies and practices. A qualitative survey was conducted with 30 workers, half of them with a mental illness, with the aim of exploring the nature and value of the construct of authenticity at work. In the first phase of our research, we used a qualitative methodology, and then in the second phase we opted for a quantitative approach by using categories, frequencies and a chi-square test to make comparisons between our participant groups (i.e., individuals with and without a mental illness) (Elliott & Wexler, 1994). Results highlight authenticity at work is characterized by intra- and inter-personal components of the Self and by a contextual component. People with mental illness recognize the role of the environment in facilitating self-disclosure and people without a mental condition highlight difficulties in social and emotional learning skills. Results confirm the importance of taking into account both individual and contextual factors to increase the perception of authenticity at work and navigate toward more inclusive organizations. The originality of this study is the finding that individuals without a mental disorder exhibited low social and emotional skills, which meant they were only able to present a partial self, so others formed images of them that did not correspond to reality. However, people with a mental illness gave more emphasis to situations when prejudice and misunderstandings, sometimes related to mental disease, affected others' perceptions and images of them. These situations resulted in work dynamics that caused social exclusion and had negative repercussions for the quality of employment relationships. The current research relates to the conference themes of Careers and the Labour Market and Diversity and Inclusion due to the focus on creating working environments that facilitate self-expression and disclosure as well as offer opportunities for growth and enrichment without the stigma associated with mental illness. Therefore, the 2030 Agenda for Sustainable Development is supported by including the relevant goals of decent work and economic growth and reduced inequalities , by creating inclusive work environments to facilitate the expression of authenticity in individual's working lives and promote mental health (Patton, 1990).

Keywords: Mental illness, authenticity at work, inclusive work environments

Behavioral signatures in multiple speed assessment

Theresa Leyens & Joeri Hofmans | Vrije Universiteit Brussel; Filip Lievens & Christoph N. Herde | Singapore Management University

science&practice

Meta-analytic research shows that the predictive validity of personality for work outcomes is low to moderate at best. We suggest that this might stem from an almost exclusive focus on personality traits, or the average level of actions, thoughts, and feelings.

Addressing this issue, we examine whether behavioral signatures (i.e., one's characteristic pattern of actions, thoughts, and feelings across a range of situations) have predictive validity for work outcomes above and beyond the average level of actions, thoughts, and feelings. To this end, we analyze data of a novel assessment method — Multiple Speed Assessment (MSA; Herde & Lievens, 2018) — in which assessors rated interpersonal behavior (Dominance, Submissiveness, Agreeableness, Quarrelsomeness) of 96 participants in 18 exercises. MSA is a new umbrella term (Herde & Lievens, 2020) for multiple, short, interpersonal simulations that allow obtaining samples of participants' actual, overt behavior in a range of situations. By using Criterion-Related Profile Analysis by Davison and Davenport (2002), a method that is specifically developed to test the predictive validity of a profile of scores, we demonstrate that the pattern of an individual's interpersonal behavioral dimensions (Dominance, Submissiveness, Agreeableness, or Quarrelsomeness) across situations does indeed account for a unique variance in teamwork and communication skills, as rated by the participant's supervisor. These findings are the first to show that an individual's behavioral signatures across situations is predictive above and beyond the average behavior. We therefore call for more attention to the dynamic interplay between person and situation as well as to assessment methods that allow revealing this interplay.

Keywords: behavioral signatures; personality assessment; multiple speed assessment

Big Four LinkedIn Dimensions: Signals of Soft Skills?

Antonio L. Garcia-Izquierdo, University of Oviedo (Spain); Jose Carlos Andrés & David Aguado | Autonomous University of Madrid (Spain)

science&practice

The use of LinkedIn as a tool in the recruitment and selection process has become routine in human resource management. However, a major drawback of such an approach is the lack of systematic and rigorous inferences on the psychological characteristics of the candidates. This study adopts signalling theory as a framework for exploring how LinkedIn profile information signals a candidate's soft skills.

The basic idea of signalling theory is that the interaction process between two people (e.g., applicant and recruiter) is composed of three basic elements: sender, receiver, and a set of signals that the sender issues to the receiver. These signals transmit the sender's unobservable characteristics (e.g., KSAO's), which the receiver can use in their interaction and communication with the sender when trying to reach an agreement. The selection process can therefore be understood as a process of negotiation between candidates and organizations.

The principal aim of this paper is to answer the following question: Is LinkedIn profile information a valid signal of soft skills? To this end, we used the LinkedIn Big Four model (Aguado et al., 2019) and an adaptation of the soft skills set used in the LinkedIn research conducted by Roulin and Levashina (2019). Using a sample of 169 ITC professionals, soft skills were measured through a self-report questionnaire, and LinkedIn profiles were assessed using rubrics for measuring the LinkedIn Big Four. The assessment of the LinkedIn profiles was carried out by a group of 12 human resources professionals. The soft skills measures were obtained through an unproctored online questionnaire completed by the participants. Every soft skill was considered as a dependent variable, while the LIBFD were considered as independent variables. We used discriminant analysis as a classification technique. Our findings demonstrate that LinkedIn Big Four Breadth of Professional Experience and Social Capital are valid signals of leadership, communication, problem solving, and entrepreneurial and commercial thinking. Moreover, discriminant analyses show significant results for: Leadership, Entrepreneurial and Commercial Thinking, Planning and Organization, and Problem Solving. As can be seen, overall ranking percentages (Hit Rate) between 55.7% (Planning and Organization) and 64.4% (Entrepreneurial and Commercial Thinking) are obtained for the four soft skills considered. This classification percentage is balanced, as the values obtained for Sensitivity and Specificity are similar.

Our research contributes to the study of LinkedIn as a method of personnel selection and the findings presented in this study offer evidence of the validity of LinkedIn to infer soft skills. In this way, professionals can avoid the unsystematic analysis of information to make decisions based on the information contained in LinkedIn profiles.

Keywords: soft skills; signaling theory, recruitment and selection

Biofeedback EEG in prevention and reduction of negative consequences of work addiction: preliminary results and barriers to providing support

Paweł Atroszko, Maciej Ciemny, Klaudia Bochniarz, Natalia Woropay-Hordziejewicz & Aleksandra Buźniak | University of Gdańsk

science&practice

Research goals

The study aimed to examine the effectiveness of alpha wave relaxation training using EEG-Biofeedback for reducing work addiction and its negative consequences, and investigate the potential barriers to providing support. Work addiction is likely the most common behavioral addiction among working populations and is related to significant individual, social and economic harm. It requires systematic and systemic solutions.

Theoretical background

Work addiction is related to the inability to relax. Occupational and outside job stresses are risk factors and consequences of work addiction. EEG-Biofeedback technology was shown to be effective in developing the ability to relax and reduce stress. Similar studies were carried out among people addicted to substances, resulting in a reduction of anxiety and decreased consumption of substances.

Design

The study consists of a screening questionnaire designed to identify people with high work addiction risk and associated decreased well-being. Individuals that scored above the established cut-off score for work addiction received feedback about the possibility of participating in a free EEG-Biofeedback relaxation training focused on stress reduction. The invitations to the screening surveys were sent to employees via employers in Tricity in Poland.

Results

The preliminary results showed that 189 of 705 (27%) of the administration staff at one of the employers who all received invitation emails completed the survey. Of them, 53 (28%) had results above the cut-off score for work addiction, with 23 (43%) having the highest possible score on burnout and 47 (89%) having a very high score on burnout. However, only one person (less than 2%) applied for the free training sessions. Also, an overwhelming majority (almost all) of the employers are unwilling to collaborate and send the invitation to screening study to their employees. Results from the main part of the study, which is the EEG-Biofeedback session, will be available at the end of the 2022 year.

Limitations

The main limitation is the difficulty accessing those qualifying for psychological support.

Conclusions

The study shows considerable problems among work-addicted individuals of not seeking and/or refusing help even when it is easily available and free. It parallels findings from addiction studies showing that more than 95% of addicted people do not seek help or/and do not recognize a problem. It points to two crucial implications. First, work addiction and its negative consequences need wider recognition to enable support-seeking among those affected. Secondly, early prevention programs

directed at young populations are necessary because they constitute feasible cost/effective solutions, overcoming barriers typical for adult working populations.

Relevance to the Congress Theme

There is high urgency to address this problem with preventive programs and psychological support. Our project shows that substantial barriers exist in providing support in this area, likely due to widespread denial among work-addicted individuals typical for addictive disorders and low corporate recognition of this problem and willingness to collaborate.

Relevant UN SDGs

The results point to an unrecognized area related to sustainable economic growth (goal 8) based on work environment and working conditions assuring good health and well-being (goal 3), particularly by drawing attention to considerable barriers in introducing support for individuals addicted to work.

Keywords: work addiction; workaholism; biofeedback EEG

Burned out by the binary: Gender non-binary employees' experiences with emotional strain

Nicholas A. Smith, OHSU-PSU School of Public Health; Larry R. Martinez, Portland State University; Mordeky C. Dullum, Portland State University; Kelly M. Hamilton, CMA Global Inc.; Sky Corby, Oregon Health & Science University

science

Research goals and why the work was worth doing

Organizations and employees are increasingly appreciating the importance of managing gender diversity in work contexts. Research related to identities that exist outside of the male/female binary (i.e., non-binary) is seriously lacking, however. In this initial investigation, we examine how having a non-binary identity might be related to psychological health at work (e.g., burnout and exhaustion).

Theoretical background

We drew on theories related to gender, stigmatization, minority stress theory, and occupational health to inform our questions, coding, and conclusions.

Design/Methodology/Approach/Intervention

We have conducted 20 interviews with gender non-binary employees to date and expect to present data from approximately 40 total individuals at the conference. All of the participants identify with identities outside of the traditional male/female binary. Interview questions focused on their experiences at work in general. We are engaging in ongoing thematic coding to identify dominant themes, in line with grounded theory methodology, and will present our grounded theory model at the conference. For this presentation, we focus on the themes related to burnout and emotional exhaustion related to having a marginalized identity, in particular.

Results obtained

Burnout and exhaustion at work manifested in three three primary ways. First, participants noted how an unsupportive work environment, or a work environment that purported to be supportive but was not supportive in practice (i.e., "performative" support) contributed to burnout. Second, they identified discussed how navigating one's non-binary identity by disclosing to, educating, and correcting coworkers was emotionally draining. Finally, they noted that their very existence at work seemed to cause disruptions among coworkers, which further contributed to burnout.

Limitations

We currently have a relatively small sample size, but are actively collecting and coding more data.

Conclusions

Our data are among the first to connect principles related to diversity and stigmatization with principles related to occupational health and burnout. Our findings suggest that managing a marginalized identity at work can contribute to work stress already inherent in basic job tasks. Organizations and employees with dominant (relatively privileged) identities can work to foster climates and cultures that are accepting of diverse identities (and non-binary identities in particular).

Relevance to the congress theme

As gender diversity increases and more employees feel comfortable expressing gender identities that have been considered nontraditional it is critically important to understand the psychological experiences that might undermine optimal performance. Our results are especially germane in the context of widespread labor shortages and increased mental health issues following the COVID-19 pandemic.

Relevant UN SDGs

Gender equality, reduced inequities, good health and wellbeing

Keywords: Gender non-binary, Transgender, Occupational health

Can PDF make you happy? The effect of job resources and digital skills on happiness and life satisfaction in the changing world of work

Arunas Ziedelis, Jurgita Lazauskaite-Zabielske, Rita Ziauberyte-Jakstiene & Ieva Urbanaviciute | Vilnius University

science

Research goals. Being happy and satisfied with life is among the most important aspirations for many. Positive aspects of work (job resources) are widely researched predictors of employee happiness (Xanthopoulou et al., 2012), but in the context of the fourth industrial revolution, digital skills are becoming increasingly important (Ghislieri et al., 2018). This study aimed to test the strength of the relationship between digital skills and employee happiness and life satisfaction and compare it with the effect of the main job resources.

Theoretical background. Job demands-resources theory proposes that individual-, job-, and organizational-level resources promote well-being by buffering against negative aspects of work and helping to satisfy employee needs. Moreover, it is well established that the extent of the impact of specific resources is not universal since their relative importance may depend on various internal and external circumstances. Rapid technological advances and the fourth industrial revolution have brought changes in how people do their work, thus possibly undermining the importance of the resources provided by the organization but highlighting the need for individual, especially digital, skills. As a result, acquiring basic digital skills for the new world of work may be a more relevant predictor of employee happiness and satisfaction than traditional job resources.

Methodology. For the analysis, we employed the representative data of one Central European country from the 10th wave of the European social survey. Data on employees' traditional work resources (i.e., autonomy, social support, feeling part of the team), basic digital skills (i.e., being familiar with preference settings, advanced search, and pdf), happiness, and life satisfaction were used.

Results. The results showed that digital skills are associated with happiness (r = .28), and satisfaction with life (r =.23), and this relationship changes only minimally after controlling for key demographic factors. Although the effects are not large, having basic digital skills is a better predictor of happiness and satisfaction than such job resources as autonomy, social support, and feeling part of a team. Regression analysis also revealed that digital skills predict happiness and satisfaction over and above the previously mentioned job resources.

Limitations. Due to the use of cross-sectional data from only one country and exclusively single-item job resources scales, the results should be interpreted cautiously and accepted as an invitation for discussion and further research. Further research should also examine the effect of a broader range of digital skills.

Conclusions. As the world of work changes, it makes sense to re-evaluate ideas about what makes people happy and satisfied. The results suggest that digital skills training can be just as necessary as conventional job design initiatives.

Relevance to the Congress Theme. The results revealed that digital skills might be as crucial as traditional job resources for happiness in the changing world of work.

Relevant UN SDGs . The study results reveal opportunities to promote the well-being of employees and are therefore relevant to the third UN SDG (Good health and well-being).

Keywords: Digital skills, job resources, happiness

Career Turning Points in Extreme Contexts: A Tragedy or an Uplift

Shahrzad Nayyeri, David Guest & Ricardo Rodrigues | King's College London

science

Careers are described as “the evolving sequence of a person’s work experiences over time” (Arthur et al., 1989, p. 8). The term experiences imply a context in which they happen (Gunz et al., 2011). Failure to capture this significant aspect causes an incomplete picture of the career development process (Akkermans et al., 2018; Hirschi & Dauwalder, n.d.). Therefore, in recent years, many scholars have called for research on the contexts in which careers evolve (Akkermans et al., 2020; Gunz et al., 2011; Gunz & Mayrhofer, 2011; Rodrigues & Guest, 2010).

Moreover, careers rarely go exactly as planned or envisioned due to experiencing career shocks. A career shock is “a distinct and impactful event that triggers deliberation about potential career transitions such as acquiring new skills, searching for a new job, changing occupations, or retiring. The triggering event may be expected or unexpected, and may or may not induce strong emotions, but it is something that occurs at a specific time and place and impacts thoughts and feelings about your career status and future career direction” (Seibert et al., 2016, 245-246).

Different contexts might cause career shocks of various natures. The growing research on extreme contexts has recently highlighted the importance of studying such work contexts (Hällgren et al., 2018b). According to Hannah et al. (2009, p. 898), extreme contexts are environments “where one or more extreme events are occurring or are likely to occur that may exceed the organization’s capacity to prevent and result in an extensive and intolerable magnitude of physical, psychological, or material consequences to—or in close physical or psychosocial proximity to—organization members”. This definition refers to the term extreme events which is defined as having three conditions: They “must (1) have the potential to cause massive physical, psychological, or material consequences that occur in physical or psychosocial proximity to organization members, (2) the consequences of which are thought unbearable by those organization members, and (3) are such that they may exceed the organization’s capacity to prevent those extreme events from actually taking place” (Hannah et al., 2009, p. 898).

The more extreme the event, the more it may shatter one's understanding of the current situation (Stevens, 1998), resulting in critical career turning points (Hodkinson et al., 2013; Strauss, 1962). A career turning point refers to a set of experiences and interpretations that led people to either exit their current career trajectory or else move deeper into it (Arthur et al., 1989b). Whereas for some people, those turning points can be a tragedy, for others who can meet them calmly, they can lift up their career. Some turning points in the career histories of people are of little emotional importance. Hancock (2009, p. 132) referred to this type of turning point as a ‘breeze’. These turning points occur frequently but only have short-term effects. They do not trigger people to reflect upon their careers. Some turning points, however, were perceived as negative and stressful. Hancock (2009) calls such events ‘gale’ and ‘hurricane’. These turning points may occur less frequently than breezes but stimulate sudden insight into careers.

Applying the life histories methodology developed by the Chicago sociologists (Arthur et al., 1989b) and using the critical incident technique, this study aims to shed light on the extreme events which can trigger career shocks, and, in turn, career turning points for people performing in extreme contexts over time. In this study, we draw on semi-structured interviews with people working in extreme contexts (e.g., firefighters, police officers, war journalists,...).

The following research questions will guide this study: Do extreme events in extreme contexts trigger career shocks that can become career turning points for people performing in such contexts over time? If so, what is the nature of those turning points? How do turning points impact individuals' careers journey over time?

Highlighting the complexity of the role of extreme contexts, career shocks, and turning points, this study contributes to two streams of research: First, it will contribute to the research on career shocks by incorporating context into this field, which helps to understand how career shocks are contextualized. Second, it will contribute to the research on extreme contexts by analyzing how such contexts appear in people's work experiences and influence their careers.

Character strengths and well-being of earning female online influencers

Małgorzata Styśko-Kunkowska & Natalia Sochacka | University of Warsaw

science

The study focuses on an arising new profession of being influencer, which has been not defined unambiguously in psychological literature yet and which has been weakly described empirically in terms of personal traits. Character strengths - in terms of Peterson and Seligman – are positive beliefs, emotions and intention of behaviors which lead person to a good life. Many studies revealed that high levels of character strengths leads to many positive outcomes including well-being and satisfaction, sense of calling, positive emotions, engagement, positive relationships, sense of meaning, accomplishments and many others. We aimed to examine which character strenghths are distinctive for female online earning influencers. Based on assumptions driven from key characretistics of character strenghts and from definition of influencers, we hypothesized that some of character strengths seems to be related with being influencer by definition, e.g. leadership, creativity, social intelligence and some character strengths seems to be important for well-being but not as much specific for the influencers.

In the study participated 125 woman aged 19-65 years old, with 66 female influencers who possessed the profile in social media, published content at least once a week, d earning money thanks to social media and self-described as a internet creator. They were compared to 59 woman who used profiles in social media but did not satisfied at least one of mentioned criteria. The t-tests revealed differences between influencers and non-influencers in leadership and in creativity, partially supporting hypotheses. Additionally, the positive correlations with well-being were found in case of leadership, creativity, social intelligence, zest, love and gratitude in both groups, and with perseverance among influencers. Strengths of correlations were higher for social intelligence and zest in case of PERMA measure and for perseverance in case of both PERMA and SWLS measures.

The study was limited to female influencers who earn by internet actions and calling themselves as creators in the Internet, so it can't be generalized for the other group of influencers. Nevertheless, it expands the knowledge about psychological characteristics and their role in well-being among female representatives in this new arising profession of social media influencers.

The study directly addresses the theme The Future is now. Contribution as it regards the competences of new arising profession.

The topic is relevant UN SDGs in the area of good health and well-being.

Keywords: Character strengths, well-being, social media

Character Strengths, Resilience and their Relationship: The Study of Hungarian Leaders

Blanka Balogh & Agota Kun | Department of Ergonomics and Psychology, Faculty of Economic and Social Sciences, Budapest University of Technology and Economics, Budapest, Hungary

science&practice

Our research aimed to find out which character strengths are the most typical in the sample of Hungarian leaders and which strengths are related to their resilience. To explore this, we used both qualitative and quantitative methods.

The moral aspects of leadership character have been researched primarily to date, especially the leadership characteristics that best underpin ethical leadership and hence ethical leadership behaviour (Wright, 2010; Brown et al., 2005; Wright and Goodstein, 2007).

Literature to date has shown that character strengths are a much stronger determinant of resilience than personal self-efficacy, social support, positive affectivity or any sociodemographic characteristic (Martínez-Martí and Ruch, 2016). Further findings suggest that higher levels of resilience, which are more prominent in coping with stress, mental health and feelings of psychological well-being, are associated with certain character strengths (Schueller et al., 2014; Peterson, 2008).

Leaders were chosen to study the relationship between character strengths and resilience because strengths themselves play a key role in leadership performance and functioning, but the study of this has received minimal attention in previous research on this specific sample. In the VIA-IS strengths framework (Peterson and Seligman, 2004), which has become most popular within positive psychology, character strengths are included that can be assumed to be the most important signature strengths for leaders (e.g., leadership, teamwork, empathy, humanity, integrity).

A total of 250 leaders (112 men and 138 women) participated in the survey. The sampling method was random and convenience: the questionnaire was distributed electronically through different media platforms, and the only condition for completing it was that the individual had to be in a leader position.

In the study, the Resilience Factor Inventory (Reivich and Shatté (2002) and the IPIP-VIA Character Strength Questionnaire were used (https://ipip.ori.org/HungarianVIAScales.htm). The questionnaire battery also included an open-ended question, which was worded as follows: “As a leader, what do you consider to be your main strengths that underpin your personal leadership effectiveness? Please describe in keywords.”

In our qualitative analysis, we categorised 580 content units, resulting in two main categories: the leader as a human being and the leader as a leader. 301 coded units described the leader as a person, and under this category we were able to distinguish three subcategories: interpersonal skills, personality traits, and people orientation. The other main dimension is called the leader as leader, and the four sub-categories here represent characteristics that are necessary to embody leadership. These are leadership competencies, leadership mindset, professional competence and leading by example.

Along the sample of 250 leaders we found that the virtues of wisdom and humanity came first, courage and transcendence came second, and justice and modesty came last. In terms of character strengths, gratitude, judgement, perseverance, vitality (zest) and curiosity came out on top - representing the virtue categories of wisdom, transcendence and courage respectively. These proved

to be the signature strengths of leaders, in the middle were strengths such as appreciation of beauty and excellence, hope and humour, and in the bottom were strengths such as modesty, humility and leadership.

In terms of the skills that support the leaders' resilience, self-efficacy ranked first and impulsivity control ranked last, although there is not a big difference between first and last place, indicating that leaders are applying all their resilience skills in a balanced way. Examining global resilience skills in relation to virtues and strengths, we found that leaders' resilience showed the strongest relationship with the virtues of wisdom, humanity and transcendence, and the strengths of social intelligence, hope and zest.

Our results confirm that leadership requires the co-presence of several strengths and that these can probably only be described along individual profiles; we cannot say that leaders must have this or that, but most importantly that they must have the strength of leadership. Our qualitative analysis also confirms this, as we have seen that one of the salient key dimensions describes the leader as a person. For the factors determining resilience, leaders scored lowest on empathy and highest on self-efficacy. Resilience is a skill that not only ensures that a leader can successfully cope with difficulties, but also thrive on them (Southwick et al., 2017). Our findings add to previous research on how resilience relates to the 24 character strengths and the six virtues that comprise them, along which useful interventions can be designed as part of leadership development programmes.

Civic happiness: a new instrument to map happiness and well-being of citizens and workers

Monica Molino & Alessandra Sacchi | University of Turin, Department of Psychology, Turin, Italy; Alessandro Mercuri, Associazione Nessuno, Turin, Italy; Aurora Comino, University of Turin

science

Research goals and why the work was worth doing

In the last five years, the social climate in Italy has been characterised by resentment, vulnerability, and psychological discomfort, especially among the most disadvantaged social classes (the poor, the working poor, youth, women, immigrants, the disabled). Moreover, distrust in public institutions risks creating a gap between people's real needs and the capacity to provide concrete responses. It is therefore necessary to provide a tool that can capture the level of happiness and subjective well-being as part of a project that promotes collaboration with policy makers, organisations, and associations.

Theoretical background

The economic wealth of a nation does not necessarily correspond to the level of well-being of its citizens. Therefore, measures other than gross domestic product are needed to inform interventions for the promotion of individual and social well-being. According to the Nobel Prize Joseph Stiglitz, "What you measure affects what you do. If you don't measure the right thing, you don't do the right thing". Most instruments are based on objective indicators, whereas in Italy today there is a need for an instrument to measure happiness and subjective well-being that asks people directly about their perceptions.

Design/Methodology/Approach/Intervention

This study aims to propose a new instrument for measuring civic happiness, namely the level of psychological well-being and satisfaction with different domains of life in a given community: 1) environment and public spaces; 2) family and housing; 3) health and safety; 4) culture and access to culture; 5) youth, school and education; 6) social relations; 7) work and life-times; 8) identity, differences, and participation; 9) use of technology; and 10) seniors and aging. In relation to the work and life-times dimension, different aspects are assessed, including job satisfaction, quality of professional relationships, perceptions of gender equality, work-life conflict, and satisfaction with family-friendly local services. The questionnaire is currently under validation in the city of Turin in cooperation with the city administration and other local organisations and associations.

Results obtained or expected (if not available, it must be made clear when they will be)

To date, 2875 citizens have completed the questionnaire and we aim to reach a representative sample of 5000 participants by November 2022. The preliminary analysis shows good psychometric properties for all dimensions. Furthermore, an investigation of the relationship between happiness, subjective well-being and each dimension is possible, including those related to work and life-times.

Limitations

The data are self-reported and the research is designed as a cross-sectional study in this first phase; however, a longitudinal investigation is possible in the future.

Conclusions

This project has important practical implications as it was set up with the aim of providing public institutions, local organisations, and policy makers with evidence-based information on citizens' happiness and subjective well-being to guide their interventions. It is one of the few tools that is entirely based on people's perceptions and allows mapping the level of happiness in different neighbourhoods.

Relevance to the Congress Theme

The project contributes to addressing some pressing issues of our time, including social change, sustainability, and inclusion.

Keywords: happiness, well-being, social change.

Congruence in perceptions of mental health and organizational performance interdependency: A two-wave study of top, middle and line managers

Christine Ipsen, DTU Management; Signe Tønnesen Bergmann, Association of Managers and Executives in Denmark; Karanika-Murray Maria, University of Leicester

science&practice

Research goals and why the work was worth doing/Motivation

There are indications that managers at different managerial levels differ in their perceptions of the links between mental health and performance and how they are enacted in their organisation. There is thus a risk that challenges and problems relating to integrating mental health and performance may remain unresolved. This work is central to a deeper understanding of why workplaces have difficulty preventing mental health and ensuring sustainable work.

Theoretical Background

The interdependence between mental health and performance is widely acknowledged. Accurate knowledge of that interdependence is of great importance for employers' practice and for achieving sustainable management. However, failing to support mental health and performance in tandem substantially affects human resources, financial, and productivity costs and is unsustainable. Despite the research[KMM1] on the interdependence between mental health and performance, less attention has been paid to how managers across different levels perceive the link. Hence, additional research on managers' perceptions of mental health-performance interdependency is warranted. The main objective of this two-wave study was to explore Danish managers' perceptions of the interdependency between mental health and performance and to compare these perceptions across managerial levels to identify potential differences.

Pertaining to our objective, we hypothesized that: There are group differences among managerial levels in their perceptions of the impact of well-being on the overall performance of the organization (self-perceptions) (three managerial levels: top, middle, line) (Hypothesis 1) . Following this, we hypothesized: There is an interaction between managerial level and Gender / Age / Educational background / Sector / Type of Industry/Business / Number of employees in the company in this relationship . Finally, conducting the study during the COVID-19 pandemic, we wanted to investigate whether the crisis influenced this understanding. Consequently, we hypothesized: The COVID-19 pandemic has/has not altered this relationship.

Design

Over two waves, survey data were collected from members of the Association of managers and Executives[CI2] in Denmark (N 1 =2211, N 2 =1520) as part of a more extensive annual survey. To assess managers' perception of interdependency, we presented this statement: I believe that employee well-being has an impact on the overall performance of the organization (Statement 1). We used a Likert-type scale (1 strongly disagree to 5 strongly agree) to record the responses. Demographic variables measured included gender, age, management level, educational degree, company size, sector (public-private), and industry. Data was collected in August 2020 and December 2021.

Results

The two surveys allowed us first to explore Danish managers' perception of the link between mental health and organizational performance and second to explore whether there are group differences among managerial levels in their perceptions of the impact of well-being on the organization's overall performance. First, the analysis reveals that managers agree that mental health and performance are interdependent. Second, the study also shows that the management level does not influence the perception of interdependence. Consequently, the perceptions are congruent across the managerial levels. Finally, the perception of interdependence remains unaltered during the pandemic.

Limitations

While the strength of this study is the unique focus on managers at different levels and their perception of mental health and performance, the study has some limitations. First, the study is a Danish study. However, it is also highly representative of the population of managers in Denmark and speaks to the hierarchy of managerial levels across organizations worldwide. Therefore, we are confident that the primary relationships and findings will apply to non-Danish managers. Second, both data rounds were collected during the COVID-19 pandemic. Although the pandemic may have changed managers' attitudes toward mental health and performance, the managerial hierarchy has not changed. Therefore, the congruence or disagreement in beliefs across managerial levels is likely to apply regardless of the pandemic. Finally, we propose a more nuanced survey to examine attitudes and seniority levels using validated attitudinal scales.

Conclusion

There is consensus on the interdependency of the mental health and organizational performance relationship across management levels in Danish enterprises, but also some points of disagreement. These are worth exploring. The next step will be to investigate managers' stress management intervention approach and whether they experience that they have the tools and programs available to solve the mental health challenges and prevention.

Contributing factors to sustainable employability and work engagement of physicians in a hospital setting

Anouk Wauthlé, Science Practitioner; Marjolein Lugtenberg, Senior Researcher; Jolanda Mathijssen, Professor; Evelien Brouwers, Professor; Margot Joosen, Senior Researcher

science&practice

Research goals

In the past decades the health care sector In Western countries has been facing multiple challenges like an increased workload, a growing complexity of care, growing costs and an aging and declining labor force. This negatively impacted the health and wellbeing of physicians, who reported higher levels of burn-out, sickness absenteeism and turnover intentions. In addition, a rising number of physicians decide to leave their jobs and upcoming physicians quit their traineeship. To maintain the quality of care and the accessibility of the healthcare in general it is important to gain a deeper understanding of what promotes sustainable employability of physicians. Previous literature shows that both individual factors such as psychological capital and work context factors such as team climate are potential antecedents of sustainable employability or work engagement. In addition, the achievement of personally meaningful work values and work is an important construct to look at.

This study aims to contribute to this understanding and focusses on the following research goals: (1) to explore which individual and work context factors are associated with work engagement and sustainable employability amongst physicians in a hospital setting, and (2) to examine the association between the capability set for work and more traditional operationalizations of sustainable employability.

Theoretical Background

Despite the emerging research on mental health and wellbeing of healthcare professionals, previous research mainly focuses on contributing factors to negative work outcomes, such as burnout and turnover intention. Less is known about the contributing factors to the positive opposite of this continuum: work engagement and sustainable employability. The capability approach suggests that people differ in the aspects of work that give them positive (or negative) energy. Importantly, if people are able (themselves) and enabled (by others) in realizing the aspects they find valuable and get positive energy from in their work, they are more likely to stay intrinsically motivated, engaged and able to cope with job demands and stress. Therefore, individual meaningful work values are important to explore since they can play a crucial role in helping physicians to stay sustainably employable.

Design and methods

A cross-sectional survey study was conducted among 250 physicians working in a general hospital in the Netherlands. Main outcomes variables were work engagement (UBES) and sustainable employability (various operationalizations). Independent variables were individual factors (psychological capital) and work context factors: team climate (Team Climate Inventory) and feeling appreciated at work. Valuable work was measured with the Capability Set for Work Questionnaire. Correlations and regression analyses will be conducted as well as multivariable regression analyses controlling for age, gender and job type.

Results

Results will be available by the end of 2022.

Conclusion – research and practical implications

The study will contribute to the understanding of which factors are associated with keeping physicians engaged, happy and healthy at work. Because of the cross-sectional nature of this study no causal relationships can be determined, this should be should be recognized as limitation.

Relevance to the Congress Theme [The Future is now: the changing world of work]

The study aims to explore contributing factors of sustainable employability and work engagement in physicians.

Relevant UN Sustainable Development Goals

Good health and wellbeing.

Keywords: Sustainable employability, work engagement, work values

Control Versus Feedback provision: HR Attributions for monitoring, privacy violations and their relationship with Well-being, job meaning & motivation

Martin Edwards, University of Queensland; Frederik Anseel, University of New South Wales; Tyler Okimito & Stacey Parker | University of Queensland

science

Research goals and why the work was worth doing

The study aims to explore how monitoring employees' digital activities shape employee HR attributions and feelings of privacy violation. In addition, we explore whether privacy violations mediate the impact of monitoring attributions on negative well-being, job meaning, and work motivation states.

Theoretical background

We explore a range of attributions based on Nishii and Wright's (2008) HR attribution framework. Specifically, we examine the extent to which perceived privacy violation is determined by employee beliefs that the organisation monitors workers for: feedback provision, information gathering for planning, legal and compliance requirements, to control workers' performance, and/or industry norms as potential attributions on feelings of privacy violation. We also draw on self-determination theory (Gagne et al., 2014) to consider the impact that control versus feedback attributions are likely to have on well-being, job meaning, amotivation, and external (social) versus intrinsic work motivation states.

Design/Methodology/Approach/Intervention.

We utilised 3 waves of survey data collection (1 month time gaps) with an online sample of workers sourced from Prolific, preselected on the basis that they work in jobs that digitally monitor and present metrics of performance. After filtering out workers who indicated that they believed that they were not being electronically monitored, we analysed a 3-wave sample of 169 workers using latent variable mediation analysis. We ensured that IVs, mediator, and outcomes were temporally separated (T1, T2 and T3 respectively).

Results obtained

We find that the more "soft HR" attributions of feedback provision with monitoring help negate employee perceptions of privacy violations, whereas "hard HR" attributions of control contributes to feelings of privacy violations. Greater privacy violation perceptions were associated with less well-being and more amotivation, and showed a negative relationship with job meaning and intrinsic motivational states (known to be related to positive employee outcomes). Both feedback attributions and control attributions have indirect relationship with lower levels of well-being, work meaning and intrinsic motivational states via feelings of privacy violation. Control attributions and norms of monitoring both have direct relationships with external (social) motivational states, control being a positive relationship and monitoring norms being negative.

Limitations

The main limitation is the sample size, which reduced through longitudinal dropout and many of the sample were unsure whether or not they were being monitored. Also, online panels may be more prone to a bias since respondents are paid for participation.

Conclusions – research and or practical implications/Originality/Value

With the increased use of electronic monitoring, where organisations are seen to be monitoring as a way to control worker output or productivity, this will foster feelings of privacy violations that are likely to lead to a sense of external (social) rather than intrinsic motivational states. More control-based attributions will also be likely to reduce employees' perceived job meaningfulness and also foster negative well-being states. However, where monitoring is conducted to help provide feedback on employee activities, employees may respond positively rather than negatively.

Relevance to the Congress Theme

The paper fits the conference themes of engagement and motivation (5) as well as organisational design and development (8) specifically job characteristics and job design.

Relevant UN SDGs

Monitoring has the potential to have a damaging impact on employee well-being; over-monitoring to control employees can be considered irresponsible and unsustainable management of human resources, care must be taken if employees are to be monitored to avoid negative outcomes and ensuring that organisations provide decent work conditions.

Keywords: Electronic Monitoring, Motivation, Well-being

7-minute science 7M179

Corporate social responsibility (CSR), justice and organizational cynicism: A fairness perspective on the imbalance of internal and external CSR

Agnieszka Paruzel, Günter W. Maier & Julia Wurm | Bielefeld University

science

Research goals and why the work was worth doing

In research and in practice, it is common sense that corporate social responsibility (CSR) has a positive impact on employees as numerous meta-analyses show. However, it is interesting to know under which circumstances CSR can have a negative impact on employees and if CSR can create feeling of unfairness and evoke organizational cynicism.

Theoretical background

In the research field of CSR, it is established that employees feel treated fairly when their organization engages in CSR, either when witnessing others being treated fairly (external CSR) or when they profit from CSR themselves (internal CSR). Building on this research, we hypothesize that this will only be the case when CSR initiatives are balanced. When external CSR is comparatively high to internal CSR, we assume that employees will feel treated unfairly and will show organizational cynicism. Contrary to the fact that procedural justice is more often studied than distributive justice, we regard distributive justice as more relevant to CSR than procedural justice and hypothesize that effect sizes will be stronger for distributive justice.

Design/Methodology/Approach/Intervention

A total of N = 116 employees participated in our correlational online study. We assessed internal and external CSR as the independent variables and distributive and procedural justice as well as organizational cynicism as dependent variables. Reliability ranged from $\alpha = .76$ to $\alpha = .95$. We investigated the fit between internal and external CSR using polynomial regression analysis and response surface analysis.

Results obtained

Applying regression analysis, we found that internal CSR was positively associated with distributive and procedural justice and organizational cynicism. Polynomial regression analysis yielded the following results: Employees experienced less distributive and procedural justice when external and internal CSR were incongruent (imbalanced). A visual and statistical examination showed a curvature on the incongruence line of internal and external CSR for distributive justice, but not for procedural justice. Coefficients of the interaction effect were larger for distributive justice ($b = -.449$, $p = .011$) than for procedural justice ($b = -.139$, $p = .164$). The interaction effect was not significant for organizational cynicism.

Limitations

The investigation was correlational and does not allow for causal interpretation. However, the research design is adequate, as this is one of the first studies in the research area of incongruence between internal and external CSR.

Conclusions – research and or practical implications/Originality/Value

Concerning theory, we promote the previously neglected role of distributive justice. CSR can be regarded as an allocation of resources and may therefore be strongly linked to distributive justice. Concerning practice, we recommend organizations to aim for a balance of internal and external CSR to counteract potential negative effects of CSR. Using a fit approach and response surface analysis is a novel statistical approach in CSR research.

Relevance to the Congress Theme

This study is relevant to the congress theme “The Future is Now – The Changing World of Work”, because CSR is highly relevant not only for environmental sustainability, but also social justice. By means of CSR, organizations can contribute to sustainability in the future.

Relevant UN SDGs

By means of CSR, organizations can contribute to the UN SDGs. The extent depends on their area of operation, as CSR initiatives are organization-specific. Potentially, CSR can contribute to the following SDGs: no poverty, quality education, decent work and economic growth, reduced inequalities, responsible production (external CSR) and good health and well-being as well as gender equality and decent work (internal CSR).

Keywords: corporate social responsibility; justice; cynicism

Corruption and System Justification - Litterature review based on PRISMA Methodology

Yohan FAVREAU & Valérie FOINTIAT | AIX MARSEILLE UNIVERSITE

science&practice

Research goals

Corruption has been the subject of research for decades in economic, political, sociological and psychological terms. In view of the negative consequences of this protean social object, much work has been done to assess attitudes towards the phenomenon of corruption, with a favourable attitude being a predictive marker for acting out.

The assessment of attitudes towards corruption is multifaceted. It covers its affective, cognitive and conative dimensions, and the targets of the assessment are themselves varied. Actors, the phenomenon, the perception of its prevalence, the intention to act, to vote for a corrupt politician or to report corruption are only a sample of the elements assessed and grouped under the generic term "attitude towards corruption". As corruption itself can be active or passive, of public or private origin, and take different forms, it is also difficult to define the phenomenon.

Over the last decade or so, only a few studies have sought to explore the links between system justification and corruption. This approach is interesting because it offers a new understanding of the status quo in societies where corruption is perceived to be widespread.

We aim to provide a state of the art of studies on system justification and attitudes towards corruption.

Theoretical background

System Justification (Jost et Banaji, 1994). According to this theory, people are motivated (to varying degrees, depending on situational and dispositional factors) to defend, support and justify aspects of existing social, economic and political systems. This theory proposes that this active support is often done by denying or rationalising injustices and other problems, even if this is at the expense of the personal and collective interests of the people concerned.

PRISMA Methodology Page, M.J., McKenzie, J.E., Bossuyt, P.M. et al. 2021. The Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) statement, published in 2009, was designed to help systematic reviewers transparently report why the review was done, what the authors did, and what they found. It should be done to ensure a systematic review is valuable to users.

Design/Methodology/Approach/Intervention

In the framework of the PRISMA method, we consulted 3 databases (PsycArticles/PsycInfo, Web of Science and Google Scholar) in order to aim at the exhaustiveness of scientific resources dealing with corruption and the justification of the system. Our query was "Bribery" OR "Corruption" AND "System justification". We then carried out a systematic review of all peer-reviewed articles in English and French in order to produce a synthesis of the state of research.

Results obtained or expected

The objective of this study is to produce a synthesis of the state of research. The results of this synthesis will be available in January 2023.

Limitations

Several factors limit the comprehensiveness of our research. We consulted 3 major databases, but these may not contain all of the world's research on the subject. Our inclusion criteria are limited to journal articles in languages we are fluent in, i.e. English and French, which may also limit our resources.

Conclusions

Our work produces a state of the art of research on the links between system justification and attitudes towards corruption and contributes to a better understanding of the phenomenon. This comprehensive and unprecedented state of the art will facilitate future research, both practical and theoretical.

Keywords: Corruption, System-justification, PRISMA

Creating a compassionate work environment for grieving employees: The role and experiences of supervisors

Sara De Gieter, Hanne Geens & Femke Legroux | Vrije Universiteit Brussel

science&practice

Research goals:

The goal of this study is to examine how supervisors can support an employee suffering from the death of a loved one in a compassionate way and how organizational initiatives can support supervisors in creating a compassionate work environment. Research on compassionate workplaces has already demonstrated the positive effects of experiencing or showing compassion for both the suffering employee as well as the compassion providers and organization (Dutton et al., 2014). However, we lack insights into how supervisors—often the designated formal contact for suffering employees—can foster such a compassionate work environment and how organizations can stimulate of hinder this through collective processes.

Theoretical background:

Within organizations, compassion refers to the interpersonal process of noticing another employee's suffering, feeling the pain, and responding to alleviate the suffering (Kanov et al., 2004). Experiencing compassion stimulates the grieving and recovery process, and strengthens the employee's feelings of being valued by and commitment to the organization (Dutton et al., 2014, Grant et al. 2008, Strauss et al., 2016). Supervisors play a focal role in the compassion experience, however, creating a compassionate work environment also requires processes of collectively noticing, feeling, and responding to suffering (Gilbert et al., 2021; Kanov et al., 2004). In this study, we examine how supervisors engaged in compassionate responding to suffering employees, and how organizational processes challenged or hindered them to respond (more) compassionate.

Methodology:

We will interview 25 supervisors who have been confronted with an employee who lost a loved one in the past 5 years. Using a narrative interview technique, we will first ask participants to share their personal experience with us, followed by questions elaborating on their personal actions and the collective processes and initiatives (or the lack thereof) supporting or hindering them in creating a compassionate work environment.

Results obtained or expected:

The first interviews are scheduled mid-November. Our data collection will be finished mid-February, the data analyses and reporting will be done from February to April. We are confident that we will be able to present our final findings at the EAWOP conference.

Limitations:

Although compassion at work is an interpersonal process occurring between members of the organization, we can only provide insights from the perspective of one actor in this process (supervisor), whereas it would be interesting to combine this with that of the suffering employee, colleagues and the organization.

Conclusions:

Almost all employees are confronted with the death of a loved one throughout their career. This situation inevitably influences the way they feel and function in general and at work. Many organizations and supervisors already acknowledge this. However so far, compassion often displays at the individual level as a result of personal initiatives. It remains unclear how organizations can stimulate a compassionate work environment with collective processes of compassion. Our study aims to contribute to this knowledge and provide policy advice.

Relevance to the Congress Theme:

Our study provides insights into how organizations and supervisors can support the mental well-being of employees who lost of a loved one, a situation that unfortunately affects almost all employees at some point in their career.

Keywords: compassionate workplace, employee well-being, employee support

Deleting and organizing irrelevant files can improve concentration and work performance – but only when people are able to mentally let them go.

Kyra Göbel & Cornelia Niessen | Friedrich-Alexander University Erlangen-Nürnberg

science

Research goals and why the work was worth doing

In view of the steadily growing amount of digital information and data files, organized work environments are important to quickly access important information and easily find one's way. However, it is still unclear how the process of organizing the digital work environment can contribute to mental relief in the short term, and whether it is depending on individual abilities to mentally detach oneself from deleted objects. Therefore, the present study aims to shed light on immediate consequences of deleting and sorting files on mental effort, concentration, and work performance in daily working life. To consider individual differences in dealing with ruminative thoughts, the individual ability to control thoughts is also considered.

Theoretical background

Being surrounded by and having to work with large amounts data files is a challenge many employees are facing in the increasingly digitized and complex world of work. Systematic organization of the work environment and avoiding clutter – that is, regularly sorting and deleting data files – are therefore important strategies which prevent distractions and enable focused work. However, the process of sorting and deleting files alone might not be sufficient to achieve positive consequences: Following the concept of distributed cognition , which proposes that cognition is routed both inside and outside the individual and that these domains are connected (Hutchins, 1995), both external (i.e., organizing the environment) and internal (i.e., controlling related thoughts) factors need to be addressed. We assume that it is important to not only delete and file irrelevant documents, but also to stop related ruminative thoughts in order to improve concentration and focused work. People having difficulties in controlling their thoughts might tend to re-think their decisions and not be able to mentally detach – with a potentially negative impact on concentration, mental effort, and work performance.

Design/Methodology/Approach/Intervention

To assess the individual ability to control thoughts, participants (N = 158) initially performed the think/no-think laboratory task (Anderson & Green, 2001). After that, participants participated in a five-day experience sampling study. During their working time, they were randomly prompted three times per day and asked questions about their sorting and deleting behavior in the past 30 minutes, about their current ability to concentrate, current mental effort, and current work performance.

Results obtained

Data from 1,476 questionnaires were analyzed using a multilevel modeling approach. Analyses showed that having deleted files did not relate to concentration, mental effort, and work performance, but sorting files was associated with higher work performance ratings. However, we identified several cross-level interactions between the individual ability to control thoughts and deleting and sorting behavior in the workplace: When people were less able to suppress unwanted, distracting thoughts, deleting files resulted in higher mental effort, and lower task performance compared to people with a higher ability. A similar pattern of results was found for sorting files:

People with lower thought control ability did not benefit from sorting files, whereas people with higher thought control ability reported better concentration and work performance.

Limitations

The main limitation of the study is that all dependent variables were based on one-item self-report ratings.

Conclusions – research and or practical implications/Originality/Value

Our study shows that organizing one's work environment can be beneficial for concentration, mental effort, and work performance – but only when people are able to stop subsequent post-decisional thoughts. These findings highlight the need to consider not only external (i.e., organizing the environment by deleting and sorting), but also internal (i.e., controlling related thoughts and stopping rumination) factors in the organization of work environments. Thus, multifactorial interventions (e.g., also providing cognitive trainings when establishing deleting routines) are needed when trying support people working in cluttered work environments.

Relevance to the Congress Theme

The world of work is changing and becoming increasingly complex. To prevent overload, it is important to understand how people deal with these changes, and how they can be appropriately supported in actively structuring and organizing their work environments.

Relevant UN SDGs

The study addresses two of the UN SDGs: By providing research results for further individual recommendations and interventions in dealing with complex, overloaded work environments, we 1) help to improve good health and wellbeing of employees, and 2) contribute to more decent work and economic growth by making organizational procedures more manageable and efficient.

Keywords: work organization, work environment, thought control

7-minute science 7M150

DEVOLEPMENT AND VALIDATION OF THE "POSITIVE ORGANIZATIONAL CULTURE SCALE (POC-S)" AND ITS RELATIONSHIP WITH WORK WELLBEING

Antonio Ortiz-Vázquez, Marisa Salanova & Susana Llorens

science

Research goals and why the work was worth doing: The main objective of this study is to validate a positive organizational culture scale (POC-S) based on prosocial behaviors and, subsequently, to analyze the relationship of its factors with the variables that make up the block of healthy employees (well-being) of the HERO model (mental competence, emotional competence, efficacy beliefs, work engagement, resilience, optimism, burnout, vertical trust and horizontal trust). The POC-S is made up of 48 items that reflect prosocial behaviors. In this way we could obtain information about how both the amount of prosocial behaviors characterized the organizational culture and what type of these influence the most the well-being of workers.

Theoretical background: There are some approaches that allow arguing and giving theoretical shape to the construct of Positive Organizational Culture (COPo) as the proposed by Luthans (2002): positive organizational behavior, being this "the study and application of positive psychological capacities and human resource strengths, which can be measured, developed and managed effectively to improve performance in the workplace". On the other hand, the HERO Model (HEalthy & Resilient Organization) refers to Positive Organizations that are characterized by the conjunction of health and resilience (Salanova et al., 2012; Salanova, Llorens & Martínez., 2019). If we define the attributes of culture as observable behaviors, it could conceptually fit into this model as organizational practices. In any case, it is also necessary to classify behaviors with a positive culture. The model does make it possible to empirically contrast which indicators of well-being it is related to and what is the degree of this incidence.

Design/Methodology: This study is part of a larger project consisting of a quasi-experimental field study using a three-stage longitudinal design in an automotive company in Valencia (Spain). At the moment, we have the results of time 1, which allows us to carry out a cross-sectional analysis for the validation of the POC-S and its relationship with occupational well-being. The construction of the POC-S began with the qualitative analysis of the company's values through inter-judge evaluation, which consisted in the extraction of psychological variables (empathy, recognition, organizational justice, trust, proactivity, curiosity, optimism, among others). The 48 resulting items have been grouped, for the moment, into the eight categories that represent the company's values. Data will be analyzed by R software by Factorial Confirmatory and Structural Equation Modelling Analyses to test mediation and moderation effects with resources and demands variables of HERO.

Expected Results: We hope to obtain the validation of the scale and a final structure of the POC-S through the application of the pertinent psychometric analyzes (establish the number of categories and the final number of items). It is also expected to obtain a directly proportional relationship between Positive Organizational Culture (behaviors) and Organizational Well-being through linear regression models[SLG5] [AOV6] . Work demands and work resources will act as moderators in the interaction between the two variables mentioned above. These results will be made in March 2023.

Limitations: First, placing the POC-S at the end of a survey made up of other questionnaires may have generated a certain acquiescence bias. It would be analyzed. Second, the current items are not grouped into categories based on any scientific criteria. Although they are grouped into eight categories, the information will actually be treated as a single block of 48 items. Finally, the collected

data belongs to only one organization. However, this limitation can be overcome by considering the very heterogeneous composition of the sample (12 departments with very different functions) and its size (2455 employees).

Conclusions: The validation of the POC-S based on prosocial behaviors will be a resource that allows knowing the organizational culture and the state in which the organizations are from a more approachable and specific perspective. The study of the relationship between organizational culture and organizational well-being, as well as its mediators (demands/resources), will allow us to know how to address possible positive psychological interventions that can improve the organizational culture towards a more positive perspective.

Relevance to the Congress Theme - "The Future is Now": As researchers of organizational well-being, it is our duty to provide tools with which we can measure and generate a subsequent change for the better in organizations through positive psychological interventions in the real context. The world of work is evolving at breakneck speed, and we must be prepared to know the state of psychosocial health of employees and how to safeguard or improve it, always taking into account the context of each organization.

Do you remember? Exploring employees' nostalgia after mergers and acquisitions

Miriam Rosa & Sven Waldzus, Instituto Universitário de Lisboa (ISCTE-IUL), Lisboa, Portugal;
Emanuel Gomes & Pedro Neves | Nova School of Business and Economics

science

Mergers and acquisitions (M&As) are frequent, but many fall short of their goals, mostly due to human factors. It is thus critical to understand M&A success from the perspective of employees. M&As imply discontinuities between past and present, requiring temporal approaches. Moreover, research on employee reactions lacks emotional perspectives. We propose that nostalgia plays a key role as a sense-making, continuity-maintaining emotion. It is defined as feeling sentimental about an appreciated, affectionate memory, and can have important benefits such as instilling a sense of continuity between past and present. However, when experienced at a collective (e.g., national) level, nostalgia can lead to the exclusion of other groups. The role of nostalgia in M&As is unknown, but we assume that it may help maintain continuity and sensemaking, but when experienced as a group member (collective), it may harm post-merger identification, a key variable for M&A success.

We took an ideographic approach, by interviewing employees and managers about their experiences. Twenty-seven interviews were conducted with people whose organizations underwent an M&A at least two years ago. The semi-structured interview guide included questions regarding nostalgic memories evoked in M&As, whether they are primarily individual or collective, to what extent interviewees identify with the post-M&A organization, and how they envision their current situation. The textual corpus was subjected to a six-stage thematic analysis, taking an abductive approach. The analysis showed six overarching themes: 1) gains and losses, 2) identification; 3) intergroup factors; 4) other risk or protection factors; 5) first reactions; and 6) nostalgia. Nostalgia was an important theme, appearing in all interviews. Participants evoked cherished moments pre-M&A, especially for those experiencing more changes and taking a negative view of the M&A. Nostalgia was often collective. An example of individual nostalgia was missing the autonomy in decision-making they had prior to the change, whereas collective nostalgia included missing past organizational traditions. Participants used nostalgia in difficult moments (when under stress at work) and saw it as bitter-sweet: comforting but tying them to the past.

Interestingly, managers saw nostalgia as unacceptable and unprofessional because it was perceived to diminish employees' availability for new organizational realities, whereas employees saw it as a positive refuge to deal with changes and guide future decisions. This mismatch can have important consequences for allowing employees' necessary sensemaking. However, only three interviews captured managerial/decision-maker participants and their perspectives, which is an important limitation of the study.

Nevertheless, this work is an important first step towards understanding nostalgia in M&As and guiding good practices such as new administrations mantaining social events, and managers allowing for planned celebrations of the past. In the scope of the EAWOP 2023 conference, the future of work in the face of change involves looking at the past, allowing it to be used as part of organizational management strategies in the quest to reduce resistance to change. This ultimately contributes to UN sustainable goal 8 (decent work and economic growth): By promoting the success of growth strategies such as M&As, innovation goals are more likely to reach their potential, and economic prosperity is fueled.

Keywords: mergers & acquisitions; nostalgia; identification

Does a Planned Day Make a Creative Day?

Wendelien van Eerde, Emma Op den Kamp | University of Amsterdam, Amsterdam Business School

science&practice

In this study, we examine whether a planned day is likely to be a creative day. We build on the daily diary study by Parke et al. (2018) that showed that planning enhanced performance, and refine it theoretically and methodologically. We add a different mediator and creativity as an additional outcome variable. We conduct the study among three randomly assigned groups: 1) one that is asked about planning in the morning, as in the original study, 2) one that is not asked about planning, to assess possible reactance, and 3) one that is asked about daily goals in the morning and their completion in the evening, to introduce more specific time management.

Parke et al. tested engagement as a mediator in the relation between daily planning and performance, and included interruptions as a moderating influence. We propose that instead of engagement, control of time is a theoretically more accurate mediator. Control of time implies feeling autonomous and confident about the use of time. Although both engagement and control of time imply a better focus, only control of time would follow from planning and dealing with interruptions. Engagement was measured as a combination of the willingness to exert effort, and cognitive and emotional energy. This is too unspecific in our view, and would not directly follow from using time management.

Additional to the self-rating of performance, we add creativity as a dependent variable. Building on the idea that control of one's own time in combination with feeling energetic enhances daily creativity, we include daily energy as a moderator in the relation between control of time and creativity.

240 participants (80 per group) will respond in a diary study over two weeks in the morning and afternoon (i.e., expected N = ca. 4800 data entries). Multilevel analyses will be conducted. The results are expected in December.

Limitations of the diary study apply, such as the self-ratings of performance, and possible effects of repeated answering over the days.

Our study will help to refine theory and, following from it, offer more specific practical advice. First of all, engagement is different from control of time. For example, engagement would imply being enthusiastic to cooperate, but control of time could mean shielding one's own time from others. Second, we answer the practical question whether daily goal setting might be a better strategy than asking people to plan. Third, we include creative performance as an outcome variable to examine whether a planned day is a creative day.

The future of work is likely to involve more flexibility in time and place, requiring more autonomy and new solutions from employees. Time management may help them to regulate their work, stay in control, completing more goals and staying energetic and creative.

Experienced shortage of time is an important factor in lower wellbeing at work, as many struggle to get things done. Provided that task design is enhanced and decent work is requested, time management may play a role in gaining more control. This study helps to provide advice about daily time management and the importance of staying energetic and mentally healthy.

Does Background Type and Blurring Affect Performance Ratings in Video Interviews?

Nicolas Roulin & Christina Scott | Saint Mary's University

science&practice

Goals: Asynchronous video interviews (AVIs) have become increasingly popular as alternatives (or complements) to more traditional face-to-face interviews. Yet, AVIs research has been largely focused on applicant reactions or behaviors, and we still know very little about how applicants are rated or the presence of biases. Importantly, because AVIs afford applicants the flexibility to record responses from their homes, elements visible in their background could influence raters' judgments and represent a new source of bias. This study examines whether raters' initial impressions and final ratings differ if applicants record their AVIs from a home-office, a bedroom, or use background blurring settings, as well as the role played by response quality.

Theoretical Background: Meta-analytical evidence suggests that applicant performance ratings are lower in technology-mediated vs. face-to-face interviews (Blacksmith et al., 2016). In AVI specifically, raters' initial impressions and final judgments can be influenced by applicants' appearance (Suen et al., 2019; Torres & Gregory, 2018). In addition, because most AVIs are recorded from applicants' homes, their surrounding environment (e.g., which room they are in, but also items like artwork, posters, etc.) becomes visible in the background of their video recordings, which may introduce unique forms of bias (Lukacik et al., 2022). This could be explained the dual-process framework for interview bias (Derous et al., 2016), which suggests that interviewers' initial impressions of applicants considered as "stigmatized" are influence by automatic processes (cognitive scripts, heuristics, and stereotypes).

Methods: We recruited 276 Prolific respondents with prior hiring experience. Participants were randomly assigned to one of six conditions in a 3 (office vs. bedroom vs. blurred background) x2 (high- vs. low-quality responses) between-subjects design. They watched a short introductory video of a male candidate and rated initial impressions. Next, they watched five video responses of the candidate (60-to-90 seconds each), and rated the candidate's overall interview performance.

Results: We tested a moderated-mediation model using Hayes' (2022) PROCESS macro (Model 15). Final interview scores were positively associated with both initial impressions and applicant response quality. Yet, background type or the use of blurring were not associated with initial impressions or final interview scores.

Limitations: This study involved a simulated selection with an actor playing the applicant role and online panel participants. The high/low-quality response scripts were very polarized, and made it easy for raters to judge the applicant as (un-)qualified. Perhaps video background plays a larger role when responses are of average quality, with more room for interpretation.

Conclusions: Recording an AVI in a bedroom was traditionally described as inadequate in popular media and research. Our findings might reflect changing normative behaviors and perceptions of AVI background due to the COVID-19 pandemic.

Relevance: This study is directly relevant to the congress theme "the future is now" because it examines AVIs, which an increasingly popular technology to select employees. It also contributes to the UN Sustainable Development Goal of "reduced inequalities" by showing that some of applicants

(e.g., from lower socio-economic status groups) can use blurring features to help “level the playing field”.

Keywords: Asynchronous video interviews, bias, interview performance

Does distributed leadership deliver on its promise? A moderated mediation model of innovative work performance and job satisfaction

Mihai Tucaliuc, Babeș Bolyai University, Cluj-Napoca, Romania

science

Objectives and theorethical Background:

Distributed leadership is extensively used in schools in order to distribute managerial workload and to increase efficiency of work coordination. Current data shows that distributed leadership is positive related to teachers and principals work satisfaction and work commitment. But in the same time the present literature did not comprehensively investigate the mechanisms that could explain the beneficial or detrimental effects of distributed leadership. Research to date showed that different sociocultural context subscribe to different ways of understanding and applying distributed leadership. Also, using the same approaches in various context it not necessarily leads to same results, but may provide diverse results, including negative effects on leaders, teachers and principals in schools.

Our hypothesis is that distributed leadership may be a double edge sword because it may reduce the distinctiveness of the organization and as a consequence can reduce organizational identification . Reducing organizational identification can impact work performance or job satisfaction .

Design and hypothesis:

Our study design is cross-sectional, we surveyed a sample of 2158 school teachers in different regions of Romania, with an average age of 42,8 years old and 245 of them were males. An online survey was distributed among different schools and the teachers were asked to complete it. As control variables we have asked participants to report their gender, age and work experience expressed as the number of years of work experience.

In our paper we tested a moderated mediation model between teachers distributed leadership, job satisfaction and innovative work performance. To explain better the relationship between these variables we used organizational identification and empowerment as mediators, dependence and distrust as moderators.

Results:

Our results show an indirect association between distributed leadership and innovative work behavior, partially mediated by empowerment and organizational identification. The indirect association between distributed leadership and job satisfaction is fully mediated by organizational identification and empowerment.

Conclussions and limitations:

Considering our findings, we think that distributed leadership is not necessarily leading to better job satisfaction or work performance, like most of the literature shows. In other words, we propose that any leadership practice must consider the culture of the country and another sociological contexts. Some limitations of our study is the transversal design and one single item scale used in the survey.

Relevance:

We think that our article is relevant because it addresses te future of using distributed leadership as a practice in schools. Most of the literature shows a lot of benefits by using distributed leadership practice, but we want to show the other part of the coin. Sometimes distributed leadership can be harmful for job satisfaction or innovative work performance. Also we explain the relations and mechanism of our findings by using individual and also school variables.

Keywords: Leadership; Distributed Leadership; Schools

7-minute science 7M38

Effects of Inclusive leadership on subordinates daily job crafting

Yuta Morinaga, Musashi University

science

This study aims to investigate the impact of inclusive leadership on day-level job crafting. While the effects of job crafting have become clearer through many previous studies and meta-analyses, research on leadership that promotes job crafting remains insufficient. In addition, most job crafting research has been conducted to identify interpersonal differences, with few detailed studies examining intrapersonal day-level variations. Therefore, it is unclear whether managers can promote job crafting by changing their behavior toward subordinates. This study is the first to focus on inclusive leadership, which is attracting increasing attention in today's society, where collaboration among diverse human resources is required, and to examine its impact on job crafting, including at the day level. Based on the Conservation of Resources (COR) theory and its related theory, the broaden-and-build theory, this study aims to clarify the mechanism by which supervisors' inclusive leadership promotes job crafting through employees' positive affect. Supervisors' inclusive leadership and provision of situational resources in the workplace to their employees may lead to an increase in the positive affect of employees' own personal resources. In addition, according to the broaden-and-build theory, positive emotional states can expand an individual's repertoire of momentary thoughts and actions and build lasting personal resources, ranging from people's physical and intellectual resources to psychological and social resources. Therefore, positive emotions are expected to lead to expansive and positive employee behaviors. Thus, positive affect encourages job crafting. We conducted a survey of 102 employees working in Japanese consulting firms using a pre-survey questionnaire and a 5-day diary survey. We conducted a Multilevel Structural Equation Model analysis using data from everyone. In the person-level analysis, the results revealed that inclusive leadership was positively related to high positive affect, and high positive affect was positively related to three types of job crafting (increasing challenging job demands, increasing social job resources, and decreasing hindering job demands). Note that person-level inclusive leadership had no direct effect on the three types of job crafting. Second, the day-level analysis revealed that inclusive leadership had an effect on two types of job crafting via positive affect: increasing challenging job demands and increasing social job resources, however, had no effect on decreasing hindering job demands. Moreover, the results revealed that day-level inclusive leadership had a direct effect on two types of approach to job crafting: increasing challenging job demands and increasing social job resources. In sum, this study is the first evidence that supervisors' day-level inclusive leadership behaviors explain variations in subordinates' day-level approachable job-crafting behaviors. In addition, the study is significant as it reveals the influence of positive emotions as a factor mediating these two variables. However, this study also has limitations. The results of the day-level analysis revealed a direct effect between inclusive leadership and the two types of job crafting. In future, it will be necessary to clarify the mechanism of variation via factors other than positive affect. Future work is required to clarify the relationship between inclusive leadership and avoidant job crafting.

Employees' change crafting in digital change processes – An initial mixed-method study

Thea Nieland, Karsten Müller, Tammo Straatmann & Luise Heyde-Schulte | Osnabrueck University

science

Research goals and why the work was worth doing – In the course of digital transformation, employees face changes due to the implementation of digital technologies in their work. We suggest that employees might show change crafting behaviours – in analogy to job crafting – to cope with the high demands imposed by these change processes. This study aims at exploring (1) if and which change crafting behaviours are shown in a digital change process, (2) which antecedents are related to the behaviours, and (3) if cross-cultural differences can be found.

Theoretical background – We build on the concept of job crafting (Demerouti, 2014) and define change crafting as changes employees initiate in the level of demands and resources to cope with the digital change process in order to make it more meaningful, engaging, and satisfying for themselves. We investigate antecedents based on Armenakis and Bedeian's (1999) taxonomy of change management factors.

Design/Methodology/Approach/Intervention – A mixed-methods approach was chosen to examine change crafting behaviours in a field study. The setting was the implementation of Microsoft Office 365 in an international company. In narrative interviews, N = 13 employees from three locations (Germany, Singapore, Brazil) reported their change crafting behaviours. In a content analysis, change crafting behaviours as well as antecedents were coded. A survey was used to assess cultural values based on Schwartz's values (2012).

Results obtained – The identified change crafting behaviours represented all categories of the crafting concept – increasing change resources, challenge seeking, and reducing demands. Individual characteristics represented important antecedents for change crafting, while change management factors (content, process, and context factors) were less systematically related to change crafting. Based on the reported patterns of antecedents and behaviours, four types of change crafters were revealed (motivated , demotivated , simplifying , and restoring status quo). For the cultural values, slight differences were found.

Limitations – Data were collected in a single company during a digital change project. While implementing Microsoft 365 is a common endeavour, generalizability of the findings needs to be tested in future research. To reduce subjectivity in the collection, analyses, and interpretation of the qualitative data, careful measures have been taken (e.g., standardized interview guidelines, establishing inter-rater reliability).

Research/Practical Implications – Findings point to a high relevance of individual attributes for engaging in change crafting – e.g., motivated crafters reported flaws in top-down change management but were themselves eager to bring the digital transformation to success. While more research is needed to understand change crafting and employees' needs, it will be also important to understand how change crafting can be fostered by change management interventions.

Relevance to the Congress Theme – The changing world of work forms the background of the present study. With change crafting, one employee-centred way to cope with the demands of recurring change and to increase the chances for successful introduction of new digital technologies is explored.

Relevant UN SDGs – The present study investigates conditions under which employees employ change crafting more likely in order to make transformation processes more meaningful, engaging, satisfying, and sustainable.

Keywords: Digital transformation, change management, coping with change

eNPS: from experience to recommendation

Paulina Robalino, Head of People Science & Research at Slik; Matias Chevillard, Data Science at Slik; Emanuel Kasianczuk, Product Manager at Slik

science&practice

In recent years the way we work has radically changed. We go through a pandemic, the great resignation, and today we are in face to the need for an intervention in workers' mental health. For organizations, surveys are a longstanding method of measuring employees, their experiences, attitudes, and opinions and gaining actionable feedback on HR development. One of these methods of measuring is eNPS. These scores are typically calculated based on responses to a single question, often whether you are likely to recommend a specific organization to friends and family, on an 11-point scale (0-10). People who select either 9 or 10 are labelled as “promoters” while people selecting options 0–6 are labelled as “detractors”. A total net promoter score is calculated by subtracting the proportion of detractors from the proportion of promoters. This philosophy of promoters and detractors can also be applied to work experiences where highly disengaged or dissatisfied employees may be expected to negatively impact their surrounding co-workers. Despite its increasingly frequent use, it must be considered that the eNPS may have certain limitations. The aim was to explore the distribution and analyse whether tenure and sex of the employee have an impact on the eNPS. A total non-probabilistic sample of 56,694 workers (59% female) from 19 companies and 13 countries aged between 19 and 69 years (M=38.72; SD=10.71). The average job tenure of the participants was 9.57 (SD=9.17) and ranged from 0 to 48 years. Participation was voluntary, and data were treated anonymously to preserve the confidentiality of the participants. The research design is descriptive, correlational, and group differences, cross-sectional and non-experimental. The results of this research confirmed that distribution shows negative highly skewed, and for 3 equal groups percentiles were 33.33= 7.7 and 66.66= 9.4. Furthermore, there are significant differences according to tenure ($F(4.56689)=70.479$; $p<.001$; $\eta^2=.04$). Participants with less than one year of tenure (M=8.41; SD=1.976) would recommend their organization more than those with 2-4 years of tenure (M=8.08; SD=2.196); 5-10 (M=8.15; SD=2.090), 11-18 (M=8.00; SD=2.216), and +19 (M=8.09; SD=2.245). In addition, participants with tenure between 5-10 years would recommend their organization more than those between 2-4 and more than 11 years of tenure. Likewise, there are significant differences according to gender ($t=14.566$; $p<.001$), men (M=8.29; SD=2.084) report better scores than women (M=8.03; SD=2.189). As a limitation, even if we found significant differences, the size of the effects is lower. Future research should consider differences between industries, and we encourage you to continue exploring the correlation with other variables (e.g., engagement, burnout, motivation). These results are consistent with the literature. It still shows the same distribution, but it should be continued exploration, especially the neutral employee group. According to the differences, it may be related to the decrease in the agreeableness trait of the BigFive model of personality, as we get older, we tend to be less complacent, and this may be leading workers to be more critical of their environment labour. As a practical contribution, the results show that the eNPS model could be helpful as an HR indicator, but we suggest that it couldn't be the only one, it always must be with other questions to explore deeper the experience of employees.

Keywords: eNPS, Employee experience, engagement

Entrepreneurial Bricolage, Wellbeing, and Business Performance

Marjan J. Gorgievski, Arnold B. Bakker, Daantje Derks & Maike Liu | Erasmus University Rotterdam

science

Research relevance and goals

Entrepreneurship is important for the economic development of societies and understanding entrepreneurial performance and well-being remains of utmost importance. Ample evidence has shown that entrepreneurs' proactive personality is important for achieving favorable business outcomes (e.g., economic growth) and individual well-being (e.g., satisfaction). However, few studies have shed light on the behavioral mechanisms through which proactive personality may foster these outcomes, and which conditions influence the strength of such relationships.

Theoretical background

This study builds on proactive personality theory and the Giessen-Amsterdam model of small business owners' success (Rauch & Frese, 2000), according to which business owners' personality and human capital can only translate into entrepreneurial success through entrepreneurial actions. In specific, we investigated whether proactive personality translates into entrepreneurial bricolage, and whether entrepreneurs' ability to recognize opportunities would strengthen this relationship. Bricolage in turn was expected to predict economic business growth. Adding the component that striving for success should not come at the cost of personal health and well-being, we also included two indicators of business owners' well-being (happiness and cynicism) to our model. Proactive personality was defined as a person's "stable disposition to take personal initiative in a broad range of activities and situations" (Seibert et al., 2001, p. 847). Entrepreneurial bricolage refers to making do with one's resources at hand to overcome new challenges.

Design and methodology

This study had a cross-sectional survey design. A sample of 291 Dutch entrepreneurs who owned and managed diverse organizations, 45% female, participated in an online questionnaire. Mean age was 41.76 (SD = 12.07). They worked in the cultural sector (24.10%), healthcare and welfare (11.7%), language media, and communication (10.3%), or other (15.10%). The number of employees ranged from zero (N = 91) to three (M = 2.21, SD = 1.22). The participants had been in business for on average 9.69 years (SD = 8.96). Variables were measured using existing and previously validated scales: The 10-item proactive personality scale (Seibert, Crant, & Kraimer, 1999; Cronbach's alpha = .68); the 9-item entrepreneurial bricolage scale (Davidsson, Baker, & Senyard, 2017; Cronbach's alpha = .87); a 5-item opportunity recognition scale (Kuckertz, Kollmann, Krell, & Stöckmann, 2017, Cronbach's alpha = .89); a 3-item scale measuring business growth (changes in number of employees, profit and financial turnover; based on Chandler & Hanks, 1993, Cronbach's alpha = .82), the 5-item cynicism subscale of the Maslach Burnout Inventory–General Survey (Schutte, Toppinnen, Kalimo, & Schaufeli, 2000) and a one-item happiness scale. Data were analyzed using structural equation modeling in R.

Results

In line with our predictions, entrepreneurs' proactive personality related positively to entrepreneurial bricolage, which in turn predicted economic business growth. As expected, moderated mediation analyses showed that entrepreneurs' ability to recognize opportunities

strengthened the positive relationship between proactive personality and bricolage. Proactive personality also related directly to entrepreneurs' happiness (positive) and cynicism (negative). However, this relationship was not mediated by entrepreneurial bricolage, because the link between entrepreneurial bricolage and happiness nor between entrepreneurial bricolage and cynicism was significant.

Limitations

The main limitations of this study relate to its cross-sectional design and reliance on self-report measures.

Conclusions

This study contributes to uncovering the black box of how entrepreneurs' personality may be related to business success and wellbeing. The results confirm expectations based on the Giessen-Amsterdam model that personality links to entrepreneurial success through entrepreneurial actions, such as being able to use one's resources in a novel way. Simultaneously, the findings indicate that these same actions do not automatically also relate to better (nor impaired) well-being.

Relevance to the congress theme "the future is now"

The world of work is constantly changing. Rather than to respond reactively, people need to be stimulated to act proactively. As this study once more underscores, running a business effectively means anticipating and self-initiating change, which includes being creative with the resources you have.

Keywords: entrepreneurship, proactivity, performance

EXPLORING THE RELATIONSHIP BETWEEN MIDDLE MANAGERS' PROACTIVE STRATEGIC BEHAVIOR AND OTHER PROACTIVE BEHAVIORS

Matthias Pfisterer, KU LEUVEN and VLERICK BUSINESS SCHOOL; Katleen De Stobbeleir, Vlerick Business School

science

Research Goals and Why the Work was Worth Doing

How are middle managers proactively initiating changes in their organizations? Fast-moving, complex organizational environments leave only limited space for top-down decision-making (Ashford et al., 2018). Scholars have argued that organizations require every level, from front-line employees to middle managers and senior-managers and executives, to be proactive i.e., to anticipate and self-initiate changes (Crossley et al., 2013; Grant & Ashford, 2008; Strauss et al., 2009). While research has predominantly focused on proactivity oriented towards shaping one's own role and immediate work environment (e.g., by seeking feedback or job crafting), far less research has explored proactive behavior directed at the organization's larger goals, such as proactive strategic behavior (Parker & Collins, 2010). Given that especially for managers, contributing to the larger organization is expected and valued, we examine how middle managers' strategic behavior affects their performance. Specifically, we suggest that middle managers' proactive strategic behavior (i.e., strategic scanning) will improve their performance, especially when used in combination with proactive behavior focused on the fit with their immediate work environment (i.e., feedback-seeking) and proactive behavior focused on making improvements in their work environment (i.e., voice). In doing so, we advance research on proactive strategic behavior and contribute by increasing our understanding of the relationship between proactive strategic behavior and other proactive behaviors and the impact of proactivity on performance outcomes.

Theoretical Background

By and large, proactivity literature distinguishes three different categories of proactive behaviors, i.e., proactive work behavior, proactive person-environment fit behavior, and proactive strategic behavior (Parker & Collins, 2010). Despite the advances of proactivity literature has made over the last two decades, research on proactive strategic behavior is still lacking and little is known about the relationship between proactive strategic behavior and other proactive behaviors. Building on prior research we develop a conceptual model to explore this gap in the present study.

Methodology

We tested our model in a sample of 266 middle manager-supervisor dyads from different companies.

Results

The results of the analysis show support for the hypothesized relationships in our model. Middle managers' strategic scanning positively predicts performance and voice acts as a mediator in this relationship, while high levels of feedback-seeking act as a moderator.

Limitations

The main limitation is based on the cross-sectional survey design in this study.

Conclusions

We show that middle managers use a combination of proactive strategic behavior, proactive work behavior and proactive person-environment fit behavior, which positively affects their performance. Our results indicate that middle managers who scan their environment to identify opportunities and threats can use voice and feedback-seeking to effectively communicate these in their organization and thereby increase their performance.

Relevance to the Congress Theme

The present study on proactive behavior is relevant to topic areas [3] and [5].

Relevance to the UN Sustainable Development Goals

Proactivity is an important aspect when it comes to achieving the “Decent work and economic growth” goal of the SDGs.

Keywords: Proactivity, Proactive Strategic Behavior, Proactive Strategic Scanning

Exploring the relationship between neurotypicals and those with ASC when completing Situational Judgement Tests

Gurleen Kaur & Dr David Gamblin | Birkbeck University

science&practice

Exploring the relationship between neurotypicals and those with ASC when completing Situational Judgement Tests – Gurleen Kaur Manku

Situational Judgment Tests (SJT) are commonly used as a psychometric measurement during the recruitment process, often for graduate roles especially. For hiring organisations SJTs are a cost-effective and convenient way to screen potential talent from a large pool of candidates (De Leng et al., 2017). It is therefore important to ensure SJTs are fully inclusive and made accessible to candidates, especially those with ASC.

Hypotheses:

H1: Those with ASC have increased difficulties with cognitive processing when sitting an SJT than neurotypicals.

H2: Those with ASC experience increased anxiety when taking the SJT compared to their neurotypical peers.

H3: Those with ASC do not find the typical SJT an accessible psychometric test.

The main theories underpinning my research is Theory of Mind (ToM) and Theory of Planned Behaviour (TBP). ToM is the cognitive ability to recognise the feelings or thoughts of others in order to develop an understanding of them and their behavioural patterns, so that they might then interact appropriately with them (Megías-Robles et al., 2020). There is very little academic research in this area but a recent article review by Balajo (2020) suggests that those who are neurodiverse (including those with ASC) are likely to find SJT more difficult than those who are not. Academic research has demonstrated strong connections between anxiety and those with ASC (van Steensel et al., 2011).

This qualitative study compared 8 graduates with ASC and 9 graduate neurotypicals on completing an SJT through the think-aloud protocol and thematic analysis. To explore the influence of anxiety in this psychometric test, all participants' anxiety levels pre and post SJT were collected using the GAD-7 anxiety scale.

Findings showed t hose with ASC reported struggles with several aspects of the SJT including hypothetical scenarios, interpretation of hidden meanings, the stress of taking the SJT and the uncomfortable scenarios on this. Those with ASC reported three times as much anxiety in comparison to their neurotypical peers.

There are limitations inherent in this study:

The study did not actively measure participants' anxiety during the SJT itself, and this could have compromised the internal validity of the study regarding H2.

Ethnicity has been shown to influence SJT performance (Whetzel et al., 2008), yet this study did not collect ethnic data. Participants from one group (i.e. neurotypical or ASC) could have been more ethnically diverse than those from the other, potentially impacting SJT scores and thus the analysis.

In terms of the practical implications of my study, it is evident that those with ASC found many barriers when completing the SJT. This study addresses a topic for which there is little academic research to compare the results to, however showing this is a novel topic. When circulating my study to those with ASC, I received positive feedback that this topic was being explored. Consequently, employers may need to review their accessibility of current SJT practices for candidates with ASC.

Intended audience: Both academic and practitioners

SDG: Reduced inequalities theme

Keywords: Autism, psychometric tests, situational judgement test

Factors influencing the participation of blue-collar workers in Worksite Health Promotion programs: a scoping literature review

Marc Damen, HAN University of Applied Sciences, Nijmegen; Annet de Lange, Open universiteit, Heerlen; Josephine Engels, HAN University of Applied Sciences, Nijmegen; Suzan Robroek, Erasmus University Medical Center, Rotterdam; Sarah Detaille, HAN University of Applied Sciences, Nijmegen

science

Research goals:

The objective of this scoping literature review is to produce an up-to-date overview of studies on factors influencing participation of blue-collar workers in WHPPs, to identify gaps in research designs and themes on this topic, and to develop new implications from the results found for future research and for implementation strategies that may enhance the participation of this target group in WHPPs.

Theoretical background:

A growing number of employers implement worksite health promotion programs (WHPPs). Especially, workers in blue-collar jobs may benefit from these WHPPs. In general, these workers report more severe physical health complaints and lower work ability than other workers (van den Borre & Deboosere, 2018). However, participation in WHPPs among this group is lower than among white-collar workers (Tsai, Alterman, Grosch, & Luckhaupt, 2019). There is little known about which factors may influence participation of blue-collar workers in WHPPs.

Methodology:

Four databases were searched: PsycInfo, PubMed, Web of Science and Cinahl. We used search terms in different combinations so that each combination contained at least all the following 5 constructs: work, lifestyle, intervention, blue-collar and participation. The first search was undertaken in February 2020 and updates were performed in February 2021 and February 2022. The search strategy was limited to English language, peer-reviewed empirical studies published after 2000. Extracted determinants of participation were categorized into 6 groups. After categorization, similar determinants were clustered and the direction of the determinant was set.

Results

Nineteen papers describing 15 studies met the eligibility criteria: nine qualitative, six quantitative. Eighty determinants were studied (quantitative) or found (qualitative). Personal characteristics were the most studied determinants. Meso and macro level factors on participation are hardly studied. Barriers for participation include shift work, travel distance and inconvenient scheduling. Faciltators for participation include peer support and health culture. Furthermore, several attitudes may influence participation, such as the attitude that WHPPs are not able to change one's lifestyle or that workplaces do not have a role in their health.

Limitations

In this review we chose not to include design studies or needs assessments. These studies could provide information on the blue-collar worker's needs, motives and attitudes. However, the outcome of these studies often is not clear. A second limitation is that no inclusion criteria on the quality of studies were formulated. Therefore, it is good to be cautious in interpreting the results. Thirdly, most

included studies were on male employees. Found results may not be directly transferrable to female blue-collar workers.

Research implications

Future research may study the prevalence of determinants that are significant and relevant in explaining participation in general, among specific target groups, such as blue-collar workers. Qualitative studies could make a comparison between perceived barriers and facilitators by blue-collar workers and other workers. Future research could study which WHPPs and implementation strategies are effective in enhancing participation. And lastly, we recommend that process evaluations always should include a more thorough analysis of who participates and why. Moreover, theory should be used in studying factors influencing blue-collar workers' participation.

Practical implications

WHPPs that do not cost a lot of effort are preferred by blue-collar workers. More active WHPPs could be organised in groups. Possible implementation strategies are: incentives, communication strategies that focus on family responsibility, combining lifestyle interventions with safety programs, leading by example, and facilitation of participation by scheduling and shorter travel distances.

Relevance to the congress theme

In western countries, labour shortages are and will be more pronounced in blue-collar than white-collar work, due to retirement of baby boomers, and a more educated younger workforce (Levanon, et al., 2021). Therefore, investment in blue-collar workers' health is necessary to attract new workers and to keep the current workforce healthy and productive.

Fake it Till You Make it? – Not for the Emotionally Intelligent. Nurses' Emotional Intelligence, Surface Acting and Occupational Well-being

Diana Kusik, Aleksandra Tokarz, Magdalena Śmieja & Kłosowska Joanna | Jagiellonian University in Krakow

science&practice

Research goals and why the work was worth doing : This study investigates the relationship between surface acting and different aspects of work-related well-being, i.e., work engagement, job satisfaction, and burnout, with a special emphasis on the moderating role of emotional intelligence abilities. Inconsistent findings on the role of emotional intelligence (EI) in the relationship between emotional work and nurses' well-being emphasize the need for further analysis and a thorough understanding of its role. In our study we consistently use the ability model of emotional intelligence to conceptualize and measure EI . Therefore, we overcome an important limitation of previous emotional labour and employee well-being research which measured EI with the use of self-reports, which may represent respondents' core self-evaluations instead of EI abilities.

Theoretical background : In order to explain the role of EI, we apply the assumptions of objective self-awareness theory, which states that discrepancies from standards that arise in a self-standard comparison process evoke discomfort, unease, or psychological strain. W e assume that surface acting can cause emotional discrepancy because a nurse presents a professional façade instead of expressing her real emotions. Therefore, w e expect that the negative effects of surface acting might be higher for emotionally intelligent nurses who accurately recognize and understand their feelings and are consequently more self-aware of their emotional states.

Methodology : The data was obtained from 374 female Polish nurses who completed a performance measure of emotional intelligence and reported on their perceived surface acting, job satisfaction, work engagement and burnout using a paper and pencil survey.

Results : Surface acting was negatively related to job satisfaction and work engagement, but it was positively related to burnout. These relationships were stronger for nurses with higher emotional intelligence.

Limitations : The presented study is cross-sectional. Because some of the data were collected using self-report measures, common method bias was assessed by performing Harman's single factor test prior to conducting the primary analyses. The sample consisted only of women, therefore, the results may not generalize to men.

Conclusions – research and or practical implications/Originality/Value : These findings provide evidence that emotional intelligence may strengthen the negative relationship between nurses' surface acting and work-related well-being. O ur findings contradict the widespread belief that emotionally intelligent individuals always have lower costs in emotionally demanding situations: the case seems to be more nuanced for emotionally intelligent nurses who engage in high levels of surface acting. By changing their work attitudes and investing less energy in their work, they can protect their authenticity, thus providing more organized functioning and better health. It emphasizes that awareness of inauthenticity in expressing emotions can be detrimental to health. This study provides healthcare organizations with insights into the importance of reducing expectations for surface acting and introducing emotional labour strategies that support self-consistency to promote well-being in nurses.

From Training to Practice: A Multi-Context, Longitudinal Study on Gender Differences in Career Ambition, Aspirations, and Progression

Niamh Dawson, The University of Queensland; Michelle Ryan & Elise Stephenson | Australian National University; Sally Knox & Mischel Luong | The University of Queensland

science

Aim: Women represent 60.4 % of all completed undergraduate and postgraduate higher degree courses (WGEA, 2021). Despite holding this majority during training, women remain underrepresented in key decision-making roles across the Australian workforce (WGEA, 2021). Our research aims to unpack the drivers that contribute to this 'black box' of career ambition, aspiration, and progression within two particularly underrepresented contexts, academia, and the military.

Background: Since 2006, women have made up the majority of enrolments in Higher Degree by Research (HDR) programs across Australia (Department of Education, 2019), with women making up 54.3% of the 2020 HDR graduates. Yet, 37% of senior leadership positions in Australian universities are held by women; the same pattern is observed in the Australian Defence Forces (ADF). Although the ADF reached a new high of 19.7% women in 2021, only 31 of the 202 senior leaders (star rank and above) were women, with no female representation above the rank of Major General (Department of Defence, 2021).

Research exploring the factors that influence why women typically have lower career advancement relative to men (e.g., Barreto, Ryan, & Schmitt, 2009) are typically categorised into internal (e.g., ambition; Davey, 2015; Kim, Fitzsimons, & Kay, 2018; Ryan, 2022), or external factors (e.g., structural discrimination; Ellemers & Barrento, 2015). More recently however, researchers have advocated for better consideration of both internal and external factors - it is often the external environment that shapes our internal choices (Faniko, Ellemers, & Derks, 2022; Meeussen et al., 2022). Whilst we know that policies alone do not redress gender inequalities in academia (Stephenson, Broadbent & Strachan 2017) or the military (Stephenson, in press), institutions do influence women's experiences and representation.

This program of research aims to understand how career and life ambitions evolve from training to practice, and what internal and external factors, as well as decision-making processes, affect this. Focusing on the context of HDR candidates and military officers enables greater insight into two highly competitive training courses, and within industries where the gender leadership gap is especially prevalent. In turn, we hope to offer insight into why it is that women remain underrepresented in leadership positions.

Design: This study will employ a mixed methods, longitudinal design to explore the gender differences in career ambition, aspirations, and progression from time of training enrolment (i.e., HDR candidates and ADF undergraduates), across 10 years. Latent growth curve analysis will be the primary analytical approach.

Method: An online survey will be administered annually via an online portal to ADF and HDR students over a 10-year period. The baseline survey will be distributed within their first year of training, and will include both Likert-style items, as well as open response questions. Participants will be asked to reflect upon career aspirations and respond to corresponding ratings measuring ambition, perceived likelihood of achievement, motivation, and confidence. Additionally, participants will be asked about other factors such as supervisory relationship, workgroup characteristics,

available role models, workplace conditions (e.g., pay, leave), career progression, incidents of bullying, and social support, as well as demographic items.

Participants will then receive a shortened version of this survey each year. In this survey, participants will be able to respond to previous responses and provide qualitative reflections of key life and work changes over the past year.

Alongside the surveys, the institutions themselves (and policies) will be analysed using process-tracing methodologies allowing for analysis of individual experiences and wider institutional changes over time (Collier 2011). This methodology enables greater consideration and understanding of key institutional changes that may impact individuals.

Results: We anticipate that gender will play a key role in ambition and career aspirations. Further, factors like supervisory relationships, workgroup and organisational characteristics, as well as institutional policies are expected to influence this relationship.

Conclusions: These findings are expected to expose the real impact that discrimination and structural barriers have on women's personal choices (i.e., ambition, aspiration, and continuation) to pursue their desired career. In turn, this program of research will offer recommendations for reaching gender parity within Academia and the ADF.

Congress Theme Relevance: The topic of gender equality examined within a longitudinal design appeals to all Future is Now facets, adressing contribution, urgency, and delivery.

UN SDG Relevance: This research addresses the UN Sustainable Development Goals (2015) on gender inequalities in two contexts; HDR and military officers.

Keywords: Gender Equality, Career Ambition, Longitudinal Design

7-minute science 7M62

Gamified survey in an organizational Setting: Card Design with instant feedback as an Enhancement for employees' survey experience and data quality –

Patrick Hofschröer, Karsten Müller & Jan Schumacher | Osnabrueck University; Thorsten Bauhaus, University of Wuppertal; Svenja Schumacher, Osnabrueck University

science&practice

Research goals: Surveys are important tools in organizations. Due to an increasing amount of survey use, survey designers should aim to avoid survey fatigue. A potential lever to increase participant motivation is gamification in survey design. To date, there is little systematic research on the effects of specific game elements in organizational surveys on participants' survey experience and response behavior. Therefore, we aimed to examine whether specific game elements (i.e., instant feedback, card design) would enhance survey experience and increase data quality in an employee attitude survey.

Theoretical background: The trend of an increasing number of surveys (Adams & Umbach, 2012; Karlberg, 2015; Porter et al., 2004) facilitates problems of survey fatigue (Turner et al. 2014) and therefore declining response rates (Stedman et al., 2019). Survey experience (SX; REF) assesses the pleasure and usability of a survey and may serve as a potential lever for the motivation to take a survey. SX may be increased through gamification in survey design. Keusch et al. (2017) showed specific effects of gamification in survey design on psychological and behavioral outcomes. However, there is a lack of systematic studies considering the implementation and assessment of gamification elements. Thus, Keusch et al. (2020) call for more experimental studies to examine effects of individual game elements on relevant outcomes.

Design: In an experimental between-group-design, employees were randomly assigned to a gamified survey version (instant feedback, card design) or a standard survey version (no feedback, matrix-design) of their employee attitude survey. The survey assessed job satisfaction, commitment, work engagement and employer attractiveness, and demographics. Survey experience served as the depended variable.

Results: Overall Sx, and pleasure were perceived as significantly better in the gamified condition. Usability did not differ significantly between the survey versions. Further, participants taking the gamified survey showed less straightlining and less item non response.

Limitations: This experimental design cannot provide any information about long-term effects like Mavletova (2015) and due to the high practical context not all items were taken from published instruments.

Research/Practical Implications: The study contributes to the growing research on gamification elements in survey design by systematically examining two game elements and their effects on survey response behavior. Practically, the results encourage survey designers to use instant feedback in a card design as a relatively easy to implement gamification design to significantly improve participants' survey experience and data quality. Addressing the challenges of lacking research on specific game elements, this study is another step towards a better understanding of single game elements and their effects on survey response behavior in the tradition of Harms (2015).

Relevance to the Congress Theme – Employee surveys are a popular tool to assess changes in the working world and may benefit from the use of gamification.

Relevant UN SDGs – " Decent work and economic growth" – We investigate how employee surveys can be enhanced through gamification. The resulting data serve as a basis for measures that improve the employee experience of decent work.

Keywords: gamified survey, data quality, survey experience

7-minute science 7M103

Ghosted? The Impact of Rejection Styles in Interpersonal Communication

Coral Zheng, David Stillwell | Judge Business School, University of Cambridge

science

Nowadays, while technology has made online communication convenient, people can also easily procrastinate on responding or even withdraw from a conversation unexpectedly, as "ghosting". This paper aims to investigate how people perceive ghosting (compared to explicit rejection) and how delaying responses moderate these perceptions. This work is particularly worth doing because it explores the underlying psychological processes of being rejected/ghosted, filling in the literature gap where rejection and ghosting were only studied at linguistic levels (not psychological) and through qualitative (not quantitative) methods. Admittedly, the communication dynamic of rejection and ghosting is widely applicable across domains, between dating partners, friends, colleagues, recruiters and applicants, and organizations.

As theories suggested, although being rejected is socially undesirable, rejection at least reciprocates the communication exchange between two parties; ghosting, on the other hand, violates this rule and may cause more intensified negative feelings and long-term consequences (LeFebvre, 2017; Pancani et al., 2022). Therefore, we hypothesized that ghosting (vs. explicit rejection) would be perceived more negatively (H1). Regarding the delayed response, we had competing hypotheses: people may either prefer immediate responses because they are risk-averse and avoidant to uncertainty (Kahneman & Tversky, 1979; H2a), or they in fact enjoy the waiting process as a pleasure of uncertainty (Bar-Anan et al., 2009; H2b).

To answer these questions, we launched an online questionnaire with a 2 (response type: rejection vs. ghosting) x 2 (response timing: immediate vs. delayed) design through Prolific (N=490). Under a social scenario, participants imagined inviting a friend to their birthday parties over a text message in one-month time and were randomly assigned to receive one of the responses from immediate rejection (friend rejected them right away), immediate ghosting (friend never responded), delayed rejection (friend was not sure then rejected them later), and delayed ghosting (friend was not sure then never responded afterwards). The dependent variables were negative emotions, interpersonal/friendship evaluations, and future engagement intentions (1-7 Likert scale for all).

The main effects supported our main hypotheses: people would rather be rejected than ghosted across all dependent variables. What appeared as the most interesting was that, while delaying a response did not make a difference between the two rejection conditions, it indeed dampened the negative perceptions of ghosting. Three individual differences were also assessed and discussed in the end, including Self-Esteem, Rejection Sensitivity, and Intolerance to Uncertainty.

One major limitation is the real-world validity, and thus we plan to apply the rejection/ghosting paradigm into business contexts later through behavioral lab studies as well as big data approaches to increase our methodological diversity and propose practical interventions. If the patterns are consistent, we would strongly advise against individuals stop responding messages to their friends, colleagues, students/professors, applicants/recruiters, etc. In conclusion, even though saying "no" is hard, ghosting might lead to worse outcomes.

Keywords: Ghosting, Rejection, Communication

How can mindfulness promote leaders' respectful inquiry? Results of three experimental studies

Annika Nübold, Maastricht University; Niels van Quaquebeke, Kühne Logistics University; Ute Hülsheger & Sjir Uitdewilligen | Maastricht University

Prior research has shown that a key function of leadership is effective communication with followers. One concept that has recently been introduced in the course of leader communication is respectful inquiry (asking open questions and listening attentively; Van Quaquebeke & Felps, 2018). So far, research has mainly focused on the outcomes and mechanisms of these behaviors, but the question of how good communication can be promoted in leader-follower interactions has been left largely unanswered. However, knowing how to strengthen leaders' ability to listen and ask the right questions is important to improve team processes and performance. A promissing way to improve communication skills is the practice of mindfulness. Being mindful means paying attention to present-moment experiences in a receptive and non-judgmental way (Bishop et al., 2004; Brown, Ryan, & Creswell, 2007). While organisational research on mindfulness mainly focused on intrapersonal aspects like emotion regulation (Hülsheger et al., 2014) and job performance (Reb et al., 2015), only few researchers studied the effects of mindfulness on interpersonal aspects like leadership behaviour or relationship quality (Arendt et al., 2019; Nübold et al., 2020). Thus, in a multi-group lab experiment with 56 teams, an online experiment with 129 leaders, and a field experiment combined with a weekly diary study with 119 leader-follower dyads, the present research investigated whether practicing mindfulness increases the amount of leaders' respectful inquiry in leader-follower interactions. Results of all three studies support the effect of mindfulness practice on leaders' respectful inquiry when rated by observers or leaders themselves. This effect was not supported, however, when followers rated the communication behavior of their leader. Furthermore, the effects of the mindfulness intervention on respectful inquiry did not always extend to work outcomes (e.g., team performance). Despite their strenghts, our studies also come with some limitations. For example, future studies should increase the time span of assessments to capture developments which potentially take longer (e.g., followers may need some time to recognize and identify new behavior patterns in their supervisors and also performance outcomes may be of more distal nature). Our findings highlight the importance of mindfulness in fostering effective communication strategies of leaders, thereby contributing to leadership theory and practice. In addition, high quality communication will be ever more important in a changing world of work, which is characterized by uncertainty, complexity and a plentitude of societal challenges. We believe that communication is key to contribute to decent work in the future.

Keywords: respectful inquiry, mindfulness, experiments

How do career resource levels differ by men and women, and how do they differentially predict career success? A systematic review.

Wika Malkowska, Northumbria University; John Arnold, Loughborough University; Laura Longstaff & Vicki Elsey | Northumbria University

science

Research Goals: Uncovering employability strategies which improve women's career success is an urgent current issue. Women accounted for the majority of employment losses during the COVID-19 pandemic (Dang & Nguyen, 2021) and were more likely to be furloughed for longer than men during lockdown (Jones & Cook, 2021). Career breaks, in turn, predict lower salary longitudinally (Evers & Sieverding, 2014). These recent events will likely aggravate the Gender Pay Gap (Peila-Shuster, 2017). Indeed, women already experience more work absences due to pregnancy, child-rearing, and other caring roles (Post et al., 2013).

Theoretical background: Women experience more boundaryless careers (Sullivan & Arthur, 2006), as they are more likely to balance work with family responsibilities which requires more workplace mobility and flexibility (Mainiero & Sullivan, 2005). Nevertheless, there is sparse systematic investigation of which strategies and behaviours enable them to successfully navigate this non-traditional career path (Frear et al., 2018).

Methodology and Results: Therefore, a systematic literature review will be conducted (predicted date of completion: 1st April 2023), compiling studies which report on gender differences in career resources and whether they differentially predict objective and subjective career success of men and women. Hirschi et al.'s (2018) career resources model will be used as a framework, as the human capital, environmental, motivational and career management resources predict career success longitudinally (Abele & Spurk, 2009; Haenggli & Hirschi, 2020). Inclusion criteria for peer-reviewed empirical studies will include testing gender as a moderator of the relationship between a career resource and career success. Also, studies which measure the mean level of a career resource by gender will be selected. The online search of databases will not be constricted by time range, as the individual components of the framework have been studied before Hirschi et al.'s (2018) operationalisation. For example, organisational career support cross-sectionally predicted women's salary and seniority more than men's (Melamed, 1995), which maps onto the environmental resource domain within the model.

Limitation: Despite ample support for Hirschi et al.'s (2018) framework, it is not an exhaustive list of employability resources. For example, Savickas' (2013) 'career adaptability' explains unique variance in subjective career success longitudinally, beyond career resources (Haenggli & Hirschi, 2020), and women show a significantly lower level of this construct than men (Hou et al., 2012). Hence, future reviews should systematically assess gender differences in other pertinent employability constructs.

Implications: It is hoped that the review will spark more quantitative, systematic research on gender differences in antecedents of career success. Moreover, the hallmark of career resources is their malleability, which allows the findings to bear implications for career counselling practice, tailoring interventions to improve the most crucial career resources for clients, considering their gender.

Value: To the author's knowledge, this will be the first review of gender differences in career resources according to Hirschi et al.'s (2018) framework, which answers the recommendation to

systematically investigate demographic differences and the societal need to promote gender equality in the workplace (Frear et al., 2018).

Keywords: employability, gender, career resources

How does the reaction of the audience impact the process of sexual identity disclosure at work?

Sara López Corlett, Lourdes Munduate, Alicia Arenas & Donatella Di Marco | Universidad de Sevilla

science

Research goals

Disclosure of sexual identity at work is crucial to the experience of many lesbian, gay, and bisexual (LGB) workers. The literature has focused on the consequences of the act of revealing or hiding their sexual identity, yet little is known about the factors involved when considering the audience's reaction to disclosure. Taking the audience into account, we aim to understand how disclosure of LGB people is related to individual and contextual characteristics and to analyze the impact of disclosure dynamics on authenticity at work and psychological distress.

Theoretical background

Di Marco (2022) proposed that LGB people have a preference to disclose or conceal their sexual identity to others, but they must also deal with thewillingness of the targets to respect and/or support their preferences. In this way, disclosure would not be a completely voluntary and controlled decision; it is also shaped by the behaviors of other people at work.

The act of coming out at work has been associated with positive factors such as authenticity, greater well-being, and inclusion, while concealing has been associated with negative outcomes such as depressive symptoms and perceived discrimination (Wax et al., 2018). Identity centrality, rejection sensitivity and internalized homonegativity have also been proposed as boundary conditions (Feinstein, 2020; Follmer et al., 2019). However, little is known about the mechanisms of disclosure when considering the audience's reaction to disclosure/concealment preferences in the workplace, and different outcomes are expected to result from this combination.

As a first step, Di Marco et al (2022) found that LGB people may encounter four different situations at work according to their wish to disclose/conceal and the reaction of the audience: segmentation, integration, distance violation, and intrusion violation. Segmentation and integration represent a successful and desired concealment or disclosure of LGB people' sexual identity, respectively. Distance violation occurs when there is a desire to disclose but third parties force concealment (e.g., not asking further about personal life). Finally, intrusion violation occurs when LGB people wish to conceal their sexual identity at work, but others force it into the spotlight (e.g., spreading rumors, asking non-wanted personal questions). These dynamics draw from boundary theory (Kreiner, 2006), based on the preferences of integrating/segmenting personal and work domains and the resources provided by the organization, in this case, the audience.

Design and methodology

251 LGB workers answered an online survey using crowdsourcing. Data analysis will include descriptive statistics, multiple regression, and mediation analyses.

Expected results

The data of this study has already been collected and data analysis is to be performed in the following month. We expect Inclusion Climate to be positively related to Segmentation and Integration, and negatively related to disclosure violations. Segmentation and Integration will be negatively related with psychological distress, while the opposite is expected to occur with Intrusion

Violation and Distance Violation. Rejection sensitivity will moderate the relationship between disclosure dynamics and psychological distress. Authenticity at Work will mediate the impact of disclosure dynamics on psychological distress. Finally, Identity Centrality and Internalized homonegativity will moderate the relationship between disclosure dynamics and authenticity at work.

Limitations

The study is limited to the experience of LGB people living in countries where legal protection and promotion exists. Data were collected at one time; therefore, causality cannot be established. Sample size does not permit comparisons between occupational sectors.

Conclusion

This study expands the boundaries of the concept of disclosure, from the personal decision to disclose to the reaction of others support or hinder this decision. It seeks to show that the reaction of the audience plays a role in the outcomes of disclosure. Implications for organizations include the need for supportive practices, yet resources must also be provided so that the preferences of LGB people who do not want to talk about their sexual identity are respected. Specific training may be provided to supervisors to understand and effectively manage the daily experiences of LGB employees.

Congress theme

The world of work is increasingly diverse. Organizations have made efforts to manage diversity in the past decade, although sometimes superficially. This study shows the nuances involved in the management of sexual diversity; a timely topic of which knowledge is rapidly changing.

UN SDGs

This study is related to goals 10 and 3 as it promotes adequate management of sexual diversity, which empowers and promotes their social, economic and political inclusion and health and well-being.

Keywords: disclosure; workplace; LGB

7-minute science 7M114

How social support buffers work-family conflict towards work ability - an examination of different facets in two European samples

Andre Werner Baumann, University of Marburg, Germany

science

Work and family are essential domains of human practice but work and family commitments are not always compatible. Previous studies have shown that a person's social environment can have a benevolent influence in challenging situations. While work-family conflict and social support have several facets, we know little about the specific buffering effects between those. Therefore, different types of social support may have various effects on different types of work-family conflict. Based on social support theory we hypothesize that perceived instrumental support has a stronger buffering effect on time-based work-family conflict, whereas emotional social support has a stronger buffering the relationship buffering effect on strain-based work-family conflict. We examine work ability as dependent variable.

We use two different samples and conduct moderation models in SPSS. The first sample consists of 505 working parents (391 female) from United Kingdom, Germany, and Slovakia and was collected from August to October 2022 (study 1: cross-sectional design). The second sample consists of 601 working parents (491 female) from Germany, Sweden, and Finland and was collected over 22 months from 2011 to 2013 (study 2: longitudinal design).

In summary, we find the interaction effects between strain-based work-family conflict and emotional social support in both samples. The interaction between time-based work-family conflict and instrumental social support is only found in study one. On a cultural level, interactions between facets of work-family conflict and social support are also only found in study one.

First, the validity of the study could be biased by self-assessment. Work ability is measured only by one item. It should be noted critically in study 2 that the two facets of social support are also only measured by one item each, so that the question arises whether the construct could be represented entirely. This limitation could be unfavorable to generalizability. Behavioral-based work family conflict is not addressed at all. The strength of the research project lies in a multiple study design and in the size and diversity of the European samples. In study 1 we use a cross sectional design, in study 2 we use a longitudinal design. We examine both perceived social support in the private context and actual received social support in the work context.

The study is able to make an important contribution to the understanding of work-family conflict in western European countries. It provides evidence on how social support as a potential resource can have a positive impact on work ability.

Keywords: work-family conflict, social support, work ability

HRM reactions to the Covid-19 pandemic: A latent class analysis approach

Kathleen Vangronsvelt & Ans De Vos | Antwerp Management School; Arne Vanderstukken, Open University

science&practice

Organizations react differently to crisis-situations, causing different implications for their workforce (Mithani, 2020). From a regulatory focus perspective (Beus, Lucianetti & Arthur, 2020; Johnson, Smith, Wallace, Hill & Baron, 2015), organizations can adopt a prevention focus (i.e., predominantly concerned with security, safety and responsibility), or a promotion focus (i.e., predominantly concerned with achievement, growth, and the realization of aspirations; Johnson et al., 2015; Sassenberg & Woltin, 2008). Regulatory focus as a collective structure, is a multilevel construct representing the process by which members of an organisations self-regulate to bring action into alignment with organizational goals (Johnson et al., 2015).

In the current study, we explore the adoption of different combinations of HR-related actions taken to cope with the COVID-19 crisis (e.g., workforce on temporary unemployment, switch-over to telework). On five moments between April 2020 and April 2021, we distributed questionnaires among CEOs and HR professionals from a variety of industries, asking them about HR-related actions implemented during the crisis (N total = 954). Next, we take a latent class analysis approach (LCA; McCutcheon, 1987) in the first dataset (April 2020) to uncover how these HR-actions tend to be co-adopted at the beginning of the pandemic. Although our approach is exploratory and data-driven, we can make careful predictions about HR actions likely to be combined, based on the theory of collective regulatory focus (Johnson et al., 2015). We then replicate this latent class analysis approach in the following four datasets (June 2020, October 2020, January 2021, April 2021) to verify whether the preliminary combinations of HR actions prolong as the pandemic persisted. Note that we controlled for level of activity in the organization during the pandemic. Finally, we elaborate on the discerned clusters by describing the HR-outcomes (e.g., level of absenteeism, perceived trust employees-employer) that are consistently linked with them over the 5 times. Although the questionnaire was repeated five times, the design was not longitudinal.

The results show that, even under strict regulations, organizations have different ways of reacting to the pandemic in terms of HR actions. Specifically, we found three classes of HRM reactions: a prevention focus class (e.g., workforce on temporary unemployment, hiring freeze, asking employees to take leave), a promotion focus class (e.g., switch-over to telework, alternative assignments, digitization), and a passive class (i.e., switching to teleworking only). Preliminary analyses further show that the promotion focus class is linked to desirable outcomes in terms of HR-outcomes, more so than the prevention focus class. These analyses will be expanded upon during spring 2023.

Contributions: First, we further insight on organizations' responses and resilience to crises (Mithani, 2020). Second, this paper aims to increase our understanding of motivational processes in the workplace, that transcend the individual level. Although interest in collective motivational processes increased (Chen & Kanfer, 2006), still few studies on collective regulatory focus exist (Johnson et al., 2015). Finally, as a (preliminary) practical contribution, our results seem to recommend that organizations should adopt the set of promotion-focused HRM practices, as these are linked to the most desirable HR-related outcomes.

Keywords: Human Resource Management, collective regulatory focus, latent class analysis

I feel for myself! Effects of an online-guided self-compassion intervention on strain and task performance after failure

Maria Undine Kottwitz, University of Bern; Wilken Wehrt, Maastricht University; Emily Kleszewski, University of Marburg

science&practice

Research goals: When stress is caused by failure experiences diminishing self-esteem, appreciation by colleagues and supervisor may be helpful. Unfortunately, supervisors and colleagues who may support the employee are not always available. As an alternative to appreciation, we propose that self-compassion (SC) may help employees to deal with stressors eliciting threat and feelings of failure. Therefore, we examine the effect of a brief online SC intervention on potential negative consequences of failure.

Theoretical background: According to the Stress-as-Offense-to-Self theory, experiencing failure threatens employees' self-esteem, leading to stress reactions. SC refers to a positive and caring manner toward oneself that can counteract threats to self-esteem, especially during difficult times (such as failures). However, recovery research has shown that a break after demanding tasks can already reduce potential consequences on well-being and performance. We propose that an instructed SC break after failure (compared to a simple break or continuing to work) will reduce negative strain reactions such as negative affect, fatigue, and deterioration in task performance.

Methodology: All participants in this online study were equally subjected to a task that evoked a sense of failure, i.e. ego-threat (difficult-to-solve anagrams that were claimed to be easy to solve). The experimental design comprised one measurement before and one after failure and intervention phase, comparing the SC intervention to a) a break and b) a working through control group. This was followed by a Stroop task. In sum, 420 participants were randomly assigned to one of the three conditions. After data cleaning, the final sample consisted of 330 participants (151 from Germany, 179 from German-speaking Switzerland). The majority were students (87%); aged 18 to 70 years; 75% were female. There were no initial significant differences in demographic and study variables between groups.

Results: The results revealed that participants in the SC condition reported significantly higher self-esteem, lower fatigue and negative affect as compared to break and working through condition. No significant differences between the conditions were found concerning performance in the Stroop task.

Limitations: The present study is based on an academic sample. Thus, future research needs to extend these findings to performance failure in other domains.

Conclusions: Flexible breaks are important, however, our results indicate that it needs more than a break to bounce back after failure. We present a brief SC intervention that can help individuals cope with failure in the absence of key sources of appreciation (e.g., supervisors or peers). Extending previous research, we highlight SC as an immediate coping strategy after failure that is superior to common recovery experiences (simple break).

Relevance to the Congress Theme: The COVID-19 pandemic has impressively demonstrated the need to adapt one's own way of working in terms of remote-work, virtual communication, and related technologies. Such changes may provide opportunities for individual learning and growth, but

little support in the face of failure. Taking a break to havecompassion for oneself, can be seen as a valuable coping strategy that enables employees to bounce back and grow during times of change.

UN SDGs: Our study aims to promote decent work and economic growth, as well as health and well-being, as part of social sustainability.

Improv(ing) interpersonal skills: Results of a pilot training intervention study

Amanda Hancock, Hill and Levene School of Business, University of Regina; Ian Gellatly, Alberta School of Business, University of Alberta; Catherine Connelly, DeGroote School of Business, McMaster University; Kara Arnold, Memorial University - Faculty of Business Administration

science&practice

Goals & Background

Career success, especially in virtual work settings, often comes down to one's ability to communicate effectively and to positively influence others. The prevalence of computer-mediated (remote) work of late has highlighted the importance for understanding outcomes of virtual training. In this study, we evaluate an "improv" intervention, an innovative new approach to training focused on being in the moment and attending to others. Specifically, we piloted a virtual improv training program with MBA students and investigated its potential to improve critical interpersonal skills as indicated by self-ratings of mindful communication (MC), transformational leadership (TFL), and helping behaviours. Mindful communication consists of being mentally present, having a non-judgmental attitude, and staying calm. TFL is a style that garners respect, trust, and admiration from others using idealized influence, inspirational motivation, individualized consideration, and intellectual stimulation. Helping behaviours describe discretionary task-related organizational citizenship.

Intervention/Method

The intervention is an interactive improvisation training designed to foster adaptability, collaboration, and joy at work (www.themakingbox.ca). An experienced improv instructor conducted standardized improv training for a group of MBA students in 4 1-hour-long sessions over 4 consecutive weeks. Participants responded to a pre-training survey (t1; N = 51), an immediate post-training survey after the last session (t2; N = 39), and a follow-up survey 1 month later (t3; N = 13). To evaluate the intervention, we compared the means of our variables of interest at t1, t2, and t3. To make the best use of the data (with decreasing sample sizes from t1 to t3), we conducted t-tests (t1-t2, t2-t3, t1-t3) with bootstrapping. Given the small sample size, we focus on effect sizes rather than significance.

Results

For MC, we found a significant increase from t1 to t2 and a significant decrease back to t1 levels from t2 to t3. For TFL and helping behaviours, we found significant increases from t1 to t2 and stability at these increased levels from t2 to t3. This suggests that for MC the benefits of improv training are stronger immediately after the training but become less noticeable as time passes after the training. For TFL and helping, the positive change persists.

Limitations

Due to the small sample size and self-reported data, the intervention effects need to be interpreted with caution. The study took place during COVID-19 when students interacted with each other online only; some variables of interest may have behaved differently if measured in an in-person rather than virtual context.

Conclusions/Originality/Value

This study introduces a promising (and fun!) intervention to improve interpersonal skills, particularly TFL and helping behaviours. Results, however, raise the question of stability of intervention effects, especially for mindful communication. Future research should test this intervention in larger (working) samples (e.g., leaders) and use active control groups. These results suggest that frequent practice may be integral to retaining some of the positive outcomes of improv training. Improv training has received limited empirical investigation and this tangible approach may hold promising potential for interpersonal skill development.

Relevance

The ability to improve interpersonal skills in virtual settings is important for the future of work.

Keywords: mindful communication, transformational leadership behaviour, improv training intervention, virtual collaboration

Improving the empowerment of family members in organizations for individuals with intellectual disability

Kristin Waßmuth, University of Valencia; Carolina Moliner, IDOCAL - University of Valencia; Rita Chiesa, University of Bologna; Yolanda Estreder & Vicente Martínez-Tur | IDOCAL - University of Valencia

science_practice

This study was carried out in organizations for individuals with intellectual disability (ID). In this context, family members often feel powerless in satisfying the unique needs of their relative with ID, are vulnerable to stress and health disparities and struggle to sustain their family life. A small body of literature suggests empowerment interventions could aid such families, yet underrepresents quantitative, solid methodology. Respectively, we inquire whether an intervention oriented to increase empowerment, implemented in the aforementioned organizations, demonstrate gains in family empowerment among those family members.

Challenging individuals to overcome difficulties and to gain control is an essential strategy to amplify empowerment. Herein, family-centeredness , thus supporting families in finding themselves capable and responsible for positive changes, and collaboration appears to stimulate empowerment. Indeed, research indicates that interventions oriented to support family members in understanding the specific needs of their relative with ID and finding strategies to meet them leads to an increase in family empowerment.

Based on previous literature, we tested a family-centered intervention where family members needed to master two challenges, social inclusion and self-determination, of their relative with ID through collaborating with a professional in designing and implementing projects. Family members assigned to the experimental condition (N = 83) participated in the intervention while those assigned to the control condition (N = 92) did not participate. Professionals evaluated empowerment levels for the corresponding family member before (T1), 3 weeks (T2) and 6 weeks (T3) after the intervention, using a short family empowerment scale (Huscroft-D'Angelo et al., 2018).

Support for the one-factor structure of Family Empowerment and reliability of the scale (α >.70 – 93) was found. Two-way mixed ANOVA indicated that family members who participated in the intervention (compared to control) significantly increased their family empowerment ($F\ (1,173) = 10.26$, $p < .01$,). Post-hoc comparisons revealed significant gains for intervention participants overtime (T1-T3); between T1-T2, but not T2-T3; and for control participants between T1 and T2.

As our study was limited to the assessment through professionals, future studies could enrich the evaluation through further subjective or objective measures. Although not being our objective, longitudinal data could give more insights into the trajectory of the empowerment effect over time and allow to capture distal effects.

Our study entails theoretical, practical and societal contributions. We extend the knowledge on the effect of empowerment interventions through using methodologically solid methods and by providing novel insights into how to stimulate empowerment. Further, family members obtain a personal resource to cope with family difficulties and contribute to a higher quality of family life. Also, empowered family members are critical to improve the well-being of their relative with ID outside centres and are likely to participate in and facilitate service provision, paving the way for organisational progress. Societally, our study promotes disability rights.

Through targeting social inclusion and self-determination of individuals with ID, our research reduces inequalities . Our intervention contributes to health and well-being of families with unique challenges.

In Which Circumstances Does the Employability Paradox Exist?

Norah Alhamdan, King's College London

science

To achieve a sustainable competitive advantage, organisations need to provide employees with up-to-date knowledge to increase their flexibility and enhance their performance.Increasing employees' competencies improves their employability, providing them with greater opportunities in the internal and external labour market. Improving its employees' internal employability enables an organisation to make full use of their competencies. However, improved external employability (the potential for better job opportunities in the labour market) can increase the risk of employees taking their newly acquired skills to another employer.The contradiction between the benefit and cost of investing in employees called the employability paradox.The term means that developmental activities enhance employees' employability and increase the risk of leaving an organisation for another employer before that organisation has achieved a return on its investment.

The employability paradox phenomenon makes many employers reluctant to invest in their employees due to the fear from incresed turnover.But organisations cannot achieve the competitive advantage without investment in their employees.Therefore, this research aims to explore the phenomenon of the employability paradox by investigating in which circumstances investment in professional development leads to either increased turnover or increased loyalty.The research will combine two analytical levels,organisational and individual,that have been rarely investigated together in the literature on employability.

The majority of employability research takes a narrow view, examining just one side of the impact of the investment in employees. For instance, most employability studies limit their investigation to the extent to which an organisation's investment benefits an individual's employability. Only a limited number of studies have focused on the impact of an organisation's investment on its competitive advantage and more research in this area is needed.The organisational level includes three aspects. First,"idiosyncratic deals",a term that refers to personalised agreements for a limited number of employees to develop the skills and professional competencies that will help them achieve their personal career objectives. Second, the concept of leader-member exchange (LMX),which is defined as the use of the relationship between employees and supervisors in the workplace as a strategy to identify valuable employees. Third, the role of human resource policies related to promotions and compensation as retention strategies for employees.The analysis at the individual level examines the impact of organisational investment practices on employees' perceived internal and external employability.The research will compares the impact on turnover of i-deals and LMX with that of HR policies that are intended as retention strategies.The research is based on social exchange theory, which states that investment in employees through the development of their competencies creates a sense of obligation among them to repay this investment with stronger performance,commitment and loyalty to their employer.

A structured questionnaire will be used to define the relationships between variables. The sample will consist of both employers and employees working in Saudi Arabia's financial industry due to the high competitvness in this sector. The results of this study are expected to be available in about a year. However, based on previous findings in the literature, it is likely to be found that using i-deals and LMX will increase employees' perceived external and internal employability. However, improved

external employability can increase employee turnover, so HR retention policies like promotions and competitive salaries should be implemented to increase employee commitment.

The limitations of this study are related to the sample, which will be drawn only from Saudi Arabian companies. Therefore, the results and implications may not hold true for other countries.Further, the sample is limited to high-potential employees and using i-deals for this group might negatively affect other employees who are excluded from such agreements,creating a sense of unfairness among them.

In conclusion,the research can contribute to filling a gap in the literature by providing a broad perspective on the employability paradox.Combining two analytical levels, individual and organisational, can provide more conclusive results than those currently found in the literature on the employability paradox, which have been limited due to an overemphasis on the individual aspect.Further, the research aims to make a practical contribution by providing HR specialists with a clearer perspective on the circumstances in which the employability paradox might occur.This can help them to formulate more integrated investment strategies for training and development and HR policies to achieve a competitive advantage and employee loyalty.

Keywords: Employability Paradox

Intervene against sexual harassment: Testing the effect of a primary prevention intervention targeting bystanders

Eva Gemzøe Mikkelsen, Maj Hansen & Kristian Stampe Nielsen | Department of Psychology, University of Southern Denmark

science

Intervene against sexual harassment: Testing the effect of a primary prevention intervention targeting bystanders

Research goals and why the work is worth doing

Multiple international studies have shown that sexual harassment is still a problem in many organizations (Svensson, 2020; Latcheva, 2017), with research pointing to both individual and organisational consequences of sexual harassment (SH). Adverse effects for victims include poor mental health (Rospenda, Richman & Shannon, 2009) and increased risk of for example depression (Friborg et al., 2017; Rugulies et al., 2020), self-harm (Jin, Lin & Strong, 2018) and suicide or suicide attempts (Hanson et al., 2020). Therefore, it is important to develop, implement, and test preventative SH interventions.

The goal of the research project is to test the effect of an intervention which focuses on bystander behaviour and the factors affecting this (e.g., aspects of the organisational culture, ethical infrastructure, and psychological safety). The study has two aims:

Testing the effects of the bystander intervention "Intervene – sexual harassment (I-SH)" through interviews and surveys. Effects are understood as changes in knowledge, attitudes, and actions of the employees regarding sexual harassment situations in the workplace. Realistic effects could be increased awareness of bystander behaviours and increased knowledge of sexual harassment and risk situations.

To investigate which organizational factors either inhibits or facilitates the implementation and effects of the intervention through group interviews.

Theoretical background

Research has shown that bystanders to bullying and SH may play an important role in how situations develop (Pouwelse, Mulder & Mikkelsen, 2018) and that interventions aimed at reducing workplace bullying by mobilising and engaging bystanders may contribute to changing a problematic group- or organisational culture (Mikkelsen & Høgh, 2019; van Heugten, 2011). Recent research suggests that mobilising bystanders [F1] also can be used for sexual harassment (Simonsson, 2020).

The I-SH is an adapted version of "Intervene" which has shown to affect factors that play a role in reducing bullying in the workplace (Mikkelsen, 2020; Mikkelsen & Høgh, 2019).

Design/Methodology/Approach/Intervention

The project is a mixed method investigation of the effects of the I-SH intervention. The intervention is a dialogue-based, user-friendly standardized intervention that organizations may employ themselves. The intervention uses short cases/vignettes, among other things, that portray real life situations, characters, and dynamics, which are easy to identify with. The aim of the intervention is to increase the participating managers and employee's 1) awareness of what constitutes sexual

harassment, 2) awareness of the negative consequences of passive or colluding bystander behaviours, 3) awareness of risk situations for SH as well as 4) an increase in constructive bystander behaviour among participants. The intervention will include a one-day seminar or workshop for managers and employee representatives with the purpose of helping them plan and execute their own interventions.

The effect of "Intervene-SH" will be measured through baseline and 6 months follow-up surveys and group interviews in the participating organisation. The purpose of baseline group interviews is to explore employees' and managers' perception of local risk factors for sexual harassment and possible stimulating and obstructive factors that may affect the implementation and effect of the intervention. In follow-up interviews these factors are also explored as well as participant's experiences of the intervention and its effects.

Results obtained or expected

The project is set to start baseline data collection Dec. 2022-Jan 2023. Planned intervention is in late March or April. It is expected that the preliminary results may be presented at the EAWOP conference.

Limitations

As this is a pilot study, the sample will be small with only one, maybe two, organisations participating. This limits the statistical power of the quantitative analyses and the generalisability of the findings. Another limitation is that the intervention is developed and tested for a specific sector. It is plausible that the intervention will need alterations to be effective in other sectors.

Conclusions

This research project is an important step towards creating empirically backed interventions to reduce sexual harassment in the workplace, of which there are few. With organisations having limited resources, it is important that the interventions they choose to invest in works.

Relevance to the Congress Theme

The presentations are highly relevant to the conference theme as it focuses on the very pressing issue of violence against women in the workplace. Since the #MeToo movement this issue have been a part of public debate in most European countries and must be addressed.

Relevant UN SDGs: Gender quality, Decent work, Reduced inequalities

Keywords: sexual harassment, Intervention research, bystander behaviour

Interventions in Workaholism: A meta-analysis

Șerban Andrei Zanfirescu & Dragoș Iliescu | University of Bucharest

science

Introduction: Workaholism is related to a considerable amount of outcomes, such as burnout, work-life conflict, perceived stress, decreased levels of well-being, lack of physical activity, and even mental health. In turn, these outcomes lead to negative individual, interpersonal and organizational consequences. Considering past literature on the consequences of workaholism or work addiction, it seems crucial to investigate possible treatment measures. Therefore, the purpose of this study is to investigate literature data on treatments and interventions against workaholism.

Method: We conducted a literature search using Web of Science, PsycINFO, and Scopus, following the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) guidelines. Search terms included workaholism, work addiction, workaholic, work addict, working excessively, working compulsively, intervention, treatment, and treat.

Results: This study is in progress, but we will likely, in the end, retrieve about 895 research articles by December 2022. A brief inspection revealed that at least two research articles investigating possible treatment measures for workaholism are randomized controlled trials (RCT).

Discussion: Results discuss the number of studies eligible for the present meta-analysis, the relationship between different workaholism interventions and outcomes, and the following moderators: sociodemographic factors, personality traits, and work-family conflict; and offer a qualitative view of current trends on interventions tailored to treating workaholism.

Keywords: workaholism, intervention, work addiction

Investigating Perceptions of Sexual Harassment in the Workplace

Charlotte Keenan, The University of Queensland

science&practice

Theoretical Background and Research Goals. Sexual Harassment is commonly defined as unwanted or unwelcomed sexual behaviour that causes offence, humiliation, or intimidation (Charlesworth et al., 2011). Sexual Harassment in the workplace is a widespread global issue, effecting roughly 55% of European women in their lifetime (Violence Against Women: an EU-Wide Survey, 2015). The consequences for the targets of sexual harassment include decreased mental and physical wellbeing (Bergman et al., 2002), in addition to impacting job-related factors, such as decreased job attitudes and increased withdrawal behaviours (Chan et al., 2008; McDonald, 2012). Detrimental effects can also be observed in poor staff morale and performance, as well as reputational damage for the organisation and losing the confidence of stakeholders (Fitzgerald et al., 1997). Current research and government reports into workplace sexual harassment have shown there is a "lack of understanding about what constitutes sexual harassment" (Respect@Work Report, 2020). This is especially the case for more common and everyday forms of sexual harassment, where there is less awareness that behaviours such as gendered 'jokes' and remarks are harmful (McDonald, 2012). This lack of clarity may play a role in whether sexual harassment is appropriately dealt with by organisations. The inability to accurately label sexual harassment behaviour can also result in lower reporting rates, potentially leading to more problematic or escalating behaviour. Thus, more research is needed to determine what factors influence perceptions of sexual harassment. The aim of this project is to examine how the severity of the sexually harassing behaviour and the response of the target influences whether behaviour is labelled sexual harassment. Method and Results. An online sample of 1,700 employees were presented with a workplace scenario manipulating the severity of sexual harassment based on Till's (1980) continuum of sexual harassment. The target's response was also manipulated. After reading the scenario, employees indicated how appropriate the behaviour was, whether the behaviour constitutes sexual harassment, and their confidence in this judgement. We also explored how participants' demographics (e.g., gender, social skills) related to the propensity to label different behaviours as sexual harassment. The data have been collected and in the process of being analysed. The key factors influencing the labelling of sexual harassment and ratings of appropriateness will be discussed. Limitations. Although the findings progress this area of research, scenario-based studies have limitations in fully capturing social realities. Conclusion and Relevance. The goal of this research is to develop tools to foster a more inclusive and prosocial future workforce, in line with the congress theme of the future is now. This research will contribute important knowledge on what influences perceptions of sexual harassment in the workplace, which pertains to the UN Sustainable Development Goals of increasing gender equality and enhancing and protecting wellbeing.

Keywords: Sexual Harassment, Gender, Sexism

Is this real? – Effect of context visual fidelity in virtual reality on mental model formation

Jan-Philip Schumacher, Tammo Straatmann & Cosima Koßmann | Osnabrueck University

science

Research goals and why the work was worth doing – Driven by digital transformation and increasingly dynamic markets organizations must constantly redesign their work processes and ensure comprehensive understanding and effective training of employees who are affected by their implementation (Dumas et al., 2018, Berman, 2014, Guiette & Vaenderbempt, 2013). Traditionally, work processes are conveyed using standardized modeling notations depicting task elements and their relations (Figl, 2017). This rather abstract and context-free nature (Poehler & Teuteberg, 2021) brings along information-pass-on barriers hindering effective understanding and implementation (Erol et al., 2010). Virtual Reality (VR) has been suggested as an educational medium with the potential to more effectively convey future processes (Straatmann et al., 2022). This study investigates how the contextualized presentation of work processes in VR with different levels of visual fidelity affects learning outcomes.

Theoretical background – We build on the multimodal theory of memory (Engelkamp, 1998) predicting superior learning outcomes when including the visual-imaginal and motor system into while learning. VR lets individuals experience processes like the real world (Botella et al., 2017), invoking a feeling of presence (Slater, 2018). Thus, learning in VR is expected to aid encoding and recall (Lokka et al., 2017) by utilizing spatial memory (Madl et al., 2015) leading to better memorization. Yet, cognitive load theory (Sweller et al., 1998) suggests that increasing context complexity (higher visual fidelity) may at some point impair the benefits stemming from its availability.

Design/Methodology/Approach/Intervention – We used a one-factor between-subject design with three conditions: No context (NC), low visual fidelity (LVF), and high visual fidelity (HVF). The N=90 participants were asked to learn a fictional work process in VR. Elementary and relational mental models of the work process were assessed via elicitation tasks (Harper & Dorton, 2019) along with control variables.

Results obtained – Results are being analyzed and will be presented at the conference. We expect mental models of participants in LVF and HVF to be significantly more complete than in NC. Further, we expect the mental models in LVF to be more complete than in HVF due to conflicting effects in presence and cognitive load.

Limitations – The experiment utilized a fictional process along with a sample of students. Future research should investigate the generalizability with a more diverse sample and within a real-world environment. Careful measures were taken to cross-validate results in the analysis and reduce subjectivity.

Research/Practical Implications – This study contributes to research on the effect of realism and presence on learning outcomes. For practice this study provides first insights of needs for realism in VR training applications, affecting cost-benefit considerations substantially.

Relevance to the Congress Theme – The present study relates to the changing world of work in assessing VR as a change management tool for training and development.

Relevant UN SDGs – The study investigates VR as a tool for qualitative education of employees ensuring decent work and economic growth.

Keywords: Virtual Reality, work processes, visual fidelity

7-minute science 7M104

Job? Adulthood? Not Yet! Procrastination and Self Perceived Employability at the transition between University and Work

KLAUDIA MARTYNOWSKA, The John Paul II Catholic University of Lublin; AGNIESZKA FUDALI-CZYŻ, Pedagogical University of Krakow; PIOTR MAMCARZ & EWA DOMAGAŁA-ZYŚK | The John Paul II Catholic University of Lublin

science

Research goals

We investigate Polish University students' procrastination regarding career decisions. A recent study suggested that around 46% of undergraduate students and 60% of graduate students engage in the postponement of academic tasks (Rahimi and Hall, 2021). Our research goals include exploring attitudes to procrastination for contemporary undergraduate students; examining the relationship between procrastination, individual attributes and self-perceived employability; evaluating the potential implications for students' well-being, making recommendations or curriculum and policy initiatives relevant to Universities.

Theoretical background

Our research explores the relationship of procrastination, defined for our study as putting off acting on one's intentions (together with other individual attributes); with self-perceptions of employability, defined as the perceived ability to secure or sustain a desired role appropriate to one's qualification level. The originality of the research is in relation to University-work-transitions in the Polish Higher Education context, contemporary global concerns about individual engagement with work and concerns relating to psychological well-being.

Design

Our study is based on a survey of 522 first-year Humanities students at a Polish University. Research tools include the Polish Self-Perceived Employability Scale (PSPES), the General Procrastination Questionnaire; while temperamental traits were measured using the Formal Characteristics of Behavioral Temperament Inventory-Revised version.

Results

Procrastination was negatively associated with behavioral characteristics such as activity, endurance and lower levels of academic engagement. Respondents who perceived themselves as employable exhibited higher levels of goal-focused behavior, while those who procrastinated more had lower levels of self-perceived employability (SPE) with potential mental health implications due to increased hopelessness over time. Hence procrastination appears to be linked to employability as a contributor to causes of graduate under-employment, delayed adulthood and potential mental health concerns, understanding of which could inform pedagogic and policy development at an institutional and national level.

Limitations

There will inevitably be some attrition from the initial cohort. There may be continuing pandemic and geopolitical effects in relation to both student perceptions and labour market conditions. The Polish context may limit generalisability in the broader sense.

Conclusions

The value of this study particularly pertains to mental health implications of contemporary students who should be future graduate employees yet may show a tendency to procrastinate over career-decision making. High levels of procrastination toward job-seeking may trigger hopelessness over time. This may result in deteriorating quality of life, well-being, or depression. Our research extends this perspective to investigate the potential longer-term effects on transitions into the workplace which would therefore be of concern to employers.

Relevance to the Congress Theme

In relation to 'The Future is Now: Contribution' as well as 'Urgency' and 'Delivery', our concern is regarding the work-readiness of the graduate workforce, their sustainable livelihoods, as well as their ability to engage proactively with the world of work from a basis of sound psychological health.

Keywords: employability, career decisions, individual attributes

Learning new work processes by doing? – Effect of enactment in virtual reality on mental model formation

Jan-Philip Schumacher, Kai-Christoph Hamborg, Tammo Straatmann & Cosima Koßmann | Osnabrueck University

science

Research goals and why the work was worth doing – Challenged by ongoing digitalization and increasingly dynamic markets organizations must continuously improve their work processes and ensure proper training of employees for successful implementation (Dumas et al., 2018, Erol et al., 2010). The training of employees is subject to high resource-intensity, especially with increasing specialization of work (Xie et al., 2021). With its advantages of effectively conveying cognitive, psychomotor, and affective job skills (Jensen & Konradsen, 2018), as well as cost-and time efficiency (Wismer et al., 2021), Virtual Reality (VR) provides a promising educational medium (Straatmann et a., 2022). This study investigates to what extent different learning conditions (observation, enactment) facilitate learning of new work processes in VR.

Theoretical background – We build on the multimodal theory of memory (Engelkamp, 1998) which predicts more effective learning outcomes through the inclusion of the visual-imaginal and motor system into the learning process. We assume that especially the enactment effect (Cohen 1981, Engelkamp & Krumnacker, 1980) improves memorization of actions in work processes compared to observational learning and learning by reading.

Design/Methodology/Approach/Intervention – We used a one-factor between-subject design with three conditions: learning by enactment (LE), learning by observation (LO), and learning by reading (LR). The N=90 participants were asked to learn a fictional work process in VR. Elementary and relational mental models of the work process were assessed via elicitation tasks (Harper & Dorton, 2019) along with control variables.

Results obtained – Results are being analyzed and will be presented at the conference. We expect the mental models of participants in LE and LO to be significantly more complete than in LR. Further we expect the mental models in LE to be more complete than in LO.

Limitations – The experiment utilized a student sample and a fictional work process. Future research should explore the generalizability with a real-world environment and a more diverse sample. Careful measures were taken to reduce subjectivity in analysis via cross-validation.

Research/Practical Implications – This study contributes to research on the effect of interactivity and presence on learning outcomes. For practice this study provides first insights considering the effectiveness of VR process training. This could yield high potential to implement a cost-effective, time- and location-independent educational medium within the organizational training program.

Relevance to the Congress Theme – The present study relates to the changing world of work in assessing VR as a change management tool for training and development.

Relevant UN SDGs – The study investigates VR as a tool for qualitative education of employees ensuring effective training to spur sustainable organizational transformation and economic growth.

Keywords: Virtual Reality, work processes, enactment

7-minute science 7M93

Linking work events to work engagement: A proposal for a diary study on the moderating role of employees' psychological capital

Aleksandra Penza & Agata Gąsiorowska | SWPS University

science&practice

This proposed study aims to gain insight into the chain between work events, emotions, and behavior and the moderating role of personal resources in this relationship. Specifically, we want to examine whether daily positive and negative work events predict the daily level of positive and negative work-related emotions and work engagement. We also want to investigate whether employees with high (vs. low) in psychological capital (PsyCap) respond differently to positive and negative work events in terms of their emotions and work engagement. Following Affective Events Theory and Broaden-and-Build Theory, we hypothesize that experiencing positive events at work will increase employees' positive emotions while decreasing negative emotions, consequently increasing their work engagement. Similarly, experiencing negative events at work will decrease employees' positive emotions and elicit negative emotions, which in turn will disrupt work engagement. However, those relationships will be moderated by PsyCap. We view PsyCap as a buffer that helps employees cope with adverse events, leading them to experience significantly fewer negative emotions without suppressing the employees' positive emotions. According to our hypotheses, we expect PsyCap will stabilize employees' emotions in response to events at work and their work engagement. In addition, we hypothesize that PsyCap makes engagement at work less dependent on emotions resulting from events at work. Considering PsyCap as an additional resource, we expect its high level to maintain employee work engagement at a relatively constant, high level. A low level of PsyCap, in turn, will lead to a greater fluctuation in employee work engagement by making it more dependent on respective events at work.

The study will be conducted using a quantitative diary among 300 employees of the municipal transport company who will complete a diary questionnaire on ten consecutive working days, once a day after working hours. The study will use the Utrecht Work Engagement Scale (UWES-9 and UWES-3) to measure baseline and daily levels of work engagement, the Psychological Capital Questionnaire (PCQ-12) to measure baseline levels of PsyCap, the Positive and Negative Affect Scale (PANAS) to measure baseline positive and negative affectivity and its short version to measure the daily level of work-related emotions. We will also determine a set of positive and negative events at work in the baseline measurement by having participants indicate what situations they encounter at work. The study will be conducted in the first half of 2023.

In summary, by taking into account that PsyCap can be further developed through targeted training interventions, the insight into the role of PsyCap in building employee work engagement seems particularly important for today's organizations. By developing a high level of PsyCap in employees, organizations can provide them with resources to cope with difficult work situations, while enhancing their well-being and a high level of work engagement.

Keywords: work engagement, psychological capital, diary study

Love it or hate it: Antecedents and dynamics of employees' preference for remote work during the Covid-19 pandemic

Svenja Schumacher, Karsten Mueller, Janna Ronnenberg, Thea Nieland & Jonas Brueggemann | University of Osnabrueck

science

Research goals: The Covid-19 pandemic led to massive changes in work design forcing employees into remote work fast. We propose employees' remote work preference as a key factor in determining employees' success in this setting. It is important to identify factors fostering the remote work preference to help employees thrive. To date, there is little and no systematic research on antecedents of remote work preference. The current pandemic with its changing work requirements provided the context to examine how organizational, work-related, and individual factors influence employees' remote work preference and how these influences change over time.

Theoretical background: The individual preference to work remotely predicts remote work success (Martinez-Amador, 2016). The dynamic situation during the pandemic regularly forced employees into changing work settings. We expect content (task digitalization), context (organizational support, physical working conditions, technical support, digital leadership), and individual factors (digital competence, boundary management) to influence remote work preference.

Methods: Data were collected in an online panel of employees (N=1009) over six months at three measurement points (Aug 2020, Nov 2020, Jan 2021). Data will be analyzed via multiple regression for all three time points to identify predictors for employees' remote work preference. To identify overall changes in the remote work preference latent growth curve modeling (LGCM) will be used. To investigate longitudinal influences of antecedents on remote work preference we will use bivariate LGCMs.

Results: Data analysis is ongoing and results will be presented at the conference. Organizational context, content, and individual factors should positively predict the remote work preference. Furthermore, we expect intercepts as well as slopes of antecedents to be associated with the change in remote work preference in bivariate LGCMs.

Limitations: The identified predictors are not exhaustive. However, they provide a first systematic integration of potential antecedents of the preference of remote work.

Research/Practical Implications: Our study systematically identifies potential antecedents of employees' remote work preference. Future research should expand this approach by also considering process factors. Additionally, the effects of employees' remote work preference on relevant outcome dimensions (e.g., job satisfaction, productivity) considering the actual work situation (e.g., through a fit approach) should be considered. On a practical level, organizations can gain insights on how to influence employees' remote work preference and support the adaptation to new work settings. Our study is the first to systematically examine antecedents of the remote work preference in a dynamic context. The results will provide indications for individualized support in fostering remote work preference in the context of new work concepts. Furthermore, this study provides a starting point for a larger research avenue addressing innovative and individualized work design in the context of new work.

Relevance to the Congress Theme – We address implications for successful work design in the context of new work, which has become crucial in the changing world of work.

Keywords: remote working, individual preference, new work

Mapping employees' individual feedback processing skills: the conceptualization of employee feedback literacy

Shana Mertens & Eveline Schollaert |Ghent University

science&practice

Feedback is often assumed to be beneficial for individuals' performance. However, this has been proven to not always be the case. In fact, feedback often seems to have no effect or even a deteriorating effect on performance (Kluger & DeNisi, 1996; Tseng et al., 2019). Scholars have, while researching the effectiveness of feedback interactions, looked into several explanatory factors, among which personal characteristics, contextual aspects, and properties of the feedback source or the feedback itself (Ilgen et al., 1979; Kluger & DeNisi, 1996). However, while feedback processing at the intra-individual level will most likely affect to which extent feedback will be effective, the individual differences in feedback processing skills have not been researched to this day. Processing feedback requires a lot of cognitive resources and individuals differ in their information processing skills (Ackerman, 1987). This implies that, while supervisors provide their employees with usable feedback, not every employee has the ability and skills to process this feedback and use it to improve their performance.

Therefore, we introduce the concept of 'employee feedback literacy'. Similar to other literacy concepts, such as information literacy (Widén & Karim, 2017), employee feedback literacy is defined and characterized by three dimensions: receiving, processing, and using information and, in this case, performance feedback. Thus, we define employee feedback literacy as 'the ability to receive, process, and act upon performance feedback at work'. This means that a feedback-literate employee has the necessary skills and is able to: 1) seek, recognize, accept, and evaluate feedback, 2) reflect on feedback and seek the necessary information to process feedback accurately, and 3) use the feedback to improve their performance, set new goals and monitor their progress.

Additionally, in a later stage, we will develop a scale to measure employees' feedback literacy. Theoretically, being able to estimate employees' feedback processing ability could explain the discrepancies in the extent to which feedback actually results in improved performances. It will, furthermore, disclose a new avenue in the limited literature on feedback processing. In practice, it would be interesting for organizations to be able to map and develop their employees' know-how with regard to feedback. In other words, measuring employees' feedback literacy will allow organizations to identify which specific skills should be addressed, for instance by means of training.

As the theme of the conference indicates, 'the future is now'. For years, researchers and practitioners have argued that there is no silver bullet or 'one size fits all'-approach regarding feedback and individual employees. Think about the ongoing discussions about the ideal feedback frequency, the way in which feedback should be provided, and the perfect time to give employees feedback. With the introduction of this concept, it will become possible to adapt feedback processes to individual employees, based on their ability and skills to receive and process feedback. In the future, in other words, feedback is based on a 'best fit'-approach. Feedback has been linked to employees' well-being and performance. Consequently, this research project is particularly relevant to the SDGs regarding 'good health and wellbeing' and 'decent work and economic growth'.

Keywords: Feedback, employee feedback literacy, performance management

Measuring Sustainable Employability among employees in low-skilled jobs: Adaptation of the MAastricht Instrument for Sustainable Employability (MAISE)

Inge Houkes, Hans Bosma, Angelique De Rijk, Emmelie Hazelzet & Pauline Mignon | Maastricht University

science

Research goals and why the work was worth doing

Due to demographic changes and a progressively complex labour market, employers are faced with a greying, overburdened workforce. Many employers develop interventions to improve their employees' sustainable employability (SE), but consider this a difficult task. SE measurement instruments based on the employees' perspective, currently fall short, particularly for the understudied group of employees working in low-skilled jobs. These workers generally have lower levels of education and a lower (health) literacy. Their work is characterized by low levels of job control and high physical demands. This may negatively impact the validity of SE measures in this target group. Earlier, the Maastricht Instrument for SE (MAISE-NL) was developed and validated. This study aims to adjust and validate MAISE-NL for use among employees in low-skilled jobs (MAISE-Easy).

Theoretical background

The MAISE builds on Van der Klink's conceptualization of SE which comprises four components: health, productivity, valuable work, and a long-term perspective.

Design/Methodology/Approach/Intervention

By means of focus groups consisting of employees with low-skilled jobs, items and response categories of MAISE-NL were aligned with the perceptions of these employees. Other items from subscales such as job control, self-efficacy and lifestyle were added. Language was checked for clarity and ambiguity. A questionnaire containing these items, and proxy variables (health and vitality) and demographics, was answered online by 1084 employees from five organizations (response rates 32-64%). Construct validity, reliability, and criterion validity were tested through PCA, CFA, Cronbach's alpha and correlations. We also performed sensitivity analyses (for sex, age and educational level). Additional data will be collected in the Spring of 2023.

Results

Analyses of the first data batch showed that MAISE-Easy comprises 10 scales divided over four areas: (1) Level of SE; (2) Factors affecting SE; (3) Overall responsibility for SE; (4) Responsibility for factors affecting SE. Reliability, and construct and criterion validity were adequate to good and robust across subgroups. Employees' SE was generally considered a shared responsibility of employee and employer, although the latter varied per factor. The analyses will be replicated for the 2023 data.

Limitations

Results may be influenced by common method variance, which is inherent to self-report and cross-sectional data. Further validation of the MAISE-Easy in larger and more varied samples is recommended.

Conclusions – research and or practical implications/Originality/Value

The MAISE-Easy is an adaptation of the MAISE. Very few survey-instruments are have been tested regarding their feasibility for employees in low-skilled jobs, and even less are adapted (research gap). Our new instrument was adapted based on both focus-groups with the target group and statistical grounds. We recommend researchers to use this instrument for SE studies in the understudied group of employees in low-skilled job. We recommend employers to use the MAISE-Easy as a needs assessment in order to develop SE interventions that will be readily accepted and effective for these employees.

Relevance to the congress theme

This research is highly relevant to the congress theme as it addresses a group of workers that is particularly impacted by recent global developments at workplaces and the labour market.

Keywords: sustainable employability, employees in low skilled jobs, questionnaire

7-minute science 7M21

Micro-business adaptation during COVID-19 pandemic

Sanna Malinen, Herb de Vries & Fraser Crawford | University of Canterbury, NZ

science&practice

Research goals and why the work was worth doing: This study sought to understand the adaptive capacity of micro businesses during an on-going crisis. This study was conducted in the context of New Zealand real estate agents to investigate how they adapted their business when confronted with the COVID-19 pandemic.

Theoretical background: Business adaptation is critical to navigate an increasingly turbulent environment (Reeves & Deimler, 2011) and the need for organisational adaptive capacity has increased during the COVID-19 pandemic due to the uncertainty and forced changes to business practices. This includes adaption of small and micro-businesses, which are key to many economies and are an integral part of many communities' make-up. However, a majority of studies in the literature focus on large organisations' collective adaptive capacity or large organisations' employees' adaptive capacity and resilience (Malinen et al., 2019; Nilakant et al., 2016; Tonkin et al., 2018). Little is known of micro-businesses resilience and how they may adapt during crises.

Design/Methodology/Approach/Intervention: This study was conducted in 2021, during the global COVID pandemic. We conducted 15 semi-structured interviews with New Zealand real estate agents, who had been in the industry a minimum of two years. Interview questions centred around participant experiences during the pandemic, learnings from past crises and strategies to maintain business operations during 'lockdowns'.

Results obtained or expected (if not available, it must be made clear when they will be): The key themes included learning from previous crisis experience, increased use of technology, and increased focus on client health and safety. In addition, participants spoke of innovative marketing techniques and increased communication with clients. The findings further suggest that real estate agents used a mix of social connections and sales techniques to continue providing their service. A strategic shift was observed, where real estate agents engaged in a more empathetic, humanistic approach where sales came second to the wellbeing of their clients.

Limitations. Key limitation of this study is sampling and only interviewing those participants who were still in business. Future research can investigate those micro-businesses who have not succeeded in their adaptation and have ceased to exist.

Conclusions – research and or practical implications/Originality/Value. This research contributes to our understanding of micro-business resilience, and demonstrates the creativity and adaptive capacity of small businesses. Learning from past crisis experience appears to be key for resilience, supporting findings from past research on large business resilience.

Relevance to the Congress Theme. Micro-businesses must be able to adapt to continuously changing circumstances. These small businesses are an important part of many community's make up, and therefore their resilience is likely to have wide-reaching implications for community wellbeing.

Relevant UN SDGs. Entrepreneurship and micro businesses are important drivers of social equity and economic security in communities.

Keywords: Resilience, micro business, adaptation

7-minute science 7M135

Modern Policing and the Use of Police Specific Measurements of Perceived Stress – Do We Get More Knowledge?

Assistant professor, Lillis Rabbing, Norwegian Police University College, Oslo

Professor Bjørn Lau, University of Oslo, Department of Psychology

Associate professor, Knut Inge Fostervold, University of Oslo, Department of Psychology

Professor John Blenkinsopp, Oslo New University College

Professor Brita Bjørkelo, Norwegian Police University College, Oslo

science

Background

Employees in the police services, either in civilian or police positions, are exposed to operational and organisational stressors in their professional practice (Violanti et al., 2017). The latter is identified as the police's predominant stress source (Shane, 2020). To gauge the character of policing, several scholars have developed police-specific measurements of perceived stress with satisfactory psychometric properties in a police population (Rabbing et al., 2022). As the number of civilian employees in the police service is increasing, they constitute an essential source of information that should be incorporated into the knowledge base for working conditions in the police. This study examines the usability of police-specific measurements when applied to the entire police population. We selected one of the most widely used police-specific measurements of stress; the Police Stress Questionnaire, PSQ-Op and PSQ-Org (McCreary & Thompson, 2006), in order to i) examine different factor structures when applied to our sample, ii) examine different aspects of validity (i.e., content and concurrent).

Method

A random sampling technique was used to select 4000 respondents from, at the time of the study, a total of 17.109 employees in the Norwegian Police Service; 560 of those invited responded, giving a response rate of 14%. Analyses of our sample verify significance according to representativity. We conduct confirmatory factor analyses (CFA) to examine how and if the factor structure that other studies using PSQ, have come up with fits our sample. For reliability, we use Cronbach's alpha score. For reliability, we use Cronbach's alpha score.

Results

Our sample, both when analysed through our entire sample and when stratified between police position (N=323) and civil position (N=237) shows poor model fits when tried on factor structures found in other studies.

Discussion

We discuss the construct of police-specific measurements of stress in general. We also discuss scale compositions and reflective vs formative, additive scales. For validity, we discuss associations between PSQ and generic scales of work-related stress, guided by established theoretical models like the Effort-Reward Imbalance (ERI) Model and the Demand-Control-Support (DCS) Model. We ask if police-specific measurements add more knowledge to the police population than general measurements may do.

Conclusions

We do not find any of the same factor structures in our sample that others have found. This may be connected to the fact that the PSQ scales were created as formative in the first place.

Keywords: Police Specific Stress Measurements, civilian and police employees, factor structure

More fun in the sum? How team members' Big Five personality traits predict the emergence of humor in teams

Christine Gockel, SRH Berlin University of Applied Sciences; Rebecca Gerlach, TU Chemnitz; Katherina Quispe Bravo, Humboldt University Berlin

science

1. Research goals and why the work was worth doing: Humor occurs in many team interactions at the workplace and has numerous positive consequences (Mesmer-Magnus et al., 2012). It is inherently social in nature: Successful humor requires an immediate reaction from listeners (such as laughter) and often leads to more humor in the interaction (as described in the wheel model of humor by Robert & Wilbanks, 2012). In this study, we focused on the emergence of humor in teams. Specifically, we examined how the production of humorous comments is influenced by one's own Big Five personality traits (= actor effects), by fellow team members' Big Five (= partner effects), and by the similarity between oneself and fellow team members.

2. Theoretical background: Team member personality characteristics have been shown to be important predictors of effective team collaboration. In this study, we refer to the Big Five model of personality, which distinguishes between extraversion, neuroticism, openness to experience, conscientiousness, and agreeableness. We base our reasoning on Moreland's and Levine's general theoretical model of group composition (1992). It distinguishes additive from interactive group composition effects (i.e., whether a group is more than the sum of its parts). A Group Actor-Partner Interdependence Model (G-APIM, Kenny & Garcia, 2012) enables us to test actor, partner, and similarity effects.

3. Design/Methodology/Approach/Intervention: Thirty-six teams with four to eight members each participated in this study (n = 201). They were recruited from different organizations in Germany via LinkedIn. Teams worked online on the desert survival task and were recorded via Zoom. The Big Five personality characteristics were assessed via a questionnaire before the team task. Humorous interactions during the team discussion were coded after data collection. We coded, for each humorous statement, who mentioned it, the target of the humorous statement, and whether fellow team members reacted with laughter.

4. Results obtained or expected: Data collection and discussion coding have been completed. Results will be available in December 2022. For the analyses, we are using a Group Actor-Partner Interdependence Model (G-APIM). We expect actor effects for extraversion and openness, and partner effects for extraversion.

5. Limitations: We examined actor and partner effects of humor in teams during a special phase of the pandemic when many people worked from home in 2021. Humor might have been especially important in those times to bridge the limited contacts. Therefore, results may be difficult to generalize.

6. Conclusions – research and or practical implications/Originality/Value: This study serves to deepen our understanding of humor in teams, specifically how personality characteristics shape the emergence of humor. The differentiation into actor and partner effects allows us to better understand the interdependencies in humorous team interactions.

7. Relevance to the Congress Theme: Our study focuses on online team collaboration, which has been prevalent since the start of the pandemic. It sheds a light on how humor emerges, which – in turn – can make online collaboration more energetic, creative, and fun.

Keywords: Humor, teams, Big Five

Multi-level interplay among creative behavior, sustainable leadership, and industry 4.0 sophistication on sustainable innovation

Saleh Samimi Dehkordi, DEAMS Department, University of Trieste, Italy; Matej Cerne, School of Economics and Business, University of Ljubljana, Slovenia

science

Research goals:

Climate change, desertification, lack of water, pollution, and lack of raw sources are among the most important long-term challenges that the world is dealing with, which increases the importance of sustainability and sustainable innovation in light of achieving economic performance. Sustainability is not considered merely an extra strategic option for companies, but rather a vital factor for firms' survival. Sustainable industry and development need employee-level sustainable innovation and a new mindset in leaders (i.e., sustainable leadership) more than ever. Therefore, this research aims to investigate the multi-level interaction among creative behavior, sustainable leadership, and unit industry 4.0 (I4.0) sophistication on employee sustainable innovation. Also, multi-level theory shows that organizations are inherently multilevel systems. This research will contribute to developing a multilevel concept in the technology management-sustainability literature.

Theoretical background:

Increasing the emphasis on sustainability in the innovation process, innovation is increasingly becoming essential for achieving sustainable development. Due to this, sustainable innovation is defined as the employee development of new goods, processes, and services that reduce or remove the harmful effect of the production on the environment while they respond to the consumers' needs. It not only increases a firm's economic performance but also helps the environment which has both long and short-term benefits either for the company or for the environment and society. Creativity is defined as generating novel and practical idea, and putting these ideas to practice into new products and services is innovation. Depending on using and performing employees' creative idea, organizations can take advantage of these opportunities for growing and adapting to changes and competing in market. Therefore, a firm can function sustainably in innovation if its employees have creative behavior and participate in sustainable innovation activity.

H1: Creative behavior is positively related to employees’ sustainable innovation.

Creativity and innovation are influenced by multiple elements. It is argued that team leaders' traits and behaviors affect and interplay with their employees' creativity. Thus, leadership plays an important role in workplace creativity and innovation. Sustainable leadership is not only concerned about creating short and long-term profits for a firm but also, improving the lives of people who are concerned. As innovation is the main key to sustainable development, it is vital for firms to complement their employees’ creative endeavors with the sustainable leadership approach.

H2: Employee creative behavior interplays with sustainable leadership in predicting employee sustainable innovation.

I4.0 sophistication is indicated by a change through knowledge, information, and internet of things as the main concepts of an innovation-based economy, and it will turn old business operations into a new one in the digitalization era. It also provides efficient management and production and it could

have a specific contextual impact on employees' creative processes leading up to sustainable innovation.

H3: There is a three-way interaction effect among employee creative behavior, sustainable leadership and I4.0 sophistication predicting employee sustainable innovation.

Methodology:

Empirical research will be conducted on knowledge-working teams from a sample of small and medium-sized companies across a wide variety of industries and workplaces. Multi-level model will be tested through quantitative techniques using MLMED.

Results obtained:

Highest levels of employee sustainable innovation are expected when creative behavior, sustainable leadership and I4.0 sophistication are all present at high levels. Moreover, I4.0 and sustainable leadership assist in transforming creativity to innovation. Therefore, it is expected that I4.0 and sustainable leadership play the role of joint moderators between employees' creativity and individuals' sustainable innovation.

Limitations:

Adaptation of organizational-level measures for sustainable innovation to the individual level. Potential challenges in obtaining two-source (leaders and employees) data.

Conclusions:

Maintaining competitiveness is necessary for responding to I4.0 challenges for all companies, and improving innovation and its context with regards to leadership and I4.0 is considered as one of the main means to maintain competitiveness.

Relevance to the Congress Theme:

Our study provides additional insight into sustainable development particularly by investigating sustainable innovation microfoundations. Growing importance of sustainable innovation is obvious, and scholars are looking for answers to the question of how to adjust innovation for sustainability matters, then transform creative behavior to sustainable innovation by considering I4.0 and sustainable leadership.

Keywords: Industry 4.0, sustainable leadership, creative behavior, sustainable innovation

7-minute science 7M02

Negotiating perceived employability in the context of undergraduate work integrated learning

Carol Linehan & Margaret Healy |University College Cork; Sylvia Dempsey, Munster Technological University

science

Prior research suggests work integrated learning (WIL) experiences constitute a significant route to perceived employability for undergraduate students (Jackson & Dean, 2022), facilitating mastery experiences (Cox & Simpson, 2016; Inceoglu et al., 2019), and leading to increased self-efficacy (Martin & Rees, 2019). However, the mechanisms through which perceived employability manifest from those experiences are less understood. Jackson & Dean (2022) suggest value in collecting more granular analysis by discipline of the impact of WIL on students' perceived employability. This study provides empirical evidence of the experiences of students completing placements in accounting roles.

Drawing on prior literature, Jackson & Dean (2022) offer a broad definition of individual (rather than organisational or societal level) employability, as encompassing work readiness, the development of generic skills and professional networks, career self-management and professional identity formation. They also recognise other important dimensions of employability, for example, career management competencies and professional socialisation. Perceived employability measured by Berntson & Marklund (2007) using an index constructed to include perceived skills, experience, network, personal traits, and knowledge of the labour market, refers to individual's sense of these employability dimensions and of their likelihood of securing work (Jackson & Dean, 2022). Higher levels of perceived employability enable students to become 'agentic learners' (Jackson & Dean, 2022, p.3), better able to compete in the labour market for graduate and subsequent roles and to navigate future careers. Empirical investigation leading to better understanding of the role of 'employment transitions' (Inceoglu et al., 2019, p.318) such as that offered by work-based work-integrated learning is needed (Inceoglu et al., 2019). Bonnard (2020) argue for an approach to employability that encompasses subjective dimensions of employability and that include students "representations of the world of work".

Using interview data gathered from 40 students before, during and following a six-month period of WIL in accounting roles, this study captures how students build representations of the world of work and their potential place in it. In effect through detailed qualitative analysis of students' subjective experiences of transitions into, during and out of WIL we track 'narratives of employability' across such experiences. In effect charting the processes by which they come to understand what an employable graduate might be and decide whether they wish to play in that game or not. The approach taken allows for variety in narratives to emerge, thus capturing differences in individual's perceptions of employability, some of which may stem from differences individuals bring to the WIL experience (Abrahams, 2017 in Bonnard, 2020) and some emerging from interactions and negotiations happening during WIL experiences e.g. whether employers affirm or negate students developing narrative of employability. The findings of this study contribute to our knowledge of how undergraduate students navigate and negotiate the subjective dimensions of perceived employability, highlighting how their interpretation of key events and organisational cues informs individual agency in securing future professional roles and determining desired career trajectories. Given rapidly changing workplaces and patterns these are important skills for graduates to develop. More broadly having a research focus that attends to future employees' subjective experiences of

workplace transitions and change will be an important element in assessing and building decent work and workplaces from all stakeholders' perspectives.

Objectification and self-objectification at work: a systematic review of the literature using PRISMA

Elsa Boulard, Christophe Demarque & Valérie Fointiat | Laboratoire de Psychologie Sociale - Aix-Marseille Université

science

Numerous studies on objectification and self-objectification at work aim to identify the antecedents and consequences of these processes. To our knowledge, no systematic review of the literature has been conducted. We used the PRISMA (Preferred Reported Items for Systematic Reviews and Meta-Analysis, James, 2020) approach to conduct a systematic review of literature on working objectification and self-objectification.

Objectification at work is a form of dehumanization that leads to perceiving and treating others (i.e., the worker) as an object (Nussbaum, 1995). More precisely, an objectified person is a person deprived of individuality or reduced to a specific function. Workers, victims of these objectification processes, tend to internalize objectifying thoughts towards themselves, and to see themselves more like a work instrument than a human (Baldissarri et al., 2017). This is referred to as self-objectification.

According to PRISMA recommandations, the review consists of two stages, the preparation and the completion, which is itself divided into three phases, namely identification, selection, and inclusion. First, the preparation stage consists of designing the framework in which the review will be conducted. Second, the execution stage aims at sorting the different references considered. We used the following search equation (objectification {title}) AND ((work) NOT (sexual)).

It emerges that the characteristics of the activity (repetitiveness, fragmentation, dependence) and the subordinating relations are sources of objectification. Moreover, the consequences of objectification are extremely harmful both for individuals, who are more likely to conform and are less happy in their work, and for organizations, which are more likely to see an increasing quitting intention or decreasing work performances. The main finding of this review is that only one study was conducted with the objective of identifying protective factors, showing the moderating effect of self-awareness in the relationship between perceived objectification and self-objectification.

We know that there are different processes of dehumanization at work (biologization, animalization) which would allow us to complete our knowledge of these mechanisms. Also, sexual objectification, from which objectification at work originates, could provide a lot of information about the functioning of objectification at work. It is therefore necessary to reiterate this review, taking into account the factors of dehumanization in general.

This review has identified current research directions in terms of predictors, consequences and protective factors of objectification at work.

This work integrates the theme 12 of the conference „Research Methods".

The objective of this systematic review is to promote the well-being of workers who are victims of these dehumanizing processes and to promote professions that are victims of inequalities in terms of consideration and recognition.

Keywords: dehumanization, objectification, PRISMA

On the Verge – Investigating When the Observation of Prosocial Behaviors in the Workplace Can Turn from Positive to Negative

Armelle Vallette d'Osia, Université de Neuchâtel

science&practice

Research goals and why the work was worth doing

Prosocial behaviors are acts that promote or protect the welfare of individuals, groups, or organizations (Brief & Motowidlo, 1986). While previous research either focused on the actor or on the target, literature on observers of prosocial behavior is scarce. In this study, we examine whether observing prosocial behaviors also positively impacts the observer's well-being and job satisfaction. Furthermore, by adding social connectedness and competitive psychological climate as moderators, we examine in which conditions an apparently positive event such as the observation of prosocial acts can either be beneficial or detrimental.

Theoretical background

Prosocial behaviors have a positive impact on the individual and organizational level with both engaging in and receiving prosocial acts improving employees' well-being (Hui et al., 2020) and performance (Grant, 2008). Furthermore, preliminary evidence suggests that observing prosocial acts has a positive effect on well-being (Chancellor et al., 2016), but the boundary conditions of this effect are unknown.

On the one hand, we argue that observing prosocial behaviors have more positive impact when observers are socially closer to actors and targets (Chancellor et al., 2016). This suggests that social connectedness, defined as the experience of belonging to a social network (Lee & Robbins, 1995) might therefore be a circumstance enhancing the positive effect on well-being and job satisfaction.

On the other hand, however, we argue that observing prosocial acts might have a less positive impact in a competitive environment (Hardy & Van Vugt, 2006). Indeed, prosocial behaviors can be used to enhance reputation and status (Berman & Silver, 2022) and therefore make others look bad in comparison. Particularly in a competitive workplace, prosocial behaviors may threaten the observer's reputation (Kawamura & Kusumi, 2020), self-evaluation (Parks & Stone, 2010), and hence well-being. Organizational competitiveness, characterized by contesting for resources, may therefore invert the positive impact of observing prosocial acts into a negative one.

Design/Methodology

Data is collected with an online two-week daily diary study among 200 participants. The observation of prosocial behaviors, positive mood, and job satisfaction will be measured daily at the end of the workday; whereas the moderators (i.e., social connectedness and organizational competitiveness, considered as rather stable characteristics) are measured in the baseline survey.

Results obtained or expected

Data will be collected in November 2022; results will be available in December and ready to be presented at the conference in May 2023.

Limitations

All measures are self-reports.

Conclusions

The positive impact of being a giver or a recipient of prosocial acts is well established but testing both upsides and downsides of observing prosocial acts offers new insights that are of theoretical and practical importance and answers recent calls (e.g., Bolino & Grant, 2016) to investigate prosocial organizational behavior in more detail.

Relevance to the Congress Theme

The workplace being more and more relational (Grant, 2007), engaging, experiencing, and observing prosocial behaviors would seem beneficial, both for the individual and the organization.

Keywords: Prosocial behaviors, Well-being

Optimal Functioning in Society: A New Perspective on Flourishing

Léandre Alexis Chénard-Poirier, Department of Management, HEC Montréal; Natalie Rinfret, École nationale d'administration publique; Jacques Forest, ESG UQAM; Nathalie Houlfort, Université du Québec à Montréal; Jérémie Verner-Filion, Université du Québec en Outaouais

science

Goals Studies show there are no clear boundaries between wellbeing at work and in other life spheres (Bianchi et al., 2021). Thus, to grasp workers' wellbeing, we need to understand what it is to be fully functioning in many life domains. Scholars in positive psychology have tried for decades to identify in which spheres flourishing people are optimally functioning. No consensus emerged and they failed to consider aspects of work, even if the Word Health Organization (WHO, 2001) identified productive work as central to mental health. In two studies, we present the Optimal Functioning in Society (OFIS) model/scale, support its validity and assess longitudinally its nomological associations with passion for work.

Background The WHO (1948) posits that healthy people are mentally, physically, and socially well. It adds that positive mental health is the capacity to realize one's abilities, cope with stresses, work productively, and contribute to the community (WHO, 2001). The OFIS encompasses these dimensions by assessing psychological, physical, and social wellbeing (two facets romantic/non-romantic relationships), performance at work, and contribution to the community. Passion for work is a motivational force that can take a harmonious (HP) or obsessive (OP) form (Vallerand, 2015). HP occurs when people freely engage in their work out of love for it. OP occurs when people compulsively engage in their work because they love it and to get contingencies like self-esteem. Studies showed that HP promotes wellbeing and OP hinders it (Vallerand et al., 2019).

Method Items were created to reflect the six dimensions of the OFIS and reviewed by experts. In Study 1 (cross-sectional) 434 U.S. workers completed the OFIS and measures of key correlates. In Study 2 275 U.S. workers completed the OFIS and passion scales on two occasions (3 months).

Results Study 1 EFA supported the OFIS 6-factor structure. Latent correlations supported convergent validity and showed the OFIS factors were positively and negatively associated with positive (.15<r<.89; flourishing, satisfaction, vitality, positive emotions, physical health) and negative (-.45<r<-.11; negative emotions, physical illbeing) correlates. Study 2 An autoregressive model supported the OFIS temporal stability (.51<β<86). A cross-lagged model showed that HP at T1 was related to psychological (β=.20), physical (β=.15), and social (romantic β=.22; non-romantic β=.25) wellbeing at T2. OP at T1 showed small relations with performance (β=.11), romantic relationships (β=.10), and physical wellbeing (β=-.11) at T2. Contribution at T1 was related to HP at T2 (β=.14). Multigroup analyses supported the OFIS discriminant validity across age, sex, and relationship status.

Limits Both studies relied on self-reported measures.

Conclusion This research validated the OFIS scale, which includes spheres of functioning at work and in people's lives. It is the first study to assess directional relations between passion and a multidimensional flourishing model. These results support that HP promotes healthy functioning (psychological/physical/social), but not positive mental health (performance/contribution). OP seems to have a limited contribution to flourishing. The OFIS multifaceted nature could help obtain fine-grained observations of workers' flourishing.

Theme/SDG This research aimed at better defining wellbeing and identify its motivation antecedents (Topics 18 & 5) and pertains to the "Good health & wellbeing" SDG.

Keywords: Optimal functioning in society, Wellbeing, Passion for work

7-minute science 7M190

Orchestrating Voicing as organisational intervention to resolve and prevent conflicts at workplaces

Liv Starheim, Southern University of Denmark

science

Problems with work-related stress caused by role conflicts, interpersonal conflicts, and “Stress as an offense to self” (Semmer et.al 2007) is documented as having negative consequences on employees' mental health. (Meier, Gross, Spector, & Semmer, 2013; Semmer et al. 2015 Mikkelsen & Einarsen, 2001; Nielsen and Einarsen 2012; Hogh, Mikkelsen & Hansen 2011). Companies' ability to prevent and manage conflicts is furthermore decisive for whether conflicts escalate to bullying. (Einarsen & Hoel; 2008, Mikkelsen, Hogh and Puggard 2011).

This study is an action research project that provides capabilities to the working environment committee in designing sustainable conflict management processes. Through three full-day workshops, the leaders and employee representatives together worked with their own organizational conflicts management system both present and for the future. The four intervention workplaces were from building construction, production, social welfare, and childcare branches.

Data were obtained through interviews before and after the intervention program and with a short questionnaire after the last workshop (N= 54) which showed high satisfaction with the workshop days. Especially the opportunity to” talk about difficult topics in a peaceful and agreeable atmosphere” and engage in a common language was secondly pinpointed by the participants as an important way of sharing, analyzing, and designing dialogue processes to handle and prevent conflicts.

The interview part of the evaluation showed that the training program moved the workplace overall attitudes toward conflict prevention, and members of safety- and cooperation committees intervened earlier and more often in conflicts. The dialogue on how to intervene in conflicts and prevent them as facilitators were pointed out as the main contribution to the workplace capability. This capability will be unfolded under the concepts of voicing, silent voicing, and pseudo voicing and how to orchestrate dialogues to move conflicts to develop workplace activities and reduce the negative impact on mental health.

Voicing

Voicing is a framework for understanding when and why employees point out objectionable conditions. In a summarized article, Elisabeth Morrison proposes a description of voicing as employees' communication of ideas, suggestions, concerns, or opinions about work-related problems with the aim of improving the functioning of the organization or units (Morrison 2011 p.375). Companies need employees to pass on information about unwanted conditions to those who can prevent damage or errors. Whether or not employees choose to come forward with reports of unwanted conditions is, in Morrison's overview, a complex trade-off of contextual and individual conditions of whether the risk of coming forward is offset by a safe organizational environment, and whether it is worth the trouble to present criticism in relation to the possibility of whether the criticism is heard and acted upon.

Silent Voicing

Managers' response to inquiries is the most crucial contextual factor for whether employees believe that it is useful to bring up conflicts and criticism. Surprisingly, in a Dutch study, the degree of

response to the employees' inquiries is rated as higher by the employees than by the managers themselves. In the four case-workplaces the employees expressed that their choice of voicing behavior was a direct extension of the experience of whether the management was willing and able to do something about the conflicts. And when the conflicts were not resolved, along the way they gave up pointing out problems and instead took over "silent voicing" (Morrison 2011), withholding information, suggestions, ideas, questions or concerns about potentially important work- or organization-related topics in silent resignation. Here, the risk of conflict level increases as studies show that the more silent voicing, the higher the risk of intragroup conflicts in the workplace (Morrison 2011).

Pseudo Voicing

A lack of response can also develop into an experience of pseudo-voicing, when the management, via e.g. well-being measurements and workplace assessments, ask for the employees' assessment of conditions at the workplace without responding to the collected information (Morrison 2011).

Not being able to resolve concrete and recurring disagreements about the work tasks is described by the employees at the case workplaces as their biggest problem. The dialogue was closed down, as management had a different notion of the causes of the disagreement. At one workplace management's description of the biggest working environment challenges was the high amount of tasks and disagreements with the clients. However, conflicts with the clients were assessed by the employees as far less severe than internal disagreements about the work tasks.

How these concepts of Voicing can contribute to orchestrating conflict-handling dialogues will be presented in the oral presentation.

Peer Influence on Depression – Co-brooding as Underlying Interaction Mechanism in Social Networks

Sophie-Theres Loose, Department of Work Psychology, University of Münster; Maarten van Zalk, Department of Developmental Psychology, University of Osnabrück

science

Over the last years, several studies reported peer influence effects on depressive symptoms, showing that friends became more similar in their levels of depressive symptoms over time (Prinstein, 2007; Stevens & Prinstein, 2005, Van Zalk et al., 2010). Little is known, however, about the interactional mechanisms that explain how peers may affect depression. Co-brooding is an maladaptive form of interpersonal emotional regulation and its usage is associated with high levels of depressive symptoms in both partners in close relationships (Horn & Maercker, 2016). One possibility is that co-brooding explains how peers affect depressive symptoms.

We conducted a pre-registered (https://osf.io/qazvd) longitudinal social network analysis to examine a) whether peer influence explains changes in depressive symptoms and b) whether co-brooding functions as an underlying interaction mechanism of peer influence; we hypothesized that higher levels of depressive symptoms predict more co-brooding over time, and co-brooding, in turn, predicts increased peer similarity in levels of depressive symptoms.

We did a social network panel study, where one cohort of psychology freshmen was invited to participate for four waves (four-week intervals). At each wave, a round-robin design was used, where participants (n = 98) were asked to indicate their relationship (e.g., acquaintances) and their co-brooding with each of the other participants. Additionally, self-reported depressive symptoms were measured. These data were analyzed using Stochastic Actor-Oriented Models (SAOM) with the R-package RSiena (version 1.2-27; Ripley et al., 2021).

Findings show evidence for peer influence on depressive symptoms, because peers became more similar in depressive symptoms over time. However, contrary to our hypotheses, co-brooding could not be identified as an underlying interaction mechanism for peer influence.

Considering limitations regarding our sample, we used a network with clear boundaries, a cohort of psychology freshmen. Therefore, influences from people outside the analyzed network might have overshadowed influences within the analyzed network. Additionally, the changes in depressive symptoms were few because of the short time intervals, which limit the power of longitudinal network analysis (Stadtfeld et al., 2020). Finally, we exclusively focused on one negative interpersonal interactional mechanism, namely co-brooding; however, other (more positive) interactional mechanisms (e.g., co-reappraisal; Horn & Maercker, 2016) have been found to explain depressive symptoms in relationships and should be examined in future studies.

To conclude, this preregistered study widened the view on influence processes as evidence showed that acquaintanceship networks provide a potential in preventing and treating depressive symptoms. To identify underlying interaction mechanisms, more research is needed that includes a wider range of interactional mechanisms across different time spans.

Our study contributes to research on coping and social support as well as management of emotions, as it underlines the potential of influences on mental health within social networks. The results contribute to understanding how to achieve the UN sustainable development goal 3 (i.e., good

health and well-being) by emphasizing the relevance of peer influences on mental health in social networks. Identifying these influences can help to promote well-being via social networks, e.g., in the work context.

Keywords: social network analysis, depressive symptoms, co-brooding

PERCEIVED EFFECTS OF TELEWORKING ON ADAPTIVE PERFORMANCE: A MODERATED MEDIATION MODEL OF LEADERSHIP EFFECTIVENESS AND NEGATIVE AFFECT

Burcu Taskan, Iscte – Instituto Universitário de Lisboa (ISCTE-IUL), Centro de Investigação e Intervenção Social (CIS-IUL), Lisboa, Portugal.; António Caetano, Iscte – Instituto Universitário de Lisboa (ISCTE-IUL), Business Research Unit (BRU–IUL)

science&practice

Due to the increasingly dynamic, complex, and frequently unpredictable nature of businesses and organizations, adaptive performance is becoming more and more important in challenging and unpredictable business situations. Due to the COVID-19 epidemic, teleworking has gained popularity as a paradigm of employment and is now employed by many enterprises to guarantee business continuity. The factors that can improve employees' ability to deal with uncertainties in their occupations, when working remotely, specifically those that may encourage their adaptive performance, have not yet been the subject of enough empirical investigations. We contend, based on the conservation of resources theory, that adaptive performance will be negatively impacted by the perceived effects of telework, and that this indirect effect will be moderated by the perception of leadership efficacy. We obtained data from teleworkers (N=227) to evaluate these hypotheses. Results showed a substantial indirect effect of perceived telework effects on adaptive performance via negative affect. Additionally, the indirect effect was moderated by leadership effectiveness, making it stronger for those who thought their leaders were effective (versus ineffective). The implications for employees and organizations are discussed.

Keywords: Adaptive performance, telework.

Perceived Sustainability Transparency of Organizations: A Scale Development and Validation Study

Lisa Hollands, Chair of Business and Ethics, University of Vechta; Nick Lin-Hi, Chair of Business and Ethics, University of Vechta; Luca Haensse, Chair of Business and Ethics, University of Vechta; Hanna Marxen, SnT, University of Luxembourg

science&practice

Research Goals. The dimensions that individuals apply in evaluating the transparency of organizational sustainability information bear great theoretical and practical relevance. However, there is no standardized scale for the measurement of sustainability transparency. Thus, the purpose of this study is to develop an instrument to measure the perceived organizational sustainability transparency from a customer's perspective.

Theoretical background. We synthesize prior research on transparency and sustainability to advance a theoretically sound scale. A particular strength of our study lies in the twofold foundation of the construct. First, we consider the three transparency dimensions disclosure, clarity and accuracy based on the concept of Schnackenberg et al. (2020). In addition, we integrate the triple bottom line sustainability model by combining the transparency dimensions with social, environmental, and economic information of the organization.

Methodology. Based on an extensive literature review, an item pool was generated. Sustainability experts were involved in the development and refinement of the items. To test the questionnaire across contexts, information material on three hypothetical organizations from different industries was developed. The criteria for the industries' selection, the material itself and the content validity of the scale was pretested (N 1 = 19; N 2 = 21). In the main study, 313 participants of 48 different nationalities completed the questionnaire. The assumed factor structure of the items was tested by means of confirmatory factor analyses.

Results. The item reduction process retained 27 items overall, yielding nine three-item subscales. Based on comprehensive validation procedures across different industries, we found strong support for the three-dimensional transparency model, with excellent factorial, convergent, and discriminant validity and internal consistency. The sustainability model yielded acceptable psychometric values except for a lack of discriminant validity.

Implications. The study sheds light on how customers perceive the transparency of organizational sustainability information and offers the opportunity to add to our understanding of the concept and its impact on other factors such as trust or sustainable consumption. The scale could serve as a flexible measure to examine the perceived status of sustainability transparency of companies and identify gaps and leverage points for improvement.

Relevance to the Congress Theme. Recently, scholars, politicians and consumers alike have called for more transparency on the sustainability activities of organizations in the future, though instruments for the assessment are still lacking. Drawing on established frameworks and combining the dimensionalities of both constructs, we advance research by developing and validating a measure of perceived sustainability transparency.

Relevant UN SDGs. The work is relevant to the SDG 12 as consumers and institutions are provided with guidance for the appraisal of sustainability transparency and can better identify (in)transparent

choices. Likewise, organizations can be supported in the construction of a transparent sustainability communication.

Keywords: sustainability, transparency, scale validation

7-minute science 7M173

Perceptions of applicants' personality traits from their resume: the role of specific cues in influencing readers' inferences

Alberto Casciano & Lorenzo Avanzi | University of Trento

science&practice

Research goals. Recruiters' perceptions of applicants' personality traits can influence employability judgments. With this contribution we aimed to study the role of some resume cues in shaping those perceptions.

Theoretical background. The presence of some specific cues was found to be related to self-reported personality traits. Including volunteer activities or teamwork skills have shown positive relations with agreeableness scores. Since recruiters use resumes to infer individual characteristics, making inferences also on applicants' personality traits, we expect to observe that a) the presence of at least one of those two information related to agreeableness could influence the same trait rater-reported scores, and b) the personality trait-specificity of the same two cues should be supported by the absence of relations with other rater-reported personality traits.

Method. In study 1 we created four CV versions, experimentally manipulating only the presence of agreeableness related cues. We randomly administered them to 173 students, asking them to read it and rate it using an other-reported personality questionnaire (Big Five Inventory). In study 2 we aimed to study the same relations in a real selection context, thus collaborating with four recruiters from two organizations and using real CVs (120 for every organization). According to study 1 manipulation, we divided archives' CVs into four groups, and asked to the recruiters to rate them using a shorten version of the BFI.

Results. In study 1, MANOVA partially confirmed the hypotheses, supporting the role of trait-relevant information in influencing personality traits perceptions. ANOVA conducted to study agreeableness showed a significant effect, with participants who read a CV version presenting at least one of the two manipulated information, assigning significantly higher agreeableness scores, compared to those who read a version lacking such trait-relevant information. The manipulation had no significant effect on the other personality traits' assessment, except for extraversion, for which the presence of both trait-relevant cues led to significantly higher extraversion ratings when compared to their absence, consistently with previous evidence. Data collection for study 2 is ongoing and will be completed in summer 2023.

Limitations. In study 1, information presented inside the experimental CVs are not fully representative of real CVs contents' heterogeneity. Secondly, other-reported personality ratings were collected between students. In study 2, we had limited experimental control on the presence of other specific cues inside resumes.

Conclusions. Results obtained so far support the idea that the presence of trait-specific resume cues can influence recruiters perceptions of applicants personality traits. Evidences like these could be useful both to recruiters – enhancing their awareness about their own inference strategies – and to applicants – striving for presenting their own qualities.

Relevance to the Congress Theme. Insights gathered from these studies are consistent with the evolution of recruitment and selection procedures, because of the wide use of resumes for

applicants screening, and also for their generalizability to newer instruments used for the same purpose (e.g. LinkedIn profiles).

Relevant UN SDGs. Decent work and economic growth

Personal Resources and Digital Work

Julia Kaesmayr, University of Applied Sciences Ludwigsburg

science&practice

Employees are facing new and multiple challenges of digital transformation process and the digitalized work itself. Past research has shown that job resources and personal resources can aid in coping with new demands, especially if resources match the demands (e. g. triple-match principle, person-environment-fit). Despite the prevalence of digital work, attempts have been made to explore the potential of personal resources particularly with regard to facilitating digital work. The aim of this study was to test whether interactive digital agency, a newly developed personal resource (Kaesmayr – under review) may buffer negative effects of digital demands while facilitating benefits digitally provided resources bring. Past research of the JDR model (Demerouti & Bakker, 2007) showed that personal resources buffer exhaustion caused by high demands. It furthermore strengthens job resources leading to a gain spiral. The digitalization of work comprises new job demands and resources. Recent studies indicated individual differences may determine whether individuals suffer or thrive in these work environments. Interactive Digital Agency (IDA, Kaesmayr - under review) as a hierarchical model whose higher order factors contain individual dispositions regarding digital work can be summarized as digital competence and digital affinity, which may function as a personal resource in the workplace. Against the background of an expanded JD-R Model reflecting digital work (Steidle et al. in preparation) the personal resource and digital work differentiating the degrees of digital information, interaction, integration, data processing and transaction were assessed. 519 public servants participated in an online survey providing information about how digital the processing of administrative action was including job demands and resources, exhaustion, job engagement, and work performance. Structural equation modeling of the digital work reflecting JD-R model (Steidle et al., 2022) confirmed the expected serial mediation. Based on these findings moderations with IDA for the dimensions interaction and transaction were detected. Participants displaying low digital competence perceived an increase in digital interaction as a higher workload, leading to more exhaustion and ultimately a lower job performance. No such relation was found for participants with high digital competence. Similarly, participants with high digital competence perceived a reduced workload when digital transaction increased, which positively affected job performance. The data collected was of a selfreported and cross-sectional sample due to practical constraints. The present research which digital personal resources may aid in thriving in a digital workplace. From a theoretical perspective, the results confirm focusing on digital personal resources in order to successfully navigate digital demands associated with digital work. The results furthermore provide insights pertaining to challenges of digital work which can be met by strengthening employees' digital personal resources. This study contributes to the congress topic "The Future is Now: the changing world of work" as it demonstrates the buffering effects of new or high demands associated with digital work. It furthermore provides guidance for individual based strategies to aid employees cope with new digital demands. Lastly, this research contributes to the goal of achieving good health and well-being.

Keywords: personal resources, well-being, JDR

Profiles of co-worker social undermining on older workers' mental well-being

Stephen Teo, Northumbria University; Kate Blackwood, Massey University; Bevan Catley, Massey University; Tim Bentley, Edith Cowan University; Diep Nguyen, Northumbria University

science

Research goals

Older workers face different types of workplace mistreatment due to their age. An example of workplace mistreatment examined in this study is social undermining by co-workers. Social undermining is argued to be a form of unethical workplace behaviors (Mostafa et al., 2021). To improve the mental well-being of older workers, it is crucial that we identified how ethical leadership could reduce social undermining and improve job satisfaction.

Theoretical background

This study is informed by social learning theory (SLT) and affective events theory (AET). Social undermining by co-workers is an example of negative affective events in the workplace (e.g., Guenter et al., 2014), which could impact on job satisfaction and mental well-being. By complying with social rules, social undermining behaviours would not be tolerated. SLT explains how employees learn what is acceptable or not acceptable from their supervisors; thus, developing a positive work environment. Hence, ethical leadership is hypothesized to have a positive impact in improving older workers' job satisfaction and mental well-being while controlling for psychosocial safety climate (PSC).

Methodology

Cross-sectional data were collected from 1,127 workers from Australia in April 2020. We conducted a latent profile analysis (LPA) to identify the underlying social undermining profiles. Previously validated scales were used to measure the constructs. One way ANOVA was conducted to establish if there was any difference between class in relation to ethical leadership, job satisfaction, and mental well-being. A multiple regression was undertaken using Model 59 of Hayes (2016) Process macro was then used to test the hypothesized mediated moderation model.

Results

Using Latent Gold 5.1 software, three latent class membership profiles were identified: (1) from no exposure [43.7%], (2) little exposure [22.5%], and (3) exposure [33.9%] to social undermining from co-workers among older workers. One way ANOVA showed significant differences in ethical leadership behaviors, job satisfaction, and mental well-being between these profiles. Multiple regression showed there was a partial mediation of job satisfaction on the relationship between social undermining profiles on mental well-being. This mediation relationship was moderated by ethical leadership such that high level of ethical leadership resulted in higher level of mental well-being and job satisfaction. Ethical leadership also moderated the relationship between social undermining and mental well-being such that higher ethical leadership reduced social undermining. While this study could be affected by common method bias (CMV) due to the collection of cross-sectional data in a single time point, we conducted post-hoc statistical checks for CMB.

Conclusions

This study offers theoretical and practical insights into the role of ethical leadership in promoting and creating a healthy work environment for older workers in order to improve their job satisfaction

and mental well-being. Our findings can be explained by AET and SLT as ethical leadership develops and reenforces the ethical conduct in the work environment via the process of social learning.

Relevance

This study is relevant to the congress theme as we examine the experience of older workers in the context of an ageing workforce in Australia. Therefore, the study examines the changing world of work as experienced by older workers. The study responded to UN's SDG #3 and #10.

Keywords: ageing workers, ethical leadership, social undermining

Reaction to Covid-19-induced remote work in German public administrations: Challenges, chances, and the role of person-environment fit

Jonas Brueggemann, Karsten Mueller & Kim Terkuhlen | University of Osnabrueck; Nicolas Mueller, Aalen University of Applied Science; Thea Nieland, University of Osnabrueck; Svenja K. Schumacher, University of Osnabrueck

science

Research goals: The Covid-19 pandemic led to a sudden and forced implementation of remote work for public administrations, regardless of employees' preferences. However, whether remote work is successful depends on the individual's preference to work remotely (Martinez-Amador, 2016). Moreover, Otsuka et al. (2021) stress that misfits between employees' remote work preference and the actual work setting lead to higher reported stress. Hence, the present study aims to understand how public administration staff perceived the abrupt shift towards remote work (e.g., challenges and opportunities), which effect the fit between preference and actual work situation has on job-related outcomes, and how this effect changes over time.

Theoretical background: Even though, the influence of individual and job factors on job-related outcomes in the context of remote work have been studied separately, the effects of the fit between the two have been neglected so far. Therefore, the concept of Person-Environment (P-E) fit as the congruence between an individual and its environment (Edwards et al., 2007) is applied to the remote work context (i.e., the fit between an employees' preference for remote work and their actual work setting) to examine effects on relevant outcomes in the context of public administration settings.

Design: Employees (N=483) of four public administrative organisations were surveyed three times over six months (Aug 2020, Nov 2020, Jan 2021). We will use content analysis by Mayring (2019) to cluster challenges and opportunities of remote work. Moreover, we will use polynomial regression and response surface analysis to analyse the effects of remote work fit on job satisfaction and perceived productivity.

Results: Data analysis is ongoing. Results will be presented at the conference. A high fit between remote work preference and the actual work setting is expected to positively influence job satisfaction and perceived productivity regardless of the direction of fit.

Limitations: Two main limitations are that, first, the study solely relied on self-reports. Thus, future studies should also consider key performance indicators. Second, the study only used data from four organisations. Thus, future studies should aim for more diverse samples.

Research/Practical Implications: This study newly considers the fit between remote work preference and actual work setting in a dynamic environment, thus stimulating further research in this field. The results potentially provide important insights for organisations on how to improve important outcomes by considering individual preference for remote work in flexible and individualized work design. Our study applied the concept of P-E fit in a remote work context examining effects on important outcomes. Furthermore, results on the development of fit over time may foster flexible and individualized work design in the future.

Relevance to the Congress Theme – We address challenges and chances associated with the abrupt shift towards remote work in public administrations as well as the role of P-E fit in the remote work domain.

Keywords: remote working, person-environment fit, public administration

Relational, Emotional, and Affective Nature of School Leadership

Niamh Lafferty, University of Limerick

science

GOALS

This study explores the relational, emotional, and affective (REA) aspects of educational leadership in Irish primary and post-primary schools. The relational aspect relates to the interpersonal i.e., between school leaders and other people within the school community. The emotional aspect relates to aspects including emotion display rules and emotional labour. The affective aspect then in this context refers to motivations, values, enthusiasms, and attitudes.

BACKGROUND

The emotional nature of academic leadership has received increasing attention (e.g., Schutz and Pekrun 2007; Schutz and Zembylas 2009; van Veen and Lasky 2005), arguably reflecting an "affective turn" (Kostogritz, 2012). Coupled with the increases in distributed leadership and the promotion of more collaborative practices (King & Nihill, 2019; Slater, 2005), calls have been made for research on the REA aspects of academic leadership (Kostogritz, 2012). Additionally, human-centred leadership which has been referred to as the "key to the 21st century" (Howard, 2015, p.1) requires REA leadership skills and practices. Relational aspects allow for greater knowledge sharing (Engelsberger et al., 2022) and trust (Brower et al., 2000) between leaders and followers. Emotional aspects facilitate positive social interactions (Hochschild, 2003) and positive affective states in followers (Edelman & Van Knippenberg, 2017). Affective skills allow for the greater engagement between followers and leaders (Hoy et al., 2006) and for leader self-reflection and greater evidenced based decision making (Hoy et al., 2006). Due to the importance of REA practices and skills for the achievement of a human-centred leadership approach, it is important to understand the REA nature of leadership as it currently exists.

METHODOLOGY

This is a correlational and cross-sectional design based on self-report measures of currently practising school leaders. A questionnaire was distributed to assess areas relevant to REA aspects of leadership. Participants provided demographical info and completed scales for constructs relevant to relational, emotional, and affective aspects i.e., School Leader Identity (Leach et al., 2008), Emotional Labour (Brotheridge & Lee, 2003), Turnover-intentions (created for this study), Burnout (Riley et al., 2017), Negative Acts Questionnaire (Notelaers & Einarsen, 2013), and Authentic Leadership Questionnaire (Walumbwa et al., 2008). The questionnaire finishes with open-ended questions for participants to add any additional information if they would like to. Participants were school leaders i.e., principals, assistant principals, deputy principals, year heads, department heads, and others who hold a senior or middle leadership position.

RESULTS

Data is currently being collected and results are expected in January, 2023.

LIMITATIONS:

This study only includes participants from Ireland, however, this can form the basis of future, widespread inquiry across Europe and beyond.

CONCLUSIONS

It is expected that the findings of this research will shed light on the REA nature of school leadership and has the potential of identifying areas of concern that need to be addressed and areas of positivity to be embraced and supported. Considering the high rate of turnover and increasing interest in sustainable leadership, this research is expected to be highly beneficial to an international body of stakeholders.

RELEVANCE TO THE CONGRESS THEME

Future is now: As European countries and schools become more diverse in their student cohorts, it is imperative that schools evolve to reflect these changes and ensure inclusivity and quality of education for all future citizens. School leaders play a pivotal role in ensuring cultures of learning, cultures of inclusivity, and the implementation of policies. Unfortunately, school leader numbers are in crisis due to recruitment and retention issues, and if this is not addressed, the future of education is bleak. To address these concerns, calls have been made to identify factors which promote an increase in numbers. This research aims to do just that by exploring the REA nature of school leadership and in so doing, identify positive factors to be promoted and negative factors to be resolved.

RELEVANT TO UN SDGS

Quality Education : School leaders play a significant role in the provision of quality education through multiple platforms. School leaders influence school culture, staff, and student wellbeing, and can be the instigators or terminators of change and policy implementation. School leader recruitment and turnover is becoming an increasing problem across the globe which is having a direct negative impact on the provision of quality education. This research seeks to identify some of the factors that may be directly influencing this dynamic through the exploration of relational, emotional, and affective aspects of school leadership.

Keywords: educational leadership, academic organisations

Respectful Leader Communication is a Booster for Debriefings in High-Risk Contexts

Stefan Röseler, Meinald T. Thielsch, Guido Hertel & Greta Schrade | University of Münster

science

Research goals and why the work was worth doing

After exercises or operations, leaders in high-risk contexts usually conduct debriefings with their followers to improve learning. We tested our assumption that respectful leader communication is a simple yet effective way to increase the effectiveness of such debriefings by enhancing psychological safety.

Theoretical background

In debriefings, sensitive topics such as errors during an operation are discussed. In order to facilitate open discussion and learning processes, psychological safety is essential. We assume that leaders can establish psychological safety through respectful communication behavior. By offering appreciation, revealing own insecurities, and soliciting supportive feedback, leaders make followers feel valued and model a proactive approach to error management. Thus, we propose that respectful (vs. neutral) leader communication leads to higher psychological safety (H1), and to higher follower satisfaction with the debriefing (H2). Furthermore, we expect that positive effects of respectful communication are qualified by leaders' gender due to gender role stereotypes, leading to lower acceptance when displayed by female (vs. male) leaders (H3).

Design/Methodology/Approach/Intervention

We conducted a preregistered experimental online study with the within factor leader communication during debriefing (respectful vs. neutral) and the between factor leader gender (male vs. female). A total of 268 firefighters (97% male, a typical gender distribution within fire departments) read two vignettes of operations and subsequent debriefings. We asked the participants to put themselves into the described situations and to report perceived psychological safety and satisfaction with the debriefing.

Results obtained

Variance analysis indicated that psychological safety ($d = 1.16$) and satisfaction ($d = 1.41$) were higher in the respectful communication condition, confirming both H1 and H2. There were no differences in the outcome ratings between male and female leader, so that H3 was rejected.

Limitations

The ecological validity of vignette studies is limited. To address this issue, we will conduct an additional field study with more valid measures of learning outcomes. Results are expected to be available in May 2023.

Conclusions – research and or practical implications/Originality/Value

By using easy to apply communication behaviors, leaders have a significant impact on psychological safety during debriefings. Our findings suggest that respectful communication is a prerequisite for followers' learning success, and that this positive effect is not qualified by leader's gender even in a highly hierarchical and male-dominated context such as firefighting. However, given that

communication behavior is often neglected in firefighting training programs, it should be integrated into regular leader training courses.

Relevance to the Congress Theme

High-risk contexts such as the fire services have long been infamous for strict hierarchies and authoritarian leadership. Our research shows that things can be different – respect pays off.

Relevant UN SDGs

Effective debriefings increase the resilience of fire services and other public rescue organizations. We thus contribute to Goal 11 “Sustainable cities and communities”.

Keywords: Learning, Gender, Fire services

Shut Up and Rot Inside? Through Anger Expression Toward Goal Attainment and Well-Being

Robin Umbra & Ulrike Fasbender | University of Hohenheim

science&practice

Research goals and why the work was worth doing: Pent-up anger at work has resulted in devastating outcomes, including aggression, murder, and suicide. Given these devastating outcomes, much research has recommended to inhibit anger all at once. Yet, anger should perhaps not be inhibited or even pacified via anger-management techniques, but instead constructively canalized toward solving the actual problem. We offer a theoretical extension of the workplace anger literature with a problem-focused coping perspective, arguing that the controlled expression of anger does favorably affect goal attainment and resource depletion via the increase of confrontive coping and the decrease of anger rumination.

Theoretical background: Our study is informed by Appraisal Theory as well as its a problem- and emotion-focused coping perspectives. We construct a dual-pathway model which conceptualizes confrontive coping as a constructive problem-focused coping strategy and anger rumination as a destructive emotion-focused coping strategy. While the problem-focused coping pathway captures the constructive energy expression of anger, the emotion-focused coping pathway captures its destructive inhibition. We extent the conceptual model by exploring person-level trait variables, reflecting potential intraindividual moderators affecting the emotion process.

Research methodology: We pre-registered our hypotheses at the Open Science Framework (https://osf.io/3tdwv/?view_only=dcf7c1a7f0944c03ad466b92c37229cf). We test our hypotheses by conducting a comprehensive field study with participants from various organizations and industries using an experience-sampling research design. We ask 150 participants to fill in structured questionnaires thrice each workday (9:30 am, 12:30 pm, 15:30 pm) across ten workdays in addition to a baseline survey. We conduct a series of multilevel confirmatory factor analyses in Mplus to verify the construct validity of the core measures. Next, we apply a series of (Bayesian) multilevel structural equation models in Mplus to test for the effects present in the dual-pathway model.

Expected results: We expect that anger felt in the moment increases confrontive coping and anger rumination during the next couple of hours. We further anticipate that anger favorably affects goal attainment and resource depletion if it is mediated (i.e., dealt with) by confrontive coping, and unfavorably if it is mediated by anger rumination. We also believe that “anger confronters” are less resource depleted at the end of a workday compared to “anger ruminators”. Final results are expected to arrive by March, 2023.

Limitations: The use of self-report measures raises concerns of common-method-bias. The repeated-measures design raises concern of method-biases (i.e., fatigue, boredom, habituation, and the Socratic effect).

Conclusions: Taken together, our hypothesized results will distinguish between the proper and improper handling of anger at work, directly serving to increase the continuous productivity and well-being of workers.

Relevance to Congress Theme: Futures changes in the world of work will lead to problems arising which may cause anger. To guarantee the continual success in the implementation of these changes, finding ways for constructively coping with them will be required. Our paper directly offers solutions

to this matter by outlining how anger can be used constructively to resolve urgent and change-obstructing issues.

Keywords: Anger, Confrontation, Rumination

Signalling diversity and inclusion: How do organisations with high commitment to gender diversity and inclusion signal it in their job adverts?

Victoria Maxfield, MMU

science&practice

This study sought to understand explicit and implicit messaging within job adverts and how this signals belonging and inclusivity to women. Previous research has considered the negative impact of gendered wording, such as 'competitive' and 'dominant' (Gaucher et al., 2011) or non-genuine diversity signals (Kroeper et al., 2020) on women's intention to apply. Meaning that organisations that are committed to D&I should be positively signalling this in their job adverts.

Theoretical background

The literature so far has shown that there are barriers to women moving into leadership roles caused in part by implicit expectations of a leader (Eagly, 1987, 1997; Schein and Davidson, 1993; Offermann and Coats, 2018). When faced with this socially constructed idea of a 'male' leader, women may feel an identity threat where the description of a role they identify with (leader) is ascribed to men (Petriglieri, 2011). Since people are less likely to apply for a job where they don't think they will 'fit/belong' (Scholarios et al., 2003; Petriglieri, 2011), it has the potential to impact gender diversity in leadership positions.

Although good work life balance (WLB) is beneficial for all genders (Firfiray & Mayo, 2017; Stich, 2020), women may experience a greater need for flexible work options (FWO) due to a higher likelihood of having caring responsibilities; however, they may worry that offers of flexible work are non-genuine. Despite the need for FWO, many people are hesitant to request them due to concerns about how genuine the offer is (DeRue & Ashford, 2010; Kelly et al., 2010; Ryan & Kossek, 2008), or the impact it might have on their future careers (Cohen & Single, 2001; Cuddy et al., 2004; Kmec et al., 2014). Starting this conversation as early as possible in the recruitment process can signal a genuine willingness to be flexible and demonstrate an inclusive approach.

Method

This study took a qualitative approach to content analysis looking at the way organisations signal their gender diversity and inclusion commitment through job adverts. Ten adverts were analysed from ten professional services or banking organisations selected from The Times Top 50 Employers for Women (2020) list (100 in total).

Content analysis as described in Erlingsson and Brysiewicz (2017) was used to identify meaning units the length of a sentence or bullet point which were built into themes.

Autonomous counting (Hannah and Lautsch, 2011) was used to identify the number of gendered terms.

Findings

The findings indicate that companies are considering the information they provide from a diversity point of view, but are failing to signal true inclusion which would make women feel welcomed. Two key themes were identified:

Flexibility – genuine offers of flexibility Lead like a man – how male based descriptors are used in the role profile

Limitations

The scope of this study was deliberately restricted to ensure the correct level of depth could be achieved; however, future research would benefit from considering a wider range of diverse characteristics including race and socio-economic background.

Practical implications

This study identified the following practical implications for hiring managers and HR departments. Consider:

what wording can be used to demonstrate that full role flexibility? using gender neutral wording assessing job descriptions to determine whether they are based on ideal worker norms that are not necessary for the role.

Keywords: Gender Diversity, Recruitment

7-minute science 7M61

Social baseline theory and the leader-follower relationship. Investigating the principle of load sharing

Per-Magnus Thompson, BI Norwegian Business School; Christian Winther Farstad, Kristiania University College

science

Why the work was worth doing: The pandemic caused an increase in remote work (e.g., home office). Consequently, knowledge is needed to better understand how this change in the social environment influences work life. Our study sheds new light on this issue.

Theoretical background:

Social Baseline Theory (SBT) proposes that the human brain expects proximity to social resources, and that in the absence of these resources, the brain will budget and predict the future differently (e.g., when alone, people perceive potential threats as more threatful). A key element of SBT is the principal of load sharing , and the idea that in close interdependent relationships, brain activity becomes more synchronized and responses to demands in the surroundings are dealt with at the dyadic level. Our study investigates load sharing in leader-follower dyads by measuring basic psychological needs satisfaction (i.e., need for mastery, autonomy, and relatedness). Applying the principle of load sharing, one would expect that leader and followers' perception of own basic needs satisfaction would gradually become more similar and synchronized over time. Therefore, we propose that in leader-follower dyads, the relationship between the individual ratings of own basic need satisfaction is moderated by dyadic tenure, such that the two ratings will become gradually more similar when dyadic tenure is high.

Methodology: Data was gathered from seven mid-size companies, representing a variety of branches (e.g., retail, construction, IT, and professional services) within private sector. Among the 443 first line- and middle-managers asked to participate, we ended up with 168 matched leader-follower dyads (a response rate of 37,9%). Both leader and follower filled out the 20-item Work-related Basic Need Satisfaction questionnaire by Van den Broeck and collegues (2010). Followers reported on the length of the relationship (i.e., dyadic tenure).

Results: Two stepwise multiple linear regression analyses were conducted. In line with our hypothesis, follower basic needs predicted leader basic needs, and vice versa, when dyadic tenure was introduced as a moderating variable. Further, a simple slopes test showed that the interaction effect was significant only in the high dyadic tenure condition. Therefore, our hypothesis was supported, suggesting that when interdependence and trust between leader and follower develops, sharing of psychological states becomes more prominent (i.e., shared intentionality)

Limitations: As this is, to our knowledge, the first SBT study in a workplace setting, there is a strong need for more empirical studies in this area.

Originality/value: Our study introduces SBT, a theory that has received extensive attention in other areas of psychology, to the leadership literature, and present empirical evidence demonstrating the relevance of this framework in organizational settings.

Practical implications: Our findings are in line with the SBT view that human beings benefit from having access to the social resources that develop gradually in long-standing, close relationships. For

example, remote work could be a social environment that, in SBT terms, has the human brain expecting less sharing of burden and threats, hence causing a decrease in well-being.

Relevance to the Congress Theme: Our paper highlights the social nature of human beings and the need for connectedness when shaping tomorrow's workplaces.

Keywords: Leader-follower relationship, Social Baseline Theory

7-minute science 7M23

Somebody's watching me! Effects of information about evaluators on applicants' use of impression management in asynchronous video selection interviews

Koralie Tchango Orji & Adrian Bangerter | University of Neuchâtel, Institute of Work and Organizational Psychology, Neuchâtel, Switzerland; Nicolas Roulin, Saint Mary's University, Department of Psychology, Halifax, NS, Canada

science

Research goals and why the work was worth doing

In asynchronous videos interviews (AVIs), applicants videorecord their answers to questions usually asked in written form or by an avatar. Answers may be analysed by algorithms. The lack of interaction with a human recruiter impacts applicants' communication, especially how they engage in impression management (IM) (Lukacik et al., 2022). Self-promotion, a self-focused tactic, and ingratiation, an other-focused tactic, are the two most used IM tactics (Stevens & Kristof, 1995). This study investigates how applicants' use of IM differs according to available information about the evaluator (goal 1). Moreover, another goal is to identify the cognitive and emotional processes in responding to AVI-based questions (goal 2).

Theoretical background

Applicants react more negatively to AVIs than other interview formats. This is due to the lack of social presence which prevents them from effectively self-presenting (Basch et al., 2020). It may be especially unclear to applicants who will evaluate their performance. Thus, AVIs may impact how applicants engage in IM. Indeed, they engage less in IM in technology-mediated interviews (Blacksmith et al., 2016). Still, this format should allow self-focused IM tactics. But as applicants do not have a target to ingratiate, there should be fewer opportunities for other-focused IM tactics. In addition, little is known about applicants' cognitive and affective processes in responding to AVI-based questions. This experiment compares the use of IM tactics (i.e., self-promotion and ingratiation) in AVIs where interviewees are informed or not about who will evaluate their responses. We predicted that information about the evaluator should lead to more other-focused IM tactics.

Design/Methodology/Approach/Intervention

160 undergraduates took part in a mock interview. They were randomly assigned to one of two conditions. In one condition, they received information about the person evaluating them. In the other one, they received no information. Then, they watched the videorecording of their interview and wrote down the thoughts they experienced (i.e., commented on their cognitive and emotional processes). Finally, they completed an IM scale (Bourdage et al., 2018).

Results obtained or expected (if not available, it must be made clear when they will be)

Participants who received more information about their evaluator engaged significantly more in ingratiation compared to those who received no information. But there was no significant effect of information on self-promotion.

Coding of participants' written comments about their emotional or cognitive processes is under way, and results will be presented at the congress.

Limitations

The study relies on mock interviews with undergraduate students (i.e., low stakes and thus lower motivation to manage impressions).

Conclusions – research and or practical implications/Originality/Value

Giving applicants an IM target gives them more opportunities for other-focused tactics (ingratiation). This could be an approach to increase applicants' perceived social presence in AVIs.

Relevance to the Congress Theme

The study's focus on a technological innovation (AVIs).

Relevant UN SDGs

Like all digital technologies, AVIs carry potential for bias. Better understanding their functioning may help limit bias.

Keywords: •AVIs •Impression Management •Ingratiation

Speed Dating in a Professional Context: An Innovative Measure for Workplace Health Promotion in Hospitals

Kerstin Rieder & Rebecca Hornung | Hochschule Aalen

science

Research goals and why the work was worth doing :

Interruptions are a common and well-known source of stress in hospitals. In many cases, they are caused by work organisation problems at the interfaces between groups and departments. However, measures to reduce interruptions are often not implemented due to a lack of time resources. This is where the newly developed concept of speed dating in a professional context comes in. The aim is to achieve an interdepartmental and interprofessional exchange in a short time and to implement solutions directly by the participants.

Theoretical background :

Interruptions are classified as stressors for employees based on theories such as action regulation theory or the job demands-resources model. The concept of speed dating focuses on reducing disruptive interruptions at the interfaces between departments and professions in the hospital.

Intervention :

Speed dating in a professional context involves employees from different departments and professional groups discussing work organisation problems and solutions in short rounds of six minutes each. The procedure is structured in the following steps: collecting questions, voting, exchange rounds, documenting and implementing in daily work. The speed-dating concept was tested in practice in a hospital with ten participants. The participants included nurses, doctors, ward managers, ward assistants and representatives from the nursing science and digitalisation departments. The concept was formatively evaluated using a short digital questionnaire. Nine participants took part in the evaluation.

Results obtained:

Many ideas, such as daily team time-outs for doctors and nurses and the creation of a digital platform for up-to-date information, were developed by the participants. The results of the short survey showed that the speed-dating sessions were generally well received. The six-minute exchange and the subsequent documentation on flipcharts were rated very good or good by all participants. Regarding the implementability of the results, the majority rated it as good or rather good. The participants see potential for improvement in the scheduling of the event. Eight out of nine participants would take part in the speed dating again.

Limitations :

This is a newly developed measure that has only been tested once with a small number of participants. Therefore, statements about the generalisability of the results are not yet possible. In addition, it is not yet possible to assess the extent to which the developed solution ideas will be consequently implemented in practice.

Conclusions :

A low-threshold concept such as speed dating can contribute to strengthening the exchange at interfaces in a professional context. In order to facilitate the transfer of the Speed Dating concept to organisations in other settings, the materials produced have been prepared for cross-organisational use.

Relevance to the Congress Theme :

Hospital staff are under particular strain due to the challenges of the coronavirus pandemic. Research in occupational and organisational psychology can help reduce stressors through innovative approaches.

Keywords: Interruption, Cooperation at interfaces, work design

7-minute science 7M172

Stay wit us – create, test and replicate a PLS-SEM Model of turnover Intention

Janna Ehrlich, Hamburg University of Technology

science

Research Goals: Mobley, Griffeth, Hand, and Meglino (1979) established a highly regarded model of turnover intention as early as the 1970s, discussing the constructs of job satisfaction and organizational commitment as critical influencing factors. The aim of this project is to recreate and replicate a modified model and test it for validity and stability over time in a longitudinal study.

Theoretical Background: The relationships presented in the model Mobley et al. (1979) of have been frequently discussed and largely confirmed in further studies and meta-analyses (Hom, Lee, Shaw, & Hausknecht, 2017; Tnay, Othman, Siong, & Lim, 2013). Based on an extensive literature review, several models that are based on Mobley et al. (1979) are discussed. Different possible influencing factors as well as the possible relationships between them were discussed. Based on this, a modified turnover intention model was created.

Humphrey et al.'s (2007) study identified three levels of work characteristics that can lead to turnover intentions: motivational, social, and contextual. Motivational characteristics are considered job characteristics in this framework (Hackman & Oldham, 1976). Social characteristics are considered critical to workplace well-being and have been identified as a level of factors by Morgeson and Humphrey (2006) and Humphrey et al. (2007). In this study, leader-member exchange (LMX) is used to operationalize social characteristics. Work context variables, such as HR practices, are also considered, while fulfilled expectations are considered a contextual characteristic (Ababneh, 2020). In summary, the model includes job characteristics, LMX, and met expectations as influencing variables, job satisfaction and commitment as mediators, and turnover intention as a target variable.

Replication is an extremely important approach in empirical science as well as it provides the important link between existing and new knowledge and thus contributes towards generalizing theories. For this reason, the modified model was tested with different datasets from different years (2012, 2014, 2016, 2018 and 2020), to show a validity and stability of the model.

Methodology: The model is examined using data from the Swiss Human Relations Barometer. The analysis of the model is conducted using the partial least squares structural equation modeling (PLS-SEM) method (Hair, Hult, Ringle, & Sarstedt, 2022) and the SmartPLS software. First, the measurement model is tested to ensure the reliability and validity of the measurement. Second, both the various effects and mediation relationships of the model are analyzed. Third different data sets used are tested for measurement model invariance and a multigroup analysis was performed to test for stability over time. A comparison was also made with other possible models in order to select the model with the best fit.

Results : Analyses of the reflective constructs were conducted using indicator loadings, internal consistency, average variance extracted, and discriminant validity. Results show that all values for all years for Cronbach's alpha, composite reliability, and AVE are above recommended thresholds. Discriminant validity is also given, as the HTMT value is below 0.85.

The VIF values of the formatively measured constructs were tested and all were below the threshold of five. Indicator weights were tested for significance and although not all were significant, they were maintained in all five survey years examined.

The assumed path coefficients for all five surveys in the model are significant and meaningful. The relationship between the influencing variables (job characteristics, LMX and met expectations) and turnover intention is mediated by job satisfaction and commitment,

Limitations: The datasets used are cross-sectional and not panel data. Thus, it is not possible to observe eventual changes within the sample. In addition, the study is limited to the variables used in the Swiss HR Barometer. Methodologically, the use of a single item to measure job satisfaction is to be criticized, since single items usually have a significantly lower validity and reliability than measuring a construct with the help of several items.

Conclusion: This project presents valid and representative results that are less susceptible to chance due to replication. The established model of turnover intention can thus be used as a valid basis for further research. One possibility would be a comprehensive cross-country analysis. Moreover, due to the high stability and validity of the model studied, it can be usefully extended in a next step.

Relevance: The explanation of quits or turnover intention has intrigued researchers and practitioners for over a century. At the same time, there is debate about whether the causes change over time and for different generations. This research project is a long-term study that focuses on establishing a stable model that also analyzes the changes over the years.

Keywords: Turnover Intention, Job Satisfaction, PLS-SEM

Stimulating life crafting: a one-week online intervention study to improve mental wellbeing

Shi Chen, Evangelia Demerouti & Leander van der Meij | Eindhoven University of Technology

science

Research goals The coronavirus and the following lockdown measures increased individuals' mental stress and strain.Life crafting could be an effective strategy for people to manage and reduce life strain because life crafting is positively related to mental wellbeing and meaning in life and negatively related to job burnout (Chen et al., 2022). The current study performed an online intervention in which we developed a life-crafting training program that stimulates the three life-crafting strategies (Chen et al., 2022): cognitive crafting, seeking challenges and seeking social resources. Our study contributes to the literature on improving mental wellbeing by suggesting how people proactively manage and reduce stress.

Theoretical background Chen et al. (2022) defined life crafting as the conscious efforts individuals exert to create meaning in their lives through (a) cognitively (re-)framing how they view life, (b) seeking social support systems to manage life challenges, and (c) actively seeking challenges to facilitate personal growth. Specifically, these strategies should better align with life goals, personal needs, values, and capabilities. Life crafting can be viewed as a proactive strategy that uses people's personal strengths and social resources to better cope with difficult times.

Design/Methodology/Approach/Intervention The whole intervention lasted seven days in total: pre-measurement (day 1), the intervention and daily reflection (days 2-6), and post-measurement (day 7). The participants were randomly assigned to one of two conditions: a life-crafting intervention group or a control group. The control group could follow the intervention upon completion of the post-measure, i.e. waitlist controls. Both groups filled out the baseline questionnaire about life crafting, stress, and meaning in life on day 1. In the following five days, people in the Life Crafting intervention took a five-day training to improve life crafting. In contrast, people in the control group just reported their daily life crafting behaviors and daily emotions. Finally, both groups filled out the post-measure questionnaires regarding life crafting, stress, and meaning in life on day 7.

Results obtained or expected Results of repeated measures ANOVA revealed that there are differences of cognitive crafting, seeking social resources, and seeking challenges, and stress between intervention group and the control group. In addition, Results of paired sample t-test showed that seeking social resources improved ($t= -5.46$, $p<.001$) and tress reduced($t =2.12$, $p =.037$). There were no changes in cognitive crafting and seeking challenges in the intervention group.

Limitations This study's first limitation is the intervention group's dropout rate was relatively high. The second limitation is that the procedure to collect data is not totally randomized. Thirdly, we only assessed changes over one week.

Conclusions our results showed that an online intervention to stimulate life crafting was able to foster seeking challenges and seeking social resources and reduce stress.

Relevance to the Congress Theme The life crafting intervention training encourages employees to reflect on their work and life in general which helps employees feel and perform well given the vague boundry between work and life.

Relevant UN SDGs life crafting contribte to ensure healthy lives and promote wellbeing for all ages by improving mental wellbeing.

Strengths-Based Leadership, Deficits-Based Leadership and Employee Job Performance: A Longitudinal Study

Jixin Wang, Erasmus University Rotterdam; Shiyong Xu, Renmin University of China; Arnold Bakker, Kimberley Breevaart & Marianne van Woerkom | Erasmus University Rotterdam

science

1.Research goals and why the work was worth doing

Although positive psychology emphasizes the importance of bridging the positive and negative, there is a lack of research on how deficits-based leadership and strengths-based leadership interact with each other and how these two leadership practices contribute to employee job performance. In this paper, we aim to explore how strengths-based leadership and deficits-based leadership influence employee strengths use and employee job performance.

2.Theoretical background

Strengths-based leadership helps employees identify, utilize, and develop their strengths while deficits-based leadership facilitates employees to spot and remediate their weaknesses. Strengths-based leadership can be seen as a resource that helps employees to align strengths with their job tasks, which aids the achievement of performance goals. Deficits-based leadership can also lead to higher employee job performance but in a different way, namely by helping employees to work on their deficiencies and acquire a broader repertoire of abilities. Based on Job Demands-Resources (JD-R) theory, this study hypothesizes that both strengths-based leadership and deficits-based leadership positively affect employee job performance (task performance and innovative behaviour), but that only for strengths-based leadership, this relation is mediated by employee strengths use.

3.Methodology

We collected data among 599 Chinese workers at three different time points with a one-month interval (N = 36 teams). We used multilevel structural equation modelling to test our hypotheses.

4.Results obtained or expected

In line with our expectations, strengths-based leadership was positively related to employee task performance and employee innovative behaviour via employee strengths use, whereas deficits-based leadership was not related to task performance and innovative behaviour through strengths use. However, the direct effect of deficits-based leadership on employee task performance and innovative behaviour was significant and positive.

5.Limitations

Only employee-rated data were used to test the theoretical model.

6.Conclusions

Our findings show that strengths-based leadership improves employee job performance by increasing strengths use, whereas for deficit-based leadership, this relation is not significant. However, most of the leadership practices in organizations are still deficits-oriented and focus on coaching employees in making up for their shortcomings. Our research results underline the importance of nurturing employees' strengths in order to help them flourish in the work context.

7.Relevance to the Congress Theme

The congress theme is “The Future is Now: the changing world of work” and it mainly concerns about how to develop competences and make changes in this turbulent world and prepare for the future. Our research sheds new lights on how nurturing strengths can build up competences and bring positive energies in the workplace to get through tough times and how in the future optimal functioning of workers can be promoted by building on their personal strengths instead of criticizing their weaknesses.

8.Relevant UN SDGs

Our research is relevant to two SDGs: a) good health and well-being, and b) decent work and economic growth. Our study shows that strengths-based leadership practices that promote strengths instead of weaknesses will contribute to the creation of a healthy work environment and the prosperity of productive employment.

Keywords: strengths-based leadership, deficits-based leadership, job performance

Successful Leadership in Top-Level Positions in Fire Services: A Competence Model

Mira von der Linde, Meinald T. Thielsch, Guido Hertel, Greta Ueltzen & Stefan Röseler | University of Münster; Sarah Weber, State Fire Service Institute

science

Research goals and why the work was worth doing. The number and complexity of emergencies has increased over the last years. Fire services, and in particular their top-level leaders, play a central role in coping with these challenges. In addition to their deployment in emergency operations or crisis management teams, top-level leaders perform operational and strategic management tasks (e.g., personnel management).

Theoretical background. Our research is based on competence modelling and leadership research (e.g., Campion et al., 2011; Yukl, 1989, 2012). Previous research has either focused on leadership styles in emergency operations or studied management competences in companies. However, it does not elaborate on the concrete competences that the top-level leaders in fire services need for their diverse tasks at the interface between public administration, fire services, and politics. This raises the question what competences these top-level leaders need to successfully manage their day-to-day work.

Design/Methodology/Approach. The first study inductively developed a competence model of top-level leaders in fire services. We used the Critical Incident Technique (Flanagan, 1954) as an explorative, qualitative research method for semi-structured telephone interviews with a total of 22 leaders (m = 21, f = 1). We followed up with a second study (N = 140) asking top-level leaders in fire services for importance ratings of the competences included in the competence model. They rated the competences in terms of their work in general and regarding certain working areas (Internal Service, Emergency Service, External Representation, Research, and Teaching).

Results. The developed competence model comprises Professional, Methodological, Social and Personal Competences for top-level leaders in fire services. The validation study supports the main findings regarding central competences included in the model. The participants rated most of the competences as at least “rather important”. Overall, the three most important competences were Communicative Competence, Decisiveness, and Planning and Organising. The validation study revealed systematic differences regarding the competences needed for the different working areas.

Limitations. The interview study and the validation study concentrated on top-level leaders assessing the needed competences themselves. Future research should add supervisor and subordinate ratings.

Conclusions – research and/or practical implications/Originality/Value. From the present competence model, we derive implications for the highest level of leadership in high reliability organisations. For the first time, an empirically based competence model is available for the highest leadership level in non-police emergency response. Based on this competence model, we propose practical implications for the competence-oriented training of top-level leaders in fire services.

Relevance to the congress theme. The developed competence model for top-level leaders in fire services enables optimal personnel selection and development. It can be used to adapt fire services to the changing world of work and build the foundation for further strategic changes.

Relevant to UN SDGs. Fire services as strong institutions are crucial for the civil protection and sustainable cities and communities in every country. Also, high-skilled and well-trained leaders can foster healthy work environments for fire fighters as essential part of our societies.

Keywords: Leadership, Fire Services, Critical Incident Technique

Suicidal Ideation in the Working Population: Testing a Moderated Mediation Model

Lanxi Wang & Kevin Kelloway | Saint Mary's University

science&practice

Suicide is among the leading causes of death in the working population (Mustard et al., 2010; Yip & Caine, 2011). Employee suicide incurs enormous emotional and financial costs not only to family members, but also to co-workers and the organization itself (Jordan, 2017; Kinder & Cooper, 2009), presenting a clear motivation for organizations to address and prevent suicide at the earliest possible stage. However, little research has explored the role of work-related factors in employee suicidal ideation and how organizations could help prevent the development of suicidal thoughts.

To address the research gap, the current study aims to investigate workplace factors that might exacerbate or alleviate suicidal ideation among employees. Building upon the Conservation of Resources Theory (COR; Hobfoll, 2011), this study explores the role of workplace resources in the process by which job characteristics influence suicidal ideation. Specifically, the goal is to test a moderated mediation model, in which job stress, transformational leadership, and meaningfulness of work are associated with depressive symptoms and hopelessness (Attell et al., 2017), which are further associated with suicidal ideation (Howard & Krannitz, 2017), while transformational leadership and meaningfulness moderating the mediation paths.

Using a cross-sectional survey design, the current study aims to collect data from 400 working individuals by February 1 st , 2023. Participants will complete questionnaires online on job stress, meaningfulness of job, leader's transformational leadership, feelings of hopelessness and depression, and suicidal ideation. Data will be analyzed using the PROCESS macro (Hayes, 2013). It is hypothesized that elevated job stress, low levels of transformational leadership, and lack of meaning of work, representing resource depletion at work, are associated with heightened suicidal ideation through increased feelings of hopelessness and depression. Transformational leadership and meaningfulness of work, on the other hand, might promote resource gain and prevent resource loss, which buffer the negative impact of job stress on hopelessness, depression, and suicidal ideation. Accordingly, it is expected that higher job stress is associated more severe feelings of hopelessness, depressive symptoms, and suicidal ideation with decreasing sense of meaning and transformational leadership, and vice versa.

Findings from the current study might provide insights into the influence of workplace factors on suicide and have important implications for workplace suicide prevention programs. Despite the cross-sectional nature of this study, which limits the ability to draw causal conclusion, findings from this study could provide basis for future longitudinal and field intervention studies. Organizational researchers and practitioners might benefit from this study and gain a better understanding of the relationship between job characteristics and employees' mental health and wellbeing.

Taking time to look at time perceptions – Investigating individual time-related dimensions in organizations

Lena Schmeiduch, Karsten Müller & Shirin Betzler | Universität Osnabrück

science&practice

Research goals: Time is a central variable in organizational life and fulfills important functions as a valuable resource and for creating structure and meaning. However, research on the measurement of time-related dimensions and investigations of how these dimensions relate to important variables of organizational functioning remains scarce. Thus, the aim of the present research is two-fold: a) to test a questionnaire for the measurement of individual time perceptions in an organizational context, and b) to systematically test relationships between selected time-related dimensions and personality dimensions as well as measures of change readiness.

Theoretical background: Interest in time as an important organizational construct has been growing. Still, there are few studies suggesting systematic frameworks and questionnaires to conceptualize different time-related dimensions. More specifically, a questionnaire that allows for the integration of time-related dimensions from previous research while also differentiating between different levels of abstraction and specifying direct relations to work-related tasks and activities is important.

Design: The questionnaire for individual time perceptions developed in this study is based on a framework for organizational time-related dimensions developed by the authors in a previous study. This framework conceptualizes 21 relevant organizational time-related dimensions (e.g., future orientation, time scarcity) within six categories (e.g., temporal focus, time as resource, time as social structure). These time-related dimensions were conceptualized in terms of individual time perceptions. In an online survey, each dimension was measured with four items and answered on a seven-point Likert scale. Additionally, correlational hypotheses of selected time-related dimensions and personality dimensions as well as change readiness were investigated.

Results: Results on internal consistency and exploratory investigations of the factor structure of the dimensions will be reported. Furthermore, confirmatory factor analyses employing structural equation modeling of the dimensions will be presented. The frameworks' category structure on the level of dimensions is further investigated. Lastly, relations between selected time-related dimensions and personality dimensions as well as individual change readiness are analyzed.

Limitations: As time is a complex construct, the dimensions of the framework can be interrelated and might not be exhaustive. The study has exploratory character and the questionnaire will need further validation in a future study.

Conclusions: The developed questionnaire can constitute a starting point for a comprehensive conceptualization of the role of individual time perceptions in an organizational context. Thus, the questionnaire can be employed to analyze relations between different time-related dimensions as well as between time-related dimensions and important organizational variables such as change readiness. We provide practical implications of how individual time perceptions interact with personality dimensions and the role they play for the specific context of organizational change support.

Relevance to the Congress Theme: To adequately assess factors relevant to a changing world of work, individual perceptions of time should be considered. To this end, a questionnaire to measure these perceptions and implications of these perceptions for individual change readiness are provided.

Keywords: individual time perceptions, time-related dimensions, change readiness

Talking about cooperation: exploring workers' expectations about the introduction of a collaborative robot

Gabriella Francesca Amalia Pernice, Luciano Gamberini & Valeria Orso | Departments of General Psychology, University of Padova Padova, Italy

science&practice

Collaborative robots (cobots) are fenceless robots that are meant to collaborate directly with humans. Cobots can support workers with non-automated tasks, thereby improving product quality and overall working conditions [1]. However, workers are frequently reluctant with respect to cobots because of aversion to change, unfamiliarity with robotics, and the possibility of a change in the working conditions [2]. Several studies have been conducted in laboratories to understand and improve human-robot collaboration, but there is a critical lack of research regarding the introduction and user acceptance of cobots in actual industrial settings [3].

In the present preliminary study, we explored the expectations and acceptance of a group of workers employed in a large company manufacturing electronic components, where a cobot was about to be installed at the assembly line. More specifically, the introduction of the cobot was meant to reallocate one worker, who was responsible of a repetitive task. We conducted a series of semi-structured interviews (approximately 10 minutes on average) that were audio-recorded for subsequent transcription and thematic analysis [4].

The sample consisted of five workers employed at the assembly line where the cobot would be introduced, they were on average 46 years old (age rage 33-54). Almost all of them had a low to medium education level (M= 10.6; SD= 2.5). On average, they had worked in the industry sector for 14.33 years (SD= 17.1). None of them had previous experience with cobots. They were in charge of different jobs: three of them were responsible for the assembly of the full electronic key. One was responsible for the pre-assembly of one component to be used for the full electronic key, which was extremely repetitive and tedious. Finally, one was responsible for replenishing the raw components needed in the assembly line. The pace of her work depended on her colleagues' assembly pace.

Overall, all participants reported to be satisfied with their work unfolded and was organised. However, the worker responsible for the pre-assembly was not gratified by her job, because of the high level of tediousness.

Regarding the expectations toward the introduction of the cobot, the majority of the participants (n= 4) were not worried about the changes of their social interactions with their colleagues. Respondents' main concern (n= 4) was related to the expected additional workload that the introduction of the cobot might bring. More specifically, they stressed the possibility that the cobot might not work properly, resulting in extra responsibilities for them. Two other employees also highlighted that cobot could cause production delays, and all of them believed that the quality of the components prepared by the cobot would be lower compared to their colleague's pieces. Moreover, one worker reported that she hoped that it would be easy and fast to learn how to use it, and two told us that they were curious about how the cobot would work.

Interestingly, they were all aware that the cobot would release a colleague from a tedious and monotonous task. They also underlined that it could be an advantage for the company to reallocate a human resource to a different task. Overall, the cobot was expected to support human work, rather than to replace human operators. Future research is meant to closely follow the introduction of the

cobot and systematically assess employees' reactions, to investigate whether their expectations would be met or would change.

Team voice interactions: How team members respond to voice during team meetings

Melissa Twemlow, Erasmus University Rotterdam

science&practice

Team voice refers to "team members as a whole expressing suggestions, concerns, and ideas about work-related issues" (Li et al., 2017, p. 1259) aimed at improving their work practices (Van Dyne et al., 2003). Recently, scholars have pointed out that team voice can benefit team performance (e.g., Huang & Paterson, 2017; Li et al., 2017). However, this also depends on the type of team voice: whether the voicing is promotive (expressing new ideas or suggestions) or prohibitive (sharing concerns or problems; Liang et al., 2012). The former can benefit the team's performance through innovations and creating a positive mood (Chang et al., 2017), whereas the latter can negatively impact a team (Chamberlin et al., 2017). Although employee voice at the individual level has received considerable scholarly attention (Podsakoff et al., 2015), voice as a team-level phenomenon remains underexplored (Frazier & Bowler, 2015; Huang & Paterson, 2017). This lack of understanding is surprising as teams tend to take concerns and ideas suggested by the whole team more seriously than from individual employees (Frazier & Bowler, 2015).

Team voice occurs through team interactions, for example, during meetings. While typically valuable to teams, speaking up during team conversations can be considered challenging to its members because it demands courage to express suggestions and question the team's status quo (Liang et al., 2012). Scholars have emphasized the strong relationship between team interactions and meeting outcomes (Kauffeld & Lehmann-Willenbrock, 2012; Lehmann-Willenbrock et al., 2017), yet it remains unknown how team voice interactions shape how members perceive their meetings and those who voice.

Therefore, in this study, we examine the micro-dynamic role of team voice as an important factor that could impact essential (meeting) outcomes. In contrast to existing research, we propose that prohibitive voice could also induce favorable results. That is, team meetings could be perceived as more effective and satisfactory when team members perceive the sharing of problems as helpful or as backup behavior. Moreover, we suggest that this requires team members and their leaders to respond positively to voicing behaviors during team interactions. Such praising reactions could spark other team members' confidence to share their own ideas or concerns during team interactions.

During a ten-week period, we gathered data from eighteen team meetings of an HR team with a one-hour duration each. After transcribing these meetings, we behaviorally coded 7331 statements by team members and their leaders using the act4team coding scheme (Kauffeld et al., 2018). Also, all team members and their leaders filled out a survey after each meeting indicating their perceived meeting effectiveness, meeting satisfaction, and promotive/prohibitive team voice during the meeting. Currently, the data is also coded for specific instances of promotive and prohibitive team voice to examine how both shape team meeting interactions. This additional coding further allows us to explore whether team members and their leader endorse, accept, or reject these suggestions (voice endorsement; Burris et al., 2012). Results can reveal crucial insights about how team members can most effectively speak up and respond to voicing employees during their team meeting interactions.

Testing the relationship between Decent Work, Life Satisfaction and Stress in Portuguese Social Economy Organizations

Luiza Motta & Leonor Pais | Universidade de Coimbra - Faculdade de Psicologia e de Ciências da Educação; Tania Ferraro, Universidade Portucalense Infante D. Henrique - Departamento de Psicologia e Educação

science

The current study aims to explore the interactions between Decent Work (DW) and Life Satisfaction (LS) and between DW and Stress and verify the impact of Stress on the Life Satisfaction of employees of the Portuguese Social Economy sector. The sample comprises 313 participants from Portuguese Social Economy organizations. The Decent Work Questionnaire (DWQ), the Satisfaction With Life Scale (SWLS) and the Perceived Stress Scale (PSS) were applied. Confirmatory factor analyses and simple and multiple linear regressions were performed. The results suggest that: (a) higher Decent Work (especially some of its dimensions) positively impacts Life Satisfaction; (b) lack of DW is associated with high Stress; and, (c) low Stress could promote Life Satisfaction. There were also interesting results found when the selection variable Gender was applied, giving us a portrait of the Portuguese working woman. The study's relevance is to expand the knowledge of the existing literature on Decent Work, Life Satisfaction, and Stress. It can also be innovative and helpful to understand the theoretical and practical impacts of the interaction of these variables in the third sector organizations, in agreement with the 2030 Agenda for Sustainable Development proposed by the United Nations. Limitations and future research conclude this study.

Keywords: decent work, life satisfaction, stress, social economy

7-minute science 7M115

The association between Executive Function and Thriving at Work

Marie-Claire O'Kane, The University of Surrey, UK

science&practice

In the modern workplace, employees need to be adaptive to constant change due to pressure on businesses to remain competitive in a global and dynamic market. Research shows our ability to adapt to change is controlled by our Executive Function (EF); higher order brain processes that regulate our behaviour to meet specific goals, where habitual behaviour is not possible or appropriate. Although there appears to be an obvious link, research on the association between EF and work is sparse, yet the limited findings showing associations between EFs and better job success and sales performance and deficits in EFs on work-related rumination and burnout warrant further investigation. One gap needing attention is how employees reach their potential to support positive health and wellbeing. Positive NeuroPsychology is gaining attention in the neuroscience space, influence by the Positive Psychology movement. However, this area is in its infancy and therefore work-related literature is, again, sparse. This study proposes a focus on the association with EFs and Thriving at Work as a valuable starting point. Thriving at Work is defined as "the psychological state in which individuals experience both a sense of vitality and a sense of learning at work". It is a self-regulating state that leads to adaptation to the expectations, challenges and opportunities in the work place. As an exploratory investigation, we simply hypothesised that EF will predict Thriving at Work and, using the BRIEF-A (an ecologically valid measure of Executive Function), investigated whether specific EF sub-scales predict Thriving at Work more strongly than others. A snowball sampling method was used to recruit participants from various industries and job roles (N= 140). A digital recruitment flyer was posted on social media platforms, and circulated to the researcher's personal and professional contacts to forward on to their own networks. Multiple regression analysis showed that EF significantly predicts Thriving at Work. Specifically, the Initiate EF sub-scale was a significant predictor variable. The model implies that issues with commencing an activity are associated with lower thriving at work. Findings warrant future research into the relationship between cognitive functioning and human flourishing. EFs are malleable and can be manipulated, therefore further research might provide a basis for introducing interventions to strengthen EFs to support individuals to be adaptive to the work environment. In particular, the association with the initiate sub-scale may point to a link with procrastination and difficulties with problem solving as impediments to Thriving at Work. However, the limitations of a cross sectional study should be noted, as this research cannot predict causality. Further research will need to probe further into the associations found. This study relates to the conference theme as the focus on human -centred organisations and human flourishing is the future of work. Support with cognitive function at work could strengthen employee's ability to reach their potential; to have the tools to thrive amidst constant change.

The bright and the dark side of digital technology use at work: A study among knowledge workers in Lithuania

Ieva Urbanaviciute, Rita Ziauberyte-Jakstiene, Arunas Ziedelis, Jurgita Lazauskaite-Zabielske | Vilnius University

science

Research goals

The present study explores the technological progress and its implications on employee well-being. The use of information, communication technologies and digital solutions has become increasingly prevalent in the contemporary world of work. While it facilitates job performance and has numerous benefits for businesses, it may also pose serious psychosocial challenges that cannot be ignored (Day et al., 2019). However, a large part of prior research on the topic is still based on a rather technocentric approach that places an emphasis on technological arrangements per se rather than employees' personal experience using them. In light of this, the I/O psychology literature calls for a better integration of a human-centred view in research on technology at work (e.g., Parker & Grote, 2020).

In the current study, we address this aspect by providing an in-depth account of positive and negative experiences (i.e., critical incidents) that employees face when using digital tools in their work tasks. In doing so, we seek to unravel key psychosocial aspects related to the "smart" component of the work environment – such as challenges, benefits, or hindrances – and link them to employee well-being.

Theoretical background

Our study is broadly situated within the framework of job demands and resources and self-determination, which we aim to apply for the interpretation of results. However, we relied on an inductive rather than deductive approach when developing this study. For this reason, we did not raise a priori hypotheses but formulated the following research question instead.

RQ: What are the key psychosocial aspects of the subjectively (un)successful use of digital technologies at work?

Method

The study is based on the enhanced critical incident technique (Butterfield et al., 2005). This method allows to collect information about "critical" events of interest in a semi-structured format and identify their underlying social, behavioural, or emotional elements. We will survey up to 50 workers (ISCO group 1-4), collecting 80-100 reports of events related to digital technology use at work. Qualitative content analyses will we used to analyze the data.

Results

The data collection is currently in progress. We expect to have our first results in February 2023. Data analyses will be conducted in March and April 2023, which will enable us to present the findings in due course.

Limitations

The reports of critical incidents may be prone to some recall bias. Despite the rich findings yielded by our chosen method, they are not subject to generalization due to the qualitative nature of the study.

Research/practical implications

Our findings unravel the psychological side of digital technology use at work. They can provide useful managerial insights into designing smarter workplaces and will also enhance current understanding about the interaction between the person and the changing work environment.

Relevance

Digitalization has a huge impact on how work and workplaces will look like in the future. The current study explores how this trend is experienced from an individual well-being perspective, thus falling in line with the congress theme and addressing the third UN sustainable development goal (good health and well-being).

Keywords: Digitalization, employee well-being, job design

7-minute science 7M200

The dynamics of resilience promoting factors: A weekly diary study with entrepreneurs during the first ten weeks of the Russia – Ukraine war

Christodoulos Katsaitis & Leonidas Zampetakis | Department of Psychology- University of Crete

science

Research goals

The question of what entrepreneurs actually experience and do when operating their businesses under adverse environmental conditions is becoming a top priority for business leaders and policymakers. The period following the Russian invasion is particularly interesting to study because under such harsh and overwhelming external conditions entrepreneurs face intense competition caused by a lack of resources, market decline and smaller profit margins. There is very little research on the within person dynamics of peoples' resilience promoting factors under adversity. Resilience promoting factors are existing, internal resources or narrower motivational and social-cognitive individual differences that are present regardless of whether someone experiences adversity, but can still serve a protective function when adversity occurs. In this study, as resilience promoting factors, we consider entrepreneurs' character strengths (CS) and examine the dynamics of entrepreneurs' CS during the first ten weeks of the Russian invasion of Ukraine. In this research, we examine entrepreneurs' trajectories of curiosity, perseverance and zest over time, autoregressive (or carry-over effects) of CS states and the moderating role entrepreneurs' dispositional affectivity.

Theoretical background

CS are individual differences in traits at the lower levels of personality and largely determine how individuals cope with adversity. Existing empirical evidence shows that CS change little, or not at all after adversity. However, it is plausible that different types of adverse events affect CS in different ways and especially when adversity is central to people's lives. We hypothesize that the mean level of entrepreneurs' enactment of character strengths will change in the weeks following the Russian invasion and the onset of expected harm or loss to their firms. This change reflects the strenuous and active process of entrepreneurs to achieve short-term goals related to their firm's survival.

Methodology

We conducted a weekly diary survey in which a sample of 67 entrepreneurs completed a structured questionnaire for ten consecutive weeks, beginning one week after Russia's invasion of Ukraine. The weekly study design spanned a reasonable time frame, allowing entrepreneurs to operate their businesses while examining dynamic fluctuations and growth in CS. Multilevel structural equation modeling growth and first order autoregressive (AR1) models were used for data analyses.

Results obtained

We found that over a period of ten weeks, beginning after the Russian invasion of Ukraine, entrepreneurs' enactments of curiosity and zest was dynamic exhibiting a positive linear trend. Perseverance enactments exhibited non-linear trends. Positive carry-over effects of character strength states were also found. Finally dispositional affectivity moderated with-person relationships such the rate of change and carry-over effects of CS.

Limitations Conclusions.

In this research, we go beyond previous cross-sectional studies, and retrospective self-reported perceptions of change in CS following adverse events. However, since we do not have pre-event assessments, these changes detected, are not necessarily associated with genuine growth in CS. We argue that changes in entrepreneurs' CS reflect primarily changes in the short-term functions of strengths to meaningfully adapt to the adverse event. Thus, we provide evidence on the dynamic role of CS in changing environmental conditions.

Keywords: character strengths, resilience, diary study

The Effect of Ethical Leadership on Intentions to Resist Future Change: The Role of Followers' Moral Attentiveness and Trust in the Supervisor

Lara Pico, Instituto Superior de Ciências Sociais e Políticas - Universidade de Lisboa; Pedro Neves, Nova School of Business and Economics - Universidade Nova de Lisboa; Miguel Pereira Lopes, Instituto Superior de Ciências Sociais e Políticas - Universidade de Lisboa

science&practice

Purpose: To maintain their competitive edge and adapt to market dynamics, organizations must change in order to adjust to the current macroeconomic scenario (Claus, 2019; Herscovitch & Meyer, 2002; Shin et al., 2012). However, about two-thirds of change processes fail (Choi, 2011; Shin et al., 2012), and resistance is the main cause (Reger et al., 1994; Szabla, 2007). Thus, we examine the mechanisms and conditions under which ethical leadership (Avey et al., 2012) is effective in reducing intentions to resist future changes.

Theoretical background: Ethical leadership is important because in the long-term it can prevent company scandals and ethical dilemmas while boosting employee morale and increasing in-role and extra-role performance (Sharif and Scandura, 2014). Furthermore, leaders can influence employees' perception of what is ethical and beneficial for them and the organization (Yukl, 2013). While other leadership theories underline the importance of ethics for leadership, only ethical leadership aims to clarify the influence of leaders' ethical behavior on followers' ethical behavior (Brown & Treviño 2006).

The relevance of ethical leadership for change management has been previously examined (Neves et al., 2018). However, we still know little about the mechanisms and boundary conditions that influence its impact on intentions to resist future change.

We argue that ethical leadership will reduce intentions to resist future changes because it signals trustworthiness. When leaders exhibit and promote normatively appropriate behaviors (Brown et al., 2005) during change processes, employees will feel the need to give back the treatment received by placing their loyalty to the organization and the leaders who represent it.

We also propose that moral attentiveness, which is "the extent to which an individual chronically perceives and considers morality and moral elements in his or her experiences" (Reynolds, 2008, p. 1028) will influence the strength of the relationship between ethical leadership and trust in the supervisor. Individuals high on moral attentiveness should develop a greater level of trust in their (ethical) supervisor, since they will automatically make moral interpretations of their leader's behavior, namely whether the behavior or its results are ethical, and consequently if the leader is trustworthy. These individuals will also perceive a violation of moral norms (by the leader) as a violation of the relationship of trust with the leader (Treviño & Brown, 2005).

Design/ Methodology: We test our hypotheses with a sample of employees from a manufacturing company using a time-lagged design. We provide to each employee two surveys with a four-week lag between them.

Results: We analyze the data with bootstrapping using the Process macro. We examine whether a) ethical leadership is a predictor of intentions to resist future changes four weeks later via an increase in trust in the supervisor, and b) if employees' moral attentiveness moderates the first path of the mediated-moderation model.

Limitations: Generalization may be a limitation because the data were collected in one organization operating in a specific sector.

Research/Practical Implications: This study contributes to ethical leadership and change management literatures. It demonstrates the relevance of ethical leadership for reducing intentions to resist future changes and highlights the importance of moral attentiveness. To anticipate and prevent potential resistance to change from employees, organizations and its leaders should take a long-term approach to change management, namely by stimulating ethical leadership during times of stability. The concern that an ethical leader shows when having the best interests of employees in mind, the openness to listen to new or divergent ideas, and the quest for making fair and balanced decisions on matters important to employees result in a greater propensity for the leader to be seen as a role model in the eyes of his followers, depending on their attentiveness to his ethical behavior (Brown et al., 2005; Mayer et al., 2005).

Originality/Value: This study opens a new path on ethical leadership and change management literature. Given the competitive and dynamic environment organizations face, we aim to have a deeper understanding of the circumstances under which ethical leadership is more effective. We also build on a recent trend (Neves et al., 2018, 2021) that argues that organizations need to prepare for change during times of stability in an effort to predict potential reactions to change.

Relevance to congress theme: Our examination of intentions to resist future changes is directly related to the idea that 'the future starts now'.

Relevant UN SDGs: Decent work and economic growth (8); Peace, justice, and strong institutions (16).

Intended audience: Academic and Practitioners.

Keywords: Ethical leadership, Intentions to Resist Future Change, Trust, Moral Attentiveness

The Effects of Psychosocial Safety Climate on Employees' Burnout: Testing the Multilevel Longitudinal, Multisource Mediation Role of Supportive and Ci

Mohd Awang Idris & Idasuzana Idris | University of Malaya, Kuala Lumpur, Malaysia

science

Psychosocial Safety Climate (PSC) is an important aspect evaluating the effect of managers' actions on employee behaviour and health. We operationalize the effect of PSCs on supervisors' supportive behaviours and employees' OCB-I on burnout, over time. Drawing on PSC work stress theory (Hall et al., 2010; Dollard & McTernan, 2011), we used multilevel longitudinal, multisource mediation outcomes to assess these behaviours and burnout. This process (with a 4-month gap) retrieved information from 538 multi-occupational employees at 70 companies in Malaysia (i.e., 73.5% response rate). We used MPlus and conducted multilevel longitudinal path analyses (SEM) to examine the mediating role of: (1) supervisors' supportive behaviour between PSC on employees' OCB-I, and (2) supervisors' supportive behaviour and employees' OCB-I between PSC on employees' burnout. Supervisors' supportive behaviour and employees' OCB-I mediated the negative relationship between PSCs on employees' burnout. Interpreting the effect of PSC (espoused PSCs) on enacted supportive supervisors' behaviour are important among employees' OCB-I in reducing other employees' burnout over time.

Keywords: positive organisational climate, supportive behavior, multisource mediation effects, multilevel longitudinal path analyses

The effects of Teleworking on Job Performance: the moderator role of Basic Psychological Needs

Martina Tasca, University of Valencia; Vicente González-Romá, Ana Hernández & Inés Tomás | Idocal, University of Valencia

science&practice

Research goals and why the work was worth doing

Telework is a growing trend used by companies and employees worldwide, that has skyrocketed in the last two years due to the pandemic. The implications of this new work arrangement are not always clear, especially concerning the performance of the employees. In this regard it is important for policy makers to understand which factors can moderate the relationship between teleworking and job performance, especially nowadays, after the COVID-19 pandemic strike. In this paper, a moderation model is proposed to understand the possible effects of teleworking on job performance depending on the satisfaction of the work-related basic psychological needs. We first assessed the difference between teleworkers and non-teleworkers regarding their satisfaction of work-related basic psychological needs (autonomy, competence, and relatedness), and their performance.

Theoretical background [IT1]

Previous literature has supported a positive relationship between teleworking and job performance. However, the conditions on which teleworking can boost employees' performance are still not clear. In Self Determination Theory, psychological motivation passes through the satisfaction of three basic psychological needs: Autonomy, Competence, and Relatedness. The satisfaction of these three basic psychological needs at work could positively moderate the relationship between teleworking and performance, so that the positive relationship is stronger when the satisfaction of the needs is high.

Methodology

Our sample was composed of 100 individuals (32% teleworkers), found through a respondent panel. Data were collected in April 2021 over two time points separated by two [IT2] weeks. Independent sample t-test was used to check for mean differences. Multiple regression analysis with SPSS was used to test the moderated model. Simple slopes for the significant moderated effects were estimated with PROCESS.[IT3]

Results

Results did not indicate any differences in the satisfaction of the three work-related psychological needs between teleworkers and non-teleworkers, but job performance was higher for teleworkers ($t=2.50$, $p<.05$). The positive relationship between teleworking and performance was supported ($b=.21$, $p<.05$). Only the moderator effect of the satisfaction of relatedness at work was statistically significant ($b=-.004$, $p<.05$), but contrary to our expectations, showing a negative moderating effect.

Limitations

The main limitation of our study is that all the data were collected through self-reported questionnaires and from the same source (employees). Additionally, generalization of the results can be compromised as our sample was collected in Spain, between a specific population into a respondent panel. Another limitation of this study is the absence of information about economic condition, or about the presence of an appropriate space to work at home.

Conclusions

Our results support the positive relationship between teleworking and job performance. In addition, it seems that for those who have a high satisfaction of relatedness at work, working from home or working from the office does not affect their performance. Instead, those who have a lower satisfaction of relatedness in the workplace, have lower performance when working from the office, but a greater job performance while teleworking. It seems reasonable to assume that, if they do not feel connected with the work social environment, home environment could be more suitable for their working necessities, by having a private space and avoid interruption from colleagues.

Relevance to the Congress Theme

Teleworking is becoming more and more a reality for workers worldwide. Even before the pandemic, teleworking was growing rapidly; and the COVID pandemic has contributed to increase its widespread. Understanding the effects of teleworking on job performance and the factors that can moderate this relationship is essential to design interventions which contribute to introduce remote working in companies in the better conditions.

Relevant UN SDGs

Good health and wellbeing. Results of this study can help to design interventions that contribute to increase performance but also the adjustment of the workers with their workplace. This adjustment can also contribute to increase wellbeing and health of workers.

Keywords: teleworking, performance, self-determination theory

7-minute science 7M116

The Emergence and Development of Organisational Values (OV)

MARAM Aqeeli, University of Leeds

science

Research Goals

Research about OV has mainly focused on either the strategic top-down processes or the personal values of an organisation's members. There is a significant gap in research about how values manifest at different organisational levels, and how they develop through social interactions.

In any organisation, the values involve both a process and a content element (Agle and Caldwell, 1999). While there are several theoretical constructs around the content of OV, very few methods or studies have been developed to track their processes (Gehman et al., 2013). Thus, the research goals are:

- study three levels of OV, espoused, enacted, embedded, and their processes,

- to understand how people make sense of OV throughout their interaction.

Theoretical Background

Feldman and Pentland (2003) argue that the only way to apply abstract concepts is through performance. Thus, this research offers a framework that looks at both the abstract value and practice as interrelated, with an ongoing recursive relationship between the two.

The research uses both sensemaking and social network perspectives to gain a comprehensive understanding of OV process within social interaction.

Design

The study was conducted in a large private company in Saudi Arabia, interviewing 48 people from four different departments, across a range of seniority levels and tenure, using semi-structured interviews.

Results

Using thematic analysis and social network analysis approach, initial results show that OV are manifested in the organisation through three main social processes; sensegiving, seeking, and enacting. These processes lead to either values creation, values matching, and values blockage. Findings also showed that the level of alignment between the values types is different. While some participants have their values aligned, other participants' espoused and enacted values are in conflict leading to the different processes of sensemaking.

Limitations

Ideally, studying the development and emergence of OV would combine ethnography with interviews, however this was not possible due to Covid-19. The research examined the process of OV during a single period therefore questions remain over how values develop over a long period of time. Doing a longitudinal study for future research could be fruitful.

Conclusion and Value

This research aimed to introduce a framework for the process of OV emergence and development. The aspired contribution of this research is showing, both theoretically and empirically, how OV is a dynamic and interactive process that involves a variety of organisational actors, and is shaped by different organisational and social processes. By integrating both sensemaking and social network perspectives into the investigation of daily practices of OV, we can open up a new set of research questions. In addition, showing the link between social processes, daily practices, and OV helps us to understand why a certain value system exists and how it could be changed.

Relevance To the Congress Theme

The research is mainly related to communication and relationships, group dynamic, and engagement and motivation.

Relevant UN SDGs

Examining the level of alignment between espoused and enacted values in a company provides an important contribution to employees' and leaders' health and wellbeing. This research helps organisational members to be more aware of an existing gap that affects their interaction, and finds solutions to align them.

Keywords: Values and Practice, Sensemaking

The Impact of the Covid-19 Pandemic on Personality, Behaviour, and Working Life

Jonathan Cannon & Stewart Desson | Lumina Learning

science&practic

Research Goals

Conducted in 2020, this research addresses three key questions:

1) How has the pandemic and related restrictions affected our behaviour?

2) How has our personality impacted our response to the pandemic?

3) What are employees' attitudes towards remote and hybrid working?

Five hypotheses were tested in the research:

1) Individuals with more introverted tendencies would prefer to work remotely

2) Extraverted behaviours would decrease as a result of pandemic-related restrictions

3) Behaviours associated with neuroticism would increase as a result of the pandemic

4) Conscientiousness would impact working hours while working remotely

5) Individuals already working remotely before the pandemic would feel less emotionally impacted than those new to remote working

Theoretical Background

The research builds on industry research on attitudes towards remote working, the relationship between personality and remote working, and mental health risk factors, such as research by Volk et al (2020).

It also aimed to produce innovative research into the challenges faced by remote workers, associated emotional effects, and the reciprocal impact of personality and new ways of working.

Design and Methodology

Participants were invited to complete a range of assessments, including:

1) Lumina Spark (a Big Five based personality assessment)

2) General Health Questionnaire (a clinically-validated measure of mental health)

3) Attitudes towards remote working

4) Demographic measures (employment, nationality, country of residence etc)

5) Attitudes towards risk-taking

4,414 participants form the final sample, mostly employed white-collar professionals, spread across the world.

Data was analysed through a range of methods assessing correlations between various variables and comparisons between groups.

Results

Results from the research as relating to the five hypotheses:

1) Individuals with more introverted tendencies would prefer to work remotely - rejected

2) Extraverted behaviours would decrease as a result of pandemic-related restrictions - accepted

3) Behaviours associated with neuroticism would increase as a result of the pandemic - accepted

4) Conscientiousness would impact working hours while working remotely - accepted

5) Individuals already working remotely before the pandemic would feel less emotionally impacted than those new to remote working – accepted

Limitations

The research was conducted on a largely convenient sample, consisting of a mostly homogenous group of white-collar professionals.

Practical and Research Implications

Further research is required among a more diverse sample, encompassing the experiences of blue-collar workers, where remote working might not be accessible.

Research on the ongoing impact of the pandemic, as we move out of restrictions, is required, in order to assess the effects of new ways of working, and how best employees can be supported as we move towards a new working world, with particular focus on mental health and new working practices.

Originality and Value

This research, building on disparate sources of information, aims to provide a holistic view of the relationships between personality, new ways of working, the Covid-19 pandemic, and mental health, aiming to provide suggestions for intervention with regards to how organisations can adapt to post-pandemic life and new ways of working.

Intended Audience

This talk is suitable for both academics and practitioners, where there is interest in the practical applications of academic research.

Keywords: Lumina Spark, Covid-19, Remote Working

7-minute science 7M67

The Interaction between S.A.F.E.R. Leadership and Safety Management Systems

Rebecca Cairns & Kevin Kelloway | Saint Mary's University

science

The purpose of this research is to further examine the characteristics of safe workplaces by looking at the interaction between S.A.F.E.R leadership (a model of safety leadership) and safety management systems (SMSs). Given that the average person spends one-third of their life working (Ahmad, 2013), it is critical to create workplaces that encourage the health and wellness of workers. One way this can be achieved is through preventing safety-related incidents in the workplace. By examining how the role of leadership and the characteristics of an organization interact to influence individual safety behaviours, we can better understand what characteristics aid in creating a healthy workplace.

There is an abundance of research on leadership (Clarke, 2013) and on the role of SMSs (Robson et al., 2007) and their effect on safety outcomes in the workplace. However, little research has focused on how these two elements interact to influence safety outcomes. We propose that safety leadership and SMSs interact to improve individuals' sense of safety control, which in turn influences their safety motivation and safety behaviours. Safety control can be conceptualized as a sense of self-efficacy and a sense of autonomy. Both feelings of autonomy and self-efficacy have been associated with stronger motivation in individuals (Jungert et al., 2012), thus we predict that safety control will positively influence motivation.

Using a 3-wave longitudinal design, this study asks participants about their perceptions of their workplace SMS, their own safety behaviours, and their leader's safety leadership behaviours. It is expected that feelings of safety control and safety motivation will sequentially mediate the relationship between SMSs and safety behaviours and that S.A.F.E.R. leadership (Wong et al., 2015) will moderate this relationship. Analysis of the data is expected to be completed in April 2023.

The principal limitation of this study is the reliance on self-report data; however, the risk of common method variance inflating the relationships of interest is mitigated by the use of longitudinal data and the explicit testing of moderating effects. This study will address a gap in the literature on leadership and SMSs by providing information on the mechanisms through which they work and by providing information on the utility of the relatively novel S.A.F.E.R. leadership model. Overall, this research ultimately hopes to provide organizations with suggestions for improving workplace safety by identifying key characteristics of safe workplaces and by providing information on which leader behaviours are most pertinent in the workplace, ultimately informing leader training practices.

This submission is relevant to the congress theme as it focuses on the contribution of safety research to future leadership and SMS practices. There has been a continuous discourse on addressing the gap between research and practice, which the S.A.F.E.R. model of leadership does by providing concrete behaviours that leaders can base their behaviours on (Wong et al., 2015), which makes it ideal for practical use. This research is particularly relevant to the UN SDGs of good health and well-being. The WHO notes that a healthy workplace is one that promotes the health and safety of workers (WHO, 2010), and this research hopes to positively impact worker health and well-being by improving safety in the workplace.

The paradox mindset – Influenced by personality, influencing intrinsic motivation?

Sabrina Schneider & Victoria Bartosch | Management Center Innsbruck

science

Research goals/why the work was worth doing : Digital technologies have increased the variety and occurrence of paradox tensions in the workplace (e.g., Danneels & Viaene, 2022; Schad et al., 2016; Schneider & Kokshagina, 2020). Paradoxes are "contradictory yet interrelated elements … that seem logical in isolation but absurd and irrational when appearing simultaneously" (Lewis, 2000, p. 760). They persist over time, challenging one to balance the diverging elements continuously (e.g., Jarzabkowski et al., 2013; Smith & Lewis, 2011). Individuals perceive paradox tensions differently – depending on their paradox mindset: While some people perceive tensions as dilemmas, others accept and embrace paradoxes as normal and energizing (Miron-Spektor et al., 2018). Consequently, understanding the antecedents and effects of one's paradox mindset is crucial. This study aims at explaining the effect of personality traits on one's paradox mindset and the effect that one's paradox mindset has on intrinsic motivation.

Theoretical background: In part one of this study, we combine paradox theory (e.g., Lewis, 2000; Schad et al., 2016) and the Five-Factor Theory (e.g. McCrae & Costa 1996, 1999) to analyze the impact of personality traits on the paradox mindset (Miron-Spektor et al., 2018). In the second part of the study, we use Hackman and Oldham's (1975) Job-Characteristics-Model to propose a moderating effect of paradox mindset on the relationship between job autonomy and intrinsic motivation.

Design/Methodology : This study applies a deductive, quantitative research design comprising a survey and an experiment with a sample of n=207 participants.

Results obtained : The findings show that out of five personality traits, solely neuroticism negatively affects the paradox mindset, possibly as they feel distressed by and try to avoid paradoxes. The results further reveal that individuals with a paradox mindset seem to be generally higher in intrinsic motivation. Yet, they are more extrinsically motivated when not experiencing autonomy in their job and vice versa, possibly as they compensate for its' lack through extrinsic incentives.

Limitations : Limitations of this study include the usage of a convenience sample and the reliance on self-reported scales.

Conclusions : This study identifies neuroticism – a tendency towards negative feelings such as anxiety, or self-doubt – as a personality trait that is an inherent antecedent negatively affect one's paradox mindset. Practically, this provides insights for recruiting criteria for roles in which a strong paradox mindset is beneficial (e.g. in creative work). Further, this study reveals a relationship between paradox mindset and intrinsic motivation, which provides managerial implications for job and organizational design.

Relevance to the Congress Theme : The Congress focuses on the changing world of work. One of the changes experienced by employees and managers at all levels is the rising necessity to effectively deal with paradox tensions (caused by the diffusion of digital technologies in the workplace). This study tackles the antecedents and consequences of paradox mindsets.

Relevant UN SDGs : This work acknowledges that individual paradox mindsets differ and thereby provide an inequality in the digital workplace. Job and organizational design can help to align

personalities to roles and to reduce negative effects for those experiencing paradoxes as more challenging than others.

References available on request.

Keywords: paradox mindset, personality traits, intrinsic motivation

7-minute science 7M87

The Relationship between e-Leadership Competencies for Satisfaction with Telework and Workplace Isolation: The Mediating Role of Leader-Member Exchang

Derron Watkins, Felipe Bravo, Isabel Rodríguez & Núria Tordera | University of Valencia

science

Digitalization is reshaping the way in which organizations function, with telework becoming more commonplace. Research has suggested that e-leadership competencies can be central to improving the work environment when working remotely. However, the relevance of these competencies for different types of outcomes in telework as well as the mechanisms through which they occur needs to be explored. Thus, this study examines the importance of e-leadership competencies for telework by analysing their relationship with employee satisfaction with telework and workplace isolation. Moreover, we consider the role of the quality of leader-member exchange (LMX) as a mediating mechanism in these relationships.

The current research is framed in the context of an E-leadership competence model and LMX theory (Graen & Scandura, 1987). The Six E-leadership competencies model (SEC, Roman et al., 2019) defines six competencies that might be relevant for leadership in telework: e-communication, e-trust, e-change, e-social, e-teams, and e-tech. Previous literature suggests that leadership competencies should have an impact on employee satisfaction and workplace isolation (Gallatin, 2018; Zeike et al., 2019) based on their effect for development of a good working environment. Leader-member exchange theory focuses on how leaders develop high-quality work relationships with their followers that produce effective results (e.g., performance and satisfaction). This theoretical approach has considered leadership competencies and skills as key factors for leaders to develop high-quality relationships with the members of their teams.

In a cross-sectional survey design, data were collected from 229 participants from different parts of the world using convenience sampling through an online survey. Participants worked remotely at least two days per week and reported to a supervisor or manager.

Structural equation modelling was used to test the mediating role of LMX. Two models were developed. The first model included the six e-leadership competencies as independent variables, LMX as the mediator, and satisfaction with telework as the outcome. The second model was the same but with workplace isolation as the dependent variable. In both models LMX was found to fully mediate the relationship between three of the six e-leadership competencies: e-trust, e-teams, and e-social. No significant mediated relationship was found for the other three competences: e-communication, e-tech, and e-change. The study sample size, use of convenience sampling, and the cross-sectional design limit the generalization of results.

E-leadership competencies were found to have a positive relationship with employee satisfaction and a negative relationship with workplace isolation. LMX was found to mediate the relationship between three leadership competencies and both outcome variables. This study extends the literature on e-leadership competencies, contributes to the digitalization of leadership competencies, provides guidance for leadership training (specifically in telework), and gives insight into improving the well-being of teleworkers.

Relevance to the Congress Theme

Digitalization of organizational processes is arguably one of the main characteristics of our changing world. This work helps to better understand the importance of e-leadership competencies for work arrangements that are becoming widespread in the global work environment.

Relevant UN SDGs

This study contributes to the UN SDGs 3 and 8.

Keywords: E-Leadership, Well-being, Telework

7-minute science 7M48

The relationship between Playful Work Design and Performance

Emanuela Caracuzzo, Flavio Urbini & Antonino Callea | LUMSA

science&practice

Research goals and why the work was worth doing:

The present study aims to investigate the relationship between Playful Work Design and Individual Performance, including task, extra-role and counter-productive behaviors. Playful Work Design (PWD) is a recent concept, introduced by Bakker and colleagues, and it consequences are until now little known.

Theoretical background:

PWD is the process by which people create proactive conditions within their work activities, without changing the nature of their work. Based on the theory of the duality of play, PWD has been empirically distinguished by two dimensions: designing fun, i.e. the use of ludic activities during work, and designing competition, i.e. the search of challenge with themselves. In line with proactivity theory, previous studies supported the positive effects of PWD on creative performance, although its relationship with performance domains (task and extra-role performance, and counter-productive behaviors) is yet unexplored. We hypothesized that PWD dimensions' will have a positive effect on task and extra-role performance, and negative effects on counter-productive behaviors.

Design/Methodology/Approach/Intervention:

Sample was recruited via email by researchers, using convenience sampling, in a cross-sectional design. Participants were 253 employees, well-balanced by gender and age. Participants filled an online questionnaire, composed by 12-item of PWD-Questionnaire and 18-item of Individual Work Performance Questionnaire. A multiple regression model via SEM was performed to test hypotheses.

Results obtained or expected (if not available, it must be made clear when they will be)

Preliminary results pointed out the PWD dimensions' were positively correlated to task and extra-role performance; however, only designing competition was negatively correlated to counter-productive behaviors. Furthermore, the results of multiple regression model suggested that only designing competition had a positive and significant effect on both task and extra-role performance. Contrary to hypothesis, PWD dimensions' had not significant effects on counter-productive behaviors.

Limitations:

Some limitations should be considered in the present study. First, the self-reported measures of PWD and individual performance may lead to measurement bias. Second, the sample size does not allow generalizing our results. Finally, cross-sectional design does not allow test causal relationship among variables.

Research/Practical Implications:

Despite previous limitations, the present study allow shedding light about importance of PWD dimensions in predicting performance domain. Furthermore, the results emphasize the distinctions about designing fun and designing competition; only the latter significantly affects task and extra-

role performance. Therefore, organizations may propose training interventions about self-competition in order to improve employees' performance.

Relevance to the Congress Theme: Relevant UN SDGs:

Good health and wellbeing.

The relationship of the ideology of psychological contracts and psychological-affective states

Nivaldo Galvão, Institute of Social and Political Sciences - University of Lisbon; Sandra Costa, ISCTE-Business School

science&practice

Research goals: how ideology psychological contract affects turnover intentions through commitment and identification among the young professionals within their organisation.

Theoretical background: Many workforce outlooks reports that Young professionals have an increasing concern with personal values and decreasing confidence about the positive impact their organizations have on society. The psychological contract (PC) as a supportive theoretical framework is based on Blau's (1964) social exchange theory (SET) and Gouldner's (1960) reciprocity norm and Tajfel's (1981) social identity theory (SIT). The reciprocal exchange can have a positive or negative consequence when the promises are (un)met enhancing the motivation to exit the company (Zhao et al., 2007; Coyle-Shapiro et al., 2019). This emotional behaviour as its route in the working relationship with the employer where a one-way exchange (benefiting only the employer) can be harmful to the employee's affective commitment (AC) and organizational identification (OI) when viewed through an ideology lens and employee has a “connection” with the employer from a shared valued-cause with expectations embedded within this relationship, whereas unmet promises as the potential to decrease their identification and commitment with the employer (Mowday, Steers, & Porter, 1979; Story & Castanheira, 2019). Following this, we raise the question of AC and OI as the potential to mediate the relationship between breach or fulfilment and intention to leave the organisation when unmet promises are perceived.

Design: We examine the relationship between an ideology-infused psychological contract with a cross-sectional methodology. We emailed surveys to young professionals through LinkedIn, obtaining a final sample of 358 participants. The majority came from branches of banks, insurance, engineering, and consultancy companies among others.

Results: We tested our hypothesis using structural equation modelling. We found that ideology fulfilment was positively related to AC (B=.14, p<.05), and AC impacted negatively turnover intentions (TI) (B=-.81, p<.01). The AC mediation effects in the relationship between IF and TI had a statistically significant negative effect (B= -.11, p<.05), thus supporting a mediation relationship through the AC. For OI, we found a positive direct relationship with IF (B=.12, p<.05), as well a negative direct relationship with TI (B=-.67, p<.01). After our bootstrap, we found that IF had no significant indirect effect relationship on TI through OI (B=.01, p>.05).

We predicted that ideology breach (IB) was positively related to TI, and the results supported this direct effect (B=.66, p<.01). We also found support for a negative relationship between ideology breach (IB) and affective commitment (AC) (B=-.58, p<.01). In addition, we found a statistically significant positive effect (B=.38, p<.01), thus supporting our mediation relationship between IB and TI through AC. Regarding OI, we found a negative direct relationship with IB (B=-.23, p<.01), and OI had also a negative direct effect on TI (B=-.52, p<.01). When assessing the indirect effects of OI, we found that OI had a positive indirect effect on the relationship between IB and TI (B=.12, p>.05) thus confirming our mediation relationship through OI.

Limitations: problems with common method variance and a need for longitudinal studies among this professional's framework. Other studies must focus also on another age framework to include a more broadening measure within HR management.

Conclusions : These results shed light on the growing importance of ideology-infused psychological contracts within the HR framework. Following the evidence, if employees are affetive committed to their organization, they should find what they do in the organization to be meaningful and be able to connect with their work (Poon, 2013). Additionally, the breach of promises (i.e., ideology breach) will increase the odds of a young employee leaving the organization.

Relevance to the congress and UN SDG's : The ideology contract as a small body of literature and this paper sheds light on the growing importance of cause-driven organisations and their power to attract and retain young professionals. There's a direct importance to the United Nations SDG's, because the cause addressed by organisations through their employees can be from SGD 1 all through the 17 (e.g. reduce inequalities through financial help or employees volunteers programme to help the most needed community), varying on the organisation's strategy.

Keywords: ideology; psychological contracts; Commitment ; Identification

The role of consultants in promoting the acceptance of a stress-management intervention

Felipe Coelho, Marco De Angelis | University of Bologna

science&practice

A positive stress management intervention appears to be a viable solution to improve personal and work-related resources that can offset the burden of job demands and promote positive psychological outcomes in healthcare professionals. However, these interventions are relatively new and there is a lack of scientific evidence on what factors may influence outcomes. The main aim of our study was to analyse and understand the potential impact of a range of process measures on the proposed intervention. More specifically, we investigated whether the training design would influence individual acceptance of the intervention and whether the role of the consultants and how they are perceived by participants would influence this relationship. Greater importance was given to acceptability because even in a well-designed intervention, low acceptability may contribute to the techniques not being adopted by participants and the intervention not being implemented effectively.

The study used a cross-sectional approach and the questionnaires used to assess the study's process measures were adapted from previous studies that focused on individual perceptions of the training design, their acceptance and the learning transfer system inventory. The sample included 100 participants from an Italian hospital, most of whom were female.

The results of our study show that the training design is associated with a higher likelihood of individual acceptance of the proposed intervention and that consultants play a moderating role in the relationship between these two variables. Moreover, the data show the importance of the consultants in the intervention implementation process, as the interaction between individual acceptance and training transfer becomes less significant depending on the strength of the moderator (i.e. how positively consultants are perceived). Indeed, the results also shed light on the value of the consultants' work. A well-perceived performance of the consultants may contribute to an individual's perception of the usefulness of the skills learned in the programme and to a higher level of motivation and acceptance towards learning. In addition, consultants may also promote individual perceptions of self-confidence and optimism, as well as an open climate in which stressful events can be shared and discussed with other co-workers, which in turn may have an impact on job resources.

The limitations of this study are related to the gender distribution and sample size, as well as cross-sectional data collection. In future studies, the same intervention and model could be tested with a larger sample and in a different setting, which would help to support and enrich the conclusions of this study.

In summary, the greatest significance of this study is the possibility of transferring the specific design of this intervention to other contexts and workers, which has proven problematic in the past when testing effectiveness. However, it is also important to remember that this information can be extremely useful for practitioners, particularly because it highlights the importance of consultants and training design to the expected outcomes of the intervention. In line with the congress theme, the implications of this study are directly related to creating a better link between the scientific approach to interventions and the practical use of knowledge. It also supports UNSDG Goal 8 to promote decent work for all. *Keywords: Positive Stress Management Intervention, Process Measures, Consultants*

The role of co-workers' team affective climate on job conflicts involving employees with disability: The hidden effects of team shared stigma against disability

Francisco José Sanclemente, Francisco José Medina, Nuria Gamero, María del Rocío López-Cabrera | University of Seville, Department of Social Psychology. Seville (Spain)

science

Research on disability and work has shown that most cases of discrimination at work were those involving employees with disability who experienced conflicts with other employees accentuated by a hostile work environment. Consequently, the main objective of this study was to contributes to bridging the existent research gap on how to deal with conflicts related to disability at work, considering mechanisms to reduce the negative impact of work conflict. In this sense, we examined the role of the affective climate and the stigma against disability at team level to understand how task and relational conflicts influence the job performance of employees with disabilities (EWD). Specifically, we analyzed the influence of task conflict perceived by EWD on their job performance informed by their coworkers without disability as a main indicator of EWD's job inclusion. First, we examined the double mediation role of relational conflict perceived by EWD and team affective climate perceived by their coworkers without disability in the task conflict-job performance relationship. Second, we used a cross-level moderating approach to examine how the stigma shared by team members without disability impacts on these relationships. Our sample was composed by 258 employees included in 66 teams from 15 organizations. Each team included one worker with disability. The study had a cross sectional design and variables were obtained by questionnaires. Two sources of information were used: EWD to measure task conflict and relational conflict, and team coworkers to measure team affective climate towards disability, team stigma against disability and EWD's job performance. Team level variables were aggregated testing previously conditions for aggregation. We used SEM and cross-level moderation with MPLUS to test our hypotheses. Our results showed that EWD's perceptions of task and relational conflict decreased coworkers' team affective climate. Nevertheless, the team affective climate increased coworkers' estimation of EWD's job performance. Additionally, team stigma against disability decreased the team affective climate and negatively moderated the relationship between EWD's perceptions of task conflict and relational conflict. Opposite to our predictions, high levels of team stigma decreased the positive influence of EWD's task conflict on EWD's relational conflict, maybe due to the avoiding interaction effect on their coworkers when the level of team stigma is high. Our research presents some limitations. First, we are unable to conclusively establish any causal relationships due to the cross-sectional design. Second, self-report measures may result in potential problem of common-method bias. Nevertheless, we followed Podsakoff's recommendations to avoid common-method variance bias. The main conclusion of our study was that adequate levels of team affective climate buffers the negative effects caused by conflicts (task and relational) on EWD's job inclusion. Finally, this study is related to the EAWOP topic "Diversity and Inclusion". Organizations must be prepared for an increasing diversity in the workforce and this diversity cover the job inclusion of people with disabilities. Likewise, this research is aligned with the "Reduced Inequalities and Decent Work" goal of UN Sustainable Development Goals (2015).

The role of leaders in identifying employees' experience of failure at work as a positive resource

Kitti Kiss & Agota Kun | Department of Ergonomics and Psychology, Faculty of Economic and Social Sciences, Budapest University of Technology and Economics, Budapest, Hungary

science&practice

People's overall satisfaction with life is more influenced by their relationships than by their job, income, or even physical health (Campbell et al., 1976). This belief is well founded: research shows that our relationships with others make us healthy and happy (Robies et al., 2014; Slatcher, 2010; Giles et al., 2005; Barth et al., 2010) And if we interpret job satisfaction and well-being in the context of work, we find that all theories of well-being at work include work relationships as a significant factor influencing our global sense of well-being at work (e.g., Warr's Vitamin model (2007), the ASSET model (Cooper & Cartwright, 2009), or Siegrist's (1996, 2009) job control-reward model). If our well-being and happiness are so significantly influenced by our relationships, what role might they play in helping us to cope with and process difficulties, failures, or mistakes at work? After all, failure is universal and part of our lives, meaning that we all face it in our lives. In the following, I will look for answers to this question and to the question of what role the relationship with the manager plays in dealing with a failure or mistake. In my thesis, I will present my research findings alongside various theoretical and research findings. My research has so far involved 30 subjects with whom I have conducted semi-structured interviews using the critical incident technique. The results show that failure and mistakes have many positive effects on both individual and organizational levels in the world of work. Namely, employees benefit from effective error management because they receive constructive feedback from supervisors and co-workers (Edmondson, 1999). And feedback provides an opportunity for individuals to change their course of action while gaining new knowledge about different types of error situations and thus becoming more aware of the situations that caused the error (Edmondson, 1999). At the organizational level, effective error management can improve organizational effectiveness if people are confident that they will not be blamed, ridiculed, or punished when errors occur (Edmondson, 1999). Nevertheless, the benefits of errors are less obvious than their negative consequences (McCune, 1997). Learning orientation, managerial support, and adequate psychological safety are needed in the workplace to raise awareness of the positive effects (Newton et al., 2008).

The story about university employees' self-efficacy and their wellbeing

Aurelija Stelmokienė, Loreta Gustainienė, Kristina Kovalčikienė & Giedrė Genevičiūtė-Janonė | Vytautas Magnus University

science

Researchers are still debating about the role of personal resources in predicting employees' wellbeing. We propose a positive story, in which employees' self-efficacy could act as a moderator diminishing the relationship between job demands and employees' health and strengthening the relationship between job resources and positive employees' attitudes towards job. These presumptions are based on the expanded Job demands-resources model (Bakker et al., 2007; Bakker, Demerouti, 2017). Cross-sectional survey in three Lithuanian universities involved 451 employees (31 percent males and 67 percent females; 57 percent academic staff, 22 percent non-academic staff and 20 percent doing both academic and administrative tasks). Occupational self-efficacy scale (Rigotti et al., 2008), COPSOQII (National Centre for the Working Environment, 2007) and UWES (Schaufeli, Bakker, 2003) were used as the main questionnaires. Results of the moderation analysis showed that in the group of employees with high self-efficacy the relationship between perceived work-family conflict and stress was weaker. However, in the same group of employees the relationship between perceived influence at work and work engagement was stronger than in the group with low self-efficacy. This story is in line with Dicke and colleagues' (2018) longitudinal research, insights from Mazzetti et al. (2021) metanalysis. Nevertheless, replication of the study in different context (type of organization, country, etc.) would be useful. The main message for practitioners – self-efficacy enhancement programs could be valuable HRM instruments in universities. Employees with high self-efficacy experience less stress because they believe they can deal with work-family conflict and they are more engaged because they know how to use influence, they have at work, effectively. This research also provides insights about significant predictors of good health and wellbeing, one of the sustainable development goals, in the university employees' sample. Consideration of employees' personal resources could help both to react to the changing world of work and to be proactive in designing valuable HRM practices.

Time to tell a different story? Positive and negative follower perceptions of their leaders' storytelling

Johannes Stark, Kuehne Logistics University; Julia A.M. Reif, Universität der Bundeswehr München

science&practice

Research goals and theoretical background

Storytelling, a form of leader-follower interaction in which past and future human experiences are shared (Boje, 1991), has received much attention in the popular management literature. Accordingly, storytelling in leadership is highly effective, driving follower commitment and innovative performance. However, in practice, leaders' storytelling may have ambiguous and even negative effects on followers. Notably, previous research on leaders' storytelling is scarce and disconnected from leadership theory, and thus fails to explain positive and negative follower perceptions of their leaders' storytelling. In the present research, we introduced and evaluated the intention-perception model of storytelling in leadership, providing a framework to systematically explain when and why unintended effects of storytelling happen.

Methodology

In Study 1, we developed the intention-perception model of storytelling in leadership, drawing on data from semi-structured interviews (N = 27 independent leaders and followers) and integrating transformational leadership and leader-member exchange theory. In Study 2 (N = 79), we developed a scale to assess followers' story perceptions and confirmed the scale's structure in Study 3, an online cross-sectional field study (N = 60). In Study 3, we also tested a main assumption of the intention-perception model of storytelling, that is, the relationship between followers' story perceptions and story effects, mediated via followers' affective arousal.

Results

Across studies, we found that story effects depend on followers' perception of the story. In particular, the better a leader's story met followers' needs (need-supply fit), the more adequate the input load transported by the story (story load), and the more positive followers' appraisal of their leader's story (story appraisal), the more positive followers' affective reactions and effects of storytelling (transformation, leader-member exchange quality, and trust in the leader).

Limitations and future research

Whereas our findings imply causal links within our model, they are based on participants' recall of story effects and may thus be affected by hindsight bias and implicit theories about story effects. In future studies, we plan to apply experimental manipulations of standardized scenarios of storytelling situations.

Conclusion and Relevance

Taking a follower-centric perspective on a common leadership practice (i.e., storytelling), our research contributes to a growing body of managerial literature, revealing how followers' responses to leader behavior vary interpersonally and across situations, and thus refuting a one-fits-all approach to leadership. Particularly, we challenge the common premise that a good story is always helpful, the more intense and personal the story the better, and that storytelling is always perceived as genuine and authentic. In that way, we provide practical insights on how leaders may improve

collaboration by tailoring their communication behavior to the expectations and needs of their followers.

Relevance to the UN SDGs

With the present research we aim to be relevant to the UN Sustainable Development Goals by contributing to the identification and development of leadership behaviors that foster employee well-being and promote decent working conditions.

Keywords: Storytelling, Leadership, Intention-Perception Shift

Towards an Understanding of Motives to Use Social Networking Sites on Well-Being

Linda-Elisabeth Reimann, WWU Münster; Hans-Werner Bierhoff, Ruhr-Universität Bochum; Elke Rohmann, Ruhr-Universität Bochum; Phillip Ozimek, FernUniversität Hagen

science

Using social networking sites (SNSs) became a routine in many peoples' lives which is strengthened by the high number of daily usage time (Pew Research Center, 2021). This includes aspects regarding social life as well as the workplace that is highlighted by the fact that two out of three employees use SNSs for their work (Leftheriotis & Giannakos, 2014) and also work-related communication after work/during recovery time (Xu et al., 2022). Therefore, a lot of research has been conducted to explore consequences of SNS use on multiple well-being variables resulting in contradictory results. A more comprehensive instrument to measure SNS use is an approach to solve this problem (Valkenburg et al., 2021). In our study, we utilized a combination of two approaches for a more detailed way to assess SNS use: (1) active/passive dichotomization and (2) assessment of underlying motives for SNS use (cf., Liu et al., 2019; Ozimek & Förster, 2021). The examined motives are the Need for Self-Presentation (NSP), the Need to Belong (NB; Nadkarni & Hofmann, 2012), the Need for Social Comparison (NSC; Vogel et al., 2015), and the Need for Entertainment/Information (NEI; Gupta & Bashir, 2018). Two studies were conducted to reach the goal of providing a suitable instrument by validating a new scale to measure both aspects of SNS use. Moreover, the scale aimed to be universally applicable for both, work-related and non-work-related related SNS activities. Study 1 (N = 597) focused on item development as well as item reduction, and identification of factor structure. The analysis resulted in an eight-factor structure that represented active and passive domains of each motive. Study 2 (N = 437) confirmed this factor structure by showing good values for model fit. Furthermore, construct and criterion validity were demonstrated in both studies. Regarding criterion validity, differences between MOTUS subscales and indicators of well-being – namely satisfaction with life, self-esteem, positive/negative affect – were of particular interest. Results revealed that the passive domains of NSP, NB, and NEI were positively related to self-esteem and positive affect. Whereas, NSC showed negative associations with self-esteem as well as satisfaction with life, and a positive association with negative affect. The validated scale is a fruitful instrument for further investigations because it can universally be adapted to specific contexts and platforms. Results are discussed in terms of their practical implications towards the understanding of possible consequences associated with SNS use. Questions for further research may be: (1) How can SNSs be used as a coping resource? (2) Can motives actually be fulfilled when using SNSs? Or (3) How can people improve their usage behavior to obtain benefits regarding well-being?

Trans-cending boundaries? Organizational consequences of gender-role violations for transgender women

Nicholas A. Smith, OHSU-PSU School of Public Health; Kelly M. Hamilton, CMA Global Inc.; Larry R. Martinez, Portland State University

science

Research goals and why the work was worth doing

Organizations and employees are increasingly appreciating the importance of managing gender diversity in work contexts. Transgender women experience some of the most discrimination, but it is unclear whether this is the result of bias against transgender people, bias against women, or bias based on violations of traditional gender norms. Our research addresses this current limitation.

Theoretical background

We drew on theories related to gender, stigmatization, social role theory (i.e., gender norm violations), and occupational stereotypes to ground our hypotheses.

Design/Methodology/Approach/Intervention

Study 1 involved in-depth interviews with ten transgender women (115 pages of text), which were transcribed and thematically coded in line with best practices for qualitative analysis. Study 2 involved 125 participants who were randomly assigned to evaluate a potential job applicant (ostensibly for a study about cybervetting) with respect to perceived hireability, discrimination likelihood, and job role suitability (based on gender stereotypes). Stimuli included pictures of applicants at different points in their gender transitions (beginning, mid-point, and end). We used a between-subjects design and note that photographic stimuli were acquired from multiple individuals who documented their transition over time.

Results obtained

Trans women in Study 1 reported receiving more positive interactions and increased feelings of acceptance among coworkers and greater acceptance in traditionally “feminine” jobs as their transitions progressed. Participants in Study 2 similarly evaluated job applicants who were near the end of their transitions (based on facial appearance alone) more positively on every outcome than those who had just begun or were in the process of transitioning.

Limitations

Our relatively small sample size in Study 1 may call the generalizability of our findings into question, but the consistency of responses provide useful background information in understanding this phenomenon. Some may criticize our use of MTurk in Study 2, but meta-analytic findings support its use for social science research and we implemented several data quality control measures and a between-subjects experimental design to increase confidence in our results.

Conclusions

These studies suggest that transgender women face a unique and complex set of challenges at work and highlight the pervasiveness of gender norms in workplace contexts. Although individuals may successfully transcend the boundaries associated with traditional gender expression, they nevertheless struggle with new challenges as women, despite no losses in human capital. As such,

gender norms continue to have pernicious effects for employees, even among those who may be least constrained by traditional conceptualizations of gender.

Relevance to the congress theme

As gender diversity increases and more employees feel comfortable expressing gender identities that have been considered nontraditional it is critically important to understand the psychological mechanisms that explain harassment and discrimination based on gender. Our results are extremely timely given these trends and the implications for protecting marginalized workers.

Understanding The Great Resignation: Who Quits and Why?

Ann Sophie Lauterbach, University of Konstanz

science

At the beginning of 2021, one-third of employees in the US and Germany were thinking about leaving their jobs (Microsoft, 2021; Xing, 2022). As this data was collected during the pandemic, one could argue that many people changed to better-paying jobs due to the high economic insecurity. However, pay only has a moderate impact on employee attrition (Allen et al., 2010; Rubenstein et al., 2018), also during the so-called post-pandemic "great resignation" (Sull et al., 2022). The great resignation is the process of a massive wave of voluntary job separations inherent to the COVID-19 pandemic (Kuzior et al., 2022). Although some attempts to explore the causes of the great resignation are made, e.g., by explaining it by occupational stress and anxiety (Jiskrova, 2022; Sheather & Slattery, 2021), by lack of citizenship and purpose (Hirsch, 2021), or by other non-materialistic factors (Kuzior et al., 2022), the ongoing attrition is not fully understood yet. In addition, it is unclear what employee subgroups reacted strongest to the post-pandemic work environment.

Instead of pay as the driving force, a toxic corporate culture and relational factors like the lack of belonging or not feeling valued are the most influential factors leading to turnover (Smet et al., 2021; Sull et al., 2022). A recent meta-analysis (Rubenstein et al., 2018) showed that younger workers were more likely to quit in a pre-pandemic context and asked future research to monitor this age-based trend. The answer might lie in younger employees' high expectations regarding what they want from their employers (Bal & Jansen, 2016), a constant search for developmental opportunities (Kuzior et al., 2022), or in a more vigorous search for meaning among younger employees (Zhou & Zheng, 2022). We argue that young people experience more dissatisfaction and, hence, play an essential part in the great resignation.

To better understand the reasons for the great resignation's unprecedented attrition numbers and to help leaders respond effectively, the aims of this study are to (1) assess the reasons for the great resignation in a German context and (2) examine whether there are specific demographic profiles of employees who quit during the great resignation.

This study is based on platform data provided by kununu, a professionally operated employer rating platform where employees can rate their employer anonymously and free of charge. We use self-reports and comments issued by employees who left their previous employer and analyze which keywords, e.g., toxic leadership, stressful environment, work-life conflict, family-unfriendly, lack of meaning, indicate certain organizational cultures that have contributed to the resignation. We utilize the R-Package RDQA for a qualitative content analysis that supports us in measuring and evaluating the prevalence, meanings, and correlations of certain words, themes, or concepts (Prasad, 2008; Stemler, 2015). While writing this for submission, we will be soon receiving the kununu ratings and comments from 2020 to 2022. Since we are dealing with a large volume of ratings and comments, we expect to process and evaluate the mixed methods data by the end of March 2023.

Despite this study's importance in exploring the great resignation discourse, working with an online platform also entails limitations. Kununu is only one platform among many others providing similar reviewing possibilities and the quality of our analysis may be improved by considering additional platforms, such as glassdoor.com. Further, we should consider varying definitions of key terms as companies and their employees will apply their own definitions of similar constructs. Nevertheless,

we take the meanings of the key terms into account and try to cluster them accordingly in our large-scale coding scheme.

Business leaders and researchers still struggle to understand the factors causing mass attrition and are looking for ways to retain valued employees. This study aims to answer the most prevalent causes for the great resignation in Germany and whether particular age groups were more affected than others. We use mixed methods and focus on longitudinal effects from 2020 to 2022. Combined with the practical need to examine how to retain valued employees, our research approach substantially contributes to the discussion on employee attrition and retention based on workplace cultures during the great resignation.

A working world that retains young talent and a diverse workforce contributes to sustainable development goals by offering structures for a better work-life balance and, thus, contribute, e.g., to better gender equality. Further, when companies realize that their toxic work culture discourages their employees, they might see the value in improving their policies and promoting employee well-being and health, which, in turn, also improves public health.

Keywords: great resignation, younger employees, content analysis

Validation of the Sense of Professional Self-Esteem Scale

Dorota Godlewska-Werner, University of Gdansk; Radek Swiecinski, Amsterdam University of Applied Sciences, Amsterdam School of International Business; Aleksandra Peplińska, University of Gdansk

science

Background: There are a few concepts related to the sense of being needed and valuable in the workplace. Some are based on objective criteria, such as professional suitability described mainly in terms of a specific educational and professional context (Rodriguez et al. 2016) or as the learning process influenced by competences required for proper performance at work (Myklebust, 2022). A sense of professional self-esteem relates to the subjective feeling of being needed, successful, significant and worthy at work. The construct is similar to general self-esteem and self-worth measuring both positive and negative feelings about the self as proposed by Rosenberg (1965), but linked to a professional area. The general self-esteem is a belief in an individual's capabilities, which has an impact on behaviour, fulfilment of objectives and taking actions (Bandura, 1994). It also regulates well-being, informs about coping with difficulties, and supports relations with others (Leary & Baumeister, 2000). High professional self-esteem means that employees value and accept their professional roles (Tinsley, 2002) and try to perform as well as possible (Ceylan, Biçakçi, Gürsoy, & Aral, 2009). It consists of five dimensions such as satisfaction with the performed role, desire to develop skills necessary in a job, commitment, feeling of adapting to work conditions and a desire to share knowledge and experience with others (Arıcak, 1999).

The aim: The main objective of this study was to construct a Polish version of The Sense of Professional Self-Esteem scale, shorter than The Turkish Scale for Professional Self-Esteem of Arıcak (1999) which consists of 30 items. The Pakistani adaptation of the Turkish scale did not yield an acceptable reliability value and was extended to 37 items. This informed the decision not to base the Polish version of the tool on the original method because an importance of adapting a method to the cultural context was noticed (Iqbal, Bibi & Gul, 2016). The goal of the research is to test the validity and reliability of the Polish version of the constructed inventory and to examine its relationship to general self-esteem.

Procedure: 255 Polish employees took part in the research. They filled three questionnaires: the experimental version of The Sense of Professional Self-Esteem Scale consisting of 6 items based on the Rosenberg's self-esteem scale (Rosenberg, 1965), the Single-item Self-report Measure of Global Self-esteem (Skevington, Lotfy & O'Connell, 2004; adapted by Atroszko, Sawicki, Sendal & Atroszko, 2017). V) and the Satisfaction with the Job Scale consisting of 5 items (Kondratowicz, Godlewska-Werner, Połomski i Khosla, 2021). The obtained data were analysed with a view to ascertaining the validity and reliability of the experimental Polish scale and examining the relationship of the obtained results with general self-esteem.

Results: Statistical analyses showed of The Sense of Professional Self-Esteem Scale is reliable - the Cronbach alpha reliability coefficient was determined to be 0.89. There is a positive correlation between professional self-esteem and a global self-esteem and satisfaction with the job.

Conclusions: The professional self-esteem is a very important factor which is not used often in European studies. The Sense of Professional Self-Esteem Scale may be used for various research studies as it is short, but still valid and reliable.
Keywords: professional self-esteem, self-esteem, validatio

We need autonomy! The role of leadership styles, job autonomy and autonomous motivation in the work engagement of outsourcing employees: A case study

Diana Kusik, Jagiellonian University in Krakow; Iga Jakubik, Warsaw University; Aleksandra Tokarz, Jagiellonian University in Krakow

science&practice

Research goals and why the work was worth doing : The question of how to sustain and stimulate the motivation and work engagement of employees is essential for Human Resource Management professionals in outsourcing organizations that face high voluntary turnover related to loss of engagement. To develop a strong rationale for HRM interventions appropriate to this context, the presented systematic mixed-method illustrative case study considers the contextual issues of mechanistic job design in outsourcing. Study 1 (quantitative) aimed to test a theoretical model of different motivational antecedents of followers' work engagement and provided empirical evidence on their relative importance. Study 2 (qualitative) was designed to understand and problematize the findings of Study 1, especially those that go beyond theory-based assumptions.

Theoretical background : In Study 1, we integrated Self-Determination Theory and transformational-transactional leadership theory with a work engagement model. In Study 2, we focused on the factor identified in Study 1 as having the most important role in work engagement, namely, followers' intrinsic motivation. We investigated leadership actions that promote it and identified thematic threads regarding enhancing followers' intrinsic motivation from the perspectives of both leaders and followers.

Methodology : This research was conducted in an outsourcing organization and includes quantitative data from an online survey in which 257 employees took part (Study 1) and qualitative data from four focus group discussions (Study 2).

Results : The results of Study 1 showed that employees who have a higher level of work engagement also have higher intrinsic motivation, and the strength of this autonomous type of motivation in predicting work engagement is higher than that of other motivational antecedents, i.e., identified motivation, job autonomy, and supervisors' leadership styles. Study 2 highlights leaders' specific activities that can be used in HRM interventions that offer substitute autonomy to outsourcing employees to support their motivation.

Limitations : We investigated one outsourcing organization and its employees' perspectives. Therefore, the applicability of the findings across other organizations in this sector may be challenged. At the same time, the purpose of a case study is to provide detailed descriptions and explanatory insights instead of generalizable results.

Conclusions – research and or practical implications/Originality/Value : Together, this research contributes to the existing literature on Human Resource Management in several ways. First, it considers the organizational context of the outsourcing sector in the analysis of factors that contribute to work engagement. Second, it bridges the research gap by showing that autonomous actions have great importance and can be introduced as substitute autonomy in mechanistically designed jobs. Third, it suggests various leadership actions that may stimulate autonomous motivation; therefore, it might also be useful for HRM professionals when introducing and developing appropriate interventions in the outsourcing sector.

Relevance to the Congress Theme : Motivational leadership

Keywords: leadership, motivation, job autonomy

When does sleep predict burnout experiences? Self-reported vs. actigraphy-derived measures

Sophia Frick, Yvonne de Kort, Evangelia Demerouti, Leander van der Meij & Karin Smolders | Eindhoven University of Technology

science&practice

Aim

We explored if and how daily sleep, measured via self-reports and actigraphy, predicts daily burnout experiences among non-clinical employees and whether these relationships depend on trait levels of burnout and sleep quality.

Background

Previous studies provide several indications that sleep may be an important determinant and risk factor for the development and experience of burnout symptoms. Clinical burnout patients feel less recovered after sleeping than healthy controls (Sonnenschein et al., 2007) and improvements in burnout are accompanied by improvements in sleep quality and physiology (Ekstedt et al., 2009). However, given that sleep is an important mechanism for recovery from daily work demands, the preceding sleep episode may also be a crucial determinant of daily experiences related to burnout. Sleeping well could support the ability to recover from daily work demands by restoring psycho-physiological systems overnight, whereas sleep disruptions may impair recovery, likely resulting in an increased intensity of burnout experiences the next day. Yet, little is known about whether sleep can predict daily experiences related to burnout in non-clinical populations and which aspects of sleep (self-reported vs actigraphy-derived measures of sleep) are most important for predicting and preventing such experiences.

The strength of the relationship between sleep and daily burnout-related experiences may depend on trait levels of burnout. According to the Effort-Recovery Theory, inadequate recovery between work episodes causes employees to invest compensatory effort, further increasing the demand on the recovery system (Meijman & Mulder, 1998). Employees experiencing higher levels of trait burnout or more sleep disturbances on a regular basis may thus be more dependent on sleep between workdays to replenish their low levels of energy and motivation. This study contributes to knowledge regarding how burnout develops by investigating if and how trait levels of burnout and general sleep quality determine the importance of sleep (quality, duration, timing, latency, efficiency, and fragmentation) for daily experiences related to burnout.

Methods

We conducted a seven-day field study among 72 working employees. The study consisted of: (1) a questionnaire assessing trait burnout and disturbances in general sleep quality, (2) a daily morning diary assessing self-reported sleep quality, (3) seven short questionnaires assessing the momentary experience of disengagement and emotional exhaustion throughout the day and (4) wrist-worn actigraphy assessing sleep duration, timing, latency, efficiency, and number of awakenings from sleep, worn throughout the study period. Momentary questionnaires were aggregated to reflect daily levels of burnout-related experiences, and two-level linear mixed models were run to test associations between sleep and burnout-related experiences.

Results

Self-reported sleep quality was negatively related to subsequent daily experiences of exhaustion. In contrast, self-reported measures of sleep were not associated with subsequent daily experiences related to disengagement. None of the actigraphy-derived sleep markers were related to burnout-related experiences at the day level. This finding suggests that it is the psychological experience of the preceding sleep episode, rather than actigraphy-derived aspects of that sleep episode, that is relevant to daily burnout experiences.

Moreover, trait burnout and trait sleep quality moderated the relationship between self-reported sleep quality and exhaustion. Daily sleep quality was a stronger predictor for the next day's energy levels when participants were more exhausted and had worse quality sleep in general. Moreover, trait exhaustion moderated the relationship between daily sleep duration and daily exhaustion, insofar that only for participants who experienced low levels of trait exhaustion, sleeping longer resulted in less daily exhaustion. This suggests that employees experiencing higher levels of trait exhaustion did not benefit from sleeping longer.

Limitations

While sleep diaries and actigraphy are commonly used to monitor sleep in research and clinical practice, both methods have limitations. Actigraphy has been demonstrated to display a low ability to detect wakeful periods during sleep episodes and self-reports are prone to response biases and errors.

Conclusions

In a non-clinical sample, self-reports were stronger predictors of daily burnout experiences than actigraphy-derived measures of sleep. Moreover, experiencing higher levels of burnout amplified the negative relationship between sleep quality and the subsequent daily experience of exhaustion. This suggests that experiencing poor quality sleep while already experiencing exhaustion may intensify the downward spiral of energy depletion found in the development of burnout. Sleep is thus of particular importance for non- and sub-clinical populations that aim to prevent long-term energy erosion.

Where the Psychopaths work: Cross-industry differences in the relation of Dark Triad and Psychological Capital

Birgit Stephan, Center for Leadership and People Management, LMU Munich, Germany; Eva Lermer, Department of Business Psychology, University of Applied Sciences Augsburg, Germany and Center for Leadership and People Management, LMU Munich

science

Research goals and why the work was worth doing

The purpose of this study was to explore differences and relationships between the concepts of Dark Triad (narcissism, psychopathy and Machiavellianism; DT) and Psychological Capital (PsyCap) across work-related industries.

Theoretical background

Both DT and PsyCap have been researched in detail. However, only the recent study (Zhu & Geng, 2021) combined both concepts in a student sample and found a positive relation of narcissism with PsyCap, and negative relation of each psychopathy and Machiavellianism with PsyCap.

As of industry differences, research (Judge & Cable, 1997) revealed that different industries attract different personalities. This effect, referred to as homogeneity hypothesis (Schneider et al., 1998), is explained by people actively choosing the company that best fits their need structure, and an organization helping employees to assimilate with industry values. Since only scattered industry differences have been found for individual DT facets (e.g., Malesza et al., 2019), this study investigated industry differences in a more comprehensive approach.

Design/Methodology

German employees (n=2,109) across 11 industries completed a survey on DT and PsyCap. ANOVAs and multiple regression analyses were used to test the hypotheses.

Results

Significant differences between industries were found for all DT facets as well as PsyCap. Highest scores for psychopathy were found among architecture, retail and consulting compared to lowest scores for education and research as well as health care. The effect of DT on PsyCap varied across industries. For industries architecture, automotive and consulting, only narcissism related significantly positively to PsyCap while psychopathy did not. For all other industries, narcissism related positively and psychopathy negatively with PsyCap. No significant effects were found for Machiavellianism.

Limitations

The study used self-reports and the groups of the different industries were not all equally sized. Future studies should therefore use implicit measurement instruments or combine self-reports with assessment of others.

Conclusions

This study is the first to explore DT and PsyCap among employees and their respective industry. The results extend previous findings by revealing differences of both concepts across and within

industries. Specific behavioral expectations are assumed to facilitate or impede the assimilation of different personalities to the work context (homogeneity hypothesis), depending on the industry. Jobs in some industries, for example, might require greater risk tolerance and use more prestige structures, which is more likely to attract psychopathic personality traits associated with lower fear of risk. This study can help to reconsider in which industries DT personalities affect PsyCap as an antecedent of workplace outcomes such as work satisfaction or job performance.

Relevance to Congress Theme

It is on us to change the future of work. Therefore, it is necessary to understand where DT personalities (such as psychopathic personalities) work and when such behavior might be beneficial or harmful. In this context, the study contributes to a better understanding in which industries differences exist and offers an explanation for them. Revealed differences can be used as basis to discuss how to improve the work environment to reduce the expectations for behavior that suits DT traits such as psychopathy.

Who Gets the Credit? The Role of Team Context on Performance Signals for Human Capital Market Value

Robert E. Ployhart, University of South Carolina; Gilad Chen, University of Maryland; Nicholas Folger, Technical University Munich; Marvin Schuth, Kühne Logistics University; Brosi Prisca, Kühne Logistics University

science

Researchers and practitioners predict that the future of work is organized in teams. Yet, teams are characterized by social complexity and ambiguity, which obscures the understanding who is ultimately responsible for performance in teams. Based on signaling theory, we therefore aim to understand how the team context changes the signal that individual performance sends on individuals' market valuations of human capital.

Theoretical background

We aim to advance theory for understanding the signal of individual performance on market valuations of human capital within team contexts, i.e., team performance and team tenure.

High-performing teams provide a strong support system for individuals. Yet, depending on whether team performance is ultimately taken as an explanation for individual performance or whether individuals are perceived as contributors to team performance, high-performing teams may harm or benefit individuals' market value.

In addition to team performance, the fact that individual performance is co-created in teams puts into question whether individual performance indeed signals the individual's — or other team members' — market value. This differentiation might become the more difficult, the longer individuals work in a team as individuals become deeply embedded in team structures.

Design/Methodology/Approach/Intervention

We used a comprehensive data set of professional European football players of the 'top-five' European football leagues from the 2008/2009 season to the 2017/2018 season. This data set allowed us to obtain objective measures for both individual and team performance (www.whoscored.com) as well as players' market values for human capital (www.transfermarkt.de).

Results

As expected, individual performance was positively related to changes in individual's market value. Yet, the team context nuanced this relationship. Team performance showed an additional positive relationship with individual's market value and strengthened the relationship between individual performance and individual's market value. Team tenure, in contrast, showed a negative relationship with individual's market value and weakened the relationship between individual performance and individual's market value.

Limitations

While the data set provides objective measures in clear temporal order, it does not allow to rule out all alternative explanations. Therefore, we cannot proof clear causality. Furthermore, despite football being a multi-million business in itself and the research question being relevant across industries, the research context might be seen as specific with limited external validity.

Conclusions

Our results provide a meso-level approach to the valuation of human capital, which has so far been examined either on the micro or the macro level. Thereby, we clarify the signaling interplay between individual performance and team performance on individuals' market value, i.e., whether team performance may amplify or distort the signal of individual performance. Furthermore, showing that team tenure weakens the signal of individual performance, we extend the discussion about firm-specificity in human capital research. These findings help individuals and organizations alike to understand individual's market value when working in teams.

Relevance to the Congress Theme

As teams are a major dimension of the future of work, this research elucidates a core aspect in the changing world of work.

Keywords: Team, performance, human capital

Who wants to lead: Relationships between the five-factor model of personality traits, lower-level facets, and Motivation to Lead

Christian Winther Farstad, Kristiania University College; Per-Magnus Thompson, BI Norwegian Business School

science

Why the work is worth doing : The concept of Motivation to Lead are found to be an important determinant for leadership careers. A narrower understanding of the individual characteristics behind leadership motivation helps researchers, recruiters, and others to interpret and direct actions more constructively.

Theoretical background : Chan & Drasgow (2001) introduced Motivation to Lead (MTL) as an individual difference construct to measure the desire to take part in leadership activities and enter leadership roles. The key assumption is that MTL develops because of engaging in leadership activities and roles. Higher levels of MTL affect individuals' willingness to participate in leadership activities and roles, where they will acquire the social skills and knowledge required to qualify and perform well as leaders in the future.

A more recent meta-analysis reported empirical evidence for the relevance of MTL, in multiple settings (Badura, Grijalva, Galvin, Owens, & Joseph, 2020). Whereas outputs of MTL demonstrate the effects of MTL, the inputs describe how individual differences characterize individuals carrying such aspirations. Whereas the five-factor model was established with the MTL already at its introduction, personality traits are criticized for being too broad to describe "how" individuals differ from each other. Studies have demonstrated how such broad traits consist of facets that are both positively and negatively related with outcomes, such as job performance (Judge, Rodell, Klinger, Simon, & Crawford, 2013).

Methodology : Over a three-year period, data has been gathered from more than 400 Norwegian students and non-students participating in psychology classes, workshops, and training activities in Norway. At the beginning of their classes/workshops/activities, participants have executed the NEO PI 3. During their classes/workshops/activities, participants have executed a questionnaire including the 27 item Motivation to Lead scale.

In addition to the five-factor model of personality, this study will include the NEO Sub-facets (Costa & McCrae, 1992; 1998) and the second-order facets proposed by DeYoung, Quilty, and Peterson (2007) in its analysis.

Limitation : As a study aimed to address leadership related information, the non-leader respondents are seen to be a limitation.

Originality/Value : By investigating lower-level facets of personality traits this study among the first to provide a narrower understanding of the relationship between traits and MTL.

Practical Implications : As relationships between personality traits and leadership often is used to describe "what is a leader", a narrower investigation of personality facets and MTL are relevant for both researchers, consultants, recruiters, lecturers, leaders, and other practitioners. As studies have demonstrated how broad traits might increase misinterpretations of leader characteristics, this study aim to help practice to make better decision, better models of leadership, and less biased "narratives" of leadership.

WOP-P Toolkit

Elena Burkey, Eleonora Giovine, Phylicia Richardson, Jacklyn Scymcyk | Florida Institute of Technology

science&practice

The Work, Organizational, and Personnel Psychology (WOP-P) Toolkit is an educational collection of tools and resources meant to assist professionals, students, as well as multinational organizations in explaining, collaborating, and finding common terminology and concepts within WOP-P. The tools and resources were created and developed around potential difficulties that individuals may come across, such as stakeholders from different cultures, when looking to share or explain what they are working on, researching, or studying within this field. The toolkit's primary objective is to support WOP-P professionals from both Western and Nonwestern countries to find a common language and terminology in the realm of WOP-P, and ultimately be better able to both communicate and collaborate with one another, as well as indirectly raise awareness of WOP-P and its sister disciplines (i.e., Industrial-Organizational Psychology).

The toolkit is comprised of two manuals, a short and a long version, a cardstock, a slideshow, as well as an infographic explaining in greater detail what the field is comprised of. It allows any professional utilizing them to have detailed information, scientific evidence, and varying formats that will allow them to effectively communicate what WOP is and how it may benefit others, at easy reach.

To assess the toolkit's utility, data was collected from a total of 11 individuals (across X countries) within the field of WOP, through the use of a survey. The team in charge at the time opted to show the results through a percentage favorable score which combined the 4 and 5 responses from the survey and was further specified as "Unfavorable" (1, 2); "Neutral" (3); "Favorable" (4, 5). When asked to assess the usefulness of the components of the toolkit, the participants indicated that the infographic [73% (US:67% / Non-US: 87%] was the most useful, with the slide deck [55% (US: 50% / Non-US:60%)] and the short manual [55% (US: 17% / Non-US: 100%)] receiving similar results. The participants indicated low use for the the long Manual [36% (US: 17% / Non-US: 60%)].

Overall, the results indicated that over 70% of participants would recommend the toolkit in its entirety, with the slide deck being indicated to be the most likely to be recommended [82% (US: 83% / Non-US: 80%)]. There were higher trends among our non-US sample when indicating if they would use the toolkit again Long Manual [55% (US: 33% / Non-US: 80%)]; Short Manual [55% (US: 17% / Non-US: 100%)]; Infographic PDF [63% (US: 50% / Non-US: 80%)]; Slide Deck [73% (US: 67% / Non-US: 80%)].

Using this feedback, the toolkit was revised and developed further by the publication of an already constructed website and a professional networking page, Linkedin; both of which will allow for the toolkit to be accessible to all professionals, students, and organizations in need which will in turn increase communication between one another to occur, and flourish. This toolkit allows for a shared, better understanding of the field of WOP, along with the potential to educate different countries on how the field of Work and Organizational Psychology may be similar, or different to, a field in their own country.

Work Addiction Risk, Stress and Wellbeing at Work: Testing the Mediating Role of Sleep Quality

Abbas Firoozabadi, Ferdowsi University of Mashhad; Frederic Dutheil, University Hospital of Clermont-Ferrand; Ekaterina Orel, National Research University Higher School of Economics; Laura Seidel, University of Ottawa; Morteza Charkhabi, National Research University Higher School of Economics

science

Attention to work addiction risk is growing; however, more studies are needed to explore the vast impact of work addiction risk on various aspects of employees' work and life domains. Although several studies have considered the antecedents or consequences of work addiction risk, this study particularly focuses on sleep quality as a potential explanatory underlying mechanism in the relation between work addition risk and three outcome variables including stress at home, stress at work and wellbeing. To do so, this study first aims to examine the direct associations of work addiction risk with the three study outcome variables. Second, it aims to consider the extent to which these associations are mediated by the employees' quality of sleep. The data was collected using an online platform and participants consisted of 188 French employees (88 females and 77 males) who were selected using simple random sampling method. Participants responded to the survey including the Work Addiction Risk Test (WART), stress at work, wellbeing, and sleep quality. The data was analyzed using JASP and SPSS-26 programs. The results revealed that there are significant positive relationships between work addiction risk and both stress at home and at work and negative relationships between work addiction risk and both sleep quality and wellbeing. In addition, the analyses of the mediation paths suggests the significant mediation role of sleep quality for the link between work addition risk and stress at work as well as the link between work addiction risk and wellbeing. However, sleep quality was found to be a stronger mediator of work addiction risk and wellbeing.

Well-being oriented HRM practices increase employee eudaimonic workplace well-being. Multilevel study from 50 countries

Agnieszka Wojtczuk-Turek, Institute of Human Capital & Dariusz Turek, Institute of Enterprise | Warsaw School of Economics

Science

Research goals and why the study was worth doing

The purpose of this article is to explain the relationship between well-being-oriented HRM practices and employee eudaimonic well-being. The realization of the fourth Sustainable Development Goal, concerned with good health and well-being of a country's citizens, was used as a moderating variable. The research undertaken in the article allows to explain the interrelationship between organizational activities and national policies for achieving Sustainable Development Goals. The purpose of the research and its international scope make a unique contribution in the field of sustainable HRM and organizational psychology. The presented research is part of an international project entitled "Sustainable Human Resource Management – Cross-Cultural Empirical Study".

Theoretical background

Based on social exchange theory, the paper explains the extent to which the practices affecting the well-being of employees, implemented in companies, are enhanced by the realization of the Sustainable Development Goal concerning good health and well-being.

Design/Methodology/Approach/Intervention

This study is based on data from over 13,000 employees representing a number of companies. The questionnaires were completed using the computer-assisted web interview method. On the basis of multilevel analysis, we demonstrate how well-being-oriented HRM explains well-being between and within groups from each country.

Results obtained or expected (if not available, it must be made clear when they will be available)

The findings show that well-being oriented HRM practices explain eudaimonic well-being between and within groups. The relationships between these variables are stronger in those countries where state policies are oriented towards the fourth Sustainable Development Goal of good-health and well-being of citizens.

Limitations

This study has two limitations: its cross-sectional design and the use of self-reported questionnaire data.

Conclusions – research and or practical implications/Originality/Value

The study is the first to explore the relationship between well-being oriented HRM practices and employee eudaimonic well-being in the perspective of international analysis.

Relevance to the Congress Theme

The proposed research problem is directly related to the topic area included in the conference program and connected with well-being.

SDGs GOAL – Good health and well-being*Keywords: eudaimonic well-being, HRM, SDGs*

Work Engagement as a mediator in the relationship between Social support and performance in digital services professionals

Eva Lousã, Ceos, ISCAP and University Of Maia

science&practice

On the basis of theories about the motivational potential of job resources, the purpose of this study is to examine how job resources (job autonomy, social support, and supervisor feedback) facilitate work engagement and task and contextual performance, taking into account different work modalities: onsite work, hybrid work, and telework. It is acknowledged that the effects of digitalization and technology on the relational aspects of work vary, and that information and communication technologies (ICT) can create both opportunities and constraints in supporting coworker relationships. In this study we predict that supportive colleagues (social support) can create positive working relationships with others which in turn will affect workers' task and context performance, and work engagement is a mediator of the relationship. Data were gathered from a cross-sectional survey of 261 workers of different Portuguese enterprises from digital services sector. Using regression analysis, this study examined the contribution of demographic and job resources variables (Job autonomy, Social Support and Supervisor Feedback) to the prediction of Work Engagement, task and contextual performance among workers who were working in three work modalities - Onsite Work, Hybrid Work, Telework. Work Engagement was analyzed as a mediator of that relationship Social Support and task and contextual performance. The results revealed that Job autonomy, Social support and Supervisor feedback accounted for the prediction of Work Engagement and also for the prediction of Task and of Contextual Performance. Social support was directly and indirectly associated with Task and Contextual Performance, through Work Engagement. Findings of the study suggest that enhancing Social support can be a potential strategy to foster Work Engagement and improve Task and of Contextual Performance outcomes. This study contributes to our understanding of the new workplace and working arrangements and the relational aspects of work.

Work-design and Occupational Well-Being

Mateusz Hauk & Olga Zwardoń-Kuchciak | University of Łódź, Institute of Psychology

science&practice

Occupational well-being is one of the main areas of interests of many companies and organizations operating in the business environment. There is a growing awareness of its role in the context of building employee engagement and efficiency, and of how it translates into the overall functioning of an individual. Recent socio-economic changes have intensified the activities of many companies aimed at maintaining or increasing the occupational well-being of employees.

When talking about the employee's well-being, the proper work-design seems to be of great importance. Hence, the aim of this study was to determine the relationship between the characteristics of work and the employee's well-being.

As for the methods, the Well-Being Questionnaire in the Work Situation by Czerw (2017) was used. It enables the subjective assessment of one's own work and its place, includes 43 items divided into four categories: positive organization, fit and development, positive relations with colleagues, contribution to the organization. Additionally, the Work-Design Questionnaire by Hauk (2014) was used in order to estimate job characteristics. The tool consists of 46 items belonging to 11 factors: the complexity of the work; physical requirements and working conditions; feedback from work; autonomy; ergonomics; feedback from others; equipment used; mutual dependence of employees; interactions outside the organization; social support - friendships in the organization; the importance of work.

162 people participated in the study, 111 W and 51 M. 88,9% of the participants had higher or incomplete higher education (10,5%), the rest - secondary education. People working and living in large cities prevailed in the study group (over 500,000 inhabitants – 73,5% of the respondents).

In order to determine the relationship between job characteristics and occupational well-being, first we performed a correlation analysis (r - Pearson's). Only in the case of 2 characteristics: physical requirements and working conditions; interactions outside the organization - no statistically significant results were obtained. In the remaining cases, significant, positive correlations were noted. The highest results were obtained for such features, as: feedback from others ($r = 0{,}690$, $p < 0{,}01$) and feedback from work ($r = 0{,}663$, $p < 0.01$). In the next step, a linear regression analysis was performed. Model including 4 factors (respectively: feedback from others: beta $= 0{,}455$, $p < 0.01$; autonomy: beta $= 0{,}265$, $p < 0.01$, feedback from work: beta $= 0{,}259$, $p < 0.01$; work complexity: beta $= 0{,}162$, $p < .01$) explains 68,1% of the variance of occupational well-being. Above mentioned results indicate that job characteristics are important predictors of employee's well-being.

The obtained results indicate also the need for more detailed analyzes of the relationship between job characteristics and employee's well-being. At the same time, it seems to be the imperative of organizations to design work and shape working conditions by increasing the level of above mentioned traits (por. Demerouti, Bakker, Halbesleben, 2015; Rudolph et al., 2017), what consequently may be connected with the employee's well-being augmentation.

It is worth to highlight that taking care of well-being of employees is directly aligned with the United Nations Sustainable Development Goals (respectively: Good health and Wellbeing).

Keywords: work characteristics, well-being, work-design

Workplace Arrogance, Need for Power, and Counterproductive Work Behaviors among Corporate Managers: The Mediating Role of Humility

Muhammad Zohaib Khan, Department of Psychology Government College University (GCU) Lahore, Pakistan / Center for Assessment, Research and Employees' Evaluation (CARE), Human Resource Group, Allied Bank Limited.

science

The accounts of arrogant managers abound, however minimal systematic research has been done on workplace arrogance, the need for power, and counterproductive work behaviours within organizations. The research article describes the results of our studies in response to this oversight. The study was carried out by following the correlational research design and the sample of N=260 corporate managers (males=181, females=79), with an age range from 30 years to 55 years (M =41.03, SD =7.06) was recruited from the different cities of Pakistan (i.e., Lahore n =40 (15.4%), Faisalabad n =38 (14.6%), Multan n =37 (14.2%), Karachi n =38 (14.6%), Islamabad n =38 (14.6%), Abbottabad n =26 (10%), and Bahawalpur n =43 (16.5%). The existing research was carried out to achieve the following research objectives, according to the first objective of the study, authors established a confirmatory factor structure of the workplace arrogance scale through confirmatory factor analysis (CFA) and retained 22 items with well-fitted indices of the one-factor solution model $\chi 2 =1.77$, (df =206, N =260), $p <. 05$, RMSEA=.05, CFI=.90, GFI=.90, TLI=.91. Furthermore, aligning with the second objective of the study, the results of the correlation analysis exhibited significant ($p < .05$) positive relationships between workplace arrogance, the personalized need for power (P nPower), and counterproductive work behaviour however, the negative association was found between the socialized need for power (S nPower), humility, and agreeableness in corporate managers. The gender differences were explored as the third objective of the study, findings of the independent sample t -test revealed that male and female corporate managers have similar scores in terms of all study variables ($p >.05$). In addition, the fourth objective of the study was achieved by identifying the significant predictors of counterproductive work behaviour, findings of multiple linear regression analysis revealed that workplace arrogance and personalized need for power with 25% of the variance were found to be significant ($p <.01$) predictors of the counterproductive work behaviour among corporate managers. The path analysis through structure equational modelling (SEM) also suggested that personalized need for power, workplace arrogance, and humility are significant predictors of counterproductive work behaviour. Lastly, the fifth objective was achieved by the mediation analysis conducted through structure equational modelling (SEM), findings demonstrated that humility significantly mediated the relationship between workplace arrogance, the need for power, and counterproductive work behaviour in corporate managers ($\chi 2 =2.53$ (CMIN/ df =5.06/2=2.53, N =260), $p <.05$, RMSEA=.05, CFI=.98, GFI=.92 and TLI=.97). Moreover, the two demographic variables such as work experience and the corporate sectors of the corporate managers have an impact on their counterproductive work behaviour and the overall model fit indices. The study provides researchers with a validated workplace arrogance scale on the corporate sample. It helps the researchers expand their understanding of the significance of these constructs in the field of industrial-organizational psychology. The study seeks to benefit many employees and employers to comprehend the nature and the association of counterproductive work behaviour with other undesirable variables in the workplace (i.e., workplace arrogance and personalized need for power).

Keywords: Workplace Arrogance, Need for Power, and Counterproductive Work Behavior.

The proof is in the pudding: Company image and work experiences are affected by diversity progress and not by diversity talk.

Valerie De Cock, Université libre de Bruxelles; Pinar Celik, Université libre de Bruxelles; Claudia Toma, Université libre de Bruxelles.

While many organizations communicate publicly about their commitment to diversity and inclusion (D&I), progress in the domain remains slow. Given this controversial relation between diversity talk and diversity progress, the current paper investigates their joint impact on organizations and workers. Indeed, while previous research has mainly focused on the positive role of diversity talk on organizations' reputation and workers' experiences, less attention has been devoted to the effects of diversity progress. However, we contend that diversity talk alone can no longer be beneficial in a context in which there is increased scrutiny on diversity progress. We expect thus first that diversity progress, more than diversity talk, should have a decisive impact on workers' company perceptions and work experiences (Hypothesis 1). Second, based on the organizational decoupling literature (Mor Barak et al., 2021) and the functionalist approach in CSR communication (Schoeneborn et al., 2020), we also hypothesize that in the case of absence of diversity progress, diversity talk will have a negative impact on company perceptions and work experiences, while having no positive effects when diversity progress is present (Hypothesis 2).

We tested these hypotheses in two studies using a 2 (diversity talk: present, absent) X 2 (diversity progress: present, absent) design. Study 1 (N=437) employed an experimental design in which participants reacted to a hypothetical situation, while Study 2 (N=240) was a correlational study in which respondents were reporting about their own organization. In line with our first hypothesis, the results show that diversity progress, and not diversity talk, consistently affects workers' company image (perceived corporate hypocrisy) and their work experiences (sense of inclusion, organizational commitment, person-organization fit, negative affect). We did not find consistent support for our second hypothesis. Interestingly, these findings suggest that in a context in which information about diversity talk and diversity progress is present, workers disregard diversity talk and primarily care about diversity progress in their organization. We believe that our main findings are relevant for the signaling theory and the repetition-frequency-model of persuasive communication and can be explained through the concepts of organizational identification and psychological contract breach.

In conclusion, this research highlights that not only objective evidence of diversity progress is necessary to ensure positive company perceptions and work experiences amongst internal stakeholders, but that it is also important to consider the subjective evaluations of workers about the progress done in the D&I domain. Organizations should indeed provide consistent and clear evidence about their progress in the domain of diversity and inclusion and should monitor workers' perception regarding diversity and inclusion efforts.

By highlighting the costs associated with a (perceived) status quo in the D&I domain and by highlighting that a lack of evidence that progress takes place, endangers the exact objectives that an organization has by communicating on D&I (positive company image & inclusive work environments), we hope to sensitize organizations to the urgency of going beyond symbolic D&I actions and adopting policies that achieve systemic change and real progress in the D&I domain.

Keywords: Diversity talk, diversity progress, work experiences
